Let  ${}_{\lambda}$ ,  ${}_{2w_{p-1}}$  and  ${}_{2w_p}$  be assigned as in Lemma 1. Thus, from Lemma 1,  $h(c_x, {}_{2w_{p-1}}) + h(c_x, {}_{2w_p}) \cong 0.0 \forall c \in I(k-1)$  and  $h(k_x, {}_{2w_{p-1}}) + h(k_x, {}_{2w_p}) = 2 \tanh(\zeta)$ . Let  ${}_{3w_{p-1}} = {}_{3w_p} = \gamma$ , where  $\gamma = (\tanh^{-1}(k_t) - k_{net}) / 2 \tanh(\zeta)$ .

$\because {}_{3w_{p-1}} = {}_{3w_p}$  and  $h(c_x, {}_{2w_{p-1}}) + h(c_x, {}_{2w_p}) \cong 0.0 \forall c \in I(k-1)$ ,

$$\because {}_{c_y} \cong {}_{c_y'} \forall c \in I(k-1).$$

Therefore,  $|{}_{c_y} - c_t| < \varepsilon \forall c \in I(k-1)$  since  $|{}_{c_y'} - c_t| < \varepsilon \forall c \in I(k-1)$ .

$$\because h(k_x, {}_{2w_{p-1}}) + h(k_x, {}_{2w_p}) = 2 \tanh(\zeta),$$

$$\because {}_{k_y} = \tanh(k_{net} + \gamma 2 \tanh(\zeta)) = k_t. \text{ Thus } |{}_{k_y} - k_t| < \varepsilon.$$

# A Feature Weighting Method by Multimedia Data Model on E-Business

Young-Jun Kim

Department of Secretarial Information Studies

Cheonan College of Foreign Studies

Cheonan, Korea

[yjkim@ccfs.ac.kr](mailto:yjkim@ccfs.ac.kr)

## Abstract

A lazy learning method has relative advantages in comparison to eager learning method. However lazy learning has relative disadvantages also. Lazy learners are sensitive to irrelevant features. When there are irrelevant features, lazy learners have difficulty to compare cases. This is one of the most critical problems and the accuracy of reasoning can be degraded significantly. To overcome this restriction, feature weighting method for lazy learning have been studied. All the methods previously proposed tried to improve some parts of this generic process with different approaches. However, most of the existing researches were focused on global feature weighting. Therefore, we propose a new local method on e-business. The motivation to try local feature weighting method is that there are situations where locally varying weight vectors can help improving classifier performance by multimedia data model on e-business.

## 1. Introduction

By using a set of previously encountered cases, each of which typically represented by a set of features, classification methods attempt to produce class descriptions that will be accurate for new cases. The class assigned to a new case can then be used to decide how to process it. There are two types of learning modes: eager learning and lazy learning. Eager learning approaches to induction produce generalizations that explicitly represent the classes under study, often in a language different from that used to represent the cases. Lazy approaches, in contrast, delay this generalization process until classification time; it is performed implicitly when a new case is compared to the stored cases and the class of the nearest one(s) is assigned to it.

There will be many potential advantages if we automate the feature the feature weighting process. Caruana and Freitag[6] described the advantages of feature selection. By adapting their suggestion, we can describe the advantages of automated feature weighting as showed follows: It gives the learning system designer freedom to identify as many potentially useful features as possible and then let the learning system automatically determine which ones get heavier weight and which ones

get lighter weight. It allows new features to be added easily to a learning system. It allows the weight of features to change dynamically as the amount of training data changes on e-business.

## 2. Backgrounds of Study

The field of machine learning was conceived nearly four decades ago with the objective to develop intelligent computational methods that would implement various forms of learning, in particular mechanisms capable of inducing knowledge from example or data. One of the vital invention of artificial intelligence(AI) research is the idea that formally intractable problems can be solved by extending the traditional scheme  $\text{program} = \text{algorithm} + \text{data}$  to the more elaborate  $\text{program} = \text{algorithm} + \text{data} + \text{domain knowledge}$ .

As seen in the above equation, applying the domain knowledge is fundamental for solving problems in the field of AI. However, the use of knowledge does nothing but shifts bottleneck of implementing the AI program from the programmer to the knowledge engineer. In other words, the process of knowledge acquisition and encoding is still far from being easy. Thus a tempting idea springs to mind: employ a learning system that will acquire such high-level concepts and/or problem-solving strategies through examples in a way analogical to human learning. Most research in machine learning has been devoted to developing effective methods to address this problem.

CBR is one of such machine learning approaches. Previous cases are used to make a solution for a new problem. From the cases available, a CBR system retrieves the most similar case(s) to the input problem and then adapts the solution of the retrieved case to the fit the context of the Input problem. The basic idea of CBR is based on the process of human problem solving. Human beings use previous experiences of problem solving when encountered a new problem to solve. This natural problem solving approach allows the reuse of problem solving experiences and is considered a breakthrough from the knowledge acquisition bottleneck in the artificial intelligence area.

A process model of Riesbeck and Schank has been a popular and most widely used CBR process model[14]. The CBR model has six major stages: indexing, retrieval,

adaptation, test, indexing and store, explanation and repair. The process of CBR also requires stored knowledge structures: case base, indexing rules, similarity matrix or metrics, adaptation rules, repair rules. The case base stores the cases previously solved and the indexing rules help searching most similar and useful cases efficiently and effectively. The similarity metrics are used to calculate the similarity or distance of a new case from a case stored in the case base and the repair rules are used in correcting failed solutions proposed by the CBR process.

In this study, we focus on the typical classification problems that have the following characteristics. The problems have discrete output classes. Hence, the performance of CBR system can be investigated by checking the results whether they are correct or not. The problems have relatively many features and have both numeric and categorical features in most cases.

### 3. Categorization of FW Methods

Feature weighting(FW) efforts attempt to find the optimal feature weight vector that makes the classifier show best classification accuracy. Feature weighting methods search through the feature weight vectors, and try to find the best one among the unlimited number of candidate weight vectors according to an evaluation criterion. However, this procedure is exhaustive because it tries to find only the best one. It may be too costly and practically prohibitive, even for a small size of feature set. Other methods based on heuristic or random search attempt to reduce computational complexity at the cost of performance. These methods need a stopping criterion to prevent an exhaustive search of weight vectors. There are four basic steps in a typical feature weighting method. (1) A generation procedure to generate candidate weight vectors. (2) An evaluation procedure to evaluate the weight vector examination. (3) A stopping criterion to decide when to stop and (4) A validation procedure to check whether the weight.

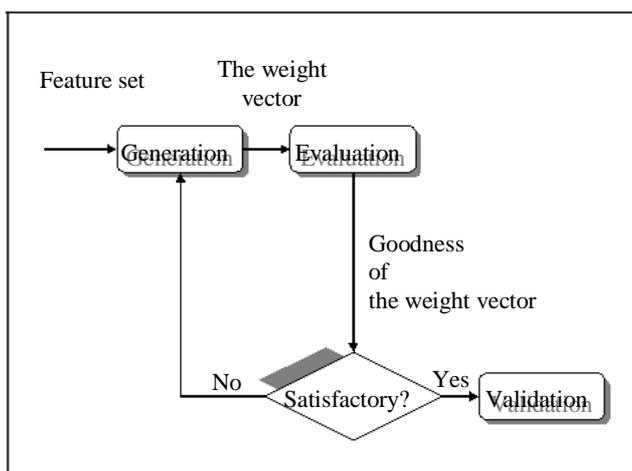

Figure 1 A generic feature weighting process

Figure 1 shows a generic feature weighting process

methods are several frameworks for categorizing feature weighting, specifically, feature selection methods[7], we will use Dash and Liu's framework as a base for our framework to Include local feature weighting methods. Dash and Liu suggested a 2-dimensional categorization framework of feature selection methods. Although their framework is of feature selection methods, there is no significant difference to the framework of feature weighting. This is because feature selection is a special case of feature weighting as we mentioned in backgrounds. Their framework considered generation procedures and evaluation functions as the most critical dimensions. Each feature selection method is grouped depending on the type of generation procedure and evaluation function used. They chose 32 methods and then grouped them according to the combination of generation procedure and evaluation function used.

However, they did not consider the dimension of the scope of weight. Hence, we add the scope dimension and present a 3-dimensional framework in order to classify local and global feature weighting methods. Table 1 shows the modified framework and categorization of some representative methods.

Table 1 Categorization of feature weighting methods in a 3-dimentional framework

Scope of Weight	Evaluation Function	Generation Procedure		
		Heuristic	Complete	Random
Global	Distance	Relief	+	-
	Information	DTI	+	-
	Dependency	+	-	-
	Consistency	-	+	+
	Classifier Error	+	+	CA
Local	Classifier Error	RC	-	This Study

+ There are several methods but they are not presented here.

- There are no known methods.

Relief and decision tree induction(DTI)[11] use heuristic generation procedures. GA generates feature weight vectors randomly. RC and this study, the feature weighting method we develop in this research, are local and wrapper feature weighting methods. RC uses heuristic generation procedure and this study uses random generation procedure.

## 4. Sequential Weighting Algorithms

### 4.1 Forward and Backward Algorithm

The generation procedure generates the feature weight values that will be evaluated by an evaluation procedure. The generation procedure can start with (1) all 0-weight values, (2) all 1-weight values or (3) randomly generated weight values. Methods that have property of (1) are called FSS methods, whereas methods that have property

of (2) are called BSS methods. In (1), feature weights are iteratively increased until no further improvement is possible. In (2), feature weights are iteratively decreased. In (3), feature weights are randomly generated in each iteration.

#### 4.2 Relief Algorithm

Relief algorithm uses a statistical method to weight the relevant features. From the set of training cases, it first chooses a sample of cases, where the number of samples are provided by the user Relief randomly picks this sample of cases, and for each case it finds near Hit and near Miss cases based on Euclidean distance measure. Near Hit is the case having minimum Euclidean distance among all the cases in the same class as that of the chosen case; near Miss is the case having minimum Euclidean distance among all the cases in the different class. The initial values of feature weights were set to zero in the beginning. Relief updates the feature weight using the information obtained from near Hit and near Miss. A feature is more relevant if it differentiates a case from its near Miss, and less relevant if it differentiates a case from its near Hit. After exhausting all cases in the sample, it selects the features whose weights are greater than or equal to a threshold. Relief works for noisy and correlated features, and requires only linear time with respect to the number of given features and number of samples. A limitation is that it does not detect redundant features. Another limitation is that the user may find it difficult to provide a proper number of samples.

### 5. Feature Weighting Procedures

#### 5.1 using Decision Tree Induction

Decision tree(DT)-based feature weighting methods use heuristic weight generation and information gain as evaluation measure. Cardie[11] showed that the use of feature weighting generated by DT can improve the performance of CBR. DT generation method such as C4.5[12] is run over the training set, and the features that appear in the pruned DT are selected. Some variations are also possible. For example, after generating a DT, original features can be weighted according to the entropy values[5].

#### 5.2 using Genetic Algorithm

There are several approaches using genetic algorithms (GA) for weighting features. The average classification accuracy of GA-kNN was almost 81%, which is very high in the sense that the accuracies of basic CBR models were approximately 63%. However, feature weighting methods using GA need to assign proper values to such parameters as maximum number of iterations, initial population size crossover rate and mutation rate.

### 6. Evaluation Procedures of Study

Evaluation procedures can be categorized differently by whether they use feedback from the performance task. Methods that do not use feedback are called filters, whereas methods that use the classifier itself as the evaluation procedure are wrappers[10]. Since the features are selected using the classifier that later on uses these selected features in predicting the class of unseen cases, the accuracy of wrapper model is high. Some evidences suggest that wrapper models are superior to filter models (e.g., Wettschereck et al.[16]) when the dependent variable is classification accuracy. However, wrapper models are often more computationally expensive[7]. Filter models and other efficient variants of wrapper models should be considered for tasks when computational expense is a critical concern. Figure 2 and figure 3 show a generic process of wrapper model and filter model, respectively, presented by John et al.[10].

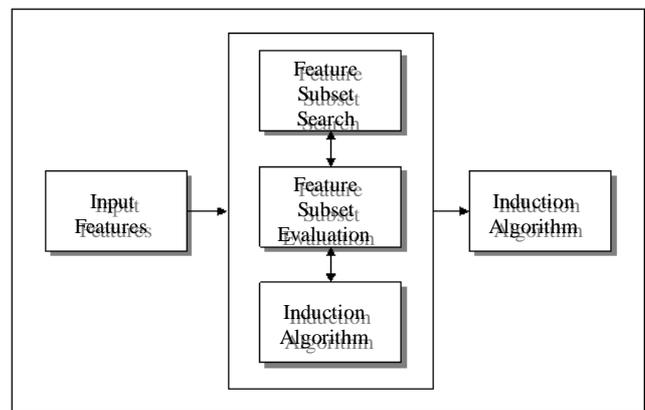

Figure 2 Process of a generic wrapper model

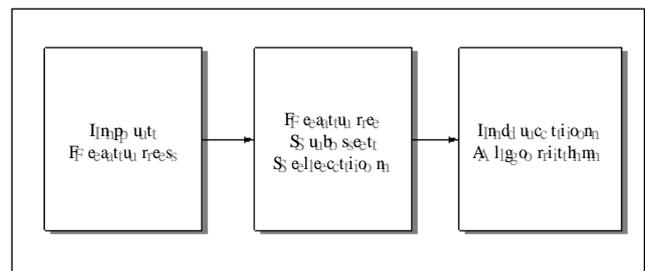

Figure 3 Process of a generic filter model

### 7. Local Feature Weighting Methods

The scope of weights means the generality of the weights in the case space. The scope of weights that most feature weighting methods produce is global: their weights apply across the entire case space. In contrast, local feature weighting methods allow feature weights to vary in different parts of the case space. In local feature weighting methods, weights can vary by class, feature value, and/or individual case or subset of cases.

Domingos' RC algorithm uses a case-specific feature weighting algorithm. RC is in many ways similar to BSS, but it makes case-specific decisions on feature relevance.

It drops features from a case if (1) their values differ from the case's nearest neighbour and (2) removing them does not decrease overall leave-one-out-cross-validation error(LOOCE). After removing features from the original case base, duplicate cases may be produced, but are not removed.

In a setting with only single nearest neighbour, RC outperformed both FSS and BSS significantly on 24 data sets, and showed increased efficiency with increasing context-dependency of feature relevance. However, RC is limited to binary weights and it is hard to extend RC to allow continuous weights.

## 8. Summaries and Discussion

There are some researches on flexible, context-sensitive, and local feature weighting. However, few researches tried to use wrapper model for local feature weighting except for Domingos. We propose a new local wrapper method for feature weighting. This system is very simple and relatively efficient among wrapper model-based feature weighting methods. Our methods overcome the limitations Of RC and this study will support more than single nearest neighbour. We can enhance the classification performance by multimedia data model on e-business.

Although the results of some applications did not showed sufficient evidences for the usefulness of the new method, we expect that it can be improved and will work effectively in most situations. That is because the core idea of the method is remembering the real experiences. The core contribution of this research can be stated as: (1) We will extend existing categorizations of feature weighting methods by including the scope dimension, and develop a new 3-dimensional framework and then develop a brand new combination of feature weighting method on e-business. (2) We will develop a new measurement called input dependency of feature relevance that will be used to determine which type of weights, i.e., local weights or global weights, is appropriate for a particular application.

# A Comparative Research on Competitiveness of Information Industry of China vs. Korea

Chang'en Zheng      Yimin Han      Qiwen Wang  
Guanghua School of Management, Peking University, Beijing, China

## Abstract

This paper explores the competitiveness of information industry of China and Korea by means of comparative research based on the analysis of statistic data and the definition of items denoting the competitiveness. Consequently, we analyze the competitive and complementary relation of information industry of China vs. Korea, and put forward a co-operation project of China-Korea information industry ultimately.

Keyword: competitiveness, competitiveness items, comparative research, information products

## 1. Compare Information Products International Trade of China vs. Korea

### 1.1. Computers and their fittings

Korea had maintained very high rate of increase in exporting computers and their fittings all along from 1994 to 1999, which was higher than 10% except for 1998 when the export decreased due to the financial crisis. Specially, it was 38.6% in 1999. While the importing also increased quickly. Although decreasing by 6.9% and 47% in 1997 and 1998 during the financial crisis respectively, the rate of increase reached 30% both in 1994 and in 1995, especially 65% in 1999. Consequently, the international trade had kept more and more surplus, which increased from 15 billion dollar in 1993 to 28 billion dollar and 43 billion dollar in 1997 and 1999 respectively.

What about China? China's computers and their

fittings foreign trade had favorable balance in 1999, but which was smaller than in 1998. In detail, the export was 107 billion dollar in 1998, while the importing is only 56 billion dollar the same year, as result of which the surplus trade balance was 51 billion dollar this year. But in 1999, the import increased by 2.9% and the export decreased by 10.1%, as result of which the surplus was only 39 billion dollar.

Table 1 shows the detailed data.

### 1.2. Communication equipment

The growth rate of Korea exporting communication equipment was about average 3% per year from 1995 to 1998, but it reached 33.2% in 1999. While the rate of increase of the import maintained more than 20% from 1994 to 1996, but the import began to decrease by 41% and 9.6% in 1998 and 1999 respectively. Consequently, the favorable balance of the communication equipment international trade was respectively: 20 billion dollar in 1993, 13 billion dollar in 1996, 27 billion dollar in 1998, 32 billion dollar in 1999. Specially, the favorable balance had a big jump in 1999 thanks for the export increasing and the import decreasing as result of the financial crisis in 1998.

With respect to China, the export was 67 billion dollar, and the import was 63 billion dollar in 1998. The export was 58 billion dollar and the import was 59 billion dollar in October 1999. So the trade maintained small favorable and small unfavorable balance of foreign trade, that is, revenues and expenditures were generally in balance.

Table 1. Compare export and import of computers and their fittings of China and Korea (millions of dollars)

		1995	1996	1997	1998	1999
Korea	export	4,810 (39.16)	5,518 (14.72)	6,266 (13.55)	5,276 (-15.79)	7,316 (38.65)
	import	3,282 (37.41)	3,800 (15.77)	3,537 (-6.93)	1,872 (-47.07)	3,081 (64.6)
	the favorable balance	1,528	1,718	2,729	3,404	4,235
China	Export	N.A.	N.A.	N.A.	10,736 (N.A.)	9,650 (-10.1)
	Import	N.A.	N.A.	N.A.	5,573 (N.A.)	5,735 (2.91)
	the favorable balance	N.A.	N.A.	N.A.	5,164	3,915

Resource: Information Annual of Korea, Statistic Annual of China International Economy.

The following table shows the detailed data.

Table 2. Compare export and import of communication equipment of China and Korea (millions of dollars)

		1995	1996	1997	1998	1999.10
Korea	export	3,919 (4.75)	3,899 (-0.53)	4,026 (3.26)	4,143 (2.9)	5,519 (33.21)
	import	2,146 (22.67)	2,604 (21.31)	2,530 (-2.83)	1,494 (-40.96)	1,350 (-9.02)
	the favorable balance	1,773	1,295	1,496	2,649	4,169
China	export	n.a.	n.a.	n.a.	6,659 (n.a.)	5,781 (-13.19)
	import	n.a.	n.a.	n.a.	6,308 (n.a.)	5,891 (-6.61)
	the favorable balance	n.a.	n.a.	n.a.	351	-110

Resource: Information Annual of Korea, Statistic Annual of China International Economy.

### 1.3. Semiconductors and their fittings

Korea increased the export of semiconductors and their fittings by about average 27% per year from 1994 to 1997. Although the financial crisis decelerated the rate of increase in 1998, the export in 1999 increased by 24.64% more than that in 1997.

After increasing quickly during 1994 to 1997, the import decreased in 1998, but increased by 16.44% in 1999. Because the world market of semiconductors and their fittings was pretty flourishing in 1995, the Korea's favorable balance of semiconductors and their fitting trade reached 87 billion dollar. After this, the favorable balance began to decrease because of the world market of semiconductors and their fittings falling off. It was 50 billion dollar in 1997 and 1998. With the demand of semiconductors and their fittings rebounding in 1999, in spite of the exchange rate decreasing, the favorable

balance reached 71.6 billion dollar.

China continued expanding the favorable balance in the world market of semiconductors and their fittings. The favorable balance was 3 billion dollar in 1998 and 13.08 billion dollar in 1999. Table 3 shows the detailed data.

## 2. Comparative Research on Competitiveness of Information Industry of China vs. Korea

### 2.1. The major competitiveness items

There are four items to estimate the competitiveness of information and communication industry in general. They are the market share in the third country, trade specialization degree index, market comparative advantage index (MCAI) and the export.

Table 3. Compare export and import of semiconductors and their fittings of China and Korea (millions of dollars)

		1995	1996	1997	1998	1999
Korea	export	17,740 (66.14)	15,158 (-14.55)	17,139 (13.06)	17,034 (-0.61)	21,241 (24.64)
	import	9,011 (40.12)	10,403 (15.45)	12,909 (24.09)	12,092 (-6.32)	14,081 (16.44)
	the favorable balance	8,729	4,756	4,230	4,942	7,160
China	export	n.a.	n.a.	n.a.	7,297 (n.a.)	9,650 (32.56)
	import	n.a.	n.a.	n.a.	6,910 (n.a.)	8,342 (20.72)
	the favorable balance	n.a.	n.a.	n.a.	387	1,308

Resource: Information Annual of Korea, Statistic Annual of China International Economy.

The export can apparently express the comparativeness, so we'll emphasize on the others.

The market share in third country: That a country's products occupy how much the market share in the third country can show its competitiveness. It is easy to understand that the more share, the stronger competitiveness.

Trade specialization degree index: it is another item that can show competitiveness. It can be formulized as:

$$\text{Trade specialization degree index} = \frac{\text{export} - \text{import}}{\text{export} + \text{import}}$$

Trade specialization degree index can show the relative advantage in export. The value of the trade specialization degree index is from -1 to 1. We can also easily know that the more value of the trade specialization degree index, the stronger competitiveness.

Market comparative advantage index (MCAI): MCAI is revealable comparative advantage excluding the market scale. Thereby, it is necessary to introduce revealable comparative advantage (RCA) for understanding MCAI.

Revealable comparative advantage (RCA) can express comparative advantage of a group of countries with different comparable economy-scale. It can be formulized as:

$X^i$  shows the export amount of  $i$  product 's

$$RCA(i) = \frac{X^i / WX^i}{X / WX}$$

quantity of a country.

$WX^i$  is the total export amount of  $i$  product in the world.

$X$  is the total export amount of corresponding country.

$WX$  is the total export amount of the whole world.

$RCA(i)$  can indicate relative advantage of a country 's competitiveness of  $i$  product in the average competitiveness of this country. We can know that if a country had a bigger export scale, the country must have a big market share in spite with lower relative advantage.

When a specific export product occupies more market

share than the market share of total export product of this country, the value of RCA will be more than 1, which means this specific product have stronger relative advantage than others of this country. Hence, the comparative advantage between countries can be estimated by RCA. But RCA has a fault that RCA cannot

$$MCA(i, j) = \frac{X_j^i / TX_j^i}{X_j / TX_j}$$

exclude the influence of economy growth. To make up it, we put forward MCA. MCA can be formulized as:

$X_j^i$  is an export quantity of  $i$  product from a country to  $j$  market.

$TX_j^i$  is the total  $i$  product import quantity of  $j$  market.

$X_j$  is the total  $I$  product from  $j$  market to the corresponding country.

$TX_j$  is the total export from  $j$  market to the entire world.

If the value of MCA is more than 1, the  $i$  product is more popular in  $j$  market, vice versa.

## 2.2. Comparative research on competitiveness of information industry of China vs. Korea

The following, we will compare Chinese and Korea competitiveness by the three items.

(1) We saw about Korea communication products' share in USA communication market to compare the competitiveness of China and Korea. It is necessary to note that we measured the Hong Kong's share separately and together with the mainland when explained.

We chose the USA market as the third country market based on the following reasons: First, USA is the most trade-partner of both Korea and China. Secondly, USA has less import-confine than others due to its pretty opening economic policy. It is better to compete freely in the market to estimate the competitiveness, while USA just advocates free competition. Finally, the import statistic data of USA is more complete, which will do good to compare.

The correlative data is in chart 1.

Chart 1. The market share in USA (%)

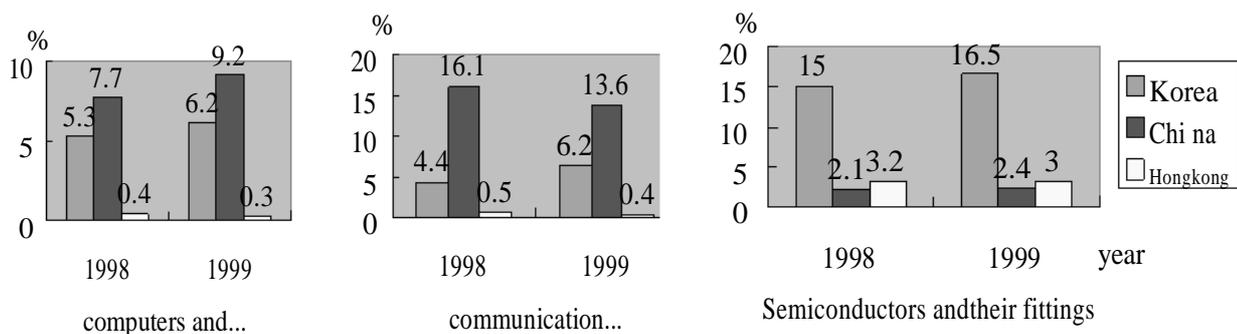

Chart 2. Compare the trade specialization degree index of Korea and China by class

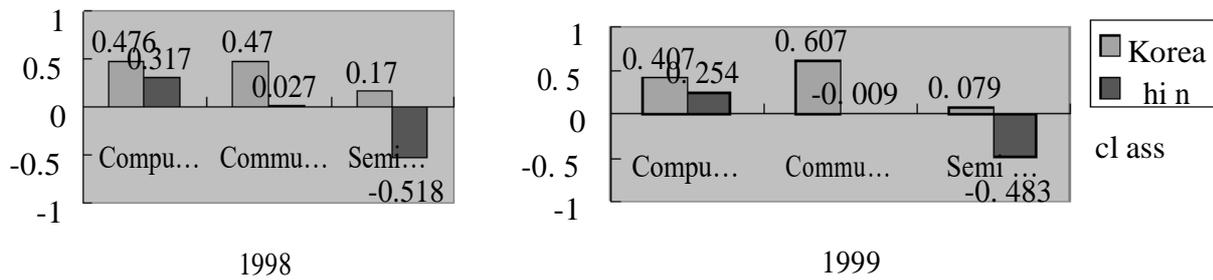

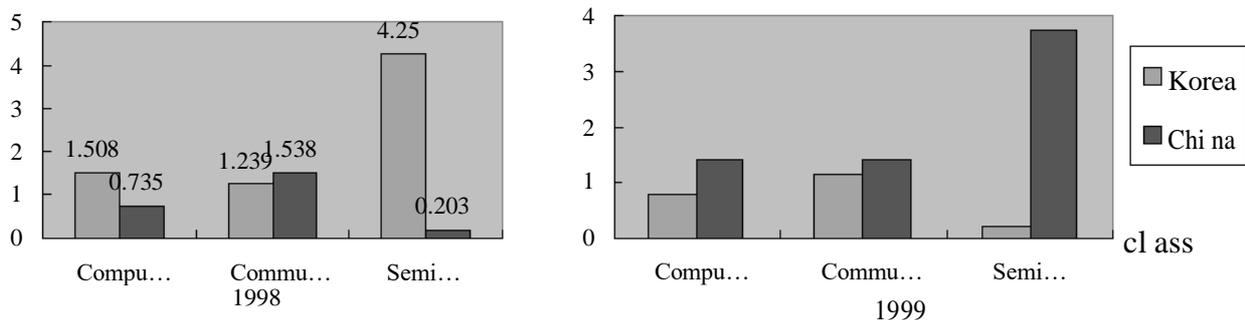

Chart 3. Compare MCA of Korea and China in USA

It can be inferred: Chinese computers and their fittings market share was appreciably more than Korea ( $7.7+0.4 > 5.3$ ,  $9.2+0.3 > 6.2$ ). With respect to communication equipment, Chinese market share was greatly more than Korea ( $16.1+0.5 >> 4.4$ ,  $13.6+0.4 >> 6.2$ ). But with respect to semiconductors and their fittings, Chinese market share was greatly less than Korea ( $2.1+3.2 << 15.0$ ;  $2.4+3.0 << 16.5$ ).

(2) The trade specialization degree index of Chinese and Korea is in chart 2.

As can be seen from the chart, Korea's trade specialization degree index of computers and their fittings and communication equipment was 0.48 and 0.47 respectively, which are pretty higher. With respect to semiconductors and their fittings, the trade specialization degree index is only 0.17, which is pretty lower.

China's trade specialization degree indexes are pretty lower except for computers and their fittings. Specially, the trade specialization degree index of semiconductors and their fittings is negative, which means the export of semiconductors and their fittings is less than the import.

(3) The MCAI of Chinese and Korea in USA is in chart 3.

The chart shows that: 1) Korea's MCA of computers and their fittings is 1.508, which is 0.735 higher than China's. This trend has lasted to 1999. 2) In 1998, China's MCA of communication equipment is 1.538, which is

higher than 1.239—Korea's MCA of communication equipment. But in 1999, Korea's MCA of communication equipment is 1.404, which is higher than 1.160—China's MCA of communication equipment. 3) With respect to semiconductors and their fittings, Korea's MCA is apparently higher than China's both in 1998 and in 1999.

### 3. Co-operation Project of China-Korea Information Industry

According to their status, we can infer Korea and China are in different developing stage. Korea has founded fundamental communication equipment, and some products have shared more the great world market. Although China has enormous potential for developing and has been growing fast, it was so late for the activity that China lags behind Korea, which is apparent according to a series of index, such as the overseas market shares, trade specialization degree index and market comparative advantage index, etc. Ground on the principle of win-win, the companies of Korea should continue transferring a great deal of technology to Chinese market. Simultaneously China should take great part in R&D relative to technology transferring, which can also flourish the northeast Asia economy.

The co-operation can be processed by three stages:

1). The first stage is from 2000 to 2001. This stage is an experiment stage, a prepare stage of co-operation. China, Korea and Japan carried out a co-research in November 1999 on economic community. The conclusion showed the major feasible co-operation domain was

information industry. During this period, we can experience the conclusion from the former research and study the experience of the former co-operation to ascertain the principle and direction of the developing. We also should research the appropriate environment policy as well as how to co-operation. Besides, the co-operation between companies and local government is also popular just like between central government.

2). The second stage will be from 2002 to 2005. This stage is the initial stage of co-operation. In this stage, confirming the specific co-operation domain and extending the former co-operation will be the emphasis. It was known that the most promising domain includes the penetrate of technology relative to CDMA, the developing of APIITest-bed and the communion of the human resources. Nowadays, China is paying more and more attention to the introducing this technology. That is to say, Korea attaches the most importance to the CDMA, while China is eager to introduce the world-class technology accordingly to benefit domestic relative industries. We can conclude that the co-operation will be feasible.

3). The third stage will extend from 2006 to 2010. This stage can regulate the co-operation. In this stage, the e-commerce and information-communication network will get quiet great progress. During this period, China will join some international organization (like WTO), so following a rational line will complete the regulation. At that time, the information industries of China will be very strong; some impossible things of nowadays will change to be possible.

The research supported by natural science foundation, project No.79970019.

# Standard Single Data Table Web Management Information System Through ASP

Yuan-Hsi Hsu  
Department of Business Administration  
Feng Chia University  
Taichung, Taiwan  
yhhsu@fcu.edu.tw

## Abstract

The new trend in computer application is to use browser as the interface and networking database. MicroSoft designed 6 objects to add on to the HyperText Markup Language (HTML) to link homepage with database. It makes web MIS easy and the result calls Active Server Pages (ASP). The purpose of this paper is to introduce a standard procedure to develop a single data table web MIS. It uses a class student roll as an example to illustrate the procedure.

## 1. Introduction

Information system must be networked or its accessibility will limit its usefulness. Ever since the browser was introduced, almost all computer users use browser as the interface in accessing information from remote computers. Browser was designed to read the web pages through HyperText Markup Language. Therefore linking the database with HTML becomes necessary. MicroSoft designed six objects (server, response, request, application, session, cookie) and web server can execute them to accomplish this. Server object is used to open database and data table. Response object is used to bring information from server to users through browser. Request object is used to send information from user's browser to server. Application object manages the web operations. Session object manages individual web user. Cookie object writes temporary information at user's computer. With these 6 objects plus SQL and VB, all the database management operations can be performed in web pages.

## 2. System Components

All management information system must be

menu-driven and user-friendly. In additions, all management information system must be able to (1) add new record to file, (2) edit existing record in file, (3) delete existing record in file, and (4) generate reports. Web MIS must be the same way. Therefore a single data table web management information system must have the following components:

1. A Mainmenu.html page for user to choose Add, Edit, Delete, and Report options.
2. In a add module, a Add.html form for user to type in new record and a Add.asp ASP to perform the actual adding of new record to file.
3. In the delete module, a KeyenterE.html form is used to ask user whose record the user wish to edit and a LooktatE.asp ASP to retrieve the correct record and put it on the screen for the user to see and to edit. In addition a Modify.asp ASP is used to actually perform the modification or replacement of old record by new record.
4. In the delete module, a KeyenterD.html form is used to ask user whose record the user wish to delete and a LooktatD.asp ASP is used to retrieve the correct record and to put the retrieved record on the screen for the user to see. In addition a Delete.As ASP is used to actually perform the deletion of record.
5. A Report.asp ASP is used to bring out the report. If there is more than one report, a reportmenu.html page should be added between the main menu and reports.

## 3. The Single Table Web MIS Structure

The about components should be structured or configured as the following figure:

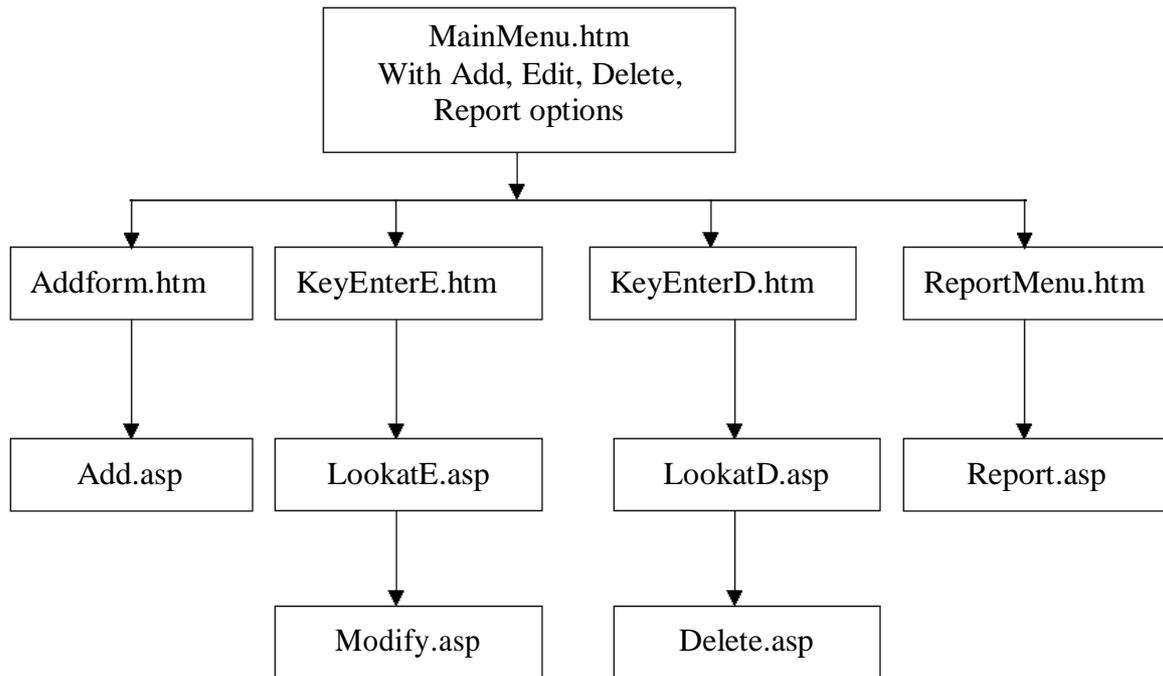

Figure 1: Single Table Web MIS Structure

To develop a single table web MIS, all that was needed is to develop a data table and write the above 5 html pages and 6 asp pages and link them based on the above figure.

#### 4. An Example

Let's use a classmate roll book as an example.

Step I: Develop an Access database and table with appropriate fields:

Database=members.mdb

Table=members

members: 資料表				
	Name	Address	Sex	Age
▶				

Step II: Write the needed 5 html pages and 6 asp pages.

##### 1. Mainmenu.htm

```

<html><head><title>Mainmenu.htm</Title></head>
>
<body>
<Body bgcolor=#00ff00>
<Center><H1>Maninenu for Single File
System</H1><br>
<p><p><p><p>
<h2> <table border=2>
<tr><td><a href="add.htm">ADD</a></td>
<td><a href="keyentere.htm">Modify</a></td>
<td><a href="keyenterd.htm">Delete</a></td>

```

```

<td><a href="reportmenu.htm">Reports</a></td>
</table>
<p><p>Please Make a Selection</h2>
<p><p><p><p>
</font></center>
</body></html>

```

##### 2. Add.htm

```

<html><head><title>Add.htm</title></head>
<body>
<body bgcolor=#00ff00>
<form method=get action="add.asp">
<H2><b>Add New Members To File</b></H2>
<p>
Name <input type=Text name ="Name1"><br>
Address <input type=Text name ="Add1"><br>
Sex(1 for Male, 2 for Female)<input type=Text
size=1 name ="Sex1"><br>
age<input type=Text size=2 name ="Age1"><p>

<input type=submit value="Preview">
</form> </h2></center>
</body></html>

```

## 5. Conclusion

The about web pages programs are standard format for all single table MIS. In application, all that was needed is to change the database name, field names to make it fit.

# The Role of the Relational Database Model in E-Business

Terrence D. Quinn

California Polytechnic & State University  
3801 W. Temple Ave., Pomona. CA 91768  
tdquinn@csupomona.edu

## Abstract

The subject of databases will be a topic we, as e-business and IT professionals will encounter quite often in the field we have chosen. There are several database formats available that I will briefly mention, but I will quickly return focus back to the most widely used and in my opinion the best out there, relational database. I believe in order for an e-business to survive or any business for that matter, it must have complete control of its database and at all phases from creation to upgrade. Not only will this paper provide an overview of the various database management system available it will also provide a real case study of how an e-business uses its relational database management system to stay competitive within its specific industry.

## 1. Hierarchical Database Model

The first database system developed was the hierarchical database model. The hierarchical model used physical pointers to link records (see Appendix A.) As its name implies, this type of model only allowed hierarchical relationships. This means that each entity at a lower level can only be linked to one entity at a higher level, this type of relationship is known as a "parent-child" relationship (see Appendix B.) Hierarchical database provides very efficient high-speed retrieval (NAU.) Unfortunately hierarchical database models have more disadvantages than advantages. Some of these disadvantages include: (1) Hierarchical databases are too difficult to modify and maintain as an organization and its needs grow. (2) It is almost impossible to represent non-hierarchical relationships. In order to be able to complete such a task you would have to relate many hierarchical databases together resulting in the production of redundant data.

## 2. Network Database Model

Another database model that is used is called the network database model. The network database model was created to represent complex data relationships more effectively than the hierarchical model could, to improve database performance, and to impose a database standard. This model is very similar to the hierarchical model and has all of its attributes plus some of its own. The network model differs from that of the hierarchical by allowing a data element to have more than one parent. What makes network database models a little less desirable is the fact that they use an even more complex set of pointer structures that can be

confusing for the end user to manipulate, and its lack of structural independence, meaning if any structural changes were made to the database all application must be revalidated before they can access the database. Due to these disadvantage the network database model was widely replaced by the relational database model.

## 3. Relational Database Model

As mentioned before, the relational database model is the most widely used and in my opinion (if that counts) the best database management system available. The relational model, first developed by E.F. Codd (of IBM) in 1970, represented a major breakthrough for both users and designers. (DS) A fine analogy that represents this transition well states "the relational model produced an "automatic transmission" database to replace the "manual transmission" database that preceded it." (DS) Unfortunately at its time of creation, the relational model was too rich; computers lacked the power to implement the model.

Presently, a majority of computers ranging from mainframe legacy systems to the fastest of microcomputers are able to handle relational database modeled software, software's such as Sybase, Oracle, DB2, Access, SQLServer and countless others, some of which we will review in detail later. So now we must answer the question, what is a relational database and more importantly how can it be used to improve an e-business?

A relational database model uses a relational database management system to perform the same basic functions that the previously mentioned hierarchical and network models performed and multitudes more. To the end user the relational database is made up of tables that store data. The beauty of a relational database is that each table, made up of rows and columns which are analogous to records and fields, and once these rows and columns (or records and fields) have been filled with the appropriate data; all operation are done on the tables themselves. Once this data is placed in a table, each table must have what is called a primary key. A primary key is simply an attribute that uniquely identifies any given row

As you may have noticed I mention two very important concepts above, the former being that the tables are filled with *appropriate* data and the later being *operations* performed on the tables themselves. What is

meant by appropriate data is data that has been normalized and what is meant by operations is Structured Query Language (SQL) used to extract information from the data tables. We will explore these two concepts in detail next.

Before any data can be placed in a table we must make sure that the tables are normalized, causing any data inserted in these tables to be normalized as well. By normalization you are insuring three things

1. All column values are atomic
2. All column values depend on the value of the primary key
3. No column value depends on any other column value except that of the primary key.

When you have applied the three rules, you say the database is in the Third Normal Form (3NF), or that it is "normalized". A normalized database generally improves performance, lowers storage requirements, and makes it easier to change the application to add new features. Remember, most software projects change it's requirements during its development, so the time spend normalizing a database will actually mean less development time. (EDM/2)

Structured Query Language or SQL for short is the relational models standard language and is composed of about 30 commands that allow you to create database and table structures, perform various types of data manipulation, and query the database to extract useful information.

The 30 commands previously mentioned fall into two basic categories: data definition language (DDL) and data manipulation language (DML).

The DDL provides the standards or SQL statement necessary to create the database schema and create the data tables within the schema (see Appendix C). The DML provides the standards or the SQL statement necessary to retrieve data or to query specific information from the database.

#### **4. Applications of a Relational Database in e-Business**

Now that we have a clear definition and understanding of a relational database, its components and how it works, one question remains; how can a RDMS help an e-business? To answer this question, as promised earlier I will use as my example one of the RDMS software's mentioned previously. In order to have a successful business any organization must at any given time be able to account for its employees, products and customers. Many companies accomplish this task by employing the help of a relational database management system. Jaafri.com, a company I currently have the pleasure of working with as part of my senior project has allowed myself and group of fellow classmate to update their website. Jaafri.com is a small firm that sells office supplies to larger firms through traditional

means as well as the Internet. Our goal by the beginning of fall 2002 is to provide Jaafri.com with a fully functional relational database management system powered by Oracle 8i software. Currently Jaafri.com is using as it RDMS Microsoft Access. Although Access is a powerful RDMS, if Jaafri.com wants to compete with other firms in its market it must chose a database management system that is scalable. We chose Oracle 8i software because Oracle has it own additions to SQL, called PL/SQL. PL/SQL stand for Procedural Language/ Structured Query Language. With this addition we will be able to write in exception handling code that will respond with a specific message if a product is out of stock, no longer available for purchase or if a substitute product is recommended.

Although very brief I hope this real life case study cast a little light on how a RDMS can help an e-business stay competitive and successful in the new economy.

## APPENDIX A

### Pointer Based Linkages Between Entities

Location	Prof#	Name	Office#	1st Student
P10	J13	Jones	SB312	P203
P11	M7	Morger	BA218	P200
P12	D23	Davis	SB 106	P201

To retrieve related data using pointers one simply follows the pointer chain.

For example, The record for Professor Jones contains a pointer indicating that the first related student is to be found at location P203 in the student file.

When the record for student 203 is retrieved it contains a pointer to the record for the next student linked to this professor (P205). That student's record points to the next related student (P207). The record at P207 contains an indicator (\*) that it is the last related record for this professor.

Location	Stud#	S_name	Class	
			Standin	Next
P200	1234	Smith	Fr	P202
P201	4678	Davis	So	P204
P202	2943	Evans	Fr	P206
P203	1874	Allen	Jr	P205
P204	4017	Lloyd	Fr	*
P205	2318	Marx	Sr	P207
P206	6021	Keen	So	*
P207	5503	Watts	Jr	*

This set of pointers forms a chain. The students Allen, Marx, and Watts are all related to Professor Smith (his advisees)

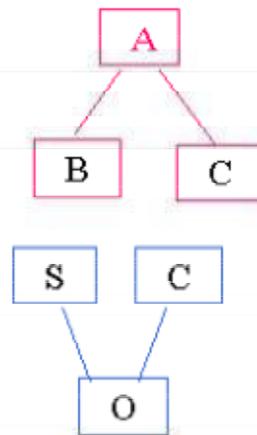

To retrieve the set of students related to a professor, we simply walk the chain by using the pointer in each record to retrieve the next related record.

Pointer: A reference device that "points" to the location of specified data in the storage medium.

## APPENDIX B

### Hierarchical and Network Relationships

- A hierarchical relationship is one where each entity at a lower level of the hierarchy is related to only one type of entity at a higher level of the hierarchy (a higher level entity can be linked to two or more lower level "child" entities)
- A network relationship is one in which an entity at a lower level can be linked to two or more entities at a higher level.
  - E.G. - an order is related to both a customer who placed it and a salesperson who made the sale
- The hierarchical model does not support network relationships.
  - To capture them a second database would have to be created and linked to the first.

## APPENDIX C

### Creating and Manipulating the Database Structure

CREATE DATABASE <database name>; allows you to create the database

CREATE TABLE<table name>; allows you to create a table

CREATE TABLE<table name>; create table with attributes and primary key designation  
<attribute1 name and attribute1 characteristics  
primary key designation, >

INSERT INTO <table name> allows you to insert data into tables  
VALUES<attributes1 value, attributes2 value, etc... >;

SELECT\* allows you to retrieve all data stored in a table  
FROM <table name>;

SELECT <column(s)> allows you to retrieve a specific record of data stored in a table  
FROM <table name>  
WHERE<condition(s)>;

# Application Service Provisioning in SMEs: The Tough Job after the Hype

## Abstract

In the late 1990s the ASP (Application Service Provisioning) model was supposed to be the perfect solution for SMEs to reduce the cost and the risk of IT investments and to access high-quality services they could not otherwise afford.

In Italy, where the vast majority of firms are small or medium sized, the ASPs market has up to now failed to attract customers, with erratic sales and no real “killer application”. Nevertheless, after the “irrational exuberance” of the late 90s, existing ASPs are slowly starting to increase their sales.

The objective of this paper is to analyse the constraints on the growth of ASPs through empirical research, aimed at:

- understanding demand-side problems, especially related to the existing investments in IT and to the inability of adopting new services without incurring a time-consuming learning process;
- indicating relationships between the SME’s experience with IT and the likelihood to adopt ASP services;
- pointing out elements that may help to understand the next phase of the evolution of ASPs.

This research investigated a population of 438 manufacturing firms in the region around Turin, in Northwestern Italy, having between 50 and 1,000 employees.

## 1. Introduction

Application Service Provisioning has been considered one of the most promising areas of e-Business. Experts thought of Application Service Providers (ASPs) as the preferred solution for SMEs to reduce the cost and the risk on IT investments and to access high-quality services they could not otherwise afford. In the late Nineties almost 500 ASPs started their activity, but notwithstanding the robust cash injections they got from VCs, few of them are still healthy and in business [1,3].

The result of the hype was that ASPs largely failed to deliver expected high-quality customized solutions, also because they did not fully understand the difficulties that SMEs had in adopting and integrating their services within their existing IT infrastructure. As a result, the failure of ASPs was particularly significant in the SME market, just where the model was supposed to be most promising [1,2]. Such initial failure has caused many ASPs to shut down their operations. This has been associated to causes such

as:

- unrealistic expectation in revenues;
- flawed business models, with vague business propositions;
- difficult of execution against a complex delivery model;
- the absence of a killer application.

In Italy, where the vast majority of firms are small or medium sized, the ASPs market has up to now failed to attract customers, with erratic sales that only now are starting to show a slight growth. The objective of this paper is both to understand the reason of the present failure and to estimate the potential of the future diffusion of the ASP throughout an empirical research of firms’ issues and needs. The population of firms to be studied was chosen to be the members of the “Industrial Union of Turin”, the main local trade association, having a size between 50 and 1.000 employees; firms in this range were supposed to be the ones which may obtain the largest benefits from the adoption of ASP. The research was based on a questionnaire made up of different sections, addressing the magnitude of investment in IT, the applications already adopted, the perception of the ASP model and the willingness to adopt it in different functional areas. The company’s CIOs and CEOs received different sections. There were 104 valid replies (about 24% of the population).

## 2. Existing ICT Infrastructure

A major part of the questionnaire was aimed at understanding the current endowment of Information and Communication Technologies in the firms involved in the research. This allows us to understand the incremental nature of ICT adoption.

### 2.1. External Connectivity

Analysing the answers given by the firms, we have discovered that the external connectivity is not developed enough to sustain a generalized use of ASP. In fact, about 40 % of the firms have low-speed connections (less than 128 KB/s) and only one third may support ASP use with broadband. [Fig.1]

As predictable, low speed connections are more frequent in the smaller firms. Only among firms with total annual sales greater than 50 million € there is a significant percentage of broadband connections [Fig.2].

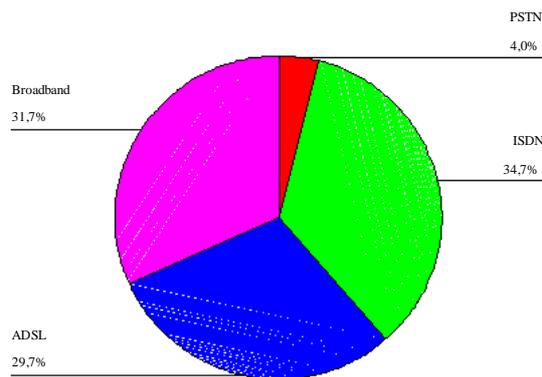

Figure 1: Speed connection to the Internet/Extranet

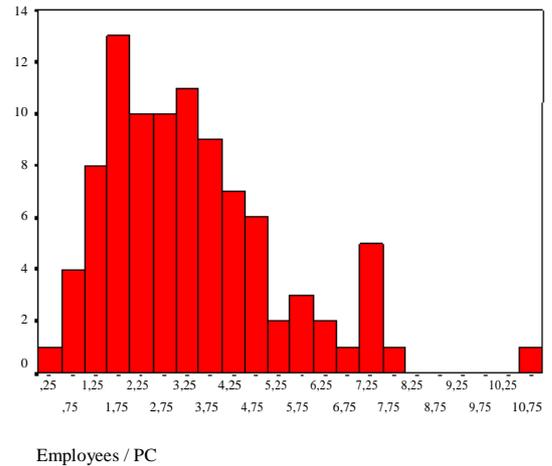

Figure 3: Distribution of PC density

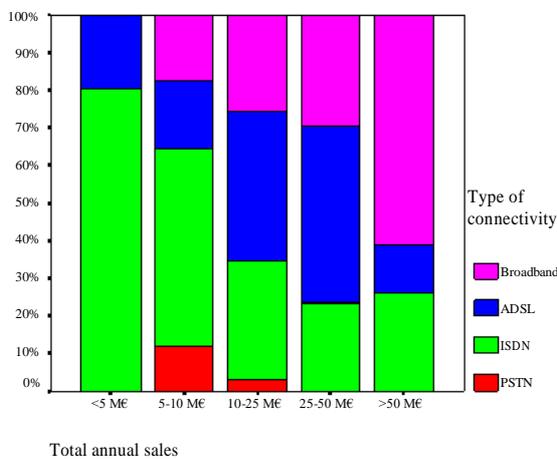

Figure 2: Connectivity vs. Total annual sales (significant at  $p < 0.003$  according to G-K  $\tau$  with “connectivity” dependent)

This bottleneck prevents ASPs from fulfilling one of their promises, i.e., the filling of the technology divide separating the larger companies from the smaller ones.

## 2.2. Diffusion of ICT in the Workplace

The diffusion of personal computers in firms is quite high. On average, firms have one PC for every 4.12 employees [Fig.3]. By adding terminals the figure becomes one workstation for every 3.07 employees.

This means that almost every employee is in some way “reached” or “reachable” by the IT applications. This figure is independent from the size of firms.

Moreover, almost all PCs (about 90% on average) are connected to the Internet. This implies that they easily be used as clients for centrally managed applications, as required by the ASP model.

## 2.3. Hardware and Software Architecture

We have observed that the client/server architecture is by and large the one with greater diffusion, either used alone or together with other solutions. There is also a certain utilization of Intranet architectures, in which clients are simple browsers. This experience with “thin clients” may facilitate the adoption of the ASP model [Fig.4].

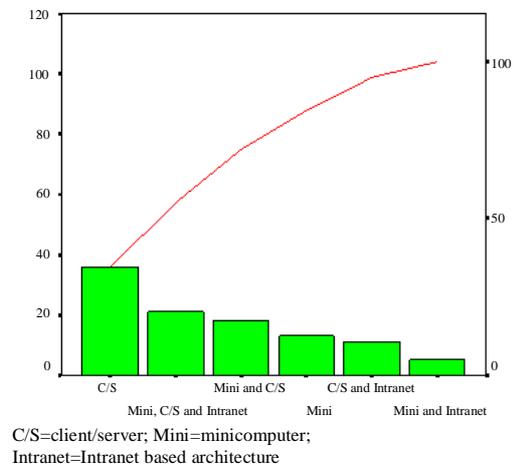

Figure 4: Hardware architecture

As expected, there is a strong relationship between the type of hardware architecture and firm size. Intranet-based architectures can be only found in firms with total annual sales higher than 50 million €. Smaller firms’ lack of experience could be another disadvantage for adopting and exploiting the ASP model [Fig.5].

From the point of view of business applications, almost 50% of firms have just adopted systems with native integration (i.e., ERP), while only 13.6% have non-integrated applications. The remaining firms had to integrate applications with custom software development [Fig.6].

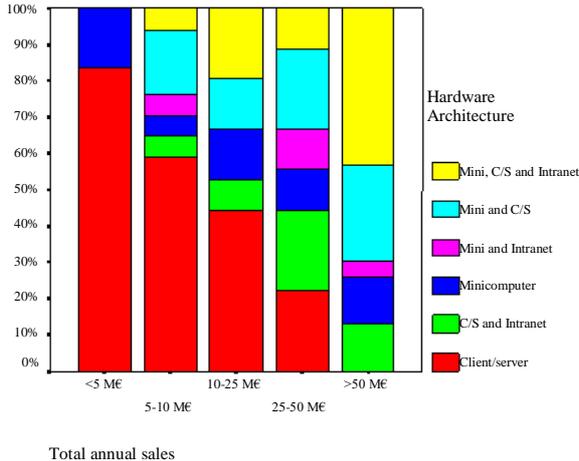

Figure 5: Hardware architecture vs. total annual sales (significant at  $p < 0.001$  according to Lambda statistic with “Hardware Architecture” dependent)

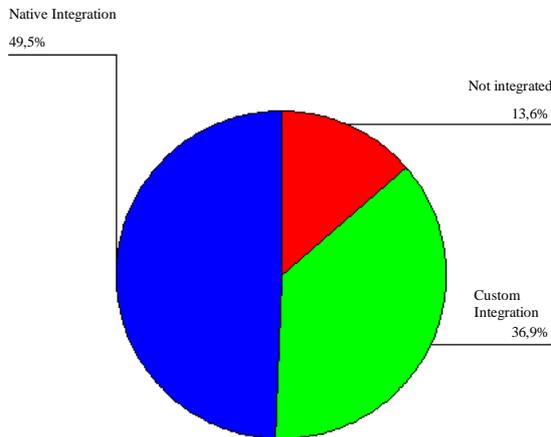

Figure 6: Level of integration of applications

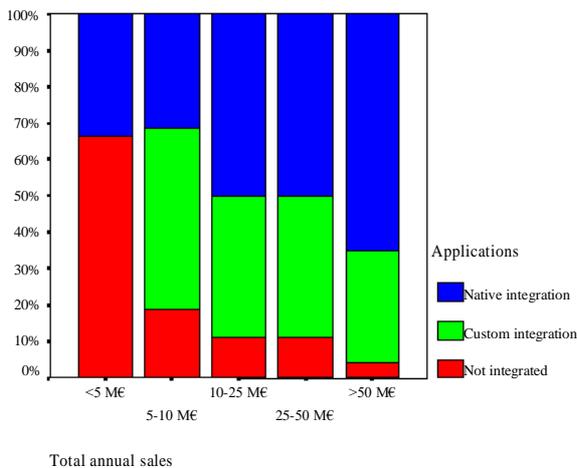

Figure 7: Type of integration vs. total annual sales (significant at  $p < 0.009$  according to Kendall’s  $\tau$ -b with “Applications” dependent)

Native integration is more common in the larger companies, even though it is noteworthy that none of the smallest ones (annual sales less than 5 million €) have attempted “customized integration” [Fig.7].

## 2.4. Available and Future Business Applications

By studying the diffusion of specific business applications in different functional areas, we see that only very few firms nowadays do not have specific applications supporting their activities [Tab.1].

Table 1: Business activity supported by specific applications

Business activity	Percentage of actual adoption
Manufacturing	87.5 %
Administration	100 %
Sales	76.9 %
Human Resources	76 %
Product Design	88.5 %

In order to estimate the diffusion potential of a number of business applications we have also considered the will/use ratio [Tab.2].

Table 2: percentage of diffusion of some applications and will/use ratio

Applications	Present adopters	Future adopters (in 2002)	Will/use
<b>Manufacturing</b>			
MRP	57,7%	8,7%	15,0%
Scheduling systems	26,0%	12,5%	48,1%
Quality control systems	47,1%	10,6%	22,4%
Production activity control	61,5%	10,6%	17,2%
EDI – Electronic Data Interchange	51,0%	5,8%	11,3%
<b>Administration</b>			
Accounting	98,1%	1,0%	1,0%
Workflow and document management	26,9%	10,6%	39,3%
Management of finances	91,3%	2,9%	3,2%
<b>Sales</b>			
e-commerce	5,8%	8,7%	150,0%
Catalogues and pricelist editing	38,5%	3,8%	10,0%
Customer Database management	68,3%	4,8%	7,0%
Newsletter editing	25,0%	5,8%	23,1%
Sales force automation	55,8%	4,8%	8,6%
<b>Human resources management</b>			
Payroll	63,5%	1,0%	1,5%
Travel expenses	34,6%	1,9%	5,6%
Recruiting, evaluation and training of H.R:	38,5%	1,9%	5,0%
publishing of internal procedures on the Intranet	19,2%	4,8%	25,0%
<b>Product development and management</b>			
EDM / PDM	26,0%	8,7%	33,3%
Project management	44,2%	10,6%	23,9%
CAD	79,8%	2,9%	3,6%
CAM	30,8%	3,8%	12,5%
CAE	21,2%	3,8%	18,2%

This is defined as the ratio between the number of firms who plan to adopt an application in the current year (2002) and the number of firms who have already adopted it. This may be considered to be a good indicator of the instantaneous growth rate for the application. Specifically, the ratio discriminates among applications approaching market saturation and the ones that are at the beginning of their diffusion process. This is relevant since the former could only be adopted through ASPs by substitution of existing installations, while the latter may diffuse directly through the ASP model.

Most firms do have a web-site, which is mainly used for offering information to customers and suppliers. Very few firms are however able to carry out transactions online [Fig.8].

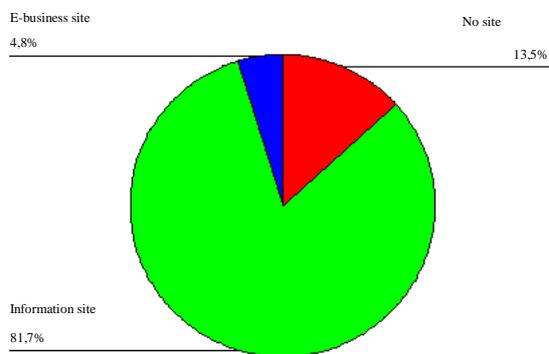

Figure 8: Web-site content

By considering the location in which the web-site is hosted, we notice that the dominant solution is through a service provider. Only 19.4% of firms have their web-site hosted on their own servers.

This type of outsourcing is generalized for the smaller firms, but is also very common among the bigger ones [Fig.9].

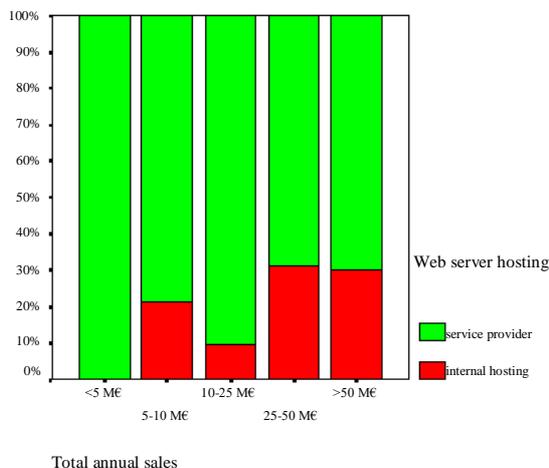

Figure 9: Web server hosting vs. total annual sales (significant at  $p < 0.072$  according to Kendall's  $\tau$ -b with "Web server" dependent)

This may be seen as the result of a high level of confidence with outsourcing. However, it may also be due to the fact that since the website is not able to perform transactions, it is not considered to be a mission critical application.

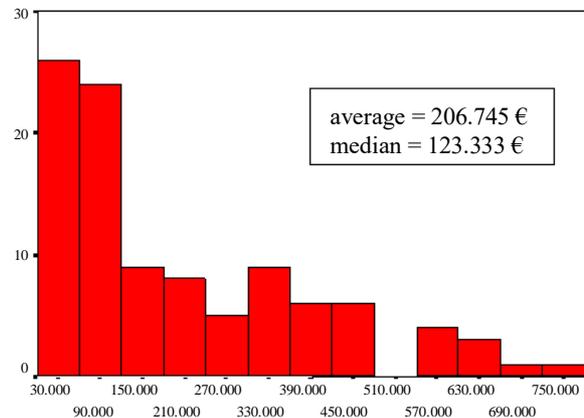

### 3. ICT Cost and Strategy

Another section of the questionnaire was aimed at understanding the cost of ICT and the assessment of the value it creates. The most relevant statistics follow.

#### 3.1. ICT Total Cost of Ownership

The cost of ICT has been calculated by adding up annual costs for hardware, software, connectivity, human resources assigned to ICT, assistance and maintenance, consultancy and training.

This total annual cost is averagely 207,000 €, but the statistical distribution is strongly skewed by few high spending firms; in fact, the median value is much more lower and is equal to 123,000 € [Fig.10].

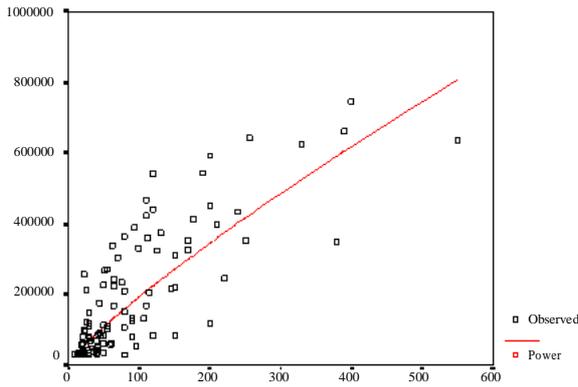

ICT annual total cost and dedicated personnel

Figure 10: Distribution of total annual expense for ICT

We have found that economies of scale in ICT are present. We have considered the number of PCs as an indicator of the size of firms' ICT functions and used the following Cobb-Douglas model:

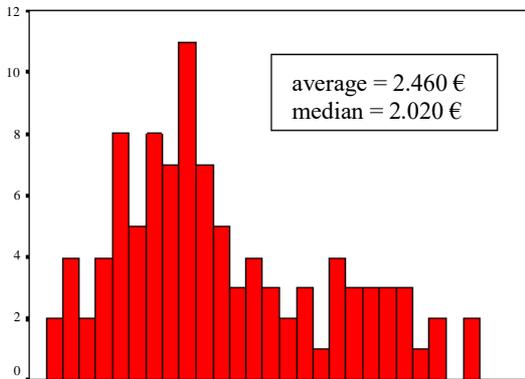

$$y = b_0 x^{b_1} \quad (1)$$

where "y" is the total annual expenditure in ICT and "x" is the number of PCs and terminals. Minimum square estimation of a linearized version of (1) has given a parameter  $b_1 = 0.8384$  (a value less than 1 indicates the existence of economies of scale) with a good level of correlation ( $R^2 = 0.618$ ). To easily understand the entity of this value, this implies that every time the number of work places managed doubles, one can have 11% of savings.[Fig.11]

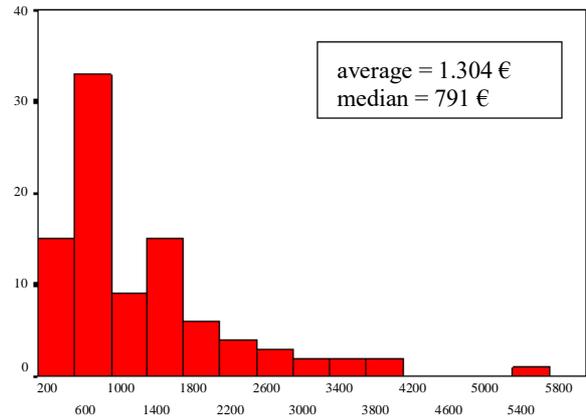

PCs and terminals  
 Figure 11: Annual ICT expenditure vs. number of work places

One of the most interesting findings of the research is associated to the analysis of ICT cost of ownership. This cost is very low, if divided by the firms' number of workstations [Fig.12] or by the number of employees [Fig.13] Thus measured, the cost of ICT is one order of magnitude less than the cost of the personnel using these technologies. In first approximation, it is evident that investments in ICT may return profits even for small improvements of productivity.

ICT annual expenditure per single work station  
 Figure 12: Distribution of the ICT cost for single workstation

Moreover, the relatively low cost of ICT may suggest that this may not represent a critical factor in determining firms' investment decisions. In fact, only 28% of CEOs recognize financial shortage as an obstacle to investing in hardware or software. Moreover, 62% of firms have stated that if savings in ICT were possible, the money would be spent in the same activity area. Another 15% of CEOs define the ICT budget to be "not so significant" if compared to the total amount of investments.

ICT annual expenditure per total firm's employees  
 Figure 13: Distribution of the ICT cost for single employee

### 3.2. Perceived Value of ICT

Firms are usually pleased with the level of the service that their ICT equipment gives to operational activities [Fig.14]. This assessment is not correlated with the firms characteristics (i.e. size), but is correlated with the architecture adopted. Dissatisfaction is located in firms that have implemented the simpler hardware architectures ("pure" Client/Server or minicomputer) or which have not integrated their business applications [Fig.15 and Fig.16].

This does not explain whether the dissatisfaction is due to the architectural choice or to the fact that applications based on these architectures may be less up-to-date.

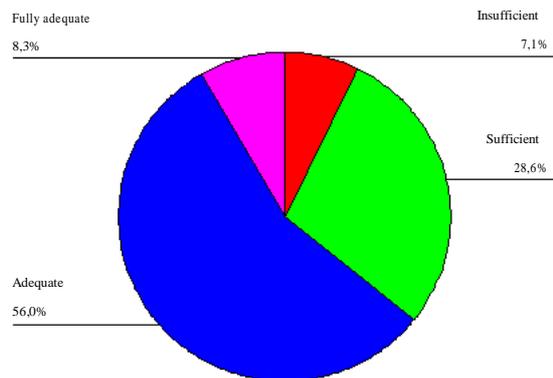

Figure 14: Level of service offered to the firm's operations

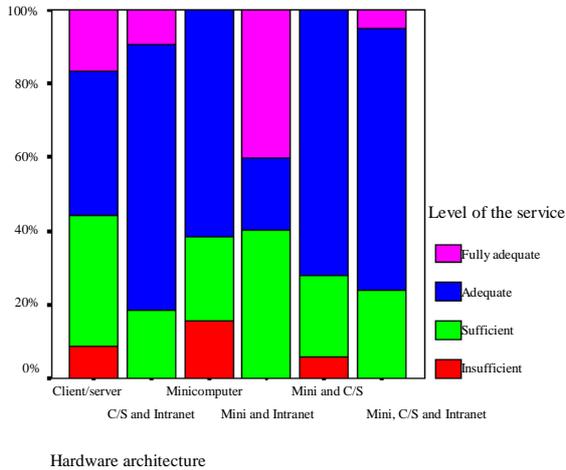

Figure 15: Level of the service offered to the operation vs. hardware architecture (significant at  $p < 0.060$  according to G-K  $\tau$  with “Level of Service” dependent)

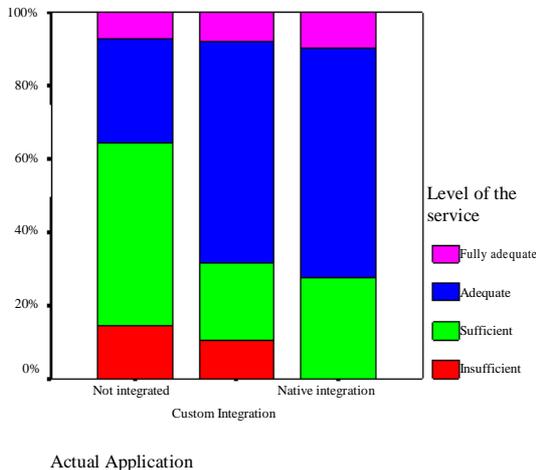

Figure 16: Level of the service offered to the operation vs. level of integration (significant at  $p < 0.040$  according to G-K  $\tau$  with “Level of Service” dependent)

We have asked both the CEOs and the CIOs to express their opinion about the cost of the ICT and the value it creates. The three options were “the value created by ICT is higher / equal / lower than its cost”. By comparing the answers provided by CEOs and CIOs we have noticed that an interesting correlation exists between the differences in the judgments and the annual expenditure per employees. CEOs are more satisfied than CIOs when expenditure is low and vice versa [Fig.17]. This correlation may suggest that the higher management is more interested in keeping costs under control, rather than in their related returns.

Incidentally, CEOs generally state that it is difficult to evaluate ICT investments properly, especially because of their lack of tangibility [Fig.18]. This difficulty is especially found in the smaller firms [Fig.19]. This may suggest that alternative models for managing ICT, such as Application Service Provisioning, must be accompanied by tools helping firms to evaluate properly the cost of ownership and the ROI of their choices.

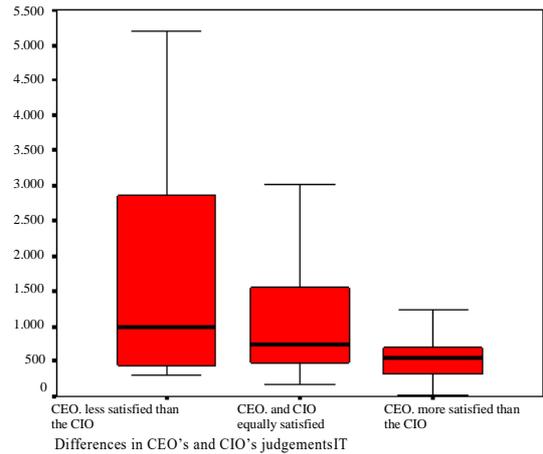

Figure 17: Differences in CEO's and CIO's judgments vs. annual expenditure per employees (significant at  $p < 0.087$  with ANOVA)

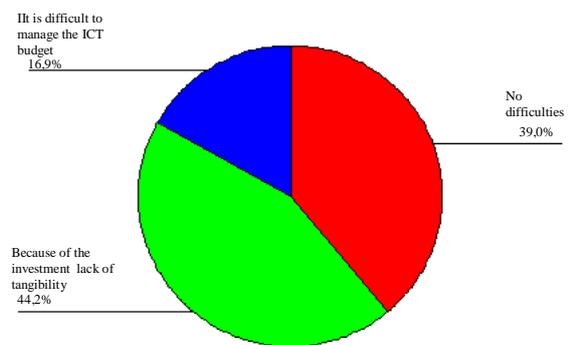

Figure 18: Difficulties in managing the ICT investments

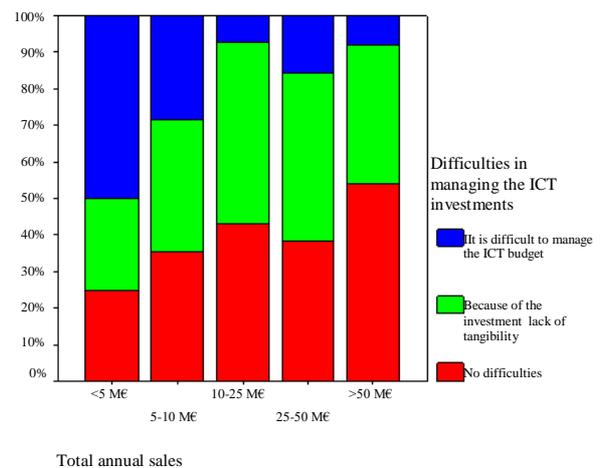

Figure 19: Difficulties in managing the ICT investments vs. total annual sales (not statistically significant)

### 3.3.The Evaluation of the ASP

In order to understand the way in which firms perceive the ASP model, the firms were asked to provide an evaluation of the importance of a number of advantages and disadvantages. The evaluations have been expressed in a Likert scale ranging from 1 to 5.

Firms generally do not give a high evaluation of potential advantages of ASP. The advantage that the firms are most interested in seems to be the external management of hardware and software upgrades [Tab.3]. The disadvantages that firms worry most about are related to losing control on confidential data and the risk of high future switching costs [Tab.4].

Table 3: Evaluation of potential ASP advantages

Potential Advantages	Average evaluation
Focus on core business	2.10
Easier access to new applications	2.73
External management of hardware and software upgrades	2.76
Continuous assistance	2.56
Proposal of new applications	2.04
Evaluation of applications	2.55

Table 4: Evaluation of potential ASP disadvantages

Potential Disadvantages	Evaluation
Loss of control on confidential information	2.96
Switching cost for changing provider	2.86
Loss of control on a strategic area	2.80
Higher total cost	2.68
Worse service level	2.40
Lower reliability of hardware	2.29
Higher vulnerability to viruses	2.44
Higher vulnerability to hackers	1.96

It is important to notice that the concentration of the evaluations between “2” and “3” means that firms are generally slightly sensitive towards both advantages and disadvantages. So, it has been considered appropriate to widen the analysis and to use Principal Component Analysis in order to define the “perceptual space” with which firms evaluate the concept of ASP.

The underlying conceptual model is a “lens model”, as used in marketing research [Fig.20]. In this model, the perception of the ASP solution is influenced by variables related to the firm’s strategic focus and by variables related to past experience with ICT. We then hypothesize that the perception of ASP influences the inclination towards adopting this paradigm and, specifically, of using ASP for new applications rather than for substituting existing ones.

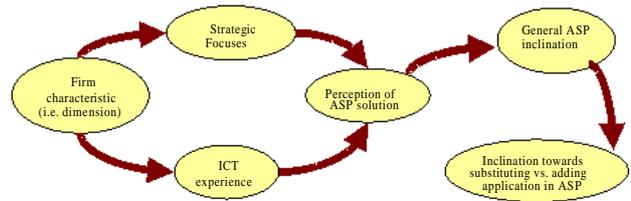

Figure 20: ASP perception (lens model)

Principal Component Analysis has shown the existence of three latent variables, or leading perceptive dimensions, that are able to explain the 61% of variance in firms’ evaluations. The following Tab.5 shows the loading parameters, which express the correlation between original and latent variables, after applying Varimax rotation. The most significant loading parameters are highlighted in grey. Looking at the table we have named “perception of advantages” the first latent variable (given by variables from 1 to 6), “perception of technological disadvantages” the second (given by variables 7 and 12 through 14), “strategic disadvantages perception” the third (given by variables from 8 to 11). To make analysis easier the latent variables have then been transformed into binary values “low” and “high”, so that each value comprises the 50% “lower” and “higher” firms.

Table 5: Factorial analysis on ASP perception

Variable	Latent variable	1	2	3
1. Focus on core business		0,639	0,197	-0,171
2. Easier access to new applications		0,741	0,011	0,026
3. External management of hardware and software upgrades		0,693	0,141	-0,024
4. Continuous assistance		0,715	0,316	-0,055
5. Proposal of new applications		0,733	-0,018	0,253
6. Evaluation of applications		0,763	-0,003	0,141
7. Loss of control on confidential information		0,088	0,681	0,238
8. Switching cost for changing provider		0,172	0,147	0,664
9. Loss of control on a strategic area		0,088	0,404	0,616
10. Higher total cost		-0,087	0,089	0,761
11. Worse service level		-0,047	0,296	0,737
12. Lower reliability of hardware		0,177	0,833	0,233
13. Higher vulnerability to viruses		0,151	0,878	0,148
14. Higher vulnerability to hackers		0,074	0,896	0,213

The three new variables now allow us to locate the firms in the perceptual space and to understand their profile. The main correlations found are the following:

- The perception of advantages is higher in firms that affirm to compete in product innovation and in the firms with direct contact to the market (not producing for firms in the same group).
- The perception of technological disadvantages is

stronger in firms with lower overall investments.

- The perception of strategic disadvantages is stronger in firms with high overall investments and focused upon cost/price competition. There is also a generalized correlation of this perception with the level of the owned ICT (external connection speed, hardware architecture, level of integration of the applications): this fact may suggest that firms with a high profile ICT equipment have reached a stronger awareness about the importance of ICT activities and, moreover, being in a better position, they are more worried about the risks that an externalisation could cause.

### 3.4. The Inclination to ASP

In order to understand the inclination of the firms towards the possibility of adopting some applications in the ASP model, we have asked them to assess their interest using values ranging from 1 (low interest) to 4 (high interest).

Table 5: Interest in ASP supply

Applications	Interest in ASP supply	No / low interest	High Interest
<b>Manufacturing</b>			
MRP	1.79	75.3%	24.7%
Scheduling systems	1.88	72.4%	27.6%
Quality control systems	1.91	75.3%	24.7%
Production activity control	1.86	72.8%	27.2%
EDI – Electronic Data Interchange	2.21	60.0%	40.0%
<b>Administration</b>			
Accounting	1.99	71.3%	28.7%
Workflow and document management	2.05	77.0%	33.0%
Management of finances	1.54	88.0%	12.0%
Office automation	1.91	70.4%	29.6%
E-mail server	1.72	78.5%	21.5%
Business website	2.33	51.7%	48.3%
<b>Sales</b>			
e-commerce	1.94	70.4%	29.6%
Catalogues and pricelist editing	1.83	75.0%	25.0%
Customer Database management	1.82	77.5%	22.5%
Newsletter editing	1.88	70.5%	29.5%
Sales force automation	2.00	67.9%	32.1%
<b>Human resources management</b>			
Payroll	1.77	77.9%	22.1%
Travel expenses	1.83	75.0%	25.0%
Recruiting, evaluation and training of H.R:	1.82	71.4%	28.6%
publishing of internal procedures on the Intranet	1.79	75.8%	24.2%
<b>Product development and management</b>			
EDM / PDM	1.82	80.6%	19.4%
Project management	1.53	87.5%	12.5%
CAD	1.39	91.8%	8.2%
CAM	1.40	93.0%	7.0%
CAE	2.29	56.5%	43.5%

We also have asked to return value 0 for applications they are not interested in at all. The average values are quite low, but it is important to notice they are burdened by a number of very negative evaluations: if we consider only the percentage of firms that have expressed a high level of interest (values 3 or 4) we can find that according to the type of application, this goes from a disappointing 7% to a more promising 43% [Tab.5].

In order to have a concise measure of firms' inclination to ASP we have defined a "high" inclination when the firm has expressed a high interest for a number of applications greater than the number of applications for which it has expressed no or low interest.

We have found that the inclination is linked with the perception of ASP. Specifically, inclination is higher for firms with a high perception of the advantages (as one might easily assume) and in the firms with high perception of technological disadvantages (which shows that these disadvantages are not so important). Moreover there is not a correlation with the strategic disadvantages dimension. This could suggest that this perceptual dimension should not constitute a real hindrance for adoption of ASP.

### 3.5. Approaches to ASP

In most cases, firms declared ASP to be a possible solution for adopting new applications (75.5%) while only 24.5% of them claimed to be interested in the substitution of the present supply model.

This finding significantly bounds the potential of the ASP market for those applications that have approached saturation.

As expected, the type of approach is correlated to the inclination to the ASP model (firms with substitution strategy generally have higher inclination). Moreover, it is correlated to the level of services offered to operations by ICT. Inclination to substitute current applications is higher for firms where service level is not satisfactory (these firms are probably looking for better solutions) and for firms where it is fully adequate (one may hypothesize that firms with greater experience are more interested in innovative solutions) [Fig.21].

### 3.6. Inclination to the Outsourcing of ICT

In our research we asked CEOs to declare their strategy regarding the possibility of outsourcing ICT [Fig.22]. Most CEOs think it is better to keep ICT activities within the firm for the applications considered to be strategic (58.1%) or even for all applications (20.3%). Very few firms are inclined to a total outsourcing (12.3%), or to a choice based only upon financial considerations (9.5%).

Firms that expressed a greater inclination to outsourcing are generally stand-alone firms (not subsidiaries of a group), with total annual sales ranging between 5 and 50 million €, and have adopted the simpler hardware architectures.

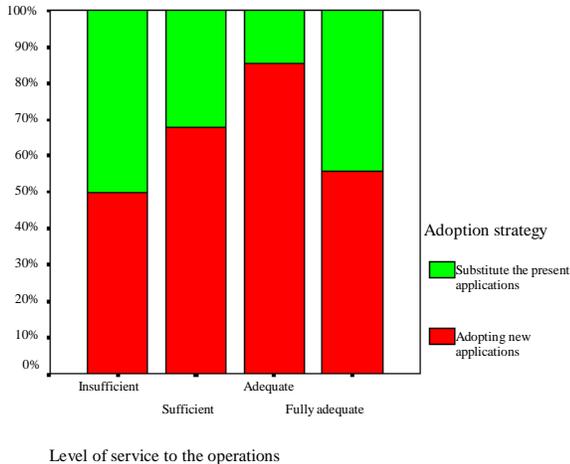

Figure 21: Adoption Strategy vs. level of service to the operations (significant at  $p < 0.05$  according to G-K with “Adoption strategy” dependent)

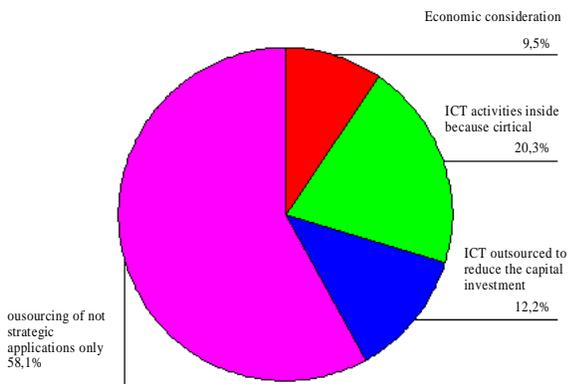

Figure 22: Inclination to ICT outsourcing

#### 4. Concluding Remarks

These summarized findings lead to concluding remarks that can be relevant to the possible evolution of the ASP market:

- The initial ASP value proposition oversimplified IT needs and costs inside firms. Firms probably do not own “state of the art” applications, but what exists is the result of a long “learning by doing” process that makes it difficult to integrate ASPs offer with existing IT infrastructure.
- It is very difficult for ASP to pursue a “low cost” and/or “one-stop shopping” strategy. ASPs will have to offer initially “additional” applications, in order to gain customers’ trust and to build long-term relationships.
- The cost of customer acquisition is high, as is the cost for keeping service levels fixed in SLAs. The

importance of on-site services will probably compel ASPs to establish alliances with systems integration firms that already have a customer oriented structure;

- ASPs will have to invest more in making their customers conscious of the benefits of their services; results shows that there is a strong positive correlation between understanding of benefits and will of use;
- Lacking a killer application, differentiation strategies (focused on a small number of innovative, non-core applications) seem to be the most promising for ASPs. Research results show that - depending on the application - the fraction of firms highly interested in acquiring them through ASPs may range from a disappointing 7% to a promising 48%;
- The “hidden cost” of this choice is the risk to miss the promise of IT overall cost reduction and of applications integration;
- “Pure player” ASPs will suffer from competition from a wide range of competitors, including:
  - specialized suppliers of “traditional” services that will modify their offer according to the ASPs model;
  - systems integrators that already control firms’ IT infrastructure;
  - software vendors, that can easily start selling their products in ASP mode;
  - telecom providers, that will bundle Application Service Provisioning inside their broadband services.

In summary, these issues greatly reduce the expected profitability of the ASP model, which will probably require a long time before becoming acceptable. Questions to be addressed by future research are related to:

- the ASP’s ability to deliver value to SMEs, becoming a key factor for their growth;
- the survival of ASP as an independent market, since vertical integration could force pure players out of the market;
- the emerging structure of the business software value chain and the characteristics of firms that will control it.

# ENAT-PT: An Enhanced NAT-PT Model

Li-An Zeng, Zhao-Hui Cheng, Li Ling, Songrong Qian, Xu Liao

Institute of Information Science and Engineering  
Fudan University, Shanghai, China  
zenglian@sina.com

## Abstract

NAT-PT would allow IPv4 nodes to communicate with IPv6 nodes transparently by translating the IPv6 address into a registered V4 address. However, NAT-PT would fall flat when the pool of V4 addresses is exhausted. NAPT-PT multiplexes the registered address' ports and will allow for a maximum of 63K outbound TCP and 63K UDP sessions per IPv4 address, but it is unidirectional. We present in this paper a novel solution ENAT-PT (an enhanced NAT-PT) , which will allow for a great number of inbound sessions by using a single V4 address. By using ENAT-PT, we can visit V6 networks from a V4 network with a small address pool.

Key words: ENAT-PT; IPv6 Transition; NAT-PT; NAPT

## 1. Introduction

The key to a successful IPv6 transition is compatibility with the large installed base of IPv4 hosts and routers. Maintaining compatibility with IPv4 while deploying IPv6 will streamline the task of transitioning the Internet to IPv6. IPv6 transition mechanisms include providing complete implementations of both versions of the Internet Protocol[1,2], and tunneling IPv6 packets over IPv4 routing infrastructures[3,4]. They are designed to allow IPv6 nodes to maintain complete compatibility with IPv4, which should greatly simplify the deployment of IPv6 in the Internet, and facilitate the eventual transition of the entire Internet to IPv6. Another important and widely used technology is NAT-PT[5-9]. Network Address Translation is a method by which IP addresses are mapped from one address realm to another, providing transparent routing to end hosts. Protocol Translation define the translation rules between IPv4 headers and IPv6 headers[10]. Traditional NAT-PT such as NAPT-PT is unidirectional while Bi-Directional-NAT-PT allows IPv4-only node to visit IPv6-only node and vice versa, but Bi-Directional-NAT-PT can not reuse a registered address for more than one session. Thus, we develop ENAT-PT to solve this problem. The most outstanding feature of ENAT-PT is that ENAT-PT is bi-directional and it requires only a small pool of registered addresses.

The rest of this paper is organized as follows. Section 2 defines the frequently used terms in this paper. Section 3 introduces background knowledge such as NAT-PT and its variations; besides, we give the

reason why ENAT-PT is proposed. Section 4 presents the principle of ENAT-PT model and describes its operation in detail. Section 5 analyzes the constraints of ENAT-PT model and discusses other considerations related to ENAT-PT. Section 6 concludes the paper.

## 2. Terms

Terms frequently used in this paper are defined as below. They may have special meaning in this paper.

Definition 1. V4 node, V6 node: In this paper, we use the term V4 node to denote V4-only node, and V6 node to denote V6-only node[1].

Definition 2. Session: A session is defined as the set of traffic that is managed as a unit for translation [11]. Sessions are uniquely identified by their session parameters. For TCP/UDP sessions, session parameters are the tuple of (Sa, Sp, Da, Dp); for ICMP query sessions, session parameters are the tuple of (Sa, ICMP query ID, Da). Sa, Sp, Da, Dp stand for source address, source port, destination address, destination port respectively.

Definition 3. Inbound session and outbound session : A session flow indicates its direction in which the session is initiated with reference to a network interface [11]. In this paper, an inbound session flow is defined as a session flow initiated from a V4 node (to a V6 node), while an outbound session flow is initiated from a V6 node (to a V4 node).

Definition 4. NAT (Network Address Translation): In this paper, NAT refers to translation of an IPv4 address into an IPv6 address and vice versa. While the V4 NAT [6,11] provides routing between private V4 and external V4 address realms, NAT in this paper provides routing between a V6 address realm and an external V4 address realm.

## 3. NAT-PT and Its Flavors

NAT-PT (Network Address Translation - Protocol Translation) is a standard track IETF RFC describing an IPv6/IPv4 translator. NAT-PT allows native IPv6 hosts and applications to communicate with native IPv4 hosts and applications, and vice versa. An NAT-PT device resides at the boundary between an IPv6 and IPv4 network. Each NAT-PT device retains a pool of globally routable IPv4 addresses which are used to assign to IPv6 nodes on a dynamic basis as sessions are initiated across the IPv6/IPv4 boundary. In addition to address translation, header translation is performed as described in the SIIT mechanism[10]. As opposed to SIIT which is a stateless translation mechanism,

NAT-PT retains state via the IPv4 to IPv6 address mappings and which are retained for the duration of each session.

### 3.1 Traditional-NAT-PT (Outbound NAT-PT)

Traditional-NAT-PT would allow hosts within a V6 network to access hosts in the V4 network. In a traditional-NAT-PT, sessions are unidirectional, outbound from the V6 network. This is in contrast with Bi-directional NAT-PT, which permits sessions in both inbound and outbound directions. There are two variations to traditional-NAT-PT, namely Basic-NAT-PT and NAPT-PT.

#### 3.1.1 Basic-NAT-PT

With Basic-NAT-PT, a block of V4 addresses are set aside for translating addresses of V6 hosts as they originate sessions to the V4 hosts in external domain. For packets outbound from the V6 domain, the source IP address and related fields such as IP, TCP, UDP and ICMP header checksums are translated. For returned traffic, the destination IP address and the checksums as listed above are translated.

#### 3.1.2 NAPT-PT

NAPT-PT extends the notion of translation one step further by also translating transport identifier (e.g., TCP and UDP port numbers, ICMP query identifiers). This allows the transport identifiers of a number of V6 hosts to be multiplexed into the transport identifiers of a single assigned V4 address. NAPT-PT allows a set of V6 hosts to share a single V4 address. NAPT-PT can be combined with Basic-NAT-PT so that a pool of external addresses are used in conjunction with port translation. NAPT-PT allows for a maximum of 63K outbound TCP and 63K UDP sessions per V4 address. For packets outbound from the V6 network, NAPT-PT would translate the source IP address, source transport identifier and related fields such as IP, TCP, UDP and ICMP header checksums. Transport identifier can be one of TCP/UDP port or ICMP query ID. For returned traffic, the destination IP address, destination transport identifier and the IP and transport header checksums are translated.

#### 3.1.3 ALG

The NAT-PT translation device may additionally contain ALG's (Application Level Gateways). ALG's are necessary where IP addresses are embedded within the payload of an IP packet. For normal packet translation, NAT-PT would not look within the payload for IP addresses. For some applications where IP addresses may be embedded within the payload, an ALG is necessary to look inside the payload and translate those IP addresses.

### 3.2 Bi-Directional-NAT-PT

With Bi-directional-NAT-PT, sessions can be initiated from hosts in V4 network as well as the V6 network. V6 network addresses are bound to V4 addresses, statically or dynamically as connections are

established in either direction. The name space (i.e., their Fully Qualified Domain Names) between hosts in V4 and V6 networks is assumed to be end-to-end unique. Hosts in V4 realm access V6-realm hosts by using DNS for address resolution.

A DNS-ALG[12,13] must be employed in conjunction with Bi-Directional-NAT-PT to facilitate name to address mapping. Specifically, the DNS-ALG must be capable of translating V6 addresses in DNS queries and responses into their V4-address bindings, and vice versa, as DNS packets traverse between V6 and V4 realms.

### 3.3 Challenge

NAPT-PT allows a set of V6 hosts to share a single V4 address, but NAPT-PT is unidirectional and applicable only for outbound sessions. With Bi-directional-NAT-PT model, however, every registered address is bound to a single V6 address. Once the address pool is exhausted, V4 nodes cannot establish sessions with other V6 nodes anymore. Thus there brings a challenge: how to establish a great number of inbound sessions by using a single V4 address ? ENAT-PT, which stands for Enhanced NAT-PT, will provide a better solution.

## 4. ENAT-PT

### 4.1 ENAT-PT Overview

ENAT-PT comprises of three parts: ENAT, NAPT and PT, see table 1.

The following of this paper mainly focuses on ENAT. For more information about NAPT and PT, please refer to references [5-11].

Table 1 ENAT-PT model components

Session Direction	Address Translation Method	Header Translation Method
Outbound	NAPT	PT
Inbound	ENAT	PT

With Bi-directional-NAT-PT, every registered address is bound to a single V6 address when a DNS query is performed and released when the session is terminated. With ENAT, a registered address bound to a V6 address would be released at the open of a session instead of the session's termination. Thus a registered address may be reused for another session just after the establishment of a session. Destination address (or source address of returned traffic) of subsequent packets of a session would be translated to the correct translated address according to their session parameters, which are retained in a session table.

### 4.2 ENAT Operation

Like NAT-PT, an ENAT-PT device resides at the boundary between an IPv6 and IPv4 network. Each ENAT-PT device retains a pool of globally routable IPv4 addresses (or registered addresses) which are used to assign to IPv6 nodes on a dynamic basis as sessions

are initiated across the IPv6/IPv4 boundary. Besides, the ENAT-PT should maintain two tables, namely session table and binding table. The session table is as follows.

V4 Address	V4 Port	V6 Address	V6 Port	Translation Address
------------	---------	------------	---------	---------------------

V4(V6) port here denotes the port associated to the V4(V6) address. There is an entry in the session table for each session.

The binding table is as follows.

Registered Address	Binding Address	State
--------------------	-----------------	-------

There is an entry for each registered address in the binding table. The state of a registered address may be free, bound, occupied, or occupied and bound. See definition 5 below.

Definition 5. The state of a registered address:

Free: the initial state.

Bound: when the ENAT-PT bind it to a V6 host.

Occupied: when a registered address is used by some session, i.e., it's in the session table.

Occupied and bound: Occupied by one or more sessions, and, at the same time, bound to a V6 address.

The ENAT operation is as follows:

1. A DNS query should be performed before a session is established. This is done by the facilitation of the DNS-ALG, which is naturally embedded in an ENAT-PT. The DNS-ALG translates the DNS query and the ENAT-PT forwards it to the DNS server. The ENAT-PT will choose a registered address whose state is not bound (or occupied and bound) and bind it to the V6 address returned by the DNS server. The address binding will be added to the binding table. ENAT-PT returns the registered address as the translation address

of the destination V6 node. This is very similar to the binding procedure in NAT-PT. If the state of the registered address is free, it should be changed to bound; if it's occupied, it should be changed to Occupied and bound after the binding.

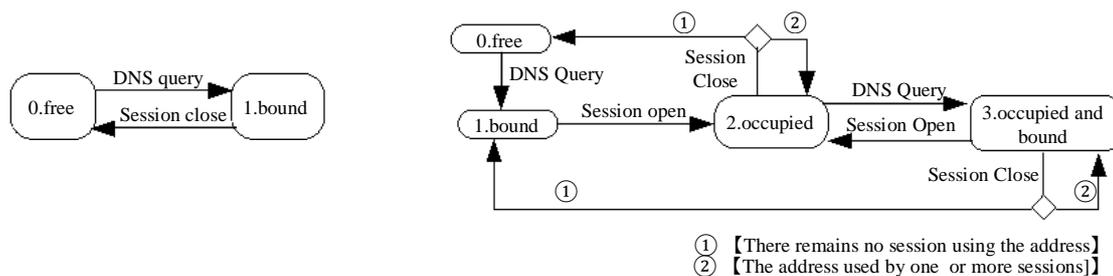

2. The ENAT-PT captures and intercepts the first packet of the session. Destination address of the packet is translated to the V6 address by querying the binding table. An entry, which contains the IP of V4 node, port associated to the V4 address, IP of V6 node, port associated to the V6 address and the translation address, will be added to the session table. Then the state of the registered address is changed to occupied and the address binding will be cleared in the binding table.

3. The ENAT-PT captures and intercepts subsequent packets of the session and translates their addresses by querying the session table.

Fig.1-(b) is the state diagram of a registered address with ENAT. It shows how does ENAT differ from NAT( see Fig 1-(a) as a contrast). Note that when a session is opened, a registered address is released and can be bound to another V6 address.

Fig.2 is an example to illustrate the operation of ENAT. Q1 and Q2 are V4 nodes while H1 and H2 are V6 nodes. There are two registered addresses in the binding table. The registered address R0 is statically bound to the DNS server. The initial state of R1 is free, see table 2. The ENAT-PT will intercept, capture and translate the packets. The session table is empty.

For convenience, we use Q1.address to denote the IP address of Q1, and R1.state to denote the state of Registered address R1...etc.

(a) The state of a registered address with NAT

(b) The state of a registered address with ENAT

Fig.1 The state of a registered address

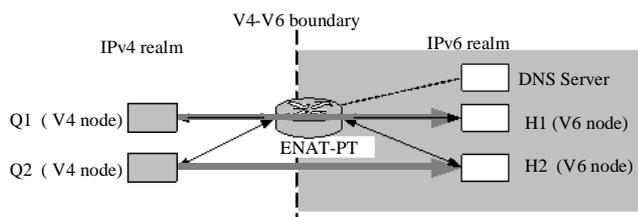

Fig.2 An illustration for ENAT

Table 2 Binding table (0)

Registered address	Bound Address	State
R0	DNS-Server.address	Bound
R1	-	Free

Assume that V4 node Q1 initiates a session to V6 node H1. The DNS server returns R1 as the translation address of H1, thus R1 is bound to H1.address now, the binding table is as follows ( see table 3).

Table 3 Binding table (1)

Registered address	Bound Address	State
R0	DNS-Server.address	Bound
R1	H1.address	Bound

When the session is open, the first packet of the session is delivered from Q1 to H1 whose session parameters are:

$$Sa = Q1.address, Sp = p1, Da = R1, Dp = p2 \quad (1)$$

Then we add the session parameters to the session table (see table 4) and change R1.state to occupied, and the binding table is as table 5.

Table 4 Session table (1)

V4 Address	V4 Port	V6 Address	V6 Port	Translation Address
Q1.address	p1	H1.address	p2	R1

Table 5 Binding table (2)

Registered address	Bound Address	State
R0	DNS-Server.address	Bound
R1	-	Occupied

Address of packets of the session is translated according to the session table. For packets from Q1 to H1, the translation is as follows:

$$(Q1.address, p1, R1, p2) \xrightarrow{\mathcal{A}} (PREFIX::Q1.address, p1, H1.address, p2) \quad (2)$$

for returned traffic, the translation is:

$$(H1.address, p2, PREFIX:Q1.address, p1) \xrightarrow{\mathcal{A}} (R1, p2, Q1.address, p1) \quad (3)$$

NOTE: The prefix PREFIX::/96 is advertised in the stub domain by the ENAT-PT device, and packets addressed to this PREFIX in the stub domain will be routed to the ENAT-PT device. The pre-configured PREFIX only needs to be routable within the IPv6 stub domain and as such it can be any routable prefix that the network administrator chooses [8].

Table 6 Binding table (3)

Registered address	Bound Address	State
R0	DNS-Server.address	Bound
R1	H2.address	Occupied and Bound

Once a registered address is released (when the session the registered address associated to is opened), it can be bound to another V6 address. For example, another V4 node Q2 initiates a DNS query (e.g., resolving the name of node H2) just after the establishment of the previous session. ENAT-PT will bind R1 to H2.address as translation address of H2, see

Table 6.

So session parameters of packets from Q2 to H2 may be:

$$Sa = Q2.address, Sp = p3, Da = R1, Dp = p4. \quad (4)$$

After the session is opened, the session table is as table 7 and the binding table is as table 5.

Table 7 Session table (2)

V4 Address	V4 Port	V6 Address	V6 Port	Translation Address
Q1.address	p1	H1.address	p2	R1
Q2.address	p3	H2.address	p4	R1

For packets from Q2 to H2, the translation is as follows:

$$(Q2.address, p3, R1, p4) \xrightarrow{\mathcal{A}} (PREFIX::Q2.address, p3, H2.address, p4) \quad (5)$$

for returned traffic, the translation is:

$$(H2.address, p4, PREFIX:Q2.address, p3) \xrightarrow{\mathcal{A}} (R1, p4, Q2.address, p3) \quad (6)$$

The above deals with TCP/UDP sessions. For ICMP sessions, the operation is pretty much the same thing, but sessions are identified by their source/destination address and ICMP query ID.

#### 4.3 ENAT Analysis

(1) When the state of a registered address is bound, it can not be bound to another V6 address. The number of sessions that can be set up at the same time by using a single registered address is depended on two factors:  $T_D$ , which is the average duration of a registered address from bound (or occupied and bound) state to occupied state, and  $T_S$ , the average duration of a session.

$$N_{max} = (T_S + T_D) / T_D \quad (7)$$

(2) In table 7, if Q1.address = Q2.address (i.e., Q1 = Q2) and p1 = p3 and p2 = p4, session parameters of the two sessions will be identical (see formula (1) and (4)). The ENAT-PT needs more information to tell one session from the other. In this case, the ENAT-PT should reject the connect request of the second session to avoid confusion. For TCP sessions, the ENAT-PT may discard the SYN & ~ACK packet, however, there is no deterministic way of recognizing the start of a non-TCP session. Fortunately, most operating systems will select different source ports (for the client) for different sessions.

(3) ENAT and NATP are both essential parts of ENAT-PT model. ENAT deals with inbound sessions and NATP deals with outbound sessions. If we use the different registered address pools for inbound and outbound sessions, ENAT and NATP need no modification. However, ENAT and NATP can share the same registered addresses pool and the same session table, but the session table should be changed to the following form because NATP will change the clients' ports.

V4 Address	V4 Port	V6 Address	V6 Port	Translation Address	Translation port
---------------	------------	---------------	------------	------------------------	---------------------

## 5. Related Considerations

### 5.1 The start and Termination of Sessions [11]

The first packet of every TCP session may be recognized by the presence of SYN bit and absence of ACK bit in the TCP flags. There is no deterministic way of recognizing the start of a non-TCP session. A heuristic approach would be to assume the first packet with hitherto non-existent session parameters as indicating the start of a new session. The end of a TCP session is detected when FIN is acknowledged by both halves of the session or when either half receives a segment with the RST bit in TCP flags field. However, because packets may be dropped or retransmitted, TCP sessions can be assumed to have been terminated only after a period of time subsequent to this detection. In addition, it is necessary for an ENAT-PT to clean up unused state about TCP sessions that no longer exist. In the case of non-TCP sessions, session timeouts must be configurable because they vary greatly from application to application. Another way to handle session terminations is to timestamp entries and retire the longest idle session when it becomes necessary.

### 5.2 Limitations[8,11]

Here are the most important limitations with ENAT-PT. They are associated with NAT-PT as well.

(1) Applications depending on global address may work improperly because a registered address may be bound to different V6 addresses at the different time or even at the same time, and vice versa.

(2) An ENAT-PT will not translate IP-address within packet payload thus applications such as SNMP, FTP will not work properly. An SNMP-ALG [14] or an FTP-ALG [15] is necessary for these applications.

(3) A DNS query must be performed before every session opens[8].

### 5.3 Security

Transport layer security techniques such as TLS [16], TCP MD5 Signature Option [17] can work properly because ENAT does not change port numbers. Security mechanisms of IP layer such as AH [18] protect the packet from address modifications and will not work.

### 5.4 Fragmentation

Although ENAT-PT does not translate transport identifiers, it has to know the port in a packet before translating the address and transmitting the packet, thus it is necessary to track record of IP fragments[19].

## 6. Conclusion

We have implemented a prototype of ENAT-PT on Linux based on BT Labs' NAT-PT implementation [20] and succeeded to initiate multi sessions from V4 nodes to different V6 nodes with a single V4 registered

address. ENAT combined with NAT-PT will provide a simple and effective solution for intercommunications between V4 nodes and V6 nodes with a small address pool. This will greatly reduce the consumption of IPv4 registered addresses for IPv4 networks to communicate with IPv6 network.

## Abstract

In a brief and creative online survey, customers identify new product opportunities. This leads to an integrated market structure/market segmentation analysis. A clickstream-based analytical CRM case study is presented.

## 1. Introduction

We developed an interactive product configuration tool that allows customers to configure their preferred products based on a finite set of product attributes/features. From the perspective of statistical modeling, our application is similar to the conjoint technique. Conjoint is a research tool that marketers frequently use to determine what features a product should have. However, our virtual prototyping (VP) application eliminates the tedious ranking or pair-comparing tasks on numerous pre-specified product configurations. Customers only need to rank their preferred products after they configure these products. Building their preferred products also enables customers to simultaneously consider all product attributes/features, therefore allowing us to measure product attributes/features interaction.

## 2. Research Applications

Our parallel test on a digital camera survey shows that although both conjoint and VP rank product attributes similarly, cross classification on four preferred product profiles yields only a 50% classification rate (hit ratio). On the attribute ranking, functional features (resolution, storage, image capacity) are the most important attributes, followed by brand (Sony, Kodak, Canon, Olympus, Nikon), and physical attributes (body type and lens) are the least important ones. On the cross classification, each respondent configures and ranks four preferred products, and conjoint attribute utilities are applied to these profiles. If two approaches produce a similar result, we would expect a nearly perfect classification. However, we only observe a 50% classification rate. Another survey on a different category also shows a similar finding. We will show a live demo of both approaches and let audiences

judge which approach more reliably captures the true preferences.

Potential use of our application includes new product forecasting and integrated market structure/market segmentation analysis. Because we let respondents freely configure their preferred products based on all product attributes, it enables us to estimate any new product share potential. New product share is further adjusted to reflect the difference in distribution, pricing, and awareness – nonlinear forms are adopted to make the share adjustment. For example, the new Kodak flash card reaches a 30% share of Kodak professional digital camera, and most of the share gain is incremental (mainly drawing from Canon brand).

The above product-focused market structure reveals brands in competition, while customer-focused market segmentation identifies individuals with similar preferences. Latent class segmentation approach is adopted, and preference towards different attributes is assumed to follow a Dirichlet distribution where Dirichlet distribution parameters are estimated using EM algorithm (see appendix). Profiling the Dirichlet segments based on configured products reveals a mix of brand and type segments - Kodak and Canon forms one of the brand-primary segments. Posterior probability analysis enables us to profile segment beyond products. For examples, one can perform media scheduling based on demographics and media usage, and one can also perform advertising copy development based on psychographics and benefit attributes.

## 3. An Analytical CRM Case Study

Our presentation is concluded with an analytical CRM case study that shows how our VP application, in conjunction with clickstream data, is used to develop an online relationship with e-customers.

A global e-commerce jewelry manufacturer offers a variety of jewelry items to those Web shoppers who register at the participating jewelry stores through an in-store kiosk (A more limited choice of jewelry items is offered to non-registrants). Since the company

guarantees a two-day delivery to their registered customers, unfulfilled orders frequently lead to orders cancellation. To be able to anticipate customers' needs and preferences, we invite their core customers to take VP survey on a regular basis. Core customers are identified based on their online surfing patterns. A separate study based on customers' clickstream data classifies customers into one of the four segments (entertainment/fun, information seeker, technology savvy, and surfer – see the table below). The entertainment/fun

segment accounts for about 25% of total customers, but generates over 60% of company revenues. This segment is also more receptive to VP survey than the other three segments. An entertaining and fun Website (jewelry auction, game-like promotion, sweepstakes, design your own jewelry, etc.) is thus customized for their core customers. Website is further personalized based on customers' preference captured during the VP jewelry-designing phase.

#### 4. Future Development

Telecom and financial services are two areas that we believe can benefit greatly from the user-design application. Significant R&D efforts are currently underway to develop VP application in the service industry.

#### 5. Appendix

$P_{ns}^i$  – probability of observation  $n$  belongs to segment  $s$  in iteration  $i$   
 $\Pi_s$  – segment  $s$  size  
 $\theta_s$  – distribution parameter estimates in segment  $s$   
 $f(y_n|\Phi) = \sum_s \Pi_s f_s(y_n|\theta_s)$  where  $\Phi=(\Pi_s, \theta_s)$ ,  $\theta_s=(B_s)$  or  $\theta_s=(B_s, \lambda_s)$   
 $B_s$  - explanatory variables parameter estimates in segment  $s$

the expectation of dependent variable ( $\mu_s$ ) is modeled as a link function of explanatory variables ( $X_p$ ),  
 $g(\mu_s)=\sum_p X_p B_{sp}$   
 $\lambda_s$  – dispersion parameter that characterizes the variance of observations in  $s$

1. At the first iteration  $i=1$ , fix the number of segment  $s$  and generate starting probability  $P_{ns}^1$  randomly.
2. Given  $P_{ns}^i$ , estimate  $\Pi_s$  by using  $\Pi_s = \sum_n P_{ns}^i / N$  and estimate  $\theta_s$  by using either closed-form expressions (e.g., mean and standard deviation of normal distribution) or a numerical optimization procedure.
3. Stop if the change in the log-likelihood between iteration  $i-1$  and  $i$  is sufficiently small where  $Ln L(\Phi) = \sum_n \sum_s [P_{ns} \ln f_s(y_n|\theta_s) + P_{ns} \ln \Pi_s]$
4. Increment iteration from  $i$  to  $i+1$ , and calculate new estimates  $P_{ns}^{i+1}$  by using  $P_{ns} = \Pi_s f_s(y_n|\theta_s) / \sum_s \Pi_s f_s(y_n|\theta_s)$ .
5. Repeat step 2 through 4.

## Abstract

The paper presents a theoretical discussion of how experts on information systems and the Internet should inform business representatives about the theoretical impact of Internet network use on competitive advantage. Its objective is to propose a model to test the effect of Internet's web tools and trust on the link between customer relationship management (CRM) and competitive advantage. Internet's web tools such as level of informational web site, level of transactional web site and level of security on the web can support the formation and maintenance of customer relationship because they facilitate the way organizations partner, interact and empower. In other words, Internet's web tools can let organizations to build tight trusted relationships with their trading customers who should become loyal to them, rather than to select customers on a transaction by transaction basis from a large pool of non-loyal ones.

## 1. Introduction

Electronic commerce (E-commerce) is maintaining business relationships by means of Internet networks. In fact, E-commerce is a rapidly growing area enjoying considerable attention in conjunction with the emergence of the Internet [29]. Electronic Commerce creates new forms of market, such as electronic matching of sellers and buyers, or enabling a direct exchange between sellers and buyers [1]. The term electronic commerce encompasses many activities carried out through computer networks and the Internet, including interorganizational commerce, intraorganizational transactions, and transactions involving the individual consumer [34].

Many recent studies have predicted that Internet generated revenue will reach more than US\$1000 billion in total by 2003 [14]. Such predictions indicate the importance that is attached to the Internet as a way of supporting business activities. The Internet itself can be regarded as the latest super-diffusion technology [11]; an amalgamation of many networks that has become

available for commercial purposes. Indeed, numerous firms have already experienced its considerable benefits [18]. One of the consequences of the development of the Internet has been the emergence of the World Wide Web, an Internet service that organizes information according to hypermedia and hyperlink paradigms [34]. The Internet's Web is the prime driver of contemporary E-commerce [35]. Given the rapid penetration of the Internet, and in particular of the World Wide Web, many companies have been involved over the last five years in planning and experimentation aimed at leveraging this new technological infrastructure for business purposes [4]. Today, the World Wide Web seems to offer the most potential as a tool for conducting business activities [4]. Firms not only use the Internet to support the exchange of goods, services, information and transactions but certain firms also expect to improve long-term relationships with customers.

There is no widely accepted definition of customer relationship management (CRM) in the scientific community. For the purpose of this paper this definition of customer relationship management will be used: it means being willing and able to change your behavior toward a customer based on what the customer tells you and what else you know about that customer [24]. In fact customer relationship management lets firms to initiate, establish, maintain, and enhance relationships with individual and organizational customers, at a profit, so that the objectives of the parties involved are met; this is achieved by a mutual exchange and fulfillment of promises. The dominating perspective within inter-organizational relationship research has been to assume that customer relationship management has a positive correlation with competitive advantage via customer loyalty.

The general assumption is that the deployment of the Internet's tools would increase switching costs and create strong competitive advantage. Switching costs encompass all the costs incurred by a customer in changing to a new supplier [25]. Firms not pursuing cost-based competitive advantages through the Internet will be left behind [31]. Competitive advantage analysis has provided the foundation for many researches on customer relationships

management [32].

Trust may have an impact on the link between electronic commerce customer relationship management and competitive advantage via customer loyalty because trust is precursor to customer loyalty. Trust has been conceptualized as existing when one party has confidence in an exchange partner's reliability and integrity [5]. Becoming a trusted partner of a customer is a key to maintaining customer relationship management. Trust can be achieved by providing the customer with valuable information using a high quality web site. Certain authors speculate that in the early stages of Internet development, trust is a critical factor in stimulating purchases over the Internet [16] mainly because of security issues, which is one of the Internet's tools used to promote commitment to customer relationship management.

Internet's web tools would not only assist in customer relationship management initiation, it would help in its improvement, and even enhancement, of relationship which leads to increased competitive advantage via customer loyalty [3]. But Loyalty can't be addressed with technology [26]. It isn't simply a matter of having better security or database systems [26]. Without the glue of loyalty via customer relationship management and improvement, even the best-design electronic commerce model will collapse [27]. The effective management of the combination of the Internet's web tools, trust and customer relationship management factors will bring competitive advantage via customer loyalty to firms. In the rush to build Internet for business purposes, it is mistake to think that only a web site is sufficient to retain customers because loyalty is a relationship phenomenon rather than a technological phenomenon. To increase the loyalty of customer via Internet's web tools, you must first use the technology to build lasting trusted long-term relationships.

The objective of this paper is to demonstrate how trust can be applied to support electronic commerce customer relationship management in order to create competitive advantage via customer loyalty. This article consists of two main parts. First, a conceptual model explaining the theoretical linkage between customer relationship management and customer loyalty will be presented and explored. In addition, the impact of Internet's web tools and trust on the linkage between customer relationship management and customer loyalty will be explained. Second, we present theoretical propositions that will underlie future empirical studies examining the impact of trust on the link between electronic commerce customer relationship management and customer loyalty in many industries.

## 2. Conceptual Constructs

A consideration of the study's objective will help to identify its key constructs, such as: the customer

relationship management construct which will play the role of independent variables, competitive advantage construct via loyalty will be the dependent variable, Internet's web tools construct will be considered as the first group of moderating variables and trust will represent in the model, the second group of moderating variables. Each of them is discussed below.

### 2.1 CRM construct components

Relationships are developed between organizations for the exchange of products, services, resources, information and so on [21]. Customer relationship management is generally viewed as processes to exchange goods and services for some form of compensation. Customer relationship management can be based upon networks. Another type of coordination among organizations has been suggested: network [21]. Networks are groups of organizational actors who participate in a general pattern of interaction [21]. Networks can be groups of organizations, but also groups within organizations. The different organizational actors can have their own particular interests, and can be allied to different network-organizations [21]. The primary goal of customer relationship management is to let companies to achieve - through empowerment, interactive management, and partnerships - competitive advantage via loyalty in relation to companies outside the network. Then customer relationship management is heavily dependent upon: empowerment, interactive management and partnerships. Each of them is discussed below.

#### 2.1.1 Empowerment

Empowerment generally refers to the process firms adopt to encourage and reward employees who exercise initiative and make valuable creative contribution [12], or do everything that is possible to help customers solve their problems. Most business representatives prefer to deal with regular customers because they are easy to serve and because they understand the firm's preoccupations [8].

#### 2.1.2 Interactive Management

Interactive management is the key aspect of customer relationship management functions [12]. It comprises all actions designed to transform the prospective client who enters into contact with the business representative into an active and effective customer [12]. It is based on the reciprocity that constitutes one important dimension of customer relationship management [6]. Feedback is part of the core of interactive management [13]. Indeed, [13] consider customer feedback as the step of the customer relationship process assessment and define it as the best way for firms to keep in touch with their customers' perceptions.

#### 2.1.3 Partnerships

Partnerships are created when suppliers work closely with customers and add desired services to their traditional product and service offerings [13]. This means resale of your firm's products and services by your customers. It also means joint development of products and services with customers. To get effective partnership with customers, some suppliers create joint ventures with customers. In other cases, customers refer to your firm's products and services when they sell their own products and services. [33] has developed an integrated model devoted to relationship phases. In this model, partner selection is considered as the first step in the relationship process.

## 2.2 Competitive advantage components

Competitive advantage is the method by which an organization attempts to achieve its mission, aims and objectives [8]. To establish and maintain a distinctive competitive advantage, a firm needs to follow six main principles: 1) it must start with the right goal; 2) a company's strategy has to allow it to deliver a value proposition, or set of benefits, different from those that competitors offer; 3) strategy needs to be reflected in a distinctive value chain; 4) robust strategies involve trade-offs; 5) strategy defines how all the elements of what a company does fit together; 6) finally, strategy involves continuity of direction [25].

Most businesses would prefer their customers become more loyal since it creates customers who are less sensitive to the business efforts of competitors [8]. Similarly, [7] suggested that loyal customers are less likely to switch to a competitor solely because of price, and loyal customers also make more purchases than comparable non-loyal customers. Some researches concluded that building a relationship with loyal customers should be a strategic advantage focus of most firms [7].

### 2.2.1 Loyalty construct

The development of loyalty involves building and sustaining a relationship with a customer that leads to the customer's repeated purchases of products or services over a given period of time. For the purposes of this research, loyalty will be considered as the final result of effective customer relationship management. The purpose is to link loyalty to the emerging theory of customer relationship management [19]. Although many authors, such as [10], distinguish between brand loyalty, store loyalty, salespeople loyalty, product and service loyalty, and so on, in this study the concept of loyalty will be considered as the combination of all these various types. Indeed, some authors, such as [13], have studied the impact of relationship marketing on customer loyalty but have not made any distinctions between different types of loyalty. They have merely specified that their conception of loyalty went beyond the idea of industrial loyalty. A final point to make is that the variable that has been

chosen to measure the competitive advantage in this study is "customer loyalty."

## 2.3 Internet's Web Tool components

Internet's web tools range from simple, associatively linked collections of static hypertext documents to interactive, integrated, customizable solutions and agent-based negotiation support; and since the Internet's web tools were initially developed to address the development of B2C transactions, they can also be effectively applied in B2B settings as well [15]. Today, there are essentially three variables that encompass the construct of Internet's web tools: the level of informational web site, the level of transactional web site and the level of security on the web.

### 2.3.1 The level of informational web site

Commercial web sites provide company information and enable communication with the firm [34]. The informational web site consists of the new Internet-based channels through which companies can display information about themselves and the products and services they offer. Companies can display catalogues of their products. A first category of products which can be efficiently displayed on the web site are products which can be digitalized and transmitted through computer networks. Electronic books, music and video tracks belong to this category. Secondly, the Internet can be used to provide information to customers about physical products such as cars, hardware or perfume etc...

### 2.3.2 The level of transactional web site

The transactional web sites allow customers or trading partners to make a purchase or check the status of an account [34]. The transactional web site consists of the new Internet-base channels through which firms can exchange formal business transactions such as orders, invoices, payments, etc [17]. The transactional web site also encompasses e-mail, two-way interactive communication, virtual community and multimedia capacities because the Internet is a fully interactive communication medium. Therefore firms may use the high level of transactional web site to interact and exchange valuable ideas and experiences, influence opinions, negotiate potential collaborations, engage in relationships, and create different types of communities. In short, the level of transactional web site refers to the extent to which organizations engage in online exchange or communication with others without feeling affected by the constraints of distance and time.

A cookie is a piece of information that allows a Web site to record one's comings and goings. Cookie can help web sites to remember information about customers and respond to their preference. Cookie can facilitate electronic transactions on the web with customers. That means web site containing cookie may enable customers to log in without having to enter a password at every visit.

### 2.3.3 The level of security on the web

One of the greatest concern about doing business on the Internet deals with the level of security in transactions [30]. In the first phase of development, the Internet has not yet been extensively used as a transaction space because of its underdeveloped security aspects [35]. The growth of the electronic commerce is tempered by organizational concern over security and the risk of making transaction process. The perception of unsatisfactory security on the Internet is one of the primary reasons hindering electronic commerce customer relationships management. Despite advances and endeavors in Internet security mechanisms like cryptography, authentication, confidentiality, integrity, non-repudiation, etc... companies are still concerned about using an impersonal transaction medium like the Internet for secure transactions [30].

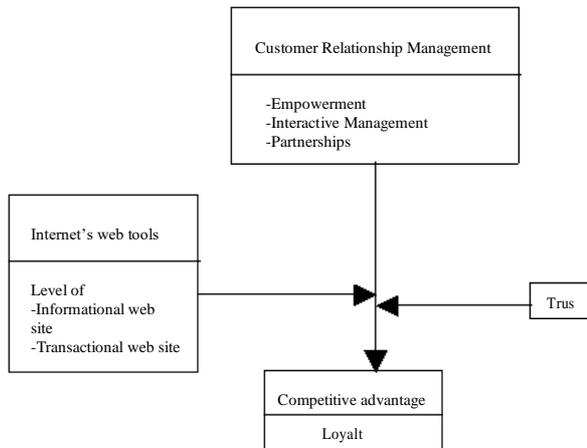

The perceived security of online transactions varies based on the specific payment procedure or money-transfer between organizations. For example, the perceived security of giving corporate credit card information directly over the Web is likely to be different from the risk of setting up a third party account and using that account number in transactions [30]. The parties involved in electronic commerce customer relationship management have to develop together effective security means and to share information about risk in order to motivate their customer participation to online transactions. Also both parties need to secure their web site during their exchange.

### 2.4 Trust

Trust is defined as the firm's belief that another company will perform actions that will result in positive outcomes for the firm as well as not take unexpected actions that result in negative outcomes [2]. Trust is also defined as a willingness to rely on an exchange partner in whom one has confidence [20]. Some companies figure out that building trust leads to more enduring relationships and more profits while a quick sale may simply let a customer leaves the relationships [27]. In inter-organizational relationship context, long-term trust of the seller has been found to be more important than short-term one [16].

The importance of trust becomes evident as a moderator of risk when buyers moves away from buying systems based upon a single transaction to one of repeat purchasers. If the trust is present, such customer relationship management is the basis for a formidable and durable strategic advantage which is measured by customer loyalty in this study [8]. After adopting a specific and more sophisticated measure of loyalty, [8] verified that trust has a causal impact on loyalty. Consistent with conventional logic, we have confirmed that the trust held by a buyer toward a seller is an important antecedent of loyalty, for at least some buying situations in a business environment [8].

## 2.5. The Conceptual Model

## 3. Theoretical Propositions

### 3.1. Theoretical impact of CRM on Customer Loyalty

Berry identifies empowerment as one of the major emerging perspectives in building relationship, this latter leads to customer loyalty [6]. Empowerment means workers can strive to meet customer requirements and needs and resolve problems; that can lead to spontaneous, creative rule breaking to turn a potential frustrated customer into a loyal one [8]. High employee turnover discourages management from investing much in hiring, training, and other relationship-building activities; this, in turn, leads to ineffective loyalty [5]. High employee turnover negatively affects customer retention or loyalty [5]. Recent literature positions employee retention as an antecedent of customer loyalty [5]. It seems that low employee turnover positively impacts customer loyalty.

**Proposition 1a:** The customer relationship management component of empowerment will have a positive and direct effect on customer loyalty.

Berry has noted that for a relationship to exist it has to be mutually beneficial [6]. The interactive management is the dominant business function for building relationship [6] which leads to customer loyalty. Interactive management occurs in the moment of truth when the customer interacts with the organization; it is in these moments of truth that relationships, leading to customer loyalty, are built [6]. Customer Relationship Management is a continuous process, requiring a company to solicit customers' feedback to ensure that their needs are being addressed; a feedback system should let a firm communicate with loyal customers [13]. The feedback

system shows its commitment to learning about and responding to customer concerns [13]. Exchange of regular communication, based on feedback, should determine whether these individuals, groups or organizations as a whole, are able to collaborate [21] and to still loyal to each other. Clearly, feedback refers to situations in which parties share and exchange information to achieve mutual goals in order to maintain their loyal endeavor.

Proposition 1b: The customer relationship management component of interactive management will have a positive and direct effect on customer loyalty.

[23] placed partnership at the extreme end of his loyalty scale, considering it to be the stage when a durable and close relationship between supplier and customer is developed. [33] outlined an integrated model of the relationship marketing process in which the selection of a partner was the first step of effective customer relationship management leading to customer loyalty. Furthermore, the perception of [28] regarding the linkage between partnerships and customer loyalty is the following: customer relationship management was effective when the first step of its process dealing with a partnership leads to the creation of valuable exchanges for both parties involved in the exchange. Obviously, these valuable exchanges were measured in the present study by customer loyalty.

Proposition 1c: The customer relationship management component of partnerships will have a positive and direct effect on customer loyalty.

### 3.2 The impact of the level of informational web site on the link between CRM and Loyalty

[34] show that a majority of firms list their expertise on their web site, including such material as curriculum vitae, important references, and employees' accomplishments. Companies which take such steps empower their employees when they have to negotiate with external customers. This empowerment process has repercussions on the relationships which the employees initiate and maintain with their customers in order to get their loyalty. Companies' contact employees are able, via the web site, to access information about their company and its products and services. A web site, then, is a tool for employee empowerment. This employee empowerment has beneficial effects which affect external customers and ultimately lead directly to their loyalty. Once employees are well informed about their company's web site content, the customers will most likely be satisfied with their services and so loyalty will develop.

Proposition 2a: The level of informational web site will be positively associated with the link between the

customer relationship management component of empowerment on the one hand, and customer loyalty on the other.

The use of electronic feedback links between firms can reduce the costs of maintaining relationship which impacts on customer loyalty. Informational web sites are used not only to facilitate interaction and feedback but also to tightly couple processes at the interface between stages of the link between customer relationship management and customer loyalty. The time taken to download graphics must also be taken into account when considering the degree to which web sites support the link between interactive management and customer loyalty. If customers have to wait too long before they can actually begin to use a vendor's web site because the graphics are too heavy, it will discourage them from exploring the web site further. A customer's frustration at moments like these will prevent the development of an interactive management. On the other hand, if the web pages appear rapidly, customers will feel like exploring the whole site in order to learn more about the company. As such, they will be ready to become involved in a durable relationship with the owner of the site, and thus loyalty will develop.

Proposition 2b: The level of informational web site will be positively associated with the link between the customer relationship management component of interactive management on the one hand, and customer loyalty on the other.

According to [22], informational web site is international by definition because web sites allow a company to attract international consumers. To this argument it is added that business globalization is supported by such an opportunity. Partnerships between firms from different countries are a common occurrence. Another argument is that a web site presented in many languages and available 24 hours a day will help to develop stronger links between companies and their customers. Ozer' [22] arguments mentioned above enable us to understand the reasons why informational web site should foster the link between partnerships and customer loyalty. A further explanation of this theoretical link is that a company's web site which presents its partners' logos induces the partners to stay for a long time with this particular company. The same thing occurs when a company presents on its web site the accomplishments of its partners. Companies also have the option of including on their web site, by external hyperlinks, connections to their partners' web sites. Companies which display their partners' web sites on their own web site will encourage them to be loyal.

Proposition 2c: The level of informational web site will be positively associated with the link between the customer relationship management components of partnerships on the one hand, and customer loyalty on

the other.

### 3.3 The impact of the level of transactional web site on the link between customer relationship management and loyalty

In fact, one study has claimed that companies often empower one or several employees to answer questions or to make comments online [9]. These actions are carried out by e-mail or through online discussion (online conferences, forums, or chat rooms) and allow companies and customers to make the most of the online contact time provided by the Internet to share their views. Companies empower their employees who react online promptly to customer complaints. The companies provide appropriate training for their employees in order to be able to offer various services, solutions, or products during interactive online contact with the customers and to modify, on the screen, the customer relationship management statements that companies use to convince customers to buy on the basis of customers' reactions and views. The home page tries to convince customers to accept the firm's position in regard to certain circumstances [9]. The use of these different tools should create customer loyalty. Likewise, these methods give value to employees and empower them during their contact with customers thus leading to an increase of customer loyalty.

Proposition 3a : The level of transactional web site will be positively associated with the link between the customer relationship management component of empowerment on the one hand, and customer loyalty on the other.

There are forms on the Internet's web that enable the customers to evaluate and appreciate the service offered by the business representatives. Feedback is one of the major components of the definition of interactive management, which leads to customer loyalty and at present, there is no better tool than the web to enable customers to give feedback. The interactive management is based on one-to-one dialogue between business representative and customer, web site tools, such as forums, news groups or chat rooms should support these dialogues; this way of interacting with customers should increase their loyalty.

Proposition 3b : The level of transactional web site will be positively associated with the link between the customer relationship management component of interactive management on the one hand, and customer loyalty on the other.

The business representatives share ideas, influence views, and establish partnership potential, through news groups, forums, and e-mail, with their customers. Such ways of doing business leads firms to develop customer loyalty. Firms involved in virtual exchange, via

transactional web site, should be motivated to become loyal to another if the partnership is based on a "win-to-win" relationship. When firms are committed to a partnership, they will include on their web site a link to the site of their partner. Such a web site will contain forms, e-mail, and so forth, which favor transactions. It is to be expected that this kind of relationship should result in loyalty. In conclusion, the partnership supported by the transactional web site should increase the loyalty between partners.

Proposition 3c : The level of transactional web site will be positively associated with the link between the customer relationship management component of partnerships on the one hand, and customer loyalty on the other.

### 3.4 The impact of the level of security on the web on the link between CRM and Loyalty

Firms that empower their employees to respond and listen to customer needs and requirements have satisfied customers, and develop strong relationships that lead to customer loyalty [13]. The company's web site protected by a secured firewall can be used to enhance the communication and collaboration among authorized employees. When the secured firewall protects the company's Internet, it becomes Intranet. The firewalls protect the intranets from unauthorized outside access. Only authorized employees are able to use them because they are limited to information pertinent to the company and contain exclusive and often proprietary, sensitive and strategic information. Company that uses the intranet (the secured private internet) to support their employees will increase their customer loyalty.

Proposition 4a : The level of security on the web will be positively associated with the link between the customer relationship management component of empowerment on the one hand, and customer loyalty on the other.

Using secure web technology such as digital signatures and digital certificates can help a company to establish and maintain interactive management relationships leading to customer loyalty. Digital certificates are used for many different types of online transactions, including electronic mail and electronic funds transfers. In fact a web site's digital certificate is a business assurance that the web site is this one of his customer and not an imitator. Because digital signatures offer a way to verify party's identity, buyers and sellers can use them to verify each other before beginning their interactive management, making it a bit easier for them to become loyal to each other.

Proposition 4b : The level of security on the web will be positively associated with the link between the customer relationship management component of

interactive management on the one hand, and customer loyalty on the other.

Businesses engaging in online partnership need to feel that their transactions are secure from prying eyes and safe from alteration. For example, a business-to-business extranet web site is a secured business network of several partners that become loyal to each other. Because of the security issue, organizations that are willing to do online business have to make concerted efforts to allay fears by offering clear security guidelines to their partners and vice versa. Both partners involved in a customer relationship management must develop effective security together and share information about risk in order to motivate participation in online transactions and to trigger their loyalty.

Proposition 4c : The level of security on the web will be positively associated with the link between the customer relationship management component of partnerships on the one hand, and customer loyalty on the other.

### 3.5. The impact of Trust on the link between electronic commerce customer relationship management and Loyalty

Trust is the necessary component that binds two parties together, moderates their risk, and implicitly guarantees their future benefits [8] such as loyal to each other. Parties can use trusted extranet to support their employees to share contract information and shipment and payment status. When customers trust an on-line business representative, they will share sensitive information with him; that information enables the company to form a more intimate relationship with customers, offering products and services tailored to their individual preferences, which in turn increase trust and strengthen loyalty [27]. Such way of doing business can quickly translate into a durable advantage over competitors [27]. Also, the internal management of production, inventory, procurement etc... can be supported by the trusted intranet functions and these functions can also be seamlessly integrated with the extranet. Parties can trust extranet connectivity because it provides secured connectivity between a corporation's intranet and the intranet of its supplier. The trusted environment of the extranet allows groups of employees to collaborate, sharing information exclusively and exchanging it securely. Since an extranet allows connectivity between businesses through the Internet, it is an open and flexible platform suitable for customer relationship management which yield customer loyalty.

Proposition 5a: Trust will be positively associated with the link between electronic empowerment and customer loyalty.

In the setting of electronic commerce, parties must trust each other before they interact and exchange.

Customer loyalty stems from continued interaction between the parties in the relationship. As long as the businesses provide interactive management of value based on their Internet's web tools to their customers, they are likely to be treated as trusted companies. In fact, business is based on trust between two parties, whether the business is conducted in person, by phone, or over a web site. The customer can get a sense of the company and the person from face-to-face discussions or from the appearance and location of the office; but this element of trust is difficult to reconstruct in electronic interactions because all the customer knows about the supplier is what can be seen on the web site. Therefore, creating trust via the Web depends on fostering interactive management through electronic means of well-established Internet's web tools. When companies treat the web as more than just a communication tool, the trust between companies will grow, a customer relationship management will be developed and maintained, and customer loyalty will be developed.

Proposition 5b: Trust will be positively associated with the link between electronic interactive management and customer loyalty.

Trust can be seen as a belief, sentiment, or expectation about a partner that results from a partner's expertise, reliability, or past behavior [8] [7]. The partnership relationship is characterized by a high-level of trust [7]. Companies are fascinated by international partnership opportunities on the Web, but they are skeptical about actually purchasing from overseas sites [16]. The international aspect of the Internet further challenges engendering trust in a partner relationship. [8] verified that trust has a causal impact on loyalty.

Proposition 5c: Trust will be positively associated with the link between electronic partnerships and customer loyalty.

## 4. Conclusion

The objective of this paper is to propose a model to test the effect of Internet's web tools and trust on the link between customer relationship management and competitive advantage via customer loyalty. Internet's web tools such as level of informational web site, level of transactional web site and level of security on the web can support the formation and maintenance of customer relationship because they facilitate the way organizations partner, interact and empower. In other words, Internet's web tools can let organizations to build tight relationships with their trading customers who should become loyal to them, rather than to select customers on a transaction by transaction basis from a large pool of non-loyal ones. The quality of web site infrastructure can directly influence the type of customer relationships management developed between firms who desire to be loyal reciprocally.

One more issue that is central to electronic commerce is the level of trust that is necessary before businesses may commit to an electronic commerce customer relationship management leading to customer loyalty. First of all many authors argued that the construct of trust is an important element of long-term buyer-seller relationships in a business environment [8]. Also, customer loyalty is a relationship built on trust between the buyer and the seller [7]. Second, trust is not only a short-term issue but the most significant long-term barrier for realizing the potential of electronic commerce on the Internet [16]. Lastly, with trust as a precursor, a customer becomes loyal to a firm [7]. In fact, trust has a direct or indirect impact either on the Internet's web tools or on the customer loyalty or on the customer relationship management or on the relations among these three constructs.

The theoretical discussion of this study will allow experts on information systems and the Internet to inform business representatives about the theoretical impact of trust on electronic commerce customer relationship management. These experts have to demonstrate to the business representative methods of fixing customer loyalty objectives when they are theoretically supported in their customer relationship management tasks by the level of informational web site, the level of transactional web site and the level of security on the web provided by the Internet to their companies.

Future research is necessary because the theoretical propositions presented in this paper must be tested. In fact, continual research is needed because Internet technology evolves so rapidly and said evolution will likely effect the relationships tested by this model's propositions. Additional research should also expand the range of Internet's web tools variables and examine their effects on the link between customer relationship management and organizational performance.

# Why are Self-Service Customers Loyal? -- A Relational Benefits Perspective

HsiuJu Rebecca Yen  
College of Management

Chung-Li, Taiwan  
hjyen@saturn.yzu.edu.tw

## Abstract

Self-service technology has been growing popular for current business practice to increase productivity and reduce cost. Issues regarding impacts of lacking human touch in technology-based interaction on jeopardizing customer relationship, however, has remained unanswered. The current study applied attribute-based model of SST and customer relational benefits model to address the concern of SST introduction and possible changes in customer relationship. A survey was conducted to test the impacts of Web-based self-service attributes on customer loyalty, and the possible mediating role of relational benefits. The results generally suggested that certain attributes of Web-based self-service are important at enhancing perceived relational benefits. Positive perceptions of confidence benefits, social benefits, and special treatment benefits obtained from the Web-based service provider resulted in higher customer loyalty. The implications of the research findings were discussed.

## 1. Introduction

The advances of information technology have brought dramatic changes in services business. More companies are offering and encouraging customers to use self-service technology which might provide substantial benefits for the firms in terms of improving productivity and cost saving (Lovell and Young, 1979; Schneider and Bowen, 1985). Consumers would choose the self-service technology (SST) option when they hold a positive attitude for enjoyment and control attributes of the SST option (Dabholkar, 1996). There are various types of SSTs interfaces, including telephone-based technologies, interactive voice response systems, direct online/Internet-based interfaces, interactive free-standing kiosks, and video or compact disc (CD) technologies (Meuter, Ostrom, Roundtree, and Bitner, 2000). The present study focus on Web-based self-service (WBSS) which is getting more prevalent recently.

It is worthy noting that the omission of interpersonal contact in the various SST interfaces could become a risk when firms implement SSTs. In fact, the interpersonal aspects of a relationship are at times found to be more important than the occasional price breaks or special service (Gwinner, Gremler, and Bitner, 1998). Therefore, it is possible that customers may become less loyal to the

relationship if the social bond between service employee and customers is weakened in the self-service technology interface. Despite of the potential risk on customer loyalty, more and more firms are motivated to introduce SSTs for a variety of advantages such as increased availability (Lovell, 1983), timesaving, and ease of use (Meuter et al., 2000). On the other hand, building strong customer relationships as a means for gaining a competitive advantage is also gradually emphasized (McKenna 1991; Reichheld, 1993). Therefore, it will be important for firms to find out how would the introduction of SSTs impact customers loyalty.

Customers would stay in a relationship if they receive certain benefits (Gwinner et al., 1998). Customers in long-term relationship normally experience three primary types of benefits beyond core service benefits, including confidence benefits, social benefits, and special treatment benefits (Gwinner et al., 1998). Could these relational benefits applied to explain customer relationship in self-service context?

Based on the above discussion, the current study aims to address the following research issues in the WBSS context. First, what are the attribute of WBSS that are influential for strengthen relational benefits? Second, are the three relational benefits important precursors of customer loyalty to Web-based service provider? Finally, this study proposed that relational benefits are important constructs mediating the relationship between WBSS attributes and customer loyalty.

## 2. Theoretical Background

Technology-based interaction is gradually becoming a popular option for service encounter, and as a critical source of influences on long-term customer relationship. In a marketspace where "products and services exist as digital information and can be delivered through information based channels" (Rayport and Sciokla, 1995, p 14), customers were not served by front-line personnel. Therefore, self-service technologies represent a typical transactional form in which no interpersonal contact is required for service encounter. During the encounter, customers using self-service technology are viewed as "partial employees" to serve themselves, and their evaluations of attributes associated with SST could be crucial in determining consumers' continuance of SST usage. The current study builds upon the attribute-based

model of SST (Dabholkar, 1996) and proposes attributes as important antecedent of customer relational benefits in the context of Web-based self-service. In specific, perceived performance, perceived efficiency, enjoyment, perceived control, and customization are suggested as significant factors in customer relationship management.

Positive outcomes gaining from strong customer relationship have been well documented in the literature (e.g., Aaker, 1992; Clark and Payne, 1994; McKenna, 1991; Reichheld, 1993; 1996), but studies regarding the relationship benefits are primarily approached from the perspective of the firm (Gwinner et al., 1998). On the other hand, customers also need to benefit either from the core product/service or from the relationship to remain loyal to a firm. This is particularly true since most products and services are offered by more than one firm (Hennig-Thurau, Gwinner, and Gremler, 2000). Grounded upon previous work on customer relational benefits (Barnes, 1994; Bendapudi and Berry, 1997; Berry, 1995), Gwinner et al., (1998) developed and empirically examining the typology of relational benefits. They suggested that customers in long-term relationship normally experience three primary types of benefits beyond core service benefits; namely, confidence benefits, social benefits, and special treatment benefits (Gwinner et al., 1998).

The first type, titled confidence benefits by Gwinner et al., (1998), describes the advantages of long-term relationship at reducing uncertainty in transactions and increasing realistic expectation for service encounter. The second type, social benefits, describes the emotional aspects of the relationship and focuses on personal recognition of customer by employees and the development of friendship between customers and employees. The third type of benefit contains both economic benefits and customization benefits and was titled as special treatment benefits by Gwinner et al., (1998). Advantages such as price breaks, fast services, individualized treatment are the special treatment benefits one normally received from staying in a long-term relationship. As the development of each type of relational benefits might be related to direct personal contact to a more or less extent, whether customers perceive any relational benefits from being loyal to a particular technology-based service provider remains unknown.

The infusion of Internet technology into services can improve customer relationship (Walsh and Godfrey, 2000). The advances of technology enhance customer relationship by automatically and effortlessly collecting, analyzing, and utilizing customer information. The Internet-based technology also provides the firm a convenient and powerful tool to interact closely with customers over time to establish a personal and more intimate relationship. Despite of these relationship marketing practices, customers still want quality services from technology-based service providers just as they always want (Bitner, 2001). While WBSS attributes might

characterize the technology-based service encounter for consumers, the performance of these attributes could subsequently form perceived relational benefits of staying with a particular technology-based service provider. The current study proposed that performance of each WBSS attributes would result in distinct relational benefits for customers.

### *2.1 Hypothetical Model*

The relationship between the four WBSS attributes and relational benefits are proposed in the following. The first attribute, perceived performance, is derived from the concept of usefulness. Perceived usefulness refers to user's belief about the probability of increasing job performance by using a specific computer software (Davis et al., 1989). The nature of perceived usefulness might not be an attribute applicable to the context of SST usage. Instead, Dabholkar (1994) proposed "performance" as an attribute replacing perceived usefulness, and is conceptualized to encompass the perceived reliability and accuracy of self-service technology. The literature has identified reliability as an important dimension to evaluate service quality (e.g., Parasuraman, Zeithaml, and Berry, 1988; Van Gorder, 1990). A similar dimension, "did its job", was found in another study as a factor relevant to consumer satisfaction with SST (Meuter et al., 2000). The capability to perform the intended task is predicted to enhance the confidence of using Web-based self-service. Therefore, it is predicted that perceived performance in using WBSS will be positively associated with confidence benefits.

The second attribute, perceived control, refers to the amount of control customer feels that she or he holds over the process or outcome of a service encounter (Dabholkar, 1996). Perceived control is important for self-service users (Langeard, Bateson, Loverlock, and Eiglier, 1981) and they often chose to use this option to feel in control during the process (Bateson, 1985). Consumers also feel satisfied with SST because this option enables them to acquired needed service without having to contract with service personnel (Meuter et al., 2000). Therefore, SST allows some customers the alternative to regain the control by performing the tasks usually conducted by service employees. Accordingly, the greater control one perceived in using WBSS, the more likely one feel confident of using the option. Accordingly, perceived control is hypothesized to have a positive and direct effect on perceived confidence benefits.

The third attribute, enjoyment, was considered as a characteristic capturing customer perception of SST (Dabholkar, 1994) or a determinant on technology usage (Webster, 1989). Dabholkar's study (1996) also discovered enjoyment as a determinant of SST service quality and intention to use SST option (Dabholkar, 1996). The literature suggested that interaction intensity and utilitarian value of the relationship are relevant to the development of social bonds (Selness and Hansen, 2001). When customers feel that it is fun to deal with a service

provider, the relationship become more enjoyable to customers (Gwinner et al., 1998). Thus, likeability of particular Web-based service provider might increase as the enjoyment of interaction escalates, which then become a good base for developing social benefits. In other words, positive affect derived from using WBSS of certain service provider could transform into the emotional aspect of the relationship and facilitate perceived social benefits of relationship. Consequently, enjoyment is hypothesized to have a positive and direct effect on social benefits.

The fourth attribute, customization, refers to the freedom to personalize the use of self-service devices in terms of time and location. Also, customization is conceptualized as the belief that WBSS offers users another option to acquire the services at their personally preferred manner. For example, some Website offer the storage that customers may place their preferred items and decide later whether they want to purchase. This option may be especially important for certain consumers and is an attribute unique in WBSS to satisfy personal shopping needs. The concept of this attribute is similar to the “when I want” and “where I want” sub-dimensions emerged in the critical incidents study by Meuter et al., (2000), and the “convenience” factor as one antecedent of e-satisfaction in a study by Szymanski and Hise (2000). The present study suggests that the attribute, customization, represent an unique offer of utilitarian value satisfy customer personal preference. And the capability to satisfy individual needs might bring positive affect to the relationship and strengthen the perception of social benefits. Therefore, it is hypothesized that customization will both have positive effects on perceived social benefits.

In addition, the nature of customization to offer special features that meets individual preference would be the characteristics most relevant to special treatment benefits. Although the nature of around-the-clock access seems to be fundamental for Internet, some technical breakdown and other maintenance problem could erode the fulfillment of customization. Therefore, we proposed that perceived customization would have a positive effect on perception of special treatment benefits.

The last attribute, perceived efficiency, is the speedy nature of WBSS to solve users’ needs than other service options. Meuter et al., (2000) found that the character to solve intensified need is the first factor determining users’ satisfaction with SST. When consumer expected a long waiting time for receiving services, the speed of delivery in SST become an important factor (Dabholkar, 1996). The fact that consumer can use Web-based self service to satisfy their needs in a fast manner could become a special benefit that customers received from using WBSS. Thus, perceived efficiency of using WBSS is predicted to have a positive effect on special treatment benefits.

Positive relationships between the three types of relational benefits and customer loyalty related constructs have been reported in previous studies (Gwinner et al., 1998; Hennig-Thurau, Gwinner, and Gremler, 2002). Regardless of the service types, confidence benefits are

believed to be the most important type of benefits (Gwinner et al., 1998), and its effects on loyalty primarily occur through satisfaction (Hennig-Thurau et al., 2002). Compared with the direct and significant effects of social benefits on customer loyalty, the direct effects of special treatment on loyalty have not received consistent support (Hennig-Thurau et al., 2002). Due to the nature of Web-based self-service, the impacts of the three types of relational benefits might function in a slightly different pattern. In specific, security and privacy issues of online transaction are still primary concerns for consumers (need supporting reference), perception of confidence benefit is predicted to have a positive effect on intent to stay in the relationship.

On the other hand, the practices of data mining and warehousing technique to record and analyze customers’ shopping behaviors allow the Web-based service providers the opportunities to provide customized offers to their customers. The information can also be utilized by Web-based service providers to present recommendations particularly fitting into customers’ interests and needs e at the real-time interaction. These performances all represent special treatment benefits that customers could experience with Web-based service provider, and is predicted to have a positive effect on intent to stay in the relationship. Finally, although the emotional element and friendship that usually exist between customers and employees are difficult to imitate, friendly treatment of the Web-based service provider toward the customers may be perceived as a social benefit to the customers. For customers who are familiar with certain Web-based self-service may see the interface as so enjoyable and become another channel for their social life, which further nurture the social benefits of using WBSS and its effect at enhancing customer loyalty.

In sum, there are 9 hypotheses proposed for the current study:

*Hypothesis 1: Perceived performance in using WBSS will have a positive effect on perception of confidence benefits.*

*Hypothesis 2: Perceived control of using WBSS will have a positive effect on perception of confidence benefits.*

*Hypothesis 3: Enjoyment in using WBSS will have a positive effect on perception of social benefits.*

*Hypothesis 4: Customization in using WBSS will have a positive effect on perception of social benefits.*

*Hypothesis 5: Customization will have a positive effect on perception of special treatment benefits.*

*Hypothesis 6: Perceived in using WBSS will have a positive effect on perception of special treatment benefits.*

*Hypothesis 8: Confidence benefits are expected to have a positive impact on customers’ intent to stay*

*in the relationship.*

*Hypothesis 9: Social benefits are expected to have a positive impact on customers' intent to stay in the relationship.*

*Hypothesis 9: Special treatment benefits are expected to have a positive impact on customers' intent to stay in the relationship.*

### **3. Research Methods and Analyses**

A self-administrated, cross-sectional survey was conducted with 459 respondents across two service industries (i.e., travel agency and bookstore). The two types of services were selected due to their distinction on contact levels. According to the taxonomy of service firms by Bowen (1990), travel agency is classified as a high contact service type and books retailing is conceptualized as moderate contact because usually standardized services are offered in bookstore. While the services are offered on the Web, the level of contact embedded in the nature of the two service industries could both be transformed into low customer contact. Consequently, customers in the two service industries might go through distinct degree of adjustment when they move from full service to self-service on the Web. It would be interesting to understand whether the reasons to be loyal self-service customers are identical for the two service types of distinct contact level.

Perceived attributes of Web-based self-service (WBSS), customer relational benefits, and loyalty were all assessed with 7-point Likert scales ranging from 1 (strongly disagree) to 7 (strongly agree). Measurement of WBSS attributes were adopted from Debholkar's study (1996) and modified to tap the nature of Web-based self-service. The scale developed by Gwinner et al., (1998) to assess the three relational benefits were revised for current study to capture the nature of the two service industries and the characteristics of WBSS. Confirmatory factor analyses performed for the two sets of constructs indicated a good fit of the measurement models to the data (both CFIs  $\geq .952$ , both GFIs  $\geq .959$ , both TLIs  $\geq .920$ ). The results also supported the measures applied in the present study appropriate measures of WBSS attributes and relational benefits.

To address the three research issues, structural equation modeling was performed to test the relationship between WBSS attribute evaluation and relational benefits, and between relational benefits and customer loyalty. The analyses revealed a good fit of the hypothesized model to the data ( $\chi^2=490.895$ ,  $df=170$ ,  $p<.001$ ; CFI=.910,

GFI=.910). The parameter estimates showed that perceived performance and perceived control in using WBSS had significantly positive effects on confidence benefits. More positive social benefits resulted from more favorable evaluations on enjoyment and customization of WBSS, and special treatment benefits are positively associated with efficiency and customization of WBSS option. In conclusion, the six hypotheses regarding WBSS attributes and relational benefits were confirmed.

In addition, the analyses also showed that all three types of relational benefits had significantly positive impacts on customer loyalty. That is, hypothesis 7, 8, and 9 are also supported in the current study. A comparison of the hypothetical model with a saturated model containing both direct and indirect effects of WBSS attributes on loyalty suggested that relational benefits are important mediators between WBSS attributes and customer loyalty.

### **3. Conclusion and Discussion**

While previous studies suggested that cognitive evaluation of SST attribute would influence consumers' intention to use self-service technology, none of these empirical studies attempted to investigate the impacts of these attributes on consumers' loyalty. This study built on the attribute-based model of SST and customer relational benefits model to study factors determining customers' loyalty in the context of Web-based self-service. The study in general suggested that WBSS attributes offers explanations for reasons that customer are willing to be loyal to a service provider as the contact is technology-based. In specific, when the Web-based self-service device is evaluated as efficient, controllable, enjoyable, capable, and customized to meet personal needs, customer are willing to stay loyal to the Web-based service provider although no contact personnel is present to establish the social bonding. This study is also important to provide evidences to show that social benefits are still important for consumers although there is no human touch in the WBSS. More importantly, social benefits in technology-based interaction can be developed through certain design of the SST device. These findings would be very important for companies that are planning to offer customers Web-based self-service as an option for service encounter.

# CRM Implementation in PR China: A Preliminary Evaluation

Satya P. Chattopadhyay  
Arthur J. Kania School of Management  
University of Scranton  
Scranton, PA 18510  
USA  
Spc354@scranton.edu

## Abstract

The scope and nature of Customer Relationship Management (CRM) implementation in Chinese enterprises is examined to identify the focus of implementations, areas of implementation, implementation strategies and perceived benefits of a convenience sample of cases selected from business press reports. The study also looks at what Chinese managers view as the key CRM concepts for beneficial performance.

## 1. Introduction

CRM implementation has been shown to be very successful in increasing the level of customer satisfaction and capable of increasing the retention of existing customers over time. Following its enthusiastic acceptance in western countries, the developing markets and the markets in transitioning economies are seeking to reap the same benefits by embracing the principles of CRM. A rough product life cycle analysis of CRM market in China shows that after a slow introductory phase in the late 1990s, it is now in a growth phase starting with 2001, the downturn in the internet and communication related industries notwithstanding [1]. Multinational companies introduced CRM into P.R. China as a tool to gain a foothold in the potentially vast market that also featured major domestic constraints and strong international competition. The early domestic entrants into the Chinese CRM market have been the burgeoning SME sector. These companies also tend to be private entities, who are in very competitive markets. Initially the focus was on software implementations that were fast and furious. Only now are companies looking more seriously at putting in place structural changes that will add teeth to their efforts at becoming serious about identifying, managing and nurturing relationships with their customers. The geographic coverage of CRM implementation is predictably in the industrialized east, and service sector implementers far outnumber their counterparts in manufacturing.

This study will look at the differences and similarities in characteristics of CRM implementation in P.R. China relative to that in developed western economies. The problems and obstacles to implementing CRM in Chinese markets will be examined. Finally, the results of a pilot study on implementation focus for CRM in China will be

reported.

## 2. Western vs. Chinese Models of CRM

The standard CRM methodology for implementation is a) strategy, b) segmentation, c) technology, d) process and e) organization. Companies following this model in the west have tried to follow this general sequence more often than not. CRM implementation starts with an assessment of the business environment in some variation of a SWOT (strengths, weaknesses, opportunities and threats) analysis. The analysis identifies the triggers for CRM implementation both within the organization and in the external environment. This analysis also is likely to focus on a medium to long term planning horizon, and include an analysis of the environment faced by key business partners beyond the traditional business functions. The output of this stage is a mission/vision statement that specifies the role of CRM in the business model of the organization.

The second stage of the implementation strategy develops a segmentation map of the organization's customers as they contribute to the stated goals and objectives of the organization. While this is usually some objective measure of profitability, it can also include measures of other non-financial indicators of business performance. The pareto type analysis identifies the group/s of customers who contribute the most to the success of the mission. The information and segmentation output are then used to guide the deployment of scarce resources to managing relationships with those customers where the likelihood productivity increase is the highest.

The third stage consists of identification and deployment of available technology to achieve desired process improvements that are necessary for achieving the CRM deployment. The focus is on defining system requirements, assessment of system requirement criteria and vendor assessment and selection criteria. The training of personnel with responsibilities of using the technology is critical in this phase, as is the smooth adaptation and/or migration of operations to the new system. The most important strategy here is to run a pilot rather than to push through radical organization wide change.

In the fourth stage, the results of the pilot are carefully evaluated. If positive, diligent planning is conducted to identify how the CRM strategy can be migrated to all processes of the organization. This will involve integrating the technology to all the processes with a

common goal of enhancing CRM features.

The final step is to re-engineer the structure of the organization and review the allocation of roles, responsibilities and functions of personnel at all level of the organization. Simultaneously, appropriate training of personnel to enable and empower them to discharge their new roles and responsibilities will be undertaken.

The whole organization will need to buy into a commitment to continuously review the CRM implementation and incorporate adjustments when warranted.

The Chinese model of CRM implementation has, so far, deviated substantially from the model outlined above.

As with many other facets of the market, the Chinese have explicitly linked CRM implementation to the WTO entry and subsequent changes in economic landscape. The CRM implementation is for the specific outcome of “increased sales.” The short-circuited causal model bypasses the need to understand the mechanism through which the outcome is achieved, and provides no incentive to focus on the necessary intermediate steps, additional inputs and environmental conditions that are also needed to ensure the outcome desired.

The pre-transition Chinese economy that ran on a socialist model was driven by allocations determined at various levels of the bureaucratic hierarchy. As such, no explicit role of customer in the “marketing” efforts. The end-result of this policy was that virtually no research was conducted on the customer side of the business.

The early ERM implementation in China was a radical departure from the selling oriented system. The multinational enterprises were unable to apply their developed strategy because of difference in market structure. In China their customer was primarily the government, or state agencies that served as buffer between them and their local customers. The “customer” was unwilling to collaborate and cooperate in way that would be necessary to design and implement CRM systems. There was no indication that CRM was worth implementing beyond very specific incentives of financial nature (which were of questionable legality in the MNC’s home country) and accommodations in business agreements that the MNCs found detrimental to their business goals.

The socialist mindset prevented automatic consideration of customer segmentation based on profitability. Without market oriented mission /vision identified, non-financial goals that could serve as objective criteria for segmentation were absent. As a result, the SMEs saw CRM implementation as primarily the acquisition of CRM software (foreign providers at first, with local providers soon bringing knock-offs to the market at lower prices), and rapid deployment in the sales management system. To the extent possible (handicapped by lack of basic infrastructure) key users of the software were provided with condensed training and sent into the field. The CRM system in most cases was an add-on to the prevailing operations and played a supplementary

rather than primary roles. Adoption was half-hearted among the key users, and non-existent among the rank and file personnel of the organizations. The critical fourth and fifth stages of the western implementation model was totally ignored. Very little effort was spent in validating the success of pilot implementations, and almost none to make structural changes in the organization that were seen as extremely important in the western model. The hyperactive growth in the technology sector with its promise of a panacea for all business problems prevented the companies from asking the tough questions about the payoff of investments in CRM technology.

The scenario underwent a significant change with the bursting of the technology bubble. The move to implement CRM continued, but the pace became less frenzied and issues of accountability, responsibility and pay-back on investments became legitimate. The issue of CRM implementation is more likely to be considered as a carefully evaluated investment rather than a statement of “market orientation in the post WTO era.”

It can be concluded that after the initial frenzy of indiscriminate headlong plunge into a scarcely understood and untested technology has passed. The Chinese market is in the process of taking a second crack at CRM implementation, but this time taking a more critical approach that seeks to proceed more cautiously, and adapt a strategy that suits the domestic conditions.

### **3. Barriers to CRM Implementation in China**

The managerial mindset possibly creates the biggest obstacle for successful CRM implementation in China. Sampson Lee [2] identifies the following as primary: restricted view of CRM as only software, difficulty to understand CRM scope and goals, affordability of implementation, poor ROI, lack of assigned responsibility and designated authority. While the present author broadly agrees with the above characterization, this picture is simplistic.

One of the main reasons for loose CRM implementation is the Chinese market itself. With China being unique among the countries of the world that can sustain reasonable growth rate through domestic market development alone, the emphasis on retention of customers is not as critical as it is in the more developed countries that it is trying to emulate. Fueled by a steady supply of new qualified entrants into the market, the CRM systems are not under the gun as they are elsewhere. So the standards for evaluation and measurement of performance are not as stringent.

Another constraint is the lack of customer information. While systems for gathering and use of customer data are bundled into most CRM software now in the market, the culture still is not comfortable with the idea of sharing information. The Chinese art of “Guanxi” focuses on the nurturing and development of personal relationships that cement the alliances in informal social networks and significantly affect the underpinnings of formal and quasi-formal business and institutional relationships in

Chinese society. However, the focus of “Guanxi” is more on the exchange of favors than on the characteristics of the actors or the scope and structure of the relationship between them. Business partners, as well as consumers are not willing, in general, to share information about each other and their operations. In addition, the information available about the environment of business and available infrastructure is spotty at best in coverage, and have been shown to have questionable validity. Any strategic planning and customer segmentation based on the above sources are not likely to be very useful.

Lack of ability and willingness to adapt western knowledge of successful CRM implementation to the Chinese context has been another obstacle. The particular cultural and macro-economic characteristics of the Chinese environment that interact with the CRM implementation strategy needs to be studied by academics and practitioners in order to develop guidelines for adaptation. Without that, the frustration level is difficult to survive.

Finally, the need to develop a more realistic expectation when it comes to outcomes of CRM implementation will also be necessary for the concept to become acceptable to mainstream organizations. The absence of expectations grounded in reality and objective evaluation mechanism to document successful CRM implementations.

So in summary, a culture that does not support extensive gathering of detailed information on transaction partners, difficulty in making necessary adaptations for Chinese environment, and lack of realistic expectations and benchmarks for measuring outcomes are the primary obstacles to CRM implementation in China.

#### **4. Results of Exploratory Study**

A exploratory study was conducted to examine the state of CRM implementation in P.R. China. The method employed was to first identify news articles in English language Chinese media. China Daily (Beijing Edition), and Business Weekly (A China Daily publication) were the primary sources. Internet based archives were used for the former, and print archives of the latter were used. The period selected for the search was January 1, 2002 to July 31, 2002. The choice was arbitrary. The period was after China was admitted to the WTO in December 2001. A total of 137 news items were uncovered that had at least 800 words of content. The results of the content analysis are provided below. There is no claim made to any statistical validity of the results, as they are from a convenience sample. However, they provide a basis on which to design future studies for more valid inferences. The articles are journalistic pieces based on interviews conducted by the reporters with principals of the companies. It is assumed that the reporters have not taken

editorial liberties.

#### **4.1 View of CRM**

The sample of selected articles were scored for their references to components in a definition of CRM: A systematic approach(12%) to the use of strategically (37%) defined business processes(15%) that incorporate technology (94%) to enhance the scope and quality of acquiring(23%), servicing(16%) and retaining(3%) customers. The percentages in parenthesis refer to the proportion of cases that made a direct or indirect reference to these concepts. It is obvious that the overwhelming majority see CRM as a technology implementation, and only a minority are recognizing the broader aspects.

#### **4.2 CRM into Organization**

Upon content analysis, the articles indicated that CRM implementation had the following penetration when it came to organizational integration and involvement: Strategy (64%), Customer Segmentation for Differential Service (42%), Technology Acquisition and Deployment (94%), Process integration( 8%) and Organization Restructuring (6%). The data again appear to be in line with a rather superficial approach to CRM implementation by domestic Chinese SMEs.

#### **4.3 Evaluation Criteria for CRM Success**

The objectives (and hence criteria for evaluating success/failure) of CRM implementation according to the sample were Customer Loyalty (86%), Prospecting Success (71%), Customer Retention (36%) and there was no mention of Cross-Sell/Up-sell (0%). These results seem to show that Chinese SMEs are only scratching the surface when it comes to the scope of CRM benefits, but they expect a high level of sales success to be a part of the resulting benefits.

#### **5. Conclusions and Implications**

This exploratory study documents the early stage of CRM implementation in market in transition that has the potential to shortly become the most lucrative in global context. The results suggest, however, the need for careful study of the constraints in the Chinese context and indicate planned changes in business culture and management thinking to achieve more consistent results.

## Abstract

In the recent years, the broader application of web-based technologies caused radical changes and a consequent rapid development within the entrepreneurial environment. In order to exploit first-mover advantages, enterprises often preferred a quick-paced introduction of E-Business solutions, hence neglecting more holistic and integrated approaches. This fact implied that E-Business solutions were usually simply and hastily embedded into the existing business processes and organizational structures. As a result, E-Business projects often did not reach the striven targets or even failed, with the consequently growing lack of trust towards the above-mentioned business approach. Hence, there is a clear need for action in the field of methodical development, deployment and integration of E-Business solutions into the entrepreneurial structure. We present an integrated framework for the engineering of E-Business, which is the result of a 3 year experience at FIR.

## 1. Background

During the past years, the fast development of new Information and Communication Technologies (ICTs) has been revolutionizing the market arena and it extended the horizon of competition [16]. Such development has been causing radical changes in all business branches [1] [2] [15] [16] [19] [22] [31] [33] [35] [39] [41] [43]. New ICTs and the related new business approaches allow enterprises to design leaner intra-organizational processes, with the result of enhancing efficiency and productivity [28] [32] [38] [40]. Besides that, ICTs can strongly influence inter-organizational processes, by supporting co-operation within entrepreneurial networks as well as by enabling their co-ordination – by means of Internet-based Business Collaboration Infrastructures (BCIs), such as Electronic Marketplaces, Exchange and Communication Platforms or Supply Chain Integrators [18] [21] [39]. Hence, web-based ICT solutions play a crucial enabling role both for new business models and for those models that, up until now, had a higher value on a theoretical than on a practical level (e.g. Virtual Organizations) [13] [31]. Anyhow, a lot of open issues and unsolved problems are still to be faced. As a matter of fact, the selection and matching of organizational approaches and suitable E-Business solutions, as well as their appropriate engineering, is a complex problem. During the past years, it often happened that E-Business solutions

were simply and hastily embedded into the existing business processes and organizational structures. As a result, E-Business projects often did not reach the striven targets or even failed, with the consequently growing lack of trust towards ICTs and the related solutions. Because of our experience with reorganization projects, we are convinced that, instead of a partial one, a holistic approach has to be followed. Hence, it is important to abstract from all methods and working procedures in use, in order to be able to build up a holistic “integration framework”. Such an approach will enable us to identify and manage causal relationships between the strategic planning, the engineering of new organizational structures and the related controlling. Furthermore, new ICT-based organizational frameworks and E-Business solutions do not have to be only appropriately developed and integrated into the existing organization, but have to be also operated, managed and maintained (operations management). This requires a methodically founded tool. Hence, in order to face all above-mentioned issues, we developed a framework, which we use to systematically develop, implement and integrate E-Business solutions in manufacturing enterprises. We will present it in the next section (section 2). Hence, we will discuss a research work that we conducted with the support of our integration framework (section 3). Thus, we will present a case study to test the concept (section 4). Eventually, we will draw a set of conclusive considerations (section 5).

## 2. The FIR Integration Framework for E-Business Engineering

### 2.1 The Research Institute for Operations Management (FIR)

The Research Institute for Operations Management (Forschungsinstitut für Rationalisierung, FIR) is an independent research service provider at Aachen University of Technology (RWTH Aachen), with a 50 year experience in developing and applying methods for the enhancement of economic and industrial growth. The FIR is a registered research association and it has about 150 member companies and associations. The FIR has 4 research departments (E-Business Engineering, Logistics, Production Management, and Service Organization) and several interdepartmental practices, in which 70 permanent employees and further 70 academic and student assistants design the operations management in the company of the future.

In accordance with the public assignment, the methods and tools that are designed in cooperation with partners within and outside of the FIR research association are made available in particular to SMEs. As mediator between practice and theory, the FIR follows the idea of an application-oriented research, and promotes the enterprises' active participation within this process. We adapt our research results to specific lines of business and specific companies, and promote their transfer into the targeted branches.

As a research service provider the FIR acts as a “lobbyist” for the companies in pre-competition research, as a partner of trade and industry and as a research institution for national and international associative projects. These public funded projects are promoted by the European Union as well as by the German Federal Ministry Economics and Technology, and the German Federal Ministry of Education and Research. Furthermore, with the help of projects for industrial and service customers, the FIR deepens its research work within a commissioned research framework. The institute cooperates with consulting institutions, which fulfill important transfer functions within the innovation and research process. Last but not least, the FIR supports its projects through various partnerships with national, European, American, and Asian research and transfer institutions.

## 2.2 E-Business Engineering at FIR

Currently, there are different and not always concordant definitions of the term E-Business, e.g. in [1] [41] or [43]. E-Business will be here defined as the “holistic ICT-based support of (dynamic) inter-organizational and intra-organizational processes and transactions” [13]. E-Business hence implies the modification of existing business relationships and might thus lead to the development of new or modified business models. Within this context, we define E-Business Engineering as all the methods and procedures that support companies of different industrial sectors to systematically develop, implement and run E-Business solutions. E-Business Engineering can be hence defined as the systematic design and implementation of E-Business solutions and models.

Within our field experience and our daily interaction with German and European SMEs, we realized that enterprises lack of appropriate and structured methods deploy E-Business in their organizations. As a matter of fact, the decision related to the adoption of E-Business solutions as well as their embedding into an organization is a complex problem which had been too often underestimated in the recent past. Because of our experience with reorganization projects, we are convinced that, instead of a partial one, a holistic approach has to be followed. Hence, it is important to abstract from all methods and working procedures in use, in order to be able to build up a holistic framework. Such an approach can enable decision-makers to identify and manage causal relationships between the strategic planning, the

engineering of new organizational structures and the related controlling. Furthermore, new ICT-based organizational frameworks and E-Business solutions do not have to be only appropriate developed and integrated into the existing organization, but have to be also operated, managed and maintained. Clearly, also the operations management under the new ICT-driven constellation requires a suitable and methodically founded support.

In order to deal with all above-mentioned issues, we developed a framework, the FIR Integration Framework for E-Business Engineering, which we use to develop, implement and integrate E-Business solutions in enterprises. The approach exploits several established methods from the fields of product and service engineering, business organization and computer science (e.g. methods of business modeling, service engineering, product design, process and system design, monitoring and planning of technology). The basic idea behind this approach is that we intended to adapt and integrate such established modeling, design or engineering methods, in order to fulfill the new modeling and organizational requirements triggered by the potentials of new ICTs and of the related solutions. This approach supports also to the development of new and innovative methods. The four layers of the framework are the most relevant design areas (business models, products and services, business processes, and IT) that, according to our understanding, guarantee a complete analysis of enterprises and help to define the appropriate structure for the development and embedding of E-Business solution in organizations (see Figure 1).

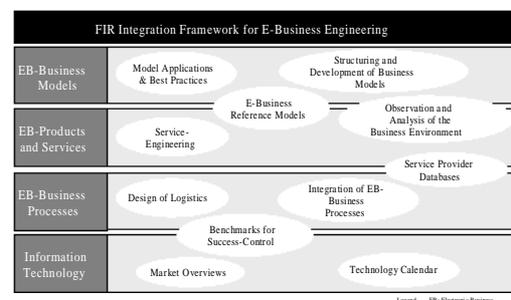

Figure 1 – FIR Integration Framework

All the different partial methods as well as their interactions represent the core elements of the integration framework, which is structured into the following layers:

1. E-Business business models. This first layer deals with the design and development of E-Business architectures that strive the achievement of more efficient inter-organizational relationships, e.g. within the exchange of products and services within manufacturing networks. The design of new business models in a networked economy as well as the definition and assessment of E-Business scenarios are also major issues. Furthermore, the design has to be done by taking into specific consideration the achievement of sustainable turnovers and profits.
2. E-Business products and services. On this layer the focus is on the systematic development of innovative

E-Business products and service portfolios, both for manufacturers and for service providers.

3. E-Business business processes. This layer concerns the analysis of the organizational and entrepreneurial changes triggered by E-Business, especially regarding inter-organizational as well as intra-organizational activities and processes that are heavily supported by electronic Information and Communication Technologies. The target is here the support of the business activities, especially inter-organizational, with integrated and efficient ICT-solutions.

4. Information and Communication Technologies. As a matter of fact, ICTs are the basis for all E-Business activities. A thorough analysis of existing and future ICTs, as well as methods of technology management and planning are the basic requirement for the efficient and targeted use of ICTs. Furthermore, the identification of application potentials of innovative ICTs as well as the attempt to integrate isolated E-Business solutions is a critical success factor.

The Integration Framework for E-Business Engineering has been really useful for the work of the E-Business Engineering Department at FIR. As a matter of fact, the framework is shared by the whole department and it hence represents a starting point and a reference for the structuring and solving of problems in our industrial projects. In fact, such an integrated model proved to be really helpful within the development of new methods of higher complexity. In the next section we will present a meta-method to develop electronic Business Collaboration Infrastructures for networked organizations that we developed using the Integration Framework for E-Business Engineering.

### 3. The Design of New Intermediaries: a Path from Business Modeling to Technology Management

As previously stated, web-based ICT solutions play a crucial enabling role both for new Business Models and for those models that, up until now, had a higher value on a theoretical than on a practical level (e.g. Virtual Organizations) [13] [31]. As a matter of fact, recent trends show that companies, in order to face the quick-paced globalization process, tend to concentrate on their own core competencies, before starting to co-operate within global networks of enterprises [16] [22] [27] [29]. This transformation process is crucial for the success of the company's business [31]. Therefore, before making a strategic decision regarding the participation to a co-operation network, the management of an enterprise has to take into consideration a wide set of aspects, such as the entrepreneurial organization, the own core competencies, the needs of the customers, the readiness of the potential partners to co-operate, and the availability of the needed technologies and tools [5] [13] [16] [33] [41].

In particular, enterprises have to weigh a set of crucial success factors in the fields of standardization and information technology management [15] [23]. For

instance, on the one side communication standards are essential to achieve an efficient exchange of information and data [3]. On the other side, branch-specific collaboration standards are crucial to establish inter-organizational workflows [19]. Furthermore, the analysis of the potentials of new technologies can help to select the most suitable technologies and tools for the support of new entrepreneurial businesses [6] [39]. A proper technology and innovation management is important to plan the development of the entrepreneurial core businesses in co-ordination with a strategic technology planning [7] [18].

As a result, in order to deploy innovative network-oriented co-operation structures, new (Internet-based) Business Models can be designed and successfully implemented [1] [34]. Amongst other aspects, the processes of intermediation and disintermediation are relevant phenomena in this context [21] [37] [38] [39].

Within this section we will present a new business modeling approach for a networked economy and hence focus on the design of information models in a networked economy (section 3.1 to 3.3). In order to identify the needed ICTs for a new E-Business Model, we will eventually outline a methodology for technology planning (section 3.4).

#### 3.1 The Internet and the New Business Models

In the management literature there are different and discrepant definitions of the concept of Business Model [1] [41][43]. Furthermore, (E)-Business Models can be classified according to the most different criteria, such as the degree of innovation and functional integration, the collaboration focus or the involved actors [35] [41] [43]. The core objective of each company is a long-term creation of added value [33]. The entrepreneurial strategy defines how such a target has to be fulfilled. A successful strategic positioning is achieved through a sustained profitability, an own value proposition, a distinctive value chain, an entrepreneurial fit, and continuity of strategic direction [33]. According to our understanding, a Business Model is an instantiation of an entrepreneurial strategy related to a specific business and it encompasses six different sub-models (see Figure 2): (1) Market model: definition of the market(s) of action (targeted customers as well as potential competitors); (2) Output model: definition of the output requirements and design of the outputs (products or services); (3) Revenue model: estimation and calculation of the expected revenues; (4) Production design: design of how the performances have to be deployed; (5) Network and information model: partner selection and configuration of the network, as well as configuration and management of the (distributed) information; and (6) Financing model: scenario-based definition of risks and expected profits to search for investors or to persuade the stock holders [12].

In the new ICT era, companies strive to exploit the advantages of the networked economy. Lately, Business Models tend to involve different enterprises with the goal of bringing higher profits to each of the participants [1]

[31]. The modeling of such co-operative E-Business Models represents a significant challenge, since there are no appropriate methods to tackle systematically such modeling issue. We developed a customer-oriented business modeling approach for intermediaries within dispersed manufacturing networks.

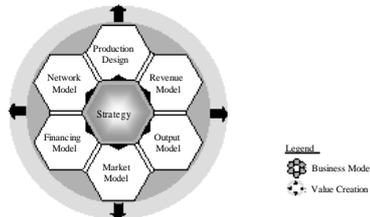

Figure 2 - Strategy, Business Model and Added Value

### 3.2 The House of Value Creation

Due to the globalization, the growing transparency of the markets and the resulting increased competition, enterprises have to focus more and more on their customers. As a matter of fact, the fulfillment of the customers' needs is an essential precondition to generate turnover. This means that enterprises have to take this aspect into deep consideration and must consequently shape Business Models that reflect the customers' needs [14]. Because of the above-mentioned reasons (see section 3.1), until now the development and adjustment of Business Models has been performed by companies mostly in a creative way. As a matter of fact, in the state-of-the-art there is hardly any holistic methodical support. A successful approach to tackle this methodical lack must be based on a strategic focus on the customer's needs. Within a running research project, we developed the House of Value Creation (HVC), a method to design customer-oriented and sustainable Business Models (see Figure 3) [12][26]. The HVC is a meta-method, since it consists of three logical pillars (input, method, and output) and of six process layers (each of the process steps requires a suitable method). The method suits explicitly the design of Internet-based Business Collaboration Infrastructures [14].

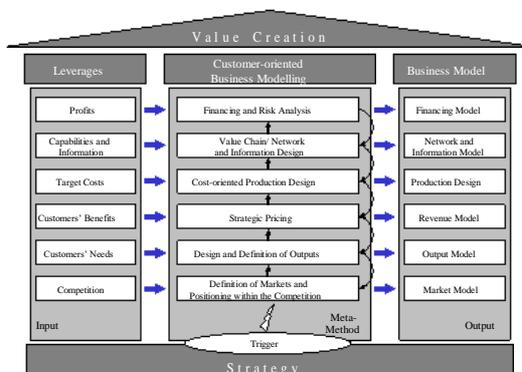

Figure 3 - The House of Value Creation

Because of our understanding of the term Business Model and because of the fact that the ultimate goal of a company is long-term value creation, the design of a

Business Model has to be definitely based upon the entrepreneurial strategy. Therefore, if not already done, the first step within a business modeling process is to define the rough entrepreneurial strategy, on which the Business Model will be based [25]. The meta-method of the House of Value Creation illustrates the correlation between a set of significant leverages (first pillar of the HVC), the Customer-oriented Business Modeling process (second pillar), and the resulting Business Model (third pillar).

As previously hinted, our Business Modeling approach encompasses six layers that correspond to six following steps of the method. The first HVC phase is triggered either by the inside or by the outside of the company – through a new idea, invention, innovation or modifications of the economical environment. The six steps of the method are [26]:

1. Definition of the markets and positioning within the competition. The initial decision regards the category of products or services to deal with (as well as the substitutes). Hence, a consequent monitoring of all strong players (suppliers, customers, and possible competitors) has to be done. This phase deals with the branch profitability and with the rivalry among existing and potential competitors. Phase output: market model, with a clear identification of the key players, customers and competitors.
2. Definition and design of the outputs. In the product design, a well-proven method is the Quality Function Deployment (QFD) [17] [30] [42]. With this approach, a customer-oriented product development can be successfully realized. Therefore, after defining markets and identifying core customers and competitors, the outputs (physical products or services) have to be shaped in order to maximize the customers' benefit according to a QFD-like method. Phase output: output model, with a detailed customer-oriented design of the outputs.
3. Strategic pricing. The identification of prices for the planned outputs should be more the result of a strategic positioning than of a cost-oriented approach [14] [16]. The price calculation should take into consideration the customers' surplus constraint as well as the strength of the competition (existing barriers of entry, such as patents, industry property rights, etc.) [20]. Phase output: revenue model, with a detailed description of how earnings will be achieved.
4. Cost-oriented production design. According to the guidelines of the revenue model, the target costs for the output model will be calculated (as the upper bound for direct costs). Hence, the requirements to the value chain will be detailed. Phase output: production design, with a detailed description of how the performances have to be achieved.
5. Partners, network and information. In this phase, starting from the requirements on performances of the value chain, the capabilities (core competencies, capacities, available modules and components, ICT infrastructure) of the own performance structure and of the potential partners will be thoroughly scanned. Phase

output: network model, selection of the partners within a specific instantiation of the value chain and network configuration, as well as information model, i.e. the approach according to which the information management issue has to be tackled.

6. Financing and risk analysis. Eventually, based upon the expected profits and a suitable scenario analysis, the risk-level as well as the need for working capital must be calculated to start the search for investors [11]. Phase output: financing model.

At each step of the HVC the corresponding targets must be fulfilled. If one step is not fulfilled, then the process should go back to a prior phase as long as the issue is tackled – with an iterative approach.

In the following section, our contribution will focus on a specific level of our HVC, namely the one regarding network and information model. A specific attention will be paid to the necessity to manage information, information flows and ICTs within distributed manufacturing networks and to the approach with which such goal set can be achieved.

### 3.3 The Design of Information Models in a Networked Economy

In the 5<sup>th</sup> phase of the HVC customer-oriented Business Modeling, starting from the requirements on performances of the value chain, the state-of-the-art and the capabilities of the own performance, information structures and ICTs, as well as of the ones of the potential partners, will be thoroughly scanned. The striven value chain will be designed and a specific network will be instantiated.

As stated in section 3.1, before making a strategic decision regarding the creation of a co-operation network, the management of an enterprise has to take into consideration a wide set of aspects, such as the entrepreneurial organization, the own core competencies and the ones of the partners, and the available technology. The gathering of all information regarding the potential network participants represents what we define as capabilities and information. According to the requirements previously identified within the production design (output of phase 4 of the HVC), a crosscheck with the capabilities of all potential partners helps to define the set of suitable partners. This process can be supported e.g. by the use of specific intermediaries such as vertical E-Marketplaces. The data about the entrepreneurial capabilities must regard both the own performances, the ICT capabilities as well as the maturity of the involved technologies [23] [31]. As a result, the instantiation of a specific network configuration can be identified. Furthermore, the definition of inter-organizational blue prints and branch-specific process standards is necessary to enable lean and efficient inter-organizational processes and workflows. The result is the network model (see Figure 4) [25]. The most relevant aspect for the following phase is that the inter-organizational processes determine the sources and the sinks of distributed information. The information design focuses on the management of the

information within such entrepreneurial networks and inter-organizational value chains (see Figure 4).

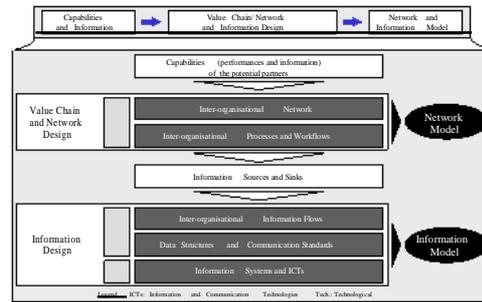

Figure 4 –Design of Network and Information Models

Within the modeling of an inter-organizational information management model, we distinguish three different layers [24]:

1. Inter-organizational Information Flows. Starting from the sources and the sinks of distributed information, the inter-organizational information flows can be derived and consequently defined. Within this process, several different aspects have to be taken into consideration: direction (e.g. one way or bi-directional information flow), involved actors (broker, network members, and related intelligent agents), involved systems (e.g. knowledge management, distributed Data Base information sources), and relationship (e.g. 1:1, 1:n, m:n). Furthermore, information flows encompass two other major dimensions: information width, which sets the different degrees of information broadcasting and transparency within the network, and information depth, which defines the scope, aggregation level and content of the information flow.

2. Inter-organizational Data Structures, Communication Standards. A crucial issue is the development of an inter-organizational data model to ensure the consistency, quality and transparency of the data. A data model encompasses also the aggregation levels for Management Support Systems (e.g. Data Warehousing and Data Mining). Furthermore, the branch-specific development of shared communication standards (e.g. based on XML) is essential to achieve and ensure a fast exchange of information and data through inter-organizational networks, as well as the integration of different ERP systems within an Internet-based BCI. The identification of the most appropriate technology standards is also important to deploy a back-end integration in each of the involved enterprises. Eventually, an appropriate solution for the security issue has to be identified.

3. Information Systems and ICTs. Enterprises have to weigh a set of crucial success factors in the field of technology management. The analysis of the potentials of new technologies as well as their diffusion and maturity can help enterprises to select the most suitable technologies to face challenges in the context of new collaborative businesses. For instance, the technical support of information flows in relation of complexity of the considered job and of the media richness (regarding e.g. real-time or asynchronous response) can be done according to the Media Richness Theory [8]. As a matter

of fact, a proper technology and innovation management is important to plan the development of the entrepreneurial core businesses in co-ordination with a strategic technology planning [6] [7] [23]. Last but not least, a make or buy decision has to be taken, e.g. between the exploitation of the services of an Application Service Provider and the development of an own platform.

Within the definition of Information Systems and ICTs, one of the most crucial issues is the identification of the most appropriate ICTs out of the set of all suitable technologies that might suit to the striven target [2] [6] [7] [8] [15] [23] [28] [32] [40]. Because of the dynamic technology development, the temporal horizon has to be considered in detail within the network and information modeling phase. As a matter of fact, the development of innovative ICT-based solutions requires an appropriate consideration of both available and future technology potentials. Furthermore, the future technology potentials usually imply an impact on the network organizational structure. This means that interdependencies between the network model and the information model have to be taken into consideration, when carrying out a middle or long term analysis. In order to meet this peculiar challenge, in the next section we outline a new planning methodology that incorporates the interdependencies between network structure and processes on the one hand and ICTs on the other hand.

### 3.4 Planning and Management of Technology

In order to fully benefit from the advantages of the inter-organizational co-operation, the network needs a sustainable support of Information Systems and ICTs. As pointed out above, the adequate identification, selection and management of suitable Information Systems and ICTs is a great challenge. In fact, there might be many different, often even partly competing network partners, whose different needs (also over the time) must be considered when selecting and assessing ICTs and electronic services to support the network [2] [6] [15] [37] [39]. Within our research, we observed that various ICTs are capable to support the different inter-organizational processes and workflows [4]. In order to guarantee smooth inter-organizational processes, the selected ICTs must therefore be integrated seamlessly. Furthermore, the high pace of technical development requires a planning process that considers both currently available and also future ICT-solutions [6] [7] [23] [40]. Finally, the potentials of future ICTs might influence the network structure, so that the business relations between participating companies may also change over the time [15] [37] [38] [39]. Therefore, potential impacts on the network must be considered and evaluated when selecting and assessing specific Information Systems and ICTs as network infrastructure. This is what we define as Integrated Planning and Management of Networks and of Information Technology [4]. Figure 5 shows how the temporal interdependencies of network structure and processes and ICTs should be integrated into the planning process. This enables the decision-makers to assess the

mutual influences and hence to deploy appropriate measures. We will now present an approach with which such an result can be achieved.

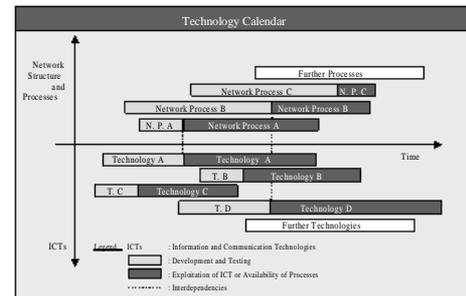

Figure 5 – Integrated Planning of Network and ICTs

First of all, because of the complexity related to this planning task, a suitable description model is fundamental for a successful planning. As a matter of fact, such a model must describe all characteristics of potential networks, the different parameters of ICTs as well as the complex links between these two clusters. As previously stated, this approach has to enable the full and sustainable exploitation of technologies over the time and herewith the implementation of new and unique network structures.

For this reason we developed an integrated description model to identify and highlight the interdependencies between different network instantiations and the underlying technologies (see also [9]). Our model (see Figure 6) fulfils the above-mentioned requirements.

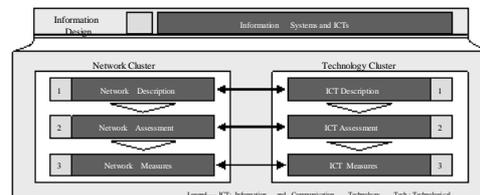

Figure 6 –Description Model for Integrated Planning

The description model consists of three layers for each of the two clusters. These layers correspond to three different steps within the planning and management process. The first layer is a crucial step within the model and it aims at the description of networks and ICTs as well as their matching. In Figure 6, the matching is represented by the arrows. In the second layer all relevant factors for the assessment of the feasibility as well as the sustainable cost-effectiveness are collected and compared. Eventually, in the third layer the necessary measures to deploy a specific network as well as to develop and exploit the appropriate ICT-infrastructure are derived. Within the last two steps a particular attention is paid to temporal constraints, as illustrated in Figure 5.

As mentioned above, the description and matching of the network and ICTs in the first layer is a complex task, because of the existence of several interdependencies between the two clusters. In order to enable an easier matching it is helpful to distinguish between network processes and organizational potentials on the one side as well as ICT functionalities and ICT potentials on the other

side (see Figure 7).

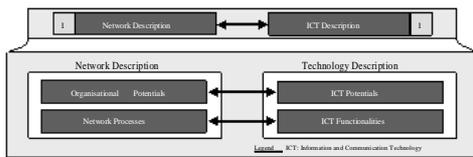

Figure 7 – First Layer of the Description Model

According to our understanding the organizational potentials represent the capability to develop and implement innovative organizational concepts (in this specific case regarding the network structure). Clearly this requires a creative process that has to take into consideration the potentials of existing and planned ICTs. Examples for organizational potentials are for instance the ability to work in distributed environments without suffering the disadvantages caused by the lack of e.g. face-to-face communication. Furthermore, examples of ICT potentials are the overcoming of temporal and spatial barriers through the use of the web-based technologies.

The network processes are the specific instantiation of the inter-organizational processes and workflows, as we previously defined within the value chain and network design of the network model (see Figure 4). These processes need to be supported by ICTs. The ICTs can be further described by their functionalities, which specify which task the particular technology can perform. According to our understanding, the functions have to be elementary, this meaning that each technology can be associated with exactly one function (see also [36]). As a matter of fact, we identified four clusters of elementary functions, and namely :

1. Input and Output functions. These functions, often also called User Interface, include especially audio and video technologies. The decision about the input and output technology that is the most appropriate to support the network partners and customers depends heavily on the information that needs to be presented.
2. Processing functions. Processing technologies allow the modification and analysis of input data to generate the needed information. The necessary processing capacity for a certain task is a relevant criterion in this context, and operating systems and programming languages must also be taken into account.
3. Transmission functions. Since the co-operating enterprises are often widely distributed, communication technologies and standards are needed to transmit information between technical devices and/or network partners.
4. Storage functions. Clearly, before and after any handling and modification of information, the corresponding data must be stored.

Although all these functionalities are not completely independent, hardware and software technologies can be identified in each cluster; hence, each cluster can be to some extent dealt with separately. The functions are described in detail by a set of parameters. Furthermore, the parameter set depends on the particular function and technology. Storage technologies, for instance, are

characterized by capacity and access time, while transmission technologies are classified according to e.g. bandwidth, bit error rate and jitter.

After the network processes have been defined, each specific network process step has to be matched with all suitable technologies that might support it. For example, the requirements related to the exchange of information and data between different network partners need to be matched with all available technologies that enable transmission functions, e.g. transmission protocols, standards or light-wave cables. As a result, the technology or set of technologies with the most suitable parameters is selected.

According to our understanding, the above-mentioned method is a successful approach to deal with the challenge to match value chain and network design with the management of technology within the information design process. In the next section we will show, with the help of a case study, how the potentials of our method can be exploited.

#### 4. The Development of an E-Business Collaboration Infrastructure

Each industrial sector has its own peculiarities; therefore, it is necessary to develop approaches and solutions that take into account such specific requirements. Our institution has experience with German SMEs of the manufacturing and machinery industry. Since we identified a remarkable need for “e-action” in this traditional and static industrial branch, we therefore decided to develop customized Business Models and E-Business solutions with a high impact onto this industrial sector. In this context we developed the case study for the present contribution. The case study has been conducted in the field of manufacturing networks for metallic material with 10 German SMEs. As a matter of fact, the generation and mailing of so-called paper-based test reports for metallic material, which documents and guarantees to the buyer specific material properties, is nowadays accompanied by several serious problems. For instance, the open issues concern the archiving of reports, the specification check of corresponding material standards or norms referenced in a test report [10]. The innovative trigger for this case study is the worldwide dissemination and acceptance of the Internet as communication and information exchange channel as well as the idea to exchange material test reports electronically. This makes the development of new intermediary services for the efficient exchange and storage of material test reports based on an electronic Business Collaboration Infrastructure feasible. Based upon the innovative idea of exchanging electronic material reports on a collaborative Internet-platform, we proposed a Business Model for an information service intermediary. We are now going to present the results obtained within the business modeling process.

1. Market model. After a thorough market analysis we identified similar solutions to manage and exchange

material reports (e.g. Document Management Systems, DMS), but we realized that none of them fulfils all relevant requirements. Hence, in the resulting market model there are no direct competitors because of the fact that the planned service is innovative and therefore it is not offered in the market yet. Furthermore, the potential customers are all the manufacturing enterprises that exchange metallic products – i.e. both ferrous metals (all sorts of steel) and non-ferrous metals (such as tin, copper, and brass) - with specified and guaranteed properties, as well the different testing and inspection organizations (such as TÜV or Dekra in Germany, Det Norske Veritas in Norway, BSI or ITS in Great Britain, SGS in Switzerland, Bureau Veritas in France)

2. Output model. We conducted several workshops with the involved SMEs and thus we gathered all the requirements related to the exchange of electronic material test reports in the manufacturing field. We distinguish two kinds of groups of services required by the potential customers of the platform:

- a) Basic service, e.g. storage, access, and remote archiving of electronic material test reports over the Internet.
- b) Value-added services, e.g. assessment and evaluation of the suppliers, nominal/actual value comparison of measures certified in a test report, batch management, offering of detailed information about material-related quality.

Other general requirements on the overall performances of the platform are: a high operating efficiency and flexibility, specific security requirements (e.g. transmission and privacy), a 24x7 hours system availability, a suitable multi user concept with different and adjustable levels of authorizations, support of surveyors of independent testing and inspection organizations.

3. Revenue model. After an analysis of the customers' benefit, we used a two-step price corridor method for the strategic pricing for shaping a revenue model [14]:

a) Identification of the price corridor of the mass, i.e. search for the price corridor that the majority of the customers is willing to bear. According to the market model, there are no direct competitors, but only some possible substitutes, i.e. providers of DMS, whose products, though, do not fulfill all relevant customers' requirements. We observed that the innovative services of the planned intermediary service infrastructure might therefore crucially change the power balance in the market of tools for the management and exchange of material test reports. The current cost to process a single material report amounts up to about 50 US\$, which clearly represents an upper bound for the price model. Since the process cost for an electronic test report drops drastically by the use of the intermediary service infrastructure, the decision was to pursue a low price corridor strategy to target a high number of customers.

b) Specification of a level within the price corridor, i.e. identification of an appropriate price level within the chosen low price corridor. A detailed analysis of the

customers' benefit of the DMS underlined that none of them can fulfill all industrial requirements. Therefore, the intermediary service infrastructure with its innovative customer-oriented services has realistic chances to be widely accepted by the target group and thus to penetrate successfully the market. In order to conquer the market and achieve the striven critical mass in terms of traffic (reports/period of time), it was furthermore decided to choose a lower pricing-level within the chosen low price corridor. A high traffic, though, does not yet guarantee a long-term success, because second-movers might come up with similar solutions and gain quickly market share. Hence, the price should be maintained very low until the critical mass in terms of branch members is also reached. With the achievement of this goal, the developed format for electronic test reports will be widely disseminated and it has therefore good chances to be accepted and adopted as a branch-specific standard. At this stage, barriers for market entry for possible competitors will be significant. The deployment of a mid or upper-level pricing within the selected price corridor will be then possible without risking to loose market shares. A potential cash cow for the business is represented by the portfolio of attractive value-added services.

4. Production design. According to the guidelines of the revenue model, the target costs for the output model will be calculated within the cost-oriented production design, i.e. design of the electronic transmission, management and storage of material reports. In the case of the "production" design for the transmission of material reports, the attention was paid to the fixed costs (i.e. target costs for the infrastructure) since direct costs (i.e. cost for the report transmission) tend to zero. Hence, the result is a platform with a targeted low fixed cost (e.g. hardware, software and mainly personnel costs). The lower the fixed costs are, the sooner the critical mass in terms of participants and transactions will be reached.

As far as concerns the design of the platform, we identified the need for the following capabilities: database based material test reports management and archiving, material science know how, trust management, and information content for value-added services.

5. Network and information model. In this phase, starting from the requirements on performances and from the capabilities, core competencies and IT infrastructure of the involved potential partners, a specific performance network as well as an information and technology framework were defined. The targeted market consists of several SMEs, of which none of them is dominating the market. It is important that all enterprises that take part to the platform must trust and be able to rely on the carrier. Hence, the managing institution of the transaction platform for electronic test reports must be an independent company. It was thus decided that the collaboration platform should not be managed by one of the manufacturers of metallic material, but by a neutral intermediary with material science know-how as well as ICT competence (e.g. data base management and archiving). As a matter of fact, the archive management

and value-added services that require particular material science know-how will be performed by the intermediary, who will outsource the other competencies to two different partners; one partner was identified to deal with trust management and another to provide information content for the other value-added services. Within the analysis of the information infrastructure, the crucial issue was the modeling of processes and the management of shared information to enable the inter-organizational and intra-organizational workflow capabilities of the planned ICT-System. Furthermore, some of the other most interesting aspects that were dealt with are the definition of process standards for inter-organizational processes and workflows, the development of an appropriate and flexible interface to deploy a back-end integration in each of the involved enterprises, and the branch-specific development of a shared standard for electronic test reports. Such standards ensure a fast exchange of the required information through inter-organizational networks as well as the integration of different ERP systems.

Last but not least, as far as the ICTs planning and management is concerned, an important part was the assessment and availability verification of the technologies that were previously selected to support the intermediary service processes. As mentioned in the section 3.4, suitable measures (i.e. further evaluation, acceptance and implementation, further development, or rejection) had to be derived for each of the selected technologies. Within the assessment phase, in order to cope with the different requirements and the need to identify the necessary measures for each partner, the use of a technology calendar proved to be really helpful to visualize critical temporal constraints (see Figure 8).

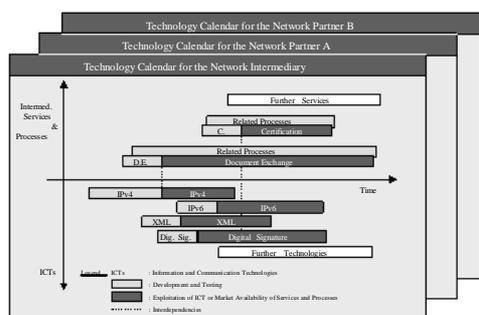

Figure 8 – Integrated Planning of Services and ICTs

6. Financing model. Because of clear privacy reasons, we are at the moment not allowed to distribute information about the financing model.

## 5. Critical Review and Conclusion

The selection and matching of organizational approaches and suitable E-Business solutions, as well as their appropriate engineering, is a complex problem. As a matter of fact, during the past years it often happened that E-Business solutions were simply and hastily embedded into the existing business processes and organizational structures. As a result, E-Business projects often did not

reach the striven targets or even failed, with the consequently growing lack of trust towards ICTs and the related solutions. In order to face successfully this issue, a holistic approach, instead of a partial one, has to be followed. In this paper we presented the FIR integration framework for E-Business Engineering, a holistic framework to systematically develop, implement and integrate E-Business solutions in enterprises. Hence, we presented the House of Value Creation, a meta-method to design customer-oriented and sustainable Business Models, which we developed with the help of our integration framework. The meta-method was validated in a specific case, namely for an information service intermediary of a collaboration network in the manufacturing industry. The HVC is also a promising approach for the development of Business Models in the case of inter-firm networks. Hence, in order to verify such a fact, we plan to test its validity also in other cases and for other branches, such as IT and logistics. As far as the project of the case study is concerned, the first step was the development of the prototypic BCI solution. Nowadays, a commercial business pilot is being deployed with the participation of all the 10 enterprises of the consortium; and the objective is to gather precious information about the feasibility of the developed Business Model as well as about the acceptance of the BCI as an efficient means to exchange material test reports. The next phase will be a commercial rollout, initially in the German market and, if the sustainability will be confirmed, on European level.

To conclude, the trend towards a tightly inter-connected economy seems to be nowadays unquestionable. On the other side, the development process towards a dynamically networked economy has just recently started. We strongly believe that, in order to be successful within a networked economy, enterprises will thus have to undergo a deep transformation process in their organizational philosophy, in their structure, in the used methods as well as in their approach to interact with external organizations. We are convinced that, in order to face the challenges of such a dynamic and insecure business context, an appropriate holistic approach is helpful to plan and hence deploy sustainable businesses.

Lingnan University, Tuen Mun, Hong Kong  
drikwan@ln.edu.hk

## Abstract

Today's rapidly evolving e-Business environment demands a higher level of collaboration and integration within the enterprise and throughout the extended trading network. Many software vendors have proposed e-solution for e-Marketplace that optimize business processes and link trading partners via the web. However, understanding how to integrate e-Marketplaces with back-end business processes to capture the advantages of supplier relationship management, supply chain integration, pricing and revenue optimization and customer management relationship is not sufficient.

Over the past few years, leading companies are aiming for a leadership position with regard to electronic Business (e-Business) in their own industries. They are targeting for the position of being the e-Sponsor rather than being the e-Partner in their portal. In virtual market with global trading via cyberspace, giant enterprises are encountering many obstacles in even starting to convert their traditional business model to an e-Business model. It is therefore important to address the Business to Business (B2B) e-Commerce successful factors initially and how they pose challenges for multinational organisations.

This paper focuses on the planning issues in managing an e-Business initiative and proposes an eBPS (e-Business Partners System) model for strategic planning of e-Business project in a multinational company. This model provides a framework to for organizing a design plan of a customer-effective B2B e-Store.

**Key:** e-Business solution, portal, B2B, eBPS, strategic framework

## 1. Introduction

Today business is either going into B2B or not to be [1]. Cyberspace now offers virtual markets for small and big business to compete as equal players, with new procedures to reach customers and new culture to work with business partners. A lot of companies were out there running a race for on-line retail business where the winner did not win anything, tremendous Internet investment were committed and profit return did not lead to a breakeven [5, 6, 8]. Learning from the B2C electronic Business (e-Business) projects experience, B2B e-Business development is taking a much more tactic approach. Recent research in e-Commerce has been focusing on Internet marketing and Wireless Computing. The fundamental drive behind is the value chain system concept that aim for company's competitive advantages by providing a digital nervous system that integrates all relevant groupware under one common infrastructure, allowing companies to make sizeable jump in efficiency, growth and profits. Although the vertically integrated chain in companies does not have to exit anymore because we could interact with suppliers and customers along the entire value chain with the support of Internet and communication technology cheaply, our legacy experience in traditional business culture is valuable. The concept of Integrated Organizational System (IOS) had led to the development of Enterprise Resource Planning (ERP) system in early 90s and now the paradigm has shifted to how to transform the company's existing ERP system with e-Business features in 2000s. This requires extensive and in-depth business knowledge of the past and vision of the future.

This paper focuses on the important planning issue of e-Business initiatives in large companies. We propose a novel eBPS infrastructure that provides a strategic framework for designing customer-effective e-Commerce applications to ensure the minimum impact of changes, maximum checkpoints for informed control and design planning of a customer-effective B2B e-Store.

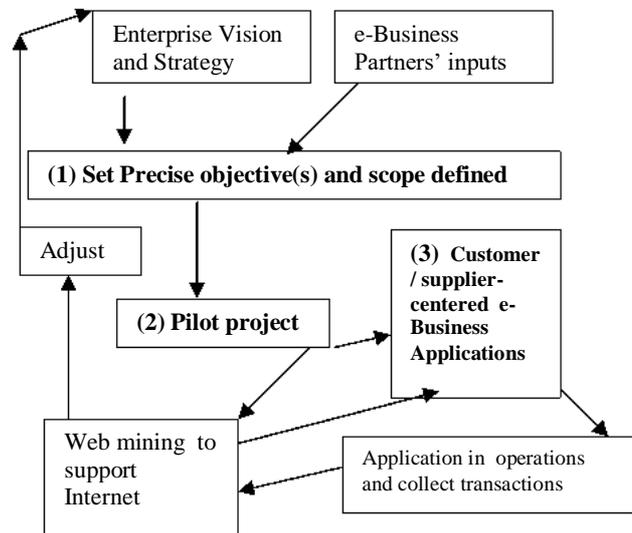

## 2. The eBPS Framework

Currently, e-Business is primarily about supply chain integration between buyers and suppliers which requires the integration of the purchasing process from the buyer, and the sales ordering process of the supplier [2]. Many software vendors claim to provide the state-of-art global e-business enterprise solutions for internet commerce that extend from front office Customer Relationship Management (CRM) to back office Enterprise Resources Planning (ERP) applications to platform infrastructure. However, the e-Commerce system is believed to have more managerial issues to resolve rather than technical issues. Based on the empirical study of many real world case studies which have attempted to catch up leader in E-Commerce, planning for strategic e-Business change, or prototyping e-Commerce strategies [4], the key constitutions of a successful e-Business planning could be summarized as follows:

1. Precise objective(s) and scope defined for business conversion (from traditional business to e-business) – Create change vision and change strategy.
2. Pilot project for secure procurement of e-Business development - Develop Leadership and build commitment.
3. Set up e-Business committee with key business executives to ensure the right progression of each checkpoint with support of change management – Manage people performance and progressively implement organizational changes.
4. Focus on customer centred (both e-customers and e-suppliers) design for customer-effective e-store or personalised web-site design – Develop culture.
5. Be a self-learning organization for quality assurance of e-services and sustainable profit in the fast changing marketplace – Deliver business benefits.

Many companies plan well, yet few translate strategy into action, even though senior management consistently identifies E-business as an area of great opportunity [8]. Hence, planning is important to ensure the implementation of the e-Business project is under control and carries out the plans for changes in e-Business strategies that were initially developed.

To clarify the inter-relationship behind these above critical success factors, below Figure 1 depicts our e-Business planning framework by means by an eBPS model. The following part of this section describes each of these steps that are built in into our proposed strategic framework.

**Figure 1: The eBPS Model – A Framework for planning e-Business initiative e-Business**

### Step 1: Objective and Scope

Multi-national companies often face critical questions in e-Commerce and they are required to be able to speedily response to change. This involves strategic planning and it is not just about technology. It is about how to use the Internet to reshape business. Competitors who have a more insight design in the development of their company web sites may destroy those who view it as a pure technology play. As such, the organizational needs and objectives of e-Business should be:

- (1) Lowered costs dramatically across their supply chains,
- (2) Taken their customer service to new levels,
- (3) Entered new markets and promote company new image,
- (4) Created new businesses opportunities and
- (5) Redefined their business relationships with the existing business profile.

Once the strategic plan is established with objective clearly defined, corresponding activities that required to be taken out to meet these objectives need to be managed and carried out. In B2B environment, one would seek control and management in business process and workflow optimization, legacy application integration, interoperability support, operational forecasting and planning. To kick off an e-Business project within a multinational enterprise, e-commerce roles and responsibilities must be assigned clearly and agreed according to the strategic plan set at the company board level.

The following scenario has taken Asia Pacific as the pilot region: -

### **The e-commerce roles and responsibilities**

Global teams, look at global aspects, some of these are: -

- Study impact of e-commerce on the enterprise
- Prioritization and controlling of projects
- Develop common platforms: Hardware, Software, Web appearance, Security, Data Structure
- Lead global projects which can not be allocated to regional business and global business
- Counsel business units and disseminate best practices
- Align with e-Commerce coordinators of global and regional business
- Identify e-venture opportunities
- Prepare / Evaluate proposal for e-Commerce Council
- Initiate change management process: Information & Training
- Define global standards for all aspects of e-commerce
- Develop and deploy global e-commerce building blocks
- Deploy the single face company presence on the web

Regional Teams, take care of regional activities, some of these are: -

- Participate in global committees to ensure the Asia Pacific regional requirements are included in the building blocks as these are defined and become available

- Continued participation in the global development & Testing to verify the availability of Regional requirements agreed upon.
- Build & deploy a regional Internet enabling architecture for the region.
- Roll Out the Active component solutions to local companies as they become available
- Manage the technical infrastructure for regional content database

E-Commerce/e-Business Development Team:-

- Responsibilities for overall regional e-commerce strategy and e-business development priorities
- Proactive co-ordination, sponsorship and development of global, regional and local e-commerce strategies & projects
- Identify, plan and accelerate the launch of promising e-business pilots / opportunities across Asia Pacific
- Effective e-commerce communication / education in the Asia Pacific region
- Active participation in global teams to define standard processes and ensure Asia Pacific region's business requirements represented.
- Define global, regional and local activities & responsibilities from Asia Pacific perspective. That is who can do what.
- Define the e-commerce business success factors for measures and evaluation.
- Supervise the deployment of 'local' web sites to ensure they do not conflict with global objectives.

All these above lengthy activities and considerations would be relatively non-technical but are critically important if an enterprise is to commit investment in a B2B e-Business project on the right track.

### **Step 2: Pilot Project Approach for Secure Development**

Years ago, companies had learnt their lesson on speedy e-Commerce development that had led to enormous maintenance cost and capital lost, and now many companies are being tied up with over scaled studies of protocol and its feasibility because of its insecure feeling of the dramatic changes in business practice. However, a quick start but under control move could compromise the dilemma and provides a first hand overview of the overall organizational e-business framework. This is beneficial to the later detail design of the e-Business

project procedure and protocol. We therefore propose to make e-business happens first without committing to uncontrollable lost, we suggest the implementing of a pilot project. The company could implement a pilot project by first setting up the new regional home page and its new country home pages, according to the global web-page design template, yet allowing individual local domestic features to exist. Secondly, pick a particular product line and convert its product information in database that is accessible to the new e-Business web-based application. Put it on-line for on-line ordering providing only with fixed price and delivery services. Thirdly, put up the advertising to attract awareness to potential business customers outside the traditional business scope. Fourthly, link up the (Vendor Managed Inventory) Supply Chain Integration where necessary. Companies could have many possibilities to build a pilot project on e-business:

- (1) Use of a B2B model on Extranet: The major issue here is to determine the list of key customers to be tested on its interactive information exchange. For example, receive forecasts and the purchasing orders, allow viewing of customer pricing, inventory levels, order status and return sales confirmation, delivery confirmation. This part would also concern the compatible issue of the company existing system(s), such as the integration to the Company's existing SAP or ERP systems.
- (2) Use of a "Business-Portal" or certain dot-com companies to test market penetration and/or sales growth potential to new customers.
- (3) Move the company regional business say, Asia Pacific aggressively into the e-commerce space by support high priority pilots and capture learning's for other initiatives.
- (4) Leverage a multi-dimensional task force to coordinate and drive initiatives. To do this, the project must have representatives from different regions and country organizations

Whichever way the company may decide upon the take off of pilot project, the objective is to maximize e-commerce benefits across all product groups and country organizations. As such, the important successful factors to B2B e-Business are: -

- Focus organization on high priority, high impact opportunities that can be scaled across

the region. It is important to avoid fragmentation to prevent future compatibility issue.

- Build regional consensus to address critical sales force, logistics, supply chain, customer care business process implications
- Integrate global initiatives to complement and/or build on regional approach.

The overall planning and control is critical when committing resources to kick off an e-Business project. The set up of a regional e-Business Committee to keep check on the pilot project milestones and interim deliverables is significant.

The following Figure 2 highlight the model of basic necessary checkpoints with expected deliverables after each milestone: -

Checkpoints	Activities and expected deliverables
First Global e-Commerce Meeting	<ul style="list-style-type: none"> <li>• 1st 'complete' meeting of all the regional representatives</li> <li>- gain the overall consensus on target agreement.</li> <li>• Partnership agreement between the Company and its suppliers companies and customers companies. Define:               <ul style="list-style-type: none"> <li>- Market place for procurement of the products / materials.</li> <li>- Market place for sales ordering of the product/services.</li> </ul> </li> <li>• Project team initiate for individual country e-Business strategy.</li> <li>• Define e-Commerce Global Key Account Plans.</li> </ul>

<p>Second Global e-Commerce Meeting</p>	<ul style="list-style-type: none"> <li>• Refine and review regional (Europe and US) e-Commerce: <ul style="list-style-type: none"> <li>– Review underway with each business unit to define its e-Commerce strategy.</li> <li>– Target completion schedule to be determined</li> <li>– Internal operations</li> </ul> </li> <li>• Analysis of competitive positioning in marketplace</li> <li>• Business Process Re-engineering Studies</li> <li>• Review the existing Organization SAP or ERP system: <ul style="list-style-type: none"> <li>- Identify the entry/exit point of company's existing system with the potential B2B e-Business web-site/application.</li> <li>- Design on the interface and data security/control issue.</li> <li>- Review of all existing web pages if existed.</li> </ul> </li> </ul>
<p>Third Global e-Commerce Meeting</p>	<ul style="list-style-type: none"> <li>• Promote &amp; support strategic change within the organization. And required with the implementation of e-Commerce initiatives</li> <li>• Action items <ul style="list-style-type: none"> <li>– Investigate and progress the formation of a "Global Business Community" with key</li> </ul> </li> </ul>

	<p>competitors.</p> <ul style="list-style-type: none"> <li>- Identification of Global Key Accounts and Nominate representatives</li> <li>- Technical support and Management control</li> <li>- Global coordination of web page development &amp; content management.</li> <li>- Development of Global e-Commerce database.</li> <li>-Implementation of Interface between new e-Business applications with company existing systems.</li> <li>-Continuous review and evaluation of 'market places'</li> </ul>
--	--

**Figure 2: The 3 checkpoints with activities and expected deliverables**

Pilot projects need to be provided with an update on the status via checkpoints wherever possible to the entire key personal in the business and should have been screened by the MIS team of the enterprise, to establish an estimate of IT resource and functionality requirements. The update included details of proposed implementation timelines, functionality enhancements to the "On-Line Store" and the project cost assumptions. The task force "learning" on the pilot project should be discussed and agreed along the development of the enterprise's global e-store since it is important to experience and capture the learning to provide further insight into current "e-Readiness".

**Step 3: Customer-centered Approach for Customer-effective Web-sites Design**

The demanding knowledge of "know-how" has gone beyond the set-up and maintains of database through the web, both academia and industry are facing the challenges of how to design a web-site infrastructure that could provide optimal on-line experience that fit the e-customers' needs, acquiring the knowledge of "know-why" for learning and value adding. Increasing unique and unpredictable customer demands for innovation speed, quality and

service has not only compelled supply chain participants to rapidly adopt new e-Business practices but also provide personalized e-services. The discovery of e-customers' preference on web site surfing could be utilized to come up with an effective web-contents/infrastructure design and management. The need to segment and identify the target audience for Internet marketing had made the requirement of Internet users become obvious only recently. Many related studies have been investigated on a touch on basis. [7] discussed a 6 steps Interactive Marketing Process on the Internet, in which the initial step had emphasized the studies of e-customers' behavioral approach. [10] proposed a scheme on e-product characteristic for internet-marketing. [4] proposed a hypothetical customer theme represent common activities or processes, that a customers want to complete when they visit a particular web site. Use the theme to create scenario as a base to design web site content and its architecture. In any e-store, the bottom line is that any e-customer should be able to come to the web-site and complete an e-service process from beginning to end in a user-friendly and intuitively correct manner. We need to encapsulate all our web

3. mally addresses common areas of customer frustration or desire of new/extended activities) to relevant customer actions by easy accessible and visible utilitarian components.
4. The popular web pages with most diversify pre-requisite sequences and longest surfing time could be identified and refine appropriately with its page content and infrastructure with an aim that lead to actual order placement.
5. The isolated and inactivate web-pages could implied browsers are incapable of access to it, further analysis on these web-page content and its dynamic links are necessary, to decide upon whether metaphor on web site is necessary.
6. Based on the association semantic discovered and the targeted customers themes, we could create an intuitive navigation system that fit general customers' mental model support the seamless completion of critical processes. This could enable e-customers' understanding in the company web-site functionality with an intuitive interface.

site surfers' on-line experience, to discover the knowledge of customer behavior On line analytical tool could help to discover what web-pages led to the page for an order commitment is valuable. Many web pages de-motivated surfers with non-focused content and/or overwhelming the surfers or e-customers with information. We suggest web-content filtering by e-customer behavior studies is necessary and that only mission-critical web pages should survived in the ultimate B2B web-site infrastructure. This could better fit the e-customers' preference, time spent and also save cost on web-page maintain as well as improve the competitive advantage of the web site. The discovery of e-customer on-line preference could help the web site design team to meet the following criteria for designing a customer-effective web site:

1. Make web site functionality intuitive by restructuring it around e-customers' preferring processes.
2. Relate utility (web site functionality that allow browsers do something useful to serve them better and faster, they nor

#### 4. Conclusion and Future work

Planning is a vital organization process that helps organization to learn about itself and promotes organizational changes and renewal for improvement. Strategic e-Business planning involves aligning investment in information technology with company's e-Business vision and strategic goals such as business process re-engineering, IT strategies and technology architecture. It results in a conceptual blueprint that specifies a company's e-Business targets, data resources, and applications architecture and technology platform. This paper has presented an eBPS strategic model with infrastructure that provides a framework for developing a blueprint to build a customer-effective e-Business within a multi-national company, with particular emphasis on minimizing changes by secure pilot project approach and maximizing control by implementing global checkpoints with e-Business committee set up. B2B e-Business application is complex and its development processes demands intensive intelligent both technically and managerially. Our proposed eBPS model which aims for minimum impact of changes and maximum communication is focused on the four important key requirements for successful B2B development. They are the :-

- (1) Objective-driven strategic planning for effective communication and minimum changes,
- (2) Pilot project approach for secure development,
- (3) Check points scheme verified by e-Business committee for informed control and
- (4) Customer-centered approach in customer-effective web-sites design for organizational learning.

The future direction of this research would focus on the design of inter-organizational system with support of business process redesign and the adoption of enabling Internet technology to realize the benefit of value chains with minimum impact of procedural and cultural changes.

## Abstract

Electronic commerce is viewed as a more and more important issue for the rapid growth of online commercial activities. The books, having the properties of numerous categories, low unit price, and the convenience of delivering, have become the major products on line. So the online bookshops are appropriate for study to find out the key successful factors of Internet business. We first conduct twice Delphi to confirm several factors that are important to success in Internet business and there are 32 factors to be chosen. We then calculate the relative weight of each factor with the Analytic Hierarchy Process (AHP) and select 14 factors having the highest weight to be the key successful factors of Internet business. These 14 factors in order of weight include the ability of managing the business change, filling the Place with Entrepreneurs and growing with them, the ability of managing the customer relationship, targeting the right customers, the price can react to market quickly, building the knowledge management systems, excellent sever ice after payment, building distribution center to develop unbeatable logistics, the ability of managing the cost, offering Great Value, the ability of marketing by database, building the goodwill and brand image, getting the trust of virtual community and maintain it continually, and the ability of developing the technology.

## 1. Introduction

U.S.A. applied Internet originally to military and education in cold war. After the application of World Wide Web (WWW) in 1989, Internet even played a more and more important rule in our life. Because of the superiority of Internet, which provides worldwide service, increases markets occupy rate, and dramatically decreases cost of communication, many operators start to develop Internet commerce. A foreign noted research institute, e-Marketer, predicts the market scale of global online

consuming will grow at the compound annual growth rate (GAGR) of 93% from 1999 to 2003.

After the depreciation of U.S. NASDAQ Internet stocks, B2C e-commerce shopping web sites, no matter local or foreign, tend to cut off their cost and transform their operating mode. However, Market Intelligence Center (MIC), followed by investigation of online shopping market in Taiwan, points out that because the boost of net-surfing population, maturation of e-commerce as well as payment mechanism, and blooming growth of online application, such as online game, internet stock booking, and web-advertisement, it's estimated that it will grow as high as 64% GAGR in three years to come. In addition, the needs of AV entertainment and living requirement are going to increase rapidly in three years [5]. Moreover, MIC claims that those who integrate the "resource of Internet and substantial channel" will be the main stream of market in the future. Building up the Internet consuming concept and strengthening related ordinance would be the key point of online shopping market.

Because books have the traits of variability, complication, low unit price, and convenient transportation. In addition, thanks to the combination and introduction of virtual community, books are suitable for sale online [22]. In this research, we think online bookshop is pretty representative of Internet industry. As a result, taking online bookshop for example, we want to explore successful Internet industries' key successful factors, which could be the blueprint of resource allocation priority.

In the concrete, the goal of the research is to understand the operation condition of online bookshop and factors affecting the operation performance, furthermore, to analyze the key successful factors of operation, which provide a direction of strategy for Internet operators and help them to face the variable environment.

## 2. Literature Review

### 2.1 Electronic Commerce

Electronic Commerce (E-Commerce, EC) is described as "the capability of buying and selling products on the Internet and other online services"[10]. Generally, the business transactions that conducted in Internet technology such as computer, information networks, electronic data exchange (EDI) and so on are called EC.

The definitions of EC vary with different perspective [10]. In communication perspective, EC is the delivery of information, products/services, or payments over telephone line, computer networks or any other electronic means. In business process perspective, EC is the application of technology toward the automation of business transactions and workflow. In service perspective, EC is a tool that addresses the desire of firms, consumers and management to cut service costs while improving the quality of goods and increasing the speed of service delivery. In On-line perspective, EC provides the capability of buying and selling products and information on the Internet and other online services. Communication process service on-line definition

EC are divided into three broadly recognized categories: intra-organizational, Business-to-Business (B2B), and Business-to-Consumer (B2C) [10]. Intra-organizational EC includes facilitating the organizational internal function and increasing the satisfaction of target customer. B2B EC is referred to facilitate and integrate the network form between organizations. B2C EC, is referred to improve the transaction between business and customer with electronic technique. Offering products/services in Internet is a kind of B2C EC and it is named as B2C. Making profit from the advertisement by establishing website attracted stream of people is another kind of B2C EC and it is named as C2B.

The key of B2B EC is to establish good relationship with the co-operational partner. C2C EC is stressed on the credit of buyer and seller. Otherwise, B2C EC put more importance on security and identification. The key of C2B EC is to attract a great number of visitors to browse the website. The Internet business we discuss in letter is focused on the B2C EC.

### 2.2 Online Bookshop

Online Stores is a kind of virtual store that consumers can purchase what they want in Internet [6]. In broad sense, online Store is defined as that consumers can order the products/services on line. In this definition, if the website only offers the information of products/services, but consumer have to order it through telephone,

fax, transfer, mail and so on, it is not on-line store. In narrow sense, online Store is defined as that all the processes of transaction, such as browsing, ordering and paying, can be done in the Internet. According to the type of products, on-line store is divided into direct commerce and indirect commerce. The deals of the digital or un-physical products are called direct commerce and the deals of the physical products are called indirect commerce [16].

Online bookshop is the virtual store that consumers can order or purchase the books on the Internet. The Online bookshops in Taiwan are divided into three groups according to their background.

#### 2.2.1 Pure Virtual Online Bookshops

Most of them were established by internet technology company. Although they did not have physical recourse, they have the Internet technology, such as e-Commerce, and operate a new brand, for example, books.com.tw and silkbook.com.

#### 2.2.2 Publishers- Established Online Bookshops

They often establish their own website as a new channel to expand their business. On their website, although they sell the books issued by other publisher, they give first places to sell the books issued by themselves, for example, YLib.com and cwbook.com.tw.

#### 2.2.3 Tradition- Established Online Bookshops

Traditional bookshops can establish their own website with the advantage of business experiences. Most of them have great database and comprehensive products, for example, kingstone.com.tw and soidea.com.tw.

Online bookshops have the advantages of globality, convenience, interaction, personalization, low rate of returned goods, and no pressure of stocks [12][14]. However, the online bookshops in Taiwan now still have some dilemmas. For example, on-line shopping is not popular yet; especially books-selling. Consumers still have doubts about security. The speed of transmission is sluggish. And the Chinese books market is far smaller than English books [12][14].

That analyzing the industry value chain of final product is a quick way to discover the key successful factors [21]. We seek out the value chain of online to help to establish the key successful factors. Traditional book-selling processes -- publish, print, general sells, and retail--play a part of new value chain and Internet processes play another part. In the new value chain of online bookshop, the business processes include the publishing, printing, purchasing from publisher, information systems of online bookshops, database of books to sell, all the data of consumers, the channels from

wholesale to retail, storing, transporting the books to consumers, website image, and website.

### 2.3 Key Successful Factors

Key Successful Factors (KSFs) are the characteristics, abilities, or assets of enterprise that can improve significantly their power to compete [1][2][7][11][18][21]. If organizations can keep their KSF, they can utilize their resources more efficiently and improve their performance [3][17]. Then they can strengthen the advantage to succeed in specific industry [6][11][18]. Each industry has its own different environments, so that the KSFs in specific industry are different to each other. To Sum up the KSFs in this study are the characteristics, abilities, or assets of enterprise to keep its persistent competition advantage with utilizing efficiently its resources in these critical factors.

### 2.4 Key Successful Factors of Online Bookshop

The major purpose in this study is to discover the KSFs of online bookshop, and these KSFs will be involved in the critical factors of virtual shop. Several researchers addressed different critical factors and we find that some of the factors are similar.

1. There are five keys to create a successful virtual store [23]: (1)setting goals (2)understanding and creating the shopping experience (3)getting to know customers (4)advertising and promoting the store (5) implementing a payment system.
2. A successful business strategy of internet shop should include [9]: (1)decreasing the cost of purchasing, transportation and storing (2)increasing the revenue by using the price strategy flexible (3)building a complete back-end systems (4)recognizing the commerce effects of traditional mass media (5)building the identifying systems (6)making an excellent internet marketing (7)putting the customer first (8)emphasizing the security and customer privacy (9)holding the promotion (10)increasing the customer loyalty.
3. A successful Internet shop store should include ten functions [13] such as (1)satisfying variable user with different connecting rate (2)collecting consumers' database (3)establishing good interaction between users (4)providing multiple purchase way. (5)ensuring transaction safety (6)using proxy program to increase service quality (7)providing a rich customerized information (8)friendly users' interface (9)fluent website framework. (10)calculating the times of website visiting.
4. Eight critical success factors are induced for successful modern businesses [20]: (1)targeting the right customers (2)owning the customer's total experience (3)streamlining business processes that impact customers (4)providing for a 360-degree view of the customer relationship (5)letting customers help themselves (6)helping customer do their jobs (7)delivering personalized service (8) fostering a community.
5. EC business managers should allocate their important business resources on activating the seven kinds of effects to keep their competition advantage [15] (1) learning effects: developing the ability to accumulate the Internet resources and experiences (2)network effects: developing the ability to operate the Internet community (3)uniqueness effects: developing the ability to collect the customers' preference (4)pricing effects: developing the ability to make discriminated price (5)efficiency effects: developing the ability to operate efficiently and improving the convenience of cross-organization (6)searching effects: developing the ability to build virtual agency (7)cooperation effects: developing the ability to make the strategy alliance.
6. Ten rules are captured with the requisite of Amazon [19]: (1)living and breathing E-Commerce (2)filling the place with entrepreneurs (3)focusing (4)branding the site (5)getting and keeping customers by offering great value (6)developing unbeatable logistics (7)staying lean (8)practicing Technoleverage (9)constantly reinventing the business (10)growing with the best.
7. Successful factors of online bookshop include [8]: (1)ensuring the bookshop orientation and providing specific service to targeted customers. (2)friendly interface and accurate search result. (3)rich book information. (4)using the customerized content and interaction to reinforce community coherence. (5)digitalized property and ability. (6)competitive price. (7)the cooperation of publisher, distributor, conveyer, media and writer. (8)the cooperation of online bookshop, ISP, and search engine. (9)brand publicity is the obstacle of follower, however, pioneer are not necessarily predominant in establishing its brand. (10)paying attention to professional ability.
8. After analyzing the characteristics of online bookshop in Taiwan, it discovers 15 essential factors [4]: (1)collection of books. (2)offering online credit card and booking service. (3)low transportation charge. (4)interaction between reader, writer, and online bookshop. (5)interaction among readers. (6) providing online full-text search. (7)issuing e-paper about culture. (8)detail information of books. (9) more discount. (10)organizing a strategy coalition with local and foreign business. (11)fast and perfect service before and after payment. (12)constructing its

own brand and publicity. (13)launching variable promotion and service periodically. (14)a bait to urge customers to visit. (15)software and hardware update.

### 3. Research Design

#### 3.1 Building The Key Successful Factors

From this review of research, this study induced 39 factors, important for managing the online shop, to be the items of Delphi questionnaire. Upon the result of Delphi questionnaire, we delete 7 factors that are not as important

as others and use the remnants (32 factors) to be the items of AHP (The Analytic Hierarchy Process). Figure 2 is the framework to find out the KSFs with AHP. Figure 2 is shown that there are 32 items, 8 dimensions (8 kinds of effects), and one target. With AHP, we compared the 32 items by pair to evaluate the relative weight of each item to find their relative importance to the dimension. With the same way, we evaluate the weight of each dimension to find their relative importance to target. Then we can assess the relative weight of items to the target.

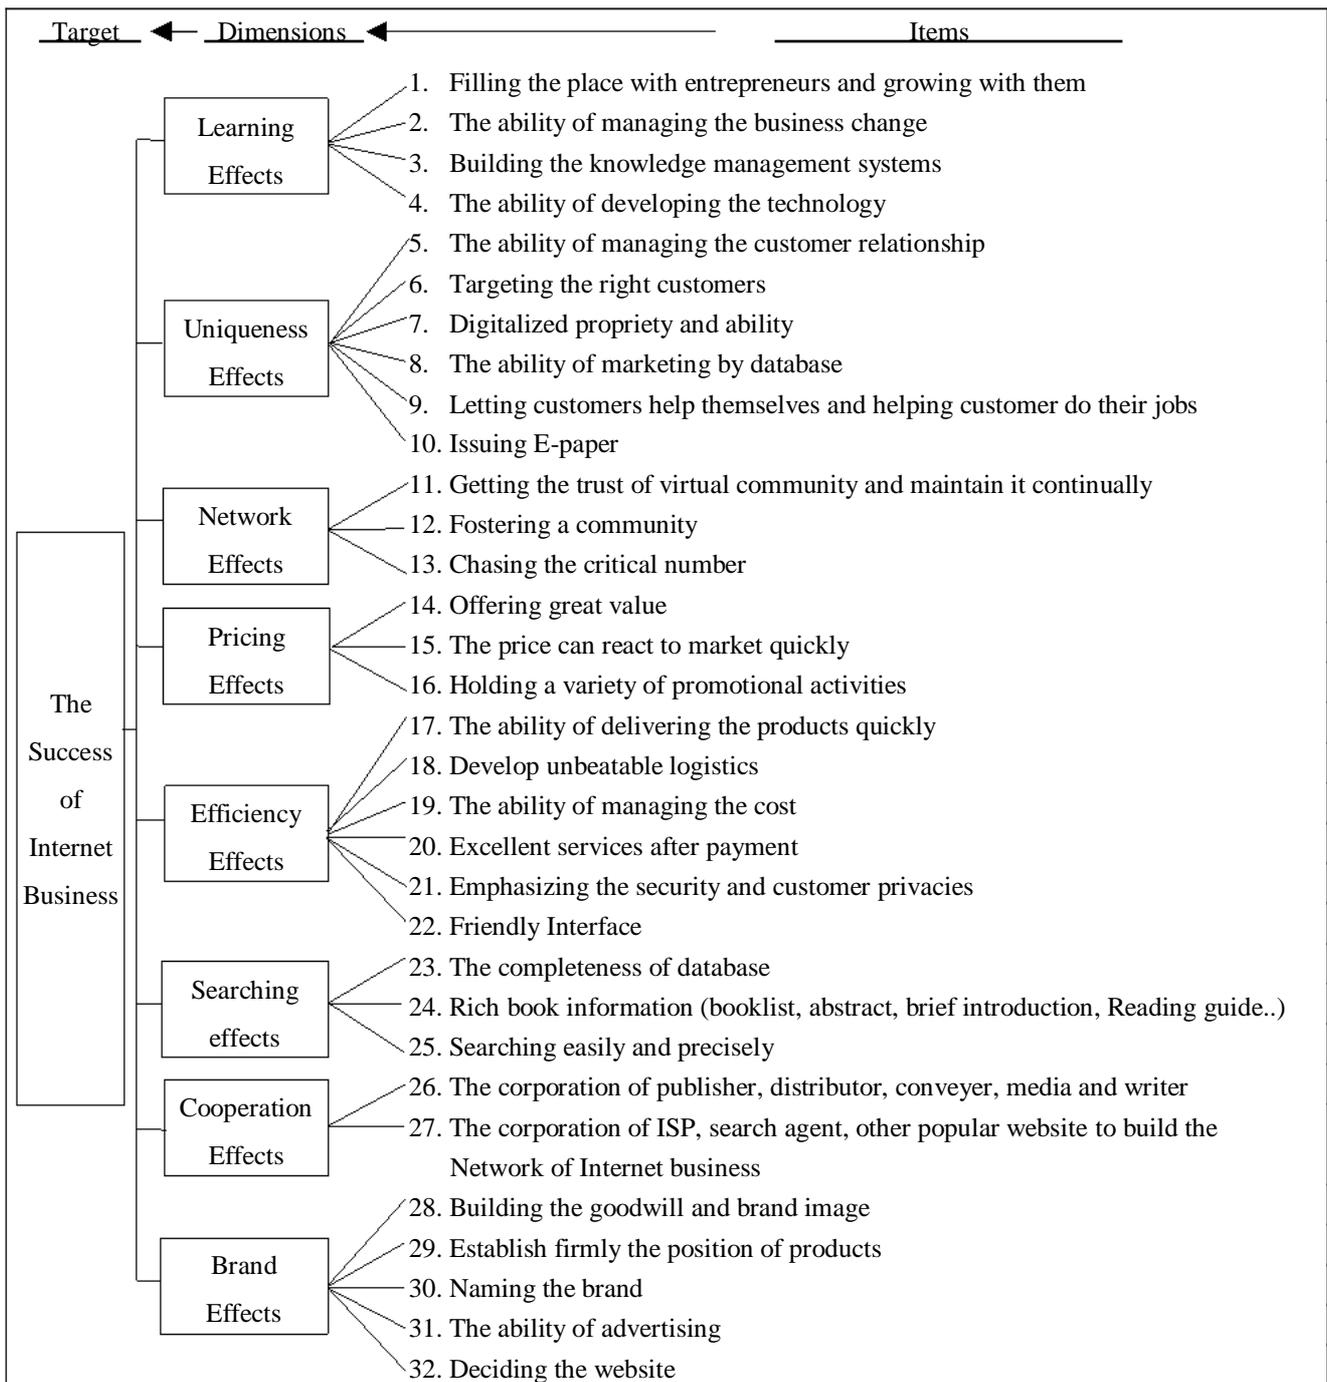

Figure 1 The key successful factors of online bookshops

Table 1 Questionnaire survey

		Release	Collect	Valid	Valid (%)
Delphi (First)	Managers of pure virtual bookshop	3	3	3	100
	Managers of online bookshop with physical store	1	1	1	100
	Managers of online bookshop establish by publisher	4	4	4	100
	Scholars	8	8	8	100
Delphi (Second)	Managers of pure virtual bookshop	3	3	3	100
	Managers of online bookshop with physical store	1	1	1	100
	Managers of online bookshop establish by publisher	4	3	3	75
	Scholars	8	7	7	87.5
AHP	Managers of pure virtual bookshop	3	3	3	100
	Managers of online bookshop with physical store	1	1	1	100
	Managers of online bookshop establish by publisher	4	4	4	100
	Scholars	8	8	8	100

### 3.2 Questionnaire Design and The Object

We conduct a survey on specialists by three phases. In the first and second phase, we conduct Delphi questionnaire twice to integrate the opinions of specialists and construct the items of AHP questionnaire. In the third phase, we carry out the AHP questionnaire to find out the KSFs. The scope of specialists should include various kinds of scholars, online bookshop manager, and other related managers. We choose eight specialists to be the objects that include the managers of pure virtual bookshop, the managers of online bookshop belonging to physical store, the managers of online bookshop established by publisher, the supplier of equipment, and

the scholars. We obtain 7 to 8 valid questionnaire in three phases (Table 1). The criterion to judge the validness of AHP questionnaire is assessing the consistency ratio (CR) with software, Expert Choice. The AHP questionnaire is valid if the CR is lower than 1.

## 4. Results and Discussion

### 4.1 Analysis of Delphi

We use five-scales approach to measure the degree that items will affect the successes of Internet business. The higher means that the object thinks the items is more important. The mean scores and standard deviation of twice Delphi questionnaire are shown as Table 2.

Table 2 The results of Delphi

dimension	Original evaluated items	Fist time		Second time		Delete
		Means	Standard deviation	Means	Standard deviation	
Learning Effects	A1.Filling the place with and growing with entrepreneurs	4.43	0.53	4.4	0.55	
	A2.The ability of managing the business change	4.14	0.69	4.2	0.84	None
	A3.Building the knowledge management systems	4	0.82	4.2	0.45	
	A4.The ability of developing the technology	3.86	1.07	4.2	0.45	
Uniqueness Effects	B1.The ability of managing the customer relationship	4.86	0.38	5	0	
	B2.Targeting the right customers	4.57	0.79	4.8	0.45	
	B3.Digitalized propriety and ability	4.29	0.95	4	0	None
	B4.The ability of marketing by database	4	1*	4.4	0.55	
	B5.Letting and helping do their jobs	3.43	0.98	3.8	0.45	
	B6.Issuing E-paper	3.43	1.27	3.2	0.84	
Network Effects	C1.Getting the trust of virtual community and maintaining It continually	4.14	0.9	4.2	0.84	None
	C2.Fostering a community	4	1*	4	0.71	
	C3.Chasing the critical number	3.43	1.27*	3.2	0.45	

dimension	Original evaluated items	Fist time		Second time		Delete
		Means	Standard deviation	Means	Standard deviation	
Pricing Effects	D1.Offering great value	4.14	0.69	3.8	0.45	
	D2.The price can react to market quickly	3.86	0.69	3.4	0.55	
	D3.Holding a variety of promotional activities	3.71	1.25*	3.6	0.55	D4, D5
	D4.The ability to make discriminated price	2.71**	1.11*	2.4**	0.55	
	D5.Not charging postage	2.71**	0.49	2.6**	1.14*	
Efficiency Effects	E1.The ability of delivering the products quickly	4.71	0.49	4.6	0.55	
	E2.Develop unbeatable logistics	4.57	0.53	4	0.71	
	E3.The ability of managing the cost	4.57	0.53	4.4	0.55	
	E4.Excellent sever ice after payment	4.57	0.53	4.6	0.55	E7
	E5.Emphasizing the security and customer privacies	4.57	0.79	4.2	0.84	
	E6.Friendly Interface	4.43	0.53	4	1.22*	
	E7.Providing various way of payment	4	0.82	3	0.71	
Searching Effects:	F1.The completeness of database	4.29	0.76	4.2	0.45	
	F2.Rich book information	4	0.82	4.4	0.55	
	F3.Searching easily and precisely	3.71	0.76	3.8	0.84	F4, F5
	F4.Interface with various languages	3.14	0.69	2.8**	0.45	
	F5. Diversified enterprise	2.43**	1.4*	2.2**	0.45	
Cooperation Effects:	G1.The corporation of publisher, distributor, conveyer, media and writer	3.86	1.21*	4	0.71	
	G2.The corporation of ISP, search agent, other popular website to build the network of Internet business	3.29	0.95	3.4	0.9	G3, G4
	G3.Having own complete channels	-	-	3	1.22*	
	G4.The ability to publish by itself	-	-	3	1.22*	
Brand Effects:	H1.Building the goodwill and brand image	4.29	0.95	4.6	0.55	
	H2.Establish firmly the position of products	4.14	1.21*	4	1*	
	H3.Naming the brand	4	1.15*	3.4	0.55	None
	H4.The ability of advertising	3.86	1.35*	3.8	0.45	
	H5.Deciding the website	3.29	1.38*	3.2	0.84	

\*\* :the means below 3 \* :the standard deviation above 1

In the first Delphi, there are twelve items have higher standard deviation (over than 1), but there are only 3 items have higher standard deviation in the second Delphi. It indicates that the specialists have the consistency about the 32 items of the second Delphi. According to the means scores of Delphi, we choose the items whose score is above 3 to be the items of AHP questionnaire. In this criterion, there are 7 items not being selected.

#### 4.2 Analysis of AHP

The 32 items of AHP questionnaire come from the

Delphi. We count the items' relative weights in each valid AHP questionnaire by Expert Choice. There are 84 set weigh values totally. Let the means of 84 set weight values to represent the weight of each item. The process and analysis of AHP are described as followed.

We compute the degrees of eight dimensions influencing the successes of Internet business by pair compared matrix. Then we compute the weights of the items under each dimension. According to the matrix, we can obtain the eigenvectors of each dimension (Table 3) to infer the KSFs of the successes of Internet business. After

Table 3 The eigenvectors of eight dimensions

Dimension	Learning effects	Uniqueness Effects	Network effects	Pricing effects	Efficiency effects	Searching effects	Cooperation effects	Brand effects
Eigenvectors	0.245	0.188	0.065	0.102	0.215	0.060	0.038	0.087

Table 4 The rank of the degree of items affecting target

Rank	Items		Weight*1000
1	A2	The ability of managing the business change	99.96
2	A1	Filling the place with entrepreneurs and growing with them	65.42
3	B1	The ability of managing the customer relationship	58.84
4	B2	Targeting the right customers	49.82
5	D2	The price can react to market quickly	47.53
6	A3	Building the knowledge management systems	46.06
7	E4	Excellent sever ice after payment	45.80
8	E2	Develop Unbeatable Logistics	43.22
9	E3	The ability of managing the cost	41.28
10	D1	Offering great value	39.78
11	B4	The ability of marketing by database	38.16
12	H1	Building the goodwill and brand image	34.37
13	C1	Getting the trust of virtual community and maintain it continually	33.74
14	A4	The ability of developing the technology	33.57
15	E1	The ability of delivering the products quickly	32.47
16	F1	The completeness of database	29.34
17	E5	Emphasizing the security and customer privacies	26.66
18	E6	Friendly Interface	25.37
19	G1	The corporation of publisher, distributor, conveyer, and writer	24.43
20	C2	Dictating fostering a community	24.12
21	H2	Establish firmly the position of products	20.10
22	F2	Rich book information	17.34
23	B3	Digitalized propriety and ability	16.36
24	D3	Holding a variety of promotional activities	14.79
25	H3	Naming the brand	14.01
26	B5	Letting and helping customer do their jobs	13.72
27	G2	The corporation of ISP, search agent, other popular website to build the network of Internet business	13.57
28	F3	Searching Easily and Precisely	13.26
29	B6	Issuing E-paper	11.09
30	H4	The ability of advertising	10.79
31	H5	Deciding the website	7.74
32	C3	Chasing the critical number	7.15

we integrate all the computation mentioned above, we could obtain the weights of all items and rank them to help us find the degree of items affecting target (Table 4).

According to the weight values from the sample, we rank the degree of the eight dimensions affecting the target (the successes of Internet shop). Learning Effects is the most important dimension (24.5%), and the other dimensions are in the order of Efficiency Effects(21.5%), Uniqueness Effects(18.8%), Pricing Effects(10.2%), Brand Effects(8.7%), Network Effects(6.5%), Searching

Effects(6%), and Cooperation Effects(3.8%).

We also can rank the influence of 32 items affecting their own dimensions in proportion to the weight value from the sample. The results are shown as followed:

1. The four items to evaluate “Learning Effects” are the ability of managing the business change (40.8%), filling the place with entrepreneurs and growing with them (26.7%), building the knowledge management systems (18.8%) and the ability of developing the technology(13.7%)

2. The six items to evaluate “Uniqueness Effects” are the ability of managing the customer relationship (31.3%), targeting the right customers (26.5%), the ability of marketing by database (20.3%), digitalized propriety and ability (8.7%), letting customers help themselves and helping customer do their jobs (7.3%), and issuing E-paper (5.9%).
3. The three items to evaluate “Network Effects” are getting the trust of virtual community and maintain it continually (51.9%), fostering a community (37.1%), and chasing the critical number (11%).
4. The three items to evaluate “Pricing Effects” are the price can react to market quickly (46.6%), offering great value (39%), and holding a variety of promotional activities (14.5%).
5. The six items to evaluate “Efficiency Effects” are excellent sever ice after payment (21.3%), Develop unbeatable logistics (20.1%), the ability of managing the cost (19.2%), the ability of delivering the products quickly (15.1%), emphasizing the security and customer privacies (12.4%), and friendly Interface(11.8%).
6. The three items to evaluate the “Searching effects” are the completeness of database (48.9%), rich book information (28.9%), and searching easily and precisely (22.1%)
7. The two items to evaluate “Cooperation Effects” are the corporation of publisher, distributor, conveyer, media and writer (64.3%) and the corporation of ISP, search agent, other popular website to build the network of Internet business (35.7%).
8. The five items to evaluate “Brand Effects” are building the goodwill and brand image (39.5%), establish firmly the position of products (23.1%), naming the brand (16.1%), the ability of advertising (12.4%), and deciding the website (8.9%)

In General, there are no certain numbers of KSFs, because each specific industry has its own special consideration. According to the weight value of each item, we could find that the accumulative weight values of former 14 items (Table 6) are about 70% of the total amount. So we select these 14 items as KSFs of successful online bookshop.

## 5. Conclusions and Limitation

### 5.1 Conclusions

If we divide the key successful factors into eight dimensions and weight its importance, we will get the

order of study, efficiency, price, brand, Internet, search and unite effort. If we explore the key successful factors of success by items, there are 14 important items whose accumulation weights reach 70%. As a result, they can be treated as key factors. According to the priority of weight, we can give following order: (1) the ability of managing the business change (2) filling the place with entrepreneurs and growing with them (3) the ability of managing the customer relationship (4) targeting the right customers (5) the price can react to market quickly (6) building the knowledge management systems (7) excellent sever ice after payment (8)Developing unbeatable logistics (9) the ability of managing the cost (10) offering great value (11) the ability of marketing by database (12) building the goodwill and brand image (13) getting the trust of virtual community and maintain it continually (14) the ability of developing the technology. The practical value of the research is that it offers a reference for online bookshop. When enterprise is hesitant to make a decision, it can refer to the list of priority and set all the condition in balance.

### 5.2 Limitation

The boundary of the research is that the framework, which is suite for assessment of online bookshop, is designed only by the consideration of items. Taking labor and time into consideration, the number of questionnaire and sample collection is not enough; therefore, it cannot reach significance. It betters off to discuss with online business operators from different direction. Besides, it is not mentioned in the research that whether the overlap of AHP and Field sampling will infect the result of Field questionnaire.

### 5.3 Following Research And Suggestion

Because it is short of time and money, this research only analyzes the weight of effectors of online business operation and lists the key successful factors. However, there are some aspects insufficient, which need subsequent studies: (1) Find out an example among all of the online stores. Compare it with 14 key effectors and testify the result. (2) According the eight items, do more detailed analysis, experts interview to collect more comprehensive items, and discover the key factors of online business operation. (3) Expand the sample scope to other type of online stores, not just only online bookshop, to understand the operation environment more

## Abstract

With the coming of a new century, the situation of EB in China has been greatly improved. Followed by the development, the pressures in and out of China may become the engine of EB in companies, and will further stir up a fashion. Under these backgrounds, it is urgent for relative sectors of government, industries, research centers and commercial sphere to fully prepare for the tide of EB, for the purpose of acting excellently in the array of EB.

Key words: the present condition of EB; the tendency of EB; the countermeasure of EB

Since 1990s, with the quicker steps of economy globalization, trade liberalization and information modernization, EB, which is a modern productive force created by the combination of information, commerce and management technology, now is propelling department economy, district economy, national economy and world economy to get on a new step.

Coming to the 21st century, after several years' hard exploration and active effort, the situation of EB in China has been greatly improved, and the tendency of EB in China has had an inkling of the matter. So it is more important for us to study on the following countermeasure.

## 1. The Present Condition of EB in China

Up to the end of 2001, EB in China had achieved satisfactory progress in several aspects, such as foundation facilities, program law and regulations, theoretical research and applied practice. It mainly shows as followed:

### 1.1 Fast Developing Foundation Facilities[1]

#### 1.1.1 Computer Network Has Made Marked Development

The four core members of network (scientific research, education, telecommunications and economy) augmented capacity and increased speed one after another. The submarine optical cable between China and America was successfully laid in January this year, so that it can provide 1000 thousand couples of information source corresponding at the same time. Before the end of this

year, the outlet bandwidth of China telecommunications will get to 150M, and the whole bandwidth of network will get to about 345M. The number of domestic net men gets double every six months, and by the end of this year, it will have reached 9900 thousand. The number of websites in Chinese has been more than 15 thousand.

#### 1.1.2 Telephone Network Increased Rapidly

Telephone network of the whole country has attained program control. The number of fixed telephones has topped 1000 million, and that of mobile telephones has topped 5 million. It means that 13 percent of whole Chinese people has had telephones.

#### 1.1.3 Television Network Has Basically Covered The Whole Country

There have been 300 million television sets all over the country. If a family is regarded as holding four persons, almost every family has had a television set.

#### 1.1.4 Communication Network Has Varied Developed

Optical fiber, microwave and satellite television have formed a core communication network.

#### 1.1.5 It Has Basically Realized Mutual Dependency Among Networks

The technology and product have been successfully manufactured to realize mutual dependency among computer, telephone and television networks, and have been put into use.

#### 1.1.6 The Terminal Products Of EB Have Come Out In 2001

They are telephone, computer, credit, integration terminal and Venus for network etc.

## 1.2 Rapidly Building Program Law And Regulations[2]

(1) Since 《The development framework of EB in China》 drafted by China Information Industry Ministry was issued in July 1999, it has consulted the broad department. If these suggests will be approved, it will come out as 《The National Program for EB Strategy》.

(2) The monographic deliberate meeting presided by Information Industry Ministry was convened to discuss the construction of EB Law.

(3) According to local situation, some districts have formulated their own EB planning. For example, the government of Shenzhen City has organized to draw up 《The Five-Year-Planning of EB Development in Shenzhen City 》. After further discussing, it will be reported for approving.

### 1.3 Actively Carrying Out Security Activity

(1) National government have issued several safe regulations about communication network and Internet.

(2) There have been many EB centers of attestation, some of which have passed the appraisal of ministry and state.

(3) Many commercial banks such as agricultural bank of China, China bank and industrial and commercial bank of China etc. have built up payment gate of network and offered payment and settling accounts by network one after another.

(4) The work to train talent has started. Some Universities have offered the courses and specialties about EB and some have provided the personnel at EB posts for training.

### 1.4 Rapidly Developing the Application of EB

(1) More than half of the governments in all levels have used network. By the end of 2000, the government network project initiated by above forty ministries and committees had shown remarkable success, including 68 ministries and committees using network, two-thirds of provinces and city governments using network to issue information, more than 2300 governmental websites and seventeen trades information websites being built.

(2) Economic departments use network one after

another. National network of finance, tax and trade has partly started, which promotes a series of golden projects.

(3) It has been effective for some enterprises to use network. They have successfully used network to carry out trade activity.

(4) It has had an inkling of the matter for sole product market to use network, such as books, clothes and white sugar.

## 2. The Tendency of EB in China

There were two bugle calls of EC in 2000, which aroused enterprises to seek existence and development, and promote competition in market.

### 2.1 Two Bugle Calls and Their Function

(1) According to the message of China Information Industry Ministry, 《The Developing Framework of EB in China》 has been issued in this spring, which directly promoted state-owned large and medium-sized enterprises to develop EB. According to the report of China High and New Technology Industry News, there will be 520 state-owned large and medium-sized enterprises to suif during this year, and they will get the supports of policy and capital from NCET and IIM. That is the first bugle call.

(2) That China joined in the World Trade Organization accelerated the application of EB in state-owned and private enterprises. Because state-owned enterprises are mainly influenced by government, and private enterprises are mainly influenced by market, they will have apparent difference in using EB. The difference will be shown in Table1.

Table1: Difference of using EC in state-owned and private enterprises

enterprises of different categories	necessity	probability	flexibility	timeliness	effectiveness
state-owned enterprises (especially for large and medium-sized)	weak	strong	weak	late	worse
private enterprises	strong	weak	strong	early	better

From table1, we can got following conclusion. Under the common conditions, state-owned enterprises have such good basic situation as credit, organization, management and technicians in using EB; at the same time, they still have some disadvantageous factors. But if some concerned ministry and committee provides capital and policy assistance as they promised, it will be likely to form a high tide to use EB in state-owned enterprises during a short period.

### 2.2 A Little Tide in EC of China in 2002

#### 2.2.1 The Overall Framework Has Initially Formed

From the above, we can see that the external environment of EB in China has made great progress during the past resent years. Because of national policy and international trade, the application of EB in China promoted by internal power and external pressure will probably raise a little tide. The pattern is shown as Figure1.

### 2.2.2 The Figure Above Displays The Function Of Each Subsystem

Above all, government sub-network will play roles of guidance, management and demonstration to circulation, production and consumption sub network. Secondly, IT sub-network will provide technical platform, safe technique and leading applying. Thirdly, bank sub-network will play the role of payment, intermediary and combined settling accounts. Finally, science and education sub-network will play the role of training talent, transmitting knowledge and cultivating technique.[3]

### 2.2.3 The Number of State-owned Enterprises Using EB Will Break Through

Under the guidance and support of government, EB will be widely used in state-owned enterprises.

### 2.2.4 Private Enterprises Will Fully Display Their Talents in Using EC

Since 2000, such websites as sohu, sina, 8848 and 3721 have revealed the strength out of the ordinary.

### 2.2.5 The Diversify of EB Will Begin to Show Ability or Talent

During the past, people mainly talked about B (business) TOB, BTOC (consumer), therefore there will increase G (government) TOB, GTOC, U (university) TOB, UTOC and CTOC (EB among consumers) during the new developing tendency.[4]

### 2.2.6 Production and Trade Suif As A Single Spark Can Start A Prairie Fire

A lot of single variety and trade websites are actively preparing for carrying out marketing and trade on network, like automobile, iron and steel, coal, furniture, building materials etc.

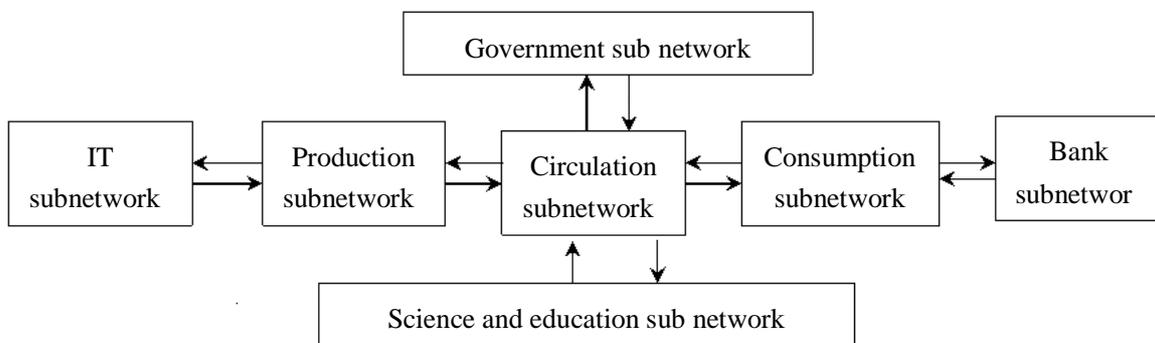

Figure1: the pattern of EB

### 2.3 Traders Will Be The Main Force of EB.

According to analysis and forecast, there will be four stages in the development of EB in China. They are technique promotion, knowledge spread, law and regulations manufacture construction and enterprises application. Although we can't say we have had good development of the former stages till today, due to the comprehensive promotion of domestic and alien, EB in our country will partly step into the fourth stage this year, and will form apparent symbol and characteristics. That is there will be many trader using EB and suif in EB.

## 3. The Applied Countermeasure of EB in China

As far as the subject of EB is concerned, we can discuss our countermeasure of EB under new condition from four aspects: Government, Trade, Enterprise and School.

### 3.1 Governmental Countermeasure

As director, manager and demonstrator of EB, government should act well as follows:

#### 3.1.1 Planning Construction of EB

It is the most important task in this field for government to construct the national EB from its framework of developing strategy to nationwide and district EB.

#### 3.1.2 Law Construction of EB

Law construction can start with market management rules and constantly summarize experience and lessons, then transfer to paralaw and formal law.

#### 3.1.3 Standard Construction of EB

It revolves many aspects of manufacture and construction such as standard of information technology, standard of safe, standard of trademark code and standard of commercial process.

#### 3.1.4 Stressing Exemplary Engineering

The National Development of Information Industry paid special attention to eleven exemplary engineering in 2000, and achieved good results on the whole. We should summarize and communicate experience on this basis so as to play its exemplary role.

### 3.1.5 Governmental Application

It is the principal application of governmental EB to invite tenders, purchase, pay and settle accounts through network, which will play its active guiding and exemplary role, and achieve immense social and economic benefit.

## 3.2 Trade Countermeasure

Responsible departments of the trade and society in our country share the guiding role of trade action. In the development of trade EB, we can consider taking some countermeasures as follows:

### 3.2.1 Sole Product Suif

We can choose important merchandise to market by sole product suif in a trade. For example, in 1999, National Committee of Economy and Trade convened a conference—"the EB conference of wholesale trade" in Guangxi province and introduced the suif of manufacturers of sugar with osmanthus flowers and some other commodities. This year, there will be more sole products to be put into market by suif. As is known, National Trade Department has ratified the trade suif project of Chinese automobile.

### 3.2.2 Trade Suif

Many specialized trades are brewing suif project one after another. Our country's "San Jin", "Shi Jin" and Property Tax, Finance and Trade all fall into this category.[5]

### 3.2.3 Comprehensive Commercial Network

Our country has progressively opened comprehensive commercial network from 163 and 169 to every department of local information through using the experience of California's commercial network.

## 3.3 Enterprise Countermeasure

The development of our enterprise's EB can consider following principles:

### 3.3.1 Deepen Understanding, Work Out Plans, Strengthen Management and Follow in Order and Advance Step By Step

First, enterprise's policymakers, management and core members of business, buying and selling members should accept training by stages and in groups to deepen understanding, strengthen knowledge and technological skills. Second, according to its own condition, an enterprise should work out good development planning of applying EB. Third, adhere to the objective request of EB to strengthen management and play its active role from

laws and regulations to technology, from system to staff, from static state to dynamic state and so on. Finally, an enterprise can do well from the outside to the inside, from the easy to the difficult, from the single to the diversity, from the marketing through network to the trade through network and carry out its own strategic plan comprehensively.

### 3.3.2 Pay Attention to the Strategic Style

According to large and medium-sized enterprises and medium and little-sized enterprises, we may use different process of entering and developing. The main differences are the style from outside to inside—to drive enterprise's EB and information by market EB, the style from inside to outside—to associate outside market EB by inside information of enterprise, the style laying equal stress on both inside and outside—to emphasize enterprise's information and EB on the one hand, and on the other hand, to emphasize introduce and link of market EB.

### 3.3.3 Organize Elaborately

It can be divided into several levels of economic and technological combination from the most simple suif of single machine to browse commerce information to open special website to engage in trade. All these tries to let efficient VS price and benefit VS price both be good.

## 3.4 Countermeasure of College and University's Science Research and Talent's Training

According to the experience of developed countries and our own national conditions, the countermeasures of college and university's science research of EB and talent's training contain the following aspects:

### 3.4.1 The Theoretic and Applied Research of EB

Science research of college and university should trace the practice of EB at home and abroad, and constantly summarize practical experience to form theories and check, rectify, develop these theories in practice, then proceed to guide practice to become the knowledge and talent treasure-house of government, enterprise and society.

### 3.4.2 Special Persons' Training

Open special courses of EB in present majors such as Marketing, Management of Enterprise, International Trade and Trading Economy.

### 3.4.3 To Open Major of EB after Receiving The Approval Of The National Department In Charge

3.4.4 Some Majors Such as Information Technology and Commercial Management Combined Open Double Degrees of EB

3.4.5 Develop International Cooperation, and Train Compound Senior Talent of EB (mainly refers to postgraduate and over levels)

#### 4. Conclusions

EB of China will set off a high tide in 21st century. It is necessary for government, enterprise, college and research organization to make effort, meet new challenges and obtain good repayment in the meantime.

## Abstract

Web-based catalog presentations play the key-enabling role in E-commerce in recent years. Existing catalog systems often acquire proprietary platforms, cannot deal with TV-like media objects, or consume network bandwidth inefficiently. With the emergence of advanced technologies of Web and multimedia, such hurdles can be removed. The Synchronized Multimedia Integration Language (SMIL), proposed by W3C allows Web designers to design complicated and vivid multimedia presentations in a declarative manner. These presentations are then rendered on a general-purpose browser by a SMIL player. Since the SMIL specification is quite new to the Internet and E-commerce societies, the functionality and applications of players is limited. In this paper, we propose a novel architecture based on Java JMF technology for tackling with such constraints. The effectiveness of the proposed system is validated through an experiment on product catalog presentations.

Keywords: Electronic commerce, electronic catalog, XML, SMIL, multimedia presentation, Java

## 1. Introduction

The advent of the Internet has given birth to Electronic Commerce (EC). In the short space of ten years, EC has shaped a new type of business world; it has greatly affected operations between business (B2B) and changed transaction channels between business and individuals (B2C). In general, effect of the Internet on commercial activity can be characterized by the three well-known facts. Firstly, it is the shifting of power from sellers to buyers through the reduction of the cost of switching and the free distribution of a huge amount of price and product information. Secondly, it is the stimulation of economic activity through the reduction of transaction costs. Lastly, it is the creation of new commercial opportunities through low cost of distributing and capturing of information, which is carried out with a speed and wide range that has never been seen before. This coincides with the study in [20], which identifies two major EC applications: product catalog which provides the information about the product and transaction

management which manages the order interactions. The first application is of particular importance since it behaves as the interface between customers and vendors. In the competitive EC environment, vendors race for consumer's "click-shopping" in one minute.

To gain the competitive edge, vendors must keep the catalog vivid, useful, informative, and interactive. In addition, the catalog contents should be designed and maintained in an efficient way. For this, multimedia, the other major enabler driving EC comes in. [1] [2] [6] [13]. In general, multimedia refers to the integration of time-based media such as audio and video and static media such as text, still images and animated images. With the convergence of the Internet and multimedia, organizations can gain a competitive edge from improving business performance [6]. Gunasekaran and Love recently proposed a framework for the design of multimedia systems in supporting numerous business applications and point out several future research directions. Puri et. al. investigated how multimedia integration enhance EC. Yen and Ng reviewed and discussed some web-based catalogs, categorized by five layers: application, presentation, organization, function, and physical form [20]. They also implemented a web-based catalog prototype in a 3D Virtual Reality Modeling Language (VRML) for mass customization of products in EC. Ehrke proposed a web-based catalog using Java technology to present car stereos to customers [4]. Shim et. al. proposed a Synchronized Multimedia Integrated Language (SMIL)-based catalog system accompanied by a presentation player written in Java [16]. For the system surveyed, the media used in presenting catalog contents ranges from text, to HTML, to 2D/3D object, and to video clips. However, there are three major shortcomings existing in these systems. Firstly, they fail to provide TV-like live catalogs. Without doubt, TV is the most efficient channel for delivering product information in spite of the Internet era. Secondly, the presentation contents are delivered mostly in a point-to-point (unicast) way so that the network bandwidth is obstructed. Finally, some of the systems violated the principal of architecture neutrality so a proprietary platform is required for running the catalog presentation.

The objective of this research is to develop a catalog presentation system for supporting EC that can effectively

---

<sup>1</sup> Corresponding author

overcome these three hurdles. We rely on our previous work in multimedia streaming [10] and the SMIL standard, building on XML, proposed by W3C provides a simple way to design multimedia presentations in a similar manner to HTML documents. Section 2 presents the information technologies that are needed in the development process. Related work in designing SMIL players is discussed in Section 3. The system architecture of the proposed Web-based SMIL player is described in Section 4. Section 5 is system demonstrations. Section 6 concludes the paper and discusses some future work.

## 2. XML, SMIL, and JMF

A SMIL player is essentially a Web-based application, which is software-intensive system and thus needs seamless integration of the emerging Web computing technology – Java and XML. Java is well recognized for its architecture neutrality, and well accepted as a vehicle for building enterprisewide information systems. XML is designed for document neutrality that can facilitate universal message exchange. Java works well in a distributed environment, allowing users and programs to share information easily, while XML provides a tool for distributing and sorting that information. In this section, we briefly review the technologies used in the study

### 2.1 XML

XML (Extensible Markup Language), developed in 1997 by W3C, is an enabling technology for facilitating vendor-neutral data exchange [3]. Similar to HTML, XML is a metadata language for defining markup languages such as SMIL, MathML (Mathematical Markup Language), and CML (Chemical Markup Language). In contrast to HTML, which describes the presentation layout of a document in a Web page, XML specifies the semantics and structure of the document. XML differs from HTML in three key concepts, namely extensibility, structure, and validation [3]. In extensibility, XML allows authors to define new tags and attributes for specifying the syntax and semantics of data. In structure, XML supports nested document structures similar to regular expressions. In validation, XML allows a document to be validated via DTD (document type declaration) specification, which identifies what elements are allowed in a document, the sequence of these elements, and element attributes, etc.

XML can be seamlessly integrated with Web in a variety of ways. The most often cited one is its ability in facilitating data exchange between heterogeneous databases due to its vendor-neutrality. It can also cooperate with some kind of style sheets such as XSL (eXtensible Stylesheet Language) or CSS (Cascading Style Sheet), a language for specifying the presentation semantics of an XML document. As a result, XML allows a document to be rendered in different format to support personalized presentation. Other interesting

applications include intelligent search engine, smart agents, and so on.

The elements and attributes in an XML document are extracted by a parser, which can be tree-based or event-based APIs. A tree-based parser builds an internal tree structure to be traversed by an application whereas an event-based parser uses callbacks according to parsing events such as the start and end of elements. Each has its advantages and disadvantages.

### 2.2 SMIL

The synchronized multimedia integration language (SMIL), developed by the Synchronized Multimedia (SYMM) Working Group of World Wide Web Consortium (W3C) in 1998, provides a simple way for designing TV-like multimedia presentations on the Web [8] [15]. The syntax of SMIL conforms to the XML standard so that one can write SMIL presentations using general text editors. There are several salient features making SMIL attractive in design Web-based multimedia presentations. Firstly, the presentation designer can indicate the spatial layout and temporal relationships of media objects of text, audio, video, image or any other media type; where and when the objects are shown. For spatiality, it differs from the text-based HTML document which follows one-dimension textual flow style on the screen, instead, SMIL uses a two-dimension layout model without scroll bars and resizing functionality [8]. For temporality, SMIL defines a set of timing constructs to synchronize a group of media objects sequentially or in parallel and to specify their begin, end, and duration times. Secondly, media objects can be distributed either from the same resource of the SMIL document or any place specified by uniform resource locator (URL) such as HTTP, FTP, or RTSP. Thirdly, a set of navigation constructs is also defined to support the functionality of HTML-style hyperlinks. Finally, media objects can be presented on client's browsers according to system and personal preferences such as network bandwidth, user language, and screen resolution.

SMIL presentations are rendered on Web browsers by a SMIL player. Existing popular players for SMIL 1.0 includes Microsoft Internet Explorer 5.0, Apple QuickTime 4.15, RealNetworks Realplayer 8, Helio SOJA [17], and CWI GriNs [5]. Most of them except SOJA can only run on proprietary platforms such as Microsoft Windows or Macintosh; this limit their usability. However, achieving smooth SMIL video presentation over the Internet is a non-trivial work which involves prefetching and buffering media objects [7].

### 2.3 Java Media Framework (JMF)

The JMF API provides three packages: Player, Capture and Conference for manipulating time-based media including playback, capture and conferencing [9]. It supports most standard media content types such as AU, WAV, MIDI, MPEG-1, and QuickTime, and AVI. There

are two JMF versions available currently: JMF1.0 (designed for playback and JMF2.0ea (early access), in which the functionality of media capture is added. With Java Media Player, developers can design media players receiving and presenting either from reliable sources such as a local (via FILE) or network (via HTTP) file or streaming sources including broadcast media, multicast media, and VOD. JMF1.1FCS supports RTP for playing broadcast and multicast media for limited media types including DVI, GSM, G723, and G711 except MPEG-1. Although JMF2.0ea improves MPEG-1 in which Layer 1&2&3 (MP3) is also supported, MPEG-1 video is still not provided. Therefore, it is a great challenge for playing RTP multicast MPEG-1 using JMF.

The JMF mechanism is a layered architecture. The data source layer is in charge of data acquisition whereas the processor layer takes care of data un-compression and passing data to renders such as monitor or sound card for presentation. There are two classes in the data source layer, namely PullDataSource and PushDataSource, in which the former is designed for local-file (including MPEG) streaming play and the latter is for networked non-MPEG streaming play via RTP. These two classes are totally different and may not be cast to each other straightly.

### 3. Related Work in SMIL Players

SMIL players available on the Internet can be generally grouped as two categories based on the environment they run: proprietary and Java-based. An up-to-date list can be found in [19]. We briefly review several major players in this section.

The first category includes Microsoft IE, RealPlayer, and GRiNS. To improve multimedia and interactivity in Web pages, Microsoft IE5.5 offers a set of attributes in the so-called HTML+TIME construct for specifying the timing behavior of media objects such as start, end, duration and repeat times [18]. HTML+TIME is implementation of the HTML+SMIL profile in SMIL 2.0, which is currently in the stage of working draft. RealPlayer from RealNetworks supports playing SMIL presentations since its G2 version in 1998 [14]. RealPlayer G2 was the first SMIL player implementation in the key vendors of networked multimedia. GRiNs (GRaphical iNterface for Smil) is another presentation system for SMIL documents along with a powerful authoring environment [5].

The second category which adopts the Java approach includes S2M2 (Streaming Synchronized MultiMedia) [11], SOJA (Smil Output in Java Applet) [17], and the JavaBeans approach [16]. Both rely on old version of JMF technology however SOJA fails to play mpeg items and S2M2 did not support streaming media objects using Realtime Transport Protocol (RTP).

## 4. The Proposed System

We utilize the Java computing and JMF technologies to develop the SMIL presentation system to meet two goals, namely RTP streaming and navigation of HTML-style hyperlinks. This section discusses our system development approach. The high-level system architecture is illustrated in Figure 1.

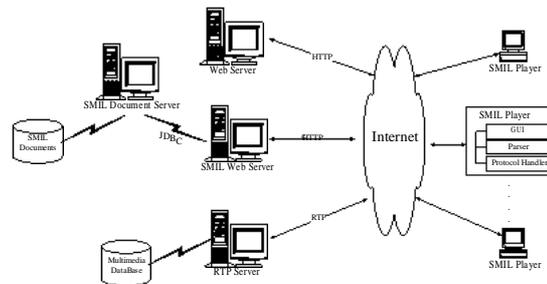

Figure 1. The system architecture

It contains Web Server, SMIL Web Server, SMIL Document Server, RTP Server, Multimedia Database containing MPEG and MP3 items, and SMIL Player on the client side. The platform where each component runs can be different. The Web Server acts as an object repository for downloading the SMIL Player applet to eliminate the need for installing the component. Thus, the Web Server shows emergent Object Web of the evolving client/server model [12]. The player contains three major components. The GUI component allows customers to retrieve catalog presentations in SMIL documents, managed by the SMIL Document Server. The Parser component, which is a SAX (Simple Api for XML)-compliant parser, a event-based parser, validates the specified SMIL document and retrieves the embedded elements and attributes. The Protocol Handler invokes the procedures for handling specific protocols such as RTP MPEG or HTTP/HTML. For the request of RTP MPEG streams, the client sends a subscription request to a multicast group for receiving contiguously transmitted demultiplexing RTP video/audio streams from RTP Server (see Figure 2).

Raw video/audio data are then fed into buffers for efficiency consideration when playing. Depacketization and Video/Audio Buffer constitutes Video/Audio Data Source which inherits from the class PullDataSource defined in JMF so JMF Player can treat video/audio raw data as coming from reliable data sources such as FILE or HTTP. Finally, the depacketized raw data in the buffer must be converted into bit streams for playing using JMF Player.

Figure 3 illustrates the sequence diagram in UML (Unified Modeling Language) for rendering RTP MPEG streams.

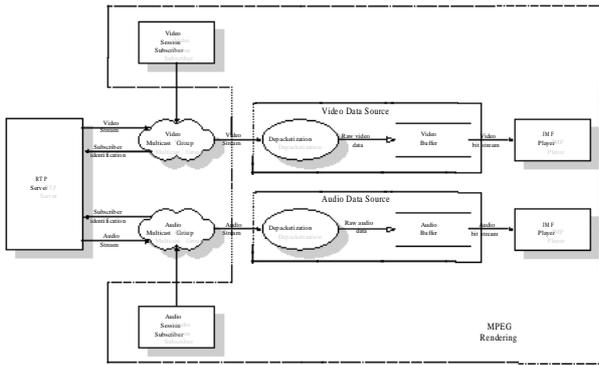

Figure 2. Rendering RTP-MPEG presentations

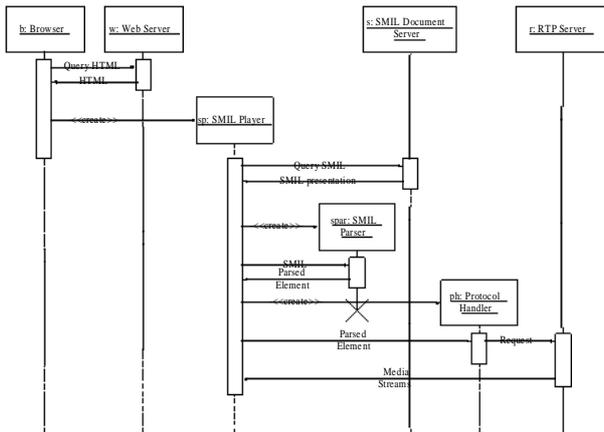

Figure 3. The sequence diagram of the SMIL player

Customers log into the catalog system via a Java-enabled browser to download the SMIL player in the applet form and create it as a player object in Java Virtual Machine (JVM) in the browser. After the customer chooses the product of interest, the player in turn contacts the SMIL document server to obtain the SMIL presentation for the product. This document is parsed and the embedded media objects are retrieved from remote multimedia databases. Finally, the protocol handler invokes the RTP render to communicate with the RTP server and renders the video and audio streams received.

### 5. System Experiments

The proposed system has been experimented on the NKFUST campus network environment for supporting a virtual EC portal site. We discuss the cases of navigation and RTP-MPEG streams in this section. Figure 4 shows the SMIL presentation document for Cisco's IP/TV product. It indicates the layout about the three synchronous media objects (one RTP-MPEG, one local HTML and one remote HTML items). It is worth noting that a subtle syntax provided by SMIL when designing a catalog presentation.

Figure 5 is the snapshot during the presentation is rendering. On the right-hand side of the panel, one can navigate the Web page as in a HTML browser when watching RTP-MPEG streams as shown in left-top screen.

The text window on the bottom provides the functionality of text caption. This greatly improves the interactivity of the presentation. Thus, the proposed system meets the requirements of spatiality, temporality, and interactivity for multimedia presentations.

### 6. Conclusions and Future Work

The work presented in this paper was motivated by the need for the development of Web-based catalog presentation system in EC. We surveyed existing systems and identified three pitfalls in existing systems, namely violating platform neutrality, inefficiency in network bandwidth, and the lack of live TV-like presentation quality. In this paper, we followed the SMIL standard in multimedia presentation and applied the emerging Java distributed multimedia computing technology to alleviate such weaknesses. The system proposed in this paper is a novel architecture for playing live TV-like SMIL. In addition, the navigation of HTML-style hyperlinks is offered by appealing to the Java Swing facility. To meet the reusability of software development, we integrate the component of RTP player developed in our previous work and SAX for parsing SMIL documents. The resulting system is at its initial stage but demonstrate an encouraging direction towards EC applications. As far as

the references surveyed, our work presented is the very pioneering study in the literature towards integrating playing RTP media and Java JMF in Web-based catalog presentations. The future work includes the performance evaluation on the network bandwidth and enhancing the system to offer VCR-like functionality for more vivid catalog presentations.

# Influences of New Trend in Development of American and Canadian E-Business upon Mainland Enterprises and Our Development Strategies

Danyang Zhu

Guangdong Textiles Imp. & Exp. Corp. (Group)  
China  
zdy@gdtex.com.cn

## Abstract

A comprehensive view of the world E-business development in the past year shows that, in spite of the turndown of the net economy for the past year and that the term "E-business" is even used by many media to represent "Foam Economy". But within some high-tech companies as well as some conventional industries under reconstruction, "Mouse Plus Concrete", another model of E-business, is now showing brand new value. Meanwhile, some conventional enterprises in the mainland are also brewing further breakthroughs in E-business in order to take the win of the coming market competition. As for the conversion of the enterprises, the model of E-business in North American countries like USA and Canada is undoubtedly the example and forerunner for domestic enterprises. In this background, the article, via a research of new situation of E-business development in North America as well as typical cases of its application in the enterprise, is intended to analyze and sum up the application characteristics and accordingly, the pressing demand for E-business as well as reasoning and measures of E-business development in enterprises.

## 1. Introduction

In March of 2002, as a member of the Exploratory Mission of Electromechanical Chamber of Commerce Enterprise Information and E-B, which was initiated by International E-B Department of Foreign Economic and Trade Ministry and China Electromechanical Products Import and Export Chamber of Commerce, the author did research work and exchange activities with IT enterprises and academic research institutes both in America and Canada. In particular, the author researched on 11 companies such as Oracle, Dell, CommerceOne, Broadvision, etc and underwent training and discussion in Austin School of Texas University upon Internet economy, E-B and electronic purchasing.

## 2. General situation of E-B development in USA and Canada

2.1 The scale of business activities (B2B) via Internet between enterprises in USA and Canada keeps increasing, which includes the following activities through Internet.

2.1.1 Coordination upon purchasing between the enterprise and the supplier.

2.1.2 Business coordination between procurement planner and warehousing and shipping companies.

2.1.3 Coordination between sales branches and wholesalers as well as retailers of their products.

2.1.4 Customer services.

2.1.5 Daily operation of the enterprise and exchange between employees in the enterprise.

2.2 The area of B2C keeps expanding, which is prominent in sales of invisible goods and service products, such as computer software, consumption of entertainment products, tickets booking, payment and information services etc. The products and services, with no need of any material form or special packaging, are transferred to the customer via Internet as electronic version, which represents the advantage of Internet sales with a strong vitality.

2.3 The trend of increase of material goods is furtherly quickened, mainly including

2.3.1 The range of products sales via Internet is expanding gradually. One or two years ago, most people bought only computer software or hardware or books on the Internet, and now it has come to all kinds of goods. Apart from standardized brand products which are accepted generally with the form of Internet sales, more and more garment, medicine, food, toys, drinks, shoes, furniture and other daily household products are put on Internet for sales and a lot of new net-shops spring like mushrooms.

2.3.2 Many conventional manufacturers and industries have established websites of their own, offering directly to their customer sales business and services. In particular, sales via Internet have shown strong competitiveness and expansion in industries like computer and car sales. What's more, to confront better with new competition, various business organizations, including famous retailers and wholesalers are establishing net-shops of their own. Especially some big retailers and wholesalers like WAL-MART, TARGET, SEARS, etc make full use of their existing brands to expand quickly Internet business as a combination of Internet sales and conventional shop sales with good results.

2.4 The E-B level of conventional industries is increasing and achieving exciting effects.

During transformation process of conventional enterprises to Internet economy, high-tech companies like

DELL, CISCO, GE, etc have achieved investment yield rate of over 250% with sale per capita as over USD650,000. After realization of Internet purchase in other conventional enterprises, procurement cost has decreased about 30% in WAL-MART, 45% in TARGET, 33% in Toy R Us. And with the employment of supply chain management technology, turnover during one year in TRACE NET has increased by 392 times, making the enterprise boom from a regional pet food supplier to a global network chain supply group of toys, garment and pet articles.

2.5 Making use of the opportunities provided by Internet economy and strengthening brand new competitiveness of the enterprise has become the mainstream of E-B in enterprises at present.

Since what the Internet economy has changed is far from a change of concepts or operating channels, the main body of E-B is a challenge to be confronted by the whole economy and all trades.

### 3. The influences of development of E-B upon development of the enterprise

Guonashi, the former president of IBM, has depicted the influences of E-B upon enterprises by pointing out that, in the case of ever-increasing of market share of Internet economy, only when the company masters operation rules of E-B market and is able to make better use of E-B techniques in specific operation of business development, can it possess space of survival and development. While world-class companies take the force of Internet and make use of it for transformation of their own, the real storm of Internet economy has been formed.

After research on companies like IBM, Oracle, Dell, CommerceOne, Broadvision, EDS, etc, we come to realize that the development of E-B has created more market growth space, while in realization process of E-B in the enterprise, the aim of the enterprise is more the achievement of increase and development of business through optimization of sales process, decrease of cost and improvement of service individualization. For example, Oracle, as the second biggest software manufacturers in the world, has achieved a sales volume of USD11,000,000,000. While the employment of Internet E-B solution project of its own saved an annual of USD1,000,000,000. of daily operation expenses, which is equal to an increase of 10% of annual profit margin. While the employment of global E-mail system has saved USD30,000,000 and the effects of the whole technology globalization is a saving of USD200,000,000 of operation expenses in global sales system. At the same time, over 50% of direct sales on the Internet have made DELL as the eventual "King of Direct Sales" and "King of Low Prices" in international PC circle and hold the first place among PC and SERVER manufacturers home and abroad from the first quarter of 2001 till at present.

In conventional industries, E-B is now more and more positive influences.

Boeing gets simultaneous visits from 38,000 persons all around the world via Internet system, which achieves an accuracy of 100% for BOM (Bill of Materials), a decrease of average revision times of each order to zero from 17, a decline of average circulating time of the order subject to internal audit from 25-30 days to 6-10 days, a drop of a series of sophisticated product data systems from 30 to 1, an increase of material velocity from 4.5 to 9 while a drop of total unit cost of 80%.

US Airlines has established individualized services to its customers via BROADVISION system on the Internet. Through a series of adjustment and alteration, the volume of tickets booked through Internet by US Airlines Website has increased by 6 times than before. Tickets booked via Internet thus have become one of the major income sources for US Airlines.

It can thus be seen that among the three themes of the current world development, i.e., information economy, globalization and sustained development, information economy with Internet economy as major instrument and carrier is the strong force to push development of productivity. The development of Internet economy undoubtedly promotes the process of globalization, while through development of E-B in the enterprise, making use of network and electronic instruments for realization of net virtual operation, expedition of business process, decrease of operation cost, establishment of a closer relation with trading partners and guarantee of "win-win" situation in business process and competition process is the key of sustained development of the enterprise, the most important influence by E-B upon the enterprise and the most important aim of the enterprise to develop E-B.

### 4. Major characteristics of E-B in North America and consideration of E-B development in domestic enterprises in China

Through the aforesaid analysis, we think that several major characteristics of E-B development in North American enterprises are in particular worth our thorough researching and practicing combined with domestic situation.

4.1 With electronic network as media of sales network, limits of conventional sales network have been broken to provide the enterprise an easier approach to the market and the customers for supply of individualized services. Global sales system of ORACLE runs through every stage like supplier, customer, booking, store, distribution etc. Through close combination of on-line supply chain management system and customer management system, effective expansion of new markets and on-line tracing and analyzing have been realized to provide to the enterprise a better idea of distribution and predicted

distribution, to make the relevant service series development and change of Internet economy surely will be defined by the customer and to increase the customer's satisfaction and loyalty. Global purchasing system, which is similar to Internet competitive bidding, guarantees sourcing world-wide with low prices and good quality as well as low prices of finished-products and good profit of the enterprise.

4.2 Reformation and conformity of sales process via E-B system assure optimized management of supply chain and optimized allocation of resources. The successful adjustment of internal processes assures DELL products the shortening of parts and fittings purchasing and store management in the supply chain, shortening of distribution stage in sales process and continuous keeping of low cost operation. As it can be seen in PC assembly factory, all the parts and fittings of DELL are stored in warehouses of its manufacturers. The order got by DELL from the customer is at the same time divided into small orders to its manufacturers, who send the parts and fittings as required to assembly factories to assembly finished products subject to sales. Last year, DELL also set up the on-line purchasing system ACCESS for most of its suppliers, thus the suppliers can have a good idea of most up-to-date information regarding store and sales in DELL, an earlier knowledge both for DELL and for the suppliers of possible shortage of parts and fittings and production can be arranged accordingly to avoid overproduction or overtime production with high cost.

4.3 Through employment of E-B measures a further increase of dealing and management proficiency is achieved and at the same time dealing and management cost in business process is lowered. On-line direct sales model based on Internet Ordering System and Customer Service Center has made average store time of DELL decrease, calculated in hours, if the control standards in the enterprise are 4 hours for desk PCs and 8 hours for servers, that means every week when the new product is supplied by DELL to its customer, its cost decreases by 1 time. The low-cost operation brought for DELL an increase of 44% solely in 2001, while during the same year the increase rate for Compaq was only 1%.

4.4 The on-line analyzing system guarantees expedition of, accuracy and scientific decisions in business information. DELL recently has adopted a Cost Pre-estimation System to support its flexible pricing strategy, according to which its 25 major suppliers for parts and fittings and other suppliers shall supply as per schedule the up-to-date cost and price information for DELL to pre-estimate the price for each part or fitting in the following months. Due to strict cost control and flexible pricing, the sale of DELL in the whole year of 2001 reached USD33,000,000,000, leaving its old competitors such as IBM, HP and COMPAQ far behind.

As can be seen from analysis of competition situation among domestic enterprises at present, the quick

bring major shocks to management framework, business model, distribution channel and development strategy in conventional enterprises and thus many new conflicts will appear. Whereas with China's entry into WTO, the enterprises are now confronting a brand new adjustment of strategic pattern and transformation of part of their business. Transformation of this kind appears to be quite difficult to start in state-run enterprises. Taking this aspect into consideration combined with developing trend for international E-B, we think that the track for E-B development in domestic enterprises can be considered of in the following three aspects.

Firstly, making full use of characteristics like continuous increase of business groups on the current Internet with combination of resource advantage of the enterprise, extensive information and ever-increasing business channels, the "Mouse Plus Concrete" model shall be applied to establish Internet virtual enterprise with Enterprise Resource Plan (ERP) System, Supply Chain Management (SCM) System and Customer Relation Management (CRM) System, to increase operation level of conventional business with modern scientific and technical methods, at the same time to accumulate practical experiences of E-B and to nurture talents familiar with operation under Internet economic situation. This is our first of E-B practice.

Secondly, according to the development strategy of the enterprise and requirements of E-B development, integration and exchange interface for information inside and outside of the enterprise shall be constructed through practices of website popularization and network construction of the enterprise. The development of E-B towards a deeper level shall be promoted through development of Internet strategic alliance and closer coordination with business partners.

Thirdly, with the government or guild as the go-between, the experimental unit or organization shall be chosen for E-B development of the enterprise. The best shall be the focus of development and subject to active popularization. Bold exploration shall be made in practices of Internet operation as leaders and forerunners.

## 5. Strategies and measures taken by mainland enterprises in further development of E-B.

5.1 The knowledge of enterprises to E-B should be increased with standardization of enterprise core business process and construction of ERP system as key of E-B development of enterprises.

The entity of E-B is the business activity. Making the use of E-information and network is the method of actualization of business activity. An enterprise is the main body of E-B activity. Through related solid evidence analysis, we consider that on the competitive platform of global market through the internet, it enlarges the advantage and inferior position ruthlessly, the good is

better, the bad is worse. In the same time, network rivals, the enterprise is not restricted in the district area; it faces the un-present global virtual network. The client admits you or not just at the moment. "The fast fish eats the slow one" and "the scope is enlarged by speed" are also the game regulation of new economic era.

So to improve the enterprises' cognition of the importance of E-B development, pay attention to the advanced experience of large enterprises' E-B development in the main targets of America, Canada and Europe. According to the requirement of market competition to regulate the internal operating mechanism of the enterprise, apply the core of information technology of internet to the business activity and enterprise's resource management. According to the international advanced management thought and international standard to regulate the external and internal business circuit, and through the information management system to solidify the circuit and improve the enterprise inner circuit, integrating the enterprise external and internal work circuit and data circuit, enlarge the gaining channel of the enterprise external and internal information and service to decrease the cost of the enterprise operation and increase the work rate, exploit new market space and improve the rate of clients' satisfaction, so as to enforce the marketing competitive ability. We can make the traditional industry earn the driving right in the next competition.

5.2 Special attention should be paid to combination of E-B platform construction and business of the enterprise itself. "Be self-reliant and construct enterprise E-B platform of enterprise" is our major principle in our work henceforth.

Though E-B is universally considered as the main mode of business in 21<sup>st</sup> century, from the China reality, the practical appliance of E-B is a large area needed to be exploited. According to the investigation of Beijing internet development center, at present, only 4.5% China exporting enterprises use the E-B to open business, 31.2% enterprises just at their beginning, still there are 23.6% having no thought of it. It shows that our enterprises' E-B is just at its beginning whether in the aspect of base construction, technical device, operating environment, it has remarkable gap with international advanced level.

From the research of E-Band network extending and marketing of the enterprise in recent years, we profoundly realise that the further development of domestic enterprise E-B first should be based on the connection of the enterprise its own business and the resource state, adopting practical attitude to constitute the E-B development program which fits the requirement of the enterprise itself. During the actualization of the program, from the enterprise itself, regard the enterprise as its largest client to meet the need of its own business. Through the exploitation of CRM, SCM and POL, on the first side improve the communicating method from the enterprise, client to the factory to improve quality of

service, on the other side through the model effect of success, absorb more and more middle and small enterprises around the enterprise through the platform, form E-trading market within the industry, improve the development of enterprise's business. ORACLE and DELL have achieved good results though the mode. "Based on oneself to set up the enterprise E-B platform" is our principle which should be obeyed in the future work.

5.3 The functions of the government, especially its key functions in standardization of market and consummation of laws and rules, should be highly recognized during development of E-B.

During the business revolution of the actualization of E-B, American Government has played a key role in the promotion of the development of E-B. From the four layers of programming, policy guiding, propaganda and training, study and exploitation, American Government promotes the E-B development. In the aspect of programming, American Government announces that the whole national TV system had gradually transferred from analog to digital from 1996 to 2005; in the same time through the law, from 1998, all the expense of the Federal Government Institute should be paid by the electronic method. The former lays a base for the united net of TV, Telephone and Computer; the latter accelerates the development of American national E-B. In the aspect of policy guiding and propaganda and training, in the early nineties, Clinton's Government regarded Information Highway as its administrative program. During the ten years, American Government issued no less than 20 items of law and regulations about E-B. The most influent ones are National Information Base Structure Guideline made by Present Clinton in 1993, Global E-B Schema issued in 1997, and in 1998, Clinton's speech on Network New Policy and draft policy of exemption for E-B, etc.

As the government active promotion and policy supporting and complete set of law and regulations, ten years has passed from 1992 when Clinton provided the imagine of Information Highway in his run for president, American Information Highway has not only started but also achieved great economic and social effect for the America and also for other countries all over the world.

From the analysis on E-B development of present domestic enterprises, the development of E-B is restricted by two levels of factors: one is the appliance extending of Information technology and informatization base and level of internal enterprises; the other is market environment and institution construction. The last restrict is more obvious. From the survey of domestic E-B development in recent years, it is not difficult to find out that the main factor restricting the development of E-B is not the technical problem but the requirement of market environment and institution arrangement. So the key point of government promoting the E-B development is primarily to accelerate the market environment and constitution construction.

In the same time, aiming at the kinds of problems met in the development of E-B, we advise to choose the enterprise which has the representative of the certain industry with good management condition and E-B technical base as an experimental unit. Supported by government special fund, organize special persons to investigate from every link of the management of enterprise supplying chain to find out the common experience which can be extended within the industry. It has important significance to bring along the E-B development of the whole industry.

5.4 Research and establishment shall be done of standards and criteria in E-B industry to guarantee the standardization of enterprise E-B development.

After more than ten years' experience, America and other western countries have formed a set of standard and regulation in E-B transaction, as advertisement of products through network and the XML standard of commodity classification. Now there are few domestic enterprises adopting such a commodity classification. So we should study carefully and are acknowledged about the technical standards (as XML, UBL, etc) adopted by the grand enterprises' E-B system in America and western countries to open the development of the E-B of enterprises. In the same time, under the guide of government or industrial association, adopt the design and classification of network products of authority standard of the interior enterprise to ensure the unified interface with grand network purchasing system of foreign countries, especially of the America and western countries. In the same time, in the course of the practice of enterprise E-B, related government departments and industrial association play a very important role in the

of making and regulation of the product exchange specially, investigating and knowing of the requirements of grand network purchasing system of America and other countries to China supplying software, organizing the technical connection of the suppliers and the purchasers, opening related industrial requirements and E-business standard training class for associating units and all those should be worked out hard at present.

5.5 Exchange and study shall be enhanced with European & American large-scale information enterprises and large-scale department stores as well as chain stores with wide E-procurement for expedited promotion of the development of E-B in mainland enterprises.

We have gained a lot during this survey, seeing with one's eyes today's the whole world fast development in the internet technology and its appliance, increasing our perception knowledge and intensifying our rational knowledge of its development course, environmental condition, practical appliance and the development trend, having acquaintance with American and Canadian information industry development and related products, technology and management actuality, especially for the development of E-B and related social environment. It is important E-B work in enterprise development to make a good technical foundation for the further development of the enterprises though regularly organizing intercommunicate with and learning from the grand information enterprises of Occident and E-purchasing large department stores and chain stores to know the trend of present network economic development and to be familiar with the E-B development environment and technical requirement in Occident.

# Tourism Website Development and User Requirements : Who are Tourism Website Users and What are Their Requirements in China

## Abstract

China tourism industry is investing to develop a "Golden Tourism Project". One of the main objectives of this project is to improve web-based tourism online service quality and implement tourism e-commerce. In order to develop successfully the project it is necessary to investigate who are main tourism website users, what are their requirements for online tourism services and how do they assess current tourism websites. The main purposes of this study are to identify current tourism website users, analyse user requirements for tourism online services and explore how design tourism websites to attract users, promote tourism landscape points and improve online tourism service quality in China. Through conducting a survey and analysing the survey results, this paper shows the behaviour characters of current tourism website users, discusses their preferences and requirements for online tourism websites, and identifies the major factors that users concern for tourism website construction in China. Components of tourism websites are analyzed and an evolution model for tourism websites in China is proposed.

**Keyword:** Tourism websites, E-commerce, Web assessment, User satisfaction, China

## 1. Introduction

The Internet facilitates various online services, creates more and more virtual products and provides new business transaction models. Tourism e-commerce is one of the fields where Internet is being widely applied in providing online services and products [3] [10]. The development of tourism e-commerce not only changes the tourism marketing models but also results in the changes of the conventional user requirement and conventional measurement of user satisfaction [14] [8]. User satisfaction, which has a great influence on

companies' market behaviour, profitability, and competitive advantage, is a very important factor for a company to establish their market competitive strategies. Hence, tourism website suppliers need to know which types of people are the main users for their websites and receiving their online services, if these users are satisfactory with current online services and which kinds of service functions need to be effectively improved.

Tourism is becoming an important industry sector in China. In 2001, China received 333,200,000 tourists and has become the top fifth tourism destination country in the world [1]. Tourists are becoming more initiative and individually in China. Simultaneously more and more educated young tourists are obtaining tourism information from the web and making various online orderings and bookings. Tourism e-commerce is benefiting tourism companies in reducing costs and reaching a large user group, also benefiting to tourists in making a clear budget and travel plan.

Base on the requirements of National Information Development in China, a current keystone of tourism industry is "Golden Tourism Project". One of the main objectives of this project is to develop tourism e-commerce and improve tourism online service quality. Today web development in China has increased to the point where hundreds of companies are creating new websites and thousands of people are being new users daily. In 2001, more than 12,450,000 computers were connected with Internet in China. There were 33,700,000 people accessing Internet, 6,720,000 of them using broad band, 21,330,000 using dial up, 5,650,000 using both technology, and the rest 1,180,000 using other information equipment and connection [4]. From 1997 to 2000, the number of people to access Internet is doubling every six months, an increasing 20%-30% since 2000 every six month. Simultaneously, user requirement for tourism online service has been increasing. Through few years practice of tourism

online service, it is very necessary for the government and tourism companies to have a clear understanding and identification for current state of tourism e-commerce applications and users' requirements for tourism online services.

There is no any research result for the development and evaluation of tourism websites in China from literature. In the case of website assessment some publications of results exist, such as [5] [7], but there are not addressing tourism websites. Benefits of tourism online service have been demonstrated, such as [12] [11] [2] and [6], but user requirement and satisfaction for tourism website design and online services, particularly in China, are not sufficiently explored.

The initial objective of the research is to provide a picture of tourism website users and their requirements in China. A further objective is to identify a potential path for the development of a customer oriented tourism e-commerce application from its current implementation. This paper therefore focuses on the identification for tourism website users and the analysis for their preferences, requirements and evaluation for tourism websites in China. The research is conducted based on a questionnaire survey. Through data analysis, this research identifies and discusses several important factors of tourism website development including accessing speed, connection expenses, site links, content/interface design and online ordering/shopping. The findings of the project are expected to help the government and tourism website suppliers in China to understand current online user requirements, preferences, satisfaction and behaviours, which will be very benefit for the development of tourism online service. Finally, Components of tourism websites are analyzed and an evolution model for tourism website development in China is proposed.

## 2. Research Method

The study is completed by four main phases: questionnaire design, subject identification, survey conduction and data analysis. In order to obtain the information about the composition of tourism website users and their assessment for tourism website service, a questionnaire was designed to include 20 questions. The questionnaire consists of three parts: part one involves user's personal information; part two involves user's requirement, behaviour and attitude in access tourism websites; part three addresses users' evaluation and suggestions to current tourism website development.

This survey was conducted in several popular Internet cafe clubs in Shijiazhang city and several typical tourism companies. The subjects are Internet cafe club members or registered customers in selected tourism websites. The most Internet cafe club members are experiential Internet users. They usually have high information requirement and have visited many tourism websites in the world. They thus could express more

user requirements to tourism websites and give good suggestions for tourism website design. The registered tourism website users have a long and continued experience in receiving online tourism services. They therefore could give a more fair evaluation and report existing practical problems.

The survey was conducted from 15 to 30 May 2001. Questionnaires were given to subjects by emails or individually handouts (in Internet cafe clubs). Total of 290 questionnaires were sent out and 196 complete responses were obtained. These responses indicated their experience in visiting tourism websites or receiving relevant online services, therefore are recognised as 'tourism website users' in the study.

This study also compares the main findings obtained with the relevant results shown in "China Internet Developing Situation Statistic Report" that is completed in June 1999 by China National Network Information Center (CNNIC).

## 3. Who Are Tourism Website Users

### 3.1 User Occupation Analysis

The survey result shown in Tab. 1 indicates that the main tourism website users are high school/university students (44.8%) and professionals (15.2%). The CNNIC [4] has similar results for general Internet users. CNNIC reported that in 19 main occupations, the biggest proportion is students (19.3%) and computer technicians (14.9%). The two results tell us that students and computer professionals are two main user groups to access Internet and visit tourism websites in China. User occupation is a very important issue to be considered for website suppliers in identifying users' requirements for online services and designing tourism websites.

**Tab. 1 User occupation**

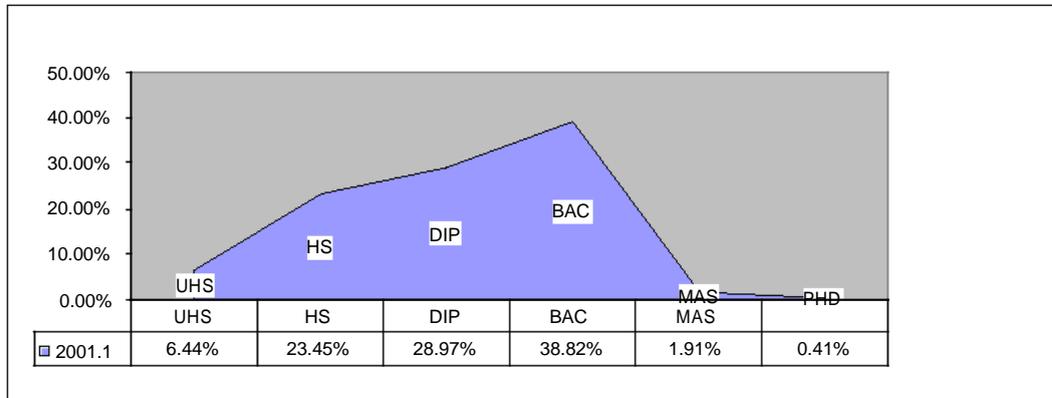

Occupation	%
Civilian	11
Student	44.8
Serviceman	10
Professional	15.2
Manager	7.5
Unemployed	7
Others	4.5

### 3.2 User Education Background

The survey found that most responses have a good education background. There are about 38% of tourism website users has a bachelor degree, and 28% of has a diploma (Fig.1). The result means that the main tourism website users are educated people. The result matches the result of CNNIC [4] which shows that 86% Internet users have diploma, bachelor or above education

background, it is little higher than the result got from the survey. The difference can be explained that Internet use is fast spreading in China during the two years (1999-2001) so that there were more non-high-educated people having become Internet users. This finding also can be explained that more non-high-educated users

have become new users of tourism websites. When more un-high educated people becoming tourism website users, tourism website designers must consider how to match the requirements of all levels of use groups.

PHD—Philosophy of Doctor, MAS—Master, BAC—Bachelor, DIP—Diploma, HS—High School, UHS—Under High School

Fig.1 User education levels

### 3.3 User Age Analysis

Age is also an important factor to determine users' preferences and choices for tourism products and services. The survey shows that about 97.5% of responses are younger than 35 years old and there is no response over 45 years to participate with the survey as an Internet cafe club member or a website register members (Tab.2). This result matches with the relevant results of CNNIC [4]. The result can be explained as that young generation more likes to use Internet as a tool for seeking information and receiving services.

Tab. 2 User age

Age	< 18	18-24	25-34	35-44	>45
%	12.5	65	20	2.5	0

### 3.4 User Income Analysis

Tab. 3 Users' monthly income and Internet accessing cost (yuan RMB)

Monthly income				
Less than 500	500-1000	1000-1500	More than 1500	No income
28%	17%	8.5%	9.5%	37%
Monthly Internet access cost				
Less than 100	200--300	400-600	Not sure	
44%	21%	13%	22%	
Payment type				
Self pay	Business cover			
61%	39%			

As shown in Table 3, most responses have a lower income or no income as most of subjects are students and young people. About 82% of users' income is less than RMB1,000 per month. Only 9.5% of users' income is over than RMB1,500 per month. About 44% of users have a monthly Internet access cost less than RMB100 and 61% of users need to pay their main connection fees by themselves. For such users who do not have strong financial ability and business financial support, the Internet connection/access fees is one of important factors to be considered for access online services

## 4. How Do Users Evaluate Tourism Websites

### 4.1 Accessing Speed and Connection Expenses

The most important factors affecting users' to receive tourism websites are identified in the survey. Responses indicate that the first important factor was "accessing speed", followed by "connection fees", and "service quality" (including information content quality and ease of use). For the question "what are the unsatisfied aspects for current tourism websites", 35% of users mark "speed is too slow". In the question "what are the most important factors for supporting a tourism website success", 40% of responses think it is "high accessing/searching speed". Website accessing speed has become one of the most important factors for users to visit websites and a major problem complained by users in China. The main reasons for having such a lower accessing speed in China are (1) the narrow bandwidth cannot meet the requirement of large information such as photos; (2) there are large amount

of users accessing same data at the same time; and (3) relevant networking technology problems, such as software architecture, search engine algorithms and server output channels, need to be solved. Therefore, the development of tourism websites needs a more effective technical support and regional infrastructure construction.

## 4.2 Search Engine and Relevant Site Links

Search engine is a key function of Internet applications. Installing a search engine to a website will help users to find what they are looking for quickly. In the question “how to know a new website”, about 69% of responses marked “by search engine and site links from existing websites”. In the question “which function is the most frequently used in web service”, search engine is listed with a high rate, following chat room, email and information content. Today’s search engines, such as SOHU, have a fast search speed and wide range of information domain, but lack a clear classification for tourism information. This makes users hard to find what they are looking for. They have to guess a website’ name or key words, and then try various solutions. Integrated tourism websites should define a suitable classification for tourism information and provide tourism packages which combine several tourism components together, such as accommodations, transports and attraction-point information. Particularly they should build enough links to related websites. As some kinds of tourism information, such as transport timetables, are often changed, database is a useful technology for maintaining up-to-date information and allows users to search both static and dynamic information on the websites.

## 4.3 Information Provision

In the responses for the question “what are the main purposes to visit tourism websites”, “to get tourism information” obtains a highest rate. For the question “what is the most popular online service on tourism websites”, “providing information” is listed as the first item. The responses also expressed a very widely information requirements for tourism websites, which involves six basic tourism factors—eating, living, travelling, wandering, enjoying and shopping, as well as relevant tourism association information such as weather, news, products and prices. The questionnaire also lists the question “what are the most important factors for a tourism website success”, 52.5% of responses believed that the most important factor is “providing large amount, updated and attractive information”, followed by “fast access speed”, “good interactive function” and “refinement/exquisite page design”. The result means that tourism website users are very concern about the information content provided on tourism websites. Therefore information provision function is the first issue to be concerned in website design.

One of the common problems for tourism website development in China is the lack of integrative online information management. As there is no tourism website registration management system in China, it is very difficult for website designers to build links from one site to relevant sites and hard for them to obtain complete tourism information of the whole country or province. The CNNIC result [4] shows that about 14% of Internet users obtained tourism information from Internet, it was rated at the 9<sup>th</sup> of the 13 main kinds of information obtained from Internet. In our survey results, about 24% of users complain that tourism information provided in tourism websites cannot meet their requirements. For the question “what are the unsatisfied aspects for current tourism websites”, “not enough useful information” is listed as the second important item. The item’s rate is higher than “high connection fees” and “poor personal security”. Therefore, when information obtaining is still a main purpose for web users, increasing useful web information and improving web information management level are two major tasks of current tourism website development.

## 4.4 Information Interchanging and Interaction Functions

In the survey, “refined page design” is marked as the second important factor for a tourism website success by users. The result indicates that web page design is affecting users for receiving online service. Many tourism websites in China don’t have a clear target user group and promotion direction. Website designers don’t understand user requirement well. These websites only focuses on a pretty interface and put many page-items (some are relevant and some not relevant to the theme of the website), therefore, they may lose the characteristics of a tourism website and make users feel the site is not very trustworthy, dependable and reliable.

“Information interchange/interaction functions” is identified as the third important factor for a tourism website success in the survey results. A lot of users are interested in online chat, online consultation and email requiring. The results reflect that users require the online service that combing information content (such as tourism guide) and community (such as web consultation). Normally, many users like to get others’ opinions for landscape points before they have a tour. They thus wish to share ideas, information, experiences and knowledge with other tourists via the websites. Tourism websites are expected to provide an interactive space to users and service providers.

## 4.5 Doing Tourism E-Commerce via Websites

In this survey, only 2.5% of responses chose “web-based e-commerce” as a “purpose to visit tourism websites”. There were more than 1/3 of responses indicating that “the main disadvantage of tourism e-

commerce” is “security problems”, followed by “payment methods”, “online cost” and “information service quality”. Almost responses didn’t have any experience in online payment. Only 5% of responses had online ordering/booking experience. Therefore, for both questions “do you have any tourism e-commerce experience” and “are you satisfied with current tourism e-commerce”, most responses marked ‘NA’. Actually almost responses did not think they really need doing web-based tourism e-commerce urgently. There are several reasons for Internet users to keep tourism e-commerce away. The first reason is that most responses have middle or lower financial ability and they think that to participate e-commerce actions will have a higher cost than traditional way. Another reason is there are security and network technical problems in e-commerce transaction/payment systems to be solved. Users don't trust e-commerce applications well. Credit cards are not popular used in China is the third reason.

## 5. Components of Tourism Websites

A successful website is one that attracts users, makes user satisfactory [7]. Basically, user satisfaction is based on two groups of evaluation criteria: 'information content' and 'ease of use' [13]. 'Information content' is the assessment of information provided on the website. That is, it is useful and up-to-date, it matches user needs and links relevant sites to the users. 'Ease of use' includes E-commerce application format design, facilitated browsing, a search engine provision, accessing speed and user control of a transaction process. Based on the two criteria, the survey identifies a number of tourism website components. These components should be taken into account when designing a tourism website.

The first component is about information content published on websites. Tourism websites should publish useful, update and clear information about tourism products and services by using photos, audio and text [12]. The information involves destinations' attractions, activities, hotels, restaurants, transportation, tours, shops, entertainment, sports and recreations.

The second component is associate information provision. Associated information includes local maps, news, healthcare, laws and culture environment that are very helpful for user to make a tourism plan.

The next is online user supports that include a fast search engine, frequently asked questions, and allowing information and products to be downloaded by users. Interaction between users and systems is also a kind of important support to users. Interactive function helps users to share knowledge and experiences directly.

In order to facility tourists to arrange their tourism plans via Internet, the tourism websites should have enough links to relevant websites which provide online

information service for eating, living, travelling, wandering, joying and shopping. It should be encouraged for web designers to build more links with relevant websites, and more packages that integrate a group of relevant services together.

Online ordering/booking for tourism products and services is another important component. Ticket and accommodation booking is the most popular application in the aspect.

The last component is about building customer relationships with tourism companies by mining customer information via their direct interaction with the website. The customer information obtained can be used to create an online customer profile and build a specialized information provision according to the profile of the users.

The six components express the standard quality criteria for tourism website design. Another survey reported in [9] shows that about 80% of tourism websites in China only implement the first four components.

Online tourism service is still a new experience for most tourism managers, end-users and customers in China. As the technology is new, tourism managers cannot clearly define their expectations, and tourism companies have not got enough feedback from customers and their experiences. Therefore, website developers have to lead the process of defining the requirements of tourism web users. The provided components are expected to help them in the development of tourism websites.

## 6. An Evolution Model for Tourism Websites in China

Business website development typically begins simply and evolves over time with the addition of features as the site takes on more functionality and complexity. Based on literature review, this study proposes a five-stage evolution model for tourism websites development in China (Figure 2).

**Stage 1: Simple and isolated:** only presenting simple tourism information and contact details of tourism suppliers/agents. The basic information provided is regional tourism destination introduction with nice pictures. The websites' owners are mainly regional destination organizations. Very few links are built with other sites. Such kind of websites only implements component 1.

**Stages 2: Interactive and integrated:** various information relevant to tourism is presented, such as train/coach timetable, hotels and souvenir information. Supporting information (such as map and news) and product catalogue are provided. Users are allowed to

make enquiries about tourism products and services. Those websites have implemented component 1, 2, and 4.

**Stage 3: Linked and dynamic:** through a destination website, users can access relevant external products and services, including transport, accommodation, tourism foods/tools, culture activities, and training/conference centres. Product and service catalogues are provided with price information which can be changed by an online database. Such websites have implemented component 1 to 4.

**Stage 4: Online ordering/booking:** based on above stages websites are designed to allow customers to make a booking via email but the payment is still carried out by using a conventional method. Further, on-line payment will be provided with the use of credit cards.

**Stage 5: High-level, full-function, and comprehensive :** building registration with user ID, and using registration scheme to provide more personality and regular services to customers for direct purchase. The stage implements all six components.

Component \ Stage	1	2	3	4	5	6
Stage 1	Y	N	N	N	N	N
Stage 2	Y	Y	N	Y	N	N
Stage 3	Y	Y	Y	Y	N	N
Stage 4	Y	Y	Y	Y	Y	N
Stage 5	Y	Y	Y	Y	Y	Y

Fig. 2 Components and stages of tourism website development

## 7. Conclusions

China has obtained initial experience in the development of tourism websites and online tourism service. As a developing country, China has different E-commerce development environment, barriers and challenges from developed countries. Through the research, we found that the main barriers for tourism e-commerce development in China are Internet access speed, web information presence, site links and application security. Many tourism websites need to have a systematic design in information content and online service items. Tourism service characteristics should be presented in webpages. Information interaction functions (online ordering/booking) need to be implemented in a high level to meet the user requirement. The interface of tourism websites is expected to improve in ease of use. It is still a long process for tourism websites to realize online payment in China. The current tasks for tourism e-commerce development should focus on redefining online

information content, building helpful web links, providing customer oriented online services and implementing more effective online booking functions. Tourism online suppliers need to identify their target user groups and seek the way to meet users' requirements in developing tourism websites and improving tourism online service quality.

## Abstract

A silent revolution is taking place in the global service industry, including a lot of enterprises in tourist industry, affecting the way companies are managed and operated in a progressively deregulated economic environment. This is the yield management, which originated from the airline industry and is used by many different kinds of tourist enterprises.

This paper is dedicated to study the yield management in tourist industry, especially taking the Chinese tourist enterprises as the example. The fact that yield management is not understood well by so many tourist companies is the reason why this paper is written. The character of being intangible, vulnerable and its particular cost structure are the most important reason for tourist enterprise to apply yield management. When studying the current situation of tourist enterprises in China, some problems facing these enterprises have been found, including that many tourist enterprises do not practice marketing segmentation properly, the particular cost structure do not influence the revenue management, and so on. Finally, the paper describes in detail how to solve problems mentioned through using yield management. Three elements are interdependent, that is, understanding the problems involved, the important principle of yield management application and the process of practicing yield management.

## 1. The Background of This Paper

Whenever we compare the operation of airlines in China and other countries, we pay attention to the fact that the foreign airlines offer price which varies with booking time, customer segmentation and consumption style, etc. But Chinese airlines followed the fixed price for all the flights in the past, where there was no yield management. And now in the market it seems that Chinese airlines offer various price. That is not yield management. In fact, yield management is not understood well by so many tourist companies. Hence it is necessary to communicate the concept of yield management.

After more than 20 years' development, the tourist industry in China has entered another important stage. Because of the low entry barriers and high investment return, the tourist industry has grown very rapidly. However, the severe competition brings about negative effects, one of which is the rate of profit of

the whole industry fall, for example, in 1998, the international tourist operators' average rate of profit is only 1.8%<sup>[1]</sup> On one hand, it is because that the profit is becoming average, on the other, most tourist enterprise do not follow scientific method to analyze the customer segmentation, and fail to connect the pricing strategy with its profit realization. The simple competing method only includes cutting the price, which is far from competitive in the complicated and changing market.

## 2. The Reason Why Yield Management is Important to Tourist Enterprises.

Yield management refers to selling the products to the right customers at the right price at the right time is the central idea of yield management. The enterprises can get the most profit by targeting segmented micro markets to maximize its revenue. The tourist enterprises share some common product characteristics that are, the intangibility, vulnerability and particular cost structure. Yield management can bring benefit to the enterprises having such characters.

### 2.1 The perishable product

Many of the tourist enterprise's products belong to perishable product. Unlike the tangible products, the service in tourist enterprises cannot be stored and sell in another time. In the enterprises with perishable product, time element is very critical in selling the products. Typical examples include airline seats and hotel rooms. Once a flight left the ground, the seats cannot be sold any more; once a night has passed, the bed cannot be slept in.

### 2.2 Cost Structure

The second character is high fixed cost, low variable cost of tourist enterprises. Entertainment parks, hotels and airlines can be very good instances to illustrate this point. The variable costs of the product are low so an incremental sale does not cost the vendor much, but enables the product to be sold at a wide range of prices rather than letting it unsold and spoil. In other words, selling such kind of products for any price, which is over the variable cost, is better

---

[1] WEI Xiaolan, "Difficult Situation and Solution of Chinese Travel Service," *Tourism Review*, 1999, 4

than not selling at all.

### **2.3 Limited Capacity of the product**

The third character is limited capacity of the product. For example, the number of beds in hotels, cars in the car rental firms, seats in the plane is limited. In this kind of situation, it is very expensive or impossible to increase the available units of the product.

### **2.4 Product being able to be booked in advance**

The fourth is that the product or service can be sold in advance. This ability helps to facilitate segmenting the market, which is an important characteristic of yield management. In airline industry, the traditional usage of yield management can be seen in the separation of business tickets and economical tickets in the airline. That is the basic segmentation in airline industry. But that is far from enough. Now the situation is that more precise segmentation is needed to achieve better performance and revenue.

## **3. Current Situation of Tourist enterprises and problems**

When we study the tourist enterprises and analyze the current situation of tourist enterprises in China, we find some problems facing these enterprises, which can be solved by adopting yield management.

### **3.1 Current Situation of Tourist enterprises**

Since China adopted the Opening and Reform policy, with the development of the tourist industry, tourist enterprises such as airlines, hotels and travel companies have grown very rapidly. And these companies are facing very rosy prospect. Up to now, in China, there are about 17000 tourist enterprises, with 300 billion fixed property value, 200 billion fixed property investment, the direct employee in the industry amounts to 1800 thousand, and annual operational revenue achieves 15 billion Yuan.<sup>[2]</sup>

### **3.2 Problems facing Chinese tourist enterprises**

Although the tourist enterprises in China develop very fast, there are serious problems facing the whole industry. On the one hand, the tourist industry grows every year, on the other, the performance of tourist enterprise in terms of revenue is becoming poor. The problems remained for years, including that many tourist enterprises do not practice marketing segmentation properly, the particular cost structure do not influence the revenue management, the current pricing system does not reflect particular

characteristic of tourist enterprises, and so on.

### **3.2.1 Structure Adjustment is disregarded**

In the past 20 years, the development of tourist industry has been depended on large-scale investment and construction. The profit of tourist enterprises has been realized by raising the product price. When the market stayed in the seller's market, it is possible to maintain operation. But when the tourist enterprises are facing the changing exterior environment, especially the serious competition of enterprises from home and abroad, at the same time, the seller's market has turned to buyer's market, the structure conflicts of the industry has become obvious. Taking hotel as an example, for years hotels adopt one fix rate, the change of the market does not influence the operation strategy of hotels. Many hotels do not pay attention to prepare guest history file, and not realize its importance and hotels disregard the market segmentation. About travel agency, the administration does not pay enough attention to the low profit situation and long-term development, thus many poor performance aiming to short-term profit can be found in many travel companies.

### **3.2.2 Lack of competitiveness**

Nowadays, many tourist enterprises have high operational cost. In terms of competitiveness, Chinese enterprises are poor compared with many foreign companies.

For example, a lot of single hotels have been built. They are small in terms of scale, do not join in any global reservation network, and also cannot afford to invest any management software. The situation of travel agency is more difficult, small companies cover a large percentage of the whole industry. These small companies compete by blindly cutting price, and accordingly lower the quality of the products. Hence, a lot of complaints take place. Checking airlines and car rental companies presents the same finding.

### **3.2.3 Too much interference of the government**

For long, tourist industry has been interfered by government of many levels, which hindered the natural competition of enterprises in the market. What is most evident is the transportation industry. From the deregulation of American airlines, we can draw a conclusion that the free pricing stage owing to deregulation is the preparation phase for enterprises to adopt yield management willingly. Taking airline as an example, for years, the airline industry has been in charged by China Civil Aviation Bureau. The decision of airplane purchase, personnel administration is made by the bureau, the airline companies cannot make these decisions that should be their responsibility. So the companies cannot join in the market competition as true enterprise. The bureau also controls the pricing and route decisions. Many companies are poor in

---

<sup>[2]</sup>Statistic Report of China National Administration of Tourism

terms of management; fail to adopt tools to combat in the market, such as pricing, product strategy, and so on. At the same time, the service of airline companies does not differentiate from each other, so the competition between them becomes the simple cutthroat competition.

### **3.2.4 Low Level of Technology in Tourist Products**

In developed countries, technology can be seen more often than before in tourist enterprise. But in China, the technology level in tourist enterprises is low. Taking travel agencies as example, many companies do not join in any central reservation system. Even the use of computer is limited. So the operational cost is quite high, lowering the profit level. Now China has become a member of WTO, tourist enterprises will face more fierce competition from foreign countries. The low level of technology adopted will not result in fast, accurate and timely service, which is the most important characteristic of future tourist industry.

Besides the above problems mentioned before, we can also find other problems, such as poor infrastructure condition, sustainable development of tourist industry is facing difficulties, and not sufficient domestic tourist consumption. There are many reasons, but it is important to pay more attention to the interior management mechanism, in order to achieve efficient competition.

## **4. How to Solve the Problems**

Yield management, also cannot solve all the problems facing tourist enterprises, can help greatly to solve problems mentioned. Yield management system helps companies to make good decision through data analysis and forecast, and achieve better service performance. It should be realized that the most important reason is that there are many attitude mistakes and operational barriers, so the starting point to practice yield management is to understand the problems involved.

### **4.1 Attitude Mistakes and Operational Barriers**

In reality, the idea of yield management is being used by some of the firms, but not deeply. What is hindering the using of yield management? We have met some common misunderstandings upon this concept. The following is a look at three popular misunderstanding about yield management's role and effect.

#### **4.1.1 Misunderstanding 1**

The first and most popular misunderstanding about yield management is that it is a computer system. Discussions of yield management appear to be inevitably linked to computer systems. With computer-based tools as its key component, yield

management can be defined as a decision support system. As being introduced before, yield management can be used to forecast demand, to optimize reservation-inventory allocations, to limit discount availability, and so on.

But yield management is neither a purely computer system nor a set of mathematical techniques. In fact, other yield management practices can be implemented with little or no investment in computer resources. Yield management programs also involve other elements other than computer modeling, for example, education and training, an appropriately designed and delivered product, and corporate policies and procedures that encourage revenue enhancement. Those three areas must be addressed in a coordinated manner when developing or enhancing a yield management program.

#### **4.1.2 Misunderstanding 2**

Another misunderstanding is that yield management takes control away from employees.

Yield management tools may accomplish some routine actions previously performed by employees. It's easy to understand. However, a yield management program, containing tools that recommend specific courses of action, will not take over a company's decision making.

For example, yield management tools might suggest that no more reservations be accepted at a specific discount rate for a particular night, or that a group rate of \$75 is too low for a certain set of nights. But the ultimate decision and responsibility for accepting those recommendations, or over-riding them and choosing a different course of actions, rest with a hotel's staff.

#### **4.1.3 Misunderstanding 3**

The third misunderstanding is that yield management works only when demand exceeds supply

The best-known applications of yield management are overbooking and discount control. They are very useful when excess demand exists. That causes many people believe that yield management only works when demand exceeds supply. But in fact, not only when demand exceeds supply, but also when supply exceeds demand, yield management can be reliable.

For example, Marriott's use of low-price advance-purchase rates is an attempt to attract customers who would normally stay at low-priced hotels. Those new products do not create demand so much as under the previous pricing regime. Yield management helps a hotel modify its pricing structure and control the sale of its product so that the hotel can expand the appeal of its product while mitigating revenue dilution that would result if such changes were not controlled.

So, besides price discounting, yield management can identify opportunities to improve the pricing

structure. Raising and lowering prices dynamically for a given date, depending on demand, is a business decision. Yield management focuses on how much of a product to sell at established prices; it works all the time.

## **4.2 Principle of Yield Management Application**

In order to apply yield management, enterprises should follow certain principles. The successful yield management companies also create some organizational characteristics.

Continuous improvement should be embraced and the company is committed to the strategic process of yield management; it should create or use proper computerized yield management software to better their performance.

The company should thrive on changes, at the same time it emphasizes its perishable inventory, tries to connect the changes inside and outside the company with the sales of the products. And when the company balance its inventory and demand, what is emphasized is not only cost, the competing environment is more important.

The company should do a lot of customer research, and recognize the customer's expectation about the products and the price, which set the base of their comprehensive pricing strategy. What's more, the company must forecast the potential demand at different price or sales point, and allocate its capacity according to the structure balance.

It is important that such company rarely oversells prime inventory while rarely undersells fringe inventory; they limit the amount of discount business; and they always attach various conditions of sale to every price offer, and so on.

In sales, the company pays more attention to the micro market, that is the different customer types, not the whole market. Thus fixed price should not be followed.

The company should make good use of the value cycle of every kind of product, and try to sell it when it is highly valuable. This decision should be based on fact, instead of imagination.

## **4.3 The process of practicing yield management and solving the problems**

In yield management, the total revenue is more important than sales volume or sales price. In order to achieve that, five parts of process are necessary. They are market segmentation, price management, demand forecast, capacity management and booking negotiation.

### **4.3.1 Market Segmentation**

No company can satisfy the needs of all customers. In order to achieve success, it is necessary to do market segmentation. Not only tangible goods can

have differentiated markets, but also service can identify evident segments. Market segmentation is important in that various customer group can be recognized according to their behavior, thus different price structure, business strategy and other marketing motivation can be established. According to Philip Kotler, in segmenting the market, the criteria such as geographic, demographic, psychological and social elements can be used.<sup>[3]</sup> In fact, besides these criteria, service can also be segmented according to the willingness to pay for a product or service, and time when customers need the product as well. In tourist industry, according to these criteria, tourists can be listed into different categories. Different types of customers have evidently various price acceptance levels.

### **4.3.2 Price Management**

Price management refers to that the enterprise provide different price to various segments according to the change of demand systematically.

Taking airline as an example, if the airline has mastered the data about the customer type and their different demand, it can set up different price level and price structure. For example, the airline can provide a discount price to those customers who book early. In fact, both the discount price in low season and the high price in high season of many tourist enterprises belong to price management.

### **4.3.3 Demand Forecast**

A company forecast the future demand according to the analysis on past sales and known trend in the future, and based on this, the company can rationally and accurately forecast the scale of different segments and according price acceptable.

Forecast is a very important process on yield management. In order to forecast systematically, the company must possess data information and scientific statistical method. The company must have both interior and exterior information.

### **4.3.4 Capacity Management**

To manage capacity of a company means to limit or adjust the availability of certain product or service according to the demand of customers. In fact, some enterprises can change the capacity, but some cannot. But some enterprises can class the capacity and implement certain limitation to some product.

### **4.3.5 Booking Negotiation**

Because most products and services of many tourist enterprise can be booked, when customers book, the company can negotiate effectively. When there is a

---

<sup>[3]</sup> Philip Kotler, *Marketing Management*, tenth edition, Prentice-Hall, 2001,10

chance that the company can negotiate with the customer, it should try to sell the most expensive product and realize the greatest value of the products.

To sum up, yield management is a scientific method to make the enterprise realize optimal revenue, whose core is price control, capacity management and booking sales. Moreover, we believe it is the right time for our enterprises to understand this idea and implement this business practice.

# Inventory Management with the Internet-Based Direct Channel in a Two-Echelon Supply Chain System

Wei-Yu Chiang and George E. Monahan

Department of Information Systems, University of Maryland, Baltimore County  
Department of Business Administration, University of Illinois at Urbana-Champaign  
kevin@wchiang.net

## Abstract

We present a two-echelon dual-channel inventory model in which stocks are kept in both the manufacturer warehouse (upper echelon) and the retail store (lower echelon), and the product is available in two supply channels: the traditional retail store and the web-based direct channel. The system receives stochastic demand from two customer segments: those who prefer the traditional retail store and those who prefer the web-based direct channel. Any order placed through the direct channel is fulfilled through direct delivery from the manufacturer warehouse. When a stockout occurs in either channel, customers are willing to shift the channel with a known probability. Customers who are unwilling to shift the channel result in lost sales. In order to develop operational measures of supply chain flexibility, we define a cost structure which captures two different operational cost factors: inventory holding costs and lost sales costs. Several insights are evident from the numerical experiments. We also examine the performance of two other possible channel strategies: retail-only and direct-only strategies. Simulation outcomes indicate that the dual-channel strategy outperforms the other two channel strategies in most cases, and the cost reductions realized by the flexibility of the dual-channel system could be very significant.

## 1. Introduction

The advent of the Internet has prompted many manufacturers to redesign their traditional channel structures by engaging in direct sales. Consider a two-echelon inventory system that consists of a manufacturer with a single warehouse at the top echelon and a retail store at the bottom echelon. Suppose orders placed online are filled through direct delivery from the top echelon. Opening a web-based direct channel alongside the existing retail store may cause havoc on the product demand structures, and thus requires the company to redesign the optimal inventory allocations. In this paper, we construct an analytical model and define a cost structure which captures the inventory-related operational costs to evaluate the performance of a two-echelon dual-channel supply system.

The pervasive presence of multi-echelon inventory systems throughout the business world has been recognized in a long time. The concept of echelon stock

was first introduced by Clark and Scarf (1960). Inventory control in multi-echelon systems is known as a challenging research area. Because of the complexity and intractability of the multi-echelon problem, Hadley and Whitin (1963) recommend the adoption of single location, single echelon models for the inventory systems. Sherbrooke (1968) constructs the METRIC model, which is capable of identifying the optimal stock levels that minimize the expected backorders at the locals subject to a budget constraint. This model has been considered as the first multi-echelon inventory model for service parts. Thereafter, a large set of models that generally seek to identify optimal lot sizes and safety stocks in a multi-echelon framework were produced by many researchers (e.g., Deuermeyer and Schwarz 1981, Moinzadeh and Lee 1986, Svoronos and Zipkin 1988, Axsäter 1993, Nahmias and Smith 1994, Aggarwal and Moinzadeh 1994). In addition to analytical models, simulation models have also been developed to capture the complex interactions of the multi-echelon inventory systems problem (e.g., Clark and Trempe 1983, Pyke 1990, Dada 1992, Alfredsson and Verrijdt 1999).

The study of multi-channel supply chains in the direct versus retail environment emerged only recently. The focus of this stream of literature is on the channel competition and coordination issues in the setting where the upstream echelon is at once a supplier to and a competitor of the downstream echelon (e.g., Rhee and Park 1999, Tsay and Agrawal 2001, Chiang, Chhajed and Hess 2002). These papers present the dual-channel design problem by modeling the price and/or service interactions between upstream and downstream echelons.

The theoretical basis for multi-echelon dual-channel inventory problem has not yet been well developed. Toward this propose, we incorporate the direct channel into a traditional two-echelon inventory system to determine the optimal inventory levels for each echelon.

## 2. The Two-Echelon Dual-Channel Inventory Model

Consider a two-echelon dual-channel supply system that consists of a manufacturer with a single warehouse at the top echelon and a retail store at the bottom echelon. Figure 1 illustrates the topology and product flows of the system. The complete set of assumptions made for the inventory model is listed below.

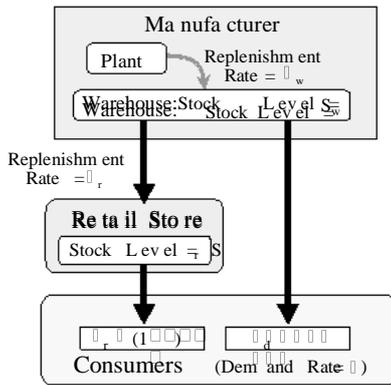

Figure 1: Two-Echelon inventory system with direct channel

## 2.1 Model Assumptions

- (1) The product is available for customers in both the retail store and the direct channel. Any order placed through the direct channel is fulfilled through direct delivery from the manufacturer warehouse. Demands across the two different channels are independent, and the total demand rate for the product in the system is  $\lambda$ . Specifically, customers are assumed to arrive at the retail store according to a Poisson process with constant intensity  $\lambda_r(1-\alpha)$ , and orders placed through the direct channel are in accordance with a Poisson process with rate  $\lambda\alpha$ , where  $\alpha$ , the direct channel preference rate, is defined as the proportion of potential consumers who would prefer buying directly from the manufacturer.
- (2) When the retail store is out of stock, customers are willing to shift from the retail store to the direct channel with a known probability called the retail channel diversion rate,  $\beta$ . Similarly, when the manufacturer warehouse is out of stock, customers are willing to shift from the direct channel to the retail store with a known probability called the direct channel diversion rate,  $\beta$ . When a stockout occurs in either channel, customers who are unwilling to shift the channel result in lost sales. Customers are assumed to be lost when both the retail store and the manufacturer warehouse are out of stock.
- (3) The warehouse replenishment lead-time and the retail store replenishment lead-time are assumed to be exponentially distributed with mean  $w$  and  $1/\mu$  respectively. A one-for-one replenishment inventory policy is applied, and replenishment backorders from the retail store are allowed at the manufacturer warehouse. A customer served from stock on hand will trigger a replenishment order immediately by EDI (electronic data interchange). Therefore, the information lead time is assumed to be zero. Under this replenishment inventory policy, the inventory position is kept constant at a base-stock level. The base-stock levels at the warehouse and the retail store are denoted by  $S_w$  and  $S_r$ , respectively.

## 2.1 The Markov Model

Based on the assumptions in the previous section, the corresponding Markov model can be constructed with the state space  $(x, y)$ , where

$x$  = stock on hand at the manufacturer warehouse,  $0 \leq x \leq S_w$ , and  
 $y$  = stock on hand at the retail store,  $0 \leq y \leq S_r$ .

Note that the stock hand at the manufacturer warehouse can be negative due to the replenishment orders from the retail store. There are four events that lead to a change of state: 1) a customer arrives at the retail store, 2) an order is placed through the direct channel, 3) a replenishment order arrives at the manufacturer warehouse, and 4) a replenishment order arrives at the retail store. Let  $p_{xy}$  be the steady-state probability that  $x$  items are on hand at the manufacturer warehouse and  $y$  items are on hand at the retail store. Then we can find the steady-state probabilities by solving the linear equation system that contains the balance equations and the normalizing constraint.

## 3. Cost Structure

In this section, we conduct an economic analysis of the model to evaluate the performance of the two-echelon dual channel system. We define a cost structure that takes into account two different operational cost factors, inventory holding cost and lost sales cost. In the sections that follow, these cost factors are specified in terms of the steady-state probabilities.

### 3.1 Inventory Holding Cost

Let  $h_w$  and  $h_r$  be the inventory holding costs in dollars incurred by the firm per item per time unit at the manufacturer warehouse and the retail store, respectively. Then, given the steady-state probabilities, the total inventory holding cost,  $C_H$ , is determined by

$$C_H = h_w \sum_{x=1}^{S_w} \sum_{y=0}^{S_r} x p_{xy} + h_r \sum_{x=0}^{S_w} \sum_{y=1}^{S_r} y p_{xy}.$$

Clearly, the first portion of  $C_H$  captures the holding cost from the manufacturer warehouse, while the second part reveals the holding cost from the retail store.

### 3.2 Lost Sales Cost

Recall that when a stockout occurs in either channel, customers who are unwilling to shift the channel result in lost sales. Moreover, customers are lost when both the retail store and the manufacturer warehouse are out of stock simultaneously. Assume that the cost of losing a customer is 1 per customer. Then the total lost sales cost incurred by the firm, denoted by  $C_L$ , can be determined by the steady-state probabilities, and is given by

$$C_L = 1 \cdot 1 \cdot r \cdot r \cdot \frac{S_w}{x \cdot 1} \cdot x_0 \cdot 1 \cdot 1 \cdot d \cdot d \cdot 0 \cdot x \cdot \frac{S_r}{y \cdot 1} \cdot X \cdot xy$$

$$\cdot 1 \cdot r \cdot d \cdot x \cdot \frac{0}{x \cdot \frac{S}{x}} \cdot x_0$$

Note that the first portion of  $C_L$  reflects the lost sales cost from the retail store caused by those customers who are unwilling to shift the channel when the retail store is out of stock, the second portion describes the lost sales cost from the direct channel caused by those customers who are unwilling to shift the channel when the manufacturer warehouse is out of stock, and the last portion captures the lost sales cost due to the stockout in both channels.

### 3.2 Total Cost and Optimal Base-stock Levels

In the model, the only decision variables are the base-stock levels,  $w$  and  $S$ . The total cost which is function of  $w$  and  $S$  is defined as the sum of the inventory cost and the lost sales cost,  $C_L$ . The objective is to find the base-stock levels that minimize the total cost.

### 4. Comparison of Channel Performance

Instead of using both the retail store and the direct channel, a firm can just use either one of the two channels to fulfill the demand. After evaluating the performance of the dual-channel strategy, we also investigate the performance of the other two channel strategies, retail-only strategy and direct-only strategy. In order to compare the channel performances, the numerical results from the two demand fulfillment strategies are juxtaposed with the results from the dual-channel strategy discussed before. The results show that the total cost of using the retail-only strategy increases in the direct channel preference,  $\alpha$ , while on the other hand, the total cost of using the direct-only strategy decreases in  $\alpha$ . We find that in most cases the dual-channel strategy outperforms the other two channel strategies for all values of  $\alpha$ .

Figure 2 illustrates the cost of using dual channels relative to using one single channel (the ratio of the total cost from using dual channels to the total cost from using either the retail store or the direct channel, depending on whichever results in a lower cost). We see that when the value of  $\alpha$  is around 0.5, that is, when the number of direct customers is close to the number of retail customers, the dual-channel strategy could lead to an impressive cost reduction. If we calculate the cost reductions that are obtained by using dual-channel strategy (compared to using one single channel), we learn that when  $\beta = \beta = 0.75$ , the average cost reduction for all values of  $\alpha$  is 54%, and when  $\beta = \beta = 0.25$ , the average cost reduction for all values of  $\alpha$  is 73%. It is clear that when the values diversion rates are low, the cost reductions realized by the dual-channel strategy are remarkable. The result reflects the fact that, when customers are less willing to deviate from their desired channel, using dual channels helps to reduce the number of losing customers, and thus leads to a lower total cost.

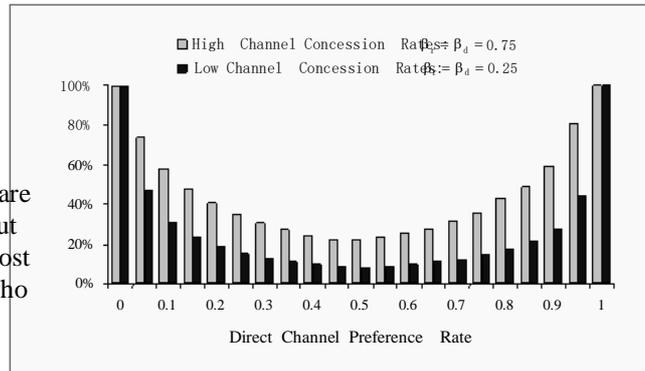

Figure 2: Cost of using dual channels relative to using one single channel

### 5. Concluding Remarks

The two-echelon dual-channel inventory model presented in this paper is constructed based on queuing theories. We analytically develop operational measures of supply chain flexibility. We define a cost structure which captures two different operational cost factors: inventory holding cost and lost sales cost. Our analysis of the model leads to an exact evaluation of system performances.

Several variations of our performance evaluation procedure are possible. For example, we have used the inventory-related cost as a criterion to evaluate the channel performance. However, sometimes achieving a high customer service level is an important objective for the system. In this case, we can easily include fill rates in the constraints or in the objective of the system optimization model for the performance evaluation.

We are not aware of any inventory model that handles the multi-echelon system with multiple channels receiving demand from different market segments. Our model has provided some insights in this important line of inquiry. However, due to the complex nature of the problem, the model is subject to some assumptions and therefore, has some limitations. For example, the results from our model may not hold if different inventory policies are applied. A more extensive investigation in this area is warranted.

# The Realization of a Stochastic Optimization Model for the Empty Container Inventory Based on EDI Information

Xin Shi  
Management Department  
Shanghai Maritime University  
Shanghai, China  
xinshi@shmtu.edu.cn

## Abstract

This paper explores the feasibility of realizing the optimization of the empty container inventory based on EDI information. Firstly the basic structure of the stochastic optimization model for the empty container inventory has been described and two models including the infinite and finite horizon model were constructed. Then several statistical test have been taken and the distribution of the inland turnover time of the empty container, the empty containers' supply and demand identified. Finally we adopt PB to develop the DSS for the stochastic optimization of container inventory based on the shipping EDI information.

Key words: EDI, empty container, DSS

## 1. Identification of the problem

With the rapid development of the container transportation and the fierce competition on the market, how to reasonably determine the empty container inventory so as to reduce the running cost has become one important issue that all the container transportation enterprises are facing to.

Essentially the reasonable determination of the level of the empty container inventory falls into the scope of the optimization of the empty transport vehicle's inventory. In general, the present research is focusing on the following two aspects: to estimate the imbalance coefficient of empty container flow by experience or statistic samples, to realize the optimization of the empty containers inventory by means of the optimization models mainly the programming model. Because of the quite great uncertainty of the container flow, it is unavoidable to collect large amount of data to support the realizing of the quantified model to optimize the empty container inventory. So this paper is ready to take a systemic study on the information transmitted through the shipping EDI platform and the construction of the stochastic optimization model, then to explore the feasibility of realizing the optimization of the empty container inventory based on EDI information.

## 2. The analysis on the function and data structure of shipping EDI platform

Transmitting the information is the traditional core function of the information service provided by the traditional EDI platform, but the content of the information service has begun to change under the present network environment, and to emphasize particularly on providing the service of the value-added information step by step. What is the value-added information? Comparing with the original information, it has an obvious increase in the content of the information obtained by reasoning, analyzing and processing a group of correlative information. For the shipping EDI platform, the developing tendency in the future is how to further dig and process the information transmitted through the shipping EDI platform rather than to transmit the information simply, and provides more value-added information to the EDI users in their daily operation. Among which, it has been one of the attentions how to provide the information support for the reasonable determination on the empty container inventory.

Now the types of information transmitted through the shipping EDI information platform are IFCSUM, BAPLIE, COSTCO, EXPUSL, CODECO, COEDOR, COARIS, ACKIAG, COARIO, COARID, and so on. From these information, we can get many valued results. For example, IFCSUM contains much information regarding the quantities and directions of the empty container flow. We can identify the running rule of the empty container flow by analyzing IFCSUM. We will explore this issue later. Here we only summarize that it is possible to realize the stochastic optimization of the empty container inventory based on this EDI information.

## 3. The stochastic optimization model for the empty container inventory

### 3.1 General Description

The basic structure of the stochastic optimization model for empty container inventory based on the storage theory can be described as follows:

$$F = (T, Q, X, D, S, L) \quad (1)$$

In the formula above:

T stands for the length of the planning time, we classify it into the type of the finite and infinite;

Q stands for the fact whether the empty containers' shortage in a short time is allowed or not;

X stands for the fact whether the model considers the empty container inventory of one point or multiple-points;

D/S stands for the fact whether the demand/supply of the empty containers is stable or random;

L stands for the fact whether the allocation and transportation of the empty containers need to take time or not;

We can construct several models based on the above basic structure. Because of the limitations of pages, we are only giving the infinite and finite horizon models which consider only one point.

### 3.2 The infinite horizon model

#### 3.2.1 The basic model

Suppose the length of the planning time is infinite. The point for considering is lack of empty container. The shortage of supply of the empty container is not allowed. Let the demanding distribution of the empty containers follows the distribution of  $G(x)$ , and the replenishing time of the empty containers is zero. The strategy  $(s, S)$  is adopted.

According to the above conditions, we argue that with the infinite planning time horizon, the attention can be focused on the period of one cycle. Suppose the inventory level at the beginning of the period is  $I$ , the amount of the empty container during this period to replenish is  $Q$ , then the maximum level can be reached to  $R=I+Q$ . We also suppose the demanding amount of the empty container during this period is  $x$ . Hence,

If  $R \geq x$ , then the expected cost is equal to:

$$E(C_1(R)) = \int_0^R h(R-x)dG(x) + \delta \times k(R-I) \quad (2)$$

In the above formula,  $h$  is the storing cost of the empty container for the single period, and it is suppose that no storing cost has occurred for the empty container distributed in this period.  $k$  is the distributing cost.

If the distribution of empty containers happened,  $\delta=1$ ; otherwise  $\delta=0$

If  $R < x$  then the expected cost is equal to:

$$E(C_2(R)) = \int_{R+1}^{\infty} b(x-R)dG(x) + \delta \times k(R-I) \quad (2)$$

Here,  $b$  means the temporary leasing cost of the empty container.

So, the total expected cost is:

$$E(C(R)) = \int_0^R h(R-x)dG(x) + \int_{R+1}^{\infty} b(x-R)dG(x) + \delta \times k(R-I) \quad (4)$$

Let the derivative of the  $E(c(R))$  is zero, then we can get  $R^*$  (namely  $S^*$ ). The next step is to obtain the value of the replenishing point ( $s^*$ ) by taking marginal analysis in the following way:

If we replenish the empty container at the beginning of the period, then the expected cost is equal to:

$$E(c(I)) = \int_0^I h(I-x)dG(x) + \int_{I+1}^{\infty} b(x-I)dG(x) \quad (5)$$

If we don't replenish the empty container at the beginning of the period, then the expected cost is equal to:

$$E(c(R)) = \int_0^R h(R-x)dG(x) + \int_{R+1}^{\infty} b(x-R)dG(x) + k(R-I) \quad (6)$$

If  $E(c(I)) \geq E(c(R))$ , then it is not necessary to replenish the empty container. Namely:

$$\int_0^I h(I-x)dG(x) + \int_{I+1}^{\infty} b(x-I)dG(x) \geq \int_0^R h(R-x)dG(x) + \int_{R+1}^{\infty} b(x-R)dG(x) + k(R-I) \quad (7)$$

When  $I=R$ , the above inequality is obviously held, therefore, it is affirmative to have the solution.

When  $I < R$ , it is also possible to held the above inequality, then the minimum of the  $I$  is  $s$ .

#### 3.2.2 The modification to the basic model

In the above model, we suppose that there is no delay in the replenishing of the empty containers, which can greatly decrease the complexity of the model. In practice, it is obvious that there is the delay of empty containers replenishing. So we must consider this issue and modify the basic model in the following.

The consideration of the delay of empty containers replenishing has two affects on the model:

One affect is the amount of empty containers stored at the beginning of this period which not only includes the amount of empty containers at the end of the last period, but also includes the empty containers that should have been distributed in the previous periods but arrive in this period. i.e. The empty container inventory of this period equals to the ones at the beginning of the period plus the ones which are in the procedure of transport.

The other affect is that the time length of decision-making should extend from this period to the delaying period. i.e. The demand of empty container considered not only includes the one of this period but also includes the empty container demand which happens in the delaying time.

Bases on the above two effects, we can make the following modification to the basic model:

$$I' = I - \frac{\tau}{\tau_0} \int_0^{\infty} x dG(x) \quad (8)$$

$$E(C_j(R_j)) = \int_0^{R'} h(R - I - \frac{\tau}{\tau_0} x) dG(x) + \int_{R'+1}^{\infty} b((1 + \frac{\tau}{\tau_0})x - R) dG(x) + k(R - I) \quad (9)$$

In the above formula:

$T$  is the delaying time,  $T_0$  is the span of this period which has been considered.

$$R' = \frac{R}{1 + \frac{\tau}{\tau_0}} \quad (10)$$

### 3.3 The finite horizon model with one point

#### 3.3.1 Basic model

In the above, we discussed the infinite model and take one period to consider. However, it is not suitable in the finite horizon model. We will construct the model in the following way.

Suppose there is  $n$  periods. The correlative assumption is the same as the infinite model.

In the  $j$ th period, the whole expected cost is equal to:

$$E(C_j(R_j)) = \int_0^{R_j} h(R_j - x) dG(x) + \int_{R_j+1}^{\infty} b(x - R_j) dG(x) + \delta k(R_j - I_j) \quad (11)$$

$$\delta = \begin{cases} 1 & R_j > I_j \\ 0 & R_j \leq I_j \end{cases} \quad (12)$$

Then we can define the whole of the optimization object as:

$$\text{Min } C = \sum_{j=1}^n E(c_j(R_j)) \quad (13)$$

To the above model, we can adopt the dynamic programming theory to solve.

Assuming  $I$  is the status variable,  $R$  is the decision variable, the equation of status transferring is:

$$I_j = R_j - D_j \quad (14)$$

Suppose  $E(g_j(R_j))$  is index function,  $E|g_j(I_j)|$  is the optimization function, then the reversing model can be constructed as follows:

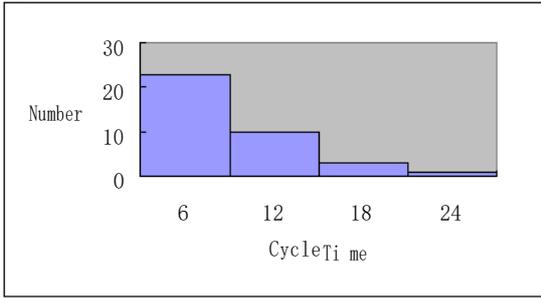

$$E|g_j(I_j)| = \min_{R_j} \{ E[C_j(R_j)] + E|g_j(I_j)| \}, \quad E(g_{n+1}(I_{n+1})) = 0 \quad (15)$$

From the above models, We can get  $R_j^*$  of every period. The  $R_j^*$  is the  $S_j^*$  of the strategy of  $(s_j^*, S_j^*)$ . The obtaining of  $s_j^*$  is the same as the infinite horizon model.

#### 3.3.2 The modification to the basic model

The above model is only suitable for this condition that delaying time of empty container replenishing is zero.

If the delay were considered, the following adjustment

should be given:

$$I_{j+1} = I_j + Q_{j+1} - D_j$$

$$E(C_j) = \int_0^{\infty} \int_0^{\infty} h(I_j + Q_{j+1} - x) dG(x) f_j(Q_{j+1}) dQ_{j+1} \quad (16)$$

#### 4. The information support for the optimization of the empty container inventory provided by the shipping EDI platform

According to the above stochastic model for empty container inventory, we can find the table:

In order to realize numeric simulation application, it is essential to acquire some statistic distribution of random phenomena and obtain the result of optimization by running the test. The random phenomena mostly include the distribution of empty containers' demand and supply and the turnover of empty containers and so on. The information can be acquired completely through the information transmitted by the shipping EDI information platform. In order to explain the feasibility further, we take advantage of IFCSUM, CODECO and COEDOR to determine the statistic distribution of all kinds of random phenomena.

#### 4.1 The distribution of the inland cycling empty containers time

According the information of EDI, We can get the statistical data of the inland cycling empty container ship anchored at Shanghai port.

Firstly, we show the statistical graph of the following samples as

Figure 1 The statistical analysis of cycle time

From the above graph, we found: the density of the inland cycling time is possible to be described by the distribution of negative exponent. So we take the statistical test as follows:

The density function of the distribution negative exponent is:

$$f(t) = \frac{1}{\theta} e^{-\frac{t-\eta}{\theta}} \quad (17)$$

As

$$E(t) = \int_0^{\infty} t f(t) dt = \int_0^{\infty} t \cdot \frac{1}{\theta} e^{-\frac{t-\eta}{\theta}} dt = \eta + \theta \quad (18)$$

So we can get:

$$\eta = \eta + \theta \Rightarrow \eta = \theta \quad (19)$$

From the sample data, we work out:

$$\eta = 3.70, \theta = 2, \theta = 1.70, f(t) = \frac{1}{1.70} e^{-\frac{t-3.70}{1.70}} \quad (20)$$

Then we can get the following

Table1: The Result of Statistical

i	f <sub>i</sub>	$\hat{p}_i$	$n \hat{p}_i$	$N \hat{p}_i - f_i$	$\frac{(n \hat{p}_i - f_i)^2}{n \hat{p}_i}$
A <sub>1</sub> : 0 ≤ t < 6.5	23	0.4872	18.0277	-4.9723	1.3714
A <sub>2</sub> : 6.5 ≤ t < 12.5	10	0.3496	12.9351	2.9351	0.6660
A <sub>3</sub> : 12.5 ≤ t < 18.5	3	0.1112	4.1161	1.1161	0.3026
A <sub>4</sub> : 18.5 ≤ t < ∞	1	0.0519	1.9211	0.9211	0.4416
Σ					2.7817

With the above table, we can get:

$$\chi^2_{0.05}(k-1) = \chi^2_{0.05}(3-1) = \chi^2_{0.05}(2) = 3.841 > 1.3402 \quad (21)$$

Based on the above analysis, we conclude that the turnover time of empty container in Shanghai port follows the distribution of the negative exponent.

By using the statistical information of other ports, we can also get the above conclusion. Then we can conclude that the arriving time of the empty container follows the Poisson distribution

It should be noted that in different port, because of the difference of the delivering distance of the inland, the difference of the storing and loading time in the port and the difference of the velocity of collecting and delivering by highway, water and railway, although the extending time of the empty container still follows the distribution of negative exponent, the parameters are different.

#### 4.2 The statistical distribution rule of the container's supply and demand

In the above, we have identified the statistical distribution rule of the inland cycling time, then we can use sample data which was dogged from the database of EDI platform to analyze the distribution rule of the container's supply and demand

Firstly we show the statistical graph of the factor as follows:

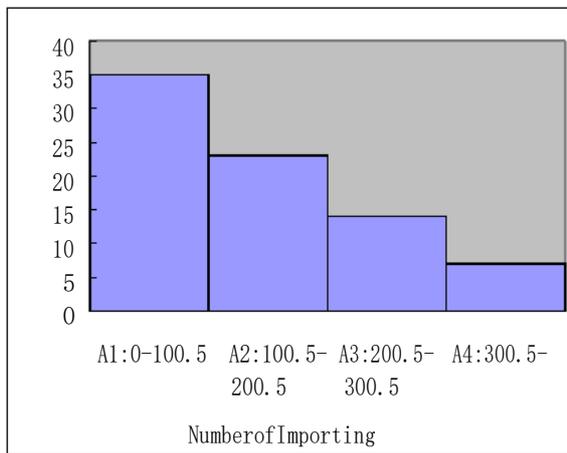

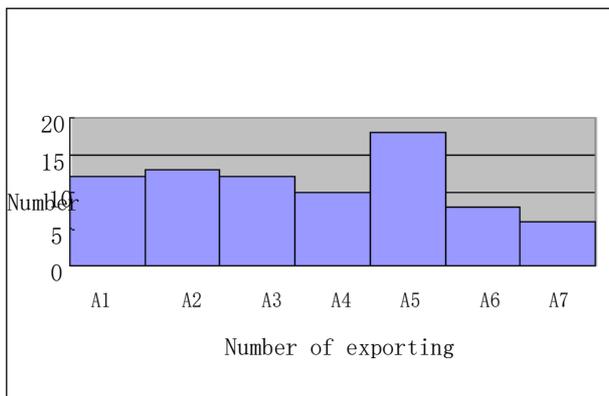

Figure 2 The statistical analysis of importing container

注: A1:0-66.5; A2:66.5-113.5; A3:113.5-160.5; A4:160.5-207.5; A5:207.5-254.5; A6:254.5-301.5; A7:301.5-

Figure 3 The statistical analysis of exporting container

From the above graph, we found: the distribution of importing empty container is resemble the negative exponent and the possible distribution of empty container follows normal distribution. So we take the similar statistical test shown in the above and we found the assumption is correct.

#### 4.3 Conclusion

From the analysis, we can find the following generally speaking, the distribution of empty container demand follows the distribution of normal distribution and that of the turnover of the empty container follows the distribution of negative. It is worthy of pointing out that it has different pattern of the distribution both at different ports and different time. Therefore, when making use of stochastic optimization model, we must get the relative EDI information actually and promptly to get the appropriate distributive pattern.

5. The developing of the decision support system (DSS) for stochastic optimization of the empty container inventory based on shipping EDI information.

Based on the model above, we adopt PB to design the DSS for stochastic optimization of container inventory based on the ports and shipping EDI information.

The system structure can be described as follows:  
(see next page)

In the above system:

The functions of the application level analysis on the container market; the optimization of the container distribution; the analysis on the container index.

The function of the data warehouse is to store the original data digged from the source of the EDI platform.

The function of database is to store some used parameters of the application level.

The function of knowledge base is to store the knowledge used by the application level.

The function of model base is to store the models used by the application level.

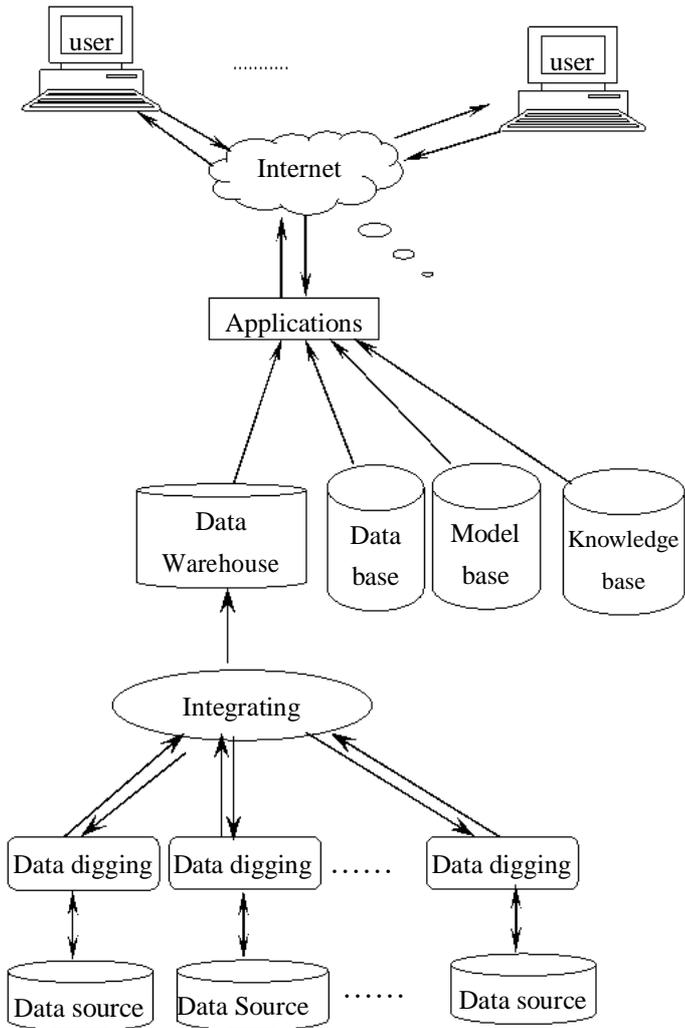

Figure 4 The Structure of DSS

Because of the limitation of time, we only design the structure and function of the whole of the system and start to develop the original system by means of PB. The task of the first phase is to realize stochastic optimization model for the empty container inventory based on EDI information. It includes three functions: digging correlative data from the EDI platform, making statistic analysis to get the distribution pattern and some parameters, and realizing the numeric simulation of the optimization models.

## Abstract

In this paper, an attempt has been made to evaluate the supplier performance by adopting evolutionary fuzzy system owing to the linguistic nature of the attributes associated with the suppliers and manufacturing units. The proposed methodology provides reasonably good performance when applied to a process industry for evaluation of supplier's performance.

## 1. Introduction

Managing of Supply Chains has gained importance for competing in the business environment in this decade. The objective of the supply chain management is to have the right product at right place at the right time. A supply chain is a network of facilities that procure raw materials, transforms them to intermediate goods and then to finished products, and delivers the products to customers through a distribution system. There are three stages in the supply chain: procurement, production and distribution.

In order to ensure the uninterrupted supply of items, purchasing manager need to periodically evaluate supplier's performance in order to retain those suppliers, which meet their requirement in terms of several performance criteria. The evaluation element typically consists of identifying the attributes, factors relevant to the decision and then measuring each vendor by considering each of the relevant factors.

It is worth to mention here that in some of the recent studies, the essential requirements advocated for suppliers' selections are quality, cost, delivery, flexibility and response [1]. In recent years, several proposals for evaluating the performance of the suppliers have been reported in the literatures. Notable among them: Categorical method, weighted point method, and cost ratio method [2, 3]. Soukep [4] suggests supplier selection strategies using weighted point method. Narasimhan [5] and Tam [6] propose an Analytic Hierarchic Process (AHP) based methodology to supplier selection. Li et al. [7] propose a new supplier performance measure employing the concept of dimensional analysis. They suggest a standardized unitless rating (SUR) by combining the weighted average of qualitative and quantitative scores associated with each supplier. Petroni and Braglia [8] use Principal Component Analysis for Vendor selection. Narasimhan et al [9] propose Data Envelopment Analysis

(DEA) for supplier evaluation and above mentioned methodologies have some advantages under specific condition only. But none offers a generic methodology, which can combine several criteria or attributes into a single measure of supplier performance. Owing to their diverse and linguistic nature, supplier attributes usually need to be categorized prior to further analysis. A cross-functional team is required to rate the supplier' attributes in linguistic descriptions like very low, low, medium, high, very high etc. Linguistic assessment of suppliers is to be carried out based on several criteria, such as quality, response to special orders, delivery performance and price. Because of the imprecise nature of linguistic attributes associated with suppliers, inconsistencies in the judgment are bound to crop up regarding the grading of supplier performance. To deal with these inconsistencies, fuzzy method is suggested to convert the suppliers' linguistic attributes into fuzzy numbers and relative supplier performance is assessed using fuzzy arithmetic.

In this paper, an evolutionary fuzzy system-based methodology is suggested for a more precise and effective assessment and evaluation of suppliers. It maintains a population of fuzzy rule sets with their membership functions, and uses the genetic algorithm to evolve a feasible fuzzy rule base. One of the key considerations in designing the proposed evolutionary fuzzy system is the generation of fuzzy rules as well as the membership functions for each fuzzy set. While dealing with a few input variables, the cross-functional teams are used to generate the fuzzy rules for several performance attributes. Since the number of fuzzy rules increase exponentially with increase in number of input variables, it is difficult for the cross functional team to define a complete fuzzy rule base for a good decision support system. It is essential to develop a genetic algorithm (GA) based methodology to evolve the optimal set of fuzzy rule base. Currently several researchers [10, 11] recommend evolutionary fuzzy systems in the areas of data classification, prediction and control problems.

## 2. Fuzzy System

In many real world applications, fuzzy systems that make use of linguistic rules are aptly suited to describe the behavior of computer systems problem, which is difficult to model mathematically. Fuzzy theorists used fuzzy sets to

represent the non statistical, uncertainty and reasoning to real life data. The membership value  $m_A(x)$  represents the grade of membership of  $x$  in  $A$ . The larger  $m_A(x)$ , stronger the grade of membership for  $x$  in  $A$ . In a  $n$ -input-single-output fuzzy system, the fuzzy rules have the following general format:

$R_j$  : IF  $X_1$  is  $Y_{1,j}$  And  $X_2$  is  $Y_{2,j}$  And ..... And  $X_n$  is  $Y_{n,j}$  Then  $Y$  is  $Z_j$

Where the variables  $X_i$  ( $i = 1, \dots, n$ ) appearing in the antecedent parts of the fuzzy rules  $R_j$  are called the input linguistic variables, the variable  $Y$  in the consequent part of the fuzzy rule  $R_j$  is called the output linguistic variables, the fuzzy sets  $Y_{i,j}$  are called the input fuzzy sets of the input linguistic variable  $X_i$  of the fuzzy rule  $R_j$ , and the fuzzy set  $Z_j$  is called the output fuzzy set of the output linguistic variable  $Y$  of the fuzzy rule  $R_j$ .

A fuzzy expert system is defined if and only if the rule sets and membership functions associated with its fuzzy sets are defined. All the fuzzy rules in a fuzzy system are fired in parallel mode. The working of a fuzzy expert system can be described as follows :

- i) Evaluate the values of fuzzy membership by energizing the inputs
- ii) Obtain the fuzzy rules which are fired in the rule set .
- iii) Adopting AND operator, club the values of membership for each energized rule
- iv) Search rule activation membership values supported by the min-max compositional rule to obtain the appropriate output fuzzy membership value.
- v) Determine the value of each output variable by defuzzification which is carried out by the weighted average method.
- vi) Take decisions according to the output values.

In this paper weighted average method is adopted to defuzzify the fuzzy output data as this methodology is only valid for symmetric output membership function. based on the crisp output data, practical decisions can be made to solve the problems. In this paper based on the crisp output data, the suppliers performance are graded.

### 3. Evolutionary Fuzzy Systems

It has been observed that majority of the existing applications, the fuzzy rules are generated by experts and decision makers conversant with the problem, with only a few inputs. The possible number of fuzzy rules for a given system grows exponentially when the number of input variable increases. For example in the evaluation of a supplier performance with 10 attributes and each attribute consists of 5 linguistic descriptions ( very low, low, medium, high, very high ) then the possible number of fuzzy rules are  $5^{10}$ . It is too difficult if not impossible for an expert to define a complete rule set for assessing the system performance. There are several methods like clustering algorithms, pattern classification methods etc. to practice an automated way to design fuzzy system. These methods are possessing a drawback related to the extractions of rules where it is possible that these rules become the independent of membership functions leading

to degraded performance of the fuzzy system especially in the case of complex system problem with large number of input variables. In several cases, the systems performance are found to be improved by tuning the membership functions and selecting suitable fuzzification and defuzzification methods. In this paper, evolutionary fuzzy system have been employed in which the fuzzy rule set, number of rules inside the rule set are generated using a powerful and intelligent search algorithm known as Genetic Algorithm to assess the supplier performance. Genetic Algorithms have recently found its growing applications in solving the several types of linear and non-linear optimization problem. GA is a matured tool and interested readers are advised to refer Goldberg[12]. This fact motivated the researchers to use this intelligent optimization tool for the generation of a set of fuzzy rules required to design the fuzzy rule base. The various constituents of the proposed evolutionary fuzzy system are described as follows.

#### 3.1 Representation

The first important consideration while designing a fuzzy expert system using GA is the representation strategy adopted to encode the fuzzy system into the chromosome. A fuzzy system is well defined only when the fuzzy rule base and the membership functions associated with each fuzzy set of a variable are specified. Thus, it is practically realized that to completely represent a fuzzy expert system, each chromosome must encode all the requisite information about the rule sets and the membership functions. The fuzzy rules in the rule base and the number of such fuzzy rules that are associated with the problem are to be evolved using GA. In order to reduce the search space, it is advocated that the maximum number of rules concerning any problem is fixed in advance. After performing exhaustive trial and error experimentation, the maximum number of acceptable rules undertaken in this study is limited to 40. Then the total length of the chromosome representing the system is  $1+5*(40)=201$ , and the system can be represented as  $S_1S_2S_3S_4S_5S_6 \dots S_{57}S_{58}S_{59} \dots S_{140}S_{141} \dots S_{199}S_{200}S_{201}$ ,

Where  $S_1$  represents the number of rules varying between 1 and 40,  $S_2, S_3, \dots, S_6$  encodes the first fuzzy rule in the rule set and  $S_{197}, S_{198} \dots S_{201}$  represents the last fuzzy rule in the rule set.  $S_1$  denotes the number of possible rules that are used to design the rule base. However, it is observed that each rule may not be feasible. A rule with a zero antecedent or consequent part is an infeasible rule and should be excluded from the fuzzy rule base. In order to ensure that the chromosome contains no infeasible rules, the fitness value corresponding to the chromosome is assigned to a very small floating number  $[0,1]$ , so that these chromosomes do not pass over to the next generation.

#### 3.2 Fitness Function

While the genotype representation encodes the rule base into a integer string, the fitness function evaluates the performance of the rule base. For prediction and

estimation problems, the mean-square error or difference error related function is most commonly used. In this paper, the mean square error function is determined to evaluate the fitness of the chromosomes.

$$E = 1/N \sum (o_i - e_i)^2 \quad \dots (1)$$

Where N is the number of evolved fuzzy rules.,  
 $o_i$  and  $e_i$  are the  $i^{\text{th}}$  expected outputs obtained by assigning priorities to the input variable

$$\text{Fitness Value} = 1 / (1 + E) \quad \dots (2)$$

Chromosomes with higher fitness value are carried to the next generation.

### 3.3 Crossover Operator

Crossover is a process by which two parent strings recombine to produce two new offspring strings. An overall probability is assigned to the crossover process. Given two parent chromosomes, the algorithm invokes crossover only if a randomly generated number in the range of 0 to 1 is greater than crossover rate ( it is also known as crossover probability), otherwise the strings remain unaltered. This probability is often in the range of 0.65-0.80.

### 3.4 Mutation Operator

After crossover, normally strings are subjected to mutation. Mutation operator randomly alters few composition of a string to produce a new offspring instead of recombining two strings. In a traditional genetic algorithm, mutation of a bit involves flipping it : changing a "0" to "1" or vice versa. It is found that the chromosome representing the fuzzy expert system is integer based instead of binary based i.e., each element of the string has an integer range representing the various states of the variable ( input / output ). The mutation operator used is thus a bit different than that used in binary encoding. Each time an element is chosen to be mutated, it is increased or decreased by replacing it by an integer in the range[ 1, 5] excluding the present value of the element . The integers of the string are independently mutated i.e., the mutation of the element does not influence the probability of mutation of another element.

## 4. Computational Exercise

The supplier performance is graded based on the attributes, which were selected from both the supplier and product's view point. They are namely quality rating, delivery performance, price rating, and service rating. In order to evolve the fuzzy rule base using Genetic Algorithms, a good fitness function is essential. Here, a least mean square function is adopted for fitness measurement, where the expected outputs are determined by prioritizing the attributes. Each feasible fuzzy rule that is evolved in the rule base has the maximum prioritized attribute in the first position, the next prioritized attribute in the second position and like wise. These priorities are analogous to weightages that are assigned to the attributes and reveals the relative importance among themselves. The fuzzy membership functions associated with the fuzzy sets of each inputs are left-triangle, triangle, triangle,

triangle, and right-triangle corresponding to the description very low, low, medium, high and very high.

The ranges and the overlap area of the membership functions are fixed. A triangular fuzzy membership function has been adopted for the representing the fuzzy sets of the output variable.

## 5. Conclusions

Supplier performance evaluation is one of the important ingredients for the successful implementation of the strategies of supply chain. Several recent studies with regard to suppliers performance were critically examined. A novel methodology based on the fuzzy logic and genetic algorithm is employed to assess the performance of supplier.

## Abstract

In this paper we will examine some implications of online data for a classical operations management model, vis. the Economic Order Quantity model. Customer waiting behavior on individual orders (which occur during stockouts) forms the basis for evaluating the potential backorders. The potential attraction of reducing inventory holding costs must be balanced with the loss due to lost sales. We clearly delineate the conditions under which it is profitable to stock out every ordering cycle, and the conditions under which the traditional economic order quantity model still holds. In order to allow practical application of the model, we develop a number of different approaches to the problem of estimating the backorder function from available on-line transaction data.

## 1. Introduction

The emergence of web based online retailing has changed the manner in which customer behavior can be tracked and profiled. A recent article profiling Yahoo presents the potential and pitfalls in utilizing this data for new business models [10]. New tools are available that allow one to target promotions and product offerings to customers predisposed to purchasing them as indicated by customers' observed past behavior.

The availability of extensive customer purchase behavior data is changing the way in which different functional areas can formulate optimal tactics and strategies. This has particular relevance for marketing. For instance; Active Buyers Guide helps visitors select models of various consumer electronic items (see <http://www.activebuyersguide.com>). They evaluate the customer's preferences for attributes by conducting a factor analysis using dynamically generated flash card comparisons. Similarly, in retailing, some sites track the online browsing behavior and have a history of items that a particular customer finds interesting. This data is used to suggest similar items for purchase. Amazon (<http://www.amazon.com>) is a popular retailer with extremely sophisticated customer management. "What Amazon.com has done is invent and implement a model for interacting with millions of customers, one at a time" (see [1]). "Customers love Amazon not because it offers the lowest prices--it doesn't--but because the experience has been crafted so carefully that most of us actually enjoy

it" (see [6]).

There are implications for inventory management as well. As an example, this data is also being used to suggest alternate items in case a particular item is out of stock, or to provide an updated estimate for the waiting time till new stock arrives. This allows the customer to make informed choices about substitution and/or backordering. This behavior is now visible to the retailer, and can form the basis for better business decisions. The challenge is not merely to suggest replacement items or provide waiting times, but to use operational policies and management strategies to better support this interaction between the firm and the customer.

In this paper we will examine some implications of online data for a classical operations management model, vis. the Economic Order Quantity model. Customer waiting behavior on individual orders (which occur during stockouts) forms the basis for evaluating the potential backorders. The potential attraction of reducing inventory holding costs must be balanced with the loss due to lost sales. We clearly delineate the conditions under which it is profitable to stock out every ordering cycle, and the conditions under which the traditional economic order quantity model still holds. In order to allow practical application of the model, we develop a number of different approaches to the problem of estimating the backorder function from available on-line transaction data.

## 2. Literature Survey

There is a significant body of recent literature on online retailing. The increasing popularity of the web has led to an explosion of research related to retail substitution behavior (see [2] [3] [8] [14] [21]). These papers illustrate the effect of detailed customer behavior data on the Operations Management literature.

The EOQ formula was initially derived in [11], and the related literature is voluminous, see e.g. [9] [23]. The EOQ model with backorders has been discussed by [9] as well. They consider a linear backorder function, and derive a policy based on a backorder cost per unit backordered per time unit.

A number of authors have extended the EOQ model by considering backorders. Backorder models where only a fraction of the demand is backordered when a stockout occurs are examined in [15] [16] [20] [22]. Our model easily handles these kinds of mixtures between backorders

(pent-up demand) and lost sales. Our model does not have explicit costs of not satisfying demand from on-hand stock. Instead, some of the demand during the stockout period turns into lost sales, which reduces revenue for the retailer.

Backorders have been the subject of extensive research in the context of stochastic models. An order point order quantity model with a mixture of backorders and lost sales is investigated in [18]. Lost sales will occur when backorders exceed a certain threshold level. General backorder costs in stochastic inventory models are discussed in [5].

The cost structure of backorders has been extended by some authors. Inventory policies when the backorder costs have fixed and proportional components are examined in [4]. Another approach to modeling the effect of stock-outs can be found in [17], where it is assumed that the demand rate is influenced by backorders. However, to the best of our knowledge, the approach to modeling the effect of stockouts presented in our model is new, as is the characterization of conditions under which periodic availability is an optimal policy.

There is also extensive research on perishable inventories, when the stock at hand may decay, or become obsolete. One representative paper [13] integrates the stocking decision with backordering. While we do not have perishable inventories, we have “perishable” backorders, in the sense that backorders grow less than proportionately with the elapsed stockout time.

Finally, in [12] a recent paper uses an exponential pent-up demand function in the context of stochastic lead times. Lee focuses on algorithms to obtain the optimal stockout period without deriving any structural results. This is the only paper we have found so far which examines a non-linear pent-up demand function. In contrast, our paper presents the structural results for any pent-up demand function, as well as the parametric conditions under which three different policies are optimal: the EOQ stocking policy, the periodic stocking policy and the no-inventory policy.

Many EOQ inventory models focus on inventory as a cost, as the original work [11] did. The decision maker controls a cost center, and attempts to minimize costs while delivering a certain service level. Often, this leads to situations where the optimal decision is unprofitable, as already observed in [22]. In contrast, our objective is to maximize profits, which allows us to choose not to operate if it is not profitable.

A different way to think of the periodic availability policies in this paper is as a bridge between classical “supply from inventory” policies (where a retailer attempts to fill demand from on-hand stock) and stockless retailing policies (where the retailer acts purely as an order taker who passes the demand on to his supplier). Indeed, both extremes are special cases of our general model.

We use fractional programming to solve the discounted cash flow optimization. A good introduction to non-linear fractional programming can be found in [7]. Our

algorithm is similar, but specifically crafted for our needs.

### 3. The Inventory Model

We make all the standard assumptions of the Economic Order Quantity (EOQ) model, but with some additional assumptions regarding what happens when the retailer runs out of stock (which is not allowed in the EOQ model). The retailer experiences a constant deterministic demand of  $D$  units of product per unit time for a given product. The retailer can place an order at any time for any quantity of product desired, and the delivery will be made after a constant lead time. There is a fixed order cost of  $F$  per order placed, a purchasing cost of  $c$  per unit purchased, non-financial inventory holding cost of  $h$  per unit kept in inventory per unit time, and since we will use continuous time discounting, a discount rate of  $r$  per time unit. The retailer sells items at a price of  $p$  per unit sold. The retailer seeks to maximize total discounted profit.

Contrary to the standard EOQ assumptions, we assume that when the retailer runs out of stock, some of the demand is backordered and some of the demand is lost. In particular, if the retailer has been out of stock for  $t$  time units, the total “pent-up” or backordered demand equals  $\bar{D}(t)$ . The function  $\bar{D}(t)$  is assumed to satisfy the following properties:  $\bar{D}(0) = 0$ ,  $\bar{D}(t)$  is concave and non-decreasing, and  $\bar{D}(t) - \bar{D}(s) \leq (t - s)D$  for all  $t > s \geq 0$ . Of course if  $\bar{D}(t)$  is differentiable, these conditions can be stated as  $0 \leq \bar{D}'(t) \leq D$ , and  $\bar{D}'(t)$  is non-increasing. It will be convenient to use a scaled version of the pent-up demand function, so we define  $k(t) = \bar{D}(t)/D$ . This function will therefore satisfy the following assumptions:

$$k(0) = 0,$$

$k(t)$  is non-decreasing and concave.

Define the subdifferential  $\partial k(t)$  of  $k$  at  $t$  as the set of all values  $x$  such that  $k(s) \leq k(t) + x(s - t)$  for all  $s \geq 0$ . In particular the assumptions imply that  $k$  is almost everywhere differentiable, and that the subdifferential  $\partial k$  always exists and is decreasing in the obvious sense, i.e., if  $t < s$ , then  $k'(t) \geq k'(s)$  for every  $k'(t) \in \partial k(t)$  and  $k'(s) \in \partial k(s)$ .

Using standard dynamic programming arguments, it is easy to see that a cyclic policy is optimal. For convenience, we will assume that the retailer starts with no stock, and with no backorders. The retailer must then decide, first, how long to allow backorders to build up before taking delivery ( $t$ ), and second, how long ( $x$ ) to keep the item in stock after that. Either of these time periods can be zero: if  $t = 0$ , the classical EOQ situation results, if  $x = 0$ , the retailer follows a “stockless” policy, i.e., the retailer is basically just an order taker.

Hence during a single cycle the following events occur. At time 0 (the start of the cycle), the retailer runs out of stock. Pent-up demand accumulates during the next  $t$  time units. At that moment, an order of  $Q$  units of product is received. The pent-up demand  $\bar{D}(t)$  is satisfied as soon as the delivery of product is made at time  $t$ , so the resulting

inventory is  $Q - \bar{D}(t)$ . Note that it doesn't make sense to not satisfy all the pent-up demand at time  $t$ : the retailer could just order  $\bar{D}(t) - Q$  more units and sell them immediately at time  $t$ . This would lead to a positive cash flow of  $(p - c)(\bar{D}(t) - Q)$  at time  $t$ . If this pent-up demand is not satisfied at time  $t$ , some of it may turn into lost sales, and the net present value of the remainder is reduced because of discounting.

During the interval  $(t, t + x)$ , the inventory of  $Q - \bar{D}(t)$  is drawn down at a rate of  $D$  by the regular demand, and at time  $t + x$  the retailer runs out of stock again. Hence

$$x = (Q - \bar{D}(t)) / D = Q/D - k(t) \quad (1)$$

or 
$$Q = D(x + k(t)). \quad (2)$$

Finally, to avoid pathological cases, we assume  $p > c \geq 0$ ,  $F > 0$ ,  $h > 0$ .

#### 4. The Optimal Inventory Policy

We first derive an expression for the net present value associated with a policy  $(x, t)$ . We assume that at time 0 the retailer runs out of stock. Then during the interval  $(0, t)$  there are no cash flows. At time  $t$ , the retailer purchases  $D(x + k(t))$  units of product at discounted cost  $e^{-rt}(cD(x + k(t)) + F)$ . At the same time, the retailer sells  $Dk(t)$  units with a discounted revenue of  $e^{-rt}pDk(t)$ . During the interval  $(t, t + x)$  the retailer sells  $D$  units of product per time period, which leads to total discounted revenue of

$$pD \int_t^{t+x} e^{-ry} dy = p \frac{D}{r} e^{-rt} (1 - e^{-rx}).$$

During this time interval inventory decreases from  $Dx$  to 0, which means that the discounted holding cost over this period equals

$$hD \int_t^{t+x} (t + x - y) e^{-ry} dy = h \frac{D}{r} e^{-rt} (x + \frac{e^{-rx} - 1}{r}).$$

Define  $\alpha = D(p - c)$ ,  $\beta = (D/r)(p + h/r)$ , and  $\gamma = (D/r)(c + h/r)$ . Then the discounted value of all cash flows during the first cycle can be expressed as

$$e^{-rt} (\alpha k(t) - F - \gamma rx + \beta(1 - e^{-rx})).$$

Finally the total discounted value of all cash flows for an infinite horizon is the single cycle value multiplied by  $1/(1 - e^{-r(t+x)})$ , which equals

$$\pi(x, t) = \frac{\alpha k(t) + \beta(1 - e^{-rx}) - \gamma rx - F}{e^{rt} - e^{-rx}}. \quad (3)$$

It is not hard to show that in maximizing (3) we can confine ourselves to the region

$$\Psi = \{(x, t) : x \geq 0, t \geq 0, (x, t) \neq (0, 0)\}$$

Hence we want to find

$$G^* = \sup \{\pi(x, t) : (x, t) \in \Psi\} \quad (4)$$

Define the function

$$f(x, t, G) = \alpha k(t) + \beta(1 - e^{-rx}) - \gamma rx - F - G(e^{rt} - e^{-rx}),$$

then we can write

$$G^* = \sup \{G : f(x, t, G) = 0, (x, t) \in \Psi\}. \quad (5)$$

We will exploit the fact that  $f$  is (jointly) concave in  $x$  and  $t$  to develop an efficient algorithm for solving problem (4).

Before we can characterize the optimal policy, we need some lemmas.

**Lemma 1**  $G^* < \beta - \gamma$ .

Proof: First, note that for all  $t \geq 0$  we have

$$\alpha k(t) \leq \alpha t = (\beta - \gamma)rt \leq (\beta - \gamma)(e^{rt} - 1),$$

and for all  $x \geq 0$  we have

$$\beta(1 - e^{-rx}) - \gamma rx \leq (\beta - \gamma)(1 - e^{-rx}),$$

hence for every  $(x, t) \in \Psi$  we have

$$\pi(x, t) \leq \frac{(\beta - \gamma)(e^{rt} - e^{-rx}) - F}{e^{rt} - e^{-rx}} < \beta - \gamma. \quad \square$$

**Lemma 2** Let  $0 < G < \beta - \gamma$ . The problem

$$z_G = \max \{f(x, t, G) : x \geq 0, t \geq 0\} \quad (6)$$

has a unique solution  $(x_G, t_G)$  given by

$$rx_G = \ln(\beta - G) - \ln \gamma, \quad (7)$$

$$0 \text{ if } \alpha k'(0) \leq rG,$$

$$t_G = \text{the unique value } t \text{ for which} \quad (8)$$

$$\alpha k'(t) = rGe^{rt} \text{ otherwise.}$$

(If  $k$  is not continuously differentiable, then  $k'(t)$  should be interpreted as a suitably chosen subdifferential of  $k$  at  $t$ ).

Proof: Note that  $f$  is separable in  $x$  and  $t$ . It is thus straightforward to show that  $f$  is jointly concave in  $x$  and  $t$ , and that (7) and (8) are the first order conditions for a global maximum.  $\square$

**Lemma 3** Let  $0 < G < \beta - \gamma$ . Then

$$\text{sign}(z_G) = \text{sign}(G^* - G).$$

Proof: We consider the obvious three cases separately.

**Case 1:**  $z_G > 0$ . Define  $\varepsilon = z_G / (e^{rt_G} - e^{-rx_G}) > 0$ , then  $f(x_G, t_G, G + \varepsilon) = f(x_G, t_G, G) - \varepsilon(e^{rt} - e^{-rx}) = 0$ , and hence  $G^* \geq \pi(x_G, t_G) = G + \varepsilon > G$ .

**Case 2:**  $z_G = 0$ . Then  $f(x_G, t_G, G) = 0$ , and since  $f(0, 0, G) = -F < 0$ , this implies  $(x_G, t_G) \neq (0, 0)$ , so  $(x_G, t_G) \in \Psi$  and  $G^* \geq \pi(x_G, t_G) = G$ . Furthermore, for arbitrary  $(x', t') \in \Psi$  we know  $f(x', t', G) \leq 0$ , and since  $f$  is strictly decreasing in  $G$  on  $\Psi$ , this implies by (5) that  $G^* \leq G$ . We conclude that in this case  $G^* = G$ .

**Case 3:**  $z_G < 0$ . We need to show  $G^* < G$ . If  $G^* \leq 0$ , we are done, since the lemma assumes  $G > 0$ . So assume  $\varepsilon = \pi(x', t') > 0$  for some  $(x', t') \in \Psi$ . We will next show that  $\Phi = \{(x, t) \in \Psi : \pi(x, t) \geq \varepsilon\}$  is compact. Note  $\Phi = \{(x, t) \in \Psi : f(x, t, \varepsilon) \geq 0\}$ , and since  $f(0, 0, \varepsilon) = -F < 0$ ,  $\Phi = \{(x, t) : f(x, t, \varepsilon) \geq 0, x \geq 0, t \geq 0\}$ . Since  $f$  is continuous in  $x$  and  $t$ , it follows that  $\Phi$  is closed. Using that  $f$  is separable and concave and that  $f$  tends to  $-\infty$  when either  $x$  or  $t$  tends to  $\infty$ , it is not hard to show that  $\Phi$  is bounded. Hence

$$G^* = \sup \{ \pi(x, t) \mid x \in \Psi \}$$

$$= \sup \{ \pi(x, t) \mid x \in \Phi \}$$

$$= \pi(x^*) \quad \forall t$$

for some  $(x^*, t) \in \Psi$ . But since  $x^* \leq z_0 < 0$ , this implies  $x^* < G$ .

The three cases together imply the lemma.

**Lemma 4** Define  $k(\infty) = \lim_{t \rightarrow \infty} k(t)$ , then

$$k(\infty) + \beta - \gamma(1 - \beta) > F \Leftrightarrow G^* > 0. \quad (9)$$

**Proof:** Note  $f(t) = k(t) - \beta - \gamma(1 - \beta)$  for every  $t \in \Psi$ , and that the bound is tight (easily shown using the same approach as the proof of Lemma 2). Hence if the condition on the left in (9) is true, there exists a  $t \in \Psi$  such that  $f(t) > 0$ . But this implies  $\pi(x^*, t) > 0$ . If on the other hand the condition on the left in (9) is false, then for every  $t \in \Psi$ ,  $f(t) \leq 0$ , and this implies  $G^* \leq 0$ .

**Theorem 1** If  $k(\infty) + \beta - \gamma(1 - \beta) > F$ , then the optimal policy  $(t^*, x^*)$  satisfies

$$t^* = \frac{1}{r} \ln \left( \frac{\beta - G^*}{\gamma} \right), \quad (10)$$

$$x^* = \begin{cases} \frac{1}{\gamma} \ln \left( \frac{\beta - G^*}{\gamma} \right) & \text{if } \beta - \gamma k'(0) > G^* \\ 0 & \text{otherwise} \end{cases} \quad (11)$$

$$k(t^*) - G^* e^{rt^*} + \beta - \gamma F - \gamma \ln \left( \frac{\beta - G^*}{\gamma} \right) = 0. \quad (12)$$

If  $k(\infty) + \beta - \gamma(1 - \beta) \leq F$ , then  $G^* = 0$  (i.e., it is optimal never to purchase the item).

**Proof:** Lemmas 2 and 3 imply that the values  $t^*$  and  $x^*$  satisfy equations (10), (11)

$$k(t^*) - G^* e^{rt^*} + \beta(1 - e^{-rx^*}) + G e^{-rx^*} - \gamma r x^* - F = 0.$$

Substituting (10) into this last equation gives (12). The statement follows from lemma 4 and the fact that  $k(t) \rightarrow \infty$  as  $t \rightarrow \infty$  for any fixed  $x$ .

Theorem 1 gives exact optimality under the conditions:

**Corollary 1** Assume  $k(\infty) + \beta - \gamma(1 - \beta) > F$ , and let  $G$  satisfy the equation

$$G + \gamma \ln \left( \frac{\beta - G}{\gamma} \right) = \beta - \gamma F, \quad (13)$$

then  $t^* = 0$  if and only if  $k'(0) \leq \frac{1}{\alpha} G$ .

Corollary 1 gives the precise conditions under which the classical EOQ policy (of not planning to run a stock) is optimal. Theorem 1 inspires the following efficient algorithm to identify the optimal policy and its notation.

define  $f(t) = k(t) - \beta - \gamma \ln \left( \frac{\beta - G}{\gamma} \right) - \gamma F$ ,

**Algorithm A:**

IF  $\lim_{t \rightarrow \infty} \hat{f}(t) \leq 0$  THEN

$$t^* = \infty; G^* = 0$$

ELSEIF  $\hat{f}(0, \beta - \gamma) k' < 0$  THEN

let  $x^*$  be the unique solution to the

$$t \text{ equation } \hat{f}(t, \beta - \gamma) e^{-rt} - k'(x^*) = 0 \quad (14)$$

(if  $k$  is not differentiable, is a

chosen  $k(x)$  gradient of  $k$  at suitably

$$x^* := (\beta - \gamma) e^{-rt} - k'(x^*)$$

ELSE  $t^* = 0$ ;

$$t^* = 0;$$

let  $G^*$  be the solution to the equation

$$\hat{f}(G^*, G^*) = 0 \quad (15)$$

END IF

$$x^* = \frac{1}{r} \ln \frac{\beta - G^*}{\gamma}$$

To prove the correctness of the algorithm, we need the following technical lemma.

**Lemma 5** The function  $h(t) = \hat{f}(t, \beta - \gamma) e^{-rt} - k'(x)$  is increasing in  $t$ , and by appropriate choices of  $x$  all values  $\hat{f}(0, \beta - \gamma) k'$  and  $\lim_{t \rightarrow \infty} \hat{f}(t, 0) \leq 0$  as  $t$  varies from  $\emptyset$  to  $(0)$ .

**Proof:** Note that we can

$$\text{write } h(t) = h_1(t, k_3(t_2)) - h_2(t, k_3(t_2)) \quad (16)$$

where  $(t, k_3(t))$

$$h_1(t) = \alpha \left( k(t) - \frac{1 - e^{-rt}}{r} k'(x) \right) - \gamma F,$$

$$h_2(t, k_3(t)) = \frac{1}{\gamma} (\beta - (\beta - \gamma) e^{-rt} - k_3(t)),$$

$$h_3(x) = \gamma(x - \frac{1}{r} \ln \frac{\beta - G^*}{\gamma})$$

Note that  $h_2(t, k_3(t))$  is increasing in  $t$ , and it can all values between  $\beta - (\beta - \gamma) k'(0) \gamma \geq 1$  and  $\beta - \gamma$  by

choosing appropriate values for the subgradient  $k_3(t)$ .

Note also  $h_3(x)$  is increasing in  $x$ . We can conclude that the second term of (16) is increasing

can't assume all values  $h_3(t) = (0, k_3'(0))$

between  $\beta - \gamma$  and  $\beta - \gamma k_3'(0)$ .

Next, we will show  $h_1(t, k_3(t))$  is increasing in  $t$

what. Choose  $x \geq 0$ . Note that the concavity

implies that  $-k(s) \geq -k(t)$  and  $s k'(s) \leq t k'(t)$

for every choice of subgradients  $k'$  of  $k$  at  $s$  and  $t$ .

Hence  $\frac{1}{\alpha} h_1(s, k_3(t)) - (h_1(t, k_3(t)))$

$$= k(s) - \frac{e^{-rs}}{r} k'(s) - \left( k(t) - \frac{e^{-rt}}{r} k'(t) \right)$$

$$\geq (s - t) \left( k'(t) - \frac{e^{-rs} - e^{-rt}}{r} k'(s) \right)$$

$$= (s - t) e^{-rt} \frac{1 - e^{-r(s-t)}}{r(s-t)} (s - t) k'(s)$$

$$\geq (s - t) (1 - e^{-rt}) k'(s) \geq 0,$$

where the next to last inequality follows  $x \leq x$

for all  $x$ . Hence  $h_1(t, k_3(t))$  is increasing in  $t$  and

all values between  $\beta - \gamma$  and  $\beta - \gamma k_3'(0)$  (inclusive) and

$k(\infty) - \gamma - F$  (the latter value possibly excluded).

**Theorem 2** Algorithm A correctly solves problem (4).

**Proof:** The IF condition of the algorithm is satisfied under which the retailer can't make a profit on the item (see the last part of theorem 1). So  $G_* = 0$  if it is satisfied. Define  $G = (\beta - \gamma)k'(t)$  and  $x_i = (\ln(\beta - \gamma)k'(t)) / \gamma$ , and the ELSEIF condition of the algorithm is  $z_i < 0$  which is equivalent to  $G < 0$  by lemma 3. Hence if the ELSEIF condition is satisfied,  $G_* = (\beta - \gamma)e^{-\gamma t} / k'(t)$  by (11) and substituting (12) gives  $t$  (14). If  $t \neq 0$  by (11) and substituting this into (12) gives (15). Finally, lemma 3 guarantees that (14) has a unique solution where (1) needs to be solved, and it is easy to show that (15) holds for (15).

A few comments are in order. First, note that the optimality of planned stockouts (the ELSEIF test of the algorithm) depends only on  $k$  the fraction of demand that is not immediately lost at the moment the retailer first stock. The condition is always satisfied when  $\theta < 1$ , so some stockouts will always be optimal. In the other hand,  $\theta > 1$ , the optimality of having some stockouts depends on the value of the fixed order costs  $F$ , and for small enough values of  $F$  it will be optimal to avoid stockouts altogether. When the IF and ELSEIF tests in the algorithm actually coincide (note  $\theta = 0$  implies  $k(t) = 0$  since  $k$  is normalized, non-concave) and hence either the retailer doesn't sell at all or he wants to avoid stockouts altogether.

The decision on whether to sell the item at all (the IF the algorithm) depends only on the maximum (normalized) fraction of demand that is not sold when the retailer has no stock for a very long time. The specific form of the function  $k$  plays a very important role in making these basic decisions. Of course in order to get an optimal stocking policy in the case that planned stockouts are optimal, more information about the demand function is necessary. Note that equation (15) can be solved using Newton's method to find the unique solution of the equation  $\gamma = \ln \gamma - \gamma$  (a convenient starting point is  $\gamma = +1$  (if  $\gamma > 2$ , the solution to the equation obtained approximately  $1 + \frac{1}{2}(\gamma - 1)^2$ ), and from calculating  $\gamma = \beta - \gamma_*$ . Equation (14) can of course be solved using bisection. When  $k$  is differentiable, the conditions which the LHS of (14) is concave involve the derivative of  $k$ , so a simple implementation of Newton's method is not recommended.

When  $k$  is piece-wise linear, the LHS of (14) is in fact convex between breakpoints of  $k(t)$ , while it is concave in

$k'(t)$  at the breakpoints. Hence once the segment which contains  $t$  has been identified, a set of Newton-Raphson steps will quickly yield the solution with great accuracy.

## 5. Estimating the backorder function

In this section we turn to the issue of modeling the backorder function. In particular, one needs to backorder the function. We will sketch a number of approaches to this estimation problem that could be used in various circumstances. Assume that a web retailer uses a web site that provides potential customers with information on how long it will be until the retailer can ship the product. Customers place an order for one unit of the product which will be shipped as soon as it becomes available, for they exit without ordering. The retailer collects the following information related to a particular product of interest. Over a period of  $M$  days, the retailer responded to  $n_i$  inquiries that the shipping delay is  $i$  days, and these  $n_i$  sales would be  $s_i$ . Note that even when the product is available for some potential customers still don't place an order. From this data we wish to estimate the underlying demand rate and the (scaled) pent-up demand function  $k(t)$ . We assume that inquiries are generated according to some stationary process with a rate  $\lambda$  per day. Let the random variables  $S_{ij}$  denote the number of units resulting from the  $j$ -th inquiry that occurs when the shipping delay is  $i$  days. We assume  $S_{ij}: j = 1, 2, \dots$  are iid random variables with mean  $\tau_i$ . If  $\tau_i$  for  $i = 0, \dots, N$  are available, one can estimate the pen-up demand function by linear interpolation on these estimates:

$$\hat{k}(t) = \frac{1}{\tau_0} \sum_{i=1}^N \tau_i \cdot \mathbb{1}_{[i, i+1)}(t), \quad i = 0, 1, 2, \dots, N.$$

The straightforward approach to estimating the average number of units sold per inquiry as a function of the number of days until shipment is of course

$$\tau_i^{naive} = s_i / n_i.$$

The problem with this approach is that the resulting pent-up demand function need not be concave, since it is possible that in the available data  $s_j > i$ . Of course it is counter-intuitive (to at least) that a longer shipping delay would lead to a higher number of units sold per inquiry, so we require that our estimates satisfy  $0 \leq \tau_N \leq \tau_{N-1} \leq \dots \leq \tau_0 \leq 1$ .

In the remainder of this section we discuss several ways to handle this estimation problem.

### 5.1 Parameter Estimation from a Functional Form

The exponential pent-up demand function is given by

$$\bar{D}(t) = \frac{\theta}{\kappa} (1 - e^{-\kappa t}).$$

This form arises if we assume that pent-up demand satisfies the differential equation  $\dot{p} = \theta - \kappa p(t)$  with starting condition 0. Here  $\theta$  is the rate at which pent-up demand dissipates (e.g. because it is satisfied by a competitor or because it is required by consumers), and the fraction of pent-up demand that is not immediately available to radioactive decay. It is not hard to show that the exponential demand-up function satisfies our assumptions. To the complete, we have  $k(\infty) = \theta/\kappa$ ,  $k'(t) = \theta(1 - e^{-\kappa t})/\kappa$ , and  $k'(0) = \theta$ .

A simple approach to estimating values and this to minimize the squared sum of errors between the calculated using the naïve  $\hat{p}_i^{naive}$  and the values of  $k$  estimated with the specified functional form is the logarithmic function given by  $\bar{D}(t) = \frac{\theta}{\kappa} \ln(1 + \kappa t)$ .

It is easy to verify that this implies  $k(t) = \frac{\theta}{\kappa} \ln(1 + \kappa t)$ ,  $k(\infty) = \frac{\theta}{\kappa}$ ,  $k'(t) = \frac{\theta}{1 + \kappa t}$ , and  $k'(0) = \theta$ .

5.2 The Customer Utility Approach

Define the average residual  $\bar{U} = \bar{U} - p$ , where  $\bar{U}$  is the utility that the average customer derives from the item if it is immediately available, and  $p$  is the purchase price. In addition, a customer has a waiting time for the item, so let  $b(x)$  be the backorder cost if the customer has to wait  $x$  time units. Then a customer decides to purchase the item if and only if  $R - b(x) \geq 0$ , where  $R$  is a customer specific variable with mean 0, and  $x$  is the time the customer has to wait for the item. For specific functional forms, one can use probit or logit regression to estimate  $\Pr(R + \epsilon \geq 0)$ , and the normalized pent-up demand function is calculated as  $k(t) = \int_0^t \Pr(\epsilon > b(x) - \bar{R}) R$ .

Clearly, since  $\epsilon > b(x) - \bar{R}$  is non-increasing in  $x$ ,  $k(t)$  cannot exceed the value of 1, and the resulting function satisfies the standard assumptions of section 2. If the function  $b(x)$  is assumed to be linear, then the estimation leads to  $k(t) = \frac{1}{\kappa} [\Phi(-v) - \Phi^1(\kappa t - v)]$ ,  $k'(t) = \Phi(\kappa t - v)$ ,  $k'(0) = \Phi(-v)$ , and  $k(\infty) = \frac{1}{\kappa} \Phi(-v)$ .

where  $\Phi$  denotes the standard normal cumulative distribution function,  $\Phi(y) = \int_{-\infty}^y \phi(z) dz$  is the familiar standard normal linear loss function (see page 458),  $v$  and  $\kappa$  are parameters obtained from the probit regression. Clearly, the estimated parameter

If the function  $b(x)$  is assumed to be linear, then the estimation leads to  $k(t) = \frac{1}{\kappa} [\ln(1 + e^v) - \ln(1 + e^{v - \kappa t})]$ ,  $k'(t) = 1/(1 + e^{v - \kappa t})$ , and  $k(\infty) = \frac{1}{\kappa} \ln(1 + e^v)$  where  $v$  and  $\kappa$  are parameters obtained from the regression and again we need be positive.

The utility approach has as additional advantages on our correct for price changes (and possibly environmental factors) in the estimation, as well as something about the impact of price changes (and additional environmental factors) on optimal policy, profit,

5.3 Piecewise Linear Approximation Using Isotonic Regression

We can use a constrained maximum-likelihood approach to obtain  $\hat{\tau}$  for the  $\tau$  that satisfies the constraints  $0 \leq \tau_1 \leq \tau_2 \leq \dots \leq \tau_n \leq 1$ . This amounts to finding the isotonic regression of the points  $(t_i, n_i)$  with  $n_i$  (see [19, p. 32]). The result is a piecewise linear approximation with breakpoints  $t_0 = 0 < t_1 < \dots < t_n$ , and slopes  $1 \geq \theta_1 > \theta_2 > \dots > \theta_n \geq 0$ . If we define  $\tau_j = t_j$  for any  $t \geq 0$ , then  $\max_{\tau} \{ \dots \}$

$k(t) = \sum_{j=0}^{j(t)} (\tau_{j+1} - \tau_j) \theta_j$

$k'(t) = \theta_{j(t)}$  if  $t \neq \tau_{j(t)}$

$\partial k(t) = [\theta_{j(t)}, \theta_{j(t)+1}]$  if  $t = \tau_{j(t)}$

6. Implications

For on-line retailers, this is an ideal example of their opportunity to inventory management policies in the context of customer behavior. Most sites already have the technology to collect extremely detailed data about the shopping behavior of visitors. The algorithm and estimation techniques presented here themselves to automation quite easily, in the same manner simple EOQ and stocking level standard routines in many existing enterprise solutions. They can be used directly to stocking policy as well as parameters on an basis, or more realistically, be used to suggest changes to a decision maker.

In case of stockouts, many savvy retailers list items similar to promote substitution, and also provide the date to allow the customer to substitute and waiting by customers allows them to attract a larger market (or at a lower cost) than if they had a fixed assortment of stocked items. Hence growing trends tend to allow customers to make their own substitution/wait/leave decisions. Whatever be the (arguable) benefits of this policy in

the “bricks” world of retailing, there are many benefits for the “clicks” world of on-line retailing. Customers are conditioned to a shipping delay, and may be willing to wait for a short time in order to get first choice. The on-line world provides a wealth of information about customer preferences, stockout and substitution behavior. In addition, to ensure that when stocks arrive, all baskets are empty. To these organizations an understanding of customer waiting behavior is essential to implement profitable intermittent ordering - clearly a strong argument for systematic analysis of stockout behavior (as well as substitution behavior) in the on-line retailing industry.

### 6.1 Enterprise Resource Planning Software

Existing ERP software today has pre-programmed routines that allow calculation of inventory parameters, safety stock (using previous order data), reorder points, and order quantities. We have also provided algorithms that are implementable as additional routines to find out the optimal stocking policy for items of interest, as well as an algorithm to calculate maximum estimator (in linear running time). This allows firms to directly implement the policies that we describe here.

Just as most stocking level calculation used to be done directly change values but to suggest changes to a decision maker, we envisage that the algorithms presented here can be used to suggest changes in policy to the decision maker. This allows for a degree of flexibility that is currently not available in most ERP systems.

### 6.2 Other Considerations

The periodic availability policies that we described have some other implications as well. Since we decrease the average inventory holding time (as compared to a pure EOQ policy), this has a significant impact on accounting measures, like Return on Equity. For online firms this may be an important consideration. Incentives and even existence of common accounting measures of profitability. Since each order is larger than the pure EOQ policy there may be quantity discounts or shipping charges that kick in if a periodic availability policy is adopted. While this is not explicitly modeled in this paper, it is plausible that quantity discounts or shipping charges such a policy even more attractive. While we have looked at the inventory policy that can capitalize on the increased visibility of customer behavior, it is equally important to have business processes that can integrate well with a regular filling of backorders. Online business models have to be

supported by all functional areas in tandem. It is certainly not enough to merely apply a periodic availability policy at the warehouse.

## 7. Conclusion

Our model is just a start however. In the future, sophisticated on-line retailers will use their customer data to model customer behavior in the face of stockouts, changes, available substitutes in the retailer's portfolio, and possibly competitive actions. Hence there will be an increasing need for models that integrate the traditional emphasis on replenishment decisions with other aspects of the system.

In this paper we start from a different perspective on the cost of backorders. We have extended the EOQ model in an intuitive manner which shows the specific conditions under which the EOQ model is optimal, and conditions under which EOQ is not optimal (or profitable) but periodic availability is optimal. This represents a simple but powerful extension of this classic inventory model. Potential extensions to this research include

considering many items to be stocked at one location, the issue of substitution between multiple items, and the ease of competition between retailers using different stocking policies. Each of these occurs in practice, and is relevant to both research and industry.

There are important applications to the field of online inventory, and there are many inventory systems, all including supply chains. In a situation where a stockout causes a partial non-linear loss we assert that it is important to assess the profitability of periodic availability.

## Abstract

This paper is based on the model proposed by Viswanathan and continue to analyze the benefit of supply chain inventories through the use of common replenishment epochs. We studied a one-vendor, multi-buyer supply chain for a single product under uncertainty demand environment. The vendor specifies common replenishment periods and asks all buyers to replenish only at those time period and the price discount to be offered by the vendor are determined by the solution to a Stackelberg game. A numerical study is conducted to evaluate the benefit of the strategy by simulation.

Keywords: Supply chain management; Inventory policy; Replenishment schedule; Uncertainty demand

## 1. Introduction

Inventory Control is a criterion of evaluating supply chain management. In a supply chain with vertical structure, optimizing inventory may be realized by enable every component department of the whole supply chain comply with the objective of minimizing the total cost as a whole due to the relationship of administration. But this circumstance does not accord with demand of enterprises constructing horizon integration, so this may not be possible in horizon supply chain. First, the vendors and buyers involved in the supply chain may belong to different corporate entities and be more keen on maximizing their own profit rather than that of supply chain as a whole. Therefore, it is necessary to devise mechanisms for increasing the coordination among entities in the supply chain.

With growing focus on supply chain management, firms realized inventories across entire supply chain could be efficiently managed through cooperation. The management of inventories in distribution or deliver process was paid more attention of scholars opposite to production/inventories systems. Distribution of inventories is important problems because as common a wholesaler usually delivers to several retailers, thus how to distribute inventories between wholesaler and retailers or among

retailers are valuable to integrate.

Axaster & Zhang (1999) analyzed the common replenishment spots impact multi-level inventory control, they supposed storehouse took advantage of common installation Stock as their lot quantity replenish policy, the identical retailers adopt the common replenishment policy, in which phenomenon when the inventory position of all of the retailers decrement to a common order point, the retailer whose inventory level is the least would set the order information. This policy results in higher cost and suits to be applied in some special cases. Viswanathan and Rajesh Piplani [4] integrated the common replenishment strategies between a vendor and more buyers, they proposed a Stackelberg game with the objective to minimize the vendor's cost, the vendor give its buyers some price discount to compensate the increasing on the buyers inventory cost, but they studied the case with definite demand which buyers faced. They did not investigate how to make price facing stochastic demand, and how the parameters of demand to impact the policy.

This paper is based on Viswanathan and Rajesh Piplani's work and studied that when the retailers face uncertainty demand from their customers, the performance of the supply chain including one vendor and more buyers. We suppose the demand of every buyers' customers follow normal distribution with their own parameters including expectation means and standard deviations. Not only two parameters but also they have other more parameters including the annual Demand, the leading time and their shortage cast, holding cost and order cost. We also suppose the vendor replenishes its inventory with lot to lot from its vendor. So its leading time is ignored. At first, the vendor must not have inventory cost, so it adapt the common replenish policy to its buyers. But the buyers cannot accept the increasing of their inventory cost, so the vendor must give the buyers some price discount to compensate with their expense. We studied the solution of price policy with common consistent discount and with their respectably discount scale. At last we investigate the total cost of supply chain as a whole is to be reduced by this common

replenishment policy with a simulation.

## 2. Problem Description

The Supply chain includes a kernel supplier and multiple retailers. The replenishment strategy of the supplier is to take place right away if it need and it does not take the leading time into account. The retailers face the demand of customers, and the demand quantity follows normal distribution. The leading time of retailers send their order can be 0 or any positive number.

Due to in this problem, the supplier is regarded as the hardcore, for the purpose of making no cost on supplier, we adopt common replenishment epochs(CRE). The vendor specifies that buyers can only place orders at specific points in time, for example, every Monday, a certain week of every month, etc. The vendor will insist the interval for each buyer  $i$  which is defined as  $t_i^c$ . So  $t_i^c$  should be an integer multiple of the common replenishment period  $T_0$ . Due to reduce the freedom of buyers placing orders to vendor and increase their inventory costs, the vendor need to provide a price discount  $Z_i$  to compensate buyer  $i$  for inventory cost increase. Therefore, this problem concentrate to determine the  $n_i$  in expression (1) and price discount factor  $Z_i$ .

$$t_i^c = n_i T_0 \quad (1)$$

## 3. Analysis of inventory cost for CRE

### 3.1 Analysis of inventory cost for no use of CRE

#### 3.1.1 Inventory cost construction for buyers

We suppose under the random condition, the optimal replenishment interval corresponding to EOQ for buyer  $i$ . Buyer  $i$  has a order quantity  $Q_i$ , its demand during leading time follows normal distribution  $N(X_{LT}^i, \sigma_{X,LT}^i)$ . And we have need to consider the safety stock.  $k$  is the safety factor, and the demand quantity in a year is  $D_i$ , shortage cost per unit per year is  $\Pi$ , setup cost for every order is  $C_{Setup}^i$ , holding cost per unit per year is  $h$ .

For buyer  $i$ , before the CRE strategy is implemented, optimal order quantity solved corresponding to the EOQ is given by

$$Q_i = \sqrt{\frac{2D_i(C_{Setup}^i + \Pi \sigma_{X,LT}^i g(k_i))}{h_i}} \quad (2)$$

$$\text{where } g(k_i) = \int_{k_i}^{\infty} (z - k_i) f(z) dz$$

and  $f(z)$  is the density function for normal distribution  $N(X_{LT}^i, \sigma_{X,LT}^i)$ . The optimal replenishment interval for Buyer  $i$  is given by

$$t_i^u = \frac{Q_i}{D_i} \quad i = 1 \dots m \quad (3)$$

Its total inventory cost is expressed by

$$\begin{aligned} \therefore TC_i(Q, k_i) &= C_{Setup}^i \frac{D_i}{Q} + \Pi \frac{D_i}{Q} E(g(k_i)) + h_i \left( \frac{Q}{2} + k_i \sigma_{X,LT}^i \right) \\ &= C_{Setup}^i \frac{D_i}{Q} + \Pi \frac{D_i}{Q} \sigma_{X,LT}^i g(k_i) + h_i \left( \frac{Q}{2} + k_i \sigma_{X,LT}^i \right) \end{aligned} \quad (4)$$

#### 3.1.2 Cost analysis for vendor

The vendor purchases the product from external supplier and follows a lot for lot policy, so the vendor does not keep any inventory and orders the required quantity whenever it receives an order from a buyer. Before CRE strategy implemented, the vendor processes each individual buyer's order separately and it only incurs cost for orders. The expression (5) is defined the total cost for the vendor in a year.

$$TC_v^U = \sum_{i=1}^m (C_{Setup}^E + C_v^i) / t_i^u \quad (5)$$

where  $C_{Setup}^E$  is the setup cost incurred by the vendor for processing the entire set of orders/deliveries.

$C_v^i$  is the setup cost incurred by the vendor for processing a specific order from buyer  $i$   
 $m$  is the number of buyers.

### 3.2 Analysis of inventory cost for implementation of CRE

Due to the CRE strategy is a problem modeled as a Stackelberg game, with the vendor acting as the leader and buyers as followers. Its solution is determined to meet the objective to minimize the vendor's cost at first, and then look for the balance spot buyers can receive.

#### 3.2.1 Inventory cost construction for buyers

Referring to the expression (4), we can obtain the total cost for buyer  $i$  is

$$TC_i^a = C_{Setup}^i / t_i^c + h_i * (Q/2 + k_i \sigma_{X,LT}^i) + \Pi \frac{D_i}{Q} \sigma_{X,LT}^i g(k_i)$$

Under the CRE strategy, the replenishment interval for buyer  $i$

is

$$t_i^c = n_i T_0 = Q_i / D \quad (6)$$

thus

$$\therefore Q_i = D_i n_i T_0 \quad (7)$$

Let

$$H_i = (h_i D_i) / 2$$

So

$$TC_i^c = C_{Setup}^i / (n_i T_0) + H_i T_0 + \frac{D_i Q_i}{n_i T_0} + \frac{\sum_{i=1}^m \sigma_i E_S(k_i)}{n_i T_0} \quad (8)$$

### 3.2.2 Cost analysis for vendor

We consider two cases: identical and non-identical discounts for buyers.

In the first case,  $Z$  is the identical discount rate. The cost of vendor is

$$TC_v^c = C_{Setup}^E / n_0 + \sum_{i=1}^m (D_i Z + C_v^i / (n_i T_0)) \quad (9)$$

In the second case,  $Z_i$  is the discount rate for buyer  $i$ . Every buyer possess identical  $Z_i$ . The cost of vendor is given by

$$TC_v^c = C_{Setup}^E / T_0 + \sum_{i=1}^m (D_i Z_i + C_v^i / (n_i T_0)) \quad (10)$$

## 4. Feasibility of CRE

At first, we consider expression (8), its derivative on  $n_i$  is

$$\frac{dTC_i^c}{dn_i} = -\frac{C_{Setup}^i}{T_0 n_i^2} + H_i T_0 - \frac{\sum_{i=1}^m \sigma_i E_S(k_i)}{T_0 n_i^2}$$

and its two order derivative is

$$\frac{d^2 TC_i^c}{dn_i^2} = \frac{2(C_{Setup}^i + \sum_{i=1}^m \sigma_i E_S(k_i))}{T_0 n_i^3}$$

$$Q \quad n_i > 0$$

$$\therefore \frac{d^2 TC_i^c}{dn_i^2} > 0$$

So for every buyer, its cost function is down convex monotonously. Thus for any  $T_0$ , we can find an acceptable  $n_i$  to minimize the total cost.

Set  $n_i^*$  as the multiple enable to minimize the total cost. Thus

$$TC_i^c(n_i^*) \leq TC_i^c(n_i^* + 1) \quad (11)$$

and

$$TC_i^c(n_i^*) \leq TC_i^c(n_i^* - 1) \quad (12)$$

From expression (11) and (12), we can deduce:

$$n_i^*(n_i^* - 1) \leq \frac{C_{Setup}^i + \sum_{i=1}^m \sigma_i E_S(k_i)}{H_i T_0^2} \leq n_i^*(n_i^* + 1) \quad (13)$$

Due to the limitation of order interval by vendor, it must bring increase of total cost of buyers. Only the price discount can counteract and is received by buyers. This is

$$Z \geq \frac{C_{Setup}^i}{D_i} \left( \frac{1}{n_i T_0} - \frac{1}{t_i^u} \right) + \frac{\sum_{i=1}^m \sigma_i E_S(k_i)}{D_i} \left( \frac{1}{n_i T_0} - \frac{1}{t_i^u} \right) + \frac{h_i}{2} (n_i T_0 - t_i^u) \quad (14)$$

Expression (14) is the constraint of CRE strategy. And the objective function is to minimize the vendor's total cost:

$$\text{Min}(TC_v^c) = \text{Min}(C_{Setup}^E / T_0 + \sum_{i=1}^m (D_i Z + C_v^i / (n_i T_0))) \quad (15)$$

If we can solve the common factor of the replenishment cycle of every buyer  $T_0$ , then the problem can be solved.

The problem of determine the  $T_0$  and  $Z$  for the vendor can be formulated as follows (P):

$$\text{Min}(TC_v^c) = \text{Min}(C_{Setup}^E / T_0 + \sum_{i=1}^m (D_i Z + C_v^i / (n_i T_0))) \quad (15)$$

subject to

$$Z \geq \frac{C_{Setup}^i}{D_i} \left( \frac{1}{n_i T_0} - \frac{1}{t_i^u} \right) + \frac{\sum_{i=1}^m \sigma_i E_S(k_i)}{D_i} \left( \frac{1}{n_i T_0} - \frac{1}{t_i^u} \right) + \frac{h_i}{2} (n_i T_0 - t_i^u) \quad (14)$$

$$i = 1, \dots, m,$$

$$T_0 \in X,$$

$$n_i \geq 1 \text{ and integer, } i = 1, \dots, m,$$

$$\text{where } X = \{1/365, 1/52, 1/12, 1/4\}$$

## 5. Solution of CRE

### 5.1 In identical discount strategy

Because  $T_0$  is a discrete time unit and  $n_i$  is a positive integer,  $T_0$  can not be solved by general solution of continuous function. So we refer to solution Viswanathan gave to similar problem, and obtain the search steps as follow:

Step 1. For each  $T_0 = x_j$ ,  $x_j \in X$ , solve  $n_i$  from expression(13).

Step 2. For each buyer  $i$ , determine  $Z_i$  from (14). Set  $Z = \text{Max}\{Z_1, \dots, Z_m\}$

Step 3 Substituting for  $Z$  and  $T_0$  to (15), determine the objective function value. Among all the  $x \in X$ , choose the value that minimizes the objective function value given by (15).

### 5.2 In non- identical discount strategy

When the vendor give every buyer to its respective discount rate to recuperate its respective losing of total cost. That is non-identical discount

strategy. In the course of solution, change the step 2 above paragraphs, substituting for  $Z_i$  to (15) is well.

## 6. Numerical study

In this section, first a numerical example with 5 buyers that demonstrate the benefits of CRE strategy is presented. Not losing generalization, we suppose buyers give their customers the service level of 95%. Their parameters are given in Table 1.

Table 1 Parameters in the experiment

No	$C_{Setup}$	H	$\Pi$	LT	$X_{LT}$	$\sigma_{X,LT}$	D	$S_{buyers}$	
1	1	16	5	20	100		30	1800	10
2	2	15	8	10	56		10	2000	20
3	3	18	20	20	88		20	1600	30
4	5	19	25	7	28		6	1400	40
5	4	20	5	6	100		17	2100	50

In the experiment, we suppose that the setup cost of each order for vendor ( $S_v$ ) is changed from 0 to 70 with 10 of span, and the setup cost for buyer ( $S_b$ ) is changed from 10 to 50 with 10 of span. No losing generalization, we consider all buyers have the same setup cost.

### 6.1 Simulation result for identical discount strategy

The result is given by Table 2. From table 2, we can see that the common replenishment interval increase with  $S_v$ , which demonstrate order cost increasing bring order interval prolonged. Even if  $S_v$  is constant, interval increases monotonously with  $S_b$ . As far the five buyers, they all increase their total cost after CRE is implemented, and that each buyer, CRE bring its total cost increased obviously.

Identical discount rates change with  $S_b$  and  $S_v$ , which is displayed in Figure 1.  $Z$  increases with  $S_v$  and  $S_b$ . That illustrates that from the point of view of vendor, increasing of order cost enhances buyers' total costs, so the discount rate is enhanced respectively.

The direct objective of CRE is to minimize the vendor's cost, from the experiment, vendor's cost is decreased obviously. The more  $S_b$  is, the more vendor's cost is reduced, furthermore, with

$S_v$  rising, vendor's costs on different  $S_b$  show convergent tendency.

For the cost of all supply chain, Figure 3 shows its variation tendency. When  $S_b > 30$ , cost of supply chain descends. The less  $S_b$  is, the easier cutting cost of the system down is. With  $S_v$  increasing, system cost decline, when  $S_b$  changes bigger, the rate for decreasing of system cost is bigger.

### 6.2 Simulation result for non-identical discount strategy

The result of non-identical discount strategy is showed in table 3. Comparing Table 2 and Table 3, non-identical discount strategy reduces more vendor's cost than identical one, because identical one regards the max value of all discount rate for every buyers as the identical rate. Thus some buyer enjoy more preferential price and vendor pays out more cost. Non-identical strategy enables each buyer to enjoy the critical discount rate from vendor according to its cost increased.

Figure 4 shows the variety of vendor's cost on non-identical strategy. And Figure 5 displays the variety of total cost of the supply chain. Relative to Figure 3, we can see that non-identical strategy bring more abatement of total cost of system than identical one, and in different term of  $S_v$ , rate of cost presents convexity more obviously with  $S_b$  than identical one.

## 7. Summary and conclusions

In this paper, a strategy of inventory policy in a one vendor, multi buyer supply chain under uncertainty demand is modeled. The buyers face uncertainty demand from their customers, and the vendor requires all buyers to place their orders at common replenishment epochs. We discuss the solution of order interval and discount rate in this problem on identical and non-identical cases. An extensive numerical study was conducted to show the influence of parameters on CRE strategy. The experiment revealed that CRE strategy can reduce vendor's cost and total cost of the supply chain. And on non-identical discount rate can bring more cost saving on the system cost and vendor's than identical strategy.

Table 2 Detailed result of numerical study for identical											
$S_v$	$S_b$	$T_0$	Ratio of buyer's cost (CRE/No-CRE)					Ratio of vendor's cost (CRE/No-CRE)		Ratio of system's cost (CRE/No-CRE)

## Abstract

E-mail is an indispensable communication tool in the modern enterprise organizations. E-mail is also so prominent for these teams that they communicate via e-mail daily, and is the main media for asynchronous meetings. This study explores the suitability of using e-mail to support group decision making. In order to reduce the communication obstacle which the group may encounter while using the asynchronous communication of E-mail, this study proposes two group techniques suitable for E-mail-Nominal Group Technique (NGT) and Round-Robin NGT. This study also explores the effectiveness of E-mail-mediated group supported by the structured group techniques and which type of task suitable for E-mail-mediated group. An experiment involving a total of 150 undergraduates was conducted. Results show that group techniques used in this study appears to be useful for facilitating E-mail-mediated group. But task type had no significant influence on E-mail-mediated group.

Keywords : E-mail, Nominal Group Technique, Task Type, Group Decision Making

## 1. Introduction

Electronic mail (E-mail) is undoubtedly the most successful application in the cyberspace. Even someone said that the e-mail has been the most successful communication technology since the invention of the TV.

E-mail also plays an important role in organization communication. Two major organizational shifts are the movement toward teams and the movement toward nonstandard work schedules. This has simultaneously increased the need for meetings and decreased the ability to meet [1]. In order to meet the new environment, one of the trends is virtual teams - groups of people who work together although they are often dispersed across space, time, and/or organizational boundaries.

After studied 12 virtual teams, Lurey and Raisinghani [2] found that e-mail was so prominent for these teams that 80% of the team members communicated via e-mail daily. Other team-based communication technologies like group telephone conferences, groupware applications, and video conferences were not often used. E-mail is the main tool to support asynchronous meeting and an important media to support future organization (virtual organization)[3].

On the other hand, most of computer-mediated communication research focused on Group Support Systems (GSS) research. Results of these studies show that using GSS brings considerable productivity promotion and reduces costs for organizations [4]. But the efforts of GSS research had limited effect on business world, GSS is diffusing slowly [5] [6]. Besides, Most of GSS research limited to "decision room" support system for synchronous communication. Mandviwalla and Gray [5] suggested that GSS research should expand to include commercial systems and to asynchronous and distributed work.

This study explores the suitability of using e-mail to support asynchronous group decision making.

## 2. Literature Review

### 2.1. Electronic mail

Massachusetts Institute of Technology designed E-mail in 1965 for experiment purpose. In 1969, US military developed ARPANET to link up computers as a network; E-mail was the most popular and frequently used application [7]. E-mail began to be used commercially in 1977.

The range of early E-mail definition is very extensive, from telex to computer conferencing system. Almost all the electronic ways to convey message can be called E-mail.

This study follows the definitions of Sproull and Kiesler [7]. An Electronic Mail System (EMS) uses computer text-processing and communication tools to provide a high speed information exchange service anyone with a computer account can create and send information to anyone who has a mailbox on that computer or on any other computer to which it is connected through a computer network.

### 2.2. E-mail-mediated Meeting

Sproull and Kiesler [8] organized a series of email meeting reports, they found that computer-mediated meeting was equal than face-to-face meeting, namely the conferee had equal time to provide opinions. E-mail also drew the status disparities of conferee. In the face-to-face meeting, the high social status conferee's opinion had obvious influence to final conclusion; the same situation is not relatively obvious in E-mail-mediated meeting.

On the other hand, conferee in face-to-face meeting

which speak in turn tended to follow and agree with previous speaker. This kind of trend was not so obvious in E-mail-mediated meeting. The result of study showed that E-mail lacked the social context to incline to be unanimous and convergent. When needing a common consensus to make decision, E-mail-mediated meeting required more time and efforts.

Shirani et al, [9] thought that E-mail was asynchronous in both time and place, which allows, and perhaps encourages, greater use of human information processing resulting in deeper analysis which is crucial in the late stages of a group decision.

### 2.3. Nominal Group Technique

Nominal Group Technique (NGT) was developed by Andre L. Delbecq and Andrew H. Van de Ven in 1968. It was derived from social-psychological studies of decision conferences, management-science studies of aggregating group judgments, and social-work studies of problems surrounding citizen participation in problem planning. The NGT overcomes a number of critical problems typical interacting groups, such as, individual inhibitions and premature evaluation in interacting groups result in a decrease in quality of group ideas in terms of creativity, originality, and practicality. And the interacting group tends to pursue a single train of thought for long periods.

Perry [10] found from interview that E-mail is great for discussing and exchanging information, but it is hard to reach a decision about something that is complex and multifaceted.

Same results also found in other literature [8, 11, 12], usually members of distributed or asynchronous group are difficult to keep consciousnesses of being in a group [6, 12]. E-mail lacks for relevant social clues to understand others' real purposes of their expression [8, 9], and when or where to stop discussing [8, 10].

E-mail is used in asynchronous situation mainly, and a kind of comparatively poor social clues communication tool [13]. For preventing the problem mentioned above, it needs special structural group technique to support [3, 14], like Nominal Group Technique (NGT) or Delphi Techniques [15].

The structural group techniques were designed to coordinate communication and solve obstacles and settle difficulties that may be encountered in face-to-face communication. And relevant researches did prove that NGT was able to reach the anticipated goal. Moreover, asynchronous communication is much more often to encounter communication obstacles. Dowling and Louis [1] found that asynchronous group can benefit from NGT than synchronous groups.

The purposes of this study are to explore the effectiveness of NGT supported E-mail-mediated group. But because the original design of NGT is in a meeting room, mediated by paper and pen, and face-to-face. The implementation of NGT with e-mail in this study would slightly change. This study took the original spirit of NGT, and referred to relevant researches [1, 15, 16], and proposed two group techniques suitable for E-mail. The one close to the original design is named "Nominal

Group Technique (NGT)". The second modification is called "Round-Robin NGT". This study also added E-mail-mediated meetings without group technique support called "Interacting Groups".

### 2.4. Task Type

McGrath [17] has combined the main ideas of a number of scientists into a conceptually related set of distinctions about tasks. McGrath proposes that there are four general processes. They indicate what the group is to do: to Generate (alternatives), to Choose (alternatives), to Negotiate, and to Execute.

Choose type tasks can be subdivided into Intellectual type and Decision-Making type (Preference type). There is a logically correct answer in Intellectual task, the goal of the task is to find out this correct answer; No obvious correct answer in Preference task, the goal of the task is to seek the common consensus while everyone having a different preference.

In the theory of information richness, Daft and Lengel [18] argued that there is an optimal fit between situational equivocality and media. And the main notion of task-media fitness theory [17] is that optimal richness requirement of tasks varies from type to type and the performance of a group depends on the extent to which the task fits the communication environment [19]. That is to say that complicated tasks relying on members' interaction to coordinate conflict and convey social clues. Complicated tasks relatively need media that can convey rich information.

## 3. Research Hypotheses

The purposes of this study are to compare E-mail-mediated meetings supported with or without group technique (Interacting group, NGT and Round-Robin NGT) and to explore which type of task suitable for E-mail-mediated group. This study focuses on group decision outcome and team relationship development. According to these goals, we developed the following hypotheses.

The purposes of NGT are to offer conferee time to deliberate, chance to participate, and a situation to concentrate on topic. NGT is superior to Interacting group no matter at productivity or satisfaction [20]. The disparity on satisfaction is especially obvious. The meetings of E-mail usually to go on by asynchronous way and members are relatively difficult to keep consciousnesses of being in a group, and to understand others' real purposes of their expression for e-mail lacking relevant social clues. Moreover, Dowling and Louis [1] found that groups using asynchronous NGT produce better decision results within shorter time than using face-to-face NGT.

NGT offer members fair chances to participate in discusses [20]. When members can participate in the meeting, and make some contribution to last decision, they will probably be satisfied with the decision, too [21]. So we proposed H1a, H1b, H2a and H2b as follow

H1a: Under conditions of Preference task, E-mail-mediated groups supported by group technique (NGT or Round-Robin NGT) will be more satisfied with the decision than those not supported by group technique (Interacting group)

H1b: Under conditions of Preference task, E-mail-mediated groups supported by group technique (NGT or Round-Robin NGT) will be more satisfied with the decision scheme than those not supported by group technique (Interacting group)

H2a: Under conditions of Intellectualive task, E-mail-mediated groups supported by group technique (NGT or Round-Robin NGT) will be more satisfied with the decision than those not supported by group technique (Interacting group)

H2b: Under conditions of Intellectualive task, E-mail-mediated groups supported by group technique (NGT or Round-Robin NGT) will be more satisfied with the decision scheme than those not supported by group technique (Interacting group)

Group members' more effective information exchange may cause them to understand their task s better and generate more creative solutions, thereby leading to better decisions [22]. The main purpose of group techniques is to dispel the communication obstacles. Besides, in Round-Robin NGT the conferee can see others' suggestion at the same time while expressing an opinion; it is to increase conferee to keep senses of participation and cohesion [23]. Members of cohesive teams tend to engage in more social interactions and view mutual opinions positively [21]. So we proposed H3a and H3b as follow.

H3a: Under conditions of Preference task, E-mail-mediated groups supported by group technique (NGT or Round-Robin NGT) will make better decision than those not supported by group technique (Interacting group)

H3b: Under conditions of Intellectualive task, E-mail-mediated groups supported by group technique (NGT or Round-Robin NGT) will make better decision than those not supported by group technique (Interacting group)

Preference task has no correct answer; it can only rely on group members to discuss, coordinate conflict, and reached a common view. Intellectualive task has an only one correct answer, members only need to participate in meeting and exchange information with each other. Do not need to coordinate the cognitive conflict of each other very much among members.

For Preference task, E-mail might be unable to offer enough social clues and decline members' satisfaction and perceived decision quality. Intelligence type task will not face this kind of situation. So we proposed the following hypotheses.

H1c: In E-mail-mediated meeting without supported by group technique

(Interacting group), groups facing Intellectualive task will be more satisfied with decision than those facing Preference task

H1d: In E-mail-mediated meeting supported by NGT,

groups facing Intellectualive task will be more satisfied with decision than those facing Preference task

H1e: In E-mail-mediated meeting supported by Round-Robin NGT, groups facing Intellectualive task will be more satisfied with decision than those facing Preference task

H2c: In E-mail-mediated meeting without supported by group technique

(Interacting group), groups facing Intellectualive task will be more satisfied with decision scheme than those facing Preference task

H2d: In E-mail-mediated meeting supported by NGT, groups facing Intellectualive task will be more satisfied with decision scheme than those facing Preference task

H2e: In E-mail-mediated meeting supported by Round-Robin NGT, groups facing Intellectualive task will be more satisfied with decision scheme than those facing Preference task

H3c: In E-mail-mediated meeting without supported by group technique

(Interacting group), groups facing Intellectualive task will make better decision than those facing Preference task

H3d: In E-mail-mediated meeting supported by NGT, groups facing Intellectualive task will make better decision than those facing Preference task

H3e: In E-mail-mediated meeting supported by Round-Robin NGT, groups facing Intellectualive task will make better decision than those facing Preference task

As to asynchronous group, relationship development is much harder than face-to-face group. But for the group supported by group technique, the technique will facilitate communication [20]. Team members should also be more willing and able to communicate freely and help each other [24]. Besides, in Round-Robin NGT the conferee can see others' suggestion at the same time while expressing an opinion; it is to increase conferee to keep senses of participation and cohesion [23]. So we proposed H4a, H4b, H5a and H5b.

H4a: Under conditions of Preference task, E-mail-mediated groups supported by Round-Robin NGT will have higher team cohesiveness than those not supported by Round-Robin NGT

H4b: Under conditions of Intellectualive task, E-mail-mediated groups supported by Round-Robin NGT will have higher team cohesiveness than those not supported by Round-Robin NGT

H5a: Under conditions of Preference task, E-mail-mediated groups supported by Round-Robin NGT will have higher team collaboration than those not supported by Round-Robin NGT

H5b: Under conditions of Intellectualive task, E-mail-mediated groups supported by Round-Robin NGT will have higher team collaboration than those not supported by Round-Robin NGT

## 4. Research Method

The research hypotheses were tested using a factorial

experiment design (2x3) with E-mail-mediated group supported by group technique and task type as independent variables. E-mail-mediated group supported by group technique with three levels: Interacting group (no group technique support), NGT support, and Round-Robin NGT support. And task type with two levels: Preference task and Intellectualive task.

NGT was adopted from the face-to-face design of Delbacq and Van de Ven [20] and modified to suit to e-mail environment. Round-Robin NGT was another version of modification.

Preference task was "Personal Trust Foundation" by Watson [25]. And Intellectualive task was "Murder One" by Pfeiffer and Jones [26]. Both tasks had been thoroughly tested by empirical studies in information systems and small group research.

Each dependent variable was measured by questionnaire. Perceived decision satisfaction and perceived decision scheme satisfaction was measured with six questions from Green and Taber [27]. Eight questions from Green and Taber [27] were used to measure perceived decision quality was measured with. Team cohesion was measured with three questions from Sashore [28]. Team collaboration was assessed with two questions from Larson and LaFasto [24]. All the original anchors and scales had been thoroughly tested by empirical studies in social psychology and information systems.

#### 4.1. Subject

A total of 150 undergraduates voluntarily participated in this study. Their average age was 19.37. The subjects were randomly assigned to teams of five members each. This team size was used because many decision teams in organization have this size. Thirty teams were randomly assigned to six experiment cells (2x3). Each participant uses e-mail software built in Windows operation system to perform a six-day experiment at home or dormitory. They communicated using specially assigned electronic mail address or their own e-mail address (controlled by backup mail transmitted to facilitator) when carry out their tasks.

### 5. Data Analysis

#### 5.1. Validity and Reliability

Data for dependent variables, collected after meeting were subject to validity and reliability analyses. The results of factor analyses for data collected showed that each question loaded highly on its intended dependent variable. All the dependent variables satisfied criteria for reliability at Cronbach's alpha 0.7. Thus, all the dependent variables had construct validity.

#### 5.2. Hypotheses Tests

A MANOVA test involving all independent and dependent variables was carried out first. Results revealed that the interaction effect of two independent variables on all dependent was not significant. With the results, separate ANOVA tests and Tukey's LSD multiple comparisons test (if needed) could be performed for each dependent variable. All dependent variables could meet homogeneity and normality requirements of the ANOVA test. Table I shows the result of tests for all hypotheses.

Under conditions of Intellectualive task, E-mail-mediated group supported by group technique (no matter NGT or Robin-Robin NGT) had higher decision and decision scheme satisfaction than those not supported by group technique (H1b, H2b). Results suggest that proper group technique could reduce the influence of group think and group shifts which leads to higher perceived satisfaction. Under conditions of Preference task, only groups using Robin-Robin NGT had higher perceived satisfaction (H1a, H2a).

As to perceived decision quality, group supported by group technique (no matter NGT or Robin-Robin NGT) had higher perceived decision quality under conditions of Preference task (H3a). Result suggests that with group techniques participants have more equal chance to participate in meeting and concentrate on task topic which leads to better decision quality. Because Intellectualive task has an only correct answer, members only need to exchange enough information with each other to solve the task. The group technique used in this study had no significant effect on decision quality under Intellectualive task (H3b).

The lack of effect on team cohesion (H4a, H4b) suggested that team cohesion depends on the accumulation of feelings and interacting experience. Group techniques in this study had no significant effect on team cohesion.

As to team collaboration, no matter under which type of task, group supported by Round-Robin NGT had better result than those not supported by Round-Robin NGT (H5a, H5b). The merit of Round-Robin NGT for conferee to see others' suggestion at the same time while expressing an opinion has a positive effect on team collaboration. However, group supported by NGT were limited to a central messages source. The team collaboration of groups supported by NGT was the same as Interacting groups. The lack of impact of Task type no on most dependent variables may be explained in two ways. First the volunteers were to learn to meet with e-mail and solve the task at the same time. Thus, the effect of task type was not so significant. Another explanation is that E-mails may be not a poor media for the volunteers in this study. According to Lee [13], the volunteers in this study were quite familiar with the computer, network and E-mail. And thus they were able to filter out necessary and rich information from the lean media – email.

Table I : Results of Tests (\* : p&lt;0.05 \*\* : p&lt;0.01)

Dependent variables	Hypotheses	P value	Notation
decision satisfaction	H1a	0.001**	Round-Robin NGT>Interacting
scheme satisfaction	H2a	0.011*	Round-Robin NGT>Interacting
decision quality	H3a	0.002**	Round-Robin NGT=NGT>Interacting
team cohesion	H4a	0.261	
team collaboration	H5a	0.007**	Round-Robin> NGT NGT=Interacting
decision satisfaction	H1b	0.032*	Round-Robin NGT=NGT>Interacting
scheme satisfaction	H2b	0.000**	Round-Robin NGT=NGT>Interacting
decision quality	H3b	0.124	
team cohesion	H4b	0.198	
team collaboration	H5b	0.016*	Round-Robin NGT> NGT=Interacting
decision satisfaction	H1c	0.916	
scheme satisfaction	H2c	0.046*	
decision quality	H3c	0.835	
decision satisfaction	H1d	0.462	
scheme satisfaction	H2d	0.855	
decision quality	H3d	0.201	
decision satisfaction	H1e	0.196	
scheme satisfaction	H2e	0.290	
decision quality	H3e	0.350	

## 6. Conclusion

The results from the experiment point to four general conclusions.

First, when under Preference task, Round-Robin NGT can provide enough ability to coordinate communication process. Results show that E-mail mediated group has better decision outcome such as decision satisfaction, decision scheme satisfaction, and decision quality and team relationship such as team collaboration.

Second, when under Preference task, though the group techniques used in this study has no significant effect on decision quality, both NGT and Round-Robin NGT can enhance decision satisfaction, decision scheme satisfaction. Moreover, Round-Robin NGT can also promote team collaboration under Intellective task.

Third, task type has no significant effect on most dependent variables. The difference of task type will not affect E-mail-mediated Groups.

Fourth, the lack of effect on team cohesion suggested that team cohesion depends on the accumulation of feelings and interacting experience. Group techniques in this study had no significant effect on team cohesion.

Meta-analyses of prior research results suggest that when teams used electronic communication, they tend to report better perceived decision quality but poorer decision satisfaction [29]. The proposed group techniques can help asynchronous group to raise perceived decision quality and satisfaction simultaneously.

Mandviwalla and Gray [5] analyzed a large amount of GSS research, and suggested that GSS research should expand to include commercial systems, expand beyond face-to-face meetings to asynchronous and distributed work in multimedia environments, emphasize complex

tasks and realistic subjects, and examine systems based on different perspectives. This study expanded traditional GSS research to asynchronous meeting and electronic mail system. This study provides a different thinking direction for relevant research.

In business environment characterized by intense competition, and globalization, asynchronous group supported by e-mail could be an effect way to solve business problems. The group technique proposed in this study can address the communication obstacle of asynchronous e-mail group. Further research must be carried out in this direction.

# Determining Successful Negotiation Strategies: The Evolution of Intelligent Agents

Jong Yih Kuo

Department of Computer Science and Information Engineering  
Fu Jen Catholic University, Taipei  
jykuo@csie.fju.edu.tw

## Abstract

Due to the desire of almost all departments of business organizations to be interconnected and to make data accessible at any time and any place, more and more multi-agent systems are applied to business management. As numerous agents are roaming through the Internet, they compete for the limited resource to achieve their goal. In the end, some of them will succeed, while the others will fail. However, when agents are initially created, they have little knowledge and experience with relatively lower capability. They should also strive to adapt themselves to the changing environment. It is advantageous if they have the ability to learn and evolve. This paper addresses evolution of intelligent agents in virtual enterprises. Agent fitness and fuzzy multi-criteria decision-making approach are proposed as evolution mechanisms, and fuzzy soft goal is introduced to facilitate the evolution process. Genetic programming operators are employed to restructure agents in the proposed multi-agent evolution cycle. We conduct a series of experiments to determine the most successful strategies and to see how and when these strategies evolve depending on the context and negotiation stance of the agent's opponent.

## 1. Introduction

Doing business on the Internet is becoming more and more popular. The use of the Internet to facilitate commerce among companies and customers brings forth many benefits, such as automated transactions, greater access to buyers and sellers, and dramatically reduced costs. The agent-based e-commerce has emerged and become a focus of the next generation of e-commerce. The intelligent agent acts on behalf of customers to carry out delegated tasks automatically. They have demonstrated tremendous potential in conducting various e-commerce activities, such as comparison-shopping, auction, sales promotion, etc [1,2].

In order to solve a problem, an agent has to have certain skills and the ability to reason about these skills. We call the reasoning abilities as "mental" skills [3]. However, when agents are initially created, they have little knowledge and experience with relatively lower capability. They should also strive to adapt their negotiation strategies and tactics to the changing environment. It is advantageous if the agents have the ability to learn and evolve. Many issues are essential in agent evolution. Firstly, evolution of an agent is closely related with agent structure. Thus, a

suitable agent structure is one of basic concerns in agent evolution. Secondly, agents should have their own mechanisms for advance evolution. Thirdly, in multi-agent system, evolution of individual agent is also related with many social concerns, such as coordination, negotiation, communication, etc. Finally, some tools can be used to evaluate the fitness of agents in the evolution procedures.. In this paper, we address multi-agent evolution for agents in e-commerce. Section 2 summarizes our service-oriented negotiation model based on fuzzy theory and the BDI model. In Section 3, we adopt an evolutionary approach in which strategies and tactics correspond to the genetic material in a genetic algorithm. In Section 4, we present an empirical study showing the relative success of different strategies against different types of opponent in different environments. Section 5 contains our conclusion.

## 2. The Service-oriented Negotiation Model

This paper addresses evolution of intelligent agents about the mental skills. Obviously, there is no limit to what one would like to include under what we call mental skills. We agree that BDI model [4,5,6] provides a simple but powerful formalism for the representation, the specification and the analysis of the mental attributes of intelligent agent: belief, desire and intention

### 2.1 The BDI Model

In the BDI architecture an agent can be completely specified by the events that it can perceive, the actions it may perform, the beliefs it may hold, the goals it may adopt, and the plans that give rise to its intentions [7]. The figure 1 represents the relationships of BDI model.

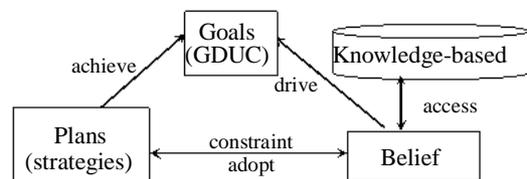

Figure 1: The BDI model of Agent

A belief model describes the information about the environment and internal state that an agent of that class may hold, and the strategies and tactics it may perform. A goal model (desires) describes the goals that an agent may possibly adopt, and the events to which it can respond. It consists of a goal set which specifies the goal and event

domain and one or more goal states – sets of ground goals – used to specify an agent’s initial mental state. There are soft and rigid goals specified by the users. We use fuzzy logic to represent the goals [8].

A plan model (intensions) describes the plans that an agent may possibly employ to achieve its goals. A plan is a sequence of strategies through reasoning mechanism (mental skills of the agent). The strategy is the combination of tactics with various weights.

### 2.2 The Goal-driven Analysis

To model user the BDI model, we use GDUC (goal-driven use case) approach [9] to structure the goals hierarchy and to analyze the plans or strategies achieving these goals. The steps describe below.

- (1) Identify actors and user’s goals to construct belief model: First, we must analyze the organization of enterprise or the environment of e-commerce to extract the basic knowledge for the agent. The knowledge can be build into a general common ontology. We also identify the users and their preferences to build the specific user-defined ontology. The ontology hierarchy can be stored into the knowledge-based of belief model.
- (2) Analyze goal hierarchy to build goal model: A faceted classification is proposed for identifying goals from domain descriptions and system requirements. Each goal can be classified under three facets we have identified: competence, view and content. The facet of competence is related to whether a goal is completely satisfied or only to a degree. A rigid goal describes a minimum requirement for a target system, which is required to be satisfied utterly. A soft goal describes a desirable property for a target system, and can be satisfied to a degree. The facet of view concerns whether a goal is actor-specific or system-specific. Actor-specific goals are objectives of an actor in using a system; meanwhile, system-specific goals are requirements on services that the system provides. We use the “use case” to structure goals hierarchy.
- (3) Analyze goal model to build plan model: According to the user’s goal and use cases, we can construct the scenarios of use cases and the possible planes to achieve the goals. Then we also evaluate the degrees of satisfaction about the planes. The ability of context sensitivity and evolution help agent adopt the negotiation strategies to achieve user’s goals.

### 2.3 Applying Fuzzy Theory to BDI Model

To model user goals, we apply GDUC to get a set of soft and rigid goals, a set of use cases, and a set of planes. For achieving these goals, agent must use particular strategies to change their mental states. We can continuously change the problem state to achieve the goal state. Thus we can apply the soft requirement [10] to formally represent the user goals.

A user goal,  $g$ , is specified by the properties of

agent’s mental state-transition  $\langle b, g, a \rangle$ , where  $b$  is the state before a plan, and  $a$  is the state after invoking the plan. A plan or strategy can thus be specified using a pair  $\langle \text{precondition, post-condition} \rangle$ . The precondition and the post-condition describe properties that should be held by the state  $b$  and  $a$ . A rigid goal describes state properties that must be satisfied. The soft goal describes state properties that can be satisfied to a degree. We use Zadeh’s test-score semantic [11] to represent the user goals. A basic idea underlies test-score semantics is that a proposition  $p$  in a natural language may be viewed as a collection of elastic constraints,  $C_1, \dots, C_k$ , which restricts the values of a collection of variables  $X = (X_1, \dots, X_n)$ . In fuzzy logic, this is accomplished by representing  $p$  in the canonical form:

$$G \Rightarrow R(P) \text{ IS } A \tag{1}$$

in which  $A$  is a fuzzy predicate. The canonical form  $G$  implies that the possibility distribution of  $R(P)$  is equivalent of the membership function of  $A$ , namely  $\Pi_{R(P)} = \mu_A$ . For example, the agent helps a user to buy high quality item and can be represented using the canonical form below:

$$G \Rightarrow \text{Quality}(\text{goods}) \text{ IS HIGH} \tag{2}$$

Where  $\text{HIGH}$  is a fuzzy predicate. The rigid goal is the specialization of the soft goal, which membership function of fuzzy predicate is 1.0.

### 2.4 The Negotiation Strategies

A negotiation strategy is the combination of tactics with various weights. A tactic generates a value for a single negotiation issue based upon a single criterion (e.g. time remaining, resource remaining).

As negotiation proceeds, the goals of agent may become relevant and the relative importance of existing criteria may vary. To reflect this fact, an agent has a strategy that varies the weights of the different tactics over time in response to various environmental. We extended the research [12,13] to proposed four types of tactics described below.

- (1) Time-dependent tactics

These tactics model the fact that the agent is likely to concede more rapidly as the negotiation deadline approaches. The negotiation must have completed at the pre-established deadline ( $t_{\max}$ ). The maximum price is  $P_r$ . When the deadline is nearly up, the price approaches the  $P_r$ . The function of tactics:

$$f_t = \alpha_t(t) P_r \tag{3}$$

$$\alpha_t(t) = k_t + (1 - k_t) \left( \frac{t}{t_{\max}} \right)^{1/\beta_t}$$

$$0 \leq \alpha_t(t) \leq 1, \alpha_t(0) = k_t, \alpha_t(t_{\max}) = 1,$$

$$0 \leq k_t \leq 1, 1/200 \leq \beta_t \leq 1000.$$

- (2) Resources-dependent tactics

These tactics generate offers depending on how a particular resource is being consumed; they become

progressively more conciliatory as the quantity of resource diminishes. Here, we use the bidder tactics. The equation is:

$$f_r = \alpha_r(t) P_r. \quad (4)$$

$$\alpha_r(t) = k_r + (1 - k_r) \frac{c(t)}{|A|} \frac{1}{\beta_r}$$

$$0 \leq k_r \leq 1, 1/200 \leq \beta_r \leq 1000.$$

$c(t)$  is the number of web at 0~t,  $|A|$  is the number of active bidding web at 0 ~  $t_{max}$ .

### (3) Prices-dependent tactics

Agent uses these tactics to maintain the goal of minimum price. Agent must get the bidding prices of all active bidding webs. The equation is:

$$f_p = \omega(t) + \alpha_p(t)(P_r - \omega(t)) \quad (5)$$

$$\alpha_p(t) = k_p + (1 - k_p) \frac{t}{t_{max}} \frac{1}{\beta_p}$$

$$0.1 \leq k_p \leq 0.3, 1/200 \leq \beta_p \leq 0.5$$

$$\omega(t) = \frac{1}{|L(t)|} \sum_{1 \leq i \leq |L(t)|} \frac{t - \sigma_i}{|\eta_i - \sigma_i|} v_i(t)$$

$|L(t)|$  is the number of active bidding webs at time t. The  $\eta_i$  represents the start time of the  $i$ th bidding web. The  $\sigma_i$  is the end time of the  $i$ th bidding web. The  $v_i(t)$  represents the highest price of the  $i$ th bidding web at time t.

### (4) Desire-dependent tactics

Agent does the best to buy the high quality goods to achieve the user desired. The curve of the price will quickly approach the  $P_r$ . The equation is:

$$f_d = \omega(t) + \alpha_d(t)(P_r - \omega(t)) \quad (6)$$

$$\alpha_d(t) = k_d + (1 - k_d) \frac{t}{t_{max}} \frac{1}{\beta_d}$$

$$0.7 \leq k_p \leq 0.9, 1.67 \leq \beta_d \leq 1000$$

## 3. The Evolution of Intelligent Agent

Genetic algorithm (GA) operators are employed to restructure agents in the proposed multi-agent evolution cycle. How to encode a solution of the problem into a chromosome is a key issue for genetic algorithms. In Holland's work [14] encoding is carried out using binary strings. For many GA applications, the simple GA was difficult to apply directly because the binary string is not a natural coding. During the past ten years, various non-string encoding techniques have been created for particular problems, for example, real number coding for constrained optimization problems and integer coding for combinatorial optimization problems. In our research, a real-coded GA uses floating-point numbers to represent

genes [15].

### 3.1 Coding Schema

In order to find proper intelligent agent, the agent's negotiation strategies are coded and represent an individual. A strategy that is the combination of tactics with various weights will determine the bidding price at time t. We have three categories of tactics: time-dependent, resource-dependent, behavior-dependent. The equation of a strategy describes below:

$$S(t) = w_t f_t + w_r f_r + w_p f_p + w_d f_d \quad (7)$$

$$0 \leq w_t, w_r, w_p, w_d \leq 1,$$

$$w_t + w_r + w_p + w_d = 1$$

Each agent is represented as a string of fixed length. The bits of the string (the gene) represent the parameters of the agent's strategy.

$$G = (t_{max}, d, r, k_1, \beta_1, w_1, k_2, \beta_2, w_2, k_3, \beta_3, w_3, k_4, \beta_4, w_4) \quad (8)$$

### 3.2 Measuring a Strategy's Fitness

A fitness function is the survival arbiter for individuals. For finding the near-optimal intelligent agent, we propose the fuzzy multi-criteria decision-making (FMCDM) approach as the evolution mechanisms, and the fuzzy soft goals to facilitate the evolution process.

We may analyze the user's goals into a goal model. Each goal can have some criteria. The evaluation of soft goal is a satisfaction degree. The relationships between goals will exist conflicting and cooperative. Most of the existing approaches in multiple criteria making lack the aspect of an explicit modeling of relationships between goals. Carlsson and Fuller [16] advocated that much closer to MCDM in the real world than the traditional MCDM are the case with interdependent criteria. Our previous work on Criteria Trade-off Analysis (CTA) has been on the formulation of soft criteria based on Zadeh's canonical form in test-score semantics and an extension of the notion of soft condition [17]. The trade-off among soft goals is analyzed by identifying the relationships between goals. A compromise overall satisfaction degree can be obtained through the aggregation of individual goal based on the goals hierarchy. The steps describe below.

(1) To compute the relationship between goals: The  $c$ ,  $c'$  are two soft goal, and  $a$  is the strategy, CF and CP denote the set of conflicting and cooperative pairs. AP denotes the set of all pairs. The conflicting and cooperative degree between two goals is defined as:

$$cf(c, c') = \frac{\sum_{(ai, aj) \in CF} (|\mu^c(ai) - \mu^{c'}(aj)| + |\mu^{c'}(ai) - \mu^c(aj)|)}{\sum_{(ai, aj) \in AP} (|\mu^c(ai) - \mu^{c'}(aj)| + |\mu^{c'}(ai) - \mu^c(aj)|)} \quad (9)$$

$$cp(c, c') = \frac{\sum_{(ai, aj) \in CP} (|\mu^c(ai) - \mu^{c'}(aj)| + |\mu^{c'}(ai) - \mu^c(aj)|)}{\sum_{(ai, aj) \in AP} (|\mu^c(ai) - \mu^{c'}(aj)| + |\mu^{c'}(ai) - \mu^c(aj)|)} \quad (10)$$

- (2) To covert connections of the goals into DNF (Disjunctive Normal Form), and to establish a goals hierarchy: We assume that goals specified by users are connected by linguistic connectives in natural language. To take these connectives into account, we proposed the use of DNF to obtain a uniform representation of the goals. According to the conflicting and cooperative degrees, a goals hierarchy of n levels is defined as a tree. This tree is important in the sense that the ordering established through the hierarchy helps alleviate the associative problem inherited in fuzzy aggregation operator.
- (3) By using fuzzy aggregation operator to compute the strategy's fitness: An extended goals hierarchical aggregation structure is proposed to facilitate goals aggregation through the fuzzy and / or operator. The fitness can be obtained through the aggregation of satisfaction degrees based on the aggregation structure.

### 3.3 The Evolution Steps

All GAs use some form of mechanism to chose which individuals from the current population should go into the mating pool that forms the basis of the next population generation. A selection mechanism known to work well in such circumstances is Tournament Selection [18]. The crossover process exchanges genetic material between individuals. We randomly select two individuals from the population. Crossover points are then randomly chosen and sorted in ascending order. Then the genes between successive crossover points are alternately exchanged between the individuals, with a probability. Mutation process works by randomly selecting some of the genes present in the population in order to mutate.

The evolution of agent describes below.

#### (1) Initial population

A GA requires a population of potential solutions to be initialized at the beginning of the GA process. Here, we randomly generate some genes to create the initial population. We also generate some genes based on the agent's belief model.

#### (2) Selection Procedure

Selection procedure may create a new good population for the next generation based on either all parents and offspring or part of them [19,20]. A sampling space is characterized by two factors: size and ingredient (parent or offspring). In regular sampling, there are several replacement strategies to replace old parents with offspring when new offspring are produced. As mentioned before, the population of next generation was formed by roulette wheel selection [19]. When selection performs on enlarged sampling space, both parents and offspring have the same chance of competing for survival. An evident advantage of this approach is that we can improve GA performance by increasing the crossover and mutation rates. We don't worry that the high rate will introduce too much random perturbation if selection is performed on

enlarged sampling space.

A reproduction operation allows strings that with higher fitness values would have larger number of copies while the strings with lower fitness values have a relatively smaller number of copies or even none at all. This is an artificial version of natural selection (strings with higher fitness values will have more chances to survive). For example, suppose that N strings are generated, and the fitness value of the ith individual string is  $f_i$  ( $i=1, \dots, N$ ). Then, the probability of the ith individual string to be selected into the mating pool is

$$P_i = \frac{f_i}{\sum_{i=1}^N f_i}, \quad (11)$$

and the number of copies for the individual string is calculated by

$$n_i = N \cdot P_i \quad (12)$$

This strategy emphasizes the survival-of-the-fitness aspects of the GA. The better strings receive more copies and go into the mating pool so that their desirable characters may be passed onto their offspring.

#### (3) Crossover

Crossover is a process to provide a mechanism for two high-fitness strings (parents) to produce two offspring by matching their desirable qualities through a random process [21]. The procedure of crossover is to select a pair of strings from the mating pool at random, then, an integer position k (called the crossover point) along the string is selected uniformly at random between 1 and (l-1), where l is the string length greater than 1. Finally, according to the probability of crossover, two new strings are generated by swapping all characters between position (k+1) and l inclusively. For example, consider two strings A and B of the population are mated for crossover

A=011|11001  
B=100|10011

Suppose we obtain k=3 as indicated by the separator symbol "|". The resulting crossover yields two new strings as shown below

A'=01110011  
B'=10011001

where A' and B' are the strings of the new generation. Although the crossover is done by random selection, it is not the same as a random search through the search space. Since it is based on the reproduction process, it is an effective means of exchanging information and combining portions of high-fitness solutions.

An agent is composed of some kinds of modules. Each module has a special feature for a particular plan. In multi-agent system, there are two phase of crossover: the inter-agent and intra-agent. With the inter-agent crossover, an agent exchanges a module with another agent. The intra-agent crossover exchanges some parameters or strategies between modules in the same agent.

#### (4) Mutation

Mutation is a process to provide an occasional random alteration of the value at a particular string

position [22]. In the case of binary string, this simply means changing the state of a bit from 1 to 0 and vice versa. A uniform mutation is first to produce a mask randomly, then change the selected string value in the position of mask where the bit value is "1". For example, consider the following selected string and generated mask:

A' = 0 1 1 1 0 0

mask M = 1 0 0 1 0 1

then, the 0-1 pattern of the string becomes as the following string,

A'' = 1 1 1 1 0 0.

Mutation occurs with a small probability in the GA to reflect the small rate of mutation existing in the real world. Mutation is needed because some digits at a particular position in all strings may be eliminated during the reproduction and crossover operations. Such a situation is impossible to be recovered by using only reproduction and crossover operations. To ensure that reproduction and crossover do not lose some potentially useful genetic materials (1's or 0's at particular locations), in mutation phase, some bits will be changed in all the strings according to the mutation rate ( $P_m$ ). In general, the mutation rate is less than 0.05. So the mutation plays a role as a safeguard in GA. It can help GA to avoid the possibility of mistaking a local optimum for a global optimum.

## 4. Experiments and Results

Over the last few years, the number of online auction houses has increased tremendously. To date there are more than 760 auction houses that conduct business online. Some examples of popular online auction house include eBay, Amazon, Yahoo! Auction, Priceline, Ubid, and FirstAuction. The types of auction that are conducted vary from site to site, but the most popular one are English, first-price sealed bid. In the English auction, the auctioneer begins with the lowest acceptable price and bidders are free to raise their bids successively until there are no more offers to raise the bid. The winning bidder is the one with the highest bid [23].

### 4.1 The Simulation Environment

In this paper, a digit video is the target item. The  $P$  is its reservation price for the target item. The bidder is given a deadline by when it needs to obtain the item. There are five predefined auctions running in the environment. These auctions have a finite start time and duration generated randomly from a standard probability distribution. The start time and the end time vary from one auction to another. The auction starts with a predefined small starting value. The process is repeated until the reservation price is reached or until the end time for the auction is reached. At the start of each auction, a group of random bidders are generated to simulate other auction participants. These participants operate in a single auction and have the intention of buying the target item and possessing certain behavior. They maintain information about the item they wish to purchase, their private

valuation of the item (reservation price), the starting bid value and their bid increment. These values are generated randomly from a standard probability distribution. They start bidding at starting bid value; when making a counter offer, they add their bid increment to the current offer, and they stop bidding when they acquire the item or when their reservation price is reached.

### 4.2 The Strategy of the Bidder Agent

The bidder agent is allowed to bid in any of the auction at any time when the marketplace is active. The objective of the bidder agent is to participate across the multiple auctions, bid in the auctions and deliver the item to its consumer in a manner that is consistent with their preferences. The bidder agent utilizes the available information to make its bidding decision; this includes the user's reservation price, the time it has left to acquire the item, the current offer of each individual auction, and its set of tactics and strategies. The output of the bidding decision is the auction the agent should bid in and the recommended bid value that it should bid in that auction. The agent's overall behavior is the amalgamation of those strategies proposed in this paper, weighted by their relative importance to the user. Mapping this to an auction environment, the bidder agent needs to decide the new bid value based on the current offer price. Let  $t$  be the current universal time across all auctions, where  $t \in \tau$ , and  $\tau$  is a set of finite time intervals. Let  $t_{max}$  be the time by when the agent must obtain the good (i.e.  $t_{max} \geq t \geq 0$ ), and let  $A$  be the list of all the auctions that will be active before time  $t_{max}$ . At any time  $t$ , there is a set of active auctions  $L(t)$  where  $L(t) \subset A$ . Since each auction has a different start and end time, the bidder agent needs to build an active auction list to keep track of all the auction that are currently active in the marketplace. The agent identifies all the active auctions and gathers relevant information about them. It then calculates the maximum bid it is willing to make at the current time using the agent's strategy. Based on the value of the current maximum bid, the agent selects the potential auctions in which it can bid and calculates what it should bid at this time in each such auction. The auction and corresponding bid with the highest expected utility is selected from the potential auctions as the target auction. Finally, the agent bids in the target auction.

### 4.3 Experimental Evaluation

Our experiments were run in an environment with 10 agents of the first generation,  $n_{max} = 100$ , 5 English auctions running concurrently, and for each auction, there are 10 participants. If the reservation price of the agent is reached or until the end time for the all auction is reached, we can get the bidding price, the bidding time, and the quality of the target item for each agent. We apply the fuzzy decision making approach to compute the fitness value of agent. Then we apply the evolution approach to generate the next generation agents. In this particular experiment, the mutation rate is 0.02. The simulations stop when the

population is stable (95% of the individuals have the same fitness) or the number of iterations is bigger than a predetermined maximum (200 in our case).

## 5. Conclusion

In this paper, we present a new approach for evolving intelligent agents in e-commerce. A goal-driven approach can construct the user's soft and rigid goals based on fuzzy set theory. The proposed BDI model represents the mental skills of the intelligent agent, including belief, desire, intention, and strategy. A FMCDM approach is applied to evaluate the agent's strategy. Agent fitness and life cycle are proposed to facilitate and control the process of agent evolution. We construct multi-agent evolution cycle, which includes states of restructuring, selection, and growing. We conduct a series of experiments to determine the most successful strategies and to see how and when these strategies evolve depending on the context and negotiation stance of the agent's opponent. Finally, we have demonstrated the usefulness of agents employing a cocktail of tactics – both for different negotiation issues and, in combination, for a single issue.

## Abstract

Multi-issue negotiation may produce mutual beneficial results to both negotiators while single-issue negotiation can not. However, there are difficulties in automating a multi-issue negotiation, since the search space grows dramatically as the number of issues increases. Although many concession strategy learning mechanisms have been proposed to deal with the problem, recent research uncovered that the fixed strategy of concession and the fixed-pie bias are the two major interferences in the automation of multi-issue negotiation. It is suggested that the lack of communication between agents may have impeded information sharing and joint-problem solving possibilities.

In this paper, we show that the fixed-pie bias can interfere with the negotiation outcome if there are non-conflicting issues. We propose a new negotiation model and an innovative algorithm that not only allows information to be shared in a controlled way, but also allows the information shared to be effectively used for conducting a systematic search over the negotiation problem space. The combined mechanism is capable of using strategies learned from counter-offers and is immune to the fixed-strategy limitation and the fixed-pie bias. It contributes to the automation of multi-issue negotiation in the context of open and dynamic environments.

## 1. Introduction

Negotiation is a human behavior existed since there is trade. People exchange products in order to give out what they have for what they need. In the age of electronic commerce, negotiation has been automated by software agents or supported by negotiation support systems (NSS). Research [10] [16] [11] [5] indicated that these automation mechanisms were able to reduce significantly the negotiation time and alleviate the negative effects of human cognitive bias and limitation. The evolution went from single-issue negotiation to multi-issue negotiation. In a single-issue negotiation, the term negotiated is limited to price. Although this kind of negotiation works for some cases such as auction houses, most companies on the Internet are generally against it since it brings out price wars that not only causes chaos in markets but also ignores the importance of other issues such as warranty period and delivery time.

Multi-issue negotiation becomes an important research area in the e-commerce domain, since it is more

beneficial comparing to single-issue negotiation [14]. However, there are difficulties in automating a multi-issue negotiation. Take a bilateral multi-issue negotiation, where there is a buyer and a seller performing a one-to-one negotiation, for example. Issues can be negotiated sequentially or simultaneously. The issue-by-issue approach suffers the drawback of being unable (or costly) to go back to already negotiated issues. Hence it is inappropriate for solving problems with inter-dependent issues. In the simultaneous approach, on the other hand, negotiators get lost easily in the complex decision tree of concessions, and the search space grows dramatically as the number of issues increases. Since we assume self-interested agents, an agent will not disclose his utility function, being afraid of the fact that the opponent will take advantage of it to squeeze surplus out of him. Given the situation, the only information disclosed are the offers proposed and the information of acceptance or rejection on the proposed offers. An algorithm is required to search the negotiation problem space for mutual beneficial agreements base on the limited information. Adopting the simultaneous approach, there are three types of algorithms:

1. Brute force: suppose that a buyer is bidding for goods from a seller. He then queries the seller for acceptance of each offer in mind, from the one with highest utility to the one with lowest. The seller may accept it or reject it. This process continues until the buyer has run out of alternatives. To speed up the process, the seller can counter-offer using the same method as the buyer. Once an offer is accepted by one of two players, the negotiation ends. This approach is similar to the continuous double auction used in Kasbah [2], and may work fine in the single-issue negotiation without time constraints (i.e. deadline, bargaining cost, etc.). However, it is hardly applicable to the multi-issue negotiation since there are generally too many alternatives generated by combining options of all the issues. Simply generating and sorting them will require a lot of memory space, not to mention querying them one by one, which can be very time-consuming.

2. Use a concession strategy learned from past negotiations: this approach works great if the market is static, which means that the general utility function of buyers/sellers does not change radically over time. Although we do not know exactly the utility function of the opponent, we learn from past negotiations to get the best concession strategy that can both speed up the negotiation and get better outcomes. However, if the

market is dynamic, this fixed strategy may not achieve mutually beneficial outcomes each time, since different opponents may have quite different utility functions over the various issues. Research [13] [12] [17] belongs to this type.

3. Use a concession strategy learned from counter offers: although rarely seen in the research, it is possible to learn a concession strategy from counter offers within a negotiation session. The rationale behind it is to find out which terms are important (weighted more in the utility) to the opponent, but less important to us. Conceding on these issues increases the possibility of being accepted by the opponent, while preserving our interests. Research [4] uses similarity criteria to make issue trade-offs; it is believed that by making an offer similar to the one by the opponent can approximate the preference structure of the opponent.

In an open and dynamic environment, such as the Internet, the third type algorithm becomes important. Goh et al. [6] conducted an experimental study on computer-supported bargaining in the context of electronic commerce, and uncovered that the fixed strategy of concession and the fixed pie bias are the two major interferences in the automation of negotiation. It is suggested that the lack of communication between agents may have impeded information sharing and joint-problem solving possibilities. The problem of fixed strategy has been addressed later in [4] (though the existence of too many assumptions has caused their research to be less applicable to real cases). However, the joint-problem solving possibilities are still constrained by the fixed-pie bias and the information shared.

In this paper, we propose a new negotiation model and an innovative algorithm that not only allows information to be shared in a controlled way, but also allows the information shared to be effectively used for conducting a systematic search over the negotiation problem space. The combined mechanism is capable of using strategies learned from counter-offers and is immune to the fixed-strategy limitation and fixed-pie bias. It contributes to the automation of multi-issue negotiation in the context of open and dynamic environments.

The sections are organized as follows: section 2 firstly explains the rationale for information sharing. Section 3 describes the negotiation model used, and section 4 gives details of the searching algorithm. Section 5 contains experimental analysis and finally the conclusion and future work is presented in section 6.

## 2. The Rationale for Information Sharing

In the context of Game Theory, the two-player bargaining game is defined as a non-cooperative game where two players attempt to divide a good, say a pie, between them. However, the pie-dividing concept may introduce the fixed-pie bias, which is a tendency for negotiators to assume that their own interests directly conflict with those of the other party [1] [18]. The problem caused by this bias seldom occurs in a bargaining since

most of them are dealing with conflicting issues. Let us consider a more general two-player multi-issue negotiation problem, where the players not only negotiate for the price, but also a date for delivering the product. The utility gained from settling for a different date is illustrated in Figure 1. At the beginning, their preferences seemed to be conflicting; nevertheless, they managed to meet at day 7, which is the best solution for both of them. The  $f$  curve occurs when a player wishes to get the product immediately or on a later date if he can not get it immediately. This example illustrates that sometimes the pie-dividing concept may be misleading, causing both negotiators to neglect a mutually beneficial solution if they do not communicate. Same problems can occur when dealing with qualitative issues such as the choice of colors, since the utility gained by each color may not always be conflicting with the opponent's preference.

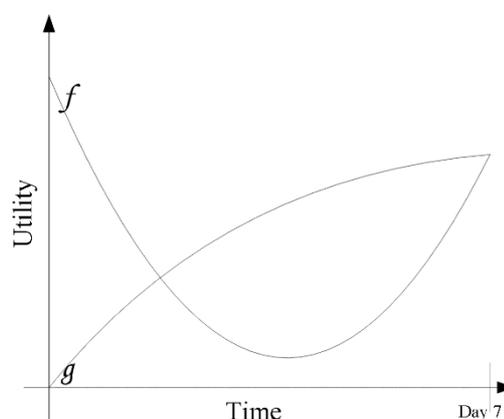

Figure 1. Non-conflicting utility case

Research [4] was based on the pie-dividing concept; however, they allow different levels of importance to be attached to various negotiation decision variables. This makes the negotiation a non-zero-sum game, where players can find mutually beneficial agreements by making trade-offs over issues instead of conceding at the utility. That is to say, by increasing some decision variables in value and decreasing some others may create an offer that will benefit one or both of the players simultaneously. However, considering the above delivery time case, we find that a mutually beneficial offer can be found by simply increasing the utility of one of the decision variables without decreasing any other (instead of conceding, one can raise the utility of the new offer). In other words, better solutions can be found if we avoid the fixed-pie bias. Nevertheless, by avoiding the fixed-pie bias, we are again lost in the enormous possible paths of solution searching. It is our belief that, by disclosing a little more information, the player with less privacy concerns can improve the negotiation outcome, and therefore benefits himself. And it is also common that, in the real life situation, a player with less privacy concerns will simply release trade-off information, such as "you can deliver the product to me immediately or a week later."

One may argue that, in the above delivery date case, the opponent will propose the offer of day 7 eventually if you did not propose it, yet in the multi-issue case, there can be a lot of alternatives that it is too hard to enumerate them all. Therefore how the information can be shared in a systematic way such that the opponent can use it to improve the solution searching process is the major concern here. Besides, the information should be disclosed in a controlled way so that it not only matches our privacy preference but also complies with our negotiation strategy. To tackle this problem, we propose a new negotiation model and an innovative solution to the searching problem in the following sections.

### 3. Tagged Multi-offer Negotiation Model

In this section we first provide an overview of our negotiation model. Then we discuss the issues of time constraints and information states.

#### 3.1 The Negotiation Model

The settings of our negotiation model are based on a non-cooperative, multi-stage, incomplete-information, and two-player bargaining game. Since this is a non-cooperative game, each player does his best to maximize his own interest and will not share information more with the other than necessary. We assume each player knows neither the other's preferences on issues, nor the utility function; therefore it is a game with incomplete information. Given such a situation, in order to reach an agreement that is beneficial to both players, the negotiation will continue for more than one stage.

Rubinstein proposed a multi-stage bargaining game [15], in which each player of the game proposes an offer in turn and the other may accept or reject it. The game will continue until an offer is accepted. Our model differs from [15] in that: Firstly, we allow multiple offers to be proposed at one time. For example, a seller can propose two offers at one time, saying "you can buy product A at price B with delivery time C or buy product A at price D with delivery time E". The buyer may counter propose with sayings like "I can only buy product A at price F with delivery time G or buy product A at price H with delivery time K". This relaxation of multiple alternating offers enables a player to disclose possible trade-off information over which the opponent can consider. It can speed up the searching process and avoid falling into local optima in the solution landscape too early.

Besides the relaxation of multiple alternating offers, we allow players to tag information of their preferences over proposed offers. For example, a vector  $\langle\langle A, 3 \rangle, \langle B, 2 \rangle, \langle C, 1 \rangle\rangle$  indicates that offer A is the most preferred, offer B is the second most preferred, while offer C is the least preferred. We allow the multiple alternating offers and the tagging of preference information because we believe the information may be "necessary" for both players to reach an agreement that is beneficial to both of them. However, how much information will be shared is a

decision made by the players. An elegant controlling mechanism is embedded in our searching algorithm (detailed in the next section), and it can be tuned according to the privacy preference of the player.

Finally, the negotiation game will end in a known period of time, no matter whether an agreement has been reached. If an agreement has been reached before the deadline, the players will continue to improve it until the deadline. If no agreement has been reached before the deadline, the negotiation fails. If more than one agreement has been reached, the latest one is chosen. This design permits better solutions to be found after the first agreement has been reached.

We name this negotiation model a TAMON (TAGged Multi-Offer Negotiation) model.

#### 3.2 Time Constraints

Rubinstein's model has a basic assumption that 'time' is valuable during the negotiation, and the fixed bargaining cost or fixed discounting factor may affect the strategy used in the bargaining. If each player has complete information about the preferences of the other, a weaker player (i.e. the one with higher fixed bargaining cost) will always lose. However, assuming each player does not know the preference structure of the other (incomplete information), the weaker player may try to cheat the other player by making the other player believe that he is actually stronger.

To simplify the TAMON model (avoiding the consideration of time-related strategies), we assume the cost of time is negligible during a TAMON game. In other words, by choosing a reasonable period of time to play the negotiation game, it is possible for both players to agree that there can be no time constraints during the period of negotiation. By this simplification we make TAMON a micro negotiation game. It does not mean that there are no time constraints any more, but that the time constraints are omitted during the TAMON game. The time constraints still exist between the current TAMON game and the next TAMON game. That is to say, to achieve an agreement, both players can play a series of TAMON game that is time constrained.

This simplification has two benefits:

1. The environment is stable during a TAMON game; therefore players can focus on the searching and improving of solutions without the need to deal with changing environmental parameters.

2. Existed time-dependent bidding strategies such as NDF [3] can be applied directly to a series of TAMON game without conflicting with "micro" level strategies used in the TAMON game.

This assumption also indicates that the goal of micro level strategies will be to find a solution given the constraints from "macro" level strategies. And macro level strategies are applied on a series of TAMON game.

### 3.3 The Information State

Each player (let  $b$  denotes buyer and  $s$  denotes seller) in a TAMON game is modeled as a 5-tuple  $I^a$  with a utility function  $U$ , a utility threshold  $U_{\text{threshold}}$ , a degree of information sharing  $D$ , a micro level strategy  $S$  and a mutually agreed period of time  $T$  to play the game:

$$I^a = \langle U^a, U_{\text{threshold}}^a, D^a, S^a, T \rangle, \text{ where } a \in \{b, s\}. \quad (1)$$

We define the utility function to be a sum of weighted contributions of  $N$  issues:

$$U = \sum_{i=1}^N w_i * u_i, \text{ where } u_i = [0,1] \text{ and } \sum_{i=1}^N w_i = 1. \quad (2)$$

The utility contributed by each issue, however, is not necessarily depending only on the value of this specific issue, but also on the values of  $K$  other issues in the offer. The occurrences of this interdependency will make it inappropriate to be negotiated in an issue-by-issue way.

The micro level strategy  $S$  is defined by the algorithm and the algorithm parameters used for generating and accepting offers (detailed in section 5). In this paper, we will assume there is only one choice of algorithm, the BGA (discussed in the next sub-section), and  $D$  does not change during the series of TAMON game. Therefore the macro level strategies contain only functions determining the value of  $U_{\text{threshold}}$ . The search space bounded by  $U_{\text{threshold}}$  in a TAMON game is illustrated in Figure 2.

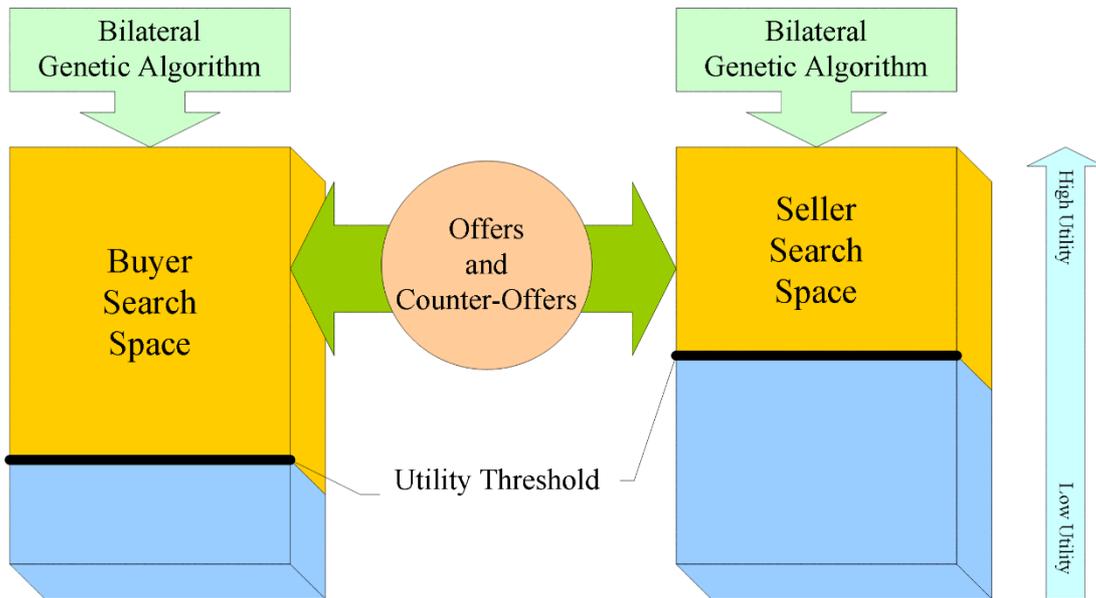

Figure 2. The Search Space in a TAMON Game

### 4. The Bilateral Genetic Algorithm

To search in the space of a TAMON game, we need a heuristic method that is computationally tractable; since the overall search space is too large that an exhaustive fashion of search is not possible. Considering a single-issue negotiation for delivery time in Figure 3, if both negotiators are using the same linear time-dependent macro level function for decreasing the  $U_{\text{threshold}}$ , their agreement can be found at the intersection of utility  $x$ . In this case, the offer generating process would be too simple that the micro level TAMON game can be set to propose only one offer in a turn and be played for only two turns (in the first turn, the buyer proposes and the seller accepts

or rejects, in the second turn the seller proposes and the buyer accepts or rejects). However, in a multi-issue search space, it is almost impossible to generate all the offers with utility  $x$  (while there are only two offers of utility  $x$  evaluated using  $f$  or  $g$  in Figure 3, there can be a huge number of offers of utility  $x$  in a multi-issue search space, especially when given nonlinear utility functions). Therefore, the searching algorithm can only propose some of them, and there is a great chance that the search algorithm will miss the right one. Suppose that a solution is guessed out at utility  $x'$  of time  $y'$  later, and then a mechanism will be required to back-search for the real optimal solution of utility  $x$ . The Bilateral Genetic Algorithm (BGA) is proposed to deal with this problem.

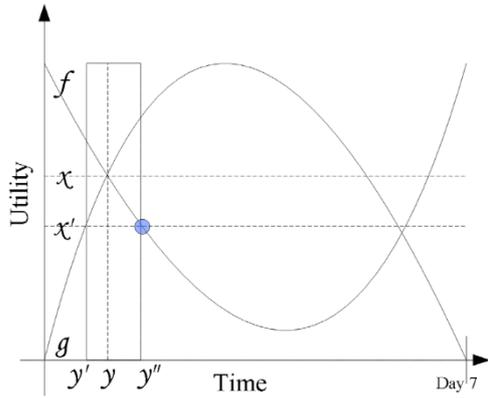

Figure 3. The Matching Point

#### 4.1 Overview of BGA

BGA is an algorithm for searching solutions to the TAMON problem. We apply the concepts of genetic algorithm (GA [8]) to the domain of offers. That is, we use a joint utility to express the fitness of an offer, and use an evolutionary approach to find out the best offer if possible. A very simple design of such an idea is to encode an offer into a single chromosome and let the fitness of it be the product (product is used instead of sum for fairness) of two utility values from the buyer and the seller. For example, let a chromosome {100, 5, 2, 3} (for readability, we use n-ary gene encoding) represents an offer with price of 100, quantity of 5 units, delivery time of 2 days and warranty period of 3 years. If the joint utility of this chromosome is high, the number of this individual will grow exponentially in the population, as stated in GA. And the population will eventually converge to the answers we want.

However, since the agents are self-interested in our scenario, each agent does not share information of his

utility with the other. Lacking the utility function from the other agent, an agent will not be able to determine the joint utility of a chromosome. Hence, both the buyer agent and the seller agent are not able to perform the selection using genetic operators on the population of offers. To overcome this problem, we propose an innovative algorithm BGA, which divides the population for evolution into a buyer side population and a seller side population, and uses two special genetic operators, B-selection and B-recombination, to handle the selection and recombination process in the presence of incomplete fitness function. Both agents must perform the genetic B-selection process and B-recombination process separately. The B-selected population will be proposed to the other player while the received population will be used to B-recombine with our B-selected population, as illustrated in Figure 4. The B-selection has a tunable sampling rate, which can select offers for proposing according to the  $D$  parameter. We will discuss the details of each operation in the following sub-sections, and then explain why it works.

Before we discuss the genetic operators used in BGA, we firstly define the parameters used in BGA:

Population Size:  $Z_{population}^a \in \mathbb{N}$ .

Crossover Rate:  $R^a = [0]1$ .

Mutation Rate:  $M^a = [0]1$ .

Chromosomes:  $C_i^a$ , where  $i \in \mathbb{N}$  and  $1 \leq i \leq Z_{population}^a$ .

Again:  $a \in \{b, s\}$ .

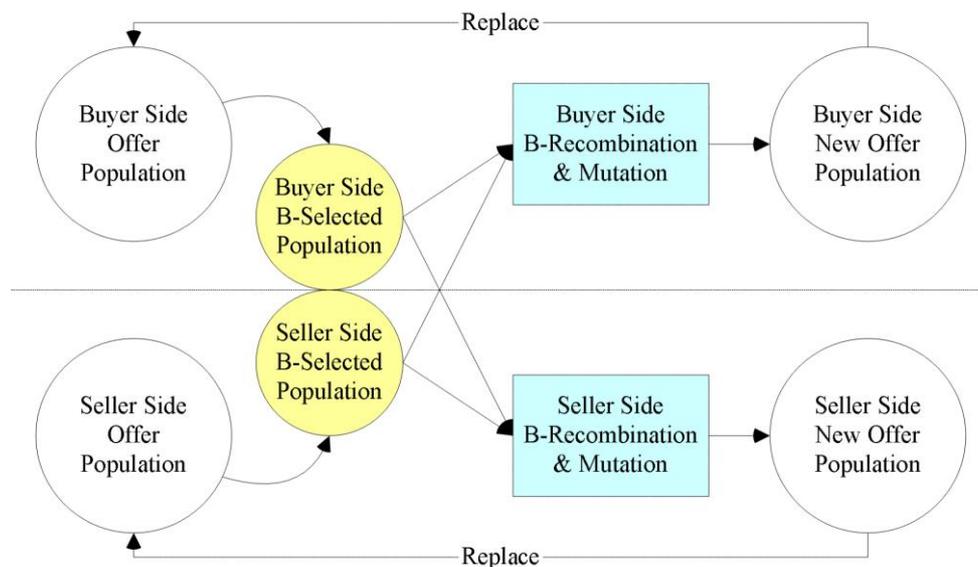

Figure 4. The BGA Evolution Process

#### 4.2 B-selection, B-recombination and B-mutation

The selection process of a GA will produce a new population with the distribution of chromosomes being proportional to the fitness of each chromosome from the old one. The one with higher fitness gets higher probability to be selected in the resulted population. B-selection does a little more: it will propose the population of chromosomes to the other agent, and the size of it will be affected by the degree of information sharing (parameter  $D$ ). The actual size of population proposed is:

$$Z_{\text{offers}} = \lfloor Z_{\text{population}} \times D \rfloor \quad (3)$$

During the agent communications, duplicated offers can be represented using a vector format  $\langle \text{Offer, Number} \rangle$ . The B-selected population then becomes offers proposed to the other player in a tagged multi-offer format. The higher value in  $D$ , the richer information in the proposed offers. If  $Z_{\text{offers}}$  equals to 1, it becomes a normal alternating offer protocol that proposes only one offer a turn.

The B-recombination operator differs from the GA recombination in that it recombines chromosomes from the different-side B-selected populations. In other words, one of the parent chromosomes comes from the buyer-side B-selected population while the other from the seller-side B-selected population. Since the population B-selected by the other agent might have different size from ours, both the received population and our B-selected population are rescaled to half of our population size before they can be put together into a joined population of size  $Z_{\text{population}}$  (see Figure 5). The joined population is then ready for B-recombination. It should be noted that, each agent might have a joined population of different size, since their  $Z_{\text{population}}$  values might be different.

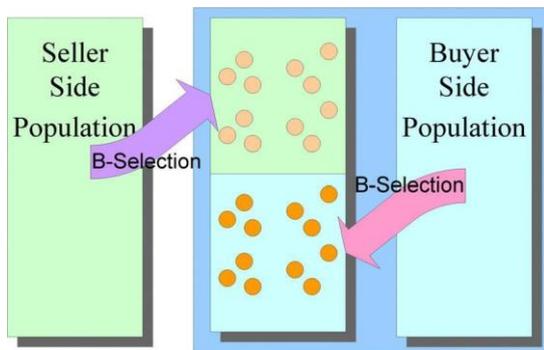

Figure 5. The Joined Population

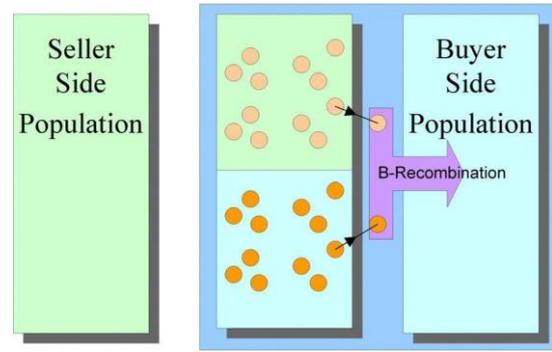

Figure 6. Performing B-recombination

B-recombination of two chromosomes produces chromosomes that represent offers applying different concession strategies. For example, recombining a buyer proposal  $\{100, 4, 2, 4\}$  with a seller proposal  $\{120, 3, 2, 2\}$  may produce a proposal  $\{100, 3, 2, 2\}$  denoting that the seller concedes at the price of value 100, and a proposal  $\{120, 4, 2, 4\}$  denoting that the seller concedes at quantity, delivery time and warranty period. Each agent performs B-recombination at his own memory space; therefore the crossover rates can be different at the two sides. After the B-mutation process, the newly generated population then replaces the old one (noted that the first generation is randomly generated). The B-mutation is similar to the GA mutation process except that it is performed separately at both sides.

We use uniform crossover in B-recombination, although it is considered to be maximally disruptive when the epistatic interactions are the nearest neighbors [9]. We believe it is required in our scenario, because it helps the B-recombination generate more possibilities of concessions assuming that the two negotiating agents may have different information spaces. For example, if the buyer can propose only one chromosome  $\{A, B, C\}$ , and the seller can propose only one chromosome  $\{D, E, F\}$ , uniform crossover makes it possible to generate a chromosome with  $\{A, E, C\}$  while one-point crossover cannot.

In the final algorithm, the B-selection is actually processed twice (Figure 7) by an agent in a turn; one for proposing offers, and one for generating half of population for next join. We need to separate these two populations since the proposed one is bounded by the utility threshold while the reserved one for next join is not. The detail of the algorithm is not explained in this paper. For interested readers, please check the web site: <http://homepage.ntu.edu.tw/~d85725004/BGA.html>.

```

GENERATE-OFFERS( $S_{pop}^r, D_{is}^r, R_{rec}^r, R_{mut}^r, b_f^r, b_u^r, \psi^r, \mu^r, \rho^r, \sigma^r, \theta^r, \vartheta^r, \chi^r$ )
1  $\chi^r \leftarrow \chi^r \cup \theta^r$ 
2 if ( $\theta^r = \phi$ ) or ( $\vartheta^r = \phi$ )
3   then  $\alpha \leftarrow \text{CREATE-POPULATION}(\rho^r, S_{pop}^r)$ 
4   else  $\alpha \leftarrow \text{B-MUTATE}(\text{B-RECOMBINE}(\text{RESCALE}(\theta^r, S_{pop}^r/2), \vartheta^r, R_{rec}^r), R_{mut}^r, \rho^r)$ 
5  $\gamma \leftarrow \text{ASSIGN-FITNESS}(\alpha, \psi^r, b_f^r)$ 
6  $\vartheta^r \leftarrow \text{B-SELECT}(\gamma, S_{pop}^r/2, 0)$ 
7  $\beta \leftarrow \text{B-SELECT}(\gamma, [S_{pop}^r \cdot D_{is}^r], b_u^r)$ 
8  $\theta^r \leftarrow \beta - \chi^r$ 
9  $\chi^r \leftarrow \chi^r \cup \theta^r$ 
10 return  $\theta^r$ 

GENERATE-FEEDBACK( $D_f^r, \theta^r, \mu^r, b_u^r, \psi^r$ )
1 if  $\sigma^r \neq \phi$ 
2   then  $b_u^r \leftarrow U(\sigma_1^r)$ 
3    $\psi^r \leftarrow \psi^r \cup \sigma^r$ 
4 if  $\theta^r \neq \phi$ 
5   then  $\gamma \leftarrow \text{AGREEMENTS}(\theta^r, \mu^r, b_u^r)$ 
6    $b_u^r \leftarrow \max\{(\gamma_j)_2 | 1 \leq j \leq \text{size-of}(\gamma)\}$ 
7    $\psi^r \leftarrow \psi^r \cup \gamma$ 
8    $\sigma^r \leftarrow \text{FEEDBACK}(\gamma, D_f^r)$ 
9 else  $\sigma^r \leftarrow \phi$ 
10 return  $\sigma^r$ 

```

Figure 7. The BGA algorithm

### 4.3 Preliminary Agreements

At the beginning of a BGA process, all chromosomes (i.e. offers) with utility higher than or equal to  $U_{\text{threshold}}$  are assigned a fitness value  $F_{\text{threshold}} = 0.99 * U_{\text{threshold}}$ . The coefficient 0.99 is designed to make the fitness value a little smaller than the  $U_{\text{threshold}}$ . Once a preliminary agreement (a proposed offer that is accepted) is reached, the associated chromosome will be given fitness equals to its real utility, which is higher than  $F_{\text{threshold}}$ . The number of this chromosome will then start to increase because of its high utility (further explained in the next sub-section). The discovery of a preliminary agreement also causes the value of  $U_{\text{threshold}}$  to climb up to the utility equaling to the one of the preliminary agreement. This climbing behavior ensures that the newly proposed offers will have a higher utility than preliminary agreements. It is the back-searching mechanism mentioned in the first paragraph of this section. In the view of macro level strategies, the value of  $U_{\text{threshold}}$  often goes down (decreasing) and does not go up, only when some preliminary agreement has been reached, it then makes sense to revert the  $U_{\text{threshold}}$  to the new high utility reached. This action is named a utility threshold reverting.

### 4.4 Implicit Parallelism in BGA

The main idea of BGA is to utilize the implicit parallelism of GA to explore all possible concession strategies and accumulate useful building blocks [7] at one

time. Implicit parallelism, named by Holland [8], is a property that:

...Even though each generation we perform computation proportional to the size of the population, we get useful processing of something like  $n^3$  schemata in parallel with no special bookkeeping or memory other than the population itself...

In BGA, only preliminary agreements contain useful building blocks that need to be accumulated in the later search. That is why we restore fitness of chromosomes to their actual utility value after they are found to be preliminary agreements (before that, all fitness values are lower than  $U_{\text{threshold}}$ ).

By B-recombining chromosomes from two populations of different sides, chromosomes representing various offer-improving possibilities are generated. The offer-improving behavior is a little bit like the similarity approximation in [4], since B-recombination try to generate an offer by recombining chromosomes from the two different populations and the resulted chromosomes will be similar to their parents. In fact, the BGA algorithm does a better job then [4] for locating offers similar to the opponent's. Because research [4] try to find similar offers by decreasing the utility distance, which is impossible if certain kinds of information about the opponent's utility function is unavailable. Their simulations work simply because there are too many assumptions (linear, conflicting, same value range and equal discrimination power over the reservation values) being placed on the opponent's utility function in their research. It makes the assumption of "incomplete information" quite weak.

B-recombination does not have a fixed-pie bias, since it does not assume a utility conceding is necessary when trying to generate an alternative. In fact, the BGA never decrease the utility of new offers, and try to increase the utility whenever possible. Once an offer acceptable to both sides is found, the utility threshold is increased, and the useful genetic information in the offer will then be accumulated in an evolutionary way.

To conclude, BGA can deal with the searching problem of a TAMON game in a computationally tractable way, and no specific assumptions are placed upon the utility function of the opponent.

### 5. Experimental Analysis

A negotiation case with mixed (including linear and nonlinear) utility function is prepared to test the capability of BGA. The utility functions for 5 issues in buying a car are listed in Table 1 (for simplicity, some of the functions are not showed in detail; mechanisms used to ensure the range of each utility value are omitted; for interested readers, complete source codes can be found at <http://homepage.ntu.edu.tw/~d85725004/BGA.html>). Two exceptions are added to override the default utility functions. They provide extra interdependency among these issues, and are the epistatic interactions as explained in [9].

Table 1. Utility functions

	Buyer	Seller
Price	$(200 - ((v \cdot v) / 200)) / 200$	$(v - 20) / 300$
Time	$\text{Cos}((2 \cdot \text{Pi} \cdot (v \bmod 7)) / 7)$	$\text{Sin}((2 \cdot \text{Pi} \cdot (v \bmod 30)) / 30)$
Type	{0.1, 0.2, 0.9, 0.5, 0.1}	$v / 4$
Color	{0.3, 0.4, 0.2, 0.7, 0.9}	{0.5, 0.5, 1, 0.5, 0.5}
Option	$(10 - v) / 10$	$v / 10$
Exceptions	If (Type = 1) and (Color = 2) then both issues get an utility value of 0.9.	If (Time = 77) and (Type = 1) then both issues get an utility value of 1.

Eighteen combinations of parameters (Table 2) are used to run the simulations. They are designed to answer the following questions:

1. Should I be the first mover? (should I propose offers firstly?)
2. How do I propose? (how much information can be disclosed?)
3. How do I response? (how much information should be fed back to the opponent regarding his proposing?)

In question 2, the degree of information sharing determines the sampling rate for proposing offers in mind, and in question 3, the feedback rate of preliminary agreements determines how much information regarding one's evaluation on the opponent's offers will be fed back to him.

Table 2. Experiment parameters

Q	Parameter Name	Parameters
1	First Mover	seller first buyer first
2	Degree of Information Sharing (DoIS for short)	1 (all) 0.1 0.0025
3	Feedback of Preliminary Agreements (FoPA)	1 (all) 0.5 0.1

As expected, the first mover has disadvantage in the TAMON game. The explanation is intuitive: since the first mover shares information firstly, the opponent is then able to increase his utility threshold firstly when preliminary agreements are found in the first turn. Readers can compare Figure 8 and Figure 9 to find out the difference (noted that the X-axis in them represents the product of DoIS and FoPA, and Y-axis the utility).

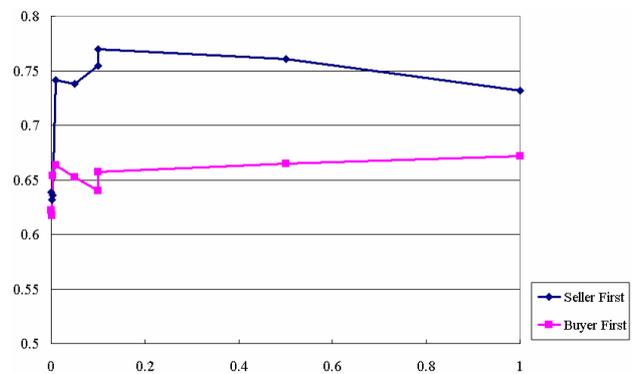

Figure 8. Buyer utility

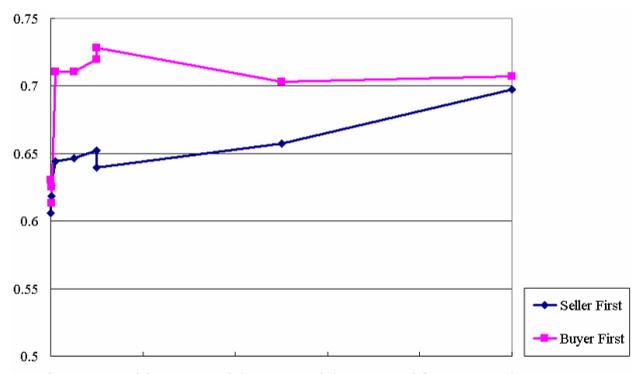

Figure 9. Seller Utility

Judging from the results showed in the following Figure 10 (FoPA = 1) and Figure 11 (DoIS = 1), we can conclude that the effects of information sharing have higher impact on the negotiation results than feedbacks. The reason lies at that the number of preliminary agreements is small comparing to the proposed offers. Since both negotiators tend to decrease the utility threshold slowly in the progress of negotiation, the number of preliminary agreements can not be very large. We also found that the degree of information sharing need

not to be very high for satisfactory negotiation results to be gained.

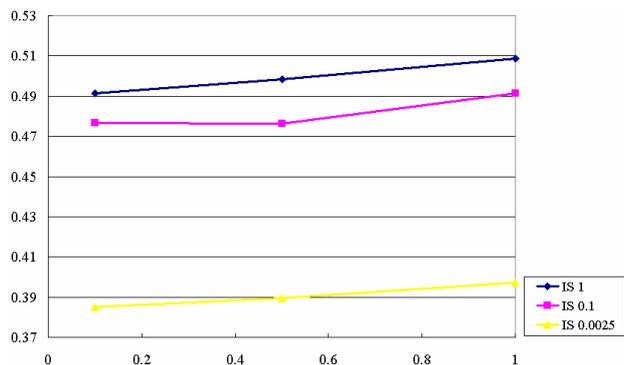

Figure 10. Effects of information sharing

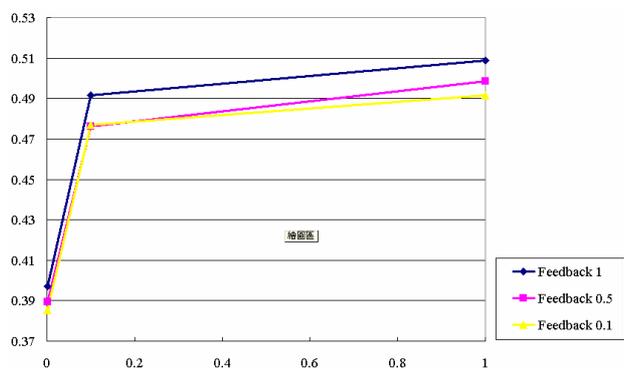

Figure 11. Effects of feedback

In Figure 12 (X-axis represents the buyer utility and Y-axis the seller utility, assuming FoPA = 1), the BGA simulation results are compared to GA simulations with same crossover rate (0.7) and mutation rate (0.02). Both population sizes are set to 400. In GA simulations, however, the algorithm has complete information of both negotiators' utility functions, and the product of buyer utility and seller utility is used as the fitness value. 1000 generations were run for the GA simulations while a period of 10 seconds was used in each micro level TAMON game simulation. We assume same bargaining power in the BGA simulations, therefore the utility threshold decreases at same speed (0.1 per micro level game) for both negotiators. Both GA and BGA simulations were run 30 times to get the average negotiation results in Table 3. The best result found by the brute force algorithm (testing all combinations) is also marked on Figure 12.

Table 3. Simulation results

	Buyer Utility * Seller Utility (Avg)	Ratio
Best	0.532946667	1
GA	0.520159512	0.976006689
BGA-1	0.508617115	0.954348993
BGA-0.5	0.491376085	0.921998608
BGA-0.0025	0.397237238	0.745360207

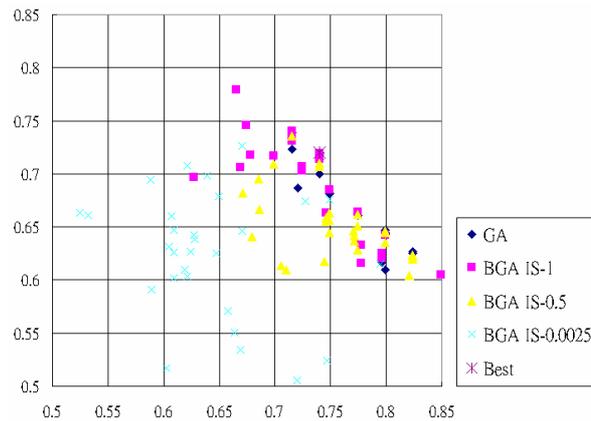

Figure 12. BGA simulations

The results in Table 3 show that BGA performs better when information is shared via the TAMON protocol. In the last case, where the degree of information sharing equals to 0.0025, only one offer was proposed in a turn (same as traditional negotiation model), and the ratio of average negotiation results drops dramatically. However, it is also found that by extending the TAMON game period, the results can be improved (see Figure 13, X-axis represents the degree of information sharing, and Y-axis the resulting utility product).

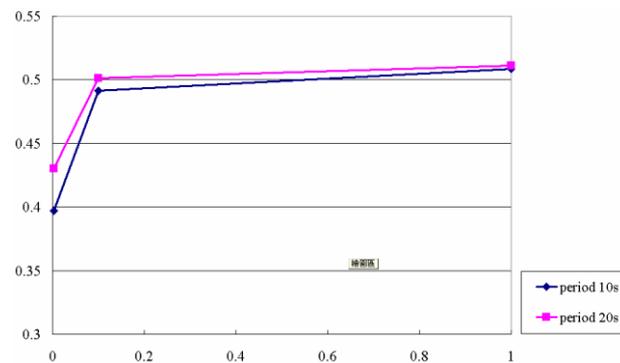

Figure 13. Effects of negotiation period

## 6. Conclusion and Future Work

We proposed the TAMON negotiation model and the BGA algorithm in this paper. The TAMON model defines a micro two-player negotiation game without time constraints, and allows more information to be exchanged in the negotiation game. The exclusion of time constraints is important for simplifying a TAMON game, since most search algorithms are not of real-time, and the search space tends to be static during the searching. It also permits a more complex search process to be conducted in a TAMON game, with a constraint that the process should be terminated after a period of time. By allowing more information to be disclosed in a tagged multi-offer format, the TAMON model incorporates the information sharing behavior into the negotiation model. We can say that the TAMON model provides a dimension for joint problem solving possibilities, yet it is still in the context of a non-cooperative game.

The BGA proposed in this paper utilizes the implicit parallelism of GA to search the solutions in a TAMON game. The elegance of the BGA is that it perfectly fits in the TAMON game since the population to be proposed is meaningfully transformed into the tagged multi-offer format, and with the degree of information sharing being taken into consideration. The algorithm is immune to the fixed-strategy limitation and the fixed-pie bias, and it is computationally tractable. It should be noted that it is not required that both players use the same algorithm in the negotiation. However, since the BGA can explore multiple strategies simultaneously, we are investigating that given the limitation of computational tractability, whether the BGA-like algorithm will be the only rational choice in a TAMON game.

We are developing a theory to measure the information disclosed in the tagged multi-offer protocol and to determine the precise effects caused by the information sharing in a multi-issue negotiation. A theory for guiding the choosing of BGA parameters, including the population size, the crossover rate and the mutation rate will also be addressed in the future work.

# E-Learning: A Study of Issues and Perspectives

Andrew Finegan  
School of Business Information Technology  
RMIT University  
Melbourne Australia  
andrew.finegan@rmit.edu.au

## Abstract

This study examines some of the issues and perspectives associated with development and delivery of an undergraduate business degree incorporating e-learning. The investigation was undertaken in an Australian University and incorporates the opinions and viewpoints of staff and students - both local and offshore. E-learning is a complex, and often poorly structured knowledge area, with many different issues, influences and agendas. For this reason Soft Systems Methodology (SSM) has been used to develop a model for analysis and for comparison of the issues with the literature.

## 1. Introduction

Most universities in Australia now offer online courses, and face challenges that include limited budgets, the availability of appropriate content, provision of student support, and the often rigid traditions in education and learning [16]. This is also reported by Cameron [2] who observes that Australian universities are making major investments in information and communication technology (ICT) upgrades. Flexible self-service, both in university administration and course delivery, is becoming increasingly important.

Consider the question posed by Cameron [2, p.42]: "...what has spurred so many Australian universities to invest so heavily in ICT upgrades, particularly in online learning and self-service?" The suggested answer is that this is a response to the increased competition for students and funds. The universities hope that e-learning technology will help them diversify their commercial interests, and enhance the variety and degree of online offerings to students and staff. However, Lee [12] expresses concern that e-learning will remain in the realm of rhetoric as long as it is no more than provision of lecture materials on the Web, with the Internet being used little more than a delivery medium.

This study, conducted in an Australian University, seeks to better understand the issues and challenges associated with e-learning. It adopts a systems approach

that incorporates the opinions, concerns, and viewpoints of the staff and students who represent the major stakeholders in applying this technology to teaching and learning.

## 2. A Systems Approach

E-learning projects typically exist in complex and poorly structured socio-technological environments, with many different issues, influences and agendas. Furthermore, Wilson [24] observes that a number of cultural discontinuities impact upon online learning effectiveness. In particular, the worldview of the learner is a key factor in better understanding how users navigate the teaching and learning interface. Therefore this study utilizes a systems approach that is suited for the analysis of complex situations where the worldview and the transformation at the learner interface is important.

Soft systems thinking seeks to explore the messy problematic situations that arise in human activity. It strives to learn from the different perceptions that exist in the minds of the different people involved in the situation [1]. This interpretive approach is strongly influenced by Vickers' [23, pp.59,176] description of the importance of appreciative systems in dealing with human complexity. Checkland [3], and Checkland and Scholes [4] have transformed these ideas from systems theory into a practical methodology that is called Soft Systems Methodology (SSM). Checkland [3, p.258] applies a core paradigm of learning to problems of complexity with poor structure, and so SSM attempts to understand the fuzzy world of complex organizations.

SSM, in its idealized form, is described as a logical sequence of seven steps [3, pp.162-183]. These are:

- Stages 1 and 2 - Expression of the problem
- Stage 3 - Selection of a Root Definition
- Stage 4 - Model Building - the Conceptual Model.
- Stage 5 - Comparison
- Stage 6 and 7 - Recommendations for Change, and Taking Action.

This is illustrated in Figure 1.

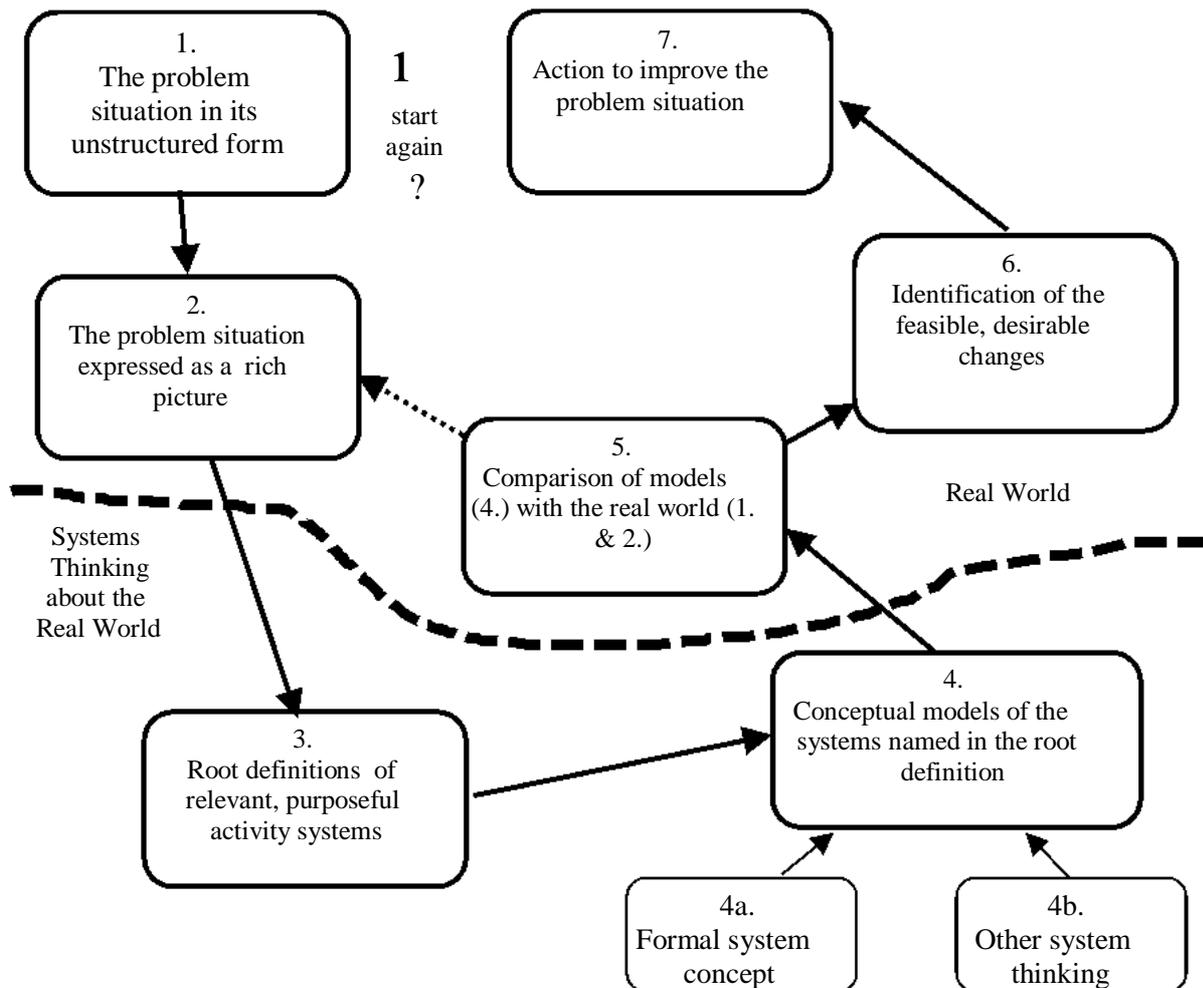

Figure 1 Summary of SSM as a seven-stage process  
 (Adapted from Checkland, [3, p.163] and Checkland & Scholes, [4, p.28])

It is most important to note that the sequence is not imposed upon the practitioner; a study can commence at any stage, with iteration and backtracking as essential components. SSM encourages investigators to view organizations from a cultural perspective.

### 3. Building a Model of E-Learning

This analysis will be conducted following the steps shown in Figure 1. This will be done rigorously for Step 1 through to Step 4, which produces a conceptual model of feasible and desirable activity. The final three steps of the methodology will be incorporated into the discussion that follows (Part 4 – Analysis of Issues).

#### 3.1 Step 1 - The Problem Situation

This step of the analysis is an unstructured narrative about the situation, and what makes it problematic. The narrative begins:

Within the Faculty of Business there is strong pressure from both the University Chancellery and the Dean's Office to undergo course renewal of all courses. In practical terms this has been translated to mean that all courses are to be repackaged and delivered online over the Internet.

Interested academic staff members have been recruited as Technical Skills Mentors to assist other staff members in this task. Academics are instructed to 'go online' before the next scheduled delivery of their course. This allows most academics between six weeks and seven months to undertake this task for one or more courses, depending on how many courses are available.

Academics are offered a choice of approved software tools to use, including Dreamweaver, WebObjects and Frontpage. Adoption of a particular tool is often either a personal preference, or the recommendation of the Technical Skills Mentor. There is no attempt to standardize to a specific tool with any study program.

Table 1: Feedback from students - delivery of courses online

Melbourne Students (15)		Hong Kong Students (32)	
Best	Worst	Best	Worst
Flexibility in when a student can study - time (9)	Less interaction with class members and lecturer (8)	Flexibility in when a student can study - time (21)	Cannot get a face-to-face answer from a lecturer (16)
Flexibility in where a student can study - place (5)	Dependence on IT that often has problems and can be slow (5)	Flexibility in where a student can study - place (19)	Less interaction with class members, teams and the lecturer (16)
Can get access to notes whenever they are needed without travelling to the uni (4)	Online communication and discussion is slow and limited compared to face-to-face interaction (4)	A less expensive way to study (9)	Need access to an up-to-date computer, the Internet and have good knowledge of computers (8)
Online forum and chat provide a good way of discussing issues with a wider variety of people (3)	Delays in getting email feedback from lecturers (4)	Access to a bigger choice of courses and courses in different countries (7)	Dependence on IT that often has problems and can be slow (7)
Can avoid using slow and unreliable university computer laboratories (1)	Reference material listed online may not be available (1)	Online forum and chat provide a good way of discussing issues with a wider variety of people (5)	Requires discipline (7)
Access to a bigger choice of courses and programs (1)	Prefer to read on paper to using a screen (2)	Attractive interface - prefer to read material off a computer (4)	Prefer to read on paper to using a screen. May be harmful to eyes (6)
		Environmentally friendly way to study (3)	Need more time to read and understand the online material (2)
		Fast way to learn (1)	Boring (2)
			Delays in getting email feedback from lecturers (1)

From the start of Semester 2 (July 2000) courses taught in the faculty of Business began to become available online. However, not all courses have a web-presence, and there are different styles of presentation and web page design. The approach ranges from single web page sites consisting of a table of hyperlinks to course resources (usually PowerPoint slides and Word documents), to complex hierarchies of pages that provide information pages and links covering all parts of a course.

The response by students is enthusiastic, but varied and often conditional. Table 1 is a summary of feedback from two groups of the investigator's students, studying the same courses in Melbourne and in Hong Kong. These are the responses to the question - what are the best and worst features of having material provided online?

In June 2001 the University entered into an alliance with an offshore education broker. The immediate effect was that a number of popular business degree programs were targeted to be offered completely online as 'international programs'. The Dean has announced that a 'flag-ship' degree - Bachelor of Commerce (known as the Generic Degree) - is to commence next semester. The main market identified for the online Generic Degree is China. Content for courses to be offered in the Generic

Degree must be finalized and available by Monday 3 December, 2001. Furthermore, the Generic Degree is standardized to Dreamweaver, and all materials must be compatible with this tool. Many academic staff are dismayed by the pressure placed upon them. They are concerned not only with the workload, but they also fear losing ownership of the material, and are concerned that assessment will be 'dumbed-down' to fit into the online environment. This concludes the narrative and Step 1.

### 3.2 Step 2 - The Rich Picture

A key goal of this stage is to achieve a structured representation of the problematic situation in as neutral a way as possible. This is achieved by building a Rich Picture. This is a pictorial representation of the structures, processes, situation, relationships and issues. It is not, however, a system diagram!

Figure 2 is a Rich Picture of the elearning - Generic Degree situation. It aims to show the elements of a slow-to-change structure, and the elements of a constantly changing process within the situation described in the above narrative.

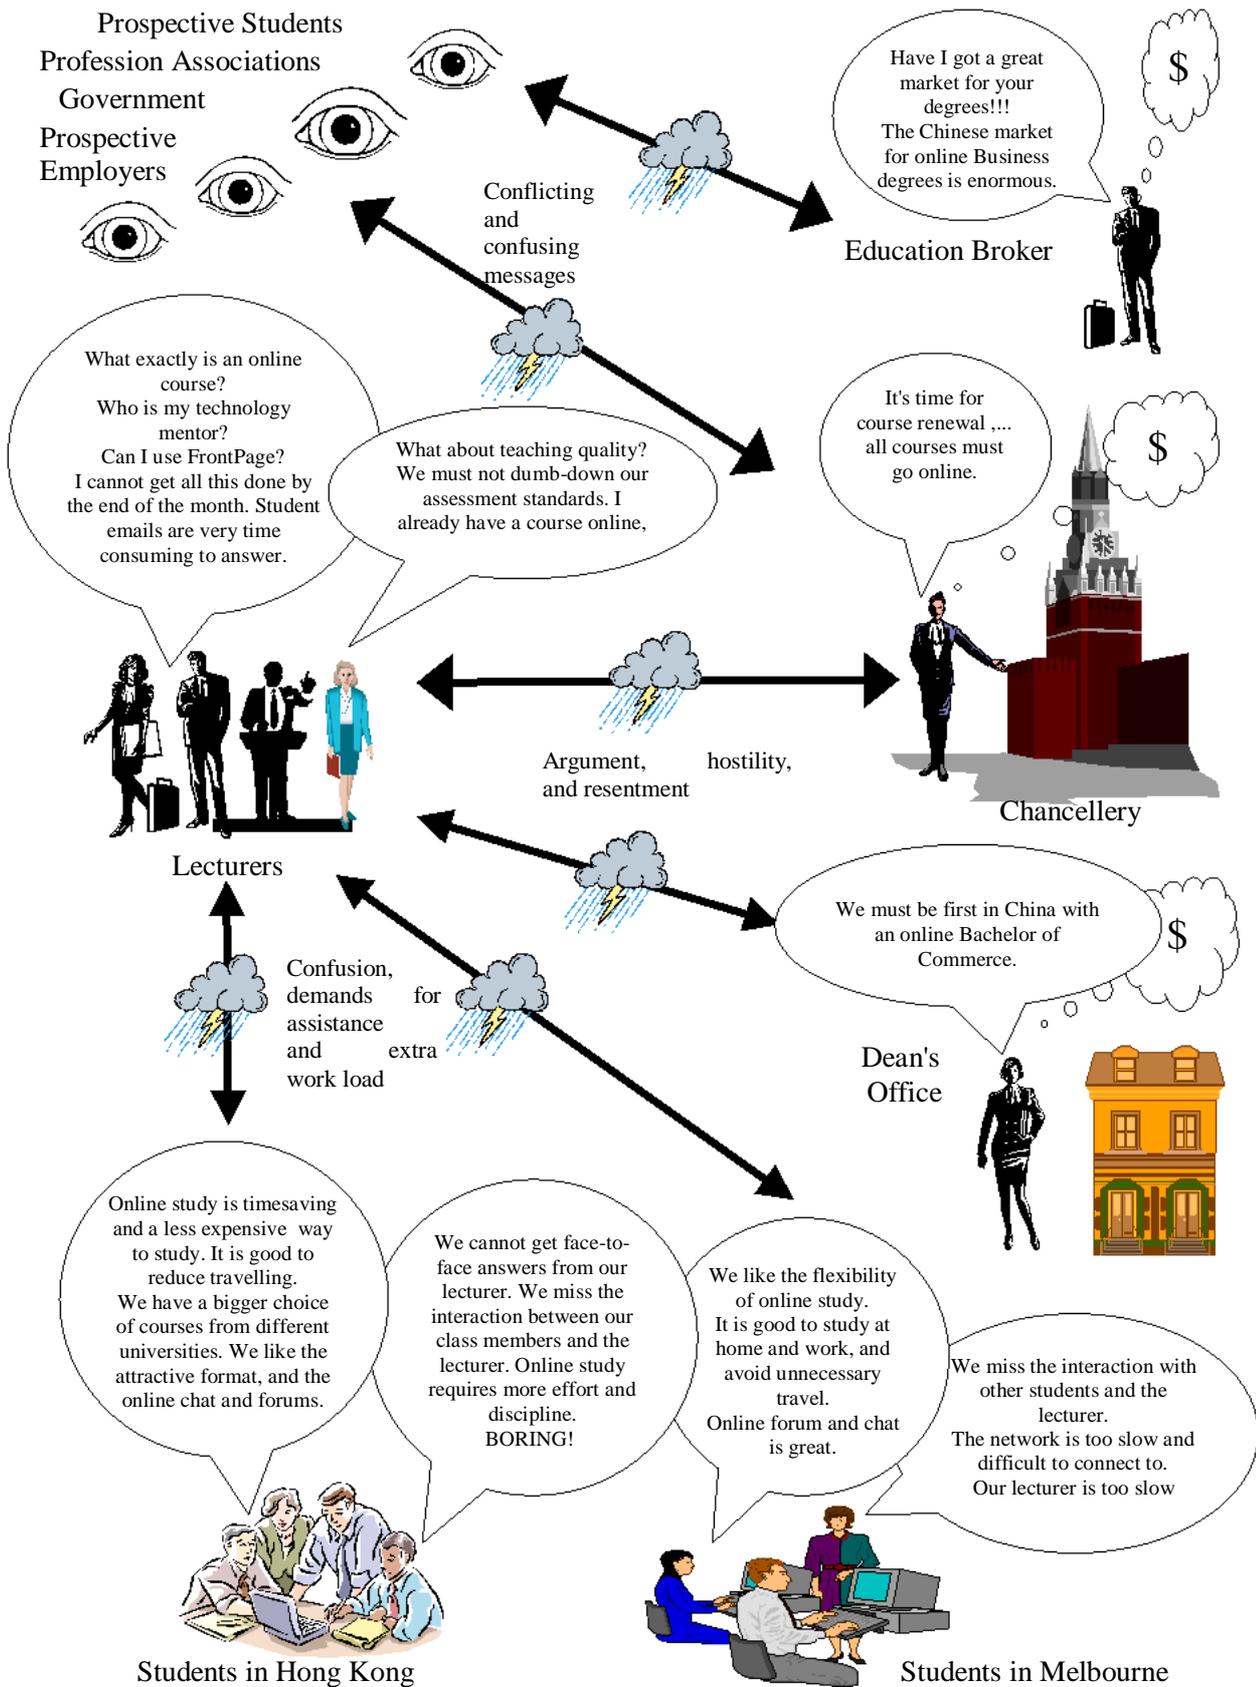

Figure 2 Rich Picture of e-Learning - Generic Degree

### 3.3 Steps 3 and 4 - The Root Definition and Model

Before creating a model, Step 3 seeks to define an appropriate system to improve the situation in a way that is desirable and feasible. This is achieved by constructing a root definition. The mnemonic CATWOE is used to check that all the components are in the root definition.

- C Clients, customers (or victims) of the system.
- A Actors who carry out activity in the system.
- T Transformation - being the conversion of the inputs into a changed form.
- W Weltanschauung (or constraining worldview) that makes this definition meaningful.
- O Owner, the person with the power to start or stop the system.
- E Environment - world surrounding the system, that provides the external constraints.

It is important to appreciate that the CATWOE is only a component checklist. The appropriateness of a root definition can only be evaluated through the dialectic process of examination, debate and argument and modification.

It is important also to examine the conceptual model derived from the root definition. Therefore, Steps 3 and 4 are presented together in this study (Figure 3). Based on the root definition, a model is drawn of the theoretical or conceptual construction. This model will show the minimum necessary activities that exist in the system to achieve the transformation described in the root definition.

The conceptual model should only include activities that can be directly carried out. There should never be the expectation that a root definition or conceptual model cannot be improved upon.

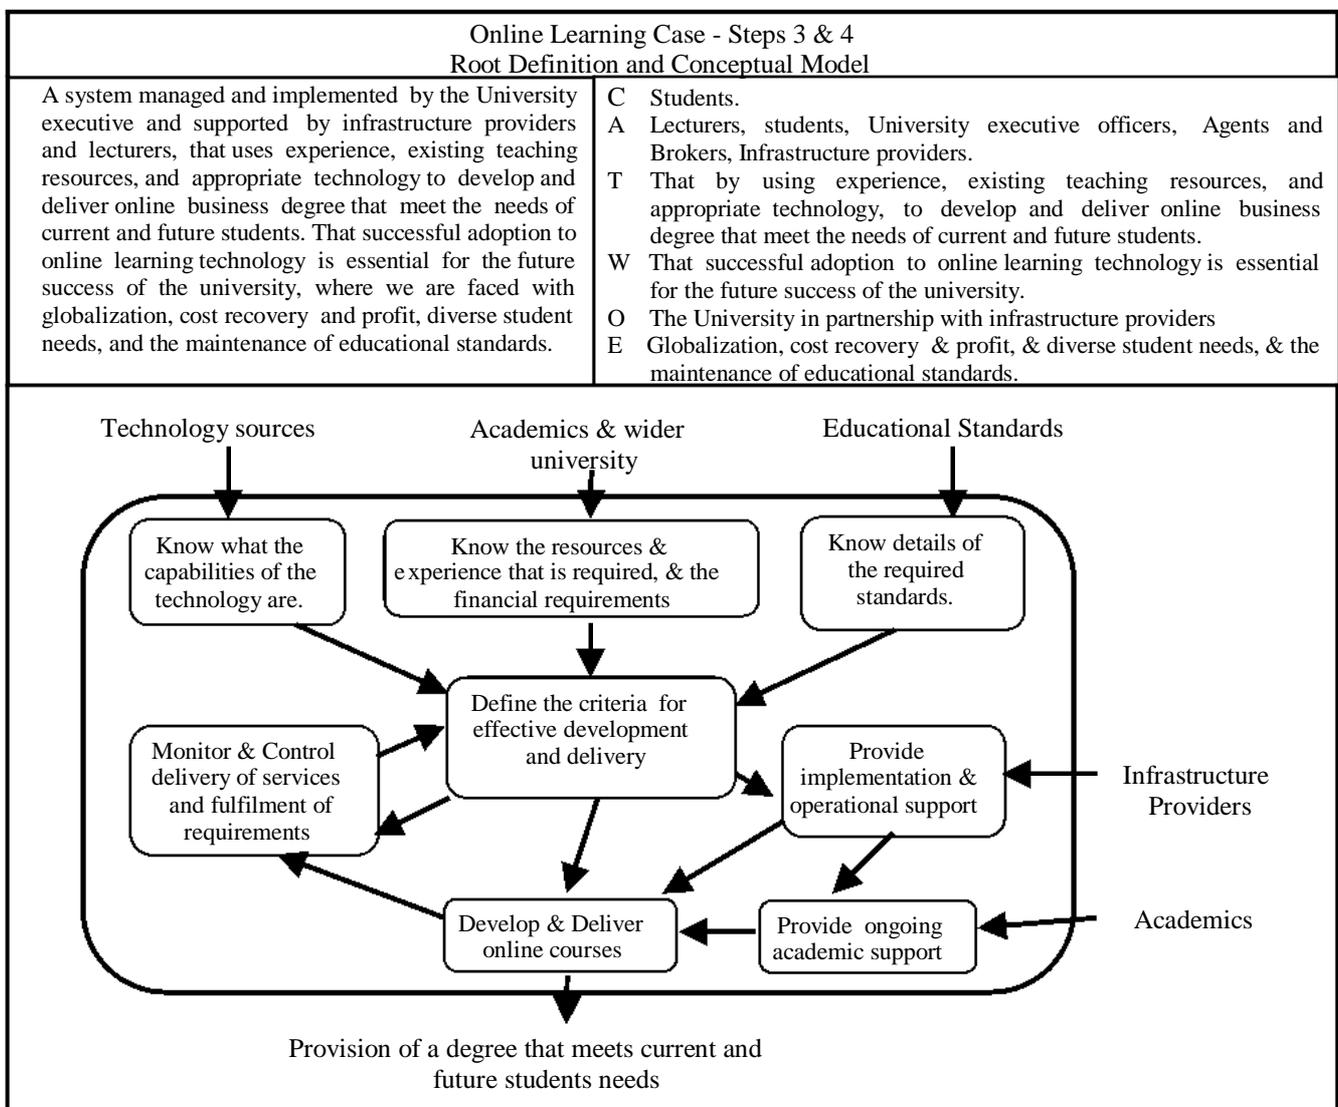

Figure 3 Root Definition and Conceptual Model

## 4. Analysis of Issues

The conceptual model illustrated in Figure 3 provides a set of activities that can be used to learn more about the situation, and in this case study it provides a framework for undertaking an issues analysis.

### 4.1 Activity 1 - Know what the capabilities of the technology are.

The first activity is concerned with acquiring knowledge of technology capabilities. As the case study shows with reference to web page creation tools, there are always choices with technology, and better choices can be made if relevant knowledge is acquired. Torrisi-Steele and Davis [22] comment on the importance of selecting web-authoring technology. In particular, skill development in web authoring and online course design can be both demanding and difficult. However, these skills are essential to realize the full potential of e-learning.

### 4.2 Activity 2 - Know the resources and experience that is required, and the financial requirements

The second knowledge activity appears to be problematic in the case study as it obviously requires collaboration between the academics - with some resources and the experience - and the university executive, who have more resources and the knowledge of the financial requirements. However, this knowledge must be integrated into the total process. As Galagan [6] observes, universities need to ensure that online learning is part of a training strategy that links to business goals.

Where there is a cross-cultural component to an e-learning initiative, Sakurai [15] and Gunawardena, Nolla, Wilson, Lopez-Islas, Ramirez-Angel and Megchu-Alpizar [10] emphasizes the need for a major commitment in time and resources. In particular, Goodfellow, Lea, Gonzalez and Mason [9] argue the need to study cross-cultural interactions within the e-learning environment with attention to the implications for learning and teaching.

### 4.3 Activity 3 - Know details of the required standards

The third knowledge activity moves the focus beyond the university into the wider community. In many cases appropriate standards have not been formalized for e-learning. A particular area of concern of many lecturers is the "dumbing-down" of assessment tasks and the preference for "soft-assessment" that occurs in particular circumstances. These issues are also of concern to the wider community, and especially prospective employers. Therefore appropriate standard should be developed in consultation with key stakeholders. Youngblood, Trede and Di Corpo [25] recommend that rules of participation should be formalized as the framework for monitoring

participation. However, this will become more complex with international program delivery and globalization.

### 4.4 Activity 4 - Define the criteria for effective development and delivery

Schelin and Smarte [18] warn that developers must assess the needs of the student population and clearly target skills and knowledge gaps before developing online courses. A set of guidelines to assist in this activity, in the form of five questions, is provided by Sheely, Veness, and Rankine [19, p.80]:

How do we do it? How do we use these packages most effectively?

How do we integrate them into existing systems?

How do we support academics to make most effective use of the tools that are available?

A particular concern in this activity is setting the criteria for development of interactive online learning. This is a major anxiety of many of the students in the case study. Sims [20] also identifies interactivity as one of the major challenges faced by designers of e-learning resources. In particular it is observed that complexity of learner-computer interactivity has yet to be fully unraveled. Swan [21] addresses this issue of design and identifies three important factors that influence student satisfaction:

1. The clarity of the design of the online course.
2. The ability to interact with instructors.
3. The support of active discussion among the students.

### 4.5 Activity 5 - Provide implementation and operational support

This activity will be directly driven by the choices made in the definition and selection of criteria for development and delivery of the system. As seen in the case study, this activity is important in terms of student satisfaction, especially with regard to the speed and reliability of Internet access. Sakurai [15] states the need to develop a network infrastructure capable of supporting rich media content, and warns that without this an online program will be just like reading text.

### 4.6 Activity 6 - Provide ongoing academic support

Within universities that are developing e-learning for the first time, the critical success factor is internal marketing. Promotion of a new way of teaching is essential, with Roberts [14, p.106] observing that "takes a lot of effort to get the old guys who are now in leadership roles to support these efforts."

However, there are attractive aspects to this activity. E-learning has the potential to bring together the best teachers, with the best learning plans and enthusiasm for learning, to the students who want it, anywhere in the world [7]. This is particularly attractive to organizations who desire flexibility in the delivery of teaching programs [26]. Schelin and Smarte [18] observe that

while you cannot compel academics to participate in e-learning, the success of these programs depends upon a large commitment from teaching staff.

#### 4.7 Activity 7 - Develop and deliver online courses

This is the activity that delivers the outcome - provision of a degree program that meets current and future students needs. This is the "operational core" upon which all the other activities focus and provide inputs. This activity is a system in its own right, and can be modelled in greater detail.

#### 4.8 Activity 8 - Monitor and control delivery of services and fulfilment of requirements

This final activity provides the monitoring and control loop that observes the performance of the system, and provides feedback to control via the criteria setting activity as necessary. This is consistent with the need identified by Herberger [11] to define and redefine the educational product outcome of an e-learning system. More specifically Leonard and Guha [13] and Chen, Lou and Luo [5] observe that the motivation for using e-learning is the promise of improved competence in completing course work. This is an example of an important performance measure to be monitored.

### 5. Conclusion

In this study a systems model has been developed to provide a framework for examination of the issues and perspectives of the stakeholders associated with this investigation of e-learning. Overall, the attitude of the students is generally positive, moderated with a concern for opportunities to interact with other students and academic staff. This is consistent with the findings of Youngblood et al. [25] and Gallini and Barron [8], that students need specific guidelines and structures for interacting over the Internet. Without these formal frameworks for collaboration, students may fail to become engaged in coherent group work that is based upon meaningful interactions.

In support of the positive responses, Sanders and Morrison-Shetlar [17] report that students have a highly positive attitude towards the addition of web-enhanced components to traditional course material. This, together with the case study, suggests that e-learning is successful when integrated into other learning delivery modes. However, more research is required in this area, especially from the viewpoints and perceptions of staff involved in the delivery of innovative "multi-mode" learning programs.

# How to Setup a Successful E-Learning System for E-Business<sup>†</sup>

Tzu-Hsin Yang and Min-Jen Tsai  
 Institute of Information Management  
 National Chiao Tung University  
 Hsinchu, Taiwan

[cindy@hc.ethome.net.tw](mailto:cindy@hc.ethome.net.tw) and [mjtsai@cc.nctu.edu.tw](mailto:mjtsai@cc.nctu.edu.tw)

## Abstract

E-Learning is burgeoning now, it develops a new way to enhance corporate competence effectiveness. Why should corporations investigate in an e-Learning system for e-Business? Because it provides a real-time and supporting learning environment for e-Business. In addition to be a profitable learning system, it can also be connected to ERP and CRM systems to generate an integrated solution for e-Business.

It lists the differences and barriers between traditional training and e-Learning. Although there are barriers, corporations still get their own reasons for setting it up. It lists the learning needs from different stakeholders. It introduces an example of LMS-LCMS integration in a learning ecosystem from IDC, and is followed by procedures to be taken to construct it.

Strategies should be correctly set and e-Learning project plans should be well defined and implemented. Success and challenge factors are also discussed to advise project leaders motivation and shortcoming elements of an e-Learning system. By calculating the e-Learning ROI, corporations can adjust their e-Learning strategies in order to keep a flexible management.

**Keywords: e-Learning, LCMS, LMS, ROI**

## 1. Introduction<sup>†</sup>

People are used to learn in the classrooms, they sat down by one another and the instructors were in front of them. They read from the blackboards and wrote down what the instructors had told and written to them. But today, the learning revolution has changed the above situations. Instructors and learners are connected via the Internet. That is so called e-Learning. In the autumn of the year 2000, the HR World is being battered by a storm. It has had many different names over the years, but today it is mainly known as e-Learning. E-Learning will not replace traditional classroom training. Frankly speaking, they are complements each of the other.

Are there relationships between traditional training and e-Learning? In fact, they will help each other with their own specific advantages. To have a more clear description,

for example, traditional training is taken place at a specific place and a scheduled time, while e-Learning happens at any place and anytime. Moreover, there are many differences between them. Corporations can choose the training approaches that can best fulfill their needs. If their learning environments are not ready for e-Learning only training. they can also choose a blended learning which combine traditional training and e-Learning approaches. This paper compares six different items between traditional training and e-Learning. E-Learning system shows clear that it is suitable in knowledge economic era via the Internet. They are shown in table 1.

**Table 1 : Comparisons between traditional training and e-Learning**

Item	Traditional training	E-Learning
Function	⊙ Training for new skills and knowledge	⊙ Training for new skills and knowledge ⊙ Strategic business tool
Training place	⊙ Physical classroom ⊙ Limited scale ⊙ Fixed location	⊙ Virtual classroom ⊙ Global wide scale ⊙ Any place
Content	⊙ PowerPoint slides ⊙ Textbooks	⊙ Animation ⊙ Simulation ⊙ Online resources
Learning schedule & time	⊙ Instructors control the topics and schedules ⊙ Instructor-Led ⊙ Fixed time	⊙ Learners control the topics and schedules ⊙ Self-Paced ⊙ Any time (24 x 7)
Problem solving	⊙ Ask instructors for help ⊙ More interactive	⊙ Ask online instructors for help (synchronous) ⊙ Message boards, chatrooms, and e-mail (asynchronous)
Evaluation	⊙ Level I to Level IV evaluations	⊙ Level I to Level V (ROI) evaluations

<sup>†</sup> This work was partially supported by the National Science Council in Taiwan, Republic of China, under Grant NSC90-2623-7-009-017, NSC 91-2623-7-009-016, and NSC91-2416-H009-012.

First, their functions are different. Although they are all trainings for new skills and knowledge, more than that, e-Learning is also a strategic business tool which can be integrated into an e-Business system and be used to achieve the business objectives. Their training places are also different - from physical to virtual classroom, limited to global wide scale, and fixed location to any place. Powerpoint slides and textbooks will be replaced by animations, simulations, online resources, and so forth.

Instructors no longer have to assign learning topics or schedules. Instead, learners have to be more active to their learning topics or schedules. They should decide what and when they want to learn. They can access online training courses 24 hours a day, 7 days a week. When learners get any questions during the online training courses, they will use different ways to communicate with instructors. They must “talk” to e-Learning instructors via the Internet by using their computers. Message boards, chatrooms, and e-mail will also help them to find someone to solve problems.

Finally, when comparing their ways of measuring training results, traditional training can only do Level I to Level IV evaluations, but e-Learning can do Level I to Level V – Return on Investment (ROI) evaluations. They are discussed in more details in the last section of this paper.

## 2. Points of Research

An e-Learning system will be a strategic business tool to increase business speed, flexibility, retention, and employee satisfaction. As projected by IDC, the market for e-Learning services, content and technology will be over \$11 billion, growing at a nearly 100% compound annual growth rate by 2003 [4].

Although, e-Learning is now getting more popular, but there are still some critical points that corporations still feel confused. This research intends to give some general ideas on how to setup a successful e-Learning system for e-Business.

It first introduces the e-Learning marketplace - four barriers and SWOT analysis are discussed. With the above two analysis results, corporations will get their own e-Learning readiness situations in their minds. Different stakeholders will have different reasons for setting up the system. One environment of e-Learning system from IDC is also introduced.

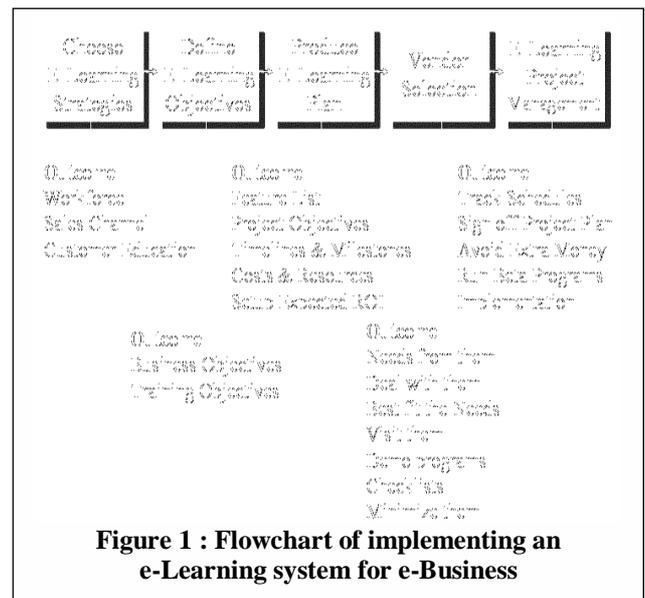

Steps that are needed to implement an e-Learning system for e-Business are proposed. They will provide general procedures which will be practical. They include strategies, objectives, plan, vendor selection, and project management. Success and challenge factors will suggest motivation and challenging powers towards the system. Corporations can improve their e-Learning system day after day by applying the factors. Finally, five ways to measure the performance of e-Learning system – level I to level V, are suggested. The paper intends to provide methodologies to setup a successful e-Learning system for e-Business by all the topics discussed.

## 3. Approaches

Related e-Learning papers are reviewed together to give general ideas and descriptions of the paper. “Analysis of e-Learning marketplace” introduces the e-Learning marketplace – it presents four barriers and SWOT to describe the e-Learning environments that corporations will be facing. “Corporate reasons for setting up an e-Learning system for e-Business” discusses the feelings of different stakeholders inside corporations about an e-Learning system despite the barriers. One e-Learning system model from IDC depicts related components – LMS, LCMS, delivery systems, and back end systems integration.

According to DigitalThink [4] and this research, there are five steps proposed as the approaches to setup an e-Learning system. Each of them is related to one another. Please refer to figure 1 for the flowchart.

“Choose e-Learning strategies” will need to know what corporations want from the e-Learning system first. According to DigitalThink researches [4], there are three categories of strategies : “workforce transformation”, “sales channel optimization”, and “customer education” strategies. “Workforce transformation strategy” will help to increase productivities and cause higher retention of employees. “Sales channel optimization strategy” will shorten time and knowledge to market, fasten delivery speed, and increase time spent on selling. “Customer education strategy” focuses on how to give customers related education and satisfactory services. “Define e-Learning objectives” will describe what corporations really want to get. There are business and training objectives. Business objectives focus on how to improve effectiveness of workforce transformation, sales channel optimization, and customer education. Training objectives are concerned with learning plans, ability to access training resources, integrations of coursewares, and so forth.

**Figure 1 : Flowchart of implementing an e-Learning system for e-Business**

“Produce e-Learning plan” provides steps to produce an e-Learning plan. It lists all tasks that must be undertaken, together with related stakeholders involved. Every key milestone is well defined and scheduled. LMS / LCMS, LAN installation, coursewares offerings and authoring are good examples of key milestones. Also, resources and costs needed have to be well arranged and calculated. Please provide predefined ROI before the performances of e-Learning system is evaluated. It will become the criteria for measuring success of e-Learning system.

“Vendor selection” helps to find suitable vendors to be corporate with. It lists seven steps needed to be taken. By following them, corporations will choose correct vendors and solutions that are best to fulfill their needs.

“E-Learning project management” suggests ways to manage an e-Learning project. It tracks project schedules, assures signing off the project plan, avoids spending extra money, runs beta programs, and implements a successful e-Learning system.

Finally, “success factors” suggests the motivation power to make the e-Learning system grow up and run smoothly. “Challenge factors” suggests the challenging power to threaten the normal behaviors of an e-Learning system. “Evaluation and ROI” lists the ways to measure the e-Learning performance using four levels (Level I ~ IV) developed by Donald Kirkpatrick and Level V enhanced by Jack Phillips. Level V will calculate corporate return on investment (ROI) [7].

#### 4. Analysis of E-Learning Marketplace

Although the market is still growing, there are many barriers needed to be overcome when planning to setup an e-Learning system for e-Business [10]. In this paper, four barriers are proposed to explain what should be conquered by most corporations. Figure 2 below depicts the four general barriers to e-Learning.

The first barrier is “budgetary considerations”. It will consider e-Learning budgets. It is expensive to setup an e-Learning system for e-Business. There are very few successful e-Learning implementation stories, so they will not spend a lot of money on it now. In fact, corporations will cut e-Learning budgets very often.

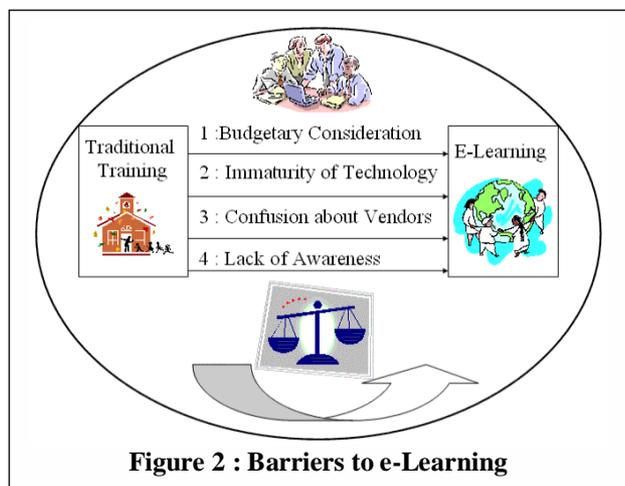

Figure 2 : Barriers to e-Learning

The second barrier is “immaturity of e-Learning technology”. The technologies are still young and new. The average life cycles of them are about two years which are too short to motivate corporations to adopt them. If corporations adopt immature e-Learning technologies, they will soon regret.

The third barrier is “confusion about the vendors”. Because the e-Learning markets are still fragmented and lacking of integrated solutions, so most vendors will have to develop the contents, technologies and services on their own. Few vendors finish developing complete solutions, they are still having experiments and researches.

The fourth barrier is “lack of awareness”. People do not know very well in which way e-Learning will really change their training models. They already get used to traditional trainings and do not feel like to accept new ways to be trained. It will take time for learners to establish new styles of habits before it gets popular.

SWOT (Strengths-Weaknesses-Opportunities-Threats) analysis of e-Learning will help corporations to know the characteristics of their e-Learning system when being applied. Figure 3 shows SWOT analysis of e-Learning. It includes the descriptive functions of SWOT to help corporations transforming from traditional trainings to e-Learning.

The strengths of e-Learning will be its advantages to get supports from top managements. It shows that e-Learning will overcome time and place barriers that traditional trainings are used to have. Instead, learners can access it whenever and wherever they want. It will not need to pay traveling costs, so the costs will be lower.

The weaknesses of e-Learning are shortages to make people feel disappointed. Especially the technology to setup an e-Learning system is new. Not many people know it very well. Also, learners may not be used to this kind of learning. They cannot see each other. They can only use computers to talk to other learners and instructors. They may need some helps from experts even more.

The opportunities of e-Learning will provide some possible ways for corporations to adopt e-Learning as their new training approach. They are the chances to be succeed or fail. Although e-Learning may have weaknesses and threats, there are still opportunities which will attract

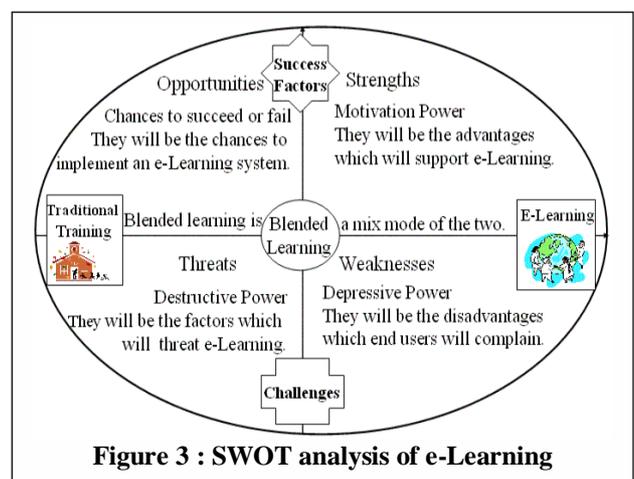

Figure 3 : SWOT analysis of e-Learning

corporations get involved with the implementation of e-Learning system. It will provide the best and quickest way to communicate with one another all over the world. It provides a new approach to reach news and knowledge of any desired place on the earth.

The threats of e-Learning will be destructive power to threaten e-Learning solutions. Since e-Learning is less interactive, learners may not have much interest on it for a long time. Technologies and requirements of e-Learning will also limit the development. If corporations know the threats of e-Learning in advance, they can be prepared to reduce the impacts.

### 5. Reasons for Setting up an E-Learning System for E-Business

Why do corporations want to setup an e-Learning system for e-Business despite the barriers ? Because it will provide an effective way for corporations to learn and gain knowledge easily. Besides, it will support a real-time, supporting, and profitable learning environment for e-Business. It will be integrated with ERP and CRM systems to give a total e-Business solution.

Why are there so many corporations interested in having an e-Learning system for e-Business right now ? Because the time has come. Traditional trainings can no longer cover all corporate trainings. Instead, e-Learning system will help to provide a more efficient way of delivering information and knowledge needed. Especially now many corporations adjust their paces to become learning organizations, what will most benefit them are knowledge and information. The ones who win will need to have good controls on their corporate intellectual capitals. In fact, the technology of e-Learning will support them successfully.

An e-Learning system will provide an online learning system to connect stakeholders via the Internet. Most of them will get what they want in a quicker time. They get different ideas of what an e-Learning system can help them with their daily works. Figure 4 below shows the relationships between different viewpoints towards an e-Learning system for e-Business.

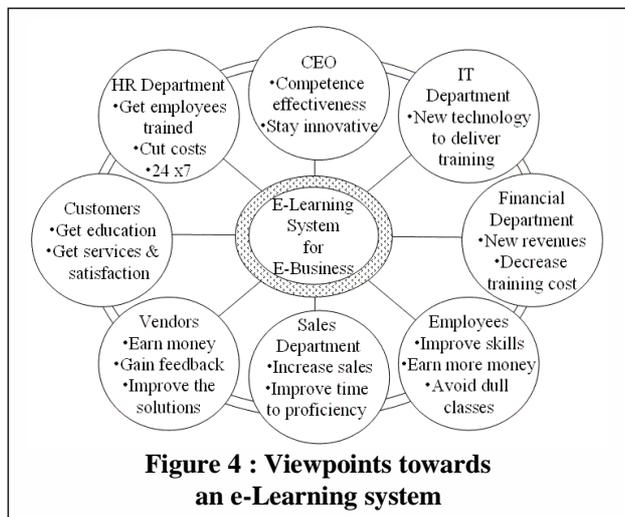

Figure 4 : Viewpoints towards an e-Learning system

CEO may view it as ways to increase competence effectiveness, reduce cycle time, and stay creative and innovative. They should have the courage to adopt an e-Learning system. Human resource departments may view it as ways to get employees trained, cut training costs, and a 24 x 7, on target training system. They should know very well that e-Learning system will improve training processes. IT departments may view it as a new kind of technology to deliver effective training courses. They should come out with the needs of e-Learning system infrastructure. Financial departments may view it as ways for a new revenue resource and decreasing training costs. Sales departments may view it as ways to increase sales, improve time to proficiency, and reduce turnover. They should provide what kinds of e-Learning strategies that will improve their selling processes. Employees may view it as ways to improve skills, earn more money, and avoid dull classes. They should learn how to use the e-Learning system. Finally, customers may view it as ways to get education, good services, and satisfaction. They will benefit from the e-Learning system and feedback to corporations.

Although, there are still some barriers between traditional trainings and e-Learning, the trends are now getting unstoppable. Clear understandings about the e-Learning system will give good profits if being used well. Since it will give different people what they want, why should there be any doubts for setting it up ? So, next step is to know the e-Learning system more, cross the barriers, and get started.

### 6. E-Learning System for E-Business

There are Learning Management Systems (LMS), Learning Content Management Systems (LCMS), content composition system, delivery system, and legacy system integration services which build up an e-Learning system for e-Business environment. Figure 5 depicts LMS-LCMS integration in a learning ecosystem from IDC [9].

The LMS is the operation system of an e-Learning system. It will manage registration, scheduling processes,

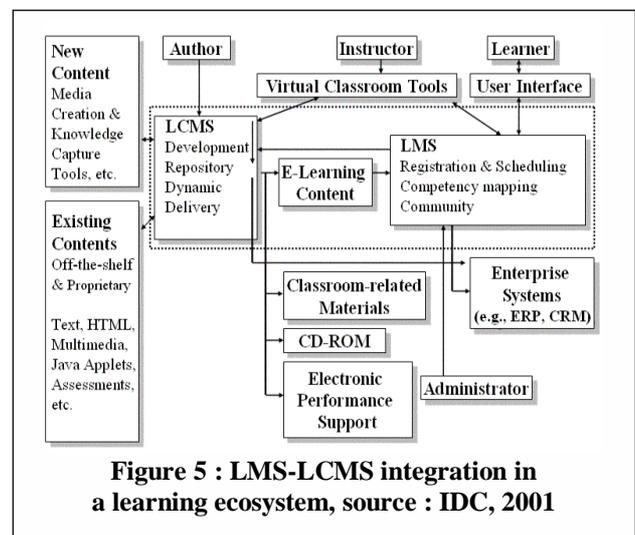

Figure 5 : LMS-LCMS integration in a learning ecosystem, source : IDC, 2001

and competency mapping community. Administer can track online, classroom-based learning events, and other training processes by using the LMS. Instructor can use virtual classroom tools to manage e-Learning courses, track learner progresses, record test scores, indicate course completions, and evaluate learners' performance. Learners can login to the LMS and access their profile from the database via users' interface. They review the course catalog and choose the courses they need. They can also search their desirable topics, and the LMS will dynamically find the courses in a repository of content for them.

The LCMS can manage the content which will be provided online, whether it is a customized content or off-the-shelf coursewares. It will provide a multi-user environment. In the environment, authors can use media creation or knowledge capture tools to create or capture e-Learning content from a central repository. Existing contents include off-the-shelf and proprietary courses. They may be text, html, multimedia, java applets, assessments formats, and so forth.

Delivery systems can provide a way for learners to interact and collaborate with instructors and other learners. It uses technologies such as voice over IP, video, whiteboard, feedback tools, breakout rooms, application sharing, and evaluation tools to create a classroom environment. The e-Learning system will be integrated to the traditional training management, performance support, ERP and CRM systems [6]. Major content vendors will support corporations with learning catalog from their content database and ERP system legacy applications. Moreover, it can also connect to customers' websites.

## 7. Choose E-Learning Strategies

Although the e-Learning system for e-Business can help corporations in many different ways, according to DigitalThink [4], the following three kinds of strategies – “workforce transformation”, “sales channel optimization”, and “customer education” strategies will best benefit corporations with highest Return on Investment (ROI). Each of them will be e-Learning enabler for setting up the system. If e-Learning project leaders need to figure out the ways e-Learning system can benefit them, please spend some time understanding the following statements and descriptions.

First, what will “workforce transformation strategy” benefit corporations ? It will increase productivity, reduce traveling time, reduce training unit costs, deliver more trainings with the same budgets, and cause higher retention of employees. It will help corporations to save more time and money to hold employees' training courses. It is also intended to improve skills, knowledge, and performance of employees.

Second, what is “sales channel optimization strategy” ? What services will the e-Learning system provide to sales departments ? It will increase time to market, updating flexibility, delivery speed and time spent on selling. The e-Learning system can allow corporations to upload the

latest product introduction files. Salesmen can download and present the files to customers. Whenever new product specs, information or open issues are posted on the e-Learning system, salesmen can get them from any place and any time when needed.

Third, “customer education strategy” will be discussed. What will the e-Learning system support for customer education ? It will provide courses for customer education, improve customer services and satisfaction. It will be a new huge ongoing revenue source for corporations. In addition to classroom trainings, e-Learning system will also give fee-based online classes to customers. It will be more effective and time independent. Also, it will attract new customers and business.

The above reasons just give some guides for strategies that will benefit corporations. It will help to get strategies needed. After corporations have viewed the explanations, please choose the one that best fits into the corporate needs. If the strategies have already been chosen, please go to define e-Learning objectives for next step procedure.

## 8. Define E-Learning Objectives

There are two types of objectives mentioned below, “business” and “training” objectives [4]. As mentioned in the last section, corporations will choose e-Learning strategies first, then related e-Learning objectives which meet the chosen strategies have to be setup. Please define e-Learning objectives that best fit into corporate needs by using the following information. Figure 6 illustrates “two types of e-Learning objectives”.

What are “business objectives” ? They include three kinds of objectives according to DigitalThink [4]. They are defined especially for business reasons and requirements. What are they ? They are “workforce transformation objectives”, “sales channel optimization objectives”, and “customer education objectives”. What are “training objectives” ? They are the objectives to provide learning plans, improve ability to access training resources, and off-the-shelf courseware integrations. It will also setup the high availability and performance web infrastructure of e-Learning system for e-Business.

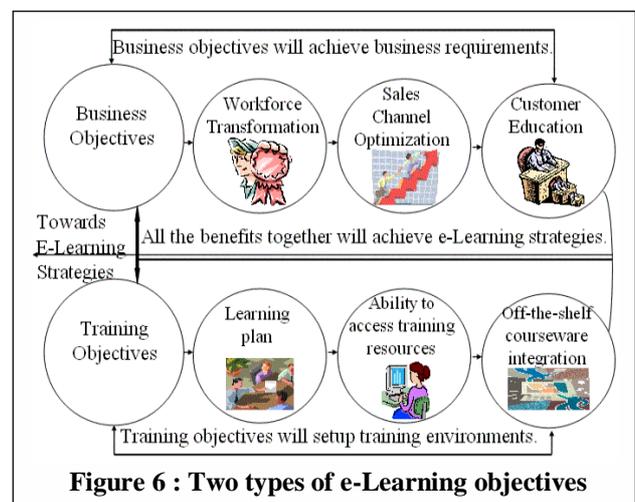

Figure 6 : Two types of e-Learning objectives

<b>Table 2 : Business objectives</b>			
<b>No</b>	<b>Item</b>	<b>Duration</b>	<b>Objectives</b>
<b>Workforce transformation</b>			
1	Course completion	10/01/02 ~ 12/31/02	Increase by 30%
2	Employee retention	10/01/02 ~ 12/31/02	Increase by 30%
3	Training costs	10/01/02 ~ 12/31/02	Decrease by 20%
4	Productivity	10/01/02 ~ 12/31/02	Increase by 20%
5	Travel time	10/01/02 ~ 12/31/02	Reduce by 30%
<b>Sales channel optimization</b>			
1	Time to market	01/01/03 ~ 03/31/03	Increase by 25%
2	Knowledge to market	01/01/03 ~ 03/31/03	Increase by 35%
3	Sales	01/01/03 ~ 03/31/03	Increase by 30%
<b>Customer education</b>			
1	Customer education revenues	04/01/03 ~ 06/30/03	Increase by 20%
2	Customer satisfaction	04/01/03 ~ 06/30/03	Increase by 50%

  

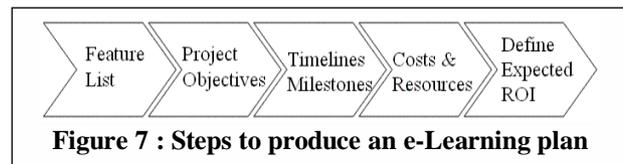

<b>Table 3 : Training objectives</b>			
<b>No</b>	<b>Item</b>	<b>Duration</b>	<b>Objectives</b>
1	Learning plan	10/01/02 ~ 10/31/02	Setup a good plan
2	Access to training resources	11/01/02 ~ 11/30/02	Improve access abilities
3	Off-the-shelf offerings integration	11/01/02 ~ 11/30/02	Make content better

Table 2 and 3 shows some examples of business and training objectives which can be chosen. Please review them and get more information about what they will be alike. Discuss with project teams and choose desirable business and training objectives. Make sure reasonable objectives are expected. After that, please find suitable vendors that can serve corporations with solutions for the implementation of e-Learning system.

## 9. Produce E-Learning Plan

A solid e-Learning project plan will help to keep the project on track. Also, it will be the primary means of communication for the project team. With combinations of DigitalThink [4] and this research, five steps are suggested and introduced. Figure 7 shows steps to produce an e-Learning plan.

First, “a feature list” must be included from reduced business and training objectives before producing the business plan. It shall include web tool being used, target audience, technology limitations, delivery deadline, funding available, subject matter experts, vendors, elaborate breakdown structures, estimates of staff hours, and budgets, and so forth.

Second, “list project objectives for the e-Learning system”. There are business and training objectives. In order to achieve the chosen objectives, information that are needed to accomplish must be detailed. For examples, reasons for achieving objectives, persons who will be in charge, priorities, time to start and end, and money needed.

Third, “list timelines and milestones”. They must include the following items : current tasks due days, next week’s tasks , tasks accomplishments , meetings held and attended, additional issues and concerns. Each of the timelines and milestones shall be discussed. They must be set reasonably and carefully. They will be checkpoints of whether the project is on-time or delayed. If the project is delayed, please find out what the problem is and try to adjust the pace.

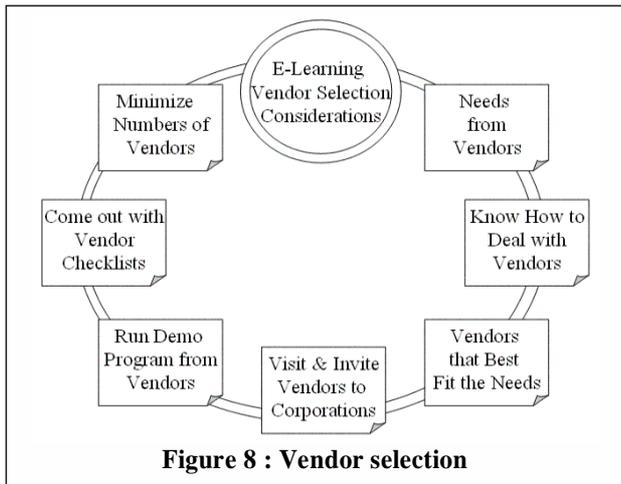

Fourth, “list costs needed and resources available”. Component costs include instructional design services, authoring software, training registration fees, and so forth. Please provide the realistic estimation of component costs. Resources will be budget, facility and technical engineers available for implementing the project.

Finally, “define expected ROI of e-Learning system”. It is the expected value of the e-Learning system. It will give some ideas about whether the e-Learning investment is worthy or not. Also, it will be a good project reason if the ROI is high enough for top managements to decide to have investments on e-Learning. It shall be adjusted when true e-Learning ROI is calculated.

## 10. Vendor Selection

It will suggest some general considerations on how to choose suitable vendors. IT departments may need new technologies to setup the e-Learning system. They can get them from e-Learning solution vendors. Vendors will provide what corporations need and gain feedback from them. Suitable vendors will shorten implementation time and help to guarantee a successful e-Learning system for e-Business.

There are three kinds of vendors : content, technology, and service [4]. Vendors of content will sell off-the-shelf coursewares. They can also work with corporate subject matter experts to produce customized courses. Vendors of technology will build e-Learning system infrastructures

**Figure 8 : Vendor selection**

and provide related technologies, for examples, installation of LMS / LCMS and integration technology of chatrooms and virtual rooms. Vendors of service will support to train tutors, develop a custom portal, integrate back end systems, and so forth. Figure 8 shows seven considerations for selecting good vendors [8].

Step one is “needs from vendors”. Corporations must know their budgets and what kinds of supports they need from vendors. They must provide RFPs which list content, technology, or service requests clearly to vendors. They will receive proposals from vendors and review what are most appropriate and satisfactory.

Step two is “know how to deal with vendors”. If corporations already find some vendors that will satisfy their needs, please also be careful to deal with them. If they are dealing with big vendors, please be sure that vendors will assign the best professional experts to serve them until the implementation of e-Learning is finished.

Step three is “choose vendors that best fit the needs”. There are many vendors right now serving e-Learning solutions. Please choose the ones that best fit the needs. Spend some time to study vendors' solutions. Please check : Do they offer the latest technologies ? Do they earn money ? Do they offer good quality services ? The information will be helpful to find suitable vendors.

Step four is “visit vendors and invite them to corporations”. Visiting vendors helps to understand their real working environments. Do they have confidences with their products ? Do they understand their products clearly ? Also invite them to corporations to give some suggestions about corporate e-Learning situations. Listen to what they suggest and judge whether they understand the problems or not.

Step five is “run demo programs from vendors”. Please ask vendors to provide demonstration programs. Please let key users run them and give feedback to vendors. By doing so, corporations can choose the solutions that will of great helps. Never buy products that are never being tested under corporate environments.

Step six is “come out with vendor checklists”. After interviewing vendors, please come out with vendor

No	Check Item
1	How long have the vendors been in business?
2	Do the vendors get reliable e-Learning implementation experiences ?
3	Can they support the contents, services and technologies needed ?
4	How are their off-the-shelf courseware integration, content development and course delivery system look like ? Are they friendly and easy to use ?
5	Are the costs of their services reasonable ?
6	Will they transfer the e-Learning technologies to the corporation ?

checklists. It will give clear comparisons among different vendors. By viewing them, corporations can know which vendors best fit their needs. Table 4 shows a vendor checklist which contains six questions. By answering the questions, corporations can see which vendors are at the top of the checklist.

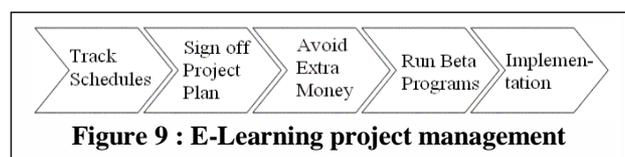

Step seven is “minimize numbers of vendors”. Choosing many vendors does not mean that all of them together will provide complete and satisfactory services. Choose the ones who will serve corporations with the best e-Learning solutions. Please have a stable and long-term relationship with them. Once corporations have finished choosing suitable vendors that will help them with the implementation of e-Learning system, please keep good communications with them.

## 11. E-Learning Project Management

There will be many elements needed to be controlled during the implementation, so please take a look at the following advices on how to manage a successful e-Learning project [2]. They are related to the e-Learning project plan which is proposed in this paper. Figure 9 depicts the chart of an e-Learning project management.

Step one is “track project schedule”. According to the e-Learning project plan, timelines and milestones are arranged. Please check whether the project is on-time or delayed. Regular meetings should be held to track project schedule. The following items should be checked : current tasks status and accomplishments, next tasks to be completed, issues and concerns. If the project is delayed, please find out the problems and try to solve them immediately.

Step two is “sign off project plan at each project milestone”. It will avoid scope creep and let the ones who complete the tasks to be responsible for the quality. When

**Figure 9 : E-Learning project management**

project team members attend meetings at the end of each milestone, they should sign off the project plan before they can move forward. The milestones of e-Learning system may expand within each phase when things go wrong.

Step three is “avoid spending extra money”. In order to control the budgets, please request a fixed-bid contract from vendors. Any “cost-plus” phrase in contracts should be avoided. It will prevent vendors from asking for extra money when the e-Learning project is delayed.

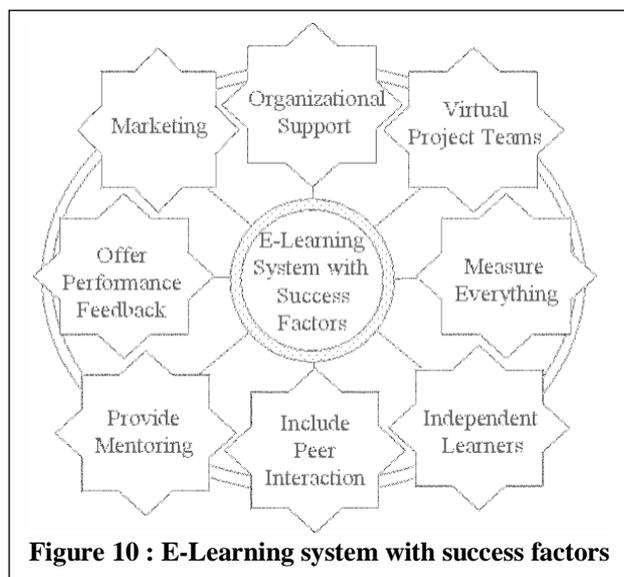

Step four is “run beta programs”. Please run beta programs from vendors in real corporate environments. Check if there are any bugs, misunderstandings about workflows, lacking of functions needed, inconvenience of user interfaces, and so forth. Gather them and feedback to vendors in writing. Wait for final e-Learning programs and test until they are ok for corporations.

Step five is “implementation”. Make sure there are engineers who will be responsible for the maintenance and use of the e-Learning system. Also, confirm with vendors to give training courses of the e-Learning system. By doing so, end users may learn how to use it. After a period of time, collect evaluation results on how they feel about the system. Improve the weaknesses and make it a more excellent system day after day.

## 12. Success Factors

E-Learning is just two years old and people are still experimenting how it works best. If an e-Learning system wants to run smoothly, what should be considered? The success factors will make the e-Learning system grow up and function properly. If corporations apply them, it will be easy for them to be successful. Figure 10 shows the e-Learning system with success factors [1] [3] [9].

The first one is “organizational support”. If top managements have fully supported on the e-Learning system usage, employees will have to practice more on how to use it. If it will be included in appraisal and salary review process, it will soon be one important part of employees' daily work.

**Figure 10 : E-Learning system with success factors**

The second one is “virtual project teams”. Members from different departments will create the virtual project teams. They will be from CEO, HR, IT, financial, sales departments, customers and vendors. They will contribute their unique skills, knowledge, or technologies to help setup the e-Learning system. They will conquer barriers across departments and implement the e-Learning solutions.

The third one is “measure everything”. It will help corporations to know where the starting and balancing points are. It will help to find out what strategies and objectives should be included or improved. Different stakeholders must be assessed to know their abilities and expected growth from the e-Learning system. The expected ROI should be set to compare with the real ROI to see whether the learning results of the e-Learning system are effective or not.

The fourth one is “independent learners”. Although the e-Learning system will try its best to be friendly and interactive, learners still have to be independent. Because web environments are quite different from a physical classroom. No instructors will push them to learn, they must learn at the required period of time. Independent attitudes will help them to learn online courses by themselves.

The fifth one is “include peer interaction”. If learners can have peer interaction by using message boards, chatrooms, communities, and so forth, they will like to spend more time on the e-Learning system. They share their ideas, experiences, and knowledge to one another from the network. By using the collaborative environment, learners will return to the e-Learning portal often.

The sixth one is “provide mentoring”. With the help of instructor mentoring, learners can avoid confusion situations about learning topics or processes. When learners take self-paced courses, they sometimes will get some questions about the e-Learning system. Maybe they will feel stuck and do not know what to do. They can either ask online instructors or e-mail their problems for advanced help.

The seventh one is “offer performance feedback”. The pretest determines learners' strengths or weaknesses. It will assess the level of learners and suggest needed courses for them to take. More over, learners can answer review questions at the end of the lessons. Learners have to wait a period of time before they can get feedback in traditional trainings. But the e-Learning system can offer performance feedback to learners, they can know their learning results immediately.

The eighth one is “marketing”. Since the e-Learning system includes customer education and satisfaction, it will be valuable and important to know how they feel about the system. Corporations must know why people want to use the e-Learning site. They must setup customer education objectives to motivate customer to use the e-Learning system. By having a good marketing, the investment of e-Learning will be adjusted to the directions which customers need and prefer.

### 13. Challenge Factors

Poor project management, undefined scopes, or no guide and roadmap to follow during the project's life cycle will harm the e-Learning system. So it is very important to know what will be the challenge factors during the implementation of e-Learning system and to avoid them in advance. There are eight challenge factors listed and discussed after [4]. Please refer to Figure 11 for the chart. Each of them will threaten the normal behaviors of an e-Learning system. The e-Learning system will have to work harder to conquer the challenges or be very weak to serve the audiences well.

The first one is “correct target setup”. Different stakeholders should be together to setup correct targets. They must decide what the business requirements are – workforce, sales channel or customer education. Also, target audiences should be correctly set. It will give good results in case there is a good strategy and plan set in advance.

The second one is “LMS / LCMS configuration”. Be aware of how the portal and tracking system are built. If they can work successfully, they will be helpful to keep good tracking of the audiences. Thus the learning evaluation results of employees will be convenient for top managements to review.

The third is “tutors and subject matter experts (SMEs) integration”. They will give the e-Learning system good services and helpful courses. It will need IT departments to work with tutors and the subject matter experts. It will help the audiences to use the e-Learning system with great satisfaction.

The fourth one is “content creation”. Decide whether to build or buy the necessary content. Whether the content is friendly or not will impact learners' attitudes towards the e-Learning system. In order to keep attentions and interest, IT departments have to create interactive and attractive contents.

The fifth one is “multiple modes of learning”. Since the e-Learning system have to serve different kinds of

learners, like CEO, managers, employees, salesmen, and customers, it has to provide a flexible approach for them to use. It needs to be engaging to the audiences.

The sixth one is “back end systems integration”. There will be many data needed for the e-Learning system to process, some of them are coming from ERP and CRM systems. For example, customer education services may need data from CRM system. The seamless integration among them will help the e-Learning system to be more powerful and useful.

The seventh one is “web infrastructure”. The system needs to serve many audiences at the same time, it will be very important to implement a high availability and performance web infrastructure. It must provide a fast and truly interactive interface for learners to get the content they want quickly and easily.

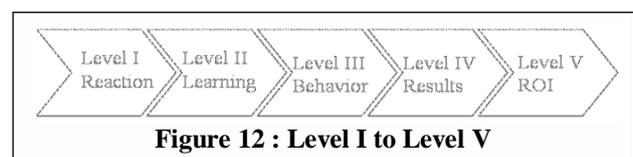

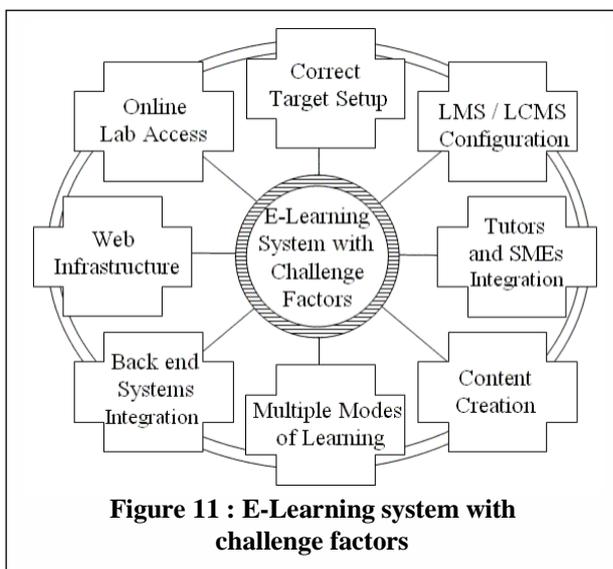

The eighth one is “online lab access”. It is necessary to help the audiences to do online access. Many of them need to be trained on the methods of using online lab. Please teach them well on how to use the system before they can have habits to do so.

### 14. Evaluation and ROI

Finally, the e-Learning system must include a systematic method to gather information about the impact and effectiveness of a learning event. The measurement results can be used to improve learning offerings, determine whether business or training objectives have been achieved, and assess the value of the learning event to corporations. Donald Kirkpatrick developed four levels which was laid out in “Evaluating Training Programs: The Four Levels.” Jack Phillips enhanced them and developed another level – Level V, to calculate corporate return on investment (ROI) [7].

Corporations can measure training effectiveness to know whether the investment in training is worthy or not. Corporations can get useful information when calculating the four factors or four levels. Each level of them cannot be used separately. There is a chain of effect among the five levels. Each level of measurement depends on the previous level, as well as the next. This paper introduces the meanings of them and gives three examples of ROI. Figure 12 depicts a Level I to Level V chart.

Level I measures “reaction”. It measures reaction of learners to training programs and whether they fit what they plan to learn from them. It will ask learners if they get useful skills and knowledge for their daily work. “Smile sheets”, which include surveys, questionnaire, or similar evaluation methods, are also provided to measure whether learning plans fit learners' expectation or not. The measurement can show that whether the training courses are meaningful or enjoyable to learners.

Level II measures “learning”. It will examine learners to see whether they achieve the skills or knowledge presented in the training programs by giving achievement tests, or whether the attitudes have been changed or acquired. It will compare “before” and “after” assessments and see to what extent have been improved after the training courses.

Level III measures “behavior”. When a training course is finished, changes of learners' working behavior will be observed. To observe learners in working environment will understand if they do what they have learned. This will calculate the training impact on learners' working.

Level IV measures “results”. It checks whether the on-the-job application does produce measurable results. If it is a sales training, it can be calculated by the increasing and decreasing of its revenues. It proposes the question of how many returns that corporations invest in trainings are gained.

Level V measures “return on investment” It checks whether the training return is greater than the investment or not. When performing the mathematical calculation of the ROI calculation, three data points are required : time period, investment, and return. According to “Calculating the Return On Your eLearning Investment” [5], there are three kinds of ROI evaluation : percentage, ratio and time to break-even. To have a more clear understanding, table 5 shows three ROI examples when fixed values : time period = 12 months, total investment = \$125,000 and return = \$500,000 are given. The ROI values will be : percentage is equal to 300%, ratio is equal to 4:1, and time to break-even is 3 months or 90 days.

## 15. Conclusion

This paper provides a good e-Learning guide and roadmap. There are useful approaches and considerations proposed to help corporations which are getting started with the implementation of e-Learning system. There are no doubts that all the topics in this paper help to setup a successful e-Learning system for e-Business.

**Table 5 : Examples of different ROI**

Three kinds of ROI	Formulation	Result
Percentage	$\frac{[(\text{Return}-\text{Investment})]}{\text{Investment}} * 100$ $= \frac{[(\$500,000-\$125,000)]}{\$125,000} * 100$	300%
Ratio	$\frac{\text{Return}}{\text{Investment}}$ $= \frac{\$500,000}{\$125,000}$	4:1
Time to break-even	$\frac{(\text{Investment}/\text{Return})}{* \text{Time Period}}$ $= \frac{(\$125,000/\$500,000)}{* 12 \text{ months}}$ $= (0.25) * 12 \text{ months}$	3 months or 90 days

Different stakeholders get their own responsibilities and jobs. CEO needs to give continuous supports. HRD and ITD will take advantages of the new training technology and provide a successful e-Learning system environment. Financial departments help to control investments and revenues. Employees improve job skills and knowledge. Salesmen improve performances on selling products. Customers can get educations and great satisfactions.

Clear understandings of inside and outside corporate environments will let corporations know where they stand. Correct strategies and objectives will setup successful directions. Suitable vendors will help to provide necessary contents, technologies, and services. Consistent project management will guarantee the quality of implementation. Success and challenge factors together to suggest overall notices for a better e-Learning system for e-Business.

If real ROI exceeds predefined ROI of the e-Learning system, the implementation of e-Learning system for e-Business can be proven to be successful. Otherwise, if predefined ROI exceeds real ROI, it means that the implementation is not as good as expected. Discuss with e-Learning project teams will help to find out what should be improved. Please adjust strategies, objectives, and ROI expectations of next year. Corporations can measure and gather different ROI year after year. They can compare what the improvements or changes are when comparing ROI of different years.

## Abstract

This paper presents and discusses the design and evaluation of an innovative educational exercise that combines elements of both learning about and learning for e-commerce. The principle guiding the design of the exercise was the provision of an opportunity for postgraduate information management and information systems students to learn about and for e-commerce through the collaborative development of a business plan. A survey distributed at the end of the module collected data on students' acquisition of knowledge and skills related to their learning about and for e-commerce on the business plan exercise. The data analysis focuses on students' acquisition of knowledge and skills relevant to entrepreneurship, and demonstrates that the collaborative development of a business plan can be an effective learning tool for students to acquire not only specific domain knowledge of e-commerce topics such as business strategy, e-commerce business models, and e-commerce technology, but also generic information, communication, and management skills, relevant to learning about and for entrepreneurship.

## 1. Introduction

As a response to the competitive challenges of the knowledge-driven economy, the United Kingdom (UK) government recently published a report encouraging higher education institutions to incorporate learning for enterprise into their curricula [4]. The UK government's promotion of enterprise has also included the award of grant support to universities via the government's Science Enterprise Challenge. Support from this grant led to the establishment in 1999 of the White Rose Centre for Enterprise (WRCE) (<http://www.wrce.org.uk/>). This paper reports on the first stage of the WRCE-funded project called Managing Innovation in the Digital Economy (<http://www.wrce.org.uk/elbidshf.htm>). This project aims to incorporate enterprise learning into postgraduate and undergraduate curricula in information management and information systems.

Higher education curricula for e-commerce can be broadly considered to be of two types: curricula about e-commerce and curricula for e-commerce [7]. A curriculum designed for students to learn about e-commerce normally focuses on introducing and

developing conceptual models of e-commerce. The approach is taught in a conventional manner through lectures, textbooks, and essay writing. A curriculum designed for students to learn for e-commerce aims to create a learning environment that enables students to acquire knowledge and skills relevant to the practice of e-commerce. This paper presents and discusses the design and evaluation of an innovative educational exercise that combines elements of both learning about and learning for e-commerce. The principle guiding the design of the exercise was the provision of an opportunity for postgraduate information management and information systems students to learn about and for e-commerce through the collaborative development of a business plan.

## 2. Entrepreneurship and the Knowledge-Based Economy

An entrepreneur is commonly considered to be someone who starts up their own, new, small business. Not every new small business start-up represents an example of entrepreneurship though in its economic sense. The concept of entrepreneurship rests on economic theory that argues that the entrepreneur "shifts economic resources out of an area of lower and into an area of higher productivity and greater yield" [3]. This definition taken from the eighteenth century economist, J.B. Say, was intended as a manifesto and a declaration of dissent: the entrepreneur upsets and disorganizes. In the same vein, the economist Joseph Schumpeter has postulated that changes, which upset economic equilibrium, are due to an innovative entrepreneur who sees change as the norm and as healthy to economy. These changes are considered to be opportunities for the entrepreneur to innovate, to create new ways of doing things, and to create resources for further economic and social development. It is in this context that the management theorist, Peter Drucker defines entrepreneur and entrepreneurship as follows: "the entrepreneur always searches for change, responds to it, and exploits it as an opportunity" [3].

The concept of entrepreneurship is often allied with the concept of innovation. Such innovation does not have to be a technical innovation or even result in a tradeable product. An innovation can be social, for example, changes in an education system or a national health service can be considered to be social innovations because they have a profound impact on society and economy as a whole.

Entrepreneurs and the practice of entrepreneurship can be found in every walk of life and in any organization.

During the technology boom of 1999-2001 an increasing number of entrepreneurial initiatives were undertaken on a global scale. Indeed, the Internet commentator Manuel Castells writes: “without the action of these entrepreneurs, oriented by a specific set of values, there would be no new economy, and the Internet would have diffused at a much slower pace and with a different range of applications” [1]. The launching of these entrepreneurial initiatives was most popular among the young. This was in part because younger generations are exposed to new waves of technology development to a greater degree than older generations. Younger generations also possess a heightened awareness of the potential business opportunities offered by such technologies (e.g. Boo.com, Lastminute.com, Yahoo.com). Unlike their older counterparts however, younger people can often lack essential experience in planning, organizing, and managing businesses; and this lack of experience has been a contributing factor in the failure of many dot.com businesses to make a sustainable profit and subsequently collapse when their initial cash flows have dried up.

In the new economy, traditional methods of conducting business still persist. In addition to these traditional methods however new business instruments and thinking are required too. In the new economy, where knowledge-based products and services are the source of organizations’ competitiveness, there are a variety of technologies to support the development and distribution of these products and services. The value of these knowledge-based commodities rests on their symbolic representation of information and not on their manufacturing value. Hence organizations need to be able to represent and manipulate information effectively. Modern technologies, particularly digital technologies, can be employed to support the production and consumption of such symbolic or intangible goods.

In a knowledge-based economy, network technologies represent both an opportunity and a threat for organizations. On the one hand such technologies act as tools that can help accelerate the process of innovation within an organization, at both technical and organizational levels. On the other hand the speed of replication that networks afford, particularly with regard to the production and consumption of digital products, can represent a competitive challenge. This duality of opportunity and threat makes engagement in innovation a key function in the knowledge-based economy: “in an e-economy based on knowledge, information, and intangibles...innovation is the primordial function” [1]. Although some commentators have argued that it is not possible to plan for innovation, manage it, or design organizational structures and processes to support it, other commentators have suggested that a systematic approach to the innovation process can be taken. One such approach

suggests that there are five elements to the entrepreneurial innovation process. These elements are: preparation, incubation, insight, evaluation, and elaboration [5]. Each element involves a set of knowledge and skills that a successful entrepreneur is expected to have acquired.

## 2.1 Preparation

Opportunity recognition (OR) is the initial stage of the entrepreneurial process. OR can be defined as “either a) perceiving a possibility to create new business or b) significantly improving the position of an existing business, in both cases resulting in new profit potential” (Christensen, Madsen, and Peterson, 1989, quoted in [5]). The same argument is shared by others (e.g. Kirzner, cited in [5]) who state that the discovery of opportunities is the core issue of entrepreneurship. Hills et al. [5] define preparation as the background and experience that an entrepreneur brings to the opportunity recognition process. In the context of the current paper, an entrepreneur needs a knowledge base to draw on in order to identify opportunities. This knowledge base usually derives from an individual’s personal experience, education and training, and knowledge of particular fields.

## 2.1 Incubation

Incubation is the part of the opportunity recognition process in which the entrepreneur contemplates ideas or specific problems. Hills et al [5] and other commentators argue that incubation is neither about conscious or scientific problem-solving nor about systematic analysis, rather it is about having an intuitive sense of problems, and involves unstructured thinking of alternatives to the problems faced.

## 2.2 Insight

Unlike incubation which refers to an ongoing process, insight usually refers to a moment of recognition. Three types of insights may occur. First, is the experience of a spontaneous recognition of a business opportunity or of a solution to a problem. Second, is the moment when a person seizes the idea that solves the problem that they have been considering for some time. Third, is the recognition of a business opportunity or problem solving idea that arises from a person’s participation in a social network. Recent research has indicated that entrepreneurs with a wider network of social contacts and comparatively greater social capital are more likely to succeed compared to those with a narrower network of social contacts and less social capital.

## 2.3 Evaluation

Evaluation is the stage at which insights are analyzed systematically. This involves a series of activities which validate the ideas. These activities include research into

whether a concept is workable, whether the idea is original and has potential, whether the idea creator has the knowledge and skills to achieve it, and whether there is a market for the development of new products.

## 2.4 Elaboration

Elaboration is the phase at which creative insights, subjected to systematic analysis at the evaluation stage, are converted into a form ready for final presentation. It is at this stage that the practical details of the business idea are worked out with care. Entrepreneurship has always been associated with the image of high risk business however Hills et al. [5] argue that it during the process of elaboration that the skillful entrepreneur engages in planning activities in order to reduce risk. These five elements of the entrepreneurial process are by no means sequential and linear. Feedback from later stages to earlier stages is possible. The results of the evaluation stage for example may need to be fed back to the incubation stage for more earnest consideration. Similarly, during the elaboration stage individuals may be asked to feedback to earlier stages of the process in terms of further preparation, incubation, insight, and evaluation.

During the process of entrepreneurship a number of factors will have an overall impact on the process including personal traits, personal cognitive style and social competence. Social competence has become increasingly important, as a substantial proportion of creative insights are generated by teams of entrepreneurs rather than single individuals and new ventures usually need to obtain their venture capital from the market. It can also be argued that social skills such as impression management, social perception, and persuasiveness strongly affect the outcomes experienced by individuals in many contexts including job interviews, yearly performance reviews, and negotiation. In addition, social competence will have an impact on face-to-face interaction between individuals within the same entrepreneurial team, and between potential entrepreneurs and investors. It can also be argued that effective interactions with others may help entrepreneurs in performing important tasks such as negotiation, raising capital, building business relationships with suppliers and distributors, and so on.

Bearing the above arguments in mind, we argue that the facilitation of students' acquisition and development of the necessary knowledge base and skills needed to engage in the entrepreneurial process should be at the heart of teaching entrepreneurship. As discussed earlier, each step of the entrepreneurial process involves a set of activities and those activities require particular knowledge and skills in order to generate the input required for subsequent activities. The teaching of entrepreneurship should focus on developing the necessary knowledge and skills for each step and for the process as whole.

Table 1. Entrepreneurial knowledge and skills

Step	Knowledge	Skills
Preparation	Domain specific knowledge	Problem framing; identifying relevant information; information searching and location.
Incubation	Domain specific knowledge	Creative thinking
Insight	Domain specific knowledge	Problem solving
Evaluation	Domain specific knowledge	Identifying relevant resources; information locating, searching and gathering; synthesising data; extracting, evaluating and organising relevant information, industry analysis; critical analysis.
Elaboration	Business planning; marketing; project management; organisation and management knowledge, risk management.	Managing project; planning business; assessing risk; attention to detail; presenting data.

Table 1 summarizes the set of specific knowledge and skills that can be acquired in class. Social competence is assumed to be a generic interpersonal skill. Although social competence is not usually taught in an e-business and e-commerce classroom setting, it can nevertheless be learned by students as they engage in team-based educational exercises.

## 3. Curriculum Design

The E-Business and E-Commerce module is a postgraduate module designed mainly for delivery on the M.Sc. Information Systems (IS) and M.Sc. Information Management (IM) programmes, within the Department of Information Studies at the University of Sheffield. Both programmes of study are conversion programmes designed for those students who are interested in IS- or IM-related subjects but whose first degree may or may not be within an IS or IM discipline.

The curriculum design is based on two general observations of the business sector. First, the myth that the new economy has been caused by e-commerce or by the Internet. Indeed many commentators have overplayed the importance of the Internet or major new technologies (i.e. mobile computing, WAP) and underplayed the fact that economic law remains more or less the same [6]. This first

myth of the new economy leads to a second myth: that compared to the old economy, barriers of entry into business in the new economy are lower. A general feeling is that doing business online is easier than doing business offline and that it is easier to enter and exit an online market. This conception of e-commerce often leads individuals to believe that setting up an online business does not need to follow a series of procedures that conventional businesses would otherwise follow e.g. business planning, risk assessment, business model and strategy. Evidence demonstrates that the lack of detailed planning in many start-ups is one of the major reasons for their failure (<http://www.businessplanarchive.org/>). The curriculum design of the E-business and E-commerce module emphasizes the fact that the fundamental economic and business principles of e-commerce in the new economy are by and large no different from those of businesses in the old economy. Within the context of an increasing number of start-ups, many of them are noticeably run by young entrepreneurs [1]. In recent years, the British government has been committed to the promotion of enterprise and innovation in industry ([http://www.dti.gov.uk/for\\_business.html](http://www.dti.gov.uk/for_business.html)). The UK's Department of Trade and Industry for example provides various services to small and medium sized enterprises and start-ups in order to ensure that businesses receive necessary and adequate support from government. The Office of the e-Envoy was established by the British government to ensure that the country, its citizens and its businesses derive maximum benefit from the knowledge economy (<http://www.e-envoy.gov.uk/>). These initiatives aim to exploit innovations of any kind in order to sustain economic growth.

On the basis of the above observations the overall aims of the E-Business and E-Commerce module are (a) to emphasize fundamental economic and business principles and to give both traditional and new business models equal consideration; and (b) to encourage students to think creatively and provide an opportunity for them to experience the entrepreneurial process during the course. Three areas that the curriculum design is intended to address are: domain specific knowledge, intellectual skills and social competence. Domain specific knowledge refers to business-related knowledge, and in this case refers to knowledge of e-business and e-commerce in particular. Students are expected to develop domain specific knowledge through lectures, seminars, writing an individual essay, and doing a group assignment. This is learning about e-commerce.

Intellectual skills and social competence are expected to be developed through a group exercise set for the module: the collaborative development of a business plan. Through group collaboration in starting up a new business, students not only further their intellectual skills but also develop their social competence. This is learning for e-commerce.

### 3.1 Collaborative business plan

Students were asked to develop a collaborative business plan on the basis of one of three case scenarios developed for the module. These scenarios were drawn from three different industries: music, information, and retail. The first and second cases focus on the development of digital products and services, while the third case focuses on traditional retailing. Developing a business plan on the basis of these case scenarios takes students through an entrepreneurial process, from initiating business ideas (preparation) to planning details (elaboration).

The provision of case scenarios was in a number of ways similar to business case studies used for teaching and class discussion. First, the problem situation presented in the scenarios allowed students to step metaphorically into a decision-maker's shoes [9], where learning can take place through the submission and collaborative testing out of ideas, and the iterative application of the combined effort to the problem at hand. Second, the case scenario helps students to develop a set of principles and concepts that can be applied in practice [2]. Through the case scenarios students are able to develop their ability to identify problems, deal with complex and ambiguous situations, and to take decisions and determine action plans. Third, in order to provide solutions to the problems, in this case to develop a sound business plan, students need to apply their domain knowledge and bring appropriate tools to bear on their analysis of the problem. As has been suggested by others, such an approach helps students to develop a set of skills that includes applying their knowledge to complex situations, formulating critical analysis, and making decisions [6]. Finally, the case scenarios are intended to encourage students to make assumptions about how they might frame their business opportunity students have the flexibility to imagine different alternatives. This not only sharpens students' industry analysis skills but also encourages students to think creatively. Indeed such flexibility is essential to the students' entrepreneurial experience.

As mentioned above, three case scenarios were prepared to describe three different types of companies located in three different industries ranging from music, information and retail. Reasons for choosing these three industries are twofold. First, these industries are currently facing challenges caused by digital technologies. For example, the retail sector faces a dilemma of going or not going online because either option will afford different opportunities but at the same time present different challenges to retailers. The information industry is facing problems of pricing information on the Internet, while the music industry is facing pressure through falling CD sales and an increase in the number of music websites which allow free music download. Second, these three industries are close to students' everyday life and students are hence able to draw together their observation, experiences, and general knowledge to generate business ideas.

Students were expected to draw up a collaborative business plan on the basis of the scenarios. They had the opportunity either to launch a start-up company or to launch a new online products and services division within an existing offline company. The structure and content of the business plan should be almost the same as a standard business plan, consisting of an executive summary, company description, industry analysis, product and service, business model, marketing and business strategy, management team, and financial forecast. In order to develop their business plan, students were asked to analyze the case scenarios in order to frame the problems that the company currently faces, find information about the current developments in the industry in which the company is located, analyze the developments in the industry to evaluate their business ideas, and apply their knowledge of marketing and business to formulate their strategies. The exercise provided an opportunity for students to further their domain specific knowledge by applying it to the exercise and to develop their intellectual skills and social competence through interaction with fellow students.

### 3.2 Implementation issues

Thirty-four students signed up for the module for the 2001-2002 academic year. The student body was diverse in terms of nationality and gender. Fifty per cent of students were home students and fifty per cent of students were international students. The gender distribution of the group was also fifty-fifty. All students were assigned to a group of four by the module coordinator. The decision about assigning students to their groups rather than allowing them to choose their own groups in this instance is based on pedagogical grounds.

First, there can be a tendency towards a divide between home and international students with students from the same cultural background or country tending to work together. A gender divide can also occur. Female students tend to work with female students while male students tend to work with male students. In an effort to encourage students to work together regardless of cultural background or gender, the decision was taken to mix students evenly on the basis of these two criteria. Second, it can be argued that forming a diverse business team can help generate good ideas as people from different social, cultural and ethnic backgrounds are able to provide valuable contributions to business ideas from different perspectives. It can also be argued that nowadays working in a diverse work environment is almost inevitable and hence students should be prepared for working with individuals from different backgrounds. Third, through working in an international team, students' social competence can be further enhanced. There were eight groups in total and copies of the three case scenarios were distributed. Groups were asked to take a decision about which scenario they would develop for their collaborative business plan. In order to avoid a situation where students

over subscribed to a particular case allocation to each case was limited to a maximum of three groups. Three seminars were organized to provide groups with an opportunity to present their business plan to other groups and to gain feedback from tutors and their fellow students. In the first seminar, the groups presented their industrial and market analysis. In the second seminar, the groups presented their draft business plan. In the third seminar, the groups presented a near-completed business plan.

### 4. Learning outcome

During the course of the module students attended lectures regularly and prepared and presented their latest work every three weeks. An advisor from the university's technology transfer office was invited to give students feedback on their business plans. The following discussion presents the results of the questionnaire survey. The questionnaire was designed to evaluate the effectiveness of the exercise as a whole, and the collaborative development of the business plan in particular, within the context of learning about and for entrepreneurship. Learning outcomes identified in this paper focus on the knowledge and skills which students stated that they had acquired through participating in the business plan exercise. The questionnaire was distributed to the students at the end of the course. The students were able to decide whether they would like to participate in filling the questionnaire. The questionnaire received a good response rate with fifty-six per cent of the students on the course completing the questionnaire. Tables 2-5 summarize the findings relating to students' acquisition of knowledge and skills through their participation in the exercise.

Table 2. Students' acquisition of domain knowledge by percentage and rank

Domain Knowledge	Percentage	Rank
Business strategy	78.9	1.5
E-commerce	78.9	1.5
Business models		
E-commerce technology	63.2	3
Success and failure of e-commerce	57.9	4.5
Marketing	57.9	4.5
Digital market	36.8	6.5
Management	36.8	6.5
Knowledge	26.3	8
Management		
Value chain	21.1	9
Management		
Information management	15.8	10
Interface design	10.5	11.5
Project management	10.5	11.5

The data in Table 2 demonstrate that the three most valued areas of domain knowledge acquired through participating in the collaborative development of the business plan were: business strategy, e-commerce business models, and e-commerce technology. The need for sound business strategy and models is a recurring theme in the retrospective analysis of the dotcom boom and bust. Learning about 'success and failure of e-commerce' and 'marketing' were also considered to be important (57.9%). The value attributed by students as to the relevance of 'success and failure of e-commerce' is of particular note. The meaning of entrepreneurship traditionally incorporates the notion of risk and the risks attendant on entrepreneurship in relation to e-commerce enterprises are no exception.

Table 3. Students' acquisition of communication skills by percentage and rank

Communication skill	Percentage	Rank
Speaking effectively	94.7	1
Presenting and conveying ideas and information effectively	84.2	2
Writing concisely	68.4	3

Social competence is a key competence in order to participate effectively in the entrepreneurial process; and the data demonstrates how students ranked the acquisition of oral skills relating to speaking and presenting above those of writing skills.

Table 4. Students' acquisition of interpersonal skills by percentage and rank

Interpersonal skill	Percentage	Rank
Working effectively In a team	73.7	1
Listening to others	63.2	2
Being sensitive to others	57.9	3.5
Providing support For others	57.9	3.5
Developing rapport	52.6	5
Negotiating	47.4	6.5
Accepting criticism and acting upon it	47.4	6.5

Acquiring the ability to work effectively in a team is clearly an essential part of an entrepreneurial education and the findings demonstrate the clear value attached to this ability by the student body. The data also point to the other- rather self-oriented nature of enterprise development as part of a group dynamic. Listening skills, being sensitive to, providing support for, and developing rapport with others were also skills identified by the majority of students as being acquired. The students felt that listening skills and being sensitive to others are critical for working effectively in a culturally diverse team.

Table 5. Students' acquisition of organizational and management skills by percentage and rank

Organisational and management skill	Percentage	Rank
Decision-making	68.4	1.5
Accepting responsibility	68.4	1.5
Setting and meeting Deadlines	63.2	3
Managing time	57.9	4.5
Meeting goals	57.9	4.5
Planning and co-ordinating tasks	52.6	6
Attention to detail	36.8	7
Managing conflict	26.3	9
Enlisting help	26.3	9
Project management	26.3	9

Key skills identified by the students relate to the successful accomplishment and achievement of a collaborative exercise: decision-making (68.4%), accepting responsibility (68.4%) and setting and meeting deadlines (63.2%). The top ranking of these skills neatly highlights a logical sequence of decision-making, taking responsibility and achieving deliverables by a certain date.

Table 6. Students' acquisition of intellectual and research skills by percentage and rank

Intellectual and research skill	Percentage	Rank
Extracting, evaluating and organizing relevant information	57.9	1
Information locating, search and gathering	52.6	2
Creating ideas	47.4	3
Identifying and solving Problems	42.1	5
Applying critical judgment	42.1	5
Identifying relevant resources	42.1	5
Synthesizing data	36.8	7
Imagining alternatives	26.3	8
Initiating and recognizing information inquiry concisely i.e. what information	21.1	9

Of particular note in this aspect of the data set is the rating of information-related skills above those of the creation of ideas. Industrial and competitor analyses will have needed to have been carried out ahead of creating ideas for new enterprises.

## 6. Discussion

Domain specific knowledge acquired by the students is relevant to all stages of the entrepreneurial process: preparation, incubation, insight, evaluation, and elaboration. The emphasis placed by the students on acquiring knowledge of business strategy, e-commerce business models, e-commerce technology, and success and failure of e-commerce appears to bear this out. The healthy

ranking accorded to 'marketing' is also encouraging in that it demonstrates that a majority of the students were also following the entrepreneurial process right through to the stage of elaboration.

In regard to generic skills, the opportunity to and their ability to articulate and express ideas orally was highly valued. In the context of the entrepreneurial process this is again encouraging, where oral communication in teams, and presentations to external agencies forms a crucial part of effective entrepreneurship. Students acquisition of interpersonal skills bears out the importance of team-work in developing innovative processes. Students' acquisition of organizational and management skills appears to focus on group decision-making, a shared division of labour, and a number of process tasks related to keeping the task on track. There appears to be less emphasis on either asking for outside help and formal project management planning. The former may be encouraging in terms of group autonomy although the latter may be less encouraging. Interestingly, students acquisition of intellectual and research skills appears to have been concentrated on the preparation and evaluation stages of the entrepreneurial process. The higher ranking accorded to information-related skills above skills of creating ideas seems to suggest that many of the students were focused during the process particularly on researching the particular industry in which their case scenario was located and again evaluating their plan against real-world industrial cases.

## 7. Conclusion

In today's knowledge-driven business environment the ability to continuously innovate is regarded as a lynchpin of a company's competitive advantage. The survey results suggest that the business plan exercise has been an effective learning instrument through which students can acquire both domain knowledge and generic skills relevant to an innovative entrepreneurial process. Such a process of innovation, taken as a whole and in regard to the information-related and other creative and social skills that process incorporates is particularly pertinent to innovation in a knowledge-driven economy. How can this process and the skills which it incorporates be taught in the classroom? In this paper we have demonstrated that through a carefully designed exercise both domain knowledge and a set of

generic skills relevant to each stage of the entrepreneurial process can be developed. Teaching entrepreneurship can be not only about teaching students subject knowledge or knowledge about how to start and run a new business, but can also be about how to help and encourage students to develop their entrepreneurial capabilities e.g. identifying an opportunity, thinking creatively, communicating effectively. Learning entrepreneurship can then be a process of acquiring not only knowledge of business strategies and models and the application of these in organizational contexts but can also be about simulating intervention in the real-world through active participation in the collaborative development of business plans. We end with a caveat. Interested curriculum designers should ensure however that the design of such a learning environment is accompanied by a well structured learning process that supports and facilitates students' progress towards their business goal.

# Teaching Internet Entrepreneurship

Gail Ross Waters

College of Business Administration  
California State Polytechnic University, Pomona  
3801 West Temple Avenue  
Pomona, CA 91768, USA  
[grwaters@csupomona.edu](mailto:grwaters@csupomona.edu)

At the beginning of 2000, Cal Poly Pomona College of Business Administration launched a task force to create an undergraduate E-Business Program. Twelve faculty members worked hard to develop a core of six four-unit courses including practicum or senior project and then began work on six specialty career tracks.

#### Required Core Courses:

- EBZ 301: Introduction to Electronic Business.
- EBZ 302: e-Business Technology.
- EBZ 303: e-Business Customer Relationship Management.
- EBZ 304: e-Business-enabled Supply Chain Management.
- EBZ 305: e-Business Enterprise Resource Planning.
- EBZ 306: e-Business Startup and Development.
- EBZ 466: e-Business Practicum.

#### Specialty Career Tracks:

1. Accounting and Transaction Processing
2. Content Creation and Management
3. Customer Relationship Management
4. E-Business Entrepreneurship and Strategy
5. Enterprise Integration Applications
6. Supply Chain Management

The first course EBZ 301 was taught January 2001 launching the program. At the end of spring 2002 we have almost 200 enrolled in the program and have actually seen seven graduates with the EBZ option/concentration (business administration is major.)

This paper concerns the development of content and process for the course EBZ 306 E-Business Startup and Development, the sixth core course requirement for the EBZ concentration. It presents a model of the course as

presented and calls for suggestions for improvement as well as enhancement.

Having taught entrepreneurship for many years and been involved in the development of many entrepreneurship courses as well as degree programs; the importance of a combination of unique learning experiences was a very clear mandate.

Historic literature indicates a varied list of pedagogues as useful for stimulating learning in the entrepreneurial classroom. Ronstadt (1985) called for an "action-oriented approach . . . go out and do it. . ."

Winslow, Solomon and Tarabishy (1997)

. . . data indicate what teaching methods were offered. They include: (1) case studies (2) lectures of business owners; (3) development of business plans; (4) guest speakers; (5) research projects; (6) community development; (7) onsite visits; (8) creation of business plans; (9) discussions; (10) small business institute counseling (11) feasibility studies (12) internships.

In fact, numerous studies have revealed that traditional textbook/lecture is an inappropriate if not boring way to deliver entrepreneurial instruction. (Ahiarah 1989 and others.)

The treatment of entrepreneurship on the Internet comes with an obvious ready-made core pedagogical tool. Effective use of this tool and the instructional materials supporting it are not so ready. My [website for EBZ 306](#), a course I teach at Cal Poly Pomona is designed for both home research and in-class presentation. I shall begin with the components of this course:

## GRADING AND EVALUATION

The following weightings will determine student evaluations.

INDIVIDUAL - <a href="#">INTERNET RESEARCH EXERCISE</a>	10%
INDIVIDUAL - <a href="#">SELF DEVELOPMENT EXERCISE</a>	10%
INDIVIDUAL - <a href="#">FOUR ASSIGNMENTS</a>	40%
INDIVIDUAL - <a href="#">BOOK REPORT eBoys or Burn Rate</a>	10%
GROUP - <a href="#">E-BUSINESS WEB BUSINESS PLAN</a>	20%
CLASS PARTICIPATION, ATTENDANCE,	10%
<a href="#">TOTAL</a>	<a href="#">100%</a>

Each component is linked to the page description for the assignment or project.

The Internet Research Exercise contains 13 carefully constructed questions to expose students to be the best sources of Internet information on individual companies and industry trends, changes, conditions and forces, that is opportunities and threats. For example, here are two questions from the actual exercise:

1. The most significant source of information on publicly traded corporations is the [Securities and Exchange Commission -EDGAR Data Base](#). It is very important for finding corporate SEC filings. Always seek the most current "Form 10-K". Click on "Search Edgar Archives." Find the blank space and type in Yahoo or Yahoo Inc. Set "Start" to 1999 and "End" to 2002. Click return. Spot the most current 10-K (you may have to scan down the page.) Click on "Yahoo Inc." and find the financial statements. ([Confused? -- try the SEC Edgar Instructions/Tutorial](#).) Copy the "profit and loss statement" and paste it on to your assignment. This copy paste is acceptable as long as you cite the 10-K using the formats found at either: [American Psychological Association - APA Style.Org Or, Purdue University English Dept. interpretation of APA and other style sheets](#).

2. Industry Analysis - Though more vague and difficult to find, the researcher is searching for external dynamics. These might include -- industry: lifecycle, concentration levels, changes, trends, successes, failures, downturns, collapses, key industry players or biggest competitors. Unless the company is on the list of largest global influencers, they are not likely to be able to individually change or impact these external or industry conditions. In effect, these "externalities" are beyond control of the individual company.

Answer 1: In your own words, create a list of five industry conditions. (No, not from the Internet, just be creative and list five) Discuss why it would be important to research and utilize current information about these conditions when analyzing or researching a company.

For example: Let's assume that I am preparing a case -- say "Yahoo.Com." I must provide information about the appropriate industry/(ies) First, I must identify the industry -- probably by S.I.C. number.

Answer 2 in 11 steps: Step 1. Click on [Hoovers.com](#). 2. At the top click on "companies & industries," then, 3. click on "industries" from the immediate menu on the left. 4. Click on "Complete List" on right side of page. 5. Type "Yahoo" into the search box and hit return. 6. Click on "YHOO NASDAQ", then, 7. click on the "industry" tab - (found on right screen.) 7. hat is the SIC number, and 8. what is the industry name? 9. Click on "Media - Internet & Online Content Providers" 10. click on SIC tab - right screen. 11. What are the three SIC Codes

related to this industry?

Yes, these two questions are a bit confusing -- indeed by design. The student is forced to discuss the questions with team members and I can use them in class for extended oral discussion. I am a bit mean, I use this same question with MBA students and have a standing threat to fail a graduate student who does not know what a P&L statement is. The copy paste in question 1 leads to a discussion concerning plagiarism and paraphrasing. If links get stale, I reward the student who emails me this information first so that I may correct the exercise.

The individual self-development exercise, provides a choice of unique challenges. The student selects the one that appears to provide the best individual learning based on interest or career track choice. These include "check your credit" with the three US credit reporting agencies. I only want a photocopy of the credit agency name and student name turned in. A student's credit report is singularly his/her business, not mine. I feel confident, however, in the process of pushing the student to examine his/her own credit report. Many do not know that it exists. They also do not connect a future SBA small business loan with this report.

Other self development items include write an individual mini business plan, establish a working business on eBay, etc.

The four assignments are designed to be the heart of the course. They are:

1. Description of the Business Opportunity including a discussion of: (a) the [Internet business model](#), (b) description of customers/target market, the [eMarketing Strategy](#), including competitive advantage, (c) brief overview of competition, (d) expectations/benchmarks, (e) start-up capital requirements (f) [fulfillment](#), inventory, warehousing, [delivery](#), or outsourcing, and part 2 - the individual 3 page website.

2. A project to learn as much as possible about the March-April 2000 dot com stock correction. (a) Select and research one Internet dot com failure (such as Boo.com.) (b) Discuss at least five major reasons why it failed. (c) Include at least 10 characteristics of the successful dot com for the next generation.

3. Generate at least three alternative web hosts for evaluation. Weigh, evaluate and analyze these three resulting in a final decision with justification. Finally, develop a step-by-step plan and schedule, detailing how you will launch your business with this provider. Considerations in analysis: shared, co-located or dedicated service, factors such as customer and technical support, uptime guarantees, facilities that can outlast disaster, connection types to the Internet, speed, flexibility, scalability, security, backup, equipment, software, and of course prices.

4. Develop a three page marketing plan for the individual business you developed in Assignment 1.

The book report on eBoys or Burn Rate. These two books were selected to provide a picture of the “golden years” of the dot com run up. Both books are readable and allow students to see what happened and a little bit about why. They are meant to be historic accounts (yes, four years ago is history in the e-world, and I am 8 dog years old!)

Finally, the e-business web business plan utilizes a format developed from experience and several recommended formats. This is a group project and involves both a three page working website (transaction software cannot function on university servers) and an oral formal presentation before the class.

For in class lectures, I use the following PowerPoint presentations:

Topic:

Introduction

Start Up Ideas - The Opportunity

Setting Up a Budget and Sticking to It

Domain Names

Creating Online Branding

Provide Customer Service

Building Community

Setting Up Storefront

Understanding Back End and Hosting

Business Planning & Venture Funding

Promoting to Your Target Market

PowerPoint:

[Introduction](#)

[Start Up Ideas](#)

[Budget](#)

[Domain Names](#)

[Branding](#)

[Customer Service](#)

[Building Community](#)

[Storefronts](#)

[Back End and Hosting](#)

[Planning & Funding](#)

[Promotion](#)

Each slide in the presentations contains both information bullets and links to relevant websites. For example:

## Top Level Domains

- Seven new TLDs listed: <http://www.icann.org/tlds/>
- Introducing .biz – the new Internet domain built especially for business: <http://www.neulevel.biz>
- ***What's in a .name?***  
<http://www.gnr.com/> A *.name* domain has three 'levels'. The first level is the actual *.name* suffix and the second and third levels are your first and last name. So a *.name* web address will look like this: *First name.Last name.name* or *Last name.First name.name*. Your email address will be easy to remember too: *First name@Last name.name* or *Last name@First name.name*.
- Registry Whois Search: <http://www.internic.net/whois.html>
- The Accredited Registrar Directory -- Listing by Location of Registrar <http://www.internic.net/origin.html>

This slide provides interesting information supported with links. The students in the laboratory each can use the links to read the supporting information while the lecturer comments. Do they ever engage in “chats” or games with the little messenger while teacher is pouring out heart and soul, you ask? Oh yes, that is why the “freeze” on instructors screen button is so critical in the pc lab. I emphasize that “frozen comments” are just long enough to cause the loss of a friend or game!

These slides are available online and students are encouraged to use them at home.

### Pedagogical Materials

I have found the following textbooks to be useful in this course:

1. Kienan, Brenda, [Managing Your E-Commerce Business](#), 448 pages, Microsoft Press; ISBN: 0735612757; 2 edition (April 4, 2001)
2. Frank Fiore and TechTV. [TechTV Starting an Online Business](#). Que Corporation, 2001. August 2001 ISBN 0-7897- 2564-9.
3. [Annual Editions for Entrepreneurship 02/03](#). Robert W. Price, Senior Research Fellow, Global Entrepreneurship Institute; McGraw-Hill Dushkin, January 2002. ISBN: 0-07-252911-3,

Course objectives or expected outcomes are simple and achievable:

#### COURSE OBJECTIVES

- Identify business opportunities
- Classify business opportunities, e.g., start-up, process improvement, new marketing channel, etc.
- Evaluate opportunities, in terms of business potential and organizational feasibility
- Design an Internet start-up or new eBusiness program within an existing organization
- Write and orally present a business plan

Finally, the following rules are critical:

1. Downloading, Scanning, Copying and Rearranging to be used as the final project will not be permitted. Violations of this will be treated as major infraction of

Cal Poly cheating rules. The Internet provides invaluable resources for students and practicing professionals. We shall learn here how to use them effectively. You will want to download and use these resources. Simply do not use downloaded or scanned text as final assignments.

2. A roll sheet will be passed at most class meetings and each absence will count 2 percentage points off the students final weighted average. If you have what you think to be a 90 weighted average after all work is completed, two absences will result in lowering that average to 86 and you will receive a B. Excuses will be considered on an individual basis
3. Assignments will be accepted late on the last day of class, not on the day or class period after they are due. They will receive only partial credit and will not be returned. This is only somewhat better than getting a 0 for that assignment. Avoid this problem by turning each assignment in on the due date.

### Conclusion

The results have been good overall. The first two attempts without a computer laboratory were tedious and difficult to work. Students of e-Commerce must be engaged in Internet navigation. Most have been doing this since teenage years. This incredible new learning tool is there classroom, their reading materials and their careers -- interaction, navigation and motivation are the critical ingredients.

# Teaching a Comprehensive Web Based Application within an IS Curriculum

David C. Wallace  
Applied Computer Science Department  
Illinois State University  
Normal, Illinois 61790-5150  
dcwalla@ilstu.edu

## Abstract

As Internet technologies have exploded over the past few years, corporations struggled to develop standards for managing their Internet resources. Since the passing of "Y2K," organizations have increasingly focused on developing an effective Internet presence. Consumer shopping on the Internet is expected to grow to around \$1 trillion by the year 2003, and Electronic Data Interchange (EDI) is expected to grow to around \$300 billion by the same year. With this escalating demand for Internet-based commerce, organizations are attempting to recruit IS personnel who can develop Internet applications, and they expect academic institutions to provide IS professionals with the skills necessary for this rapidly changing technological environment as well as traditional skills needed for the mainframe environment. With limited resources, academic institutions have been revamping their curriculum to accommodate the growth of the Internet and to maintain the more traditional IS core curriculum. By utilizing readily available computer hardware and software, academic institutions can provide an effective and active Internet learning environment.

## 1. Introduction

Preparing IS professionals is a challenge for academic institutions factoring in a rapidly changing technological environment. With the explosion of Internet technologies over the past few years, organizations have struggled to develop standards for effectively managing their Internet resources. Consumer shopping on the Internet is expected to grow to around \$1 trillion by the year 2003, and Electronic Data Interchange (EDI) is expected to grow to around \$300 billion by the same year (Grover, 2001). With this escalating demand for Internet-based commerce, organizations are trying to recruit IS personnel who can develop Internet applications, and they expect academic institutions to provide IS professionals with the skills that are needed for this rapidly changing technological environment as well as traditional skills needed for the mainframe environment. With limited resources, academic institutions have been revamping their curriculum to accommodate the growth of the Internet and to maintain the

more traditional IS core curriculum. The demand for both Internet and mainframe skills remains strong as indicated by the high salaries and vacant positions in the job market for IS professionals.

Eventually, the mainframe and the Internet (client/server) environments will have to be integrated into one complete, comprehensive system. Skills developed in the more traditional mainframe environment will have to be incorporated into a complex networking system that can seamlessly transfer information from one environment to another without giving up security or efficiency. The IS professional has to possess the skills for both environments; he/she will play the role of an integrator.

With limited resources academic institutions must provide these skills for their IS professionals. Much has been written concerning the implementation of mainframe base technology. Yet, how can academic institutions incorporate the client-server technologies of the Internet with traditional mainframe technologies? One of the most popular personal computer (PC)-mainframe configurations has been to provide a mainframe connection called a gateway to a local area network (LAN) where the PC becomes a terminal for the mainframe. Under this configuration academic institutions can access both PC and mainframe software. By utilizing computer hardware and software products already available on the PC, academic institutions can provide an effective and active Internet learning environment.

## 2. Tools

The software tools needed for the client-server environment can be readily found within the operating system of the PC and the common software products that academic institutions provide for their introductory classes to the PC environment. Software like Web browsers, text editors, and database management software are common components of a PC environment. Since students often use their own computers to work on projects at home or in their dormitory rooms, it is also important that resources be readily available for this use.

The client-server environment requires the operating system to be both a client computer as well as a server computer. This dual role demands software that can be

used to develop the client-side applications and software that can be used to emulate the server-side operations. Figure 1 illustrates this relationship.

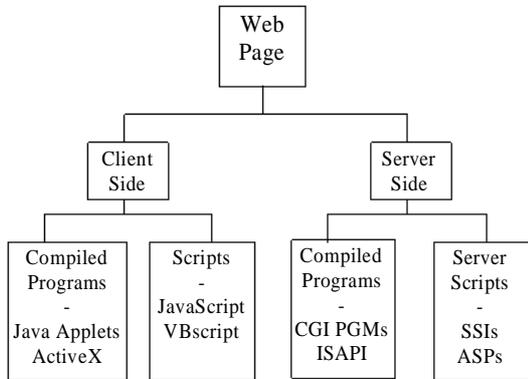

Figure 1. Client-Side and Server-Side Relationship

Web site development requires client-side components like Java applets, ActiveX, and scripting languages (JavaScript or VB Script). The server-side components are compiled programs called CGI (Common Gateway Interface) programs written in languages like Visual Basic, JAVA, PERL, ISAPI, or COBOL; and scripting languages like Active Server Pages (ASP) and Server-Side Includes (SSIs). Choosing components is a matter of surveying the market to find the most popular components or testing the components in typical Web applications to determine which performs the most effectively. Using the most common tools is a reasonable approach to this decision; Java Applets, JavaScript, and Active Server Pages are some common Internet components.

Windows 98 provides a web server manager software called “Personal Web Server” that can support server-side applications. Either Netscape or Internet Explorer can support client-side applications. The database management software called ACCESS is a common database management tool that can be used to illustrate database applications on the Internet. ACCESS is a relational database that can be accessed and updated using the Structured Query Language (SQL). Microsoft’s SQL Server is a more industrial strength database management system that can be upsized from within ACCESS. Both relational databases and SQL are the most common database components on the Internet today. Students can also acquire ACCESS at a considerable discount for their home use.

## 2.1 Setup

Personal Web Server (PWS) can be used to develop server-side applications very easily. Unfortunately, it can only handle 10 Web connections from client computers. Each connection forms a communication socket between the

server and the client computer. Yet, for a development environment, it gives us the type of control and performance that can be expected from a more enterprise-driven server like Microsoft’s Internet Information Server (IIS) or the Apache Web Server. Once the Web site is developed using PWS, a developer simply moves the Web pages, images, databases, and other components to a production server like IIS or Apache that can be accessed by anyone on the Internet.

PWS allows the developer to establish root directories and virtual directories needed to house a Web site. Figure 2 illustrates the main window that points to the root directory “C:\DAVE.” The root directory is the actual starting position on the Web server for the Web site. It can be changed to any directory on the server using the PWS manager’s “Advance Menu.” The advance menu can also be used to establish virtual directories that can hold executable files, databases, and other components that are often linked to Web pages.

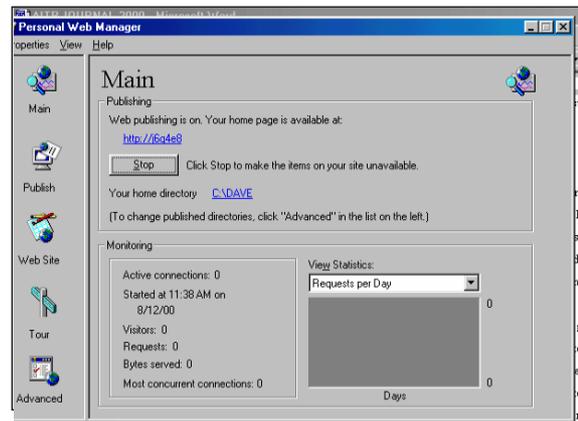

Figure 2. Personal Web Server – Manager

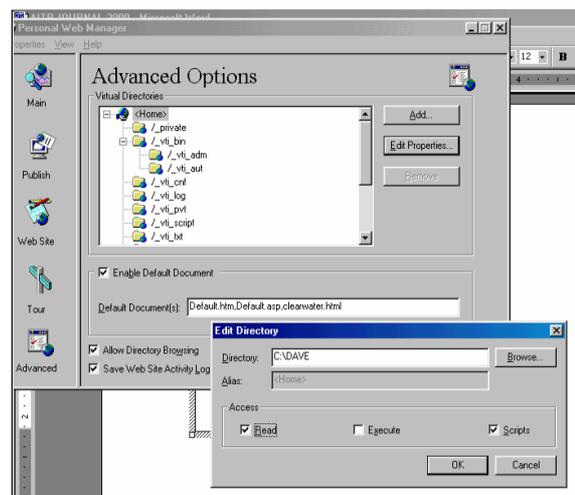

Figure 3. PWS Advanced Options

Figure 3 demonstrates the use of the advance menu to add (“ADD”) virtual directories or change (“EDIT”) the root directory. The PWS manager default document can point to the index page or the main page within the root directory; these are the pages first seen by the user when they type the URL address within their browsers. Using the Snap-In tool within IIS, the user can also designate root directories, virtual directories, and document settings.

The PWS manager allows the developer to control access to directories connected to the Web site in terms of “READ,” “EXECUTE,” or “SCRIPT.” The “READ” option permits the user to download Web pages, images, or any other components on the Web pages that reside in the current directory. The “EXECUTE” option permits the user to execute any CGI programs within this directory. Finally, the “SCRIPT” option allows the user to execute server-side scripts within this directory. These privileges are important because they allow the Web developer to control the directories where Web pages, images, databases, and programs are stored. This setup establishes an environment that can be used to train IS professionals.

### 3. Database Design

Database design is essential for developing any Web site that requires tables of information to update and retrieve data. This topic is often presented in earlier courses in an IS curriculum; but could be presented as part of a comprehensive Web site development course. The discussion should focus on relational database design, since over 95% of database access on the Internet is relational databases. Relational design involves the normalization process, which can help IS students understand possible relationships between tables of information. The normalization process is beyond the scope of this paper and should be reviewed if necessary, but it will produce easily maintainable and accessible data tables. The relationship diagram is an important tool generated by this process; Figure 4 provides an example of a relationship diagram.

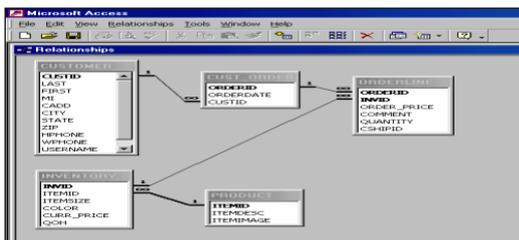

Figure 4. Relationship Diagram

Once the relationship diagram is generated, ACCESS or Oracle (ACCESS is more readily available on student’s computers) can be used to design each table: to identify the

data fields, the characteristics of each field (text, number, size, validation rules, etc.), primary keys, and foreign keys. ACCESS is a personal database which can be used in a development environment to gain the knowledge and experience of relational databases. Yet, Oracle would be a more appropriate relational database for the client-server environment of the Internet. SQL commands will work with either database allowing ACCESS to be a viable alternative to Oracle in the development process.

The next step is to load the tables with sample information. To expedite the loading process, the instructor can provide the data for copying into the tables.

### 3.1 Structured Query Language (SQL)

The database will reside on the server-side computer. The Web pages that will access the database and process the resulting information will also be stored on the server-side computer. When a user requests a Web page that has some server-side processing, the server-side scripts or CGI program is executed before the page is sent to the client’s computer. Structured Query Language (SQL) is used within the server-side scripts or CGI program to access the database. Specifically, embedded SQL commands access and update the tables within the database. Internet developers should have a good working knowledge of SQL statements.

By using the Query option within ACCESS, the IS developer can easily generate from the most basic to the most complex SQL statements. Figure 6 is an example of a standard JOIN statement between the “Customer” and the “Cust\_Order” tables. The resulting table is a combination of information from two tables for customer number 5.

```
SELECT FIRST, MI, LAST, CADD, CITY, ZIP, HPHONE,
ORDERID, ORDERDATE
FROM CUSTOMER, CUST_ORDER
WHERE
CUSTOMER.CUSTID = CUST_ORDER.CUSTID
AND
CUSTOMER.CUSTID =5;
```

FIRST	MI	LAST	CADD	CITY	ZIP	HPHONE	ORDERID	ORDERDATE
Sally	T	Flag	891Willis	Normal	61790	(309) 555-2331	5	11/1/00
Sally	T	Flag	891Willis	Normal	61790	(309) 555-2331	6	11/1/00

Figure 6. Join SQL Statement

The “JOIN” statement reflects the power of relational databases. SQL can take information from more than one table from one query. The relationship diagram helps the developer trace the connections between tables using the “WHERE” portion of the SQL statement.

Notice the connection between the customer table and customer order table is customer ID. The “WHERE” portion of the SQL statement can shape this relationship with an “equal to “ condition (CUSTOMER.CUSTID=UST\_ORDER.CUSTID). ACCESS thus provides a mechanism to build a solid insight into relational design and database processing.

#### 4. Web Site Development

Generating a sound Web Site Plan will prevent confusion and add continuity to the development process. The focus of the Web Site Plan should reflect the logical information flow between the client and the server computers. The logical flow should be developed into a Web Site Flowchart. Figure 7 provides an example of a Web Site Flowchart.

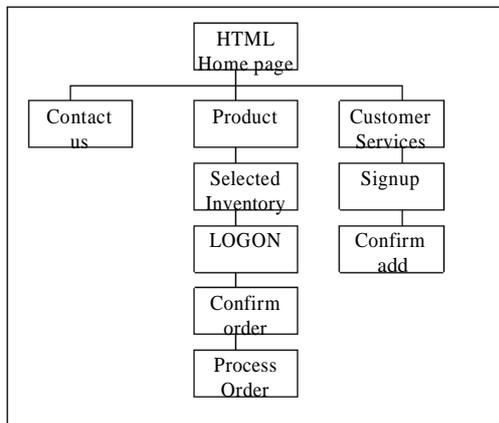

Figure 7. Web Site Flowchart

Once the Web Site Flowchart is developed, the developer can start to visualize the information needed for each page on the diagram. This information might be needed to access databases, to pass to subsequent pages, to be placed in cookie files, or simply to add aesthetic value to the web page. For example, the “Selected Inventory” page in Figure 8 requires the image of the selected product along with its sizes, colors, and availability. This information is taken from two tables: (1) product and (2) inventory. The user provides the quantity and the selection of an item. According to the Web Site Plan, the “Selected Inventory” page will pass inventory item and quantity to the “LOGON” page so that the information can be passed along to the “Order Confirmation” page. The latter page will calculate shipping, taxes, and totals. Figure 8 shows the portion of the Web Site Plan involving this process. The complete Web Site Plan will entail the complete development process.

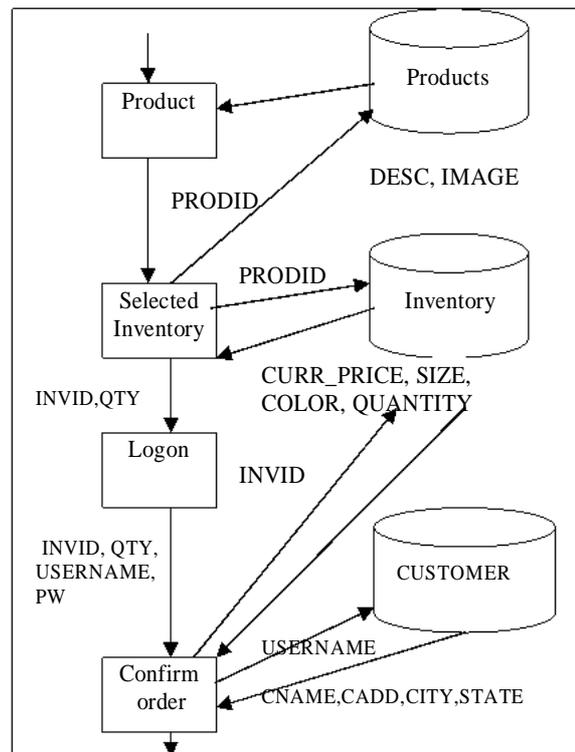

Figure 8. Partial Web Site Plan

#### 4.1 Coding

The Web Site Plan provides the more detail information needed to process data and display this information on a Web page. Yet, the Web pages will also include the images, logos, background colors, style sheets, animation, and other design components that will bring the Web pages to life for the user. A layout sheet is a good tool for displaying how colors, images, animation, frames, tables, and scripts should interact and coordinate with each other to present a logical, consistent, well-constructed Web page.

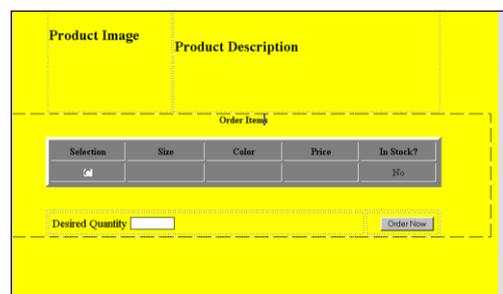

Figure 9. Web Page Layout Sheet

Figure 9 illustrates an abbreviated sample of a layout sheet with its various components. By subdividing the various components of the Web page into the heading that is read first by a browser and the body where the action takes place or originates, the developer can place server-side scripts in strategic locations where the results can be displayed on the Web page. For example, product's image and description from the product table must be retrieved before the individual sizes and colors from the inventory table. Both tools serve to formulate the Web page and guide the coding process.

## 4.2 Active Server Pages (ASP)

The title bar on the Web page will carry the description of the product. The developer can access the product table and retrieve this description using Active Server Scripts (ASP) that relies on an Open Database Connectivity (ODBC). ASP uses a server object that can be opened and executed using embedded SQL statements.

```

Setup Server Object:
<% Set ConDW = Server.CreateObject("ADODB.Connection")%>
Open Server Object:
<% Dim DBPath, DrvType %>
<% DBPath = Server.MapPath("customer.mdb") %>
<% DrvType = "Driver={Microsoft Access Driver (*.mdb)};" &
    "DBQ=" & DBPath %>
<% Set connCW = Server.CreateObject("ADODB.Connection") %>
<% connCW.Open DrvType %>
Execute Server Object with query string:
<% queryString = "SELECT proddesc, prodimage " & _
    "FROM product " & _
    "WHERE prodid = " & intProdID %>
<% Set rsProduct = conDW.Execute(queryString) %>

```

Figure 10. Server Object Sequence

```

<!-- create a query string to retrieve item and image -->
<% queryString = "SELECT * " & _
    "FROM inventory " & _
    "WHERE prodid = " & intProdID %>
<% Set rsItem = conDW.Execute(queryString) %>
<% intloopCount = 0 %>
<% Do While Not rsItem.EOF %>
<!-- set first button checked -->
<TR><TD ALIGN=CENTER width="112"><INPUT
TYPE=RADIO
    NAME=invid VALUE=<% =rsItem("INVID")
%>></TD>
<TD ALIGN=CENTER width="117"><% =rsItem("ITEMSIZE")
%></TD>
<TD ALIGN=CENTER width="114"><% =rsItem("COLOR")
%></TD>
<TD ALIGN=CENTER width="113"><% =rsItem("CURR PRICE")

```

Figure 11. Displaying Retrieved Items

Figure 10 illustrates the sequence of commands that retrieves records from a table within a database. Notice that the embedded SQL statements are placed in a string variable called "queryString" and that ASP scripts are surrounded by the "<%>" and "<%>" delimiters. The Server

Object executes this query string. This pattern can be replicated for each Web page that accesses a database using ASP scripts.

Figure 11 demonstrates a SQL execution where the result is a table of records. These records are placed in a record set called rsProduct. The developer can display these records with ASP scripts (<% =rsProduct(PRODDESC) %>) using a looping process. Figure 11 demonstrates the looping process that can be coded to display records coming from the record set.

Passing information between Web pages is essential when subsequent Web pages require the information or simply needs to pass it to the next Web page. As indicated by the Web Site Plan, some Web pages will have to use or pass information from a previous Web page. Figure 12 shows how product ID (prodid) is sent to the Order Page using the URL method. The Order Web Page receives the variable using the "Request.QueryString" method. Once the product ID is received, the embedded SQL statement (queryString) can use it to retrieve a record from the product table (See Figure 12). Notice that the name of Web pages with ASP scripts has the ".asp" extension.

```

Send Product Page:
<A href="order.asp?prodid=<% =rsProd("PRODID") %>"
  <% =rsProd("PRODDESC") %></A></td>
Receive Order Page
<% intProdID = Request.QueryString("prodid") %>

```

Figure 12. Passing URL Variables

Often variables must be sent to another Web page using the "Form" method. The sending page will have a form with variables. This form can be passed to another Web page along with its variables. The receiving page will use the "Request.Form" method to receive the variables.

```

Form Data Passed:
<FORM NAME=FrmlLogin METHOD="POST"
ACTION="ordersconfirm.asp">
<INPUT TYPE=HIDDEN NAME=invid
    VALUE=<% =Request.QueryString("invid") %>>
<INPUT TYPE=HIDDEN NAME=quantity
    VALUE=<% =Request.QueryString("quantity") %>>
<TABLE WIDTH=60%>
<TR><TD WIDTH=50% ALIGN=RIGHT>User ID:</TD>
<TD WIDTH=50% ALIGN=LEFT><INPUT TYPE=TEXT
    SIZE=15 NAME=username></TD></TR>
<TR><TD ALIGN=RIGHT>Password:&nbsp;</TD>
<TD ALIGN=LEFT><INPUT TYPE=PASSWORD SIZE=15
    NAME=password></TD></TR>
Form Data Received:
<% passInvid = Request.Form("invid") %>
<% passQuantity = Request.Form("quantity") %>
<% passUsername = Request.Form("username") %>
<% passPassword = Request.Form("password") %>

```

Figure 13. Form Data Pass

Figure 13 shows how form data between the Logon Web page and the Confirm Order Web page is sent and received. The Web Site Plan along with the Layout Sheets should show the variables included with forms and the variables to be passed as URL data. Figure 13 shows that the Logon Web page receives inventory ID (invid) and quantity from the Order Web page. The sending page places these values as hidden variables within the form called "frmlogin." This form also receives the username and password from the user. The Logon Web page will pass to the Confirm Order Web page four form variables as indicated by the Web Site Plan.

### 4.3 Testing/Debugging

Testing and debugging generally occurs at four levels: (1) the code level, (2) the page level, (3) the unit level, and (4) the system level. The code level focuses on segments of code that accomplish a specific task like accessing specific records from a database, displaying images, or linking to other pages. At this level display statements can be used to evaluate the status of variables at a specific point in the execution of the Web page or to identify the extent of execution of the Web page. Figure 14 identifies some typical display statements for a Web page with ASP script variables and some alert statements for JavaScript variables. The display statements will help the developer track the execution of the program and the value of the variables during execution. This technique is very beneficial when debugging a Web page.

```

ASP Display Method:
Quantity = <% =passquantity %>
Password = <% =passpassword %>
Javascrpting ALERT method:
<SCRIPT LANGUAGE="JavaScript">
function checkit(frmOrderItems)
{ alert("within checkit")
var strUserName, strInvid, strQuantity,
strURLParams
alert("before loop")

```

Figure 14. Testing/Debugging Statements

The page level testing looks at how all of the components on the Web page work together to achieve an overall purpose. Figure 15 illustrates a simple Test Plan that can determine the accuracy and success of all the actions involved on one Web page. Notice that the expected and actual results generate remarks that help the developer solve any differences between them.

Unit level testing involves identifying a complete process to accomplish a given task. Customer ordering involves more than just one Web page, but the ordering process is one unit or transaction. The Test Plan should identify all possible logical outcomes associated with the ordering process. Each of these outcomes should be tested

in order to verify that the Web site handles these situations correctly. Any discrepancies should be noted in the remark column and addressed with the appropriate actions. Other possible transactions or units can include customer signup, customer services, and customer feedback. Of course, the number of units depends on the size of the organization and the Internet services that it provides.

Item	Expected Result	Actual Result	Remarks
1. Initial load	Home Page	Home Page	
2. Image Load	5 Images	4 of 5	Logo failed
3. Receive Pass	Selected	Selected	
ProdID product			
4. Link to Program	Pgm Page	Pgm Page	
5. Retrieved Product			
Data	Description	No Values	SQL failed
6. Date Retrieved	Current Date	Current Date	
7. Calculate total	Total Sales	Wrong Total	Calc. not correct
8. Text Spelling	Correct Sp	Correct Sp	

Figure 15. Test Plan

Finally, testing and debugging at the system level focuses on navigating amongst all the various units on the Web site including ordering, customer services, and administration. A Test Plan at this level will list all the possible units on the Web site, which are often listed on the index or main page as links to other Web pages. The expected and actual results consist of the appearance of the correct Web page for each hyperlink to include both forward and backward links. Any differences between expected and actual results should be noted and placed as an appropriate remark on the Test Plan. These remarks help the developer rectify any user navigation problems.

### 4.4 Documentation

The final stage in the development process is documentation. Documentation is used to provide a basis for review and to update the Web site. Web sites are dynamic because they change with technology and market conditions. The organizations must be able to this challenge of a rapidly changing environment. Establishing a documentation standard for the organization will provide continuity and consistency in the development process. The documentation becomes the "road map" during the analysis process that will expedite future enhancements and improvements of the Web site. Figure 16 shows an abbreviated set of documentation for a Web Site. The

documentation can include test plans to verify the Web site's performance.

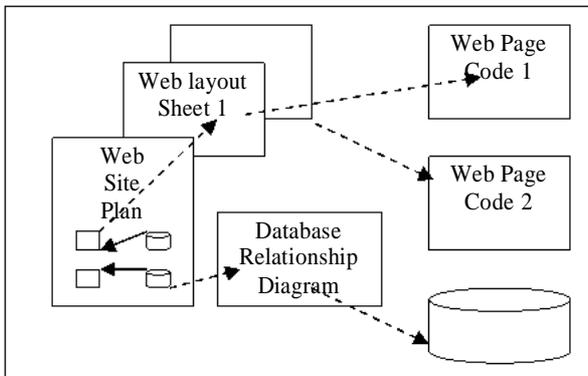

Figure 16. Web Site Documentation

Internet will dramatically increase over the next few years, and with this escalating demand for Internet-based commerce, organizations are expecting to recruit IS personnel who can develop applications on the Internet. With limited resources, academic institutions have been revamping their curriculum to accommodate the growth of the Internet as well as to maintain the more traditional IS core curriculum. By utilizing readily available computer hardware and software, academic institutions can provide an effective and active Internet learning environment.

## Abstract

Numerous business-to-consumer (B2C) Internet enterprises have failed over the past few years. Many reasons have been proposed for the failures of these e-businesses. This empirical study examines one possible reason for lack of success of B2C, the extent to which this online shopping opportunity actually alters the traditional purchasing behavior of the retail consumer. Based on accepted marketing theory, the findings indicate more retail shoppers use the Internet for information gathering than for actual purchasing. Clearly, Internet buyers have choices in their purchasing decisions.

## 1. Introduction

In the past few years, numerous business-to-customer (B2C) e-commerce startups have been unsuccessful. The reasons for this lack of success have been debated extensively. In the popular press much attention has been directed at many proposed contributing factors to e-business (B2C) failures. These factors include, but are not limited to: evaporation of the market for initial public offerings, the failure of consumers to adopt online buying practices, ill conceived business plans, flawed pricing structures, the ability of consumers to better detect price discrepancies, limited or no customer service, security and trust issues, the cost of attracting customers, and general lack of old-fashioned merchandising [1] [2] [3] [5] [9] [10] [12]. Clearly, much of the problem with these failures was the hype associated with the Web. Many entrepreneurs thought that setting-up a Web Site would attract customers by the thousands to buy their products or services. The reality is that there is no substitute for sound management and marketing practices.

Companies such as Amazon.com and eBay have held on during the e-commerce shakeout. Amazon and eBay (an online book seller and a person-to-person online auction, respectively) had the advantage of being first movers, but both have continually changed their sites to offer their customers what they want. For example, Amazon.com has used software to hone in on customer buying patterns. eBay uses a rating system for to buyers to rate sellers on quality of merchandise, speed of delivery, and other factors [12].

E-business entrepreneurs knew that the Internet would benefit consumers by allowing them to easily compare prices among competing retailers to find the

lowest price for purchase. However, making effective use of online competitive price information, and actually purchasing online has been more difficult for consumers than online retailers originally thought [5]. While this online price comparison opportunity is available to Internet users and may be helpful, the question that remains is to what extent this online shopping opportunity actually alters the traditional purchasing behavior of the Internet consumer.

As noted above, the popular press has repeatedly reported on the recent e-business failures. However, these reports do not have a theoretical foundation, and are not based on a scientific study. This research project explores the actual purchasing practices of Internet users. In this study, based on marketing theory, we analyze the online shopping practices of Internet users to discern how they utilize the Internet in their actual purchasing process. Based on these results, we offer some possible explanations of their buying behavior as well as suggestions for future research.

## 2. Background

Over the years, marketing research has developed a theoretical model for describing consumer decision making in the purchasing decision process. It consists of five major phases as follows: (1) need identification, (2) information search, (3) alternatives evaluation, (4) purchase and delivery, and (5) after-purchase evaluation [8]. This model offers a generic overview of the consumer's decision making process, and is not always followed by a consumer, nor is it a linear process for the consumer.

Recently, this consumer decision model was extended to web purchasing, in the form of a framework called Consumer Decision Support System [11]. While this framework addresses all five of the decision making phases, our research focuses on the use of the Internet in the second phase, the information search, and the fourth phase, purchase and delivery.

The second stage, information search, can occur internally by recalling information stored in memory, or it can occur externally. The external information search for an Internet user can be greatly enhanced by the Web, which is fast, readily accessible, and essentially free. Internet databases and product search engines can be very beneficial at this stage.

The Web consumer's search will generate a set of preferred alternatives, which will be compared and

evaluated to derive the fourth stage, the ultimate purchase decision. However, the alternatives include many buying options, only one of which is purchasing online. Since each phase of the decision making model is independent, the Internet user may purchase the product either online or offline, even after using the Web to gather information on product(s). In fact, the purchase decision may actually favor a traditional retailer, since utilizing an online retailer often involves uncertainty as to credit card privacy, timely arrival of the product, satisfactory return policy, and even accurate vendor pricing. This study collects data on how online shoppers use the Web in the second stage, information search, and whether or not they have actually purchased goods or services on the Web, the fourth stage.

### 3. Overview of the Study

The purpose of this study is to determine the buying practices of Internet users. This study is an extension of a past study done in 2000 using students as subjects [6]. At the suggestion of reviewers and discussants, we extended the study to include a cross section of shoppers.

In this study, a sample of 137 consumers from an American shopping mall was chosen from a typical American city. Shoppers were chosen at random at times and on days viewed by the mall marketing manager as appropriate for conducting the survey. Shoppers were asked to fill-out a questionnaire (Table 1) and assured anonymity in filling out the survey. The questionnaire was validated with a test group before giving the instrument to the one-hundred and thirty-seven consumers used in the survey.

**Table 1: Questions and Responses**

Question	Responses
1. Please indicate your sex.	A. Male B. Female
2. Please indicate your age.	A. 18-26, B. 27-31, C. 32-36, D. 37-40, E. Over 40
3. Please indicate your marital status.	A. Unmarried, B. Married
4. Indicate the number of hours per week you are currently employed.	A. None B. 1 to 15 C. 16 to 25 D. 26 to 40 E. Full time
5. Highest level of education attained.	A. Some high school B. High school graduate C. Some college D. College graduate E. Graduate work
6. Total approximate amount of family's annual income.	A. \$10,000 or less B. \$10,000 to \$25,000 C. \$25,000 to \$40,000 D. \$40,000 to \$50,000 E. More than \$50,000
7. Use of the Internet for personal communication	A. Frequently B. Occasionally

purposes.	C. Seldom D. Never
8. Use of Internet for business purposes.	A. Frequently B. Occasionally C. Seldom D. Never
9. Use of Internet for pricing purposes.	A. Frequently B. Occasionally C. Seldom D. Never
10. Use of the Internet for purchasing purposes.	A. Frequently B. Occasionally C. Seldom D. Never

The first three questions are used to collect demographic data on the users in this study. This will allow us to compare the demographics of our sample with the demographics of previous studies on Internet users. The next three questions (4, 5, & 6) are used to determine buying potential through employment status, education level, and income. The next two questions (7 & 8) are used to determine personal and business use of the Internet by shoppers. The next question (9) is used to determine how the shopper uses the Internet in determining information about products or services, the second phase of the consumer decision model. The last question (10) serves to determine whether users purchased a product or service over the Internet, the fourth stage of the consumer decision model.

### 4. Findings

The demographics of our sample are distributed as follows. In our sample, approximately 39% were male and 61% were female, approximately 36% were between 18 and 26 years old, 33% between 27 and 40, and the users over 40 years old accounted for about 31%. Approximately 52% were married, 45% were not married.

With the exception of gender, the demographics of this study fit very well with those of the typical Internet consumer as reported by the latest Gvu Center Survey at Georgia Institute of Technology [4] in 1998. The Gvu Survey indicates that most users are between the ages of 16 and 40 (approximately 60%). Most of the users in this study are between the ages of 18 and 40 approximately 70%. In the Gvu Survey 64% were male and 36% female. In this study, there are approximately 61% women and 39% men participating. Our population consisted of a cross section of American shoppers (72%) had some college and as indicated by the 1998 Gvu Survey almost 90% of Internet users had at least some college. In the Gvu study, approximately half of the respondents were married and half were not. In this study, 55% were married and 45% were not.

Time spent on the Internet by users for personal and business use varied. Approximately 86% of the shoppers in the study used the Internet for personal use. For personal use purposes, approximately 54% use the Internet frequently, 20% use the Internet occasionally, 12% seldom use the Internet, and 14% never use the Internet for personal use.

Approximately, 66% use the Internet for business purposes. Frequent use for business purposes is 27%, occasional use is 20%, seldom use is 19%, and 34% did not use the Internet for business purposes.

We analyzed aspects of the consumer decision model. The results of this study indicate Internet consumer application of Phases 2 and 4 of the five-phase consumer decision model [8]: 1. Need identification, 2. Information search, 3. Alternatives evaluation 4. Purchase and delivery, 5. After-purchase evaluation.

Over 71% of the users in this study use the Internet to gather information (Phase 2) on products or services for pricing, but only 57% actually make the purchase (Phase 4) on the Internet. As stated earlier, the use of the Internet offers an online price and product/service comparison opportunity, but this online shopping opportunity only partially alters the purchasing behavior of the Internet consumer as seen by the 14% who do not purchase (Phase 4) on the Internet.

#### 4. Discussion

This study confirms that Internet users have choices in their purchase decision. It demonstrates that many of them use the Web to access information in order to compare products and services. However, it appears that fewer of these same Internet users have broken away from their traditional purchasing habits to actually use the Web to buy products and services. While most of these Internet users find the Web helpful in the information search phase of the purchase decision, fewer apparently are comfortable enough on the Web to actually consummate their purchase online.

The findings of our study are consistent with the e-commerce concepts proposed recently by noted IT author Peter Keen (2001) [7]. He states that the central problem that the Internet poses for shopping online requires that we trust people and organizations in which we have no experience. We are interacting with organizations, which we have never seen, whose identity we may not be able to validate. And all of this is occurring in situations where misunderstandings occur frequently and are difficult to correct. Modern, online trust involves trust relationships with entities we have never met face-to-face, where the proverbial handshake is absent.

So, how does an e-commerce firm overcome this trust obstacle? In order for the Internet to become a viable and profitable media, online companies must heed Keen's advice and build trust in their relationship with the customer. One possible alternative is to look to a successful e-commerce firm like Amazon.com, which was mentioned above. Amazon.com ensures that every customer interaction is a two-way dialog, that customer questions are fully answered, that customer problems are immediately handled, and that the customer is kept informed of their order status. Over time that attention to the customer's concerns builds a trust relationship that has translated to an 80% repeat business rate for Amazon.com [7]. E-commerce firms must offer more than products that customers want. They must also build

customer trust with policies that ensure convenience, credit, security and easy returns. E-commerce firms must take the fear out of the purchasing transaction process for their customers.

#### 5. Conclusions and Suggestions for Future Research

This study extends previous exploratory research examining consumer buying practices on the Internet. The previous study [6] involved the Internet buying behavior of American University students. The current study extends this research to American retail shoppers chosen at random in a retail shopping mall.

The findings of the current study indicate that while 71% of the respondents use the Internet for information search in the purchasing decision process, whereas only 57% of those surveyed, have actually purchased products or services over the Internet. The findings are consistent with the previous study using students as subjects. Customers do have choices in the purchasing process and will buy goods and services using the approach that satisfies their need for trust at the time of purchase.

One advantage of this study over the previous study was that a better cross section of shoppers was surveyed, as opposed to the last study where only student subjects were used. The study could be extended to include questions on ethnicity of shoppers and types of products and services purchased. A more global perspective on purchasing could be achieved using an international sample.

# A Quality of Service Framework for Internet Share Trading

Hong Xu, Jairo Gutierrez and Qiang Lu  
Department of Management Science and Information Systems  
The University of Auckland  
Auckland, New Zealand  
lucyxu\_6963@yahoo.com

## Abstract

The recent Quality of Service (QoS) architecture proposed by the Internet Engineering Task Force (IETF) enables a set of new network services providing possible solutions to improve the quality of the Internet-based services. The interest of this research is to find a customizable QoS network solution for the Internet based share trading business by deploying these QoS architectures in order to address the quality issues in the Internet Share Trading Business. The construction of the QoS theoretical framework begins with the identification of the Internet service capabilities required by the Internet share trading business through a case study. The appropriate QoS architectural design is selected through matching the existing QoS architectures with the identified service capabilities. The QoS technological strategies and QoS capabilities are thus derived from the selected QoS architectural design. Additionally, the effectiveness of the proposed QoS architectural design is evaluated against the current implementation by using computer simulation.

## 1. Introduction

With the increase in Internet service availability that occurred during the 1990s, the Internet has become more frequently integrated into business practices. It has lowered worldwide communications costs for individuals and businesses and opened up unprecedented opportunities and challenges for conducting business. This integration has also brought new threats to businesses relying on the Internet due to such issues as the varying quality of Internet service. Internet share trading business is a typical example of an online business affected by this issue.

The Internet related quality issues raised by the Internet share trading business have been regularly reported in the news, and discussed in academic research. Problem identified to date have included slow response times [20] [22], service unavailability during busy periods [7] [11], reliability problems [11] [21], and in the worst case, service being completely brought down by security attacks [4] [15]. These problems have also occurred to big industry players such as E\*trade and Charles Schwab. Hence enhancing the quality of the

Internet service available to business users is a critical issue in the industry.

The recent Quality of Service (QoS) architecture proposed by the Internet Engineering Task Force (IETF) enables a set of new Internet network services providing possible solutions to improve the quality of the Internet based services. However, the existing principle for the development of QoS solutions takes a technological focus without addressing the quality of service requirements of the business.

The interest of this paper is to find a customizable QoS network solution for the Internet based share trading business. The following research questions are specifically addressed in this paper.

- How does current IP network provide service support for Internet share trading businesses?
- Why does the current IP network fail to provide quality of service support for Internet share trading?
- How can Internet share trading business apply IP QoS techniques to solve the service quality issues in Internet share trading?

The structure of this paper is: first, a literature study is conducted to review the relevant research issues including quality of the Internet share trading business and IETF QoS architectures; Secondly, the research methodology is presented and the research framework is introduced; Thirdly, a case study is outlined to identify and specify the service capabilities required by the Internet share trading business; Fourthly the proposed QoS theoretical framework including technological strategies (or, QoS capabilities) and architectural design is discussed; Lastly, a performance evaluation for the proposed QoS solution by using computer simulation is reviewed.

## 2. Literature Study

### 2.1 Quality of the Internet Share Trading Business

In the Internet share trading business model, the Internet has been an integral part of the business. Quality of the Internet service has been emerged as a critical factor for evaluating the overall business performance.

The Internet has enabled service channels for the business which allow online investors located at one end of the channel to access the share trading services provided by the brokerages located at the other end. This new service channel enhances the interaction between brokerages firm and online investors, totally eliminating the person-to-person contact required by traditional share trading. Hence the quality of the Internet service required by the business is characterized as end-to-end service assurance.

Currently many surveys and case studies have evaluated quality of Internet share trading business, identifying Internet-related factors of timeliness, reliability, availability and security as important for online investors to monitor. These four factors can be used to described business-required end-to-end service assurance (Figure 1).

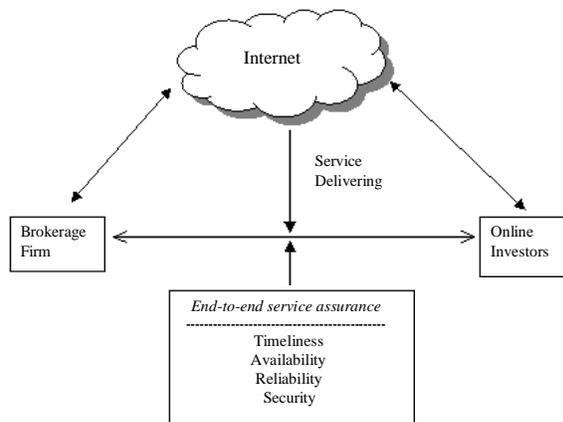

Figure 1. Quality of the Internet Share Trading Business

### 2.1.1 Timeliness

Timeliness is a critical attribute affecting the service quality of the Internet share trading business [14] [19]. Timeliness is also referred to as responsiveness of the services [8].

Due to the fact that share prices are subject to change, online investing services need to be delivered in a real-time manner. Even a second's delay in share transactions, may cause real money loss for the investors. Online investors expect fast responses from the system so that their share trading transactions can be processed rapidly. Currently there is no industry regulation requiring a transaction to be executed within a set period of time [19], although increasing timeliness in the service does help firms attract more businesses.

### 2.1.2 Reliability

Reliability, one of the fundamental requirements urged by business refers to consistency of performance [8] [23] Internet share trading business requires consistent levels of Internet service support. For example, in the US, the

Securities and Exchange Commission (SEC) understands an absolute guarantee of service is difficult to implement in the Internet share trading, but it may require online brokerage firms to conform to certain statistical standards of service proactively.

Another sense of reliability refers to the accuracy of the service [17]. Internet share trading businesses should have the ability to detect and rectify any faults in order to ensure reliability of the service.

### 2.1.3 Availability

Availability is another important factor in the Internet share trading business [14] [25]. Online service must be accessible at all times to businesses, especially during the peak trading hours.

NASF Regulations remind brokerage firms of their obligations under SEC staff legal bulletin No. 8 to ensure that they have adequate capability to handle high volume or high volatility trading days [14].

### 2.1.4 Security

Security is one of the greatest concerns for Internet share trading business as the entire operations are monetary and information-based transactions [12] [4] suggests that a robust security solution for transaction processing should satisfy certain security requirements including confidentiality, authentication, data integrity and availability, all of which need to be met by the Internet services as well as the whole business.

Recent news reports continually disclose these quality issues as well as the many complaints raised regarding these issues. The complaints include slow performance [20] [22], system unavailability [11], reliability problems [11] [21], and security attacks bringing down the system [15]. These indicate that the current Internet quality does not provide the satisfactory level of service support for the business in term of these attributes such as timeliness, availability, reliability and security.

## 2.2 IETF QoS Architectures

Technically, the Internet Protocol (IP) plays a key role in facilitating Internet connections. The Internet is so called the network of IP networks. The current IP network applies end-to-end design principles [18]. It can only support one class of service: *best effort*. Hence the main drawback of the IP network is that it makes no guarantee about when data will arrive, how much can and cannot be delivered, and how reliably delivery will be. And it has no security feature as well.

Recent QoS architectures proposed by the Internet Engineering Task Force (IETF) such as Integrated Services (IntServ), Differentiated Services (DiffServ) and Multiprotocol Switching (MPLS) have opened up the new possibility to build new capacities of the network service which can improve the service quality of the

Internet network service. In the following sections service features of three QoS architectures are introduced.

### 2.2.1 IntServ

The key service feature of IntServ is to pre-reserve the required network resource in terms of user's requirements. In this way, IntServ can provide a certain level of resource assurance to meet the user's QoS requirements such as strict delays required by real time applications.

In comparison with the current IP network service, IntServ has enforced the following QoS features so as to enhance the service quality of the existing IP network services

#### □ □ Resource Reservation

Resource reservation is the key QoS feature enforced by IntServ. With this resource reservation technique, IntServ can provide resource assurance for critical applications with absolute delay requirements.

#### □ □ Admission Control

IntServ enforces admission control over the reservation path in order to limit the access by non-critical applications and to guarantee the network resource for critical applications.

#### □ □ End-to-end control

IntServ uses end-to-end signaling protocol such as RSVP to set up the reservation path, so it thus enforces an end-to-end control function and can also dynamically respond to the changing traffic conditions in the network.

### 2.2.2 DiffServ

The DiffServ architecture has provided an alternative resource allocation scheme in order to enforce service differentiation [5]. Network resources are allocated to traffic streams by a service provisioning which mainly includes classifying and policing the traffic upon entry into a DiffServ network and forwarding that traffic within the network. Hence, DiffServ can provide relative service guarantee to meet different user's QoS requirements.

The main QoS feature of DiffServ is that it can enable traffic prioritization which prioritizes the network service for use by different types of businesses and different users. Since this resource prioritization function is mainly implemented at the point of traffic aggregation, it can be referred to as per-hop based resource prioritization [2].

### 2.2.3 MPLS

MPLS was originally developed as an alternative approach to support IP over ATM. It allows IP routing protocols to take direct control over ATM switches

The key technique of MPLS is known as label switching, which uses a short fixed-length label encoded into the packet header and used for packet forwarding. All the labels assigned by end points construct a Label Switched Path (LSP). By using the label switching

forwarding engine, there is no need to perform routing look-ups on each node over the LSP when the data packet passes through. Thus, the MPLS network addresses the scalability issue and can support a large network.

An MPLS network needs a LDP – a signaling protocol to set up LSPs. And the LSP setup needs the routing selection to determine the next hop information. Two routing approaches can be employed for the LSP setup: one is hop-by-hop routing, still used by the current IP network and the other is explicit routing.

CR-LDP, recently developed signaling protocol uses constraint-based routing and can establish an explicit route also referred to as a constraint-based route or CR-LSP. The CR-LDP allows resources to be preempted or reserved for explicit routes based on relevant traffic parameters such as peak data rate (PDR), committed data rate (CDR), peak burst size (PBS) and committed burst size (CBS) [1].

As a consequence MPLS functions that go beyond the routing tasks can fundamentally enhance the current IP network for both features and services. It has enforced the following QoS features:

#### □ □ Performance Optimization

Performance optimization can be achieved by way of traffic engineering [26, p. 10]. Traffic engineering is the process of controlling how traffic flows through a network to optimize resource utilization and network performance [6].

MPLS-based traffic engineering allows traffic to use multiple paths, rather than the single optimal path used by conventional-based networks. MPLS supports traffic engineering through the deployment of constraint based routing. The deployment of constraint-based routing not only provides route but can also meet QoS requirements [13].

#### □ □ MPLS based Tunneling

MPLS can enable tunneling encapsulation by encoding a label outside the IP header. This is one of the ways to set up tunneling. The other way to enable MPLS-based tunneling is that MPLS allows multiple labels to be encoded into a packet to form a label stack. Such nested LSPs can create a multilevel hierarchy where multiple LSPs can be aggregated into one LSP tunnel [9].

#### □ □ End-to-End Path Control

In the MPLS network, LSPs need to be set up by the signaling protocols before data traffic can pass by. Additionally, LSPs setup by using the route pinning option can further enforce a sense of control over the path established. In this sense, MPLS can enforce end-to-end path control that the current IP network lacks.

#### □ □ End-to-end Resource Management

In the MPLS network, CR-LDP can allow resource preemption or reservation for the CR-LSP, this thus enables end-to-end resource management. It allows for

resource sharing among a number of CR-LSPs which compete for the same pool for resources. The weight parameter can be used to determine the CR-LSP relative priority when assigning excess nodal bandwidth or when working under congestion conditions [1].

Table 1 summarizes the QoS features enabled by the three QoS architectures.

Table 1. QoS features enabled by three architectures

QoS Features	IntServ	DiffServ	MPLS
Resource Allocation	Resource Reservation	Per-Hop Resource Prioritization	End-to-end Resource reservation or End-to-end Resource Prioritization
Admission Control	Per-hop admission control at every node	Per-hop admission control at edges	None
End-to-end Control	Reservation Path	None	Explicit Route
Traffic Engineering	None	None	Explicit Route
Security	None	DiffServ based Tunneling	MPLS based Tunneling

### 3. Research Methodology

This study uses a multi-method research methodology (Figure 2.) which was adopted from [16]. It involves three phases of study: a case study in the first phase is used to identify and specify the QoS requirements of the Internet share trading business; a QoS theoretical framework is constructed in the second phase of the study in order to build theory regarding Internet QoS technological exploration in the Internet share trading investing business context; computer simulation in the third phase is used to evaluate the proposed QoS solution built based on the proposed framework.

The role of the case study in this research is to investigate service support features of the Internet service used for the Internet share trading business. The understanding gained can help identify the QoS requirements of the business in order to establish the guidelines for the construction of the QoS theoretical framework. A single case study is chosen in this research. [10] advocate the single case study as it can help in understanding the construct being studied in as much detail as possible within its context.

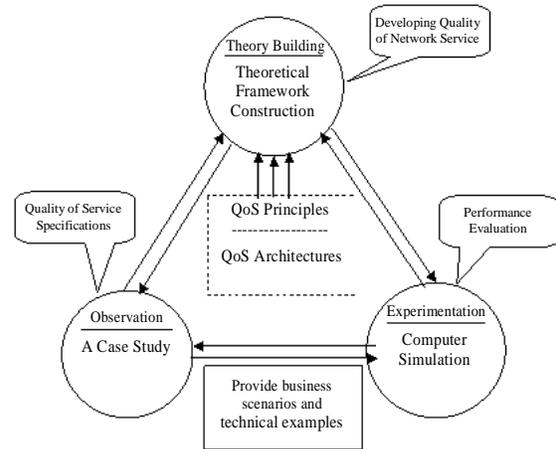

Figure 2. A Multi-method Approach

As a key part of the study, a theoretical framework construction aims to build a QoS theoretical framework, which provides both Internet QoS technology strategies and architectural design. The relevant research findings can enhance the existing Internet QoS theory. As shown in figure 2. The process of framework construction is on top of the existing IETF Internet QoS principles and QoS architectural design. This consists of two stages: building the theoretical proposition and proposing the architectural designs. The theoretical proposition is to provide Internet QoS technological strategies to meet the QoS requirements of the businesses. The architectural design is to propose a QoS architectural design to improve the service quality of the Internet for use by Internet share trading business. This architectural design is also proposed in the theoretical layer, which is a technological framework covering a set of relevant techniques. The integration of QoS strategies and QoS architectural forms a complete QoS solution.

The role of simulation in this study is to evaluate the performance of an IP network using the proposed QoS architectural design. This study uses ns<sup>®</sup> as a simulation tool. It is a tool which can provide an integrated setting to construct a simulation model, execute the simulation, and analyze the results. It can map and translate the principles of QoS architectural design into the simulation model for measurement and testing.

### 4. Case Study

#### 4.1 Case Descriptions

Established in 1975 in Singapore, the ABC group was one of the largest brokerage firms in Singapore. It offered total investment products and services in far eastern Asia including Singapore, Malaysia, Thailand, Hong Kong, Indonesia, and Sri Lanka, to satisfy investors' financial requirements.

ABC launched its electronic share trading system in 1996; it was Singapore's first electronic on-line trading

system to harness the latest technology to complement existing trading capabilities for investors. This online trading system, called ALPHA, was initially an extranet system using remote access technologies, where investors could place share orders by directly dialing into the firm's network. Having been the first mover, ALPHA succeeded in attracting most local clients who were keen to try electronic trading. In 1997, ALPHA was upgraded to support Internet based share trading so that investors could place orders through Internet channels.

ALPHA has been one of the successful cases of online business in Singapore. Through ALPHA, the firm has widened its reach and increased its brokering volume, which in turn has broadened the brand and appeal of its name. However, it has not performed well consistently. ABC received many investors' frustrated calls and many complaints regarding the business operation. The following examples illustrate some of the difficulties:

- □ Investors cannot trade shares at the price they hoped, due to the transmission delay. This is because the share price has already changed before the ALPHA system could process the order and route it to the share market.
- □ Investors cannot get real time up to the minute share prices since live quotes cannot be delivered in a timely manner.
- □ Investors wait too long for confirmation. Sometimes investors might end up buying twice as much stock as they intended.
- □ The order transaction is terminated half way through, due to system or transmission errors.
- □ Investors cannot access their accounts during busy periods.

Senior management at ABC understood that service quality enforcing only at ABC was not able to solve ALPHA problems. The Internet service is the key here, hence managers expect to find a cost-effective Internet solution to improve the quality of ALPHA. Managers brought up many issues regarding the Internet service support from the Internet service provider (ISP).

One thing is certain, quality issues always occur unpredictably. Breakdowns in service quality are mostly linked to market volatility, which is associated with sudden rise in trading volume. This specifically causes many concurrent access requests for the ALPHA system which obviously generates network congestion. This subsequently affects the business performance. Hence, the questions raised here are:

*Could ISPs monitor and control such situations?*

*Can ISPs prevent the occurrence of congestion from the outset?*

In addition, managers have always tried to compare the Internet based ALPHA with the initial extranet based ALPHA. The Internet can reach more customers and

offer a more rapid and flexible way of share trading, so it provides more business opportunities. However, it lacks the privacy and security that the extranet ALPHA possessed. The extranet allows the registered members to access the investing service thus enabling private communication to provide the business with privacy during the transmissions. There are fewer security risks on the Extranet as well. Questions raised here are:

*Can the Internet enforce such private communication?*

*Can the Internet add in more security features?*

Furthermore, the share trading business is a mission-critical business and business data generated are time-sensitive; it needs a guaranteed level of network service to ensure a satisfying level of service quality. However, such a guarantee is difficult to achieve since the Internet is a publicly shared network and ABC has to compete with other businesses for network resources. Managements' concerns here are:

*Can the Internet promise ABC better services for their online investors?*

*Can the Internet prioritize its mission critical data against other types of data?*

## 4.2 Case Analysis

The case study presents specific examples of the Internet share trading business. The above mentioned quality issues show that the current Internet cannot provide a satisfactory level of service quality for the Internet share trading business in terms of quality attributes such as timeliness, availability, reliability and security. Table 2 lists several specific examples regarding these quality issues.

Table 2. Quality Issues for Internet Share Trading

<i>Quality Attributes</i>	<i>Issues</i>
Timeliness	Slow transactions Delay in real time quotes
Availability	Service halt halfway Web site down Account Inaccessible
Reliability	Discrepancy in transactions
Security	Account being misused Account being accessed in an unauthorized way

The case study also indicates that these quality issues always occurring unpredictably. These issues are the potential risks to affect the Internet share trading businesses in attaining the consistent level of business

performance. Moreover, the current Internet seems not to have the relevant service features to improve this situation, which is summarized as follows:

□ □ Lacking monitoring and control

It seems that ISPs cannot provide effective monitoring and control for Internet services in order to prevent the occurrences of the service quality problems in a more proactive way.

□ □ Lacking service prioritization

This case suggests that ISPs can only provide one standardized Internet service for all customers. In this sense, the ISP cannot provide a customer oriented service. However, business data generated from online investing which is a kind of mission-critical data requires a higher service priority than non-mission critical data.

□ □ Lacking performance tuning

Because the volume of the share trading business is very unpredictable due to the volatile nature of the business and traffic demands on the Internet, it is very difficult for the Internet to maintain a stable and predictable level of service quality at all times. Hence, in this turbulent environment, the business requires new performance tuning tools that can quickly detect and correct the performance problems so that a consistent level of service quality required by the business is maintained. Moreover, the connection between the firm and the ISP is a common gateway where much network traffic aggregates and is easily congested by the network traffic during peak hours. The case shows that ISPs did not have such service features which can effectively minimize the possibility of congestion.

□ □ Lacking security

It is agreed that the current Internet lacks adequate security features, particularly for the sensitive financial data generated from the Internet share trading business. Hence it is necessary to enhance the security on the Internet and implement new security mechanisms.

## 5. Framework Construction

### 5.1 Design Considerations – Meet the Service Requirements

The case study above shows that the current IP network lacks certain service features and capabilities to provide a satisfactory level of service quality for the Internet based share trading. Therefore it cannot provide a preferred service for the business, it cannot consistently allocate enough network resource for the business, and it cannot dynamically adapt to the changing traffic conditions.

In this situation, it is necessary for the Internet to build new service capabilities for the Internet share trading businesses. These capabilities are also the specific requirements for building a customized QoS solution by

deploying QoS architectures. In the following sections service capabilities are discussed and QoS architectures are evaluated accordingly.

#### 5.1.1 Service Prioritization

The Internet share trading business is characterized as a mission-critical business. Mission criticality usually refers to a map of urgency and importance [9]. It requires a higher priority of Internet service support than a non-critical business.

The Internet needs techniques which can prioritize the network services to be used by different types of businesses. This is necessary because the Internet is a public-based network and business applications of the Internet share trading need to compete for the same pools of network resources with other types of applications.

Specifically, this network service prioritization can be performed in terms of critical levels of the business or specific QoS requirements. QoS requirements can be specifically described using QoS measurements such as delay, jitter, throughout and loss.

As discussed above, the IP network services are required to prioritize the network services so as to provide better quality of service for the Internet share trading business. By investigating the QoS architectures, both DiffServ and MPLS architectures can enforce resource prioritization by using resource allocation techniques. A DiffServ network can enforce per-hop based traffic prioritization, which focuses on classifying and policing the traffic, whereas the traffic prioritization enabled by an MPLS network service is on an end-to-end basis.

By investigating the requirements of Internet share trading businesses, it was decided that both prioritization ways were useful in this business context. First, since the Internet share trading business is a typical one-to-many online business, the traffic aggregation point such as the first node linking to the brokerage firm may easily be congested by the data traffic. Enforcing per-hop traffic prioritization in this focal point can mitigate the network congestion. Secondly, end-to-end traffic prioritization is also required when Internet share trading business data has to compete for the network resource with other types of data traffic over the same network path.

#### 5.1.2 Proactive Monitoring and Control

The Internet share trading business requires a proactive network solution to attain the network resource assurance rather than to passively adapt to the varying quality of the Internet. This requires new tools to monitor and control the network traffic in response to the varying situations. All three QoS architectures can enable this capability.

An IntServ network can pre-reserve a network path with the required resource for a traffic flow or a application so that the absolute service guarantee over this network path can be achieved. A DiffServ network

can enforce monitoring and control by controlling the amount of traffic of each forwarding class at the edge of the network. An MPLS network provides an explicit routing mechanism that can support constraint based routing. Constraint based routing can exercise monitoring and control by assigning pre-defined constraints such as bandwidth allocation to CR-LSPs being generated.

All the three QoS architectures can monitor and control the service in a proactive manner since they all require the QoS provisioning to specify the service profiles being committed before they enforce the service.

MPLS can enforce end-to-end path control by using explicit routes while DiffServ can enforce per-hop control. Since the Internet share trading business needs both a per-hop and end-to-end solution, both MPLS and DiffServ can be applied in this business context.

### 5.1.3 Active Performance Optimization

The Internet is required to proactively monitor and control the network services. This function specifically needs to regulate and adjust the traffic loads passing over the network channel in terms of the above service prioritization policy. This can effectively minimize the network congestions always occurring in the current Internet. Moreover, it ensures that the business application of the Internet share trading business can receive the amount of network resources required.

More specifically, the Internet needs performance optimization techniques which can effectively optimize the network performance. The specific goals include:

- □ allocate enough network resources for the business
- □ select the network path with the required network resources
- □ select an alternative network path when congestion taking place on the original path selected

The process of optimizing the performance of networks through efficient provisioning and better control of network flows is often referred to as traffic engineering. By searching proper QoS architectures, MPLS is the only QoS architecture which has this service capability. By using constraint-based routing, MPLS can perform traffic engineering to maximize the utilization of resources in the network or to minimize congestion in the network. Specifically, MPLS-based traffic engineering can “route traffic around congested hot spots and optimize resource utilization across the network” [26, p. 156].

### 5.1.4 Private and Secure Channel

The Internet share trading business requires both privacy and security in order to protect sensitive financial data from possible network layer traffic. To achieve this objective, the business requires a public shared IP network that is also capable to provide VPN services.

VPNs must be implemented using the tunneling mechanism. Both QoS architectures DiffServ and MPLS, support tunneling mechanisms to enable VPN over the Internet.

MPLS can manage a large number of tunnels than DiffServ. This is because MPLS can support more traffic differentiations due to a finer level of forwarding granularity; whereas DiffServ only supports a small number of forwarding classes based on per-hop behaviors defined. Hence MPLS is a preferred architecture to implement VPN over the public IP network so as to provide a private and secure channel for the Internet share trading business.

## 5.2 Framework

Figure 3. illustrates the proposed QoS framework which consists of two parts: QoS architectures and QoS capabilities.

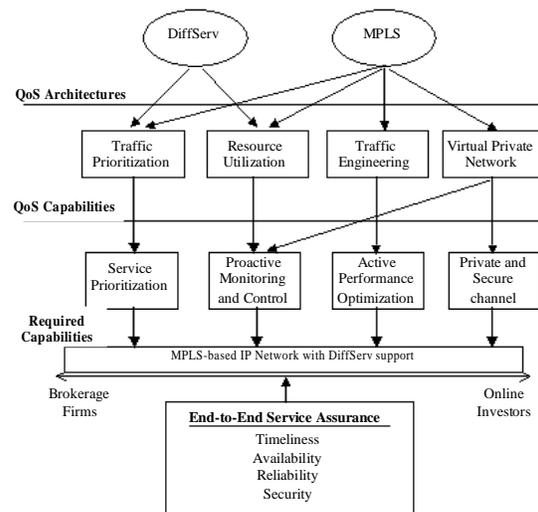

Figure 3. The Applied QoS Framework

### 5.2.1 QoS Architectural Design

MPLS is an important emerging technology for enhancing IP for both features and services. MPLS is a suitable mechanism to provide traffic engineering since MPLS allows sophisticated routing protocol capabilities as well as QoS resource management techniques to be introduced to IP networks. Hence with the advent of DiffServ and MPLS, IP traffic engineering has attracted a lot of attention in recent years.

MPLS-based Traffic engineering can provide the traffic engineering tools that are prerequisite for DiffServ. In the other hand, DiffServ can provide per-hop QoS enforced at the edge of the network so that the amount of traffic flow can be controlled. Therefore, it is likely that the combination of DiffServ/MPLS will play an

important role in the provision of some form of quantitative service guarantees in the Internet. [13]

The proposed MPLS-DiffServ architectural design is similar as the functional architecture proposed in [24]. The idea is that a MPLS-DiffServ service can support fine-grained traffic differentiation and policing in the edges of the network through the notion of IP pipes. Packet forwarding on an aggregate basis is based on the packet service class. In the core of the network, individual pipes are not distinguished and pipe level information is not maintained.

### 5.2.2 QoS Capabilities

The above MPLS-DiffServ architectural design has combined the QoS features of both MPLS and DiffServ. This can enforce the following new QoS capabilities which can provide QoS-enabled IP network services.

#### □ □ Traffic Prioritization

Both MPLS and DiffServ can build this QoS capability. MPLS enforces end-to-end based resource priorities while DiffServ enforces per-hop based resource prioritization. This proposed QoS design can enforce the traffic prioritization on both end-to-end basis and per-hop basis.

#### □ □ Resource Utilization

Both MPLS and Diffserv can enable this QoS capability. MPLS enforces this capability by end-to-end path control while DiffServ enforces this capability by per-hop control. Both architectures want to exercise control for the available network resource. Both can use traffic policing tools to regulate the traffic flow, providing both statistical bandwidth allocation by using through combining the function of traffic engineering as well as providing guaranteed bandwidth allocation [24].

#### □ □ Traffic Engineering

This QoS capability regards MPLS-based traffic engineering. With the support of the powerful MPLS function - explicit route mechanism, MPLS enforces the provision of network resources along the network paths and allows the traffic flow to use multiple path rather than single optimal path. In these ways, it optimizes the over network performance.

#### □ □ Virtual Private Network

This proposed design chose MPLS-based VPNs. CR-LDP can establish CR-LSPs across the network. Each CR-LSPs can be viewed as a tunnel. Importantly, this VPN is QoS enabled which can ensure resource assurance along each tunnel.

## 5.3 Framework Analysis

The construction of the QoS theoretical framework is done through mapping the business-required service capabilities into the QoS design. Therefore the QoS architectural design and QoS capabilities enabled by this

design can meet the quality of service requirements of the Internet share trading business. The following sections discusses how this applied QoS framework can be employed to address the quality issues in the Internet share trading business are discussed.

The quality issues regularly occurring in the share trading business are related to timeliness, reliability, availability and security of the IP network service. In the above-mentioned QoS framework, four capabilities can be enforced by the proposed MPLS-DiffServ architectural design that can solve these quality issues. The details are discussed below.

Traffic prioritization can prioritize the network services to be used by the Internet share trading so as to ensure the sufficient resource allocation required by the business. In addition, it also allows the Internet share trading business to preempt the network path with the required network resource.

Resource utilization can provide the specific tools to proactively monitor and control traffic flows to ensure the business will get the committed network resource over the paths between brokerage firms and online investors.

Traffic engineering enabled by MPLS based explicit route mechanisms can dynamically optimize the performance of the overall network. This ensures effective link utilization so that the business can select the network path with the sufficient network resource or can select the alternative network path when network congestion is taking place on the original path selected.

VPNs can be used to construct the private channels over the public network. These private channels only allow the authorized members of the brokerage firms to be accessed.

All these QoS capabilities can improve speed, reliability and availability of online investing services. In addition, VPNs can enhance the security and can effectively prevent denial-of-service security attacks.

## 6. Performance Evaluation

Based on the above-proposed framework, the proposed IP network solution should deliver service with lower delay, lower jitter, higher throughput and lower loss compared to current IP networks. However, this is the assumption subject to performance tests. Hence a performance study was carried out by using the computer simulation tool *ns* version 2.1b8a (<http://www.isi.edu/nsnam/ns>). In order to make the study worthwhile, two simulations were conducted, including both the proposed IP network service and the current IP network service. Performance of the proposed IP network was evaluated through the comparisons of two sets of simulation results by using the measures mentioned above: delay, jitter, throughput and loss

Figure 4. shows the general simulation model built by using *ns* simulator version 2.1b8a (*ns2*). It contains the

details regarding IP network behaviors includes topology, traffic model and protocol design

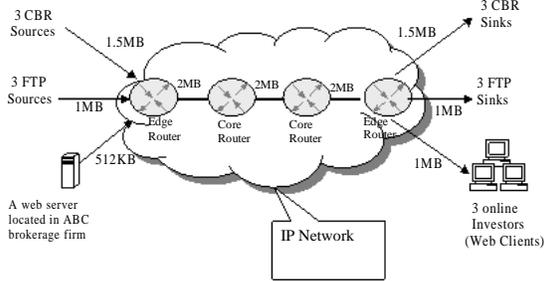

Figure 4. General Simulation Model

In order to make a fair comparison for the performance of two types of Internet services, the two simulation models apply the same topology and traffic sources. The key differences between the two simulations are the service functions and associated functional architecture implemented in the routers.

The simulation results presented in Figure 5. shows that the proposed IP network with QoS support can consistently provide better performance than the current IP network.

## 7. Conclusions

The paper has established an applied QoS theoretical framework for the Internet share trading business. This framework provides some practical guidelines for fast and secure Internet services with high reliability and high availability so that the quality issues raised in the Internet share trading business can be addressed.

One contribution of this paper is the identification of the service capabilities required by the Internet share trading business. Taking into account these business-required capabilities, the applied QoS theoretical framework constructed can provide the relevant QoS capabilities that match with the identified service capabilities required by the Internet share trading business. This has opened up a broad research perspective for developing a customizable QoS solution for electronic commerce, not just limited to the Internet share trading business.

# Beyond Customer Relationship Management: Selling Chain Management for E-Business Practices

Chian-Hsueng Chao<sup>†</sup>

<sup>†</sup> Department of Information Management, National University of Kaohsiung,  
Kaohsiung, Taiwan  
<sup>†</sup> cchao@nuk.edu.tw

## Abstract

Traditional 4Ps (product, price, place, and promotion) sales/marketing strategies are no longer a match for the dynamism of global markets in the e-business era. Today's one-to-one relationship marketing practice requires significantly more information about customers' behaviors, preferences, and patterns than other marketing strategies. Most sales opportunities in enterprises arise in a complex web of team-selling environments where sales team members need to share information, coordinate activities, and align sales processes in order to achieve a sales goal. Enterprises that used to implement CRM applications realize that their systems, which are not sufficiently flexible and interactive to streamline sale processes, have failed to engage customers in ways that create values, enhance individual purchasing experiences and retain loyalties. All these issues drew attentions from CRM to selling chain management. Selling chain management is a combination of customer relationship management, integrated marketing communications, and order fulfillment strategy situated in a multi-channel environment. The major purpose of selling chain management is to transform customer contact into profits. This paper shows that the integration of sales, marketing, and customer service applications with business intelligence system will help enterprises to manage one-to-one marketing and relationship management strategies. The selling chain management that reinvented itself from traditional sales/marketing strategies will undoubtedly be the best solution to today's e-business Internet marketing.

## 1. The Missing Link of B2B2C

The globalization of markets and the resulting competitions are the driving forces for organizations to optimize their business strategies and operations constantly. Today, customers are in charge and make the rules. Consumers are demanding solutions customized to meet their specific needs. Consequently, the challenge is shifting from product-centric marketing to customer-centric marketing. In order to compete in today's real-time economy, every business must be able to quickly identify and respond to the changing market conditions and customer needs. These sales challenges are made worse further by difficulties in pricing, promotion, and relationship-management. In the real-time economy, sales have a deep impact on downstream decisions, as well as decisions related to outside supply chain trading partners. For these reasons, Customer Relationship Management (CRM) now moves from a pure sales

productivity tool to a technology-enabled relationship management strategy in a supply chain scheme.

The CRM is a combination of business process and technology seeking to profile an enterprise's customers from different perspectives. It contains call center service and support, customer contact management, and sales/marketing automation that help to eliminate cost inefficiencies by streamlining and unifying customer information and other internal/external administrative works. However, due to the current one-to-one relationship marketing practices, enterprises that used to implement CRM applications realize that their systems, which are not flexible and interactive to streamline sale processes, have failed to engage customers in ways that create values, enhance individual purchasing experiences, and retain loyalties. Many enterprises with extended selling channels have difficulties responding to the dynamic market conditions. Therefore, a new generation of application framework for one-to-one relationship selling is emerging. Selling chain management is a combination of customer relationship management, business intelligence, enterprise application integration (EAI), and integrated sales/marketing strategy situated in a multi-channel environment.

## 2. The New Dimension of Channel Integration

Emphasis has been placed on the back-office integrations since the emerging of new supply chain practices in the mid-1990s. Today, there are many strategies on the enterprise back-office system integrations, such as enterprise resource planning (ERP) and enterprise application integration (EAI). These solutions are trying to create a unified communication channel that allows enterprise business processes to permeate different departments, divisions, and supply chain partners. In the meantime, there is a growing trend in the marriage of ERP with CRM. The reasons are in two folds; (a) to maintain the integrity of business processes from production to sales automation and (b) the growing importance of customer care. With the combination of ERP and CRM, the enterprise will be more adaptive and flexible to engage customized services.

In today's e-commerce, the customers are in control, and a business must realign its value chain around the customers to eliminate inefficiencies and customize information, products, and services. A set of CRM is not enough to handle diverse group of customers, especially when dealing with one-to-one relationship marketing. To maximize selling power and retain customers, selling

chain management is becoming the central issue in gluing enterprise back-office business-to-business (B2B) and store-front (or front-end) business-to-customer (B2C) practices (Figure 1).

The applications of selling chain management, by definition, must automate processes across multiple user types and functional areas. Selling chain management is a broad set of sales/marketing solution that includes the following strategic areas: data acquisition and analysis (such as data mining and warehousing), marketing intelligence (such as business intelligence tools), sales force automation (SFA), customer services (such as CRM), product catalog and pricing services, proposal/quote/contract management, order management, fulfillment, and the integration of back-office system (such as ERP). The purpose of selling chain management is to build an adaptive marketing strategy such that the entire selling process will be more active and flexible than traditional 4Ps marketing approaches allowing sales teams to better handle any sales activities.

This new dimension of channel integration strategy increases customers' value by satisfying customers' requirements and providing them with the best solution. With marketing intelligence, personalized customer care service will offer valued-added one-to-one relationship marketing to enhance individual purchasing experience and retain customer loyalties with enterprise. This effort can be achieved through the introduction of business intelligence in selling chain practices as will be discussed in the following section.

### 3. Technological Framework

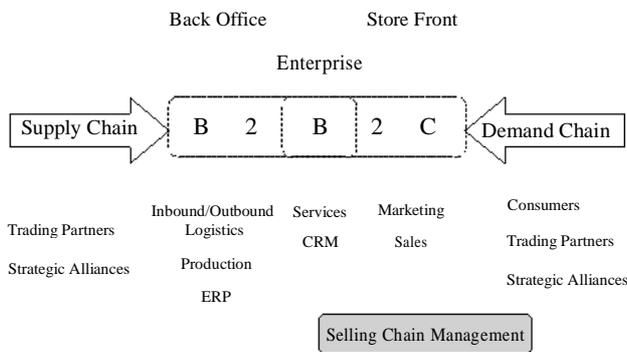

Figure 1 Enterprise B2B2C Model

Selling chain, with an emphasis on purchasing process and customer care, represents a new shift in enterprise computing. This new dimension of channel integration brings both opportunities and challenges to enterprise to refine their business strategies and supporting information systems. The application of selling chain management includes technologies from initial customer contact to production and delivery of final goods or services. The scope also focuses on the gathering of customer data and information. Data acquisition is an important issue in

selling chain management. In today's e-commerce practices, all business data are transmitted over a variety of communication channels because the essence of e-commerce lies in the communications of business data among organizations, supply chain trading partners, and customers. For a typical buying pattern, click-stream through an enterprise's web site, buttons pushed on a touch-tone phone, postal mail/email and faxes are all part of communication with customers. This information by now is not captured in meaningful way to maintain a comprehensive view of the attributes and patterns of customers. With the focus shifts from product-marketing to customer-centric marketing, business intelligence (BI) helps to coordinate information between brick-and-mortar and online initiatives. It relies on integrated data from a variety of information sources: web site, call centers, customer profile and transaction log, operational database, ERP system, and even third party data. The BI analytical and segmentation applications offer tools for data mining as well as decision-making in enterprises. In selling chain management, data acquisition does not only capture customer preferences and patterns, but it also presents customers with personalized information in the purchasing process. The fully integrated selling chain management application has the ability to record and analyze all the activities of prospects and customers, whether the contact mechanism is via the web or a call center. This "automatically-collected" treasure of user behavior information theoretically gives the enterprise a huge advantage over brick-and-mortar competitors, who cannot easily record customer and prospect behavior. The existence of an effective relationship management and click-stream/call-stream data warehouse is one of the most important long-term success differentiators in the e-commerce practices. Other technologies, such as interactive voice response (IVR), computer telephony integration (CTI), are beneficial to selling chain management. The fully interactive nature of the Internet changes everything in the world of self-service. The blending of SFA with customer self-service brings new business opportunities. Relevant information and intelligence support processes all can be aligned and implemented in real-time at anywhere.

With the convergence of B2B, B2C, BI, and real-time relationship management, the personalization of customer information is now possible. A robust selling chain management suite for customer care applications enables new kinds of interactions, new kinds of information, and comprehensive access to all customers and enterprise portals. This customer care can foster joint problem-solving, convenient self-service, and self-selling. Given the information customers need in the purchasing process, they will sell to themselves and service their own information needs. In other words, customers can be an enterprise's best sales forces. The technologies to facilitate these highly interactive communications are summarized in Figure 2.

#### 4. Conclusion

Customization is the rule of the 21 century marketing trend. Multi-channel and multi-technology strategies represent the next frontier of sales force integration. Personalization provides value to customers by allowing them to find solutions that better fit their needs and saves them time in searching for their solutions. By interacting with customers electronically, their buying patterns can be evaluated and the services can be provided. To deliver the right product or service to the right customer for the right price via the right channel at the right time are the essence of selling chain management.

This paper shows that the integration of sales, marketing, and customer service applications with business intelligence system will help enterprises to manage one-to-one marketing and relationship

management more effectively. This technological framework still hold promising with the coming era of mobile business. The IP convergence strategy will provide a solution that joins the two worlds of voice communications (telephony) and data traffic together. The usefulness of the mobile channel will be largely driven by new selling chain applications that enhance the overall customer values. With self-service applications in hand, customers will be able to touch the resource of an enterprise. The customer drives the entire value chain, determining what is to be produced, when, and at what price. The customer will interact with the entire business ecosystem, not just the individual company. The selling chain management that reinvented itself from traditional sales/marketing strategies will undoubtedly be the best solution to today's e-business Internet marketing.

# Towards Customer Knowledge Management: Integrating Customer Relationship Management and Knowledge Management Concepts

Henning Gebert, Malte Geib, Lutz Kolbe, Gerold Riempp

Institute of Information Management

University of St. Gallen

St. Gallen, Switzerland

henning.gebert@unisg.ch, malte.geib@unisg.ch

## Abstract

The concepts of customer relationship management (CRM) and knowledge management (KM) have been recently gaining wide attention in business and academia. Both approaches focus on allocating resources to supportive business activities in order to gain competitive advantages.

CRM focus on managing the relationship between a company and its current and prospective customer base as a key to success. A good relationship with the customer leads to higher customer satisfaction. Content customers are loyal and therefore more valuable customers. This directly affects the revenue stream.

KM sees the knowledge available to a company as a major success factor. Through superior knowledge companies can accomplish their results faster, cheaper and with higher quality than their competition. Knowledge about customers, markets and other relevant factors of influence allows faster utilization of opportunities and more flexible reaction to threats.

From the perspective of a process owner both CRM and KM approaches promise positive impact on the cost structure and revenue streams for a company in return for allocating resources from the core business into supportive functions. This investment is not without risk as many failed projects in the areas of CRM and KM demonstrate.

In this paper we show that the benefit of using CRM and KM can be enhanced and the risk of failure reduced by integrating both approaches into a customer knowledge management (CKM) model. Managing relationships requires managing knowledge for the customer, knowledge about the customer and knowledge from the customer. KM takes the role of a service provider for CRM, managing the four knowledge aspects content, competence, collaboration and composition to satisfy customer requests within stated budget restrictions. The findings are based on literature analysis and six years of action research, supplemented by case studies and surveys.

## 1. Introduction

The concepts of customer relationship management (CRM) and knowledge management (KM) have been recently gaining wide attention in business and academia. Both approaches focus on allocating resources to supportive business activities in order to gain competitive advantages. Although both concepts are currently mostly

treated as separate research areas, we see high synergy potential in an integrated approach.

### 1.1 Objectives

The challenge of achieving a good relationship can be seen as serving each customer in his preferred way, therefore requiring to manage “customer knowledge” [4]. Many knowledge management approaches, as presented by KM models, see managing knowledge as independent from the supported business processes. Knowledge and its management is seen as inherently valuable, a view not generally shared by the process owners, who bear the costs for supportive activities but are measured by their ability to generate revenue and control costs, which in many cases is not measured in knowledge, but in services or products [7, p. 1].

In this paper we will show that integration of CRM and KM concepts on process level are beneficial for both management approaches. A CRM-oriented knowledge management focuses on the knowledge most valuable to the company: Customer knowledge. A KM-oriented customer relationship management receives a framework to manage the knowledge required for high quality relationships in a cost effective way. Both approaches directly interface in the area of information management, as both decide which content should be explicated and disseminated. The resulting customer knowledge management (CKM) model describes basic elements for a successful customer knowledge management. It wants to serve as a frame of reference for integrated CKM activities both on enterprise and project level.

In order to integrate KM and CRM on process level, both resource oriented concepts must be aligned towards the business oriented process view. This modification is based on a literature analysis and is the reason for the emphasis on the theoretical foundations. Furthermore, the implications of the integration approach described in chapter 3.3 as well as the case study in chapter 4 provide tangible recommendations for practitioners.

### 1.2 Research scope, methodology and structure

The CKM model bases on the foundations of business engineering (BE), a research approach developed at the institute of information management (IWI-HSG) at the University of St. Gallen [28, p. 13]. Business engineering differentiates between the levels of strategy, processes and

systems. The research described in this paper concentrates on the process level of CRM, KM and subsequently CKM, while on different points interdependences with the system level are discussed.

The primary research approach employs “action research” as defined by GUMMESSON: “On the basis of their paradigms and preunderstanding and given access to empirical, real-world data through their role as change agent, [...] action scientists [...] generate a specific (local) theory which is then tested and modified through action. The interaction between the role of academic researcher and the role of management consultant, within a single project as well as between projects, can also help the scientist to generate a more general theory, which in turn becomes an instrument for increased theoretical sensitivity [...]” [17, p. 208]. This foundation is enriched by complementing in-depth case study that help validating research questions, aligning existing models with reality, and finally prompting new research challenges. The CKM model is based on nearly 6 years of research<sup>1</sup>. The research partners AGI, Asean Brown Boveri, Bank Austria, BASF, Credit Suisse, Deutsche Telekom, DKV, Helsana Insurance, Landesbank Baden-Württemberg, St. Galler Kantonalbank, Swisscom IT Services, Union Investment and Winterthur Life & Pension.

This paper is structured into three main chapters. The theoretical foundation in chapter 2 analyzes some current approaches in the fields of CRM and KM and identifies relevant elements concerning integration into a CKM model. The necessary modification to the current approaches and the main elements of the integrated model are discussed in chapter 3. Chapter 4 offers a sample application of the model in a business environment, based on an action research report conducted with a research partner. The paper concludes with a summary, a critical reflection and an outlook on further research possibilities.

## 2. Theoretical Background

### 2.1 Customer Relationship Management

Increasing competition and decreasing customer loyalty have led to the emergence of concepts that focus on the nurturing of relationships to customers. Customer Relationship Management (CRM) emerged as an amalgamation of different management and information systems approaches, in particular Relationship Marketing and technology-oriented approaches such as Computer Aided Selling (CAS) and Sales Force Automation (SFA). Following SHAW, we define CRM as an interactive process achieving the optimum balance between corporate investments and the satisfaction of customer needs to generate the maximum profit. It involves: [40]

- measuring both inputs across all functions including marketing, sales and service costs and outputs in terms of customer revenue, profit and value.
- acquiring and continuously updating knowledge about

customer needs, motivations and behavior over the lifetime of the relationship.

- applying customer knowledge to continuously improve performance through a process of learning from successes and failures.
- integrating the activities of marketing, sales and service to achieve a common goal.
- the implementation of appropriate systems to support customer knowledge acquisition, sharing and the measurement of CRM effectiveness.
- constantly flexing the balance between marketing, sales and service inputs against changing customer needs to maximize profit.

#### 2.1.1 Knowledge in CRM processes

To integrate marketing, sales, and service activities, CRM requires strong integration of business processes which involve customers. These front-office or CRM processes are mostly unstructured and non-transactional. Their performance is predominantly influenced by the underlying supply with knowledge about products, markets, and customers [6][13][36].

CRM processes can therefore be considered as knowledge-oriented processes with the following characteristics which have a strong correlation: [12]

- Knowledge intensity*: CRM processes require knowledge from heterogeneous, not necessarily computational sources, to pursue process goals.
- Process complexity*: CRM processes mostly have complex structures or even no clear structure at all. This implies that a high degree of knowledge is necessary for the execution of a process.

Knowledge flows in CRM processes can be classified into three categories:

- Knowledge for customers* is required in CRM processes to satisfy knowledge needs of customers. Examples include knowledge about products, markets and suppliers [13].
- Knowledge about customers* is accumulated to understand motivations of customers and to address them in a personalized way. This includes customer histories, connections, requirements, expectations, and purchasing activity [4][6].
- Knowledge from customers* is knowledge of customers about products, suppliers and markets. Within interactions with customers this knowledge can be gathered to feed continuous improvement, e.g. service improvements or new product developments [13].

Managing these different knowledge flows is one of the biggest challenges of CRM. The most important issue is how to collect, store, and distribute only the knowledge that is needed and not waste time and effort on collecting and storing useless knowledge [4].

To identify relevant knowledge that is needed in business processes, methods of Business Process Engineering can be used [3][18][19]. To integrate different CRM processes, often process reengineering projects are

<sup>1</sup> Further information under: <http://ccckm.iwi.unisg.ch>

carried out. These projects provide process models that can form the basis for an analysis of knowledge flows in CRM processes.

To determine CRM processes that need to be integrated and analyzed with regard to their knowledge needs, we will analyze existing conceptualizations of CRM.

### 2.1.2 Current CRM approaches and process orientation

The origins of CRM can be traced back to the management concept of *Relationship Marketing* (RM). LEVITT was one of the first to propose a systematic approach for the development of buyer-seller relationships [22]. Relationship Marketing is an integrated effort to identify, maintain, and build up a network with individual customers and to continuously strengthen the network for the mutual benefit of both sides, through interactive, individualized and value-added contacts over a long period of time [39, p. 34].

RM is of largely strategically character. As such, although business processes are regarded as important [30], a holistic view on business processes connected to RM is missing.

On the other hand, CRM was influenced by several information systems concepts, focusing on distinct application areas. For example systems for Computer Aided Selling (CAS) and Sales Force Automation (SFA) were responsible for the control and automation of sales processes, whereas other systems for service or marketing automation focused on service resp. marketing processes. In the course of process integration these systems continually merge towards integrated CRM systems.

A widely accepted classification of systems connected to CRM is the following [37, p. 8]:

- *Operational* CRM systems improve the efficiency of CRM business processes and comprise solutions for sales force automation, marketing automation, and call center/ customer interaction center management.
- *Analytical* CRM systems manage and evaluate knowledge about customers for a better understanding of each customer and his or her behavior. Data warehousing and data mining solutions are typical systems in this area.
- *Collaborative* CRM systems manage and synchronize customer interaction points and communication channels (e.g. telephone, email, web).

Whereas operational CRM systems focus on the support of distinct front-office business processes, analytical and collaborative CRM systems only have a supporting role for operational CRM.

Apart from the strategy-oriented concept of RM and systems-oriented concepts, there are several CRM approaches with special focus on business processes [36]. Most of these approaches define marketing sales, and service as core CRM processes, neglecting that these are functional areas which have to be integrated by defining cross-functional business processes. Others focus on specific activities, but don't propose a process framework for

CRM.

Our goal is to overcome these shortcomings by proposing a process model consisting of business processes relevant in the context of CRM. This framework may be used as a starting point for the analysis of knowledge flows in CRM processes.

### 2.1.3 Status and challenges of CRM in real-world applications

Case studies and action research with our business partners support the assumption that the management of knowledge in CRM processes is a critical success factor.

Especially important for our business partners is the identification of prospective customers as well as the discovery of cross- and up-selling opportunities within the existing customer base. We thus observe an extensive use of applications for analytical CRM. Although several companies are far advanced in the implementation of a continuous process for analytical CRM, the majority still has difficulties in managing the relevant knowledge. In particular, the challenge to ensure a consistent knowledge flow from the point of development of knowledge about the customer (in marketing, sales, and service) to the point of utilization, where the knowledge has to be presented in adequate form and complexity is far from being solved.

Another subject of considerable relevance is the management of customer service. All of the participating companies have call-centers that handle service inquiries. One of the major challenges remains the provision of the right knowledge for call-center staff to handle inquiries in an adequate timeframe. To address this challenge, some companies have projects for the implementation of supporting knowledge management tools. Another future challenge is the use of multiple communication channels to address customer service needs. All companies show further potential to exploit self-service technologies with the aim of increasing service quality and decreasing service costs. Using these technologies will raise the question of how to synchronize different communication channels to ensure consistency towards the customer.

Closely connected to service management is the handling of customer complaints. Although all our partner companies have a process for complaint management, many reveal shortcomings in the analysis and utilization of complaints for continuous improvement.

### 2.1.4 Summary

Literature research and work with our business partners suggest that the management of knowledge in CRM processes is a critical success factor. For an analysis and improvement of knowledge flows, a CRM process model can be used as starting point. Existing conceptualizations of CRM in the literature either lack process-orientation or don't provide a process framework for CRM that is detailed enough to suit this purpose.

## 2.2 A review on Knowledge Management Models

The steady interest for knowledge management in academia and business circles alike has spawned many KM models, that try to capture the inherent qualities as well as the dissemination and development characteristics of knowledge in order to assess methods and techniques of managing it in a business environment.

While many knowledge management models offer valuable insights into the nature of knowledge, their difficulties of justifying the management of knowledge within the business environment is a point of constant criticism [5], [8]. To understand the reason for this it is important to analyze the foundations of the modeling approaches used. Almost all knowledge management models can be traced back to a basic approach when analyzing knowledge. The models either view knowledge as an entity with distinctive attributes, that can be decomposed and its details analyzed, or they view it as an integrated whole and focus on its relations to the surroundings. Within this paper the former view will be called an epistemological perspective, the latter an ontological perspective. The following analysis provides an introduction into this differentiation.

### 2.2.1 Epistemology oriented KM models

As a philosophical research area, epistemology investigates the nature of knowledge itself. Epistemological knowledge management models therefore view knowledge as an entity that can be decomposed into discrete, relevant attributes, based on the epistemological foundation held by the modeler. There are many different epistemological views in philosophy, but mainly the cognitivist and the autopoietic approaches have been of significance in the area of knowledge management [44]. The cognitivist approach describes knowledge as stored in distinct knowledge structures, that are created through rule based manipulation and can exist independently from an individual, while the autopoietic approach states that knowledge is context sensitive and basically embodied in the individual [44, p. 55f.]. The following description will focus on the autopoietic approach on knowledge management.

According to the autopoietic epistemology an individual observes its environment and acquires knowledge by interpreting data through an informational process [42]. Individuals can actively transfer knowledge between themselves through articulation and different types of interaction [45].

Based on the autopoietic theory, the main differentiating characteristic of knowledge is the difficulty of its articulation. Knowledge that can be easily articulated is labeled “explicit knowledge”. Knowledge, that is difficult to articulate and therefore difficult to transfer is labeled “tacit knowledge” [32, pp. 3-25] which was superseded by the term “implicit knowledge”. With their SECI knowledge management model Nonaka and Takeuchi have formulated an encompassing epistemological autopoietic oriented knowledge management model [27, p. 45]. Other examples of epistemological oriented knowledge manage-

ment models with an autopoietic approach include the models of Boisot [1] and McLoughlin & Thorpe [25].

### 2.2.2 Ontology oriented KM models

Also based on philosophical research, an ontology represents systematic account of Existence. It is an “explicit specification of a conceptualization: the objects, concepts, and other entities that are presumed to exist in some area of interest and the relationships that hold them” [16, p. 1].

Ontology knowledge management models therefore view knowledge as “black box”. The characteristics of knowledge are defined through its relationships with a constructed universe of discourse, encompassing all dimensions that are relevant to the modeler.

Modeling dimensions frequently used by ontological knowledge management models include a process dimension, an agent dimension (individual vs. group) and a financial dimension. The latter is based on the intellectual capital research, and will, due to the specific aims of the models, not be discussed further within this paper.

Process oriented KM models focus on the characteristics of knowledge during its life cycle. They analyze the relationships and environmental variables that influence the processes of knowledge development, dissemination, modification and use. Examples for process oriented KM models include Probst [34] and Wiig [47]. Agent oriented KM models focus on the characteristics of knowledge during the flow between individuals. They analyze the variables that expedite or hinder the flow of knowledge in social networks. Examples for agent oriented KM models include Wenger [46] and Enkel [11].

### 2.2.3 Hybridization of KM models

The perspectives of epistemology and ontology have high synergy potentials. Though it is possible to analyze the structure of an entity and its relations separately; in trying to assess the business benefits of knowledge management, both the inherent characteristics and relevant relationship variables of knowledge must be taken into account.

Most KM models developed within the last decade therefore exhibit characteristics of both views. Nonaka has integrated an agent ontology dimension in 1994 [20] and he tries to fully bond both views in his concept of “ba” [27]. The process oriented KM model of Demarest focuses by definition on the processing of explicated knowledge [7]. Still a fully balanced model is yet to be created [24].

### 2.2.4 The inherent value of knowledge

Peter Drucker and others speak of knowledge as “the most important resource of the 21<sup>st</sup> century” [9, p. 1]. To determine what kind and how much knowledge a business process requires to achieve top performance must be the first step of a supportive knowledge management system [7, p. 1].

Epistemology oriented KM models share an inherent

disability to assess this question. They focus on the inner characteristics of the entity knowledge and neglect the relationships to the environment per definition. To assess whether a certain knowledge entity is explicit or implicit does not allow to draw any conclusions about its value in a business process. Epistemological KM models are therefore not able to support business processes when trying to identify and manage valuable knowledge.

Ontology oriented KM models display relationships between knowledge entities and their environment. They should therefore be able to help the process owners to identify and manage valuable knowledge by offering a suitable knowledge management process dimension. However when analyzing ontological KM models, it becomes apparent that many processes described are completely self oriented. They focus on the knowledge life-cycle, such as knowledge development, knowledge dissemination and knowledge modification [23]. Based on this view, knowledge management processes are independent business processes, taking a similar position in an enterprise as marketing or sales; knowledge itself and its management possesses inherent value.

We criticize this endorsement of inherent value to knowledge and knowledge management. While knowledge becomes more important to all business processes, it is still a resource that abides the laws of economics: It has a diminishing marginal utility and its management does normally not directly generate business value. A change in alignment of the KM models is required to tap the supportive performance for managing knowledge in a CRM environment.

### 2.2.5 Action research results

The stated gap between the self-conception of knowledge management models and the requirements of business process owners could be verified through research within our partner companies.

A survey based on 241 questionnaires with a reply of 60 and 19 detailed telephone interviews comprised the following results: The managers demand an evaluation framework that supports them in operating the content flow within and between their processes and maintaining a concise and performance oriented content base. Information requirements driven by new CRM systems strain the service capabilities of employees with customer interaction in subsidiaries and call centers. A manager's issue is not about how to commonly create and disseminate knowledge in an effective way. While the research partners spent substantial resources on knowledge management they still try to get their exponentially growing content base of semi-structured documents under control. They want to know which content to keep in which state to run their processes more efficiently and effectively.

Therefore another area of intense interest is the identification of employees according to their competences. While process managers see distinct improvement potential using expertise directories or yellow pages, the restrictive European data protection acts and the ambiguous

position of these systems concerning human resources activities, stalls such approaches in many companies. While several research partners have isolated solutions in single departments, especially IT and internal consulting, only one partner in the insurance industry has set up a company wide skills management project. To analyze the customer requirements in this project a two day interview session was conducted. 9 stakeholders with customer oriented assignments ranging from operatives to the middle management were interviewed in 45 to 60 minutes sessions. All interviewees confirmed a high demand for expertise location services within their business processes and were willing to support the project financially. The stated requirements included a better transparency of their own workforce concerning skills, qualifications, abilities and required trainings as well as the potential of fast identification of required resources within other parts of the company. The main difficulties were seen in constructing a competences base relevant to the own business process while minimizing the effort for the employees updating their personal profiles.

Storage of knowledge across business processes is another area of interest for research partners. While a third of the companies have large scale community structures in place, most of them concentrate in one core process, such as research & development and other areas of high expertise. In organizations that structure along customer oriented processes communities of practice that span organizational team structures are currently not explicitly managed. The lack of possibilities to bridge the temporal and geographical gaps between the different customer teams is seen as a major hindering factor. Nevertheless, the role and management of these complementary organizational structure is seen as vital. One research partner has started a multi-million euro project with a major focus on enhancing his capabilities of using forms of virtual work independent from temporal, geographical constraints and embedded into the existing organizational structure.

### 2.2.6 Summary

While the integration of epistemological and ontological approaches into an encompassing knowledge management model is progressing, the direct process support by knowledge management required by the research partners and survey participants can still not be served. This limitation is based on the self-conception of KM models stated in chapter 2.2.4. To address this challenge, we propose a customer oriented knowledge management (cKM) model described in chapter 3.2.

## 3. Proposing a CKM framework

### 3.1 CRM process model

Based on previous research by SCHMID, literature research and work with our business partners, we propose the following process model for CRM which describes business processes relevant for CRM [35]. Based on this model, we can identify relevant activity fields for knowl-

edge management, in order to improve these processes.

### 3.1.1 CRM business processes

Marketing, sales, and service are primary business functions [33] with the characteristics of a high degree of direct customer interaction and knowledge intensity, which makes them primary targets for CRM. We therefore derive our process model by detailing these functions into relevant business processes which may be cross-functional. A CRM business process involves the processing of customer knowledge to pursue the goals of relationship marketing. Usually it also involves direct customer contact and the exchange of information or services between enterprise and customer. Such processes are either triggered by the customer (with the aim of receiving information or services), which involves a transfer of information from customer to enterprise, or are triggered by the enterprise with the aim of delivering information or services to customers. Each process handles a specific business object which distinguishes it from other processes. We identified 6 relevant CRM business processes: *campaign management*, *lead management*, *offer management*, *contract management*, *complaint management*, and *service management*.

In contrast to transaction marketing, relationship marketing is based on interactive, individualized contacts [15, p. 11]. *Campaign management* is the core marketing process which implements the ideas of relationship marketing. We define it as the planning, realization, control and monitoring of marketing activities towards known recipients, who are either existing or prospective customers. Marketing campaigns are individualized (one-to-one marketing [31]) or segment-specific, usually use different communication channels, and offer at least one communication channel for feedback from the recipients to allow interaction. Campaigns may be triggered by the enterprise or by the customer. The objective of campaign management is to generate valuable opportunities or “leads” which can be further qualified by *lead management*. An earlier approach which focuses on one-way communication from enterprise to customer is the concept of direct marketing [26].

*Lead management* is the consolidation, qualification, and prioritization of contacts with prospective customers. Contacts may be received from *campaign management* or other sources, e.g. the *service management* process. The objective is to provide sales staff with a qualified and prioritized list of presumably valuable prospective customers to allow a precise and effective address within the offer management process.

*Offer management* is the core sales process. Its objective is the corporation-wide consistent creation and delivery of individualized, binding offers which fulfill all requirements for direct conclusion. An offer management process may be triggered by a customer inquiry, a qualified lead, or an otherwise discovered opportunity.

*Contract management* is the creation and maintenance of contracts for the supply of a product or service. As such,

it may support *offer management* or *service management* processes in the preparation of an offer. Especially important in the service sector, contract management comprises the maintenance and adjustment of long-term contracts, e.g. for outsourcing agreements or insurances.

Within the scope of *complaint management*, articulated dissatisfaction of customers is received, processed, and communicated into the enterprise [41]. The objectives are to improve customer satisfaction in the short-run by directly addressing problems that led to complaints, and to feed a continuous improvement process to avoid complaints in the long-run.

*Service management* is the planning, realization and control of measures for the provision of services. A service is an intangible output of an enterprise generated with direct involvement of customers or some of their assets. Examples include maintenance, repair, and support activities in the after-sales phase as well as the provision of financial or telecommunication services after the conclusion of contracts.

### 3.1.2 CRM activities

In addition to CRM business processes, CRM requires activities to design interfaces to customers at customer interaction points.

*Interaction management* is the analysis and selection of media-based communication channels, e.g. interactive voice response (IVR) or the world-wide-web (WWW), to achieve the optimal channel mix [38]. The objective is to increase the quality and value of interactions while at the same time decreasing the cost of interactions by shifting customers to less costly channels, e.g. web-self-service.

Closely connected to interaction management is *channel management* which addresses the challenge of configuration and synchronization of different communication channels [14]. Key objectives are to define organizational responsibilities for each channel, to avoid conflicts between channels, and to ensure consistent knowledge flows over different channels.

### 3.1.3 Enabling factors

*Opportunity management* has an outstanding role in the context of CRM. In contrast to the rigid structure of processes like e.g. *lead management* which prioritizes valuable contacts derived mainly from *campaign management*, the aim of *opportunity management* is to realize specific opportunities discovered locally by sales and service staff [2]. This can be achieved by the expansion of competences of employees with direct customer contact and the provision of techniques and simple rules for identification and selection of promising opportunities [10].

## 3.2 A customer oriented KM (cKM) model for CRM

In the conclusion of chapter 2.2 we stated that the endorsement of knowledge with an inherent value is the main reason that many KM models have difficulties to prove the value of managing knowledge within a business

environment. The following chapter offers a way to realign a KM model directly to a business process, in this case the CRM process framework of chapter 3.1.

### 3.2.1 Knowledge requirements of CRM

To achieve their goal of serving the customer the individuals performing in CRM must understand and address the customer's processes [29]. They therefore require three different types of customer oriented knowledge:

- They need to understand the requirements of customers in order to address them. This is referred to as “knowledge about customers”.
- Customer needs must be matched with the services and products available. All knowledge required here for can be summarized under the term “knowledge for customers”.
- Finally customers gain many experiences and insights when utilizing a product or service. This knowledge is valuable as it can be used for service and product enhancements. This “knowledge from customers” must be channeled back into an enterprise.

All three types of customer oriented knowledge will be henceforth summarized under the term “customer knowledge”. A cKM model addressing CRM requirements focus on managing customer knowledge. All other knowledge is therefore neglected in the model.

### 3.2.2 Building a customer oriented cKM model

Knowledge is created, located and captured, disseminated, modified and used constantly within all CRM business processes. However CRM does not require self-oriented knowledge management processes. It requires goals for managing the knowledge critical for its business processes.

The cKM model therefore transforms the KM process perspective of ontological KM models into a KM goal perspective. The KM goal perspective offers process owners different options to focus on when managing critical knowledge entities. The cKM goal perspective encompasses four goals (see figure 1):

Figure 1: Knowledge Management Pyramid

- The goal of knowledge transparency supports the execution of business processes in defining their requirements concerning the manageability of customer knowledge. A high degree of manageability requires a high degree of transparency.
- The goal of knowledge dissemination supports the business process owners in defining the degree of customer knowledge distribution required between all individuals that take part in process activities. The management of dissemination requires the management of knowledge transparency.
- The goal of knowledge development supports the business process in defining the requirements concerning the adaptation and creation of knowledge. Even so knowledge can be created by an individual based solely on his or her own context, valuable customer knowledge development from a CRM process perspective requires the ability to disseminate knowledge between individuals. The management of knowledge development therefore requires the management of knowledge dissemination.
- The goal of knowledge efficiency is based on the diminishing marginal utility of customer knowledge. The goal of knowledge efficiency supports the business process in selecting the knowledge crucial for the CRM process from the large body of knowledge available. Knowledge efficiency requires the manageability of knowledge development, because it necessitates a high level of understanding of current and future customer needs essential for enhancing the CRM processes. To voluntarily destroy or disregard customer knowledge, based on the understanding that this knowledge will actually hinder the knowledge flows within a business process, is one of the most difficult managerial decisions, because it requires a decisive decision within an uncertain environment.

The four management goals constitute a cascading framework for analyzing the customer knowledge requirements of a CRM business process. The first three can be compared to the process perspectives of existing KM models such as [43]. Most importantly the KM goals are stripped of their self orientation; they do not add value by themselves but serve as a subsystem for business processes.

### 3.2.3 Managing four aspects of knowledge

While allowing process owners the direct articulation of their knowledge needs, the four KM goals do not provide guidelines for managing customer knowledge based on its relevant characteristics and additional relations. The cKM model therefore is enhanced through the integration four aspects *content*, *competence*, *collaboration* and *composition* as shown in this chapter.

Relevant *aspects* of knowledge can be extracted by

analyzing existing KM models that focus on explaining characteristics and relations of knowledge entities. As shown in chapter 2.2 most KM models fall into this category. The relevance of a knowledge aspect for a CRM process is subject to the following preconditions:

- A knowledge aspect must be of business significance; changes in its parameter values must impact either the cost or the revenues of the CRM process.
- A knowledge aspect must be measurable and manageable within a business process.
- An additional knowledge aspect must form a consistent framework with already chosen aspects; there should be no overlapping in characteristics or dimensions.

Though the number of aspects integrated in a KM model must be based on all relevant aspects, the cKM model described in this paper is based on the action-research results of the CC CKM. As a complete derivation is beyond this paper, we show the basic elements based on an analysis of the SECI model of Nonaka / Takeuchi [27].

This choice is based on the following criteria:

- The model is widely accepted both in the scientific community and the business environment.
- It possesses a “simple” structure, offering one epistemological and one ontological knowledge aspect. Both are well defined.
- The parameter values of its epistemology and its ontology have high a high degree of overlap with the empirical findings.

As described in chapter 2.2, SECI is basically an autopoietic epistemological KM model, focusing on the knowledge aspects of implicit and explicit knowledge. The scientific foundation for this characteristic was published by Polanyi in 1968 [32]. According to Polanyi each individual possesses an amount of implicit knowledge which influences the ability to articulate and therefore explicate and also create knowledge. In the SECI model the difficulty of articulation differentiates implicit from explicit knowledge. Both knowledge entities only exist within an individual. While media, such as text or images, can be used to store and carry their essence in a way, the carried knowledge can only be reconstructed via informational processing through another individual.

The individuals accountable of a business process use both implicit and explicit knowledge to perform their tasks. In addition a business process includes explicated knowledge, mostly in terms of documents, which exists independent of individuals. A process manager is therefore not so much interested in the difference between explicit and implicit knowledge in an individual, a factor that is beyond his control, but in the ratio between explicated and explicit/implicit knowledge, that offers high business performance and adaptability in case of personnel changes while fulfilling external requirements such as financial audits. The process owner can therefore manage the amount of explicated knowledge, henceforth termed the knowledge aspect of “content” as compared to the amount

of explicit and implicit knowledge available in individuals, henceforth termed the knowledge aspect of “competence”.

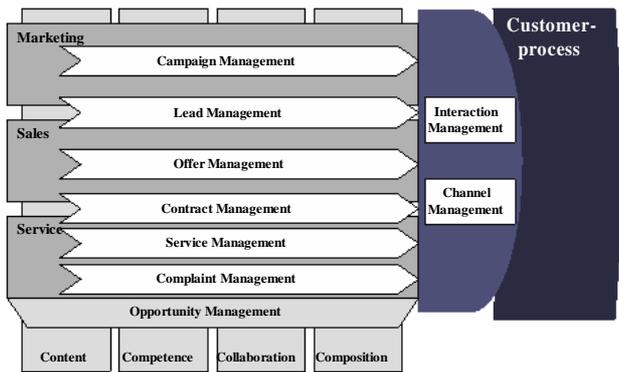

The epistemological view of the SECI models was enhanced through the integration of an ontological agent dimension by Nonaka and Hedlund [20]. The agent dimension describes the possibilities of knowledge dissemination by the four parameter values: individual, group, organization and inter-organization. These parameter values are based on the view of a commercial organization. From a CRM process perspective, only two of these parameter values are of interest. Process interaction with customer focus always includes at least two partners, a service provider and a customer; personal knowledge management is therefore only interesting in terms of sharing knowledge in the process context. From a process perspective there is also no differentiation between an intra-organizational and an inter-organizational process. This leaves the parameter values group and organization. The parameter group represents the dissemination of knowledge between few individuals, henceforth represented by the knowledge aspect of “collaboration”. The parameter value of organization represents the knowledge dissemination between a large number of individuals, henceforth termed as knowledge aspect “composition”. The latter term describes the level of structuring required to relay knowledge, such as this paper, to a large group of individuals. Both knowledge aspects are important for a CRM process, as the cost of dissemination through composition is much more expensive than through collaboration. Also collaboration offers the possibility of relaying implicit knowledge which is not possible through composition.

### 3.2.4 Summary

The cKM model described in this chapter offers goals and aspects of knowledge, that support the management of knowledge within a business environment. The four knowledge aspects of content, competence, collaboration and composition allow the management of knowledge based on the characteristics and dimensions with direct impact to the process performance.

## 3.3 Towards Customer Knowledge Management

We observe in practice that customer relationship management and knowledge management have an considerable synergy potential (see figure 2). While KM acts as a service provider for CRM, the interdependences and mutual benefits between the two approaches result in a merger of equals. The subjoining of knowledge management elements allows CRM to broaden from its mechanistic, technology driven and data oriented approach, enabling it to encompass both the elements of technology and people orientation. Knowledge management is thereby able to prove its value directly within the process chain.

**Figure 2: Customer Knowledge Management model**

As integration area we have chosen the process dimension. Because most CRM and KM research does not directly focus on the process dimension, we stated the modification required to allow a direct integration into a process framework. The following chapter gives a brief overview of a joint model, balancing the approaches of knowledge management and customer relationship management.

### 3.3.1 CRM, customer knowledge and knowledge goals

As described in chapter 3.2.1, CRM manages knowledge for, from and about the customer, a customer lock-in through superior services and products.

Knowledge *for* customers is mainly generated in processes within the enterprise, such as research and development and production. Campaign management is responsible for collecting this knowledge and refining it according to the customer requirements. It is then distributed to the other CRM processes, mainly offer management, contract management and service management. CRM manages knowledge transparency and dissemination of knowledge for customers. Maintaining the balance between comprehensibility and precision is the main challenge when managing this kind of knowledge.

Knowledge *about* customers is captured mainly by offer management, service management, complaint management and, if available, contract management. Main user processes of knowledge about the customer are campaign management and service management, because both processes personalize their services based on user criteria. Knowledge about the customer must be transparent within the company, however its dissemination beyond the border of an organization must be controlled, as knowledge about the customer can often be directly transformed into competitive advantages. The development of such knowledge is also expensive, because knowledge explication is taking time and attention away from the main task, i.e. serving the customer. Interaction management offers possibilities of gaining knowledge about customers automatically via electronic media. The question of how much data about the customer an enterprise can transform into knowledge is the critical challenge when managing knowledge about the customer.

Knowledge *from* customers can be captured in similar ways as knowledge about customers. Gaining knowledge

from customers is based on the fact, that customers gain their own expertise while using a product or service and can be seen as equal partners, when discussing changes or improvements. This aim is not commonly understood in the business world and its impacts poorly researched in academia [13]. To utilize this knowledge from “outside experts” as change agent it must be channeled into the back end processes of an enterprise, such as the research and development process. Even so valuable knowledge from customers is mostly gained at the service points, an enterprise must check its CRM processes for their capability of serving customers. To bend CRM away from their service goal in order to capture higher amounts of knowledge from customers is a short sighted goal.

### 3.3.2 Knowledge aspects and the enabling factor

The knowledge aspects support CRM in maintaining its primary goal of service for customers, by managing knowledge for, about and from customers. The management of content allows CRM process owners focus on the messages they want to deliver to customers. Competence management streamlines processes, as it bridges the gap between an individual receiving a customer request and the individual solving it. Collaboration support allows teamwork with less time and space constraints. Composition enables scaling the former three beyond the team context, as structures and indexes allow faster access to knowledge by navigation and search.

### 3.3.3 Summary

As shown, the integration of CRM and KM approaches benefits the utilization in both areas. While the CKM model displays the major integration elements, the performance benefits of the integrated approach however can only be shown in specific process implementations.

## 4. Enhancing knowledge dissemination in a customer service center

The following excerpt of a action research case of a large fund managing bank (LFMB) shows the business impact of the CKM view in a typical CRM environment. The case focuses on a major element within modern CRM concepts, the call or communication centers (CCC), that in many companies consolidate the communication channels phone, fax and email serving a geographically dispersed client base.

### 4.1 Large Fund Managing Bank (LFMB)

Founded by 14 private banks in 1956, our research partner LFMB offers specialized funds for private and institutional investors. In December 1999, the company moved up to the top three players of the German fund market managing assets of EUR54bn.

Because our research partner primarily works as specialized service provider for the founding banks, the CCC serves bank employees and retail customers alike. This requires a profound knowledge of the banking and funds

environment. The CCC employees possess a high expertise in their chosen profession, many of them having specialized degrees and multiple years of working experience within the banking environment.

The CCC consists of 120 employees, two thirds offering the more general first level support while one third specializes in second level support on complicated and dynamic knowledge areas such as funds in specific international area.

#### 4.2 KM challenges of customer service

In order to address their customer needs, CCC employees utilize different information sources. News and important information concerning services and products are provided by an internal unit named information management (IM). This content is still mostly disseminated via email. While this is possible without investments into the technical infrastructure, each CCC employee must organize his or her content individually and new employees have no knowledge base to build on. The amount of content disseminated also strains the network environment as the usual informational email includes frequently 10 up to megabytes of attachments and thus its transfer via simple mail transfer protocol (SMTP) to nearly 150 recipients results in a data transfer volume of up to 1.5 gigabytes for one email.

IM therefore started implementing a new information channel using basic web technology. The resulting intranet presence, termed "surfMe", is intended to be a centralized platform offering information about products and services that can be used by CCC employees when serving customers on the phone.

After one year in service, the role of "surfMe" entered a critical stage. While the amount of content included in the system started to put a strain on maintenance for IM, it still failed to accomplish full acceptance by the CCC employees: Important information was not available instantly and the missing search functions prolonged the critical time to retrieve content when searching for information while serving a customer on the phone.

While thinking about changing the technical infrastructure IM brought up the case within the context of the CC CKM in order to achieve a comprehensive analysis of the challenges hindering the success of the new communication channel.

#### 4.3 Relevant knowledge goals and aspects

Based on two one-day workshops, the CKM model was used to analyze the success factors for redesigning the existing communication channels based on LFMB's customer knowledge processes.

The focus of the project was to provide the CCC employee with knowledge for the customer. Because many members of IM were former CCC employees, IM has a very good overview of the knowledge available and required by the CCC; knowledge transparency therefore was not an issue. The main knowledge goal of the project was enhancement of knowledge dissemination. A follow-up

with knowledge development was also seen as important, as most knowledge used within CCC is created in other departments such as product management and marketing. Because knowledge delivering to the CCC-employees, working to solve this challenge was delayed until the basic solution for dissemination was operative.

After determining the knowledge goals, relevant knowledge aspects and its manifestations were identified. The demands of the CCC employees showed a major shortcoming in the current design of knowledge *composition*. The navigational structure was unwieldy, searching for content was not possible.

IM itself required improvement on the knowledge aspects of content and composition. The major content challenge, requiring up to 50% percent of the time spent for "surfMe", was identified in the transformation of documentation from MS office format delivered by other departments into content displayable in a web browser. The composition challenge matches with the requirements of CCC. The constant growth of the "surfMe"-structure required increasing maintenance and tied employees to their job roles as web managers, as assigning new colleagues became increasingly expensive. Even though it was not in the original focus, the possibilities of adding the knowledge aspect of competence via an expertise directory was discussed during a workshop. Foundations of this knowledge aspect already existed within the electronic phone books offered by "surfMe" that serves as a rudimentary yellow pages system.

#### 4.4 Results

Through the use of the CKM model as analyzing tool, relevant weaknesses of the current knowledge management configuration could be identified and communicated in a structured and coherent way. This led to a customer and maintenance friendly architecture for the new application, which was tested in a rapid prototype. The resulting reengineering project for "surfMe" concentrated on the removal of the identified weaknesses, which had a profound impact on the requirements specification for the new technical solution, namely stating flexible transformation of office documents into HTML (rendering), in place editing of documents on the server, an automatic maintaining search indexer and a navigational bar that can be managed by editors as mandatory features. Similar results were obtained in projects with other research partners.

### 5. Summary and outlook

We observed in multiple cases [21], that management of knowledge is a critical success factor for CRM. Knowledge management methods with the aim of supporting CRM have to be process-oriented.

Based on literature and action research, we tried to show, that CRM and KM have high synergy potential and should be used in conjunction. To achieve a good integration we proposed a business process model for CRM comprising six relevant business processes: campaign management, lead management, offer management, con-

tract management, service management, and complaint management. Additional activities for the implementation of the customer interface are interaction management and channel management. We identify four relevant knowledge aspects: content, competence, collaboration, and composition to supplement the CRM processes. These aspects allow a structured approach for the identification of opportunities for business process improvement by KM.

On reflection, the proposed business process model for CRM provides an initial point for the process-oriented application of KM. However, it has insufficient granularity to allow a thorough analysis of potentials for process optimization by KM. The four knowledge aspects provide guidance in the discovery of optimization potentials. They do not replace a method for process-oriented KM, but form the foundation for such a method subject to further research.

To address the mentioned shortcomings, we will advance and detail the CRM process model so that it describes knowledge flows among the processes. Furthermore work on a method for Customer Knowledge Management which aims at using the four knowledge aspects to improve the CRM processes is underway.

The main focus will be the measurement and proof of tangible performance improvements achieved.

## Abstract

A framework is developed to enable transition from a typical real estate agency towards an e-business enabled business environment, based on an agency configuration located in Townsville, Australia. This transition is modeled according to a number of stages. In the strategic audit stage, a TOWS matrix is suggested which combines Porter's Five Forces Model of Competition, adapted with a SWOT analysis. The next stage of an e-business case development for this real estate setting differentiates among inside partners, nearside partners, and external partners. Stage three states the composition of the systems analysis team, whereas in stage four the system architecture and infrastructure are specified, including a number of relevant legislative issues. Subsequently, the web interface design-stage is elaborated on, including accessing issues by different user groups. Two extreme examples of customer interfacing are presented to illustrate the need for the interface to be flexible, information gathering, and execution focused. These four stages summarize the transition process real estate agencies may work through to become fully e-business enabled.

## 1. Introduction

Real estate in Australia has been slow to embrace e-business. Without a direct and immediate impact on revenues, some entrepreneurial businesses have trouble justifying the expenditure. Others, viewing real estate as a "people" business, consider e-business a hindrance to relationships. Still others cite the idiosyncratic nature of real estate transactions and portfolios, the difficulty of adapting off-the-shelf software to meet their specific requirements and the high cost of custom programming [2].

It is our belief that real estate management may not have a good grasp of what a total e-business solution has to offer in today's real estate environment, and moreover, not a clear picture of how to progress from a "traditional" (albeit basic Web-supported) business setup towards an e-business enabled configuration. This paper attempts to address this very issue, and presents a framework for

making this transition a reality, while illustrating how e-business enabled real estate interactions and transactions could enhance business and create new opportunities. This framework is applied to a real estate business in Townsville, Australia; which, for confidentiality purposes, is referred to as company XYZ in the remainder of the paper.

## 2. Local Industry Environment

With the current trend to smaller families, people remaining single longer and the ageing population, there will be an ongoing need for residential accommodation and commercial business to service the population as it grows.

Townsville, North Queensland, in Australia enjoys a broad economic base which is underpinned by manufacturing, government administration, defense, port facilities, extensive educational facilities, a stable and ever increasing tourist industry, and a large self supporting retail sector.

Townsville and environs count in excess of 60 real estate agencies. Of these, at least 9 belong to major national and international franchise groups including L.J. Hooker, Century 21, Knight Frank and Ray White. In addition to the real estate firms, there are the residential land developers who provide about 900 newly developed blocks each year to service the Townsville market. The real estate firms also play a part in selling the residential land on behalf of the developers.

A further subset is the building industry which builds spec homes that the agents are engaged to sell. This generally results in a flow-on effect when the new home buyer looks to vacate the existing family home by selling it through an agent, and so the circle continues.

The real estate industry in each state has its representative body in the various Institutes, such as the Real Estate Institute of Queensland (REIQ) in Queensland. These disparate bodies tend to work independently of each other, and of the national body, the Australian Real Estate Institute. As a result, there are varying policies and procedures that make it difficult for agencies to reconcile. An example is the variety of key principles and guidelines that have been developed to accord with changes to the Australian Privacy Act.

Company XYZ consists of four offices, employing 25 staff. Each of the offices has an administrative officer who is responsible for day-to-day activities, receiving and redirecting inquiries, attending to agents needs and the preparation of sales documentation. In addition, there is a central administration manager who attends to the "business" of the business, that is payroll, financial management and maintenance of the rent roll.

The real estate wing of the value chain has a marketing manager who works with agents and the clients to ensure that the properties are featured in such a way as to gain maximum exposure and have maximum potential for sale. The marketing manager has graphic design and copy writing skills that are used in advertising and promotion of both the real estate business and the properties it represents.

A manager oversees the operations of the four offices, aided by an administrative assistant responsible for tasks such as preparation of routine correspondence, travel arrangements, appointments, compilation of statistical data for reporting and follow-up. A sales force of 17 real estate agents, directly accountable to the manager, completes the staffing requirement.

All sales people are employed under Australian Workplace Agreements that guarantee them a retainer and a share in the commission structure. Commission is charged to clients in accordance with the recommendations of the REIQ (5% of the first \$18,000 and 2.5% of the balance of the gross sales price for residential properties). Generally, negotiations take place on commercial property sales which can equate to between 1% and 2% on the gross sales price. The Principal of the company XYZ pays agents a 30% share of the normal commission, 20% on commercial sales, and negotiates commission on major commercial and industrial sales in excess of \$500,000. The company generally resists negotiating away the standard REIQ commission rate with residential vendors so as to maintain consistency.

In addition, there are unique share arrangements with land developers and builders, negotiated on an individual basis. The company 'conjuncts' on commission when a listed property is sold by another agency, and expects the same in return when it sells a property listed by another agency. The business also retains a rent roll.

A proposed organizational structure is shown below.

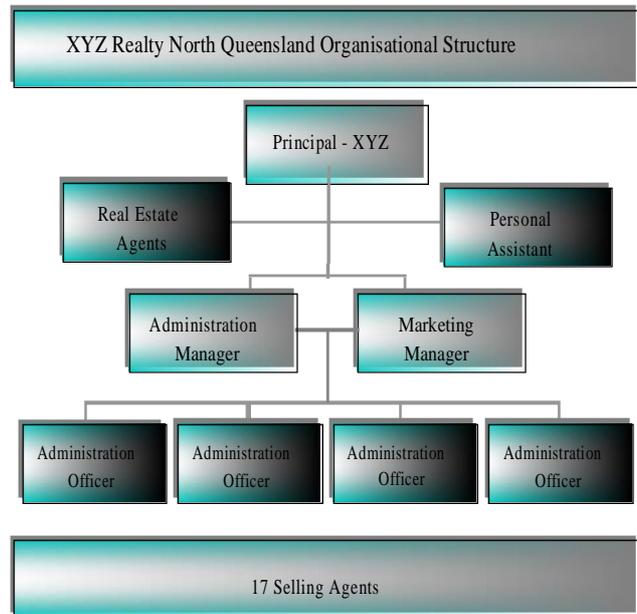

Fig 1: Company XYZ: organizational structure

XYZ currently services the residential market through the sale of existing houses, builders spec houses and its property management services. It also specializes in commercial and industrial property and vacant land sales on behalf of the developers. Initially, XYZ was established primarily on a platform of residential house sales that provided the majority of the revenue to the business, particularly in the early establishment phase. Moreover, Townsville is home to some 10,000 military personnel who are housed generally in rental accommodation owned by the Defence Housing Authority (DHA), or leased by the DHA from private owners. XYZ is one of a number of real estate agencies which provides real estate services to the DHA.

A natural extension to the residential unit was commercial sales, where more particular expertise is required to enable an understanding of turnover-, value-, and potential-issues, leading towards the hiring of specialist agents in this area on the sales team.

In addition to the above revenue streams, XYZ has a rent roll of some 1,000 properties. This is managed primarily by the Principal, with the assistance of the office manager, who undertakes the day-do-day administrative functions, inspections and maintenance arrangements. XYZ realizes a 7.5% management fee on all rental payments, as well as a commission fee for the arrangement of maintenance services to the properties. XYZ is also the managing agent for two neighbourhood shopping centres in Townsville, for which a management fee is paid, based on a percentage of tenancy rent.

XYZ is looking at further expanding its business into areas such as entrepreneurial activities, project management, financial planning and lending services to complement the current business activities.

### 3. Transitional Framework

#### 3.1 STAGE 1: Strategic Audit

For this purpose, Porter's Five Forces Model of Competition [10] could be adapted with a SWOT analysis into a TOWS Matrix [9], asking two critical questions: First, what is the structure of the industry, and how is it likely to evolve over time: Second, what is the company's relative position in the industry?

The TOWS Matrix, shown below, is the Threats-Opportunities-Weaknesses-Strengths matrix that enables an organization to assess the best strategies after assessing how the strengths, weaknesses, opportunities and threats relate to each other and how they can be used to highlight areas that need an avoidance strategy and areas that offer advantages. For instance XYZ's decentralized system and geographic spread allows it to serve communities across the Townsville region and take advantage of local neighbourhood opportunities because of its in-situ status. This would fall into the SO Strategies Square.

	<b>Strengths (S)</b> List Strengths (1 Æ 10)	<b>Weaknesses (W)</b> List Weaknesses (1 Æ 10)
<b>Opportunities (O)</b> List Opportunities (1 Æ 10)	<b>SO Strategies</b> Use Strengths to take advantage of Opportunities	<b>WO Strategies</b> Overcome Weaknesses by taking advantage of Opportunities
<b>Threats (T)</b> List Threats (1 Æ 10)	<b>ST Strategies</b> Use Strengths to avoid Threats	<b>WT Strategies</b> Minimize Weaknesses to avoid Threats

Fig 2: Company XYZ : TOWS matrix structure (source: Miller, A., 1998)

This results in the preparation of a blueprint that maps out where the company is going over the next five years. Underpinning the strategic plan must be a business plan which details the operational allocation for the activities

planned for the next year including goals, objectives, financial allocation, key performance measures and projected outcomes. In addition, monthly short-term plans are developed for company reporting, including sales figures, listings and financial performance.

Strategic information systems can be viewed as one of four types in a step-wise progression [11]:

Step 1: Those that share information via technology based systems with customers/consumers/ and/or suppliers and change the nature of the relationship.

Step 2: Those that produce more effective integration of the use of information in the organization's value adding process.

Step 3: Those that enable the organization to develop, produce, market and deliver new or enhanced products or services based on information.

Step 4: Those that provide executive management with information to support the development and implementation of strategy (in particular, where relevant external and internal information were integrated in analysis).

The move towards an e-business enabled agency can therefore be seen as a progression to step 3, and eventually step 4 in the information systems strategy.

#### 3.2 STAGE 2: Development Of An E-business Case

An e-Business case must be systematically assembled to enable a clear and concise plan to be formulated from the following questions:

Strategic justification: "Where are we going?"

Operational justification: "How will we get there?"

Technical justification: "When will we get there?"

Financial justification: "Why we will win?"

Collaborative justification: "Who will we be taking with us?"

To successfully create an inter-enterprise community it is necessary to examine the links organizations have with one another, with the strategy for capturing electronic channels [8].

The methodology includes the following steps:

Define power relationships among the various players and stakeholders.

Map out the extended enterprise to include suppliers, buyers and strategic partners.

Plan the electronic channels to deliver the information component of products and services.

The discussion of how to gain power raises two important questions:

How might alliances with other firms across industries or even with competitors help us?

How do we need to restructure ourselves to seize the opportunity or ward off a threat?

Participants in the inter-enterprise organization of Company XYZ are shown in Figure 3 below:

Inside Partners	Nearside Partners	Network Partners
Information Technology Providers Agents Administrative Staff Management	Buyers Sellers Landlords Tenants Solicitors Conveyancers Real Estate Agents Purchasers' Financial Institutions Vendors' Financial Institutions	Councils Land Titles Office Office of State Revenue Other Government Departments (eg. Main Roads, Contaminated Sites Registry) Insurers Telephone Companies Electricity Companies Newspaper Delivery Army housing etc.

Fig 3: Partners of collaborative inter-enterprise organization of company XYZ

These strategic partners are classified as inside partners, nearside partners, and network partners [1]:

Inside partners; those required for the development and support of the business plan.

Nearside partners; those that will assist in the tactical implementation.

Network partners; that will assist and enable the business model but will not require close day-to-day or strategic coordination

Each of these partnerships is elaborated on next:

### 3.2.1 Inside Partners – systems architecture

These partners are sourced for building or modifying the architecture required to create an e-business extended enterprise for the real estate agency. Issues that need to be explored when choosing this partner include:

Experience – how many marketplaces have they built so far, what is the transaction flow through those marketplaces, how do they compare to what company XYZ is intending to build?

Ownership – What is the company structure? Can XYZ buy into the partner company, giving them an equity position and a say in the future direction and management of company XYZ?

Cost – what is the total cost? XYZ-benchmarks need to be set, and limits of exposure established, so that the expense doesn't spiral out of control.

Integration – the new marketplace needs to be fully integrated into the other applications within the company,

such as any legacy systems, and new off-the-shelf applications [3].

### 3.2.2 Nearside Partners - The Selling Process

Nearside partners in the real estate selling process are financiers, conveyancers, and valuers. By integrating the processes and workflows of these partners, XYZ can provide a faster and more efficient service to customers. For example, when a sales agent executes a sales contract, a workflow is generated for the conveyancers to conduct a title search on the property. This title search is raised only once, and is stored online so that it can be 'shared' by all three parties. Currently, all three would conduct their own search independently of one another, and pass on the cost to the customer. (\$12.60 per search). Using EDI, each of the partners can access and use a secure section of the system to post and track information required to complete the transaction. By combining and coordinating all the aspects of the process, a more efficient and cost effective customer delivery channel is created. Savings from these synergies can be treated as a benefit to the individual partners bottom line, or used to generate increased market share through packaged incentives, such as a finance/conveyance package.

### 3.2.3 Nearside Partners - The Rent Roll

These include trades people, cleaners and general maintenance services, providing services to both landlords and tenants. Landlord and tenants can go online and choose one of the service providers listed, and detail the specific job that is required.

Again, a workflow is created, allocating the job to the required service provider. Payment for the service is coordinated, yielding a commission to XYZ for its involvement. By incorporating the service provider into the workflow management, it enables XYZ to maintain control over supply and the level of the service delivery offered. By providing consistent and effective service delivery to its tenants and landlords, XYZ creates customer loyalty.

An integrated CRM system collates the data of services used, and prompts future potential business. For example, twelve months ago a landlord used one of XYZ maintenance services to clean the gutters on their rental property. The CRM system raises an event notification that sends an automated response letter to the landlord asking if they would like XYZ to arrange to have the gutters cleaned again. The letter requests the landlord to either log in on XYZ's secure web site, or call a customer service representative. The landlord is pleased at the level of service, the service partner is happy for the additional work, and XYZ has generated some additional revenue.

### 3.2.4 Network Partners – External Support

Network partners include organizations, such as the local authority and other statutory bodies involved in the

industry, i.e. the urban land development committee, media and industry associations, and the like.

After partners have been selected, a program of ongoing measurement needs to be developed to ensure that the partnership is the best possible for the desired outcome, and that all partners are embracing the common goals of the alliance.

### 3.3 STAGE 3: Systems Analysis Team

Company XYZ's systems analysis team consists of:

The principal (to keep the all on task and focused on desired company directions)

The administration manager (for practical advice and input in relation to the historical operation of the business)

The marketing manager (to sell the product to strategic partners, both during the development and implementation phases)

A senior sales agent (to provide input from their field experiences)

An IT consultant (to advise on appropriate software, hardware and interactive web site design)

Management consultants (to undertake customer/staff surveys, facilitate focus groups, liaise with preferred strategic partners, facilitate change management and training issues)

A scribe or person (to record all activities of the project meetings)

End-user representation (to provide agent/customer input and feedback)

### 3.4 STAGE 4: System Architecture And Infrastructure

Company XYZ currently operates with independent computer systems located at each of the offices. The systems communicate via email. Financial management is carried out at the main office, with little feedback to the branch offices. Development of systems architecture and infrastructure is required to support the inter-enterprise e-business initiative.

A local area network (LAN) is to be set up between the branch offices, the main office, and participating partners, enabled by ISDN data links to form a wide area network (WAN), and designed to incorporate G3 wireless application protocol (WAP) devices. In the main office, an application server is to be installed. Data sources include:

General public queries on available properties and data requests from strategic partners

Queries and requests of owners of properties managed by XYZ.

Field data and requests from sales agents (through notebook computers, PC's, WAP devices, etc.)

Requests, links, and feedback from government agencies and regulators.

A number of legislative issues, as they relate to XYZ, for future attention and integration into the new e-business enabled platform include:

Retail Shop Leases Act 1994

Residential Tenancies Act 1994

Property Agents and Motor Dealers Act 2000 Code of Conduct

Land Act 1994

Duties Act 2000

Privacy Act 1988

Auctioneers and Agents Act 1971

Electronic Transactions Act 2000

Trust Accounts Act 1973

Property Law Act 1974

Land Titles Act 1994

Land Sales Act 1984

Traffic Infrastructure (Roads) Act 1991

Integrated Planning Act 1997

Fair Trading Regulation 2001

Anti Discrimination Act 1991

XYZ staff must become cognisant of consumer and contract law as it applies to the real estate industry. For example, the company's trade practices and consumer protection responsibilities, issues covered by intellectual property, copyright and patents legislation and its responsibilities in relation to keeping and reporting against a Trust Account, Local Authority regulations regarding services, requirements and charges, such as cost of rates, water and water allocation, and even rubbish collection days.

National Privacy Principles need to be integrated into the new platform. The discussion about privacy essentially encompasses those things that a company can and cannot do with personal information. "Personal Information" is information from which a person can be identified either by use of their name or a description of them or their circumstances.

The Privacy Act regulates the way personal information is handled at all stages. This includes:

How the information is collected

How the information is used

To whom the information is disclosed

How the information is handled and stored

When the information is destroyed

In this context "privacy" is distinguished from security and confidentiality. "Security" relates to the way in which personal information in a system, (either manual or computerize, is protected from misuse and loss and from unauthorized access, modification or disclosure. "Confidentiality" relates to the secrecy afforded to particular information and prevents its disclosure in certain circumstances. Whilst security and confidentiality go hand in hand in protecting information, privacy is broader and covers the whole "information lifecycle".

As was illustrated above, strategic partners operate within a complex legislative structure, which must be adopted across the network of partners.

#### 4. Web Interface Design

The web interface links the real estate customer to the inter-enterprise organization, and is the 'front end' basis of a new e-business model for the company XYZ.

In this context, XYZ must meet specific web design criteria. It must work with its web design project team and develop its initial site design. The QFD model, proposed by Hamilton and Selen, (2002) [4] may provide a starting point for determining the initial design parameters. The web site design incorporates active learning [6] to enhance interest and marketability.

A detailed specification is prepared in consultation with the web designer and the XYZ Systems Analysis Team to ensure that all the criteria are addressed and included.

The XYZ Systems Analysis Team must consider a variety of web related features, including:

- Web Site Design, Site Hosting and Web Metrics
- Network and Database Management
- Training, Support and Site Management
- Web Content Management Solution
- Multi-channel/Systems Integration
- The Customer's Online Experience
- Bulletin Boards and Event Calendars
- Real Estate Listing, Ordering, and Editing
- Maps, GIS and Visuals
- Cost of Mortgage Calculators
- Solicitors, Schools, Medical Facilities, Shops, Community Organizations, Transport, etc
- Relevant Databases
- Finance and Legal Details
- Purchase, Rental, Facility Management and Lease Data
- Allowed Transactions
- Ethics and Security.

The following simple questions will determine if a Web page is well designed:

How quickly does it download?

How easy is it to navigate?

How well does the search work?

How readable is the content?

Is the page and the content uncluttered and appealing?

Real Estate is ideally suited to a daily changing web page, incorporating the movement, addition and deletion of properties for sale; informative articles; and tips and hints to prospective customers. Web page maintenance and continuous updating is an absolute imperative.

Customer needs must be efficiently communicated through multiple integrated channels. XYZ must set up seamless complementary interactions between traditional and e-channels; the telephone, facsimile, face to face, web, email. Channels other than face-to-face are to be seen as facilitators. For example, a client may value the

ability to have a comprehensive description of a property with some photographs available online but this will rarely replace a physical examination of the property. In order to secure sales, XYZ must 'push' clients towards physical visits of properties and completion of sales transactions.

The web interface must seek to use existing relationships to grow revenue, use integrated information from all channels for service excellence, and facilitate the provision of consistent replicable multi-channel processes and procedures.

All of the interfaces (and the systems supporting it) should be totally client focused. A number of access points within the e-business enabled real estate agency are elaborated on below:

##### 4.1 XYZ Main Office Staff Resident Application Server

Administrative staff, sales staff and management in the central office access the application through the LAN and WAN for operating the business and for the purpose of administration, sales and rent roll maintenance.

##### 4.2 XYZ Staff Company Application Server

Administrative staff, sales staff and management in the other three offices access the company application server over the ISDN line for day-to-day needs for operating the business and for the purpose of sales and administration.

##### 4.3 XYZ Staff Remote Application Server

Generally remote access will be undertaken by sales agents from notebook computers to access contract templates for sales, as well as statistical data to assist sales.

##### 4.4 Restricted Access

Some areas would require authentication and only be accessible by a restricted group of users. For example, property owners may be able to access restricted sections of the site to view rent collection, management fee payments and allow them to "order" a service such as plumber or gardener. The system will notify XYZ of the request, which will then be arranged and subsequently charged to the property owner's account with a commission payment for the service to XYZ. Other examples include participants to a conveyance accessing a common conveyance 'file', and updating or retrieving information.

##### 4.5 General Public Access

This is the strategic "face" of the organization, the public part of the company's online presence.

The customer must be able to readily tailor and select services and goods to meet their wants. The authors

recently developed an approach for segmenting markets and development of a dynamic web interface for this purpose [4],[5].

Furthermore, the e-business system allows for product customization, pricing and contract management, quote and proposal generation, appropriate commission agreements and promotion management. These require the interfaces with the client to be flexible, as well as information gathering and execution focused.

It must integrate customer content, contact information, end-to-end business processes, extended enterprises or partners (providing inter-enterprise customer care) and all customer applications (such as telephony). It must be focused towards opportunity creation and tracking [7].

Two extreme examples of possible interface interactions are described as they apply to XYZ:

#### Example 1:

A member of the public is looking for a property in a particular suburb. A click on the suburb will bring up the Graphical Information System (GIS) interface or electronic map that is pre-loaded with all properties available for sale.

The potential customer can then click on social infrastructure find out what parks, schools, churches etc are in the immediate area. The road network layer can be displayed and local shopping centres and other areas of interest.

Once the customer has decided on the area of interest, a click on the GIS locator will display details of properties for sale. For instance, if the area in Smith Street appeals to the customer, a click on the house for sale in that street will result in a photograph of the house being presented on the screen with a drop down box in which the customer can choose to see the price, the size of the land, location of services (sewerage etc) and perhaps a layout plan of the house.

#### Example 2:

If, however, the customer is looking for a house in a certain price range, then a form can be presented with drop down boxes allowing a choice of queries to be entered to match the customer's criteria, e.g. between \$200,000 and \$250,000; three bedrooms with ensuite and double garage. All of the houses in Townsville listed with XYZ and matching those criteria will then be presented for further investigation.

From there the customer can choose a house and retrieve the photograph and details through the GIS interface described above.

As the customer moves from this web-interface area, a screen should be triggered inviting the customer to enter details of name and contact for enable follow-up. This follow-up occurs in a timely manner, such that sales agents take over with the personal touch to provide further information and make inspection arrangements with a view to completing a sale, deploying internet enabled laptops and WAP devices.

## 5. Conclusion

A framework was developed to enable transition from a typical real estate agency towards an e-business enabled business environment, based on an agency configuration located in Townsville, Australia. This transition was modeled according to a number of stages, including a strategic audit, development of an e-business case, the setting up of a systems analysis team, discussion of the system architecture and infrastructure, and finally the Web interface- design .

## Abstract

In this paper, we examine the impact of actor-network field on value creation by integrating the concepts of actor-network and organizational field. In electronic business and commerce, researchers have emphasized the various sources of value creation, yet little attention has been paid to examine the issue from a cognitive or “field” perspective. Using Trend Micro as a case study, the paper demonstrates how a firm can construct a field in the community of Internet to create value and profits. Our approach and analysis are dynamic, rather than static. We show how Trend Micro is able to drive its associated actors, customers and business members to develop an evolutionary, dynamic actor-network field that serves to decrease uncertainty and increase trust. This, in turn, creates a lock-in effect and thus leads to enormous value creation.

Keywords: Actor-network Field, Trend Micro, E-Business, Case Study

## 1. Introduction

The rise of the Internet creates many advantages for e-business, particularly in increasing value [1] between transaction parties. The study, based on institutional theory [9,29], explains how organizations use the Internet to construct an effective institution or field to create value. According to Williamson [35] and Coase [7], this paper regards the source of value creation as efficiency increase and uncertainty decrease. We also observe the value creation is not a static process but a dynamic evolution.

Although some of the new institutionalism theorists argued the focus of institutional theory is on stability [e.g., 13,15,32] the alternative school of institutional theory stresses on the importance of institutional change [e.g., 3,5,8,26]. Especially, as Greenwood, Suddaby, and Hinings [14: 58] noted, most of the previous studies of field emphasized much less on field dynamics to understand “how and why institutionalized practices within a field atrophy or change.” Lawrence, Winn, and Jennings [21] further proposed adding the temporal characteristic is necessary for investigations of the

dynamics of institutionalization. In the case of Trend Micro, the institutionalized process at a field level is a dynamic process. Particularly, the rise of information technology such as the Internet per se means a dramatic change; it has substantial implication for organizational network forms [28]. Based on the approaches of institutional dynamic, we thus consider the institutional theory is applicable to exploring the effect of field change on value creation.

According to the revenue of Trend Micro from 1991 to 1999 (see Figure 1), we find an interesting phenomenon. That is, the growth of revenue is practically slow before 1995; however, the growth of revenue is soaring after 1995. The dramatic change is due to the rise of the Internet, which forms the division of two entirely different actor-network fields of Trend Micro: off-line actor-network field before and on-line actor-network field after the emergence of the Internet. The on-line actor-network field, providing an efficient and integrated on-line anti-virus service, accelerates the great growth of revenue. This leads us to understanding how Trend Micro uses an on-line actor-network field to create value.

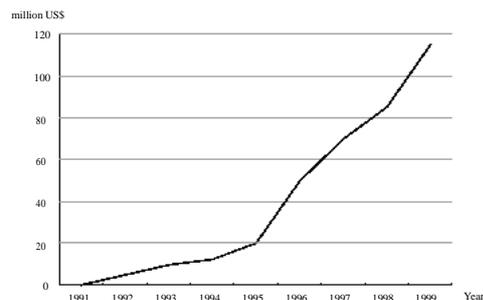

Figure 1. Revenues of Trend Micro from 1991 to 1999

(Data source: @Trend, 1999)

In this paper, we first propose an important construct of actor-network field and hold that the evolution of actor-network field is a dynamic process. Second, this study argues that organizations could effectively use the Internet to construct an on-line actor-network field, which manages and provides a collective recognized interactive model, to reduce environmental uncertainty, increase efficiency, and finally create value between actors. These arguments are shown in Figure 2. An on-line

actor-network field, based on the concepts of both organizational field and actor-network, enables actors of the field to follow the new rules, belief, and technical systems to create the shared values. Furthermore, we use a single case study of Trend Micro to clarify these arguments and to explain how the organization uses the Internet to construct an on-line actor-network field and to create value.

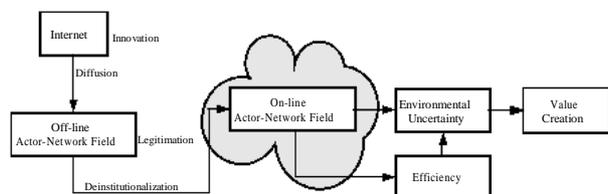

Figure 2. Conceptual model of the value creation

The paper is organized into three sections. First, we discuss the institutionalized process and the construct of actor-network field; also, we explore the relationship between on-line actor-network field and value creation. Second, the method and data of this study are introduced. Next, we analyze the value creation by Trend Micro. Finally, we summarize the results and contributions, and propose implications for firm strategies.

## 2. Theoretical Background

Lawrence, Winn, and Jennings [21] indicate “the process of institutionalization: objects are first recognized, then accepted by relatively few actors, and then widely diffused and broadly accepted within a field,” and finally reach to saturation and complete legitimacy [38]. During the institutionalized process, the concept of diffusion is viewed as a process in which an initial idea is transmitted in a social world [19], and consists the notion of searching legitimation of organizations [3]. Lawrence, Winn, and Jennings [21] hence suggested that institutionalization begin at the emergence of the new innovation such as new practices, rules, or technologies, and end prior to deinstitutionalization. The process of institutionalization, that is, an innovation at birth, is diffused, and then remains diffuseness throughout the field, and finally establishes legitimation.

For the discussion of field, we focused on a new term of field, namely, an actor-network field, based on the two constructs of “actor-network” [6,18,20] and “organizational field” [9]. Organizational field is defined by DiMaggio and Powell [9: 148] as “organizations that, in the aggregate, constitute a recognized area of institutional life: key suppliers, resources and product customers, regulatory agencies, and other organizations that provide similar services or products.” In other words, organizational field, a large and dynamic network, concerns the relationships between members and then

shapes an institution that affects the members of the field [3]. The concept of organizational field is also defined as “a set of equivalent firms that all produce the same product or service” [1]. Boons and Strannegård [3] suggested that the actors, in an organizational field, adapt to and contribute to the pressures and values of the field, and thus help materialize the characteristics of the organizational field. The organizational actors constituted an organizational field around a central issue and they had more interaction than the organizations outside the field [29,15]. The choices of organizational action, therefore, are not only determined by internal arrangements of organizations but also determined by the legitimate options defined by the actors in a field [29]. Greenwood and Hinings [13], additionally, stated that the organizational field is considered as with a taken-for-granted quality, which enables organizational actors to unconsciously accept the prevailing template as an appropriate, right, and proper way of doing things.

However, the organizational field concept is insufficiently attuned to all the possible actors’ relationships within a field. As [11] proposed the critique: institutional analysis disregards individual actors. DiMaggio and Powell [10] also recognized the institutional theory neglects the analysis of adding individual actors. The members of an organizational field are often organizations, but the actors of field are, rigidly defined, not only organizations but also, probably, individual actors. Because the “resources and product customers” [9] within a field is not solely the participating business customers; the individual actors might be also the significant ones in the field.

In contrast, “actor-network field” concept, combining the two constructs of “actor-network” [6,18] and “organizational field” [9], explicitly highlights the analysis of the institution constructed by relations of all possible actors in a field. The actor-network concept, as proposed by Latour [18] and Callon [6], concerned about “how actors, human as well as nonhuman, become “convinced” that a technology, artifact, text, image, and so on, is real” [3]. This concept stresses that a stable actor-network is established from the interrelations of the actors’ common activities. As Latour [18] pointed out, the survival of an action network implies that it provides the actors’ identity and the network stability, in turn, accepted by actors. Boons and Strannegård [3] also argued that the goal of the network constructed by actors is for network stability. Nevertheless, the term, “actor-network,” would lack the implication of organizational field. As Scott [32] noted, the “network” would be depicted as the flows or linkages shaped by participants. In contrast, the field, a common channel of discussion and dialogue for actors [15], is an arena of institutional life [9].

This paper thus integrates the concepts of organizational field and of actor-network into the “actor-network field,” and concerns the institutional interaction network of all possible actors in a field, including organizations and individual actors. Furthermore, we define the “actor-network field” as the institutionalized life area [9], providing a common channel of discussion and dialogue [15] where actors, organizations or individual actors [6,20], in a dynamic network linkages [3,21], experience the shared values and pressures collectively [3,14], and then the established field also affects the actors of the field.

While a company uses the Internet to provide an effective and dependable service structure in actor-network field, the field will be formed an on-line actor-network field. The on-line actor-network field can be viewed as a reliable interactive institution for actors to lower environmental uncertainty. As North [25] noted, in an economic exchange environment, institutions are dependable and efficient frameworks so that institutions could contribute to uncertainty reductions. Furthermore, the on-line actor-network field also has the efficient property conducting to environmental uncertainty decrease and value creation.

### 3. Method and Data

#### 3.1 Research Strategy and Sample

In this study, we choose Trend Micro as a single case study to explore the unique phenomenon of value creation, which is through on-line actor-network field. Based on the two reasons as follows, this study draws on Trend Micro as a single case study. First, for anti-virus service firms, especially anti-virus e-business firms, Trend Micro can be a business with considerable competitive advantages over the globe. Second, the Internet swept over Trend Micro in 1995, which displayed an interesting point of dramatic change of value creation in Trend Micro. These subtle phenomena lead us to explore the real cause of the remarkable achievement.

#### 3.2 Data Collection

Data collection, data analysis, and conceptualization are hard to be divided in the process of investigation, so we also adopt the principle of iterative of Glaser and Strauss [12] in the process of data collection. The closure point of data collection in this paper is when theoretical saturation [12] is reached.

Besides, to increase the construct validity of this paper, according to the principle of data collection as Yin [37] suggested, we use multiple sources of evidence. First, we collect the secondary data through Trend Micro’s webs and current press information to preliminarily gather the

historical events in Trend Micro. Second, because of the incomplete information in the first stage, we use focused interviews [24] and e-mails to fill the gap of historical events in Trend Micro to collect the first data. Five staff of Trend Micro, whose positions are marketing managers, sales manager, product manager, and the producer of web site of Trend Micro, respectively, are interviewed. Besides, we also receive and review the manuals of products and partners of Trend Micro with the assistance of these interviewees. These data are helpful to reconstruct all the evidence. The means we use is founded on the method of “triangulation” proposed by Patton [27] to develop the convergence of multiple sources of evidence and heighten construct validity [37].

Moreover, to increase the reliability of the information in the case study, this study establishes “a chain of evidence” [37] to illustrate the exploring process of a question, evidence, and results. This outcome of the exploring process is respectively pictured in Figure 1, Figure 3, and Figure 4.

#### 3.3 Data Analysis

In data analysis, this paper uses the two analytical techniques of “time-series” and “pattern-matching” [37]. In the first stage of analysis, we use the analytical technique of chronologies, a special form of time-series analysis. Yin [37] proposed allocating events in a chronology can make researchers clearly understand the causal relationship of events in a specific period.

In the second stage of analysis, the technique of “pattern-matching” is employed. This technique compares the consistence between an empirical pattern and the pattern of theoretical proposition. Yin [37] further argued if the two patterns coincide, it can reinforce internal validity.

In next section we discuss the evolution of Trend Micro in a longitudinal approach. Also, the detailed discovery showing the causal relationship between on-line actor-network field and value creation is illustrated in the following sections.

### 4. The Analysis of Value Creation by Trend Micro

This paper collects and chronicles the historic events in Trend Micro, as shown in Table 1. We employ a longitudinal approach to analyze the historic events in Trend Micro by dividing them into four stages: (1) the stage of foundations: 1988-1989; (2) the stage of independent anti-virus product development: 1990-1994; (3) the stage of expanding Internet anti-virus service: 1995-1998; and (4) the stage of integrated Internet service: 1999-2002. We further analyze and illustrate the

four periods of value creation by Trend Micro (see Figure 3).

Table 1. The chronology in Trend Micro

Year	Historic events
2001	Market HouseCall, integrated with the patent of Trojan System Cleaner.
2001	Market PC-cillin2002.
2000	Ally itself with UniSVR Corporation providing eDoctor anti-virus outsourcing service.
1999	Market “eManager” software for e-mails security management.
1999	Market “WebManager” software for webs security management.
1999	Establish five eDoctor laboratories, in America, Germany, Taiwan, Japan, and the Philippines; undertake the local eDoctor business.
1999	Unveil “eDoctor” anti-virus outsourcing service.
1998	Unveil “Trend Virus Control SystemTM.”
1997	“On The Fly” was granted American technological patent.
1996	Unveil InterScan VirusWall.
1996	Unveil the anti-virus system of “ScanMail for Exchange” for Microsoft Exchange Server.
1996	Unveil InterScan WebProtect, a group software anti-virus system.
1996	Develop the patent technology of “Macro TrapTM” to intercept and clean the unknown document macro viruses.
1996	Develop ScanMail for Lotus Notes.
1996	Market HouseCall for on-line scan virus.
1995	Unveil PC-cillin95.
1994	Unveil “Mobile Protect” system.
1994	Ally itself with Intel to market “Intel LANDesk Virus Protect” and provide the network security and anti-virus technology for Intel.
1993	Unveil StationLock, an interface card designed for anti-virus and access control.
1992	Develop “Chipaway Virus”; Intel integrated “Chipaway Virus” into the network card of Ethernet Express 16.
1991	“Server Protect,” an anti-virus core technology, was authorized to Intel and marketed to European and America by the renamed brand of ‘LANDesk Virus Protect’.
1990	Market PC-cillin.
1988	Founded in California USA; use a “rule-based” method of the monitor viruses’ behavior to detect the unknown viruses.

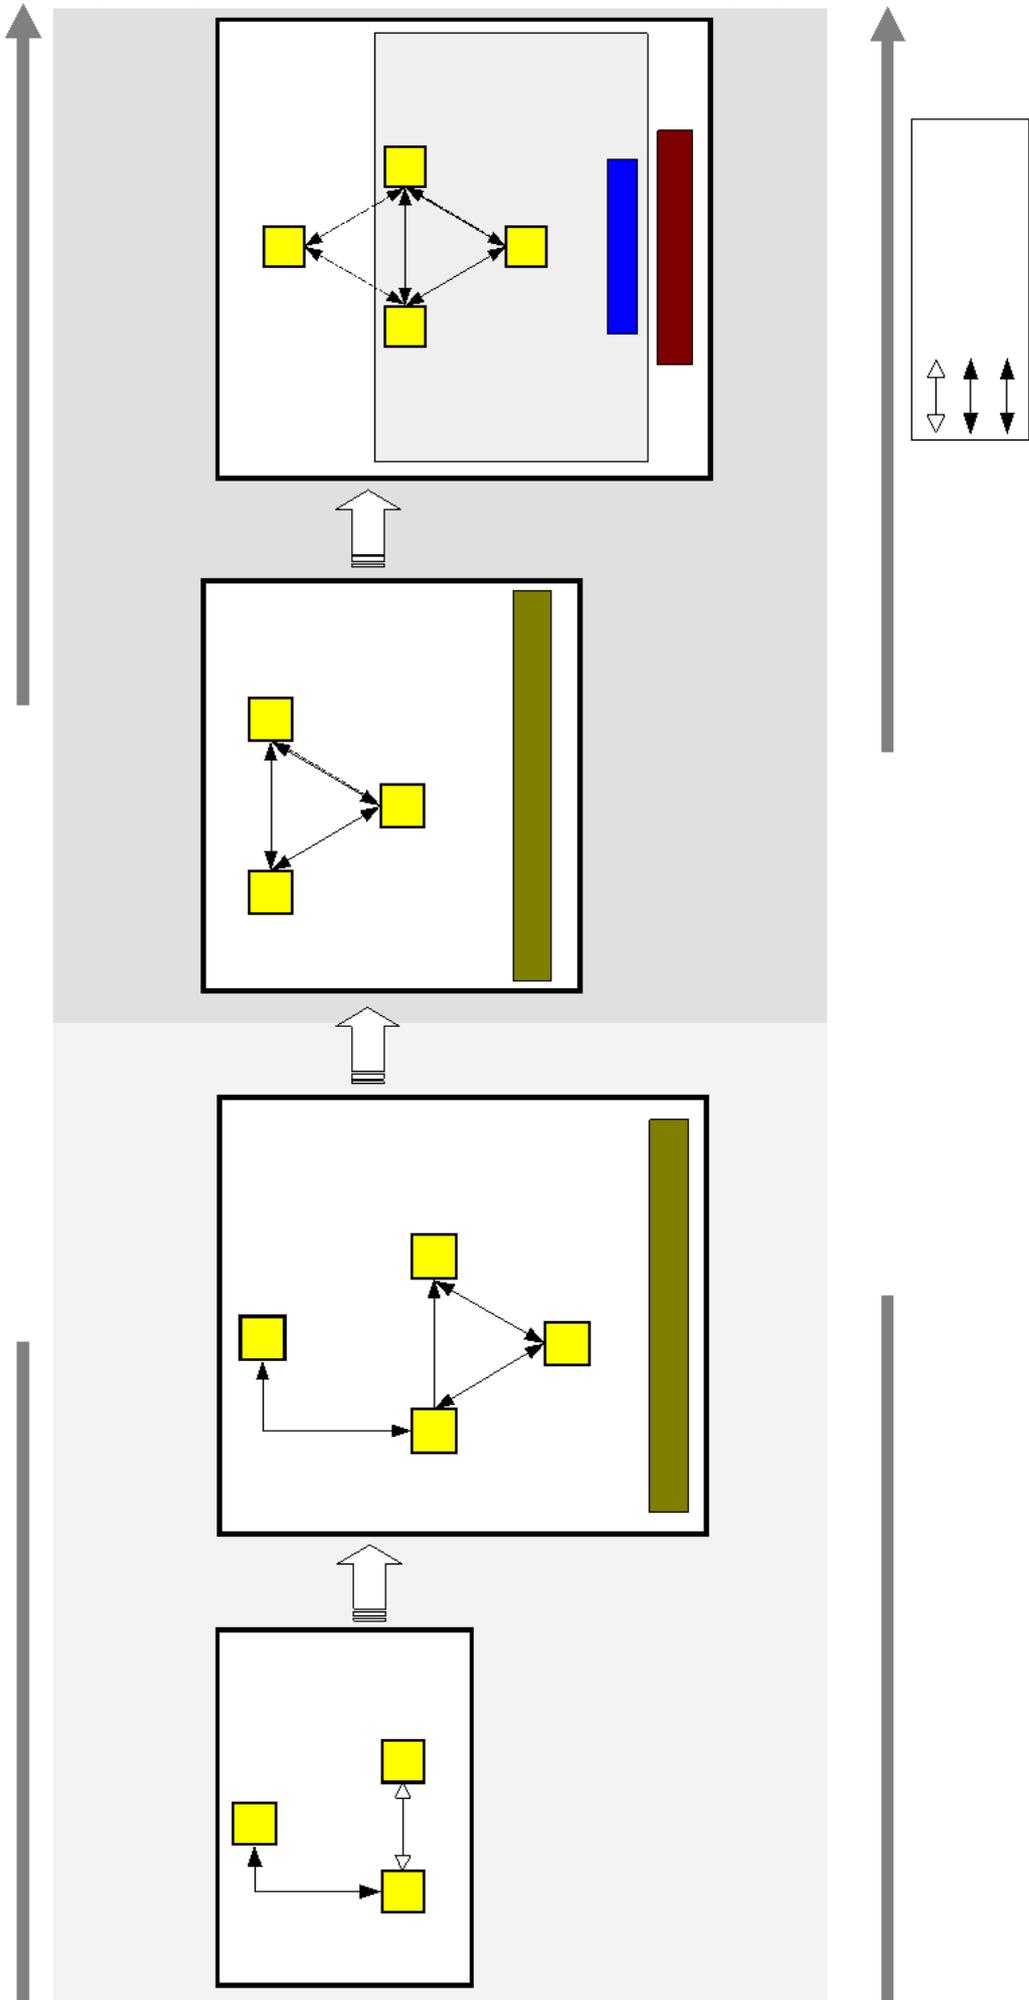

#### 4.1 The stage of foundations, 1988-1989

The actor-network field of Trend Micro in this period is shown as Stage I in Figure 3. In this period, Trend Micro did not really launch the anti-virus business. The focus of the business strategy was on allying itself with an anti-pirated software firm such as Rainbow Technologies Corporation in order to establish the business foundations. Although the boot-type virus happened to rise, it had no serious impact on businesses and end-users. The computer users, hence, were not significantly influenced by the uncertainty of virus attack. On the other hand, PC-cillin did not come to the market in this stage, though this product was successfully developed. Trend Micro with its customers, consequently, did not construct a recognized actor-network field.

#### 4.2 The stage of independent anti-virus product development, 1990-1994

The actor-network field of Trend Micro in this period is shown as Stage II in Figure 3. There are two focuses of the business strategy in this phase. First, Trend Micro allied itself with such computer hardware companies as Intel to enhance the reputation of Trend Micro in

America. Second, it established the PC-cillin agencies through the world to expand the market channels. In this period, Macro viruses happened to appear; meanwhile, Trend Micro’s anti-virus service provided the mailing service of the quarterly-updated computer virus codes. This practice was accompanied with two shortcomings. First, the uncertainty of virus attack that customers met was increasing between updating services of virus codes. Second, the cost of mail service was high between transaction parties. For service organizations, it is essential that they deliver the efficient service that could create advantages and economize associated costs [16]. However, according to the inefficient off-line actor-network field of Trend Micro and its parties, the type of field failed to effectively decrease environmental uncertainty resulting from computer viruses. The performance of value creation during this period, accordingly, was defined as a value creation of low level.

### 4.3 The stage of expanding Internet anti-virus service, 1995-1998

The actor-network field of Trend Micro in this period is shown as Stage III in Figure 3. In this period, the focus of business strategy was on Internet anti-virus service. Hence, it significantly changed the actor-network field of Trend Micro with its parties. For example, in 1995, Trend Micro developed the technique of 'One Button Update' that customers could update the computer virus codes on the Internet in real time. In 1996, Trend Micro developed a series of anti-virus products for enterprises such as OfficeScan, ScanMail for Exchange, InterScan VirusWall, and InterScan WebProtect. In 1998, Trend Micro developed Trend Virus Control System (TVCS), a centralized management platform, which enabled the information management department to setup, monitor, and manage all anti-virus softwares. The Internet anti-virus services or products lead to an efficient on-line actor-network field and regulate the behaviors of the field members in a recognized interactive institution. This kind of field, therefore, can decrease environmental uncertainty caused by viruses. As argued in [25], institutions are characterized with dependable and efficient frameworks in order that they can help reduce uncertainty. Many studies also show the evidence that the Internet could be employed to accelerate the service delivery and reduce service costs and uncertainty [e.g., 4,16,23,34]. The performance of value creation in this period, accordingly, was defined as a value creation of middle-high level.

### 4.4 The stage of integrated Internet service, 1999-2002

The actor-network field of Trend Micro in this period is shown as Stage IV in Figure 3. In this period, Trend Micro continued to provide the Internet anti-virus pattern of the last period for their end-user customers; moreover, Trend Micro provided a more integrated anti-virus Internet service. For example, PC-cillin2002 not only has the functions of the previous editions but also incorporates the function of the personal firewall. That is, end-user customers in the on-line actor-network field have access to services of efficiency and decreased uncertainty of virus attack owing to a more integrated Internet service actor-network field. For business customers, the focus business strategy of Trend Micro was on using eDoctor service to provide an integrated Internet anti-virus service. eDoctor offers the OfficeScan, ServerProtect, ScanMail, InterScan VirusWall and Trend Virus Control System with authorization. Business customers obtained eDoctor anti-virus service from

eDoctor service center, whose anti-virus technology was supported by Trend Micro. Wise and Morrison [36] showed businesses need to consider how to lower uncertainty, e.g., "Which exchanges should we participate in?" or "What software should we invest in?" Besides, due to the devotion to IT activities involving uncertainty, organizations need to decide which IT activities should stay in-house and which should outsource to the specific expert parties [22]. Lacity and Willcocks [17] suggested that selective IT sourcing be the most contribution to cost reduction among the three alternatives of total insourcing, total outsourcing, and selective sourcing. According to the implication of these authors' arguments, if a business can provide an integrated service for its customers and customers choose selective IT sourcing, it could decrease uncertainty through customers' neglect. The eDoctor and PC-cillin2002 integrated the Internet anti-virus service, thus a more institutionalized and efficient on-line actor-network field that further significantly lowered the uncertainty of virus attack. The performance of value creation during this period, accordingly, was defined as a value creation of high level.

## 5. Results and Conclusions

Based on the theoretical and empirical discussion, we illustrate the results of analysis as shown in Figure 4. Figure 4 shows the processes and results of Trend Micro using the on-line actor-network to create transaction value. The evolution process is from 1987 to 2002. In the period, the three main types of computer virus appeared, i.e. the boot-type virus, the macro virus, and the e-mail virus. In the first stage of this case, from 1988 to 1989, the boot-type viruses appeared. In the second stage, from 1990 to 1994, the macro virus emerged.

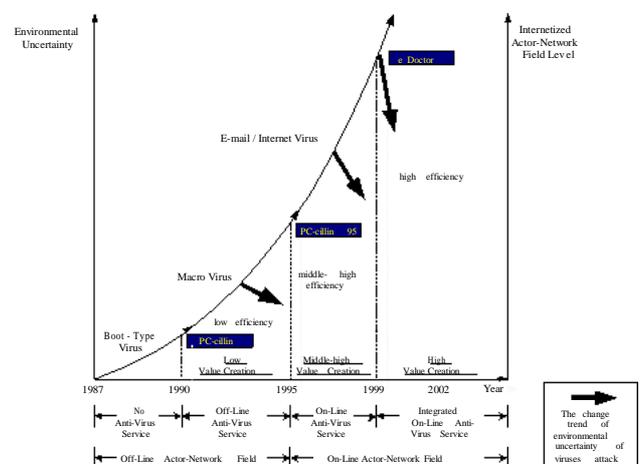

Figure 4. The curve of create value of Trend Micro

And in the third and fourth stages, from 1995 until

now, the most popular type of virus is the e-mail virus. The boundaries of these stages are just the emergence of three representative products, PC-cillin, PC-cillin 95, and eDoctor. Before 1995, prior to the PC-cillin 95 entered the market; Trend Micro with its actors of the field remained an off-line actor-network field. The anti-virus service of this period is called “off-line anti-virus service.” After 1995, the PC-cillin 95, especially eDoctor, entered the market; Trend Micro with its actors of the field transforms an on-line actor-network field. From 1995 to 1999, the anti-virus service is called “on-line anti-virus service.” Since 1999, the anti-virus service has been called “integrated on-line anti-virus service.” The evolution of actor-network field also presents three levels of efficiency, three changing trends of environmental uncertainty of virus attack, and three levels of value creation. As the Internetized level of the on-line actor-network field increases, the environmental uncertainty of virus attack is continually decreased, the efficiency is unceasingly improved, and the value creation is thus constantly increased.

In sum, we argue that, first, the higher the level of the Internetized actor-network field, the lower the uncertainty of virus attack. Second, the higher the level of the Internetized actor-network field, the higher the efficiency in the anti-virus service. Third, the higher the efficiency in the anti-virus service, the lower the uncertainty of virus attack. Fourth, the higher the level of the integrated Internet anti-virus service, the lower the uncertainty of virus attack. Finally, the lower the uncertainty of virus attack, the higher value creation.

In the longitudinal analysis of this case study, we find that because the former off-line actor-network field of Trend Micro lacks efficiency in the first two stages, the transaction value could not be significantly increased. In contrast, the on-line actor-network field in the later two stages can lower the uncertainty of virus attack and further increase value creation in that it has high efficiency.

Consequently, this paper makes two contributions. First, we propose an important and novelty construct “actor-network field,” based on a perspective of dynamic evolution. Second, according to the case of Trend Micro, the important issue arises in this paper that organizations can effectively use the Internet to construct an on-line actor-network field to facilitate the reduction in uncertainty and finally contribute to the value creation between actors.

## Abstract

In this paper, we examine the impact of actor-network field on value creation by integrating the concepts of actor-network and organizational field. In electronic business and commerce, researchers have emphasized the various sources of value creation, yet little attention has been paid to examine the issue from a cognitive or “field” perspective. Using Trend Micro as a case study, the paper demonstrates how a firm can construct a field in the community of Internet to create value and profits. Our approach and analysis are dynamic, rather than static. We show how Trend Micro is able to drive its associated actors, customers and business members to develop an evolutionary, dynamic actor-network field that serves to decrease uncertainty and increase trust. This, in turn, creates a lock-in effect and thus leads to enormous value creation.

Keywords: Actor-network Field, Trend Micro, E-Business, Case Study

## 1. Introduction

The rise of the Internet creates many advantages for e-business, particularly in increasing value [1] between transaction parties. The study, based on institutional theory [9,29], explains how organizations use the Internet to construct an effective institution or field to create value. According to Williamson [35] and Coase [7], this paper regards the source of value creation as efficiency increase and uncertainty decrease. We also observe the value creation is not a static process but a dynamic evolution.

Although some of the new institutionalism theorists argued the focus of institutional theory is on stability [e.g., 13,15,32] the alternative school of institutional theory stresses on the importance of institutional change [e.g., 3,5,8,26]. Especially, as Greenwood, Suddaby, and Hinings [14: 58] noted, most of the previous studies of field emphasized much less on field dynamics to understand “how and why institutionalized practices within a field atrophy or change.” Lawrence, Winn, and Jennings [21] further proposed adding the temporal characteristic is necessary for investigations of the

dynamics of institutionalization. In the case of Trend Micro, the institutionalized process at a field level is a dynamic process. Particularly, the rise of information technology such as the Internet per se means a dramatic change; it has substantial implication for organizational network forms [28]. Based on the approaches of institutional dynamic, we thus consider the institutional theory is applicable to exploring the effect of field change on value creation.

According to the revenue of Trend Micro from 1991 to 1999 (see Figure 1), we find an interesting phenomenon. That is, the growth of revenue is practically slow before 1995; however, the growth of revenue is soaring after 1995. The dramatic change is due to the rise of the Internet, which forms the division of two entirely different actor-network fields of Trend Micro: off-line actor-network field before and on-line actor-network field after the emergence of the Internet. The on-line actor-network field, providing an efficient and integrated on-line anti-virus service, accelerates the great growth of revenue. This leads us to understanding how Trend Micro uses an on-line actor-network field to create value.

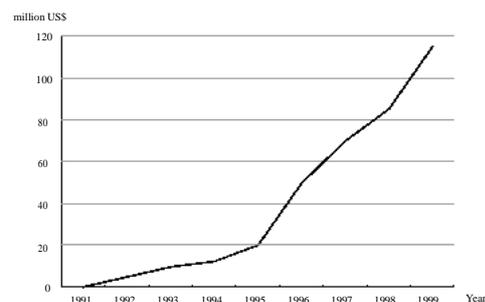

Figure 1. Revenues of Trend Micro from 1991 to 1999

(Data source: @Trend, 1999)

In this paper, we first propose an important construct of actor-network field and hold that the evolution of actor-network field is a dynamic process. Second, this study argues that organizations could effectively use the Internet to construct an on-line actor-network field, which manages and provides a collective recognized interactive model, to reduce environmental uncertainty, increase efficiency, and finally create value between actors. These arguments are shown in Figure 2. An on-line

actor-network field, based on the concepts of both organizational field and actor-network, enables actors of the field to follow the new rules, belief, and technical systems to create the shared values. Furthermore, we use a single case study of Trend Micro to clarify these arguments and to explain how the organization uses the Internet to construct an on-line actor-network field and to create value.

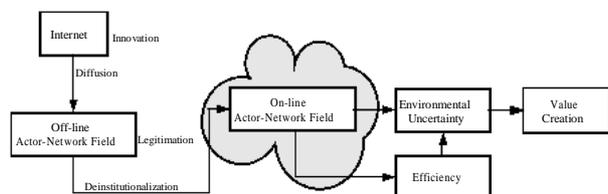

Figure 2. Conceptual model of the value creation

The paper is organized into three sections. First, we discuss the institutionalized process and the construct of actor-network field; also, we explore the relationship between on-line actor-network field and value creation. Second, the method and data of this study are introduced. Next, we analyze the value creation by Trend Micro. Finally, we summarize the results and contributions, and propose implications for firm strategies.

## 2. Theoretical Background

Lawrence, Winn, and Jennings [21] indicate “the process of institutionalization: objects are first recognized, then accepted by relatively few actors, and then widely diffused and broadly accepted within a field,” and finally reach to saturation and complete legitimacy [38]. During the institutionalized process, the concept of diffusion is viewed as a process in which an initial idea is transmitted in a social world [19], and consists the notion of searching legitimation of organizations [3]. Lawrence, Winn, and Jennings [21] hence suggested that institutionalization begin at the emergence of the new innovation such as new practices, rules, or technologies, and end prior to deinstitutionalization. The process of institutionalization, that is, an innovation at birth, is diffused, and then remains diffuseness throughout the field, and finally establishes legitimation.

For the discussion of field, we focused on a new term of field, namely, an actor-network field, based on the two constructs of “actor-network” [6,18,20] and “organizational field” [9]. Organizational field is defined by DiMaggio and Powell [9: 148] as “organizations that, in the aggregate, constitute a recognized area of institutional life: key suppliers, resources and product customers, regulatory agencies, and other organizations that provide similar services or products.” In other words, organizational field, a large and dynamic network, concerns the relationships between members and then

shapes an institution that affects the members of the field [3]. The concept of organizational field is also defined as “a set of equivalent firms that all produce the same product or service” [1]. Boons and Strannegård [3] suggested that the actors, in an organizational field, adapt to and contribute to the pressures and values of the field, and thus help materialize the characteristics of the organizational field. The organizational actors constituted an organizational field around a central issue and they had more interaction than the organizations outside the field [29,15]. The choices of organizational action, therefore, are not only determined by internal arrangements of organizations but also determined by the legitimate options defined by the actors in a field [29]. Greenwood and Hinings [13], additionally, stated that the organizational field is considered as with a taken-for-granted quality, which enables organizational actors to unconsciously accept the prevailing template as an appropriate, right, and proper way of doing things.

However, the organizational field concept is insufficiently attuned to all the possible actors’ relationships within a field. As [11] proposed the critique: institutional analysis disregards individual actors. DiMaggio and Powell [10] also recognized the institutional theory neglects the analysis of adding individual actors. The members of an organizational field are often organizations, but the actors of field are, rigidly defined, not only organizations but also, probably, individual actors. Because the “resources and product customers” [9] within a field is not solely the participating business customers; the individual actors might be also the significant ones in the field.

In contrast, “actor-network field” concept, combining the two constructs of “actor-network” [6,18] and “organizational field” [9], explicitly highlights the analysis of the institution constructed by relations of all possible actors in a field. The actor-network concept, as proposed by Latour [18] and Callon [6], concerned about “how actors, human as well as nonhuman, become “convinced” that a technology, artifact, text, image, and so on, is real” [3]. This concept stresses that a stable actor-network is established from the interrelations of the actors’ common activities. As Latour [18] pointed out, the survival of an action network implies that it provides the actors’ identity and the network stability, in turn, accepted by actors. Boons and Strannegård [3] also argued that the goal of the network constructed by actors is for network stability. Nevertheless, the term, “actor-network,” would lack the implication of organizational field. As Scott [32] noted, the “network” would be depicted as the flows or linkages shaped by participants. In contrast, the field, a common channel of discussion and dialogue for actors [15], is an arena of institutional life [9].

This paper thus integrates the concepts of organizational field and of actor-network into the “actor-network field,” and concerns the institutional interaction network of all possible actors in a field, including organizations and individual actors. Furthermore, we define the “actor-network field” as the institutionalized life area [9], providing a common channel of discussion and dialogue [15] where actors, organizations or individual actors [6,20], in a dynamic network linkages [3,21], experience the shared values and pressures collectively [3,14], and then the established field also affects the actors of the field.

While a company uses the Internet to provide an effective and dependable service structure in actor-network field, the field will be formed an on-line actor-network field. The on-line actor-network field can be viewed as a reliable interactive institution for actors to lower environmental uncertainty. As North [25] noted, in an economic exchange environment, institutions are dependable and efficient frameworks so that institutions could contribute to uncertainty reductions. Furthermore, the on-line actor-network field also has the efficient property conducting to environmental uncertainty decrease and value creation.

### 3. Method and Data

#### 3.1 Research Strategy and Sample

In this study, we choose Trend Micro as a single case study to explore the unique phenomenon of value creation, which is through on-line actor-network field. Based on the two reasons as follows, this study draws on Trend Micro as a single case study. First, for anti-virus service firms, especially anti-virus e-business firms, Trend Micro can be a business with considerable competitive advantages over the globe. Second, the Internet swept over Trend Micro in 1995, which displayed an interesting point of dramatic change of value creation in Trend Micro. These subtle phenomena lead us to explore the real cause of the remarkable achievement.

#### 3.2 Data Collection

Data collection, data analysis, and conceptualization are hard to be divided in the process of investigation, so we also adopt the principle of iterative of Glaser and Strauss [12] in the process of data collection. The closure point of data collection in this paper is when theoretical saturation [12] is reached.

Besides, to increase the construct validity of this paper, according to the principle of data collection as Yin [37] suggested, we use multiple sources of evidence. First, we collect the secondary data through Trend Micro’s webs and current press information to preliminarily gather the

historical events in Trend Micro. Second, because of the incomplete information in the first stage, we use focused interviews [24] and e-mails to fill the gap of historical events in Trend Micro to collect the first data. Five staff of Trend Micro, whose positions are marketing managers, sales manager, product manager, and the producer of web site of Trend Micro, respectively, are interviewed. Besides, we also receive and review the manuals of products and partners of Trend Micro with the assistance of these interviewees. These data are helpful to reconstruct all the evidence. The means we use is founded on the method of “triangulation” proposed by Patton [27] to develop the convergence of multiple sources of evidence and heighten construct validity [37].

Moreover, to increase the reliability of the information in the case study, this study establishes “a chain of evidence” [37] to illustrate the exploring process of a question, evidence, and results. This outcome of the exploring process is respectively pictured in Figure 1, Figure 3, and Figure 4.

#### 3.3 Data Analysis

In data analysis, this paper uses the two analytical techniques of “time-series” and “pattern-matching” [37]. In the first stage of analysis, we use the analytical technique of chronologies, a special form of time-series analysis. Yin [37] proposed allocating events in a chronology can make researchers clearly understand the causal relationship of events in a specific period.

In the second stage of analysis, the technique of “pattern-matching” is employed. This technique compares the consistence between an empirical pattern and the pattern of theoretical proposition. Yin [37] further argued if the two patterns coincide, it can reinforce internal validity.

In next section we discuss the evolution of Trend Micro in a longitudinal approach. Also, the detailed discovery showing the causal relationship between on-line actor-network field and value creation is illustrated in the following sections.

### 4. The Analysis of Value Creation by Trend Micro

This paper collects and chronicles the historic events in Trend Micro, as shown in Table 1. We employ a longitudinal approach to analyze the historic events in Trend Micro by dividing them into four stages: (1) the stage of foundations: 1988-1989; (2) the stage of independent anti-virus product development: 1990-1994; (3) the stage of expanding Internet anti-virus service: 1995-1998; and (4) the stage of integrated Internet service: 1999-2002. We further analyze and illustrate the

four periods of value creation by Trend Micro (see Figure 3).

Table 1. The chronology in Trend Micro

Year	Historic events
2001	Market HouseCall, integrated with the patent of Trojan System Cleaner.
2001	Market PC-cillin2002.
2000	Ally itself with UniSVR Corporation providing eDoctor anti-virus outsourcing service.
1999	Market “eManager” software for e-mails security management.
1999	Market “WebManager” software for webs security management.
1999	Establish five eDoctor laboratories, in America, Germany, Taiwan, Japan, and the Philippines; undertake the local eDoctor business.
1999	Unveil “eDoctor” anti-virus outsourcing service.
1998	Unveil “Trend Virus Control SystemTM.”
1997	“On The Fly” was granted American technological patent.
1996	Unveil InterScan VirusWall.
1996	Unveil the anti-virus system of “ScanMail for Exchange” for Microsoft Exchange Server.
1996	Unveil InterScan WebProtect, a group software anti-virus system.
1996	Develop the patent technology of “Macro TrapTM” to intercept and clean the unknown document macro viruses.
1996	Develop ScanMail for Lotus Notes.
1996	Market HouseCall for on-line scan virus.
1995	Unveil PC-cillin95.
1994	Unveil “Mobile Protect” system.
1994	Ally itself with Intel to market “Intel LANDesk Virus Protect” and provide the network security and anti-virus technology for Intel.
1993	Unveil StationLock, an interface card designed for anti-virus and access control.
1992	Develop “Chipaway Virus”; Intel integrated “Chipaway Virus” into the network card of Ethernet Express 16.
1991	“Server Protect,” an anti-virus core technology, was authorized to Intel and marketed to European and America by the renamed brand of ‘LANDesk Virus Protect’.
1990	Market PC-cillin.
1988	Founded in California USA; use a “rule-based” method of the monitor viruses’ behavior to detect the unknown viruses.

#### 4.1 The stage of foundations, 1988-1989

The actor-network field of Trend Micro in this period is shown as Stage I in Figure 3. In this period, Trend Micro did not really launch the anti-virus business. The focus of the business strategy was on allying itself with an anti-pirated software firm such as Rainbow Technologies Corporation in order to establish the business foundations. Although the boot-type virus happened to rise, it had no serious impact on businesses and end-users. The computer users, hence, were not significantly influenced by the uncertainty of virus attack. On the other hand, PC-cillin did not come to the market in this stage, though this product was successfully developed. Trend Micro with its customers, consequently, did not construct a recognized actor-network field.

#### 4.2 The stage of independent anti-virus product development, 1990-1994

The actor-network field of Trend Micro in this period is shown as Stage II in Figure 3. There are two focuses of the business strategy in this phase. First, Trend Micro allied itself with such computer hardware companies as Intel to enhance the reputation of Trend Micro in

America. Second, it established the PC-cillin agencies through the world to expand the market channels. In this period, Macro viruses happened to appear; meanwhile, Trend Micro’s anti-virus service provided the mailing service of the quarterly-updated computer virus codes. This practice was accompanied with two shortcomings. First, the uncertainty of virus attack that customers met was increasing between updating services of virus codes. Second, the cost of mail service was high between transaction parties. For service organizations, it is essential that they deliver the efficient service that could create advantages and economize associated costs [16]. However, according to the inefficient off-line actor-network field of Trend Micro and its parties, the type of field failed to effectively decrease environmental uncertainty resulting from computer viruses. The performance of value creation during this period, accordingly, was defined as a value creation of low level.

### 4.3 The stage of expanding Internet anti-virus service, 1995-1998

The actor-network field of Trend Micro in this period is shown as Stage III in Figure 3. In this period, the focus of business strategy was on Internet anti-virus service. Hence, it significantly changed the actor-network field of Trend Micro with its parties. For example, in 1995, Trend Micro developed the technique of 'One Button Update' that customers could update the computer virus codes on the Internet in real time. In 1996, Trend Micro developed a series of anti-virus products for enterprises such as OfficeScan, ScanMail for Exchange, InterScan VirusWall, and InterScan WebProtect. In 1998, Trend Micro developed Trend Virus Control System (TVCS), a centralized management platform, which enabled the information management department to setup, monitor, and manage all anti-virus softwares. The Internet anti-virus services or products lead to an efficient on-line actor-network field and regulate the behaviors of the field members in a recognized interactive institution. This kind of field, therefore, can decrease environmental uncertainty caused by viruses. As argued in [25], institutions are characterized with dependable and efficient frameworks in order that they can help reduce uncertainty. Many studies also show the evidence that the Internet could be employed to accelerate the service delivery and reduce service costs and uncertainty [e.g., 4,16,23,34]. The performance of value creation in this period, accordingly, was defined as a value creation of middle-high level.

### 4.4 The stage of integrated Internet service, 1999-2002

The actor-network field of Trend Micro in this period is shown as Stage IV in Figure 3. In this period, Trend Micro continued to provide the Internet anti-virus pattern of the last period for their end-user customers; moreover, Trend Micro provided a more integrated anti-virus Internet service. For example, PC-cillin2002 not only has the functions of the previous editions but also incorporates the function of the personal firewall. That is, end-user customers in the on-line actor-network field have access to services of efficiency and decreased uncertainty of virus attack owing to a more integrated Internet service actor-network field. For business customers, the focus business strategy of Trend Micro was on using eDoctor service to provide an integrated Internet anti-virus service. eDoctor offers the OfficeScan, ServerProtect, ScanMail, InterScan VirusWall and Trend Virus Control System with authorization. Business customers obtained eDoctor anti-virus service from

eDoctor service center, whose anti-virus technology was supported by Trend Micro. Wise and Morrison [36] showed businesses need to consider how to lower uncertainty, e.g., "Which exchanges should we participate in?" or "What software should we invest in?" Besides, due to the devotion to IT activities involving uncertainty, organizations need to decide which IT activities should stay in-house and which should outsource to the specific expert parties [22]. Lacity and Willcocks [17] suggested that selective IT sourcing be the most contribution to cost reduction among the three alternatives of total insourcing, total outsourcing, and selective sourcing. According to the implication of these authors' arguments, if a business can provide an integrated service for its customers and customers choose selective IT sourcing, it could decrease uncertainty through customers' neglect. The eDoctor and PC-cillin2002 integrated the Internet anti-virus service, thus a more institutionalized and efficient on-line actor-network field that further significantly lowered the uncertainty of virus attack. The performance of value creation during this period, accordingly, was defined as a value creation of high level.

## 5. Results and Conclusions

Based on the theoretical and empirical discussion, we illustrate the results of analysis as shown in Figure 4. Figure 4 shows the processes and results of Trend Micro using the on-line actor-network to create transaction value. The evolution process is from 1987 to 2002. In the period, the three main types of computer virus appeared, i.e. the boot-type virus, the macro virus, and the e-mail virus. In the first stage of this case, from 1988 to 1989, the boot-type viruses appeared. In the second stage, from 1990 to 1994, the macro virus emerged.

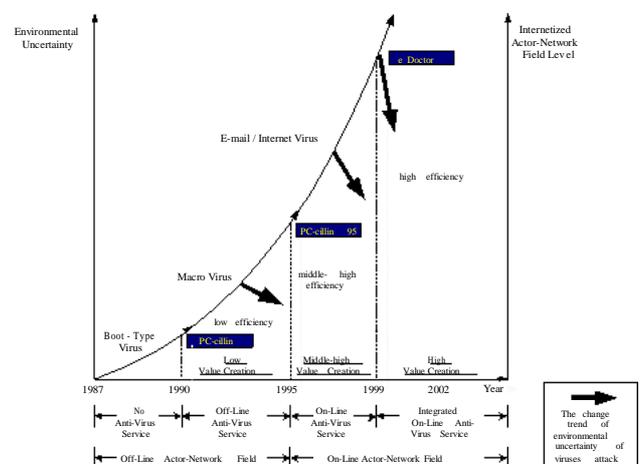

Figure 4. The curve of create value of Trend Micro

And in the third and fourth stages, from 1995 until

now, the most popular type of virus is the e-mail virus. The boundaries of these stages are just the emergence of three representative products, PC-cillin, PC-cillin 95, and eDoctor. Before 1995, prior to the PC-cillin 95 entered the market; Trend Micro with its actors of the field remained an off-line actor-network field. The anti-virus service of this period is called “off-line anti-virus service.” After 1995, the PC-cillin 95, especially eDoctor, entered the market; Trend Micro with its actors of the field transforms an on-line actor-network field. From 1995 to 1999, the anti-virus service is called “on-line anti-virus service.” Since 1999, the anti-virus service has been called “integrated on-line anti-virus service.” The evolution of actor-network field also presents three levels of efficiency, three changing trends of environmental uncertainty of virus attack, and three levels of value creation. As the Internetized level of the on-line actor-network field increases, the environmental uncertainty of virus attack is continually decreased, the efficiency is unceasingly improved, and the value creation is thus constantly increased.

In sum, we argue that, first, the higher the level of the Internetized actor-network field, the lower the uncertainty of virus attack. Second, the higher the level of the Internetized actor-network field, the higher the efficiency in the anti-virus service. Third, the higher the efficiency in the anti-virus service, the lower the uncertainty of virus attack. Fourth, the higher the level of the integrated Internet anti-virus service, the lower the uncertainty of virus attack. Finally, the lower the uncertainty of virus attack, the higher value creation.

In the longitudinal analysis of this case study, we find that because the former off-line actor-network field of Trend Micro lacks efficiency in the first two stages, the transaction value could not be significantly increased. In contrast, the on-line actor-network field in the later two stages can lower the uncertainty of virus attack and further increase value creation in that it has high efficiency.

Consequently, this paper makes two contributions. First, we propose an important and novelty construct “actor-network field,” based on a perspective of dynamic evolution. Second, according to the case of Trend Micro, the important issue arises in this paper that organizations can effectively use the Internet to construct an on-line actor-network field to facilitate the reduction in uncertainty and finally contribute to the value creation between actors.

# Approach to E-Business: A Case Study of Shanghai Tobacco Group Corporation

Kun Zhao, Donghui Yu, Zhongming Chen, Lihua Huang  
Dept. of Information Management & Information Systems, School of Management  
Fudan University  
Shanghai 200433, China  
zkfudan@sina.com.cn, dhyu@263.net

## Abstract

With the fast development of Internet, e-Business is prospering in the recently five years. Many traditional companies have been convinced of this revolutionary change, and they are exploring a feasible way to adapt to the transition. Chinese companies have weaker bases than the developed countries, but they are also cognizant of the big trend, and are making great efforts to grasp the opportunities. This paper introduces a practical Chinese case that illustrates the increasingly strategic role of e-business applications in traditional manufacturing industries. The company we studied is a large Chinese tobacco corporation, which locates in Shanghai, one of the most developed areas of China. After the WTO entry of China, the regulation system of Chinese tobacco industry will be transformed from STMA (State Tobacco Monopoly Administration) to a more open one. This will bring about more competitive pressures to Chinese tobacco enterprises. How can traditional large corporations adapt to the real new economy in the new environment, it is a big problem that most of the Chinese tobacco corporation faced on. Sensing the challenges and opportunities, Shanghai Tobacco Group Corporation started to search after a new development way, and they intend to develop an e-business application model to improve its distribution processes to integrate their purchasing, manufacturing, delivering, logistics, and sales. Studying such a typical large company, it may be helpful for other large company in other industry.

This paper first reports the background of Chinese tobacco industry and a brief history of the IT applications in Shanghai Tobacco Group Corporation (in the next part we use SHTG for short), then we discuss the environment and business factors that led to the e-business application. Based on the above introductions and discussions, we illustrate an e-business solution to handle the situation SHTG faced.

Keywords: e-Business Model; E-Business applications; Enterprise Information System; Strategic Information Systems;

## 1. Introduction

Information technology (IT) is transcending its

traditional back office role toward a strategic role in the recent years. It has been successfully applied by many companies to increase their competitive advantages [1,2,3,4]. It plays more comprehensive roles in wide scopes of business domains than before. In business world, IT does not only reduce the corporation's cost and increase its efficiency, but also change the industry structure, the rules of competition and the organizational structure [2,5,6,7]. In past twenty years, the rapid growth of the Internet and Internet based applications is stimulating an ever-increasing number of businesses to participate in e-business worldwide. For Example, United Parcel Service, Dell Online, Ford Motor Company, Seven-Eleven Japan, and etc., they are the well-known companies who pioneered e-business applications in their own industries and greatly leveraged their competitive competence by use of IT. E-business is one of the hot application areas of today's business, and it shapes a new landscape of business competition.

In this paper, we will introduce a practical case — Shanghai Tobacco Group Corporation (SHTG) and explain how and why SHTG expends its IT to the domain of e-business applications and integrates the operations of the company with its enterprise-wide information system.

In the first part, we will give a brief introduction on the background of Chinese tobacco industry and a brief history of information system applications in SHTG. Next, we will introduce the current situation of SHTG's IT applications. In the third part, we will discuss the problems SHTG faced in today's environment of running businesses and what will happen after the China's entry into WTO. Based on the above introductions and discussions, an e-business solution to handle the situation SHTG faced is introduced. In summary and discussion, we will discuss the significance of this case study.

## 2. Background

### 2.1 Background of the Industry

The China's tobacco industry is regulated by the system of state monopoly administration. All the tobacco related operations, such as growing tobacco leaves, cigarette manufacturing, distribution and sales, are all

regulated by the State Tobacco Monopoly Administration (STMA). STMA exercises a strict control role over tobacco production by planning. Tobacco makers have to coordinate their production in line with the production quotas issued by competent administrative authorities. Under this system, the tobacco production and sales are regulated and protected by the Tobacco Monopoly Law. Furthermore, the Chinese tobacco wholesale and retail markets are also protected by the government by measures such as the restriction of tobacco import, the imposition of high import duties and the establishment of non-tariff trade barriers. Table 1 is the Chinese import duties rate of tobacco related products in 2001. Compared with other industries, tobacco industry is a closed one.

Table 1 The Chinese import duties rate of tobacco related products in 2001

Tobacco related products	Import duties rate (%)
tobacco leaves	34
homogenized or “reconstituted” tobacco (such as strips)	54
tobacco	57
cigarettes	65 (regulation rate) and 36 (effective rate)
cigarette paper	45

China’s tobacco industry has experienced a long period of prosperity. According to the STMA’s statistics, Chinese tobacco industry has provided an accumulative 697.4 billion Yuan RMB for the country over the past ten years. Some 10 percent of the revenue for the national finance and taxation comes from the tobacco industry in China.

Undoubtedly, SMA system and protection from the government play key roles behind the prosperity and success of the tobacco industry. The success of a tobacco enterprise is guaranteed by output quotas, which is assigned by STMA. Therefore, manufacturers primarily put their main resources on their production and product quality.

## 2.2 A Brief History of SHTG’s IT Applications

The IT history of SHTG started from the late years of 1970s when it was still Shanghai Cigarette Factory (SHCF). At that time, it introduced single-chip computers in the application field of process control in 1978, which aimed at automating its manufacturing process for cigarette manufacture. In 1982, several microcomputers were put into use in the management areas, such as the allocation of worker force, payoff accounting and cost accounting. And then SHTG expended its IT application

into the domains of inventory management and financial accounting. In this period, all the applications of IT in SHTG were isolated systems. Their functionalities were limited to the organizational units where they were deployed. What they did in IT deployment was just embedding the existed processes in silicon and software<sup>[7]</sup>. However, the situation of SHTG’s IT was in line with its need of IT. Because what it focused on in business operation at that time was to improve its efficiency in production and lower its operational cost under the protection from SMA system.

At the late of 1980s, having seen that IT had expended to many operational units and considering the future trends of IT applications, SHTG decided to leverage its IT applications to a new level. The establishment of a network based on Novel structure in 1987 started its attempt toward this goal. What SHTG had done first was to establish a network within SHTG so as to integrate all of these applications and facilitate communications among different applications.

Entering into 1990, an excellent opportunity for SHTG of fast development came when Shanghai’s Pudong area was established as a developing zone by the central government. Shanghai was opened wider to the outside. Shanghai has gained the focus from the whole China and the world. Many foreign companies flushed into Shanghai to establish their own branches or invest to create a new one. In 1993, SHTG was founded, and the scale of the corporation increased many times compared with SHCF. Besides SHCF, SHTG includes other enterprises, sub-companies and holding companies, e.g. the Tobacco Trading Center, tobacco leaf grow bases (13 in total), Guanshenyuan Food (Group) Corporation and others. Its business scope expanded from tobacco related products to food, drinking, real estate, transportation and others. Its enterprises cover many parts of China, for example SHTG cooperates with other 15 tobacco limited companies distributed in different provinces of China. With the incentive from the managerial abilities of European and American companies and increasingly intense competitiveness among Chinese tobacco market, SHTG felt an urgent need to leverage its ability to manage such a large scale group corporation and to enlarge its market share.

## 3. Current Situation of SHTG’s IT: Enterprise Information System

### 3.1 Structure of Current Information Systems

In the middle of 1990s, SHTG set up a information system plan, which outlined its blueprint of enterprise information systems and proposed a schedule to implement it during a five-year period. Several partners

from the tobacco industry and IT industry were included in the development of the application systems. The subsystems such as executive information system (EIS), row material management (RMM), inventory management (IM), coding management (CM), auxiliary material management (AM), manufacturing schedule (MS), quality control (QC), cost control (CC), equipment management (EM), statistical analysis (SA), data capturing and collection (DCC), finished goods circulation (FGC), comprehensive statistical processing (CSP), financial accounting (FA), human resource (HR), intranet and office automation (OA) have been implemented and put into use in SHTG. Figure 1 show the structure of SHTG's enterprise-wide information system. These systems were developed in hope that the deployment of IT would help the corporation to realize its strategy of leveraging its managerial competence.

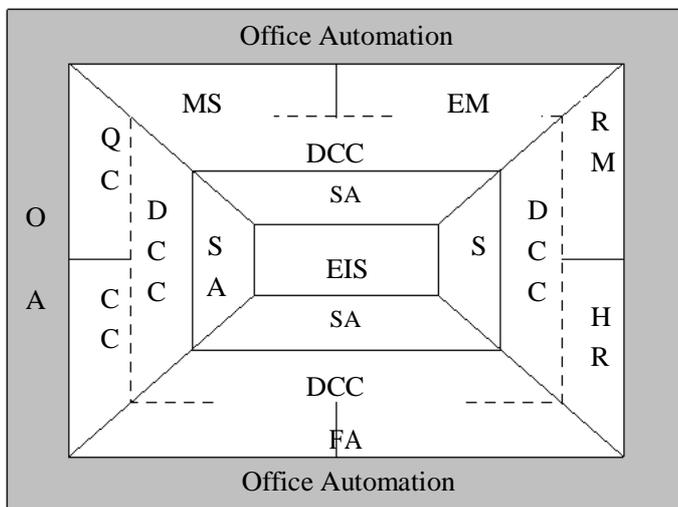

Figure 1 A IS pyramid structure of SHTG

Figure 1 shows that there are four levels in the IS pyramid structure of SHTG. They are divided into four different level: Decision Support Level, Information Services Level, Transaction Processing Level and Office Automation Level, from the top (center of the diagram) to the bottom (out ring of the diagram) separately.

- In Decision Support Level, EIS provides information for executives of every managerial level. It is the top level of all the applications;
- Information Services Level is a mediate layer between EIS and other lower level subsystems. It captures and processes data from its sub-level applications. It provides statistics analysis to all subsystems and it is actually incorporated in the subsystems. But it is logically independent from its incorporated subsystems;
- Transaction Processing Level, the third layer of the pyramid structure, is made up of the

different functional subsystems as mentioned above. These subsystems are applied in specific application fields separately. Different systems use different processing approaches and generate a large amount of different data, both structured and non-structured, and they are essential to the decisions of executives. These subsystems are the main body of SHTG's IS that supports the daily operation of SHTG;

- Office Automation Level is a level to support the office automation for middle executives. It is a channel for information transformation. It is logically the infrastructure of the whole information system as showed in figure 1.

Furthermore, the system not only facilitates internal communication of everyday operations, but also helps the company acquire the external information, for example, it links with the other intranets of SHTG, and connects to Internet.

### 3.2 Benefits from IT Applications

The existed information system covers the main value chain of SHTG. In manufacturing, it provides the function of manufacturing schedule, quality control, cost control and equipment management systems. In material supply and inventory aspect, it integrates the row material management, inventory management, coding management, auxiliary material management and finished goods circulation systems. In management domain, it has the function of statistical analysis, human resource management, financial accounting, and office automation systems. The implementation of these systems bring benefits to SHTG in the following aspects:

- Facilitating the communication throughout the group;
- Having the first-hand information when market changes;
- Lowering inventory level of row material;
- Improving managerial efficiency and productivity;
- Supporting decision making for the top executives of the group;
- Improving skills of all end-users in using computer; and
- Leveraging IT competency.

## 4. China's WTO Entry — Changing the Competitive Rules

At the beginning of the new century, China welcomed a historical turn — she joined the World Trade Organization (WTO) on November 10, 2001. However, it is not a good news for the Chinese tobacco industry.

China's tobacco market will further integrate itself into the world's free trade system characterized by open international business competition. For the Chinese tobacco industry, how it reacts after the WTO entry has become an issue of great concern.

Though according to the agreements, STMA can still temporarily apply the Tobacco Monopoly Law after China's entry into WTO, China will lower the tariff on tobacco imports eventually. On the other hand, STMA has to reform itself to adapt to the free market environment. Its regulation over the tobacco manufacturing and sales market will be more loose and indirect. Generally speaking, China's WTO entry will bring great pressures to the tobacco industry. Homemade cigarettes and foreign cigarettes will compete fiercely as soon as China releases down many regulations. In the wake of global competition, Chinese tobacco industry is expected to choose either to catch up with the steps of the counterparts in advanced countries or to give up and be driven out of the industry, as the superior will survive while the inferior will die. For the tobacco industry, the good times of being cosseted under the protection of the government will go away.

### 5. The Solutions of SHTG to Face the WTO Entry Challenges

To respond to the challenges imposed by WTO entry

and the changes of domestic market, SHTG sets its corporation strategy with the support of IT. Concerning that production could not guarantee the success in the future tobacco market any more, SHTG turns its strategic focus on marketing—a lesson it must learn in the new industry environment. Establishing a new marketing network to maintain its market share is in its agenda, an e-business solution is therefore proposed.

#### 5.1 The current market channel and selling chain

Figure 2 illustrates the current selling chain of cigarettes sales in SHTG. Its customer can be generally classified into three groups: local customers, domestic customers and international customers. They are accessed through different market channels.

Local customers refer to the customers within Shanghai area. They can be accessed through the Cigarette Wholesale and Retail Net of SHTG. They are the only customers who can be reached by the net so far. Cigarette Wholesale and Retail Net of SHTG has more than 24,000 members distributed in the whole Shanghai area. Among them, there are over 600 shops directly belong to the sub-branches of SHTG, over 1,000 chartered shops belong to the top 8 supermarkets in Shanghai and more than 20,000 retailers. They are all licensed by SMTA.

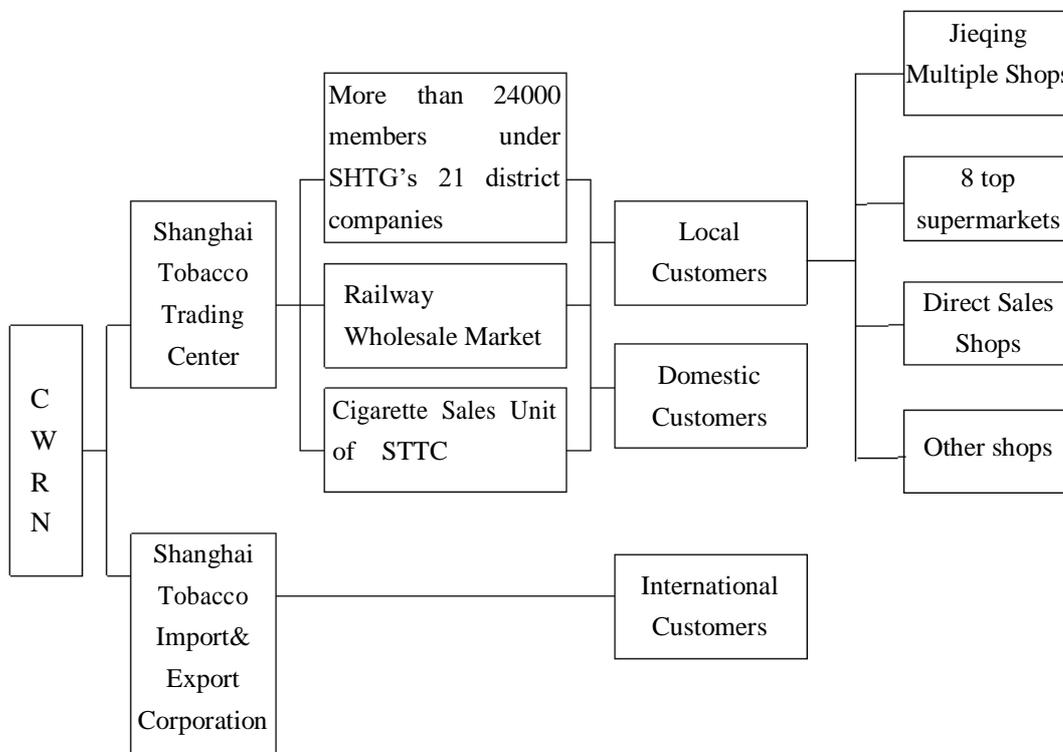

Figure 2. Current wholesale and retail network of SHTG

Domestic customers refer to the domestic customers outside Shanghai area. They are can be accessed through orders from other provinces. The orders can be obtained in the tobacco trade fair, which hold twice a year. Though the orders obtained could be varied in terms of quantity and other transactional details such as finish time and transportation means each year, the total quantity of production output can not over-fulfill the quota issued by SMTA for the enterprise each year. So the vary in orders would not influence the total requirement.

International customers are accessed through the orders from the sub-branches of Shanghai Tobacco Import and Export Corporation (STIEC). The production output for the orders should be planed according to the plan set by the Foreign Trade Ministry of China. These orders would not influence the total requirement as well.

### 5.2 E-business Based Model of Marketing and Selling Chain Management

The above introduction shows that SHTG has a long selling chain, e.g. the customer can be reached only via

many intermediaries. Its sales net structure is complicated comparably. Its customer profiles are different, too: they are located at different part of the country (e.g. countryside, city), and in the different walks of life. As regard to the WTO entry and the changes of domestic market, it is imperative to integrate all its existed market channels so as to make it works in a more efficient way. Put it specifically, SHTG need its CWRN to achieve the following goals:

- Making best use of the existed CWRN, e.g. fast respond to the requests from its retailers and distributors;
- A mechanism to manage its relation with its customers (CRM);
- A better way to promote its products; and
- Expanding its existed CWRN, which covers only Shanghai area now, so that the other regions can be reached.

Based on above requirements, an e-business based model of marketing and selling chain management is articulated, as Figure 3 shows it.

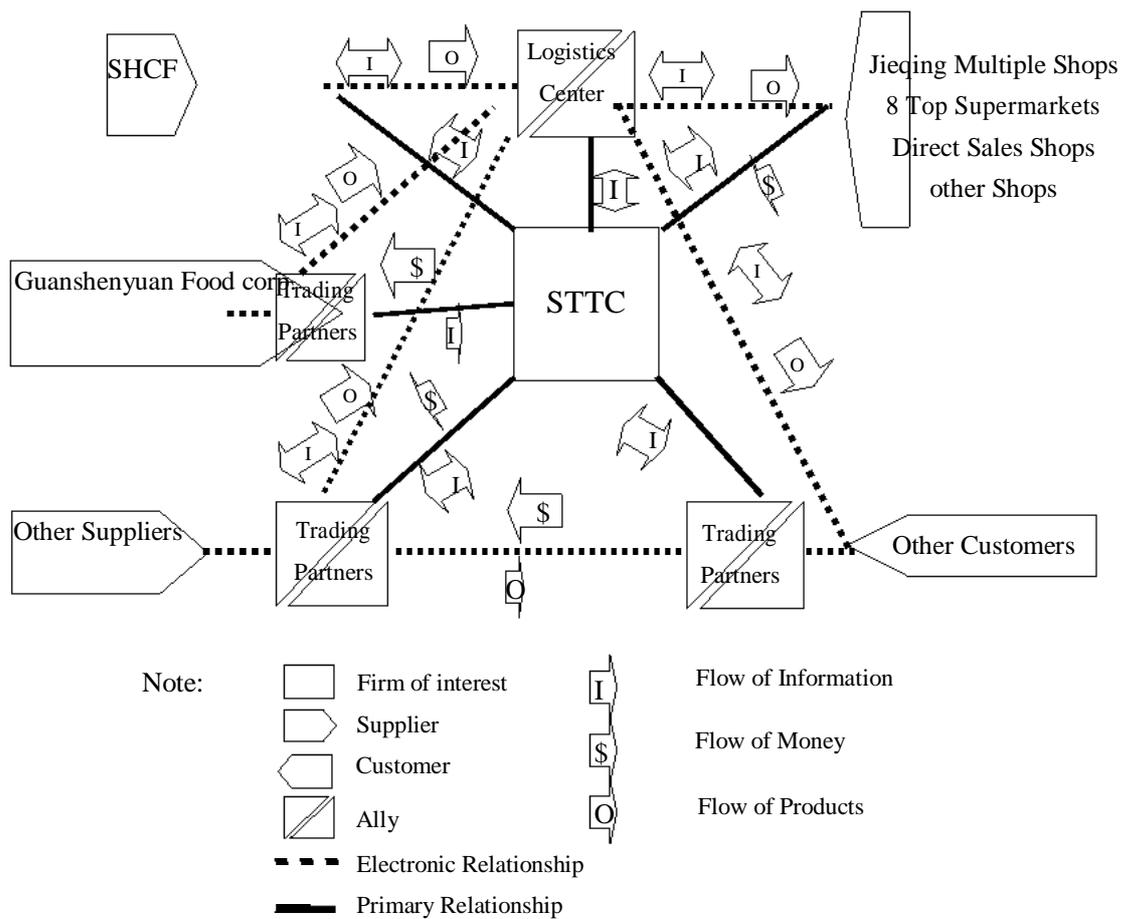

Figure 3 An e-business based model of marketing and selling chain

### 5.3 Value Net Integrator and Sales Channel Integrator

Shanghai Tobacco Trading Center (STTC) is an organizational unit of SHTG and it will act as the core unit for all e-business-related applications in SHTG. It also acts as value net integrator [9] and sales channel integrator in SHTG. As a value net integrator, it is the core unit for all sub-corporations of SHTG. It will integrate the whole value of the corporation through collecting, integrating and distributing information that is distributed in the different value activities of value chain [3] in whole SHTG. As a sales channel integrator, it will integrate all sales channels in SHTG through the coordination of sales activities in the selling chain.

For example, by viewing the information related to the inventory of its subordinated shops via a POS, which is connected to the STTC, the top executives of SHTG can easily know the sales performance of the shops, and then with the support of data mining systems, the top executives can also know the consumer behaviors. With this information, the top executives can easily know what and when the customers need, and then decisions can be made rapidly and automatically. The STTC can also integrate information about suppliers and forward it to the customers, or in reverses, prepare information related to customers for suppliers. In doing so, the STTC also acts as an information integrator.

The model is hoped to support the corporation to carry out its corporation strategy goal of being a value integrator of the industry in the following aspects:

- Coordinating the relationship among the members linked by selling chain by conducting

the activities of capturing, collecting, analyzing and distributing information;

- Strengthening its “core” position in the selling chain, so as to leverage its competence in information accessibility; and
- Facilitating the corporation with other enterprises, improving the efficiency of the selling chain.

### 5.4 Single Contact Service

SHTG is a comprehensive corporation. Besides tobacco related products and services, it also provides other products and services, e.g. sugar, food, drinking, and others. For example, Guanshenyuan Food (group) corporation, which is running in the food industry, is one of its holding companies. It is necessary for STTC to provide information services not only for tobacco related products and services, but also for other products and services as well. So the STTC will be implemented as an integrated platform for SHTG to carry out its all operation activities. The single contact service model provides a better solution to this requirement.

By single contact service solution, STTC will integrate all information services in a platform so that it can improve the internal operation environment and different business units can exchange information efficiently in SHTG. As regard to the customers and suppliers, it will provide a “total solution” for them — get all they want and finish all the transactions at a single point.

Figure 4 gives the main frame of e-business based selling chain model of SHTG. It illustrates the above ideas.

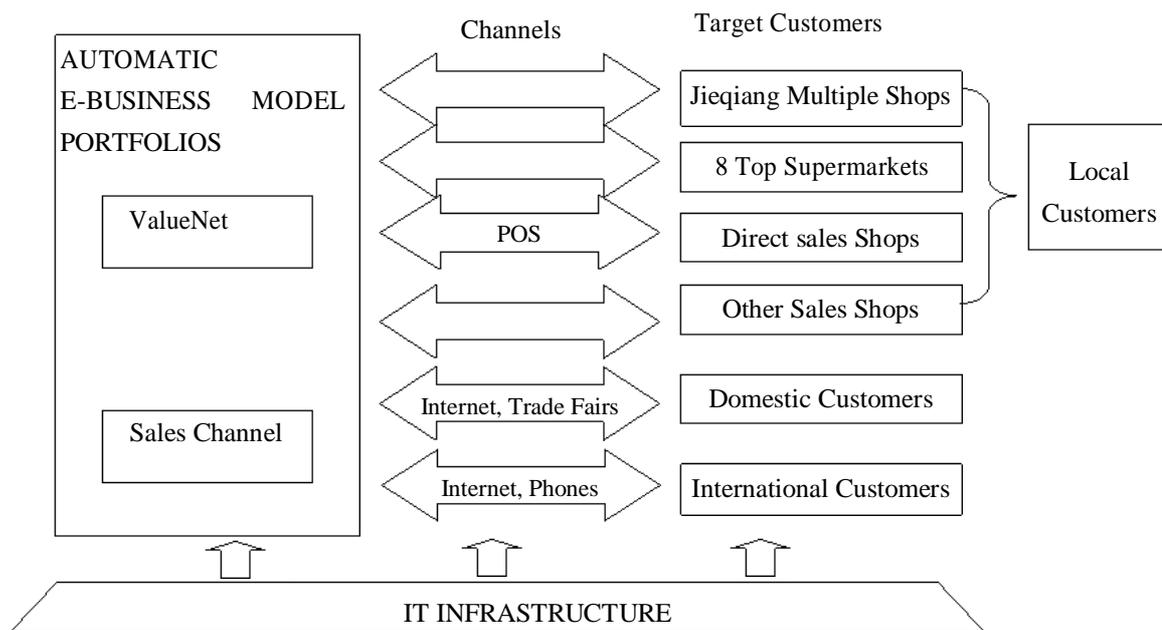

Figure 4 Mainframe of e-business based selling chain model of SHTG

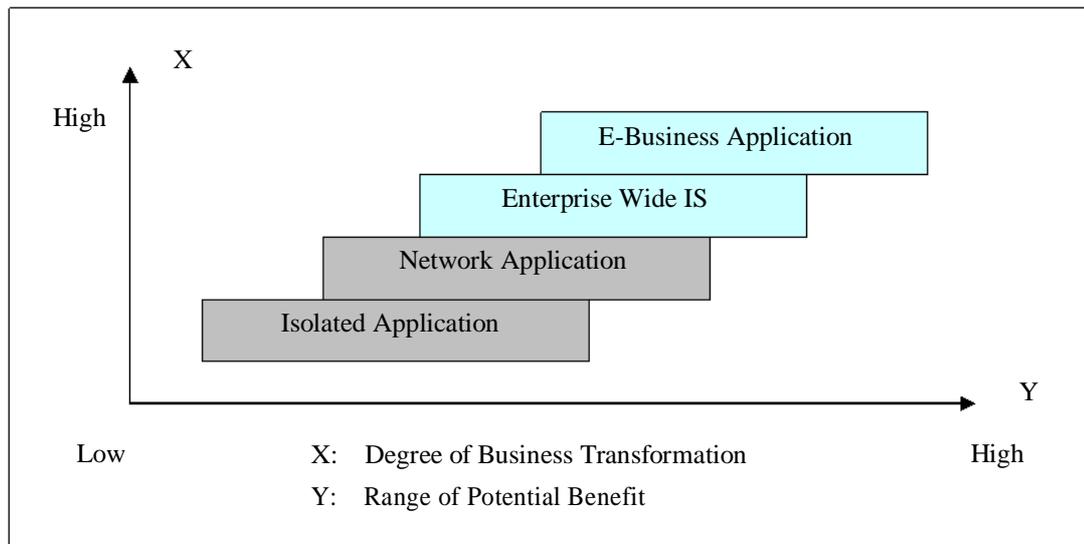

Figure 5 SHTG's IT application trajectory

## 6. Summary and recommendation

In this case study, we illustrate the roadmap of SHTG to e-business. Figure 5 outlines SHTG's IT trajectory. Following the framework developed by Venkatraman[6] and Davidson[10], we can observe that SHTG's current IT is at the phase of business redefinition. Therefore, it is inevitably that great changes will happen in the organizational structure and processes. Taking the current problems SHTG facing both in the business domain and external environment domain into account, several beneficial conclusions can be reached for SHTG.

- It is imperative to settle the contradiction between the operation in the SMA system and the operation in the open tobacco market, e.g., transform from production oriented management to marketing oriented management and make its organization system closer to the market;
- It is imperative to accomplish the innovation of the organizational form and mechanism;
- It is imperative to thoroughly reform the current system of internal institutional establishment, management system and distribution system of enterprises.
- It is important for the top executives to recognize the inevitability of changes to the organization when IT is deployed if SHTG want its investment in IT will deliver desired benefits to the organization.

## Acknowledgments

This paper is based on researches supported by 863 High Tech Project of China (2001AA414120) and Nature Science Foundation of China (NSFC: 70171009). The

authors of this paper would like to thank all the staffs and executives of the Information Center of SHTG. They sacrificed much of their valuable time in accepting our interviews and provided us with a lot of valuable information about SHTG. We would like also to thank all the other members of our research group, for they have done excellent works in collecting, analyzing and processing the materials. Furthermore, without their contributions in shaping the ideas, the composition of this paper could not be true.

## Abstract

This paper deals with empowerment of the offline customers (who are responsible for 99% of retailing), to have the benefits of being online and have all the shopping experience, in fact, with a greater presentation appeal.

The models proposed here bypass all the above limitations and gives any customer an online shopping / subscription experience, even without the knowledge of operating a PC.

This “Offline Empowerment I” also deals with the other mentioned problems by: presentation enhancement, bypassing connectivity, reducing security hassles etc.

This is achieved by some technical and logical segregation of presentation layer and business logic layer across the Internet. Thus, removes the bottlenecking in the adoption of e-shopping, paving way for a greater E-business.

Of course, the rewards depend on the successful implementation of the presentation logic, business logic and the overall strategy.

## 1. Introduction

A nation with diverse tastes and preferences, India, has globally been recognized as a source of skilled technical manpower. With the advent of Information technology, Indian industry and manpower, to a greater extent, have geared up themselves in this promising area to transform their businesses on Internet. But, with a heap of promises and predictions, it is evident that the E-Business didn't come up to the desired levels.

Generally, there are various reasons attributed to it:

- Downward trend in economy
- The rapid technological changes difficult to keep pace with.
- Non-feasible business models,
- Lack of awareness in customers.
- Security concerns etc.

Let's have a look at the data by TNS Interactive - Global eCommerce Report - June 2002 India:

[1]

Data collected in 4 largest cities.

Percentage of total population who are Internet users

Year 2000 = 10%

Year 2001 = 13%

Year 2002 = 16%

Male = 24%

Female = 10%

Online Shoppers

1% of surveyed total population

4% of surveyed Internet Users

Main reason for not buying online (in India)

Too difficult / lack of knowledge

In a developing region like India, the growth of Internet user has not attained a substantial maturity, owing to many of the reasons like: Internet awareness and connectivity. Corporate bodies will have to use the power of the Internet to correct inefficiencies in the value chain, transform the role of the company to managing the value chain, device strategies to cut costs and improve business processes.

M E Porter has rightly identified the “... Need to create strategies that involve new, hybrid value chains, bringing together virtual & physical activities in unique configurations”. Competitiveness in E business can only be achieved by a strong business model, which in turn consists of efficient business processes. Therefore, at the micro level, it is actually the business process that is making a particular model feasible, strong and effective. This business model should stand in unison with the efficient processes as well as the technological implementation of the model. The Internet channel of tomorrow will largely be a hybrid one with customers seeking value at the lowest cost from each component channel. Companies that realize this & modify their channels appropriately are likely to benefit the most from the introduction of Internet into retailing.

The net has helped reach the customer directly circumventing the two traditional indirect buffers - mass, media & retailers. Hence, it can work as a medium of communication and to business with. E-tailing, however, appears to be a couple of years away. Today, E-retailing comprises less than 1% of retail sales in the USA & much less in India.

Therefore, in the Indian context it becomes really essential to target the offline masses to be enabled by Internet based shopping experience. But the following are the limitations:

- Poor knowledge for operating a PC.
- Lack of awareness about Internet.
- Inherent fears about security.
- Slow connectivity - a major hurdle in e-shopping.
- Internet is not being utilized as an effective media of presentation, which is required for powerful sales closing.
- Diverting the customers from traditional channels to online.

This paper deals with empowerment of the offline customers (who are responsible for 99% of retailing), to have the benefits of being online and have all the shopping experience, in fact, with a greater presentation appeal. The model proposed here bypasses all the above limitations and gives any customer an online shopping experience, even without the knowledge of operating a PC.

The "Offline Empowerment model" also deal with the other mentioned problems by: presentation enhancement, bypassing connectivity, reducing security hassles etc. This is achieved by some technical and logical segregation of presentation layer and business logic layer across the Internet. Thus, removes the bottlenecking in the adoption of e-shopping, paving way for a greater E-business. Of course, the rewards depend on the successful implementation of the presentation logic, business logic and the overall strategy.

## 2. Offline Empowerment

Consumers expect the same experience and the same answer anytime, anywhere, anyhow... their choice... are we consistently offering our customers the convenient, easy and enjoyable shopping experience they expect?

The notion of "Offline Empowerment" is aimed at providing the benefits of Information & Communication Technology to the masses, in Indian context it refers to developing the processes suited to the needs of those people who are 'offline and not computer literate'.

In this paper we will postulate two approaches towards the "Offline Empowerment":

- The Virtual Show Room Model.
- The Offline Enterprise Model.

Years 2000-2002 have witnessed a gloomy phase in the E-business scenario all over the world. Economic values of the companies eroded, the basis of competition shifted, new business alliances evolved and perished, and it became harder for anyone in their industry to turn a profit. Electronic commerce is changing the shape of competition, the speed of action

and nature of leadership. Managers everywhere are feeling the heat. The companies are at E-commerce crossroads and there are many ways to go. But which road will lead to success? Which business models, management strategies & tactics will make them successful?

According to a recent study by Confederation of Indian Industry (CII) & the consultancy company PriceWaterHouseCoppers, the total E-business in India is expected to be worth Rs 55,000 crores by year 2005. Thus, the Indian corporate are also reassessing their expectations of E business. Corporate can use the power of the internet to correct inefficiencies in the value chain, transform the role of the company to managing the value chain, device strategies to cut costs, improve business processes, and to look at greater transparencies among the business partners. [2]

The basis of competition & wealth creation in the digital economy is not only good use of information, quality, speed or effective decision-making, but it is business model innovation.

Competitiveness in E business can only be achieved by a strong business model, which in turn consists of efficient business processes. Therefore, at the micro level, it is actually the business process that is making a particular model feasible, strong and effective. This business model should stand in unison with the efficient processes as well as the technological implementation of the model.

## 3. Making it Click

The Internet channel of tomorrow will largely be a hybrid one with customers seeking value at the lowest cost from each component channel. Companies that realize this & modify their channels appropriately are likely to benefit the most from the introduction of Internet into retailing.

The net has helped reach the customer directly circumventing the two traditional indirect buffers - mass, media & retailers. Hence, it can work as a medium of communication and to business with. E-tailing, however, appears to be a couple of years away. Today, E-retailing comprises just about 0.89 % of retail sales in the USA & much less in India. [4]

There has been a fundamental flaw in one of the assumptions of E-retailing that everything could be sold online profitably and to anybody.

A recent study has predicted that E-commerce in India will jump from between Rs. 25 crore & Rs. 28 crore in 2000 to Rs. 220 crore in 2001. However, the study also points out to the fact that certain barriers need to be surmounted to exploit the potential of E-tailing. The first and foremost is the fact that there are only 5 million net users in India, out of whom only 2 millions are active. Besides 75% of net users are males.

Secondly, wide range of products usually has to be delivered offline and in the shortest time which makes managing the supply chain, a nightmare. Thirdly, with low margins on a variety of products, especially FMCG products (about 5 -10%), deep discounting may not be possible on the net. [5]

We will have to give some way to pragmatism by pondering on the issues like: What kinds of shopping activities are likely to make consumers migrate to net? How do shoppers compare and contrast their shopping options? Will e-retailing and net usage increase or decrease among different segment of customers?

Such perplexities of consumer behavior are hardly a new phenomenon. Traditional marketers have always been thrashing such problems even before the emergence of the Net and online shopping. But, out of that effort came a sophisticated understanding of the context in which a buying decision occurs, an understanding that is as valid online as off.

It is true that customers buy different products for different reasons at different times. This seems obvious. But the profile and indiscriminate use of online marketing tactics for all types of online consumers - regardless of their awareness level, interest and buying behavior - shows that many online marketers don't quite get it.

Through trial and error or sheer luck, some online marketers have achieved impressive results with these powerful new tools. But between their rush to adopt these tools and their over-reliance on data about Internet purchasing, online business-to-consumer marketers have tended to ignore some fundamental truths about consumer behavior. And without a full understanding of these truths, the promise of E-marketing in the B2C sector will largely go unfulfilled.

#### 4. Virtual Showroom model

In the contemporary attempt, I am presenting a business model consisting of some business processes being conceptualized on the fact that Internet is largely a presentation medium for the sale of a product. Business operating in today's economy can thrive only when they approach electronic commerce with the customer in mind. This means knowing how, when and why they shop and what their motivations, emotions, expectations and fears are.

We all know that books and CDs consist of a lion's share of the products sold online; both of these products do not require the utilization of an efficient presentation. The question is that, are we not able to fully utilize the presentation capability of Internet or the presentation capability of Internet is impoverished?

I quote her AIDAS theory of sales that stands for Attention, Interest, Desire, Action and satisfaction. [6]

We can realize the importance of creating attention, which invokes interest in the product and ultimately leads to sale. Attention, being a strong prerogative for sale goes hand in hand with interaction of the customer with the product, features and specifications.

Now imagine the customer with a desktop PC, who is browsing the internet over a dial up connection, struggling hard to download a single small size two dimensional static view of the product along with written specifications. Again & again he has to wait, if at all he has to accomplish a purchase. This selling process is largely driven by the customer's initiative & he is being repeatedly asked to click here and there. Unguided by any sales man & immediate query quenching, he finally types out some different URL in the browser's address box & presses GO.

A poor point of purchase strategy and hence even less than 1% of retailing is E-retailing. Nonetheless are hassles of credit card, security, passwords etc.

The virtual showroom model deals largely with presentation enhancement, hence increasing the attention and interaction resulting into higher probability of sale.

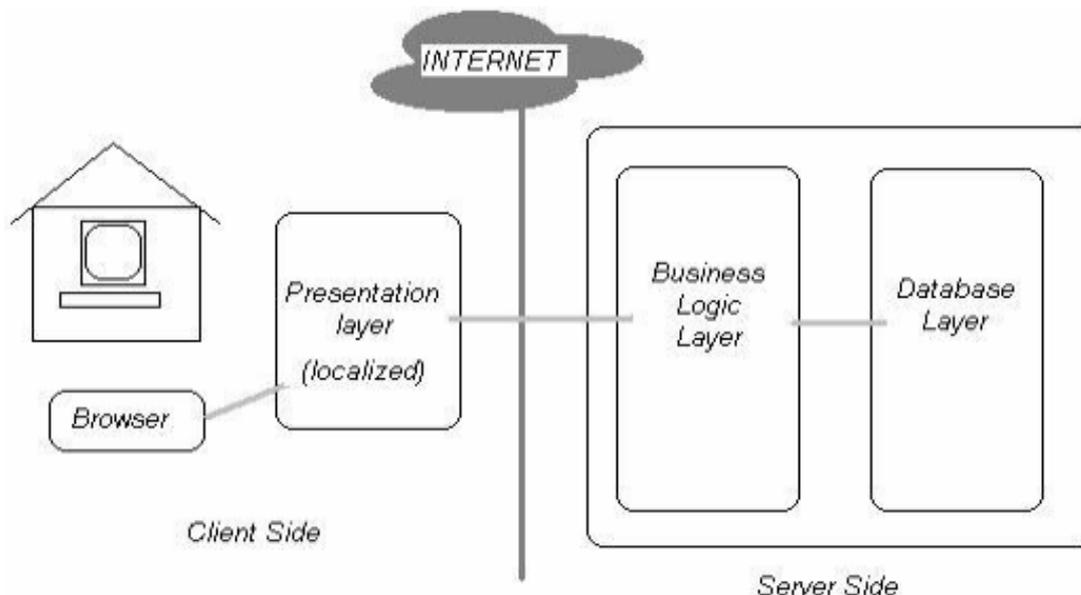

Lets first have a look at the existing web application system, which consists of three tiers namely the client, the middle tier and the backend (database layer). The client is connected to the middle tier via Internet. This middle tier (server) is actually hosting the presentation layer and the business logic layer.

Now a potential customer who is browsing the website is constantly interacting with the presentation layer of the middle tier; connectivity being Internet. This presentation layer is very important and the only media in the hands of a marketer online.

Ever experienced the downloading patience required for a graphic file? Streaming video and audio are still a distant dream says an Internet advertising consultancy, Jupiter- "Widespread use of streaming video and audio will depend on high speed net connections, which aren't expected to be adopted by a critical mass of household (30 million) until 2005" [7]

Then what will happen to our "presentation enhancement", "audio-video interaction" and better attention? The answer lies in the localization of the presentation layer. Once the presentation layer is localized then we exploit the best possibilities of a desktop PC for greater interaction. Also, we can take the much required "Human touch" in the sales process.

To achieve this, the virtual showroom model utilizes product catalogue demonstration software recorded on a compact disk, which the company's business partners will use for the virtual showroom display. (see fig 1)

## 5. Virtual Showroom model operationalized

The business firm based on this model will seek its business partners (franchise) like departmental stores, other outlets etc. By doing so, the firm is actually utilizing the existing customer base of the departmental store.

A PC along with a big display, full multimedia, touch screen etc will be installed at the departmental store for a virtual showroom setup. The business partner will divert the potential customers to this showroom setup where they will be interacting lively with the product features. E.g. In the “clothes and apparel” section of virtual showroom, we can see a full video of a model sporting the chosen outfit etc.

The Virtual Show room Model (fig 1)

Now with the help of this software on the demonstration CD, the customer will navigate through the showroom, also a real salesman will assist him. This PC is connected to Internet. As soon as a customer goes for a purchase, the order is processed via an e-mail to the parent company’s server. Thus the order is processed and the commodity can be delivered soon.

Also, there are no hassles of insecure money transaction as the business partner would be accepting the cash and will issue the receipt (business partner being the same trusted store of the customer). Off course money can be transferred to the parent company’s account via online account transfer facilities viz ICICI etc.

## 6. Advantages of the model

- Encashing the existing the customer base of the business partner into the segments of associated

product or differentiated product. E.g. Purchasing the car accessories like stereo system, interior furnishings etc. online, after purchasing a car.

- Added “human touch” for powerful sales closing which is not available conventionally.
- Greater interaction, increased attention.
- Secure money transaction (for the end customer)
- Better logistic support can be provided if the transportation can be outsourced and insured.

## 7. Offline Enterprise Model

The Virtual Showroom dealt with the presentation enhancement and slow connectivity while the Offline Enterprise model talks about yet another hinderance in the way of E-Business in India "The large number of potential customers who are off Line"

No E-Business can survive in the long run by targeting only 1% of the total population who are online. We will have to develop some configurations so as to include those people who are 'offline and not computer literate'.

The Offline Enterprise Model is a generic model which is for information based portals, it lays emphasis on the offline presence and operations of any business entity. I will explain this model by an illustration. Think about online job search databases, matrimonials etc which are primarily information disseminators. Now the persons using these facilities are supposed to be online and first of all computer literate, what about those millions who are not?

They are not able to take the advantage of the online aggregation of centralized data. Also the online databases exclude the large offline information which is otherwise available in print media etc.

For such models, there is no bridge between the information online and offline. The information which is online remains online and the information which is from offline sources remains there.

Offline Enterprise model deals with this disparity by bridging this information barrier. You need to catch the offline audience with some offline presence. Recall the case of Online job database. The clients of this business are distributed in the following ways :

- Big Companies jobs are listed online.
- Many of the jobseekers are also online.
- Much larger number of small to middle firms job listing are not online
- Large number of jobseekers are still not online.

How about developing a business process where these four segments can come on a common platform, the unique fusion of Offline and Online. Let us see how the business takes shape after applying the Offline Enterprise Model.

A web based portal will continue to be the source of information dissemination for online listed companies and job seekers. Simultaneously the Enterprise will have Offline presence for the purpose of data collection and generating the offline clients.

This way the portal has listed the data of Online companies and offline companies and firms(which were previously dependent only on print media for publishing the job)

Now the job seekers who are online do have a option of continue searching the jobs online. Moreover, the job seekers who are offline can be sent a customized news letter, generated according to their own profile i.e Qualifications, skills, experience, age etc. (Imagine the appointment section of the newspaper with only the job listings suitable for you). Offcourse the job database portal will charge the subscription fees.

Advantages of The Offline Enterprise model:

- Bringing the two worlds together.
- Large number of potential customers.
- Greater customization which is otherwise not seen in Offline media.

Thus, we see that the concept of “Offline Empowerment” can not only nucleate some unique configurations for the E-Business models but can also be used to cater the requirements of the large number of offline Indian population in various ways. The above two models are generic in nature and can be applied to several business concepts. The success of the application will certainly depend on the effective deployment, robust planning and operations.

# Cost-Benefit Analyses of Internet Investments

Michael Holm Larsen & Kim Viborg Andersen

Department of Informatics  
Copenhagen Business School  
DK-2000 Frederiksberg, Denmark  
{mhl, kva}.inf@cbs.dk

## Abstract

“Do we get value or money?” or “Do we have an attractive ROI?” are vital questions that any organisation is encountering today in pursuing an exploitation of the Internet. No matter whether exploitation is in regard to a focus on internal efficiency or external effectiveness the organisation carefully needs to verify the investment in terms of expected costs and likely benefits.

The research question of the paper is to identify the different approaches to cost-benefit methods of Internet investments and to provide an overview of what the approaches sheds light upon. Moreover, the paper provides two examples of cost-benefit analyses. Finally, the paper provides a applicable short-list of important activities and decisions in a cost-benefit analysis.

The paper suggests that cost-benefit analyses should not only contain content variables, but also include flow variables of the communication process, i.e. the variables of volume, data integration, diversity and span.

## 1. Introduction

Investment analysis in information systems is not a new focus area, neither for researchers and consultants or companies and organisations (Hamilton & Chervany 1981, Willcocks 1994). It is nevertheless an area in constant development where the methods for evaluation of investments are becoming more and more varied and the technology is developing at a rapid pace. This paper presents an introduction to cost-benefit analyses of Internet-investments. Our ambition is to give the reader a subtle picture of the cost and benefit sides, enable the reader to distinguish between financial and non-financial methods and understand the content and flow variables. Flow variables are also called process variables.

There may be many reasons for investing in information and communication technology (ICT) and especially in the Internet. For an organisation, the arguments may range from operational or tactical to strategic statements, or they may represent a combination – depending on the situation. The reasons why an organisation wishes to invest in the Internet may be:

- $\frac{3}{4}$  Commercial vital reasons, as if e.g. it is vital to the organisation’s core business or in connection with a project activity.
- $\frac{3}{4}$  Enforced reasons, as if e.g. a supplier or distributive trade demands it and has the negotiating capacity to do so.

- $\frac{3}{4}$  Cost saving and/or profit-earning motives.
- $\frac{3}{4}$  Compensation reasons, as e.g. after a burglary or a damaging virus attack.

Irrespective of reasons, it is often a good idea to make a feasibility study of resource requirements and expected output/benefits – i.e. a cost-benefit-analysis.

Just as the reasons may vary, the level of ambition may also be diverse, and in connection with utilising the Internet, the company can choose to focus on information, communication, transaction and/or integration.

Today, several software programmes include very advanced tools to perform CBA’s. It applies e.g. to IT Service Vision in the SAS-package ([http://www.sas.com/offices/europe/denmark/itsv/itsv\\_manager.html](http://www.sas.com/offices/europe/denmark/itsv/itsv_manager.html)).

At several trade associations and consultancy firms, it is possible to download templates with which to perform CBA’s. The EDI-Council’s server e.g. has a direction to EDI-investments (excel format), which can be downloaded through [www.edu.dk/74.htm](http://www.edu.dk/74.htm). The same applies to the American Office of Risk Ass. And Cost-Benefit (see URL: <http://usda.gov/agency/oce/oracba>). An increasing need for visibility of Internet-solutions within a growing number of fields also creates a need to clarify the contributions from the Internet. When the IT-department proposes to upgrade Windows XP, developing a new intranet or supplying all salesmen with a PDA (Personal Digital Assistant) such as Palm Pilot, the question is: “What does the company gain from these investments?”.

## 2. Research Approach

The research task of the paper is to presents an explorative study of cost-benefit analysis (CBA) practice and research.

The research question of the paper is to identify the different approaches to cost-benefit methods of Internet investments and to provide an overview of what the approaches sheds light upon.

The research method is a literature review of cost-benefit analysis highlighting existing research finding and focus areas. Moreover, the paper reviews different approaches to cost-benefit analysis.

Moreover, the paper provides two examples of cost-benefit analyses. Finally, the paper provides a practical short-list of important activities and decisions in a cost-benefit analysis.

### 3. Literature Review

A common definition of cost-benefit analysis is that it maximizes a social welfare function that aggregates unweighted and unrestricted preferences, e.g. Adler & Posner (1999). Moreover, Adler & Posner (1999) argue that constrained cost-benefit analysis is consistent with a broad array of appealing normative commitments, and it superior to alternative methods of project evaluation.

Cost-benefit analysis has traditionally been concerned with the meso- and macro- levels of the economy focusing on the welfare of a defined society (Mishan 1971, Brent 1996). Also, cost-benefit analyses are used in various sectors and industries, e.g. Noy (1999), Honig & Lampel (2000), McDonald (2001).

Cost-benefit analysis is applied to the evaluation of various phenomena (Fischer 1994, Nolan et al. 1999). In particular, cost-benefit analysis is widely used on a micro-level evaluation projects, investments, new businesses, etc. (Ngwenyama 1999, Bleichrodt & Quiggin 1999, De Haan & Mol 1999, Julnes 2000, Lee & Cunningham 2001, Dey & Gupta 2001, Bleichrodt & Quiggin 2002).

Applications of cost-benefit analysis ranges from specific and well defined projects to support decision making to "new" management problems within enterprises such as improvement of the quality of working life (De Haan and Terra, 1988), advanced manufacturing techniques (De Haan and Peters, 1989), and environmental management (De Haan and De Groene 1993, Yedla & Parikh 2001).

De Haan & Mol (1999) argue that there are two basic principles for cost benefit analyses at the level of the firm. Firstly, any measure to improve the performance of a firm can be seen as an investment and thus should be evaluated accordingly. Secondly, only changes in the relevant items caused by the measure have to be taken into account.

### 4. Cost Benefit Analysis

One perspective argues that often Internet investments are not a choice, but an almost unavoidable spiral with very few options. As a part of the launching of Microsoft, the company will not support earlier versions of Windows (95, 98 and 2000) after the month of July. It does not mean that you cannot use Windows 2000 after the 1<sup>st</sup> of July. But it means e.g. that you cannot expect new gadgets, software and different kinds of hardware to function together with earlier versions of Windows. It is possible e.g. to purchase a printer, but you might have to upgrade to Windows XP to make it function, and in this way a lock-in effect of the customer is obtained, cf. Hax & Wilde (1999).

Another approach to internet-investments regards it primarily as a learning process. It is more important to allow room for experiments with the technology than to settle on one single solution. Correspondingly, attention may be focused on knowledge sharing and exchange or establishing IT and Internet competence in the organisation, which will not necessarily give measurable

results in pounds and pences –and especially not in the short term.

Two main schools of measuring effects have crystallized: financial and non-financial measurements or said in a more popular way: "hard and soft" measurements, cf. Dempsey et al. (1998). At company level, the financial methods include bottom line results for the organisation or department, present value and cost-benefit analyses of projects. At society level, the financial methods comprise effects on the GNP, export/ import, the interest rate and, if any, supply and demand effects.

An alternative financial evaluation method of IT investments is to use the "real options" theory, cf. Li & Johnson (2002). Li & Johnson suggest that different models are used depending on the level of the technological "switching costs" and the competitive situation of the organisation. The real options theory can also be used as a starting point for strategic actions and support the decision-making process relating to evaluation and justification of IT investments (Kim & Sanders 2002).

At company level, the non-financial methods deal with portfolio and "balanced score card" techniques and at society level with more general issues such as qualification of the labour force. Environment, working environment and social responsibility may be focus areas on both company and society levels.

Table 1: Measuring Effects.

	Financial Effects	Non-financial Effects
Company Level	Return on investment (ROI), Net Present value (NPV), Cost-benefit	Portfolio, Balanced Score Card, Environmental, Working Environmental, and Social Responsibility
Society Level	Gross National Product (GNP), Export/Import, Interest Rate, Supply and Demand	Environmental, Working Environmental, and Social Responsibility, Job Content and Quality

In large organisations with several IT-projects running simultaneously, portfolio management of the IT-projects is often necessary (Solomon 2002). In this connection, it may be an advantage to perform cost-benefit analyses of the individual IT-projects/investments to allow management to see where the money has been spent, why it is or is not necessary to maintain projects and which resources are vital to continue the drive. Therefore, portfolio management makes it necessary to establish comparable criteria in cost-benefit analyses.

Regardless of perspective, it is rarely an advantage to disregard the financial perspective. Attention to the operating profit and ROI (return on investment) is crucial,

cf. King (2002).

## 5. Objectives and Principal Elements in CBA

To make a proper cost-benefit analysis (CBA), it is crucial to know the owner of the investment and what objectives the owner, i.e. person, department or private/public organisation, wants to achieve with the IT-investment. A number of studies show that IT-investments are not always based on or part of a strategy, which is why the relevance of cost-benefit analyses might be unclear (Clarke 1995). Even when the objectives are clearly stated, it is paramount to know where and how to achieve and measure the benefits. In other words, it is necessary to have general strategic objectives that can be decomposed into measurable and localised benefits.

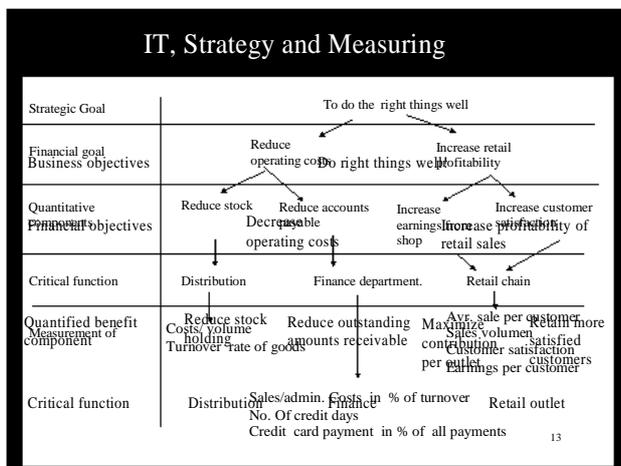

Figure 1: IT, Strategy and Measuring.  
Source: Developed after (Willcocks, Feeny et al. 1997).

CBA's of Internet solutions assume that they have a direct or indirect impact on e.g. the company's operating profit as direct cost saving or indirect cost avoidance measures and that the strength of the impact is expedient and feasible to determine (situation 1). Others believe that the relation between organisation and IT, including derived effects/learning processes, is so complex that it is futile to talk about CBA of IT (situation 2). Others again argue that it only has limited value to focus on the company's CBA of IT in the network society. Instead, we ought to focus on the dependencies – static as dynamic - of which both the technique and the company are part. CBA is hardly the most suitable tool for such purposes (situation 3).

## Fundamental choices before CBA

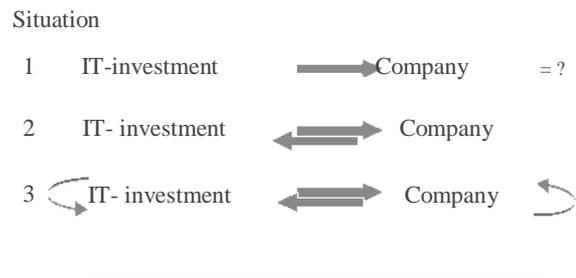

Figure 2: Fundamental Choices Prior to CBA.

### 5.1 CBA Elements

A relevant CBA question to an IT-project is: What does it cost and which benefits do we derive? However, after this question it becomes more difficult. A basic advice is to clarify the conditions on which the CBA is based, including the organisation's general approach to IT-projects and management of IT-projects (Cadel and Yeates 2001).

It makes a big difference whether the approach favours an extension of the ideas in the waterfall model about IT-systems development separating pilot surveys (Bødker, Kensing et al. 2000), implementation and utilisation (Earl 1999) or whether e.g. the phases are regarded as an integrated and repetitive process.

The simple CBA comes in three versions:

- ¾ Economic efficiency model
- ¾ Resource allocation model
- ¾ Alternative costs model

The economic efficiency model focuses on the IT-project's costs (C) and benefits (B). In allocating resources, e.g. between one department's application of an Internet solution and another department's system application, allocation weights are used to ensure that department 2's benefits are larger than department 1's costs (disadvantages) in e.g. presentation of an Internet solution. Finally, the alternative costs can be evaluated, i.e. do department 2's benefits from the Internet solution exceed the reallocated resources in the department and the loss, if any, in department 1 as a result of the Internet solution.

## The Simple CBA

---

Economic efficiency:  $\frac{B-C}{(B: \text{benefits}, C: \text{costs})}$

Allocation politics:  $\frac{a_2 B - a_1 C}{(a: \text{allocation weights})}$

Alternative costs:  $a \frac{a_2 B - a_2 R - a_1 L}{(L: \text{loss}, R: \text{re-allocation})}$

Figure 3: The Simple CBA.

Of course, it may be difficult to determine benefits, but some benefits are more difficult to determine than others. The figure below lists a range of factors that can be measured directly such as productivity, production costs, administration costs and IT-expenses. The figure's right side shows effects that are more difficult to measure such as increased control of resources and job satisfaction. Whereas the left side illustrates all the interesting measures or input reflecting such measures, the right side may be seen as variables explaining why some Internet solutions are not appreciated or fail to get support from employees.

Table 2: Measuring Benefits.

Measurable Benefits	Benefits difficult to measure
Increased productivity	More efficient use of production facilities
Lower production costs	Improved resource control
Reduction of employees	Improvement of planning function
Lower IT-expenses	Increased flexibility
Lower third party supplier costs	Punctual and more information
Lower administrative costs	Improved organisational learning
General cost reduction	Increased job satisfaction
	Improved decision making
	Improvement of routines
	Increased user/customer satisfaction
	Improvement of image

A third of the orders are placed with sales representatives at visits, another third via telephone/fax/e-mail, a sixth via physical purchases in shops and a sixth with the suppliers via the Internet.

The administrative costs are estimated to be DKK 80,- per order (ordering, invoice processing, payment). When reordering, the total administrative cost is estimated to be DKK 100,-.

Now, an internet-based purchasing solution is established. It requires an initial investment of DKK 1 million, including training. If all purchasers are going to

have a PDA, it will cost another 3 million.

In the solution, the useful life of the investment is estimated to be 2 years after which the replacement price will be DKK 2 million. If the austerity model without PDA is chosen, the replacement price after 2 years will only be DKK 500,000.

From day one, 300 suppliers are part of the solution, and at the end of the first year another 100 suppliers have joined. At the end of the second year, another 250 have joined. At the beginning of the first year, 40% of all orders are covered by the solution. At the end of the second year, it is estimated that 80% of all order lines are covered. At the end of the second year, it is also estimated that the total decline in faulty orders is 50% among orders placed via the Internet. The increase in the number of digital suppliers and orders including the reduction in faulty orders is a linear and inter-polar process.

The interest level is fixed at 7%.

A government agency wants to introduce self-service via the Internet. The objective is to improve citizen service, make cold hands warm and facilitate analyses of work processes.

The agency is primarily occupied with case administration and has approx. 100 employees. The annual payroll costs are DKK 32.5 million (in total 166,000 working hours). 55 employees are directly engaged in casework (in total 91,300 hours). The total operating budget including payroll costs amounts to DDK 51 million, out of which 18.5 million is allotted to other operations. This amount is not affected by the Internet solution.

Annually, there are 8,000 completed cases (on average 12.5 hours/case), 17,300 inquiries from citizens about cases (on average 15 minutes spent directly) and 7,000 inquiries from citizens (telephone, letter, fax, e-mail) that have nothing to do with concrete/non-completed cases (on average 10 minutes spent directly, 10 minutes follow up).

In addition, there are 2000 annual inquiries from politicians, departments and other bodies (on average 20 minutes spent directly, 30 minutes follow up).

Table 3: Consumption per hour before implementation of IT-solution and after implementation of alternatives A and B.

			Alternative A	Alternative B
Workflow	Sorting and achieving	10.000 h	5.000 h	5.000 h
	Find cases	15.000 h	4.000 h	21.000 h
	Evaluate content	5.000 h	5.000 h	23.000 h
	Meetings	35.000 h	25.000 h	37.000 h
	External meetings	21.207 h	10.000 h	45.000 h
(1)	Total	85.207 h	49.000 h	131.000 h
Inquiries	Handling the case	15 min. x 17.300	5 min. x 10.000 inq.	5 min. x 50.000 inq.

		inq.		
	General inquires	10 min x 7.000 inq.	3 min. x 17.000 inq.	1 min. x 87.000 inq.
	Internal / from politicians	50 min. x 2.000 inq.	15 min. x 1.700 inq.	10 min. x 31.000 inq.
(2)	Total	7.169 h	2.108 h	7.083 h
(3) Other		72.634 h	72.634 h	72.634 h
Total		166.000 h	123.742 h	210.717 h

They have now adopted an Internet solution that involves complete indexation of cases, IT-project management on case, employee, department and management levels and 'open' access to all input, output, content and benchmarks for at least one person other than the relevant caseworker. The initial investment (development and implementation) including training is estimated to DKK 1½ million and adjustment of existing applications will cost another 4 million. The useful life of the solution is estimated to be one year with an annual replacement price of DKK 750,000. The interest level is fixed at 7%.

In alternative A, the number of time-consuming direct inquires about specific cases declines. As a result of the Internet solution, citizens can now find answers to some inquires from the information available at the Internet. There is a small drop in inquiries about the progress of cases from other employees and politicians, but a significant drop in the number of minutes that each inquiry takes. On the other hand, there is a marked increase in general inquiries. However, now they only take 3 minutes compared to 10 minutes previously.

In alternative B, the number of inquiries explodes from all sides: case inquiries increase from 17,300 to 50,000, general inquiries increase from 7,000 to 87,000 and 'internal' inquiries increase from 2,000 to 31,000. A cost benefit analysis is made for alternatives A and B.

## 5.2 The Point is the Result as well as the Process

Partly, examples A and B provide inspiration by showing two interesting cases, and partly they illustrate that efforts to acquire the necessary data often give us the chance to look at the IT-solution in ways that we would not have done without a CBA. We are forced to explicate preconditions and assumptions about IT-investments. We readily admit that often it does not make sense to make a CBA. In several studies at the Department of Informatics, we have continued our research into the elements in CBA that can be measured directly or are difficult to measure. We distinguish between content variables and flow (process variables).

## 5.3 Content and Flow Variables in Determining Benefits

Content variables in a CBA may include capacity, interaction, values and orientation. The capacity variable deals with the quality of information, efficiency and effectiveness. The interaction variable focuses on control and power, including customer relations. Values comprise e.g. stress and legal protection. Finally, orientation relates to how often the Internet solution leads to a more digital decision-making process reducing other communication and decision forms. In a large-scale international study, we have found that the effects are unmistakably positive on the capacity side, but predominantly negative on the value side.

Figure 4: Content Variables.

Through the process variables, we focus on the flow in communication. The four variables in the flow analysis include volume, data integration, diversity and span. We might expect that companies selling via the Internet would score 100% on the variable data integration. But that is not at all the case. Only 25% of the companies selling via the Internet are capable of effecting an automatic integration with the IT-systems in charge of executing orders (delivery, production, etc.). Approx. 14% of the companies have integrated Internet sales with the invoice system (Danmarks Statistik 2002).

Table 4: Process variables (flow)

Variable	Description
Volume	What percentage of the total number of documents is exchanged via this solution?
Integration	What percentage of documents received digitally is forwarded digitally?
Diversity	What percentage of the total number of different types of documents is included in the digital solution?
Span	What percentage of business partners takes part in the digital exchange?

Source: Andersen et al. (2001).

## 6. Managerial Overview of the CBA of Internet Investments

In this paper, we have looked at different approaches to and perspectives on cost-benefit analyses of Internet investments. We have especially focused on distinguishing between financial and non-financial methods and the identification of content and flow variables.

In the paper, we have highlighted a number of recommendations summarised in the table below:

No.	Recommendations
1	Identify the owner of the planned investment
2	Identify investment objectives
3	Choose perspective (additional earning capacity, cost reduction, development of communication/relations and/or learning/knowledge management)
4	Choose method (financial and/or non-financial)
5	Identify content variables in CBA
6	Identify flow variables in CBA
7	Perform the CBA

However, cost-benefit analyses should not stand alone. Often, it is an advantage if organisations look at "Total Value of Ownership" (TVO). TVO consists of three elements, cf. Dempsey et al. (1998). The first step involves a thorough cost-benefit analysis to evaluate the expected increase in value from the investment. Second, sturdy management processes are important to integrate IT and Internet into the normal business planning. And finally, it is important to have some experience in business evaluation to be able to make difficult trade-offs efficiently.

## 7. Conclusions and Future Research

The paper addresses the important issue of cost and benefit evaluation when organisations are considering investing in exploitation of the Internet.

In particular, the paper address different approaches to CBA and suggests that evaluation ought to consider content as well as flow variables

The paper presents two case studies. The first case study is from the private sector and deals with purchasing via the Internet. The second study, which is from the public sector, deals with self-service via the Internet.

Finally, the paper provides an applicable short-list of important activities and decisions in a cost-benefit analysis.

Future research will go into in-depth case studies and comparable studies in order to provide further empirical data. Moreover, the analysis method will be challenged with other bodies of theory in order to provide a robust approach.

## Extended Abstract

The development of IT, especially the emergence of Internet, has influenced the purchasing behaviors of customers in recent years. Many literatures argue that the Internet leads to intense price competition and the market will finally evolve into a frictionless state because the consumers can acquire the product information more and more easily. However, some research results show this is not always true. For example, Lee found that the price of used cars auctioned in the e-market is higher than that of the conventional market in Japan; Bailey did a research on the products, such as books, CD and software in Boston area and indicated that the e-market's price is higher. So in order to explain the influence of information technology on consumers, we build a search model in this paper and use the search theory to analyze it.

Our model inherits some characteristics from some previous search models and discusses an important variable--search cost. The first search model, the Hotelling Model, regarded travel costs as consumers' search costs and pointed out that search cost is a source of monopolization. But it did not take the factor of sellers, which might influence the search cost as well, into account. Although Salop, Bakos, Zettlemeyer, Rajav Lal improved this aspect of Hotelling's model, their definitions of search cost did not differ much from Hotelling's in essence. Different with these models, we bring forward an inventive idea that the search costs are divided into two parts: one is called systematic search cost and the other is nonsystematic search cost. Systematic search cost is the cost of accessing a seller and negotiating the price, which may occur in every purchase, and it is a feature of markets. Both transportation fee and calling fee belong to this part. Generally speaking, buying the products in a conventional market would cost

consumers more systematic search cost than in an e-market. On the other hand, nonsystematic search cost isn't an innate feature of markets and can be controlled by sellers. They can manipulate this part of search costs through many ways like the products' design, marketing, the layout of product-selling homepages and so on. The more the products deviate from the normal, the higher this kind of cost is. And the nonsystematic search cost is optional, which means that consumers may buy a product before knowing its exact utilities.

In this paper, we mainly discuss the equilibrium of oligarch markets. It assumes there are two firms selling the same kind of products in the market. The first one is the leader and the other is the follower. Every consumer is buying at most one item from the two sellers and can return the dissatisfying items with paying the return cost, which is also a feature of market. It is supposed that there is no difference of quality between the products of the two sellers, but there may be some non-quality differences, such as the appearance and the design of the products. Consumers know the prices, the systematic search costs, and the non-systematic search costs. However, they don't know the gross utilities they will derive from the product but know the distribution pattern of the utility. The search pattern of customers could be illustrated in a search tree. In each stage of the search tree, customers can choose an action from the action set according to the expected utility of each one. On the other hand, sellers must make the decisions of the two variables: prices and the nonsystematic search costs. The decision-making process is a two-stage perfect-information game. First, the sellers must seek the price equilibrium under certain combination of nonsystematic search cost. Secondly, after solving the problem of sub-game equilibrium, we can get the nonsystematic search cost equilibrium and it comes the equilibrium for the whole problem.

By simulation, we get the equilibriums of the market for some special cases. And some managerial implications derived from the simulation results are that in a low-return-cost market, the higher systematic search cost, such as the transportation fee and the calling fee, may cause the followers of the market gain less. If this kind of search cost is high, people are relatively unwilling to search and buy the products of the less famous producer, that is, the follower's products. And even after buying the follower's products, because the return cost is low, many consumers would choose to return the dissatisfying items. So in a low-return-cost market, the higher systematic search cost is a disadvantage to the follower. It is recommended that the followers may invest in information technology, e.g. the Internet to make search easier and lower the systematic search cost. By realizing the information technology first, the follower can put the leader into a disadvantageous circumstance. Therefore, the leaders, on the other hand, should also

utilize the technology to consolidate their power in the market as well. And in a high-return-cost market, the higher systematic search cost is also a disadvantage to the follower. The application of information technology can also benefit the follower and the leader. In addition, different from the low-return-cost market, our results show that in the high-return-cost market followers might choose to differentiate themselves to increase the non-systematic search cost. Because of the high nonsystematic search cost, the consumers would buy the products directly without knowing the exact utility of the product. Moreover, the high return cost would keep the consumers from returning the dissatisfying products. In this way, the followers lock the consumers who might originally not buy the products after knowing the exact utilities of them. Even if the leaders build the electronic transaction market firstly, the followers can also differentiate themselves to set a defense state against the competitors.

# An Intelligent Interface Integrated Services Environment for Electronic Commerce

## Abstract

This paper proposes an intelligent interface integrated services environment for electronic commerce. It contains four main modules, i.e., dialog manager, EC transaction ontology, information collector, and data analyzer. The dialog manager manages the transaction history of the user to collect the user-specific information. It also provides different helping functions for the user. The EC transaction ontology stores the business type of electronic commerce in the system. It classifies the business process into eight categories, i.e., transaction type, ordering pattern, merchandise type, logistic type, customer category, transport vehicle, delivery type, and service type. It also provides the relations and constraints between different business steps. The information collector instantiates and dispatches different information agents to extract, filter, and synthesize relevant transaction data from different data sources timely. The data analyzer is the main component of the system. It instructs the dialog manager to provide proper helping functions for the different users. It then uses the user model to classify the knowledge and skill level of a user. It also predicts the goal of the user by using case-based reasoning and fuzzy Petri-Net to recommend the user with the best transaction plan and browsing behavior. Finally, it monitors the quality of service that the system provided for the user. This environment not only provides an integrated human-machine interface but also manages the business information thoroughly for the users.

## 1. Introduction

The pervasive connectivity of the Internet provides the best mediation for a company to reduce the cost of products and establish closer relationship with customers. These companies usually incorporate the selling and marketing policy to provide interactive, friendly, and reliable services for the user. Electronic commerce (EC) should become the critical successful factor to compete with others in the modern network marketing [1][3][6][13][15]. The supply chain management (SCM) and customer relationship management (CRM) play important roles in EC. The SCM provides the efficient management method to deliver products from the supplier to the customer quickly. It incorporates the supply chain resources including ordering, logistics, manufacture, and

distribution to response any change of the market timely. The CRM provides an interactive, kind, and customer-made service to understand and serve their users. It incorporates the personalized service for different users to achieve the most loyalty and the maximum benefits for the company perfectly.

Many industries complete business transactions through the traditional or semi-automatic procedures, i.e., electronic data interchange, to buy or sell goods. They usually use some traditional or special communication equipments to exchange transaction information. These data exchange process may cause some limitations. First, the data contained in the business process may not be able to combine into an information chunk completely. It may cause some process delay or mistake, e.g., ordering and dispatching, if it only works done by hand or separate the whole transaction process into many pieces steps. Second, both the buyer and seller may produce misunderstandings or lose the chance to make competitive advantages if they cannot obtain complete, sufficient, and transparent information just in time. Third, they didn't provide a friendly and customize human-machine interface for the users in the traditional transaction procedure. It may obstruct the transaction process for different kinds of users. Finally, they didn't provide any systematic and suitable assistant and helping for the user with different experiences to complete the business transaction properly.

Many systems have been proposed to solve the above shortcomings. They try to use EC contained in the above to automat the business process. Seldom of them provide an integrated service environment for the users. They don't provide a transparent interface to integrate the data that located in heterogeneous data sources and distributed in many different sites. They also cannot provide an anytime service to present the business information just in time. They usually ignore the privilege of the user to understand and utilize the information in the process of EC. Moreover, many systems only provide a stereotyped interface for the user to yield the system. They don't consider the requirements and the working environment for the user with different experiences and proficiency.

This paper proposes an intelligent interface integrated services environment for electronic commerce. It contains four main modules, i.e., dialog manager, EC transaction ontology, information collector, and data

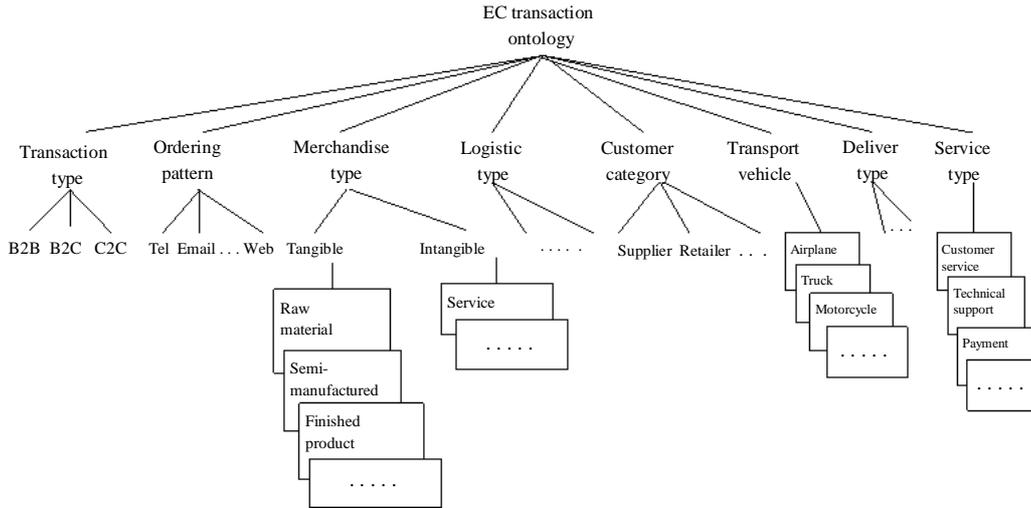

Fig. 2 EC transaction ontology

## 5. Information Collector

Information collector dispatches different information agents to retrieve related transaction data. The information agent is responsible to retrieve data from different data sources or heterogeneous database. It was generated from the agent pattern library that contains different agent components to do different tasks. The information collector instantiates and composites these patterns to construct different information agents. It retrieves, filters, synthesizes, and sends the most reliable data that the agent collected so far to the data analyzer. Each agent plays the role of intelligent anytime agent by recording the retrieved data in the information model. The information model contains the characteristics and the up-to-date data of the information sources. Note that the execution of the pattern library was implemented by Sun's Java remote invocation (RMI) [14]. Fig. 3 shows the pattern of Connect\_data\_server in the pattern library.

Pattern name: Connect\_data\_server

Pattern task: Data server connection

Receiving: Data server location, database type

Production: Connection status

Context: N/A

Executor:

```
import java.rmi.*;
import java.sql.util.Vector;
public interface Connect_data_server extends Remote
{ void accept(Agent agent) throws RemoteException;
  Vector Connect() throws RemoteException, SQLException;
}
public interface Agent extends java.io.Serializable
```

```
{ void run();
}
```

Fig. 3 The Connect\_data\_server pattern

## 6. Data analyzer

The data analyzer performs four tasks, namely, user modeling, plan prediction, user assistant, and quality of service monitoring. The user modeling classifies the user into different skill and knowledge level. The user profile contains the user-related information, e.g., habit, preference, and consumer behavior. The data analyzer uses the above information to classify the users. It preliminarily uses fuzzy ART neural model [2] to classify the users into different groups (Fig. 4). Each group contains the users with same characteristics. It then discriminates the knowledge and skill level of each group of the users. The former evaluates the accuracy, usefulness, direction, and reliability of the user's into five levels, namely, expert, senior, junior, novice, and amateur [8]. The latter measures the correctness, precision, dependency, and effectiveness. The correctness,  $U$ , measures the correct steps to do business process.

$$U = 1 - \sum_{i=1}^n e_i \quad (1)$$

where  $e_i$  represents illegal or wrong steps in the business process and  $e_i \in [0,1]$ . The precision,  $P$ , represents the average number of operations to complete the business transaction.

$$P = \frac{\sum_{i=1}^n t_i}{n} \quad (2)$$

where  $t_i$  is the number of operation to complete the  $i^{\text{th}}$

transaction and  $n$  is number of transaction. The dependency,  $D$ , represents the dependency between the business steps.

$$D = \frac{\sum_{i=1}^{n-1} I_i \cap I_{i+1}}{n-1} \quad (3)$$

where  $I_i$  is the  $i^{\text{th}}$  step of the business process and  $n$  is the total number of step in the business process. The effectiveness,  $E$ , measures the efficiency of the user to complete the transaction.

$$E = \frac{\sum_{i=1}^n w_i}{n} \quad (4)$$

where  $w_i$  represents the time to finish the task and  $n$  is the number of completed task. The dialog manager may provide different helping functions, interaction modes and graphical user interface for each group of users with different knowledge and skill proficiency correspondingly [8].

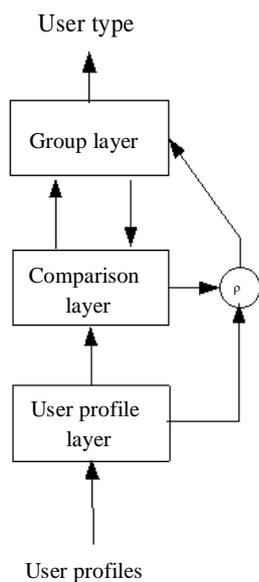

Fig. 4 Fuzzy ART for user classification

The plan prediction predicts the transaction plan of the user by using case-based reasoning (CBR) [4][8][9] and fuzzy Petri-Net [5]. The former technique uses the past business history of the user to find the most similar plan. The latter technique uses the similar business plan and the user profile to predict the possible browsing behavior.

The user assistant provides a robust assistant for the user to complete the business transaction with the help of EC transaction ontology. First, it checks the completeness and rationality of the transaction data. It then guides the user to input relevant data in the

transaction steps. It also recommends the appropriate actions, steps, and browsing behavior for the user to complete the transaction. The quality of service monitoring measures the service quality (SQ) of the information sources.

$$SQ = F(A, C, R, T) = A * W_a + C * W_c + R * W_r + T * W_t \quad (5)$$

where  $A$ ,  $C$ ,  $R$ , and  $T$  represent the availability, consistency, reliability, and timelessness of the information source, respectively.  $W_a$ ,  $W_c$ ,  $W_r$ , and  $W_t$  are the respective weights. Fig. 5 shows the fuzzy levels of the SQ.

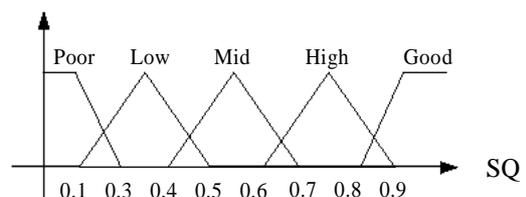

Fig. 5 Fuzzy levels of the service quality

## 7. Conclusions

We have proposed an intelligent interface integrated services environment for electronic commerce to provide an integrated human-machine interface and business information management. The environment contains four main modules, namely, dialog manager, EC transaction ontology, information collector, and data analyzer. The dialog manager manages the transaction history and supports different styles of interaction patterns and helping functions for the user according to its experiences and knowledge level in business transaction. The EC transaction ontology provides eight categories of business process to assist the data analyzer handling the transaction information. The information collector instantiates and dispatches different anytime information agents to extract, filter, and synthesize relevant transaction data from different data source timely. The data analyzer is defined as the major component to instruct the dialog manager; discriminate the skill and knowledge level of the user; predict the goal of the user; and monitor the quality of service.

In summary, the proposed intelligent interface integrated services environment exhibits the following interesting features. First, it differentiates a business user into different levels according to the skill and knowledge level of the users. It then provides an adaptive interface to complete business transaction process for the user. Second, it identifies the content of the EC transaction and depicts them into the EC transaction ontology clearly. The ontology may provide great helping for the users in intelligent interface. Third, it uses the agent pattern library to instantiate and dispatch appropriate anytime information agents to collect the

transaction data. These agents can be endowed with different tasks in the information collection process within the divergence data sources. Fourth, the user modeling separates the user classification into two phases. It discriminates the users into different groups by adopting the fuzzy ART neural networks. It then uses the fuzzy measurement to evaluate the levels of the user according to its skill and knowledge level. Finally, it uses CBR and fuzzy Petri-Net to predict the possible business plan and browsing behavior.

## Abstract

This study attempts to determine the optimal goods ordering periods for internet stores by considering time-dependent consumer demands and close demand-supply interactions. In order to capture dynamic and time-sensitive consumers, the entire study period is divided into a number of ordering periods with various duration. In the demand side, the study formulates a consumer utility function to construct a binary logit model, which determines consumers' choice probabilities between internet shopping and conventional in-store shopping. The expected choice probability of choosing internet shopping is aggregated by a transformation probability density function of individual income based on the logit model. Then, the study further aggregates individual consumer choice probability to estimate the total demand for internet stores by considering variations in access time to retail stores, and delay time of receiving ordered goods. In the supply side, the study formulates transportation costs considering extra labor cost due to 24 hours business hours of internet stores, and constructs inventory costs reflecting the relationship between the batch ordering of goods, which are made by internet store operators to their suppliers and continuous ordering of goods, which are made by their consumers. Finally, a case study and sensitivity analysis are provided by R-company in Taiwan to illustrate the application of the models. The results show how the operators of internet stores should determine the number and duration of ordering periods in response to time-dependent consumer demand, thereby maximizing their profits.

Keywords: Internet shopping, Time-dependent consumer demand, Transportation cost, Inventory cost

## 1. Introduction

Electronic Data Interchange (EDI) and related technologies are making it less expensive to transmit demand information to suppliers. Besides, information flows-based internet shopping has significantly improved consumer service performances by reducing the order processing time and offering goods delivery information such as when the ordered goods will be delivered to consumers. Since the real time demand is known via internet, the inventory costs will be lower by ordering goods from wholesalers or manufactures fewer quantity but more times according to the demand pattern and shipping them directly to consumers. However, high ordering frequency and small order quantity of consumers' internet shopping behavior makes it more expensive to deliver ordered goods to individual consumer [18]. Due to economies of scale, it is cheaper to transport larger amounts per shipment. However, it will also result in higher delay time of receiving ordered goods, consequently, consumers' intention to shopping via internet is sinking lower. This involves a trade-off between the demands of internet stores and logistics costs. Therefore, service strategies must achieve not only the goals of making logistics costs low but also satisfying consumer needs. One of the crucial factors to determine an optimal service strategy is consumer demand for that goods. The assumption of a constant demand is seriously questioned in recent times, since in reality; the demand is generally varied with time. For instance, the peak demand for food products is likely to occur at lunchtime. Therefore, in this study, we explore how to determine the optimal number of ordering periods for internet stores by taking time-dependent consumer demand and demand-supply interactions into account.

The issues regarding internet shopping have been extensively investigated in many studies (e.g., [19, 22, 23]). [4] stated that the home-shopping system eliminated drive time and checkout time, and allowed shoppers to access to distant stores. On the other hand,

one of those disadvantages might be waiting times for ordered goods [28]. Past studies about consumers' shopping mode choices between internet shopping and store shopping focused largely on assessing the benefits and problems of internet shoppers or evaluating factors influencing consumers' intention to adopt internet shopping using collected data (e.g., [11,22]). Others discussed the demographic and psycho-graphic characteristics of internet shoppers in accordance with surveys on local shoppers (e. g., [12, 26, 27]). [17] proposed a network equilibrium framework for analyzing consumers' selection of internet shopping versus store shopping, and assumed consumers to be multicriteria decision makers. In the supply side, [18] concluded the major problem of electronic commerce is that there is more frequent orders with smaller order quantities, thereby resulting in high transportation costs. Hence, [16] designed an optimal mix strategy of drop shipping and in house inventory for e-retailers and identified the optimal solution to the model under uniform, exponential, and normal demand distributions. In another line of research, the physical distribution problems have been extensively investigated in many studies (e.g., [5-10]) but most of studies assumed inelastic demand and ignoring time-dependent consumer demand. Moreover, little has been done to exam the impact of time-dependent demand and 24 business hours of internet shopping on logistics cost.

The internet stores in this study are assumed to operate as retailers who order a batch of goods from wholesalers or manufactures and cooperate with the third party forwarders. In order to capture dynamic and time-sensitive consumer demands, the entire study period is divided into a number of ordering periods. The study area is also divided into a variety of zones with different retail store densities to reflect various spatial competitions between internet stores and retail stores. In the demand side, the study formulates a consumer utility function considering factors such as goods price, delay time of receiving ordered goods, access time to retail stores and individual income, and then constructs a binary logit model, which determines consumers' choice probabilities for internet and conventional shopping modes. Delay time of receiving ordered goods is determined herein as time span between consumers' goods ordering time and goods receiving time, and depends on the goods delivery cycles accommodating lead time for processing and handling. The expected choice probability of choosing internet shopping is aggregated by a transformation probability density function of individual income based on the logit model. Then, the study further aggregates individual consumer choice probability to estimate the total demand for internet stores by taking into account variations in access time to retail stores, and delay time of receiving ordered goods across different ordering periods. Variations in access time to retail stores mainly result from different spatial densities and opening hours of retail stores across different zones and different ordering periods; while delay time of receiving ordered goods varies with the change in internet store operator's goods

delivering cycles, which in turns depend on consumers' demands during each goods ordering period.

Furthermore, in the supply side, the study formulates transportation costs considering extra labor cost due to 24 hours business hours of internet stores, and constructs inventory costs reflecting the relationship between the batch ordering of goods, which are made by internet store operators to their suppliers and continuous ordering of goods, which are made by their consumers. Logistics cost functions for each ordering period are formulated by analytical approach. Then, integrating with the consumer demand model above, a nonlinear mathematical programming model is further formulated to solve the optimal number of ordering periods during the study period as well as the delivery cycles in each ordering period by maximizing the internet store profit subject to the demand-supply interaction.

The remainder of this paper is organized as follows. In section 2 we will formulate the choice model of teleshopping and aggregate consumer demand for goods of each ordering period. Nonlinear programming problems are formulated in Section 3 to determine the optimal number and pattern of ordering periods by maximizing profits subject to the demand-supply equality. In Section 4, numerical experiments are performed to illustrate the effect of the optimal solution to changes in parameters. Finally, Sect. 5 summarizes the study and presents the conclusion.

## 2 Consumer demands for internet stores

Three important groups of factors affecting the shopping behavior are characteristics of goods, the attributes of different shopping modes, and the characteristics of consumers [24]. Generally, goods that need detail examination before purchase are considered less appropriate for internet markets [14]. Thus, goods discussed here are those appropriate for internet markets. In order to capture the dynamic and time-sensitive consumer demand, the study formulates models of consumer choice probability. In the model, we address issues such as differences in consumers' socioeconomic characteristics, temporal variations in consumers' goods ordering time and spatial variation in consumer locations and differentiate competitions between internet stores and retail stores in urban and non-urban areas.

### 2.1 Individual characteristics

Let  $U_k(t, j)$  represent the total utility of a consumer who orders good at time  $t$  zone  $j$  via shopping mode  $k$ . Furthermore,  $U_k(t, j) = V_k(t, j) + e_k$ , where  $V_k(t, j)$  is the deterministic component;  $e_k$  is a random utility component, which represents the unobservable or immeasurable factors of  $U_k(t, j)$ . Suppose that all  $e_k$  are independent and identically Gumbel distributed, the choice probability of choosing shopping mode  $k$  can be estimated by the binary logit model [3] as

$$P_{TS}(t, j) = \frac{e^{U_{TS}(t, j)}}{e^{U_{TS}(t, j)} + e^{U_R(t, j)}} = \frac{e^{U_{TS}(t, j) - U_R(t, j)}}{1 + e^{U_{TS}(t, j) - U_R(t, j)}}, \text{ where}$$

subscripts TS and R denote internet store shopping and retail store shopping, respectively. The difference in the utility value of consumer shopping via internet stores and retail stores determines the choice probability of choosing internet shopping, which can be rewritten as

$$P_{TS}(t, j) = \frac{e^{v(t, j)}}{1 + e^{v(t, j)}} \quad (1)$$

where  $v(t, j)$  denotes the difference in the utility values of consumer shopping via internet stores and retail stores.

The utility function  $v(t, j)$  discussed here has the following specification:

$$v(t, j) = b_0 + b_1 \frac{P_{TS}}{I} + b_2 t_{TS,t} - b_1 \frac{P_R}{I} - b_3 t_{t,R,j} \quad (2)$$

where  $P_{TS}$  and  $P_R$  denote the price levels of goods via internet shopping and retail shopping, respectively;  $t_{TS,t}$  is the delay time of receiving ordered goods when consumers order goods via internet shopping at time  $t$  and  $t_{t,R,j}$  denotes the access time when consumers purchase goods via retail stores in zone  $j$  at time  $t$ ;

$I$  represents the consumers' income;  $b_1, b_2, b_3$  are parameters; and  $b_0$  reflects consumers' relative preference for internet shopping. The average value of time for delay time of receiving ordered goods,  $VOT$ , can then be estimated by Eq. (2). That is,

$VOT = \frac{\int v(t, j) f_I(I) dI}{\int v(t, j) f_I(I) dI} = I \frac{b_2}{b_1}$ , which increases with consumers' income  $I$ .

Assume that individual consumers with different personal income are served by the same supply condition, then the expected choice probability of choosing internet shopping for all consumers can be further estimated by aggregating individual consumer's choice based on the binary logit model and income distribution. The generalized exponential family of distributions may be used to describe income distribution [2]. Herein, we assume personal income  $I$  to be distributed with a normal distribution with a mean of  $m$  and standard deviation of  $s$ . The probability distribution function

(pdf) of  $I$  is  $f_I(I) = \frac{1}{\sqrt{2\pi}s} e^{-\frac{1}{2}(\frac{I-m}{s})^2}$ . From Eq.

(2), other thing being equal,  $v(t, j)$  is a function of  $I$ , so the pdf of  $v(t, j)$  can be expressed by a transformation of pdf of  $I$ . Then, the pdf of  $v(t, j)$ ,  $f_{v(t, j)}(v(t, j))$  can be written as:

$$f_{v(t, j)}(v(t, j)) = f_I \left( \frac{b_1(P_R - P_{TS})}{b_0 + b_2 t_{TS,t} - b_3 t_{t,R,j} - v(t, j)} \right) \left| \frac{b_1(P_R - P_{TS})}{(b_0 + b_2 t_{TS,t} - b_3 t_{t,R,j} - v(t, j))^2} \right| \quad (3)$$

Consequently, taking the expected value of choice probability of choosing internet shopping gives the following expression for the expected choice probability

$$E[P_{TS}(t, j)] = \int_0^1 P_{TS}(t, j) f(P_{TS}(t, j)) dP_{TS}(t, j) \quad (4)$$

The difference in utility values between internet shopping and conventional shopping determines the probability of choosing internet shopping,  $P_{TS}(t, j)$ , in Eq. (1); in other words,  $P_{TS}(t, j)$  is a random variable transformed by  $v(t, j)$ . Hence, the pdf of  $P_{TS}(t, j)$  is shown as

$$f(P_{TS}(t, j)) = f_V \left( V = \ln \frac{P_{TS}(t, j)}{1 - P_{TS}(t, j)} \right) \left| \frac{1}{P_{TS}(t, j)(1 - P_{TS}(t, j))} \right| \quad (5)$$

Substituting Eq. (5) for  $f(P_{TS}(t, j))$  in Eq. (4), then Eq. (4) can be rewritten as

$$\begin{aligned} E[P_{TS}(t, j)] &= \int_0^1 P_{TS}(t, j) \partial f(P_{TS}(t, j)) dP_{TS}(t, j) \\ &= \int_0^1 P_{TS}(t, j) \partial f_V \left( \ln \frac{P_{TS}(t, j)}{1 - P_{TS}(t, j)} \right) dv(t, j) \\ &= \int_0^{\bar{N}} \frac{e^{b_0 + b_1 \frac{P_{TS} - P_R}{I} + b_2 t_{TS,t} - b_3 t_{t,R,j}}}{1 + e^{b_0 + b_1 \frac{P_{TS} - P_R}{I} + b_2 t_{TS,t} - b_3 t_{t,R,j}}} dI \\ &= \int_0^{\bar{N}} \frac{e^{b_0 + b_1 \frac{P_{TS} - P_R}{I} + b_2 t_{TS,t} - b_3 t_{t,R,j}}}{1 + e^{b_0 + b_1 \frac{P_{TS} - P_R}{I} + b_2 t_{TS,t} - b_3 t_{t,R,j}}} \frac{e^{-\frac{(I-m)^2}{2s^2}}}{\sqrt{2\pi}s} dI \quad (6) \end{aligned}$$

## 2.2 Variations in consumer goods ordering time and locations

The impacts of consumers' goods ordering time on their choice probabilities are further analyzed. The delay time of receiving ordered goods is defined as time span between consumers' goods ordering time and goods receiving time, and is shown in Eq. (2) and past studies as an important factor affecting the probability of choosing internet shopping. Once ordering periods are set, the closer the goods ordering time occurs to the deadline of the ordering period, the shorter the time span between consumers' goods ordering time and goods receiving time is, and vice versa. Moreover, long access time to retail stores or delay time of receiving ordered good arises when the number of retail stores is few in sparse areas or consumer goods ordering time happened to be not at business hours. Therefore, it is important to understand how the goods ordering time, which is associated with the delay time of receiving ordered goods and access time to retail stores, affects the utility functions and choice probabilities.

Herein, suppose the entire study period is divided into  $S$  continuous ordering periods, and  $T_i = (t_{i,0}, t_{i,m})$ ,  $i=1, 2, \dots, S$ , is the duration of ordering period  $i$ , where  $t_{i,0}$  denotes start time and

goods, which have been: (1) consumed by consumers, (2) delivered, and (3) ordered by the internet store operator to suppliers. The shaded area in the figure represents the number of “item-hours” for items held by the internet store. Moreover, denote  $t_{i,0}$  as time when the internet store operator orders batch  $O$  and  $Q_{i,0}$  as the number of items ordered in batch  $O$ .

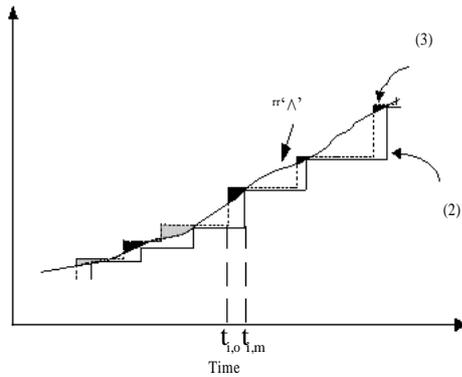

Fig. 1. Inventory cost profile

Inventory cost per item of goods per unit time can be estimated by purchasing cost per item,  $p$  and inventory carrying rate,  $w$ . Therefore, the total inventory cost of ordering period  $i$  resulting from the difference between operator's batch ordering time and consumers' goods ordering time is  $IC_i = pw [Q_{i,r} (t_{i,m} - t_{i,r}) - \int_{t_{i,r}}^{t_{i,m}} q_t]$

And, average inventory cost per item of ordering period  $i$  can be obtained by dividing  $IC_i$  by the total consumer demand of that period, that is  $AIC_i = \frac{1}{Q_i} pw [Q_{i,r} (t_{i,m} - t_{i,r}) - \int_{t_{i,r}}^{t_{i,m}} q_t]$ . Moreover,

average inventory cost per item of the entire study period is

$$AIC = \frac{1}{S} \sum_{i=1}^s AIC_i = \frac{1}{S} \sum_{i=1}^s \frac{1}{Q_i} pw [Q_{i,r} (t_{i,m} - t_{i,r}) - \int_{t_{i,r}}^{t_{i,m}} q_t]$$

Consequently, the average logistics cost per item of the entire study period can be expressed as the sum of average transportation cost per item and average inventory cost per item, that is

$$ALC = ATC + AIC = \# \frac{1}{S} \sum_{i=1}^s \frac{1}{Q_i} (c \partial y_{t_{i,m}} + pw [Q_{i,0} (t_{i,m} - t_{i,0}) - \int_{t_{i,0}}^{t_{i,m}} q_t]) \quad (11)$$

### 3.2 Formulation of the optimal problem

The profit during the entire study period can be computed by the price level per item sold at internet stores,  $p_{TR}$ , purchasing cost per item,  $p$ , average logistics cost per item,  $ALC$  and total consumer demands for items sold at internet stores over the entire

study period,  $\sum_{i=1}^s Q_i$ , such as

$$t = (p_{TR} - p - ALC) \sum_{i=1}^s Q_i \quad (12)$$

where  $t$  represents the total profit of the internet store over the study period. A non-linear programming problem is formulated herein to determine the optimal number and duration of ordering periods by maximizing the operator's total profits subject to demand-supply equality. From eqs. (6), (8), (11) and discussions so far, the nonlinear programming problem is formulated as follows:

$$\text{Max } t = (p_{TR} - p - ALC) \sum_{i=1}^s Q_i \quad (13a)$$

st.

$$ALC = ATC + AIC$$

$$= \# \frac{1}{S} \sum_{i=1}^s \frac{1}{Q_i} (c \partial y_{t_{i,m}} + pw [Q_{i,0} (t_{i,m} - t_{i,0}) - \int_{t_{i,r}}^{t_{i,m}} q_t]) \quad (13b)$$

$$Q_i = \int_{t=t_{i,0}}^{t_{i,m}} q_t^{TS} = \int_{t=t_{i,0}}^{t_{i,m}} \int_{j=1}^n q_{t,j} E[P_{TS}(t, j)] \quad (13c)$$

$$E[P_{TS}(t, j)] =$$

$$= \int_0^{\infty} \frac{e^{-b_0 + b_1 \frac{P_{TS} - P_R}{I} + b_2 t_{TS,i} - b_3 t_{R,j}}}{1 + e^{-b_0 + b_1 \frac{P_{TS} - P_R}{I} + b_2 t_{TS,i} - b_3 t_{R,j}}} \frac{e^{-\frac{(I-m)^2}{2s}}}{\sqrt{2\pi s}} dl \quad (13d)$$

$$\sum_{i=1}^s (t_{i,m} - t_{i,0}) = T \quad (13e)$$

$$i = 1, 2, \dots, s$$

Eq. (13a) is the objective function that maximizes the total profit of the internet store operator over the entire study period. Eq. (13b) defines the average logistics cost per item as described. Eq. (13c) represents the total consumer demand for items sold at the internet store during ordering period  $i$ . Eq. (13d) expresses the expected choice probability for items sold at the internet store. Eq. (13e) restricts that the summation of the duration of all ordering periods must be equal to the entire study period.

### 4. Numerical example and sensitivity analysis

A case study is presented as follows to demonstrate the application of the proposed model based on available data from R-company in Taiwan. To simplify the study,

we merely selected 6 cities from all cities currently served by R-company as our study zones, and assumed one operating day, i.e., 24 hours, as the study period and each unit hour as our study unit-time. Base values for parameters in the utility function, logistics cost function and study zones are either calibrated using stated preference survey or estimated from real data and are shown in Table 1, 2 and 3, respectively. The multipliers reflecting extra cost during different ordering periods,  $y_{t,m}$  are 2 during AM 0:00~9:00, and 1 during other regular hours. Fig. 2 depicts the time-dependent demands for items from consumers in Taipei City, and Fig. 3 represents the total time-dependent demands for items from consumers over the whole study area. The model is programmed using Visual C++, and the results are summarized in Table 4 and Figs. 4-8.

Table 1. The initial values of base demand parameters

Parameter	Initial Value
m	353.4 NT \$/hr
s	199.2 NT \$/hr
$b_0$	2.5
$b_1$	-0.06
$b_2$	-0.018
$b_3$	0.095
V	25 Km/hr

Table 2. The initial values of base supply parameters

Parameter	Initial Value

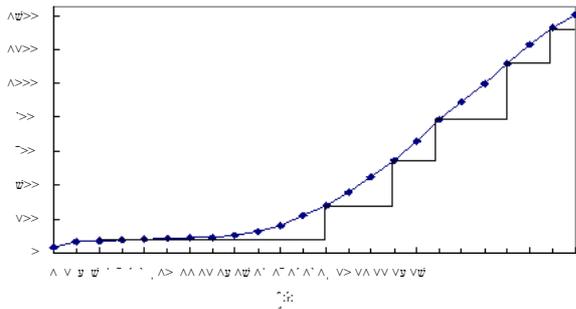

Fig. 5 Cumulative consumer demand for items of internet stores and cumulative delivered items

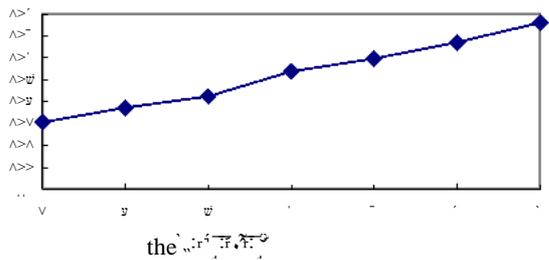

Fig.6 Average logistics cost per item vs. the number of ordering periods

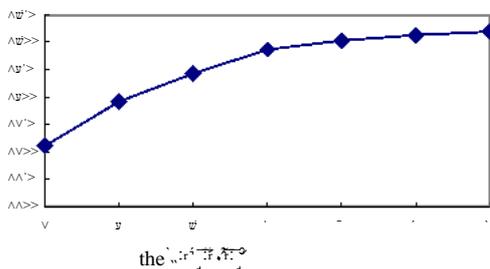

Fig.7 Consumer demand for items of internet stores vs. the number of ordering periods

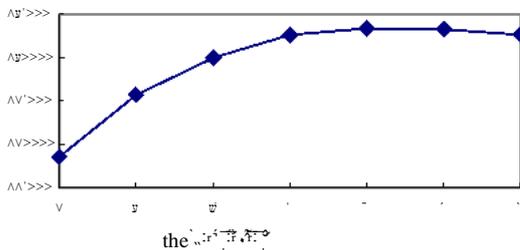

Fig. 8 Profit vs. the number of ordering periods

As shown in Fig. 4, the dotted line represents time-dependent consumer demands for items, while the solid line represents time-dependent consumer demands for items sold at internet stores. Figs. 3 and 5 indicate that there are a large number of items

demanded between 13:00 and 23:00 and indicates that there are also high densities of ordering periods; by contrast, the duration of ordering period is 10 hours at night, implying very low demand during this period. Moreover, as shown in Fig. 6, average logistics cost per item is increasing with the increase of the number of ordering periods during an operating day. However, though consumer demands for items of internet stores indeed increases with the number of ordering periods as shown in Fig. 7, yet the profit is not increasing in the same way but is maximized when there are 6 ordering periods during a day as shown in Fig. 9. Moreover, the optimal batch ordering time made by the internet store operator to the supplier is 0.5 hour before the deadline of each ordering period.

Table 5 lists the optimal objective function values under different values of fixed transportation cost. The study further performs sensitivity analyses to investigate how average logistics cost per item, consumer demand for items sold at internet stores and the total profit of the internet store over the study period are affected by changes in the value of fixed transportation cost as shown in Figs. 9-11. Table 6 presents model results under different values of variable transportation cost per item. Figs. 12-14 show how average logistics cost per item, consumer demand for item sold at internet stores and total profits of the internet store over the study period are affected by changes in the value of variable transportation cost.

Table 5 Model results under different fixed transportation cost

Base value of fixed transportation cost (C)	700	850	1000	1200
Optimal number of ordering periods	7	6	6	6
Consumer demands of internet stores	1414	1403	1403	1403
Average logistics cost (NT dollars)	104.796	105.709	106.907	108.464
Profits (NT dollars)	134710	133331	131819	130582
Ordering periods	0:00~3:00 3:00~13:00 13:00~15:00 15:00~17:00 17:00~19:00 19:00~21:00 21:00~0:00	23:00~3:00 3:00~13:00 3:00~13:00 13:00~16:00 16:00~18:00 18:00~21:00 21:00~23:00	23:00~3:00 3:00~13:00 3:00~13:00 13:00~16:00 16:00~18:00 18:00~21:00 21:00~23:00	23:00~3:00 3:00~13:00 3:00~13:00 13:00~16:00 16:00~18:00 18:00~21:00 21:00~23:00

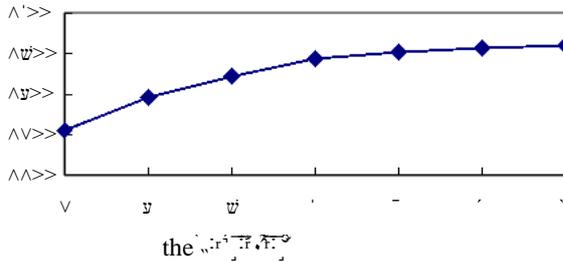

Fig. 10 Consumer demand for items of internet stores vs. the number of ordering periods under different fixed transportation costs

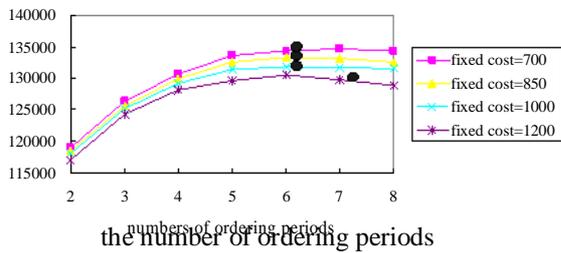

Fig. 11 Profit vs. the number of ordering periods under different fixed transportation costs

Table 6 Model results under different variable transportation costs

Variable cost (r)	85	100	125	150
Optimal number of ordering periods	7	6	6	5
Consumer demand for internet stores	1414	1403	1403	1387
Logistics cost per item (NT dollars)	90.4233	104.967	129.967	153.822
Objective function value (Profits, NT dollars)	154886	133331	98256.2	63145.3
Ordering periods	0:00~3:00 3:00~13:00 13:00~15:00 15:00~17:00 17:00~19:00 19:00~21:00 21:00~0:00	23:00~3:00 3:00~13:00 13:00~16:00 16:00~18:00 18:00~21:00 21:00~23:00	23:00~3:00 3:00~13:00 13:00~16:00 16:00~18:00 18:00~21:00 21:00~23:00	1:00~12:00 12:00~15:00 15:00~18:00 18:00~21:00 21:00~1:00

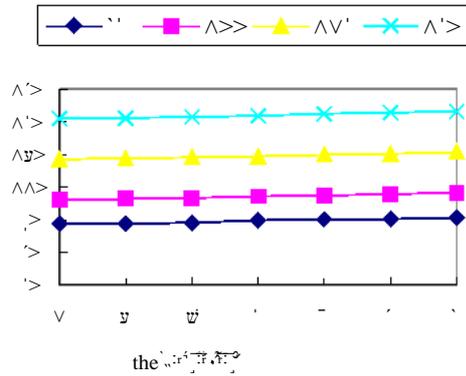

Fig. 12 Average logistics cost vs. the number of ordering periods under different variable transportation costs

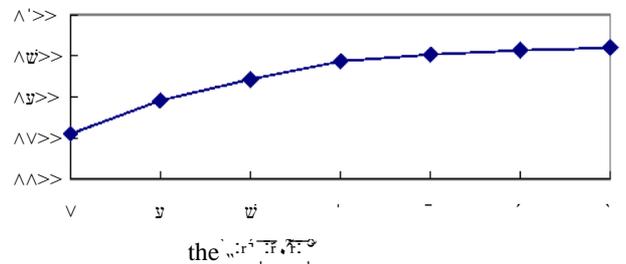

Fig. 13 Consumer demand for items vs. the number of ordering periods under different variable transportation costs

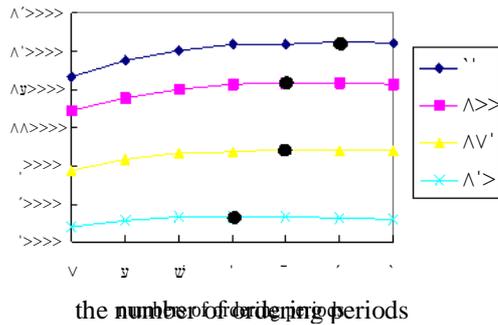

Fig. 14 Profit vs. the number of ordering periods under different variable transportation costs

The higher the value of fixed transportation cost leads to the higher average logistics cost per item and consumer demands for items of internet stores are identical no matter what value of fixed transportation cost is as shown in Figs. 9-10. Fig. 11 shows that a lower value of fixed transportation cost will result in a higher profit and the optimal number of ordering period is 6 no matter the value of fixed transportation cost is, 850, 1000 or 1200 NT dollars, while it is 7 when the value of fixed transportation cost is reduced to 700 NT dollars. Fig. 12 also shows there is a higher average logistics cost per item with the increase of variable transportation cost. Furthermore, it shows that the increased revenues from rising consumer demands for items of internet stores due to increase in the number of ordering periods may not be offset by the impact of the increasing variable cost per item on average logistics cost per item. As a result, the optimal number of ordering periods is 5 when variable cost is 150 NT dollars per item as shown in Fig. 14.

## 5. Conclusions

This study attempts to determine the optimal goods ordering periods for internet stores by considering time-dependent consumer demands and close demand-supply interactions. In order to capture dynamic and time-sensitive consumers, the entire study period is divided into a number of ordering periods with various duration. In the demand side, the study formulates a consumer utility function and then constructs a binary logit model, which determines consumers' choice probabilities between internet shopping and conventional in-store shopping. The expected choice probability of choosing internet shopping is aggregated by a transformation probability density function of individual income based on the logit model. Then, the study further aggregates individual consumer choice probability to estimate the total demand for internet shopping stores by taking into account variations in access time to retail stores, and delay time of receiving ordered goods across different ordering periods. Furthermore, in the supply side, the study formulates transportation costs considering extra cost due to 24 hours business hours of internet stores, and constructs inventory costs reflecting the relationship between the batch ordering of goods, which are made by internet store operators to their suppliers and

continuous ordering of goods, which are made by their consumers. Logistics cost functions for each ordering period are formulated by analytical approach. Then, integrating with the consumer demand model above, a nonlinear mathematical programming model is further formulated to solve the optimal number of ordering periods during the study period by maximizing the internet store profit subject to the demand-supply interaction.

Finally, a case study and sensitivity analysis are provided by R-company in Taiwan to illustrate the application of the models. The results show that there are a large number of items demanded between 13:00 and 23:00 and indicates that there are also high densities of ordering periods; by contrast, the duration of ordering period is 10 hours at night, implying very low demand during this period. Moreover, the internet store operator may change the number and duration of ordering periods in response to time-dependent consumer demand. Average logistics cost per item also may influence the optimal number and duration of ordering periods, in a way that the number of ordering periods decreases with the increase in either variable cost or fixed transportation cost.

In conclusion, this paper formulates an integrated model to determine the optimal number and duration of ordering periods by taking time-dependent consumer demand, and demand-supply interactions into account. These considerations have not yet been theoretically formulated and analyzed in past literature. It is envisaged that the results of the developed models not only shed light on understanding consumers' internet shopping behavior and its relationship with the operators' service strategies, but also provide guidance on marketing, delivery and ordering strategies for internet stores in response to time-dependent consumer demand.

## Abstract

Recently e-business has become the focus of management interest both in academics and in business. Among the major components of e-business, ERP (Enterprise Resource Planning) is the backbone of other applications. Therefore more and more enterprises attempt to adopt this new application in order to improve their business competitiveness. Owing to the specific characteristics of ERP, its implementation is more difficult than that of traditional information systems. For this reason, how to implement ERP successfully becomes an important issue for both academics and practitioners. In this paper, a review on critical successful factors of ERP in important MIS publications will be presented. Additionally traditional IS implementation and ERP implementation will be compared and the findings will be served as the basis for further research.

Keywords: E-business, ERP, Critical Successful Factors, Literature Review

## 1. Introduction

Recently the focus of IT application has shift from computerization and automation to electronic transaction or the so-called E-business which is regarded as the most important improvement to commercial competition. Therefore, e-business has come into the limelight not only academically but also commercially. The key components of e-business include Customer Relationship Management (CRM), Supply Chain Management (SCM), Enterprise Resource Planning (ERP), E-Procurement, Knowledge Management (KM) and so on [7]. Among these components of e-business, ERP is the backbone of other applications [7][10]. Davenport [4] indicates that ERP integrate all the information flowing through a company- financial and accounting information, human resource information, supply chain management, customer information seamlessly. This integration can overcome the information island problem in traditional IT application and increase efficiency and effective. In addition, with the use of central database, it can promise to provide accurate and real time data in business operation. For traditional businesses, with the adoption of ERP, it can employ the best practice of ERP to reengineer their business process. In contrast, for new established

businesses, it can apply best practice into the templates for their system design. Markus and Tains [10] also indicate that both small and large companies benefit both technically and strategically from investments in ERP. Because of the advantages discussed above, more and more business administrators attempt to adopt ERP recently. In U.S more than 70 percent of Fortune 1000 companies have either begun implementing an ERP systems or plan to do so over the nest few years [7]. In Taiwan, ERP adoption is also becoming more and more popular in nowadays.

Although ERP is a powerful tool for business operations, yet we can find that many businesses have experienced failure in ERP implementation. And those who declared their success in ERP implementation remain suffer different problems after installation. Davenport [4] indicated that the biggest problems of ERP implementation are not technical challenges, but business problems. Although, ERP can deliver great rewards, managers can not afford to ignore the high risks it carry. ERP's implementation is usually more difficult than that of traditional IS, because of the specific characteristics of ERP.

Based on the discussions above, we can find that how to implement ERP successfully becomes a critical issues in the development of e-business. Although many reports had proposed critical successful factors about ERP implementation, we are still in need of a systematic view of this issue, because many papers usually focus on special cases and do not present a substantive theory. Therefore an overview of the critical successful factors of ERP implementation has become crucial for e-business implementation.

In order to provide the basic structure for further studies, this study surveys into numeral journal papers about this issue and analyzes these articles based on the Lucas's [8] perspective. First, the characteristics of ERP are summarized in order to illustrate why ERP implementation is different from other IS implications. Next, the theoretical background of this paper is illustrated and employed for later analysis. Third, the research method of this study will be illustrated. Fourth, analysis method and results will be presented. Finally, the conclusions and limitations of this study will be

discussed.

## 2. The Characteristics of ERP

Markus and Tanis [10] summarizes several characteristics of ERP, each of them with important implications for the organizations that adopt them. These characteristics include:

- (1) Integration.
- (2) Packages.
- (3) Best Practices.
- (4) Business process reengineering.
- (5) Some assembly required.
- (6) The way to integrate legacy system.
- (7) Rapid change.

In contrast to traditional IT applications, ERP is costly and enterprise wide. Therefore, there are more challenges than department wide IT applications. Besides, business always choose package to be the solution for ERP. Therefore, the consequence of ERP implementation is reversed, and ERP customization becomes an important issue. These attributes are different from traditional in-house development IT applications.

## 3. Theoretical Background

### 3.1 The Key to Successful Information System Implementation

Lucas [8] proposes a systematic review about the critical successful factors of IS implication in the book: "Implementation the Key to Successful Information Systems". In this book, Lucas [8] defines information systems as "Information systems provide information to support decision making and control in the organization". Based on this definition, ERP is a kind of IS implementations in the organization. Therefore, based on Lucas's framework, this study will survey and analyze literatures which incorporate ERP critical successful factors.

In the discussions of critical successful factors of IS, we must identify the definitions of IS success first. Lucas [8] had mentioned four different success criteria:

- (1) Time to complete the project/time estimated to complete;
- (2) Actual cost to develop project/budgeted cost for the project;
- (3) User satisfaction;
- (4) The impact of the project on the computer operations of the firm.

In addition, five measures of IS success are often employed by IS research [8]:

- (1) The use of the system;
- (2) User satisfaction;
- (3) Favorable attitudes;
- (4) The degree to which a system accomplishes its original objectives;
- (5) Payoff to the organization from a system.

Lucas [8] defines IS implementation as "an on-going process which includes the entire development of the system form the original suggestion through the feasibility study, systems analysis and design, programming, training, conversion, and installation of the system." In the context of ERP, this sequence is inversed [4]. Because choose among ERP packages is always the solution for ERP implementation. Therefore, the issues about vendor selection, outsourcing contract management, cooperation with outside consultant and so on have become more important than traditional IS implementation.

Different types of implementation research are proposed by Lucas [8] includes theories (insight), surveys of factors, and case study, etc. The relationship between these types of research is illustrated in figure 1.

Lucas [8] also synthesizes past studies into a conceptual framework in order to be the base for understanding IS implementation. Four constructs are included in this framework: Client actions, Technical characteristics, Attitudes toward systems, Decision Style, Personal and situational factors, and successful implementation. This conceptual framework is illustrated in Figure 2.

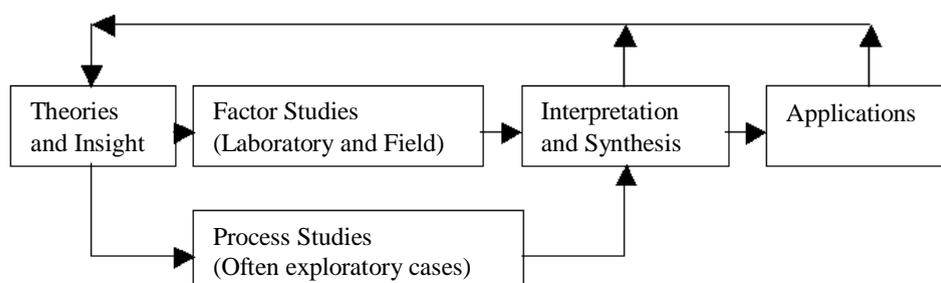

Figure 1. The Implementation Research Process [8]

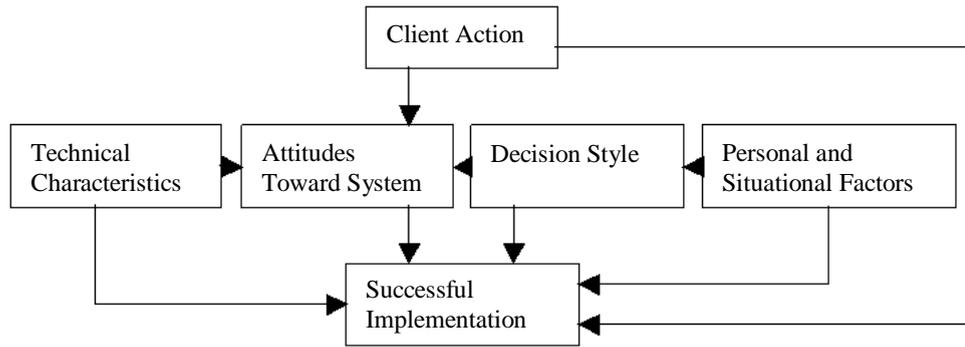

Figure 2. A Conceptual Framework about IS Successful Implementation Factors [8]

### 3.2 Justification of Research Approach

Although Lucas's framework focused on general IS implementations, it can also be applied to a specific IS implementation, especially in the context of ERP implementation. Based on the Lucas definitions about information system and IS success implementation, this study infers that Lucas's framework is still suitable for ERP implementation in general. On the other hand because of the specific characteristics of ERP, there must be some differences between traditional IS implementation and ERP implementation. Therefore, this study attempts to modify this framework based on literatures about ERP implementation successful factors. This study will propose a modified framework that is tailored for ERP implementation.

### 4. Research Methodology

This study is based on a study of journal articles. Conference proceeding papers, master's theses, doctoral

dissertations, textbooks, and unpublished working papers are excluded in this study. This is because only journal articles that we can browse completely from various powerful digital database. In addition, we believe that ERP is new IT implication and most of the newest research results will be published in journals. Journal articles are first hand information and suitable for this study. Three main digital databases are employed in this study, including ABI/INFORM, SDOS and EBSCO Online. Full text papers have been collected from on line PDF files and hard copies from the library.

Selected nine articles in this study are all related to the critical successful factors of ERP implementation. These papers are from Production and Inventory Management Journal, Communications of the ACM, Information Systems Management, IEEE Software, International Journal of Production Economics, European Journal of Information System, Industrial Management, Harvard Business Review. (Table 1.)

Table 1. Summary of Selected Research Papers

Period	Author(s)	Title	Published Journal
2002	Scott and Vessey	Managing Risks in Enterprise Systems Implementations	Communications of the ACM
2002	Motwani et al.	Successful Implementation of ERP Projects: Evidence form Two Case Studies	International Journal of Production Economics
2002	Akkermans and Helden	Vicious and Virtuous Cycles in ERP Implementation: A Case Study of Interrelations Between Critical Successful Factors.	European Journal of Information Systems
2002	Umble and Umble	Avoiding ERP Implementation Failure	Industrial Management
2001	Weston	ERP Implementation and Project Management	Production and Inventory Management Journal
2000	Willcocks	The Role of the CIO and IT Functions in ERP	Communications of the ACM
1999	Bingi et al.	Critical Issues Affecting an ERP Implementation	Information Systems Management
1999	Holland and Light	A Critical Success Factors Model for ERP Implementation	IEEE Software
1998	Davenport	Putting the Enterprise Into the Enterprise Systems	Harvard Business Review

## 5. Analysis Method

The analysis framework of this study is based on Lucas's [8] framework that is shown in Fig. 1. Five constructs of this framework are: (1) Client Actions, (2) Technical Characteristics, (3) Attitudes toward Systems, (4) Decision Style, and (5) Personal Situational Factors.

### 5.1 Client Actions

Two variables in the client actions class are extremely important in this dimension: management support and user involvement and influence [8].

### 5.2 Technical Characteristics

Technical variables can be divided into two main categories, which are absolutely mandatory for success and can greatly enhance the appeal and usefulness of a system. Variables in the first category include accuracy of input and output, reliability of an online system, the completion of processing on schedule for a batch system etc. Variables in the second categories such as the design of interface can be used to encourage use and satisfaction with the system [8].

### 5.3 Attitudes Towards Systems

Lucas [8] indicates that the attitude toward a specific stimulus like the input and output equality of a computer system is a good predictor of the use of a voluntary system or satisfaction with a mandatory systems. Besides, Davis et al. [5] also indicates that user attitude has positive effect on user intention to use computer technology. And user intention is the predictor of user behavior. Therefore, user attitudes will play an important role in IS successful implementation.

### 5.4 Decision Style

Decision style is the characteristics people have to deal with a decision problem, and this set of variables will affect IS implementation and the use of computer-based information system. Variables included in this category are personal cognitive style and complexity, etc [8].

### 5.5 Personal Situational Factors

The difference of personal variables such as age, education, length of time in the company, etc, can greatly influence the success of implementation [8]. Davis et al. [5] also indicates that when discussing about user acceptance of IS, external variables in Technology Acceptance Model (TAM) play an important role in IT acceptance. Individual difference is one of the categories of external variables and these characteristics will affect the success of IT implementation. Agarwal and Prasad [1] also propose similarly. They insist that individual differences are important factors in IT acceptance.

To summary the discussions above, we find that if we want to understand how to implement an information system successfully, we need an overall consideration. Factors of different levels are included in Lucas's framework: Managerial Level, Technical Level, and Personal Level.

## 6. Analysis Results

A total of nine articles were included in this analysis. This study analyzed the identified articles by year of publication, research method employed, case selected, critical successful factors proposed by selected articles, and key dimensions of ERP implementation.

### 6.1 Year of Publication

From Table 2 we can find that, the starting year of ERP CSF (Critical Successful Factors) related research publication appeared in 1998. In that year, Davenport's research "Putting the Enterprise into the Enterprise System" that was published in Harvard Business Review. This paper became one of the pioneers of ERP research. Besides, in the mid 2002, there are four papers about ERP CSF published in journals. From this trend, we find that ERP attracts more and more researchers recently

Table2. Year of Publication

Year	1998	1999	2000	2001	2002	Total
Count	1	2	1	1	4	9

### 6.2 Research Methods Employed by the Selected Papers

As regards to the research methods employed by the selected papers, we divide the selected articles into three categories based on Implementation Research Process [8] perspective: case study, factor studies, and theories/insight. Case study is the method that has often been used in ERP CSF studies (Table 3). The reasons for this phenomenon include:

- (1) ERP has just been proposed in recent years, so we still have to collect more samples into our data bank.
- (2) With sparsely data, we don't have enough information to do quantitative study.
- (3) For some business, ERP is a kind of strategic information system, therefore few enterprises want to release the corporate confidential information.

In addition to case studies, many author's simply presented their insight or experience. From table 3, we find that none of research conducts the empirical study. Therefore it is recommended that further studies be try to collect data from business.

### 6.3 Cases Selected

From the above discussions, we can find that case study is the most popular research method so far. The cases conducted in the past are arranged in Table 4.

### 6.4 Critical Successful Factors of ERP Implementation

The selected articles have proposed sixty-eight critical successful factors (Table 5). Of course, these variables are overlapping and we will analyze them in the next section.

**Table 3. Research Methods Employed by the Selected Papers**

Research Method	Case Study	Survey Study	Theories/Insight	Total
Papers	Davenport [4]; Holland and Light [6]; Akkermans and van Helden [2]; Motwani et al. [11]; Scott and Vessey [12]	N/A	Bingi et al. [3]; Willcocks [15]; Weston [14]; Umble and Umble [13]	
Count	5	0	4	9

**Table 4. Cases Selected**

Papers	Cases Selected
Davenport [4]	Elf Atochem Inc.
Holland and Light [6]	Threads Inc. and Statco Inc.
Akkermans and van Helden [2]	Two anonymous cases (medium-sized manufacturing firm in the aviation industry)
Motwani et al. [11]	Two anonymous cases (Pharmaceuticals industry and Footwear industry)
Scott and Vessey [12]	Dow Corning Inc. and FoxMeyer

**Table 5. Critical Successful Factors of ERP Implementation**

Authors	Critical Successful Factors
Davenport [4]	(1) Careful deliberation (2) Top management directly involved in planning and implementing
Holland and Light [6]	(1) Strategic Factors (Legacy systems, Business vision, ERP strategy, Top management support, Project schedule and plans) (2) Tactical Factors (Client consultation, Personnel, BPC and software configuration, Client acceptance, Monitoring and feedback, Communication, Trouble Shooting)
Bingi et al. [3]	(1) Top management commitment (2) Reengineering (3) Integration (4) ERP consultants (5) Implementation time (6) Implementation costs (7) ERP vendors (8) Selecting the right employees (9) Training employees (10) Employee Morale
Willcocks [15]	(1) Senior-level sponsorship, championship, support and participation (2) Business themes, new business model and reengineering drives technology choice (3) Multifunctional teams, time box philosophy, regular business benefits (4) CIO as strategic business partner (5) Nine core IT capabilities retained/being developed in-house (6) In-house and insourcing of technical expertise preferred (7) Supplier partnering (strong relationships and part of team) (8) ERP perceived as business investment in R&D and business innovation rather than primarily as a cost-efficiency issue.
Weston [14]	(1) Top management and cross-functional support (2) Project proposal (3) Clear deliverables (4) Clear assessment of business risk (5) Strong project manager and sound project plan (6) Awareness of the dangers of scope creep (7) Change management process (8) Training
Umble and Umble [13]	(1) Strong leadership provided by an executive management planning committee (2) The implementation is viewed as an ongoing process (3) Implementation teams are composed of the company's best workers representing all functions (4) Mid-level management is totally involved in the implementation (5) Excellent project management techniques are used (6) The old systems are eliminated (7) Proper measurements are implemented and closely monitored (8) An aggressive but achievable implementation schedule is established (9) Successful change management techniques are applied (10) Extensive education and training is provided.
Akkermans and van Helden [2]	(1) Top management support (2) Project team competence (3) Interdepartmental co-operation (4) Clear goals and objectives (5) Project management (6) Interdepartmental communication (7) Management of expectations (8) Project champion (9) Vendor support (10) Careful package selection.
Motwani et al. [11]	(1) Incremental, bureaucratic, strategy led cautious implementation process (2) Cultural readiness (3) Inter-organizational linkages (with the vendor) (4) Careful change management
Scott and Vessey [12]	(1) Organizational culture (2) Project management (3) Excellent business vision (4) Strong leadership (5) Stand the company in good stead

## 6.5 Dimensions of ERP Critical Successful Factors

In Table 5, we have arranged these factors into fourteen main critical factors based on the frequency that are proposed by the selected articles (Table 6). Based on the results in Table 6, we find that the top five factors are: Project Management, Top/Middle Management Support, Business Vision, Personnel/Employee/Acceptance, and Vendor Selection.

In order to understand the similarities and differences between ERP and traditional IS applications, fourteen categories from Lucas's [8] framework (Figure 2) are compared in Table 7 in which Client Actions is highly correlated between these two contexts. Yet in Lucas's framework, Decision Style and Personal Situational Factors are not emphasized in the domain of ERP. Other factors that are emphasized in the context of ERP are not equally emphasized by Lucas's framework. We can find that these specific factors are caused by the specific characteristics of ERP, therefore they may not be the key successful factors of traditional IS implementation.

**Table 6. Main Critical Successful Factors**

Categories	Frequency
Top/Middle Management Support	8
Project Management	14
Business Visions	6
BPC/BPR	3
Change Management	3
Careful Deliberation	2
Consultants	3
Personnel/Employee/Acceptance	4
Vendors Selection	4
Training	3
Project Team	3
Culture	2
Legacy System	2
Others	11

**Table 7. Comparison of CSF Between Traditional IS Implementation and ERP Implementation**

Dimensions of Lucas's Framework	Dimensions of Author's Arrangement
Client Actions	Top/Middle Management Support Project Team
Technical Characteristics	Legacy Systems
Attitudes Toward Systems	Personnel/Employee/Acceptance
Decision Style	N/A
Personal Situational Factors	N/A
N/A	Project Management
N/A	Business Vision
N/A	BPC/BPR
N/A	Change Management
N/A	Careful Deliberation
N/A	Consultants
N/A	Vendor
N/A	Training
N/A	Culture

## 7. Conclusions

Since the critical successful factors of ERP implementation are focused in this survey. Based on our analysis, we conclude the following points:

(1) Critical successful factors in traditional IS implementation and ERP implementation are not

exactly the same.

(2) Three of the five dimensions proposed by Lucas [8] are often used to explain the success of ERP implementation.

(3) In the selected papers, case study is the most commonly utilized method to understand critical

successful factors of ERP implementation.

- (4) Although critical factors have been arranged into fourteen categories, but we are still lack of a well-defined theory to understand their relationships.
- (5) Based on the results of this study, we suggest that future study should do survey research that focus on a cross-sectional field study.

## 8. Limitations

The main limitation of this study is that only three digital databases are used to collect related studies, some omissions may occur. In addition, theses, dissertations, textbooks, and conference proceedings papers are not included in this study. It is possible that other related studies are included in the above materials. However, we have included all major MIS publications in our study.

# Integrated Collaborative Planning Within the Supply Chain: The Future of ERP

Mark Richter

California Polytechnic Pomona University  
Pomona, CA USA

[MarkRichter@RBAworld.com](mailto:MarkRichter@RBAworld.com)

## Abstract

By examining case studies using Collaborative Planning it becomes apparent the need to integrate with Enterprise Resource Planning applications. This process would help avoid errors, save time, and produce cost reductions across the supply chain.

## Introduction

Enterprise Resource Planning (ERP) has become a boon to many corporations with its ability to integrate information systems through out a corporate structure. By using central databases and information sharing, departments can save money, reduce time for different operations, improve communication, improve customer service, and reduce errors. With ERP's success on the corporate level, it has become apparent that a benefit can be obtained by integrating the supply chain in the same fashion. This year PeopleSoft and SAP have introduced new modules to help companies manage supply chain integration. Collaborative Planning is the technology needed to advance corporations in the future.

## The Bull Whip Effect

The bullwhip effect happens when a constant demand becomes varied throughout the supply chain. This phenomenon happens because of lack of communication and each member of the supply chain must make their own forecast based on the current demand of the other members. If a retailer forecast the inventory levels that they need and pass this demand on to the wholesaler, then the wholesaler will make forecasts based on the new demand from the retailer. Since the data was achieved from a forecast and not actual sales or POS data, most likely the forecast will be off. Now, when the wholesaler places an order with the distributor with the newly skewed numbers, the wholesaler will make an erroneous forecast since their demand data is incorrect. They will pass on the distorted demand to the factory. This effect causes peaks and valleys in the ordered. This happens because when the retailer orders too much and it is multiplied throughout the supply chain, it creates a surplus. Now that there is a surplus the members tend to overreact and order to little, but at the same time that number is diminished each step in the supply chain causing

a shortage. By sharing sales data between the members they can better forecast together what the demand will be, thus defeating the bull whip effect.

There are many benefits by attacking the bullwhip effect that the members can realize. By smoothing out the ordering demand and eliminating the peaks and valleys that are associated with the bullwhip effect, CPFR can help increase the retail in-stock levels [3]. A retailer increases sales when they increase the in-stock level because they do not lose potential sales. This also gives the power to incorporate category management strategies, which in turn allow for better product mix and promotional timing. Retail outlets can also carry lower safety stock since the forecasted data will be more accurate. This also creates a new operating platform for the manufactures. Before they were in a push system where they would create the product and push it on the customer. Now they can move to a pull environment where they pull the demand from the customer. This is also a make-to-demand model compared to a make-to-stock model. The advantage in this is that safety stock for all members is decreased, while inventory cost decreases simultaneously. Greg Belkin of Retailsystems.com suggests another benefit of CPFR is that it crash-proofs the supply chain. Since the data is in real time, companies can respond quickly to extreme changes in the supply chain, including the loss of a distribution center. Because the members of the supply chain have a real time collaboration tool, they can jointly solve the problem and rectify the problem quickly. Belkin as states that a company's stock price can drop on average 8.62% on news that there has been a disruption in their supply chain.

Decreased inventory levels translates to freed up capital. Since less warehouse space is needed, less money needs to be invested into buildings. Fewer inventories are purchased at one time freeing up more money for the company. This can lead to being out of debt. It also opens many doors for the company as they may increase marketing budgets, increase research and development, or spend more money on quality testing.

## CPFR: A Viable Solution

CPFR stands for Collaborative Planning, Forecasting, and Replenishment. "CPFR [is] a web-based standard that enhances vendor managed inventory and continuous

replenishment by incorporating joint forecast” [9 p.239]. The process involves two or more companies comparing their historical data, such as demand, sales, and inventory levels. The two companies can then compare where there are differences of discrepancies and work together to create better forecast. The overall goal of CPFR is to synchronize all the members of the supply chain. The goal is to open up the communications between members of the supply chain and allow for better forecasting. Information that is shared between the members is past sales trends, scheduled promotions, and forecasts. BusinessWeek.com reported that companies could enjoy a three-point increase in their overall profit margin by implementing CPFR. The ultimate goal of CPFR is to provide more accurate information that can add value to the supply chain by increasing sales and profits.

The main benefit of this process is it attacks the bullwhip effect. As can be seen later in the Heineken case, better forecasting and planning were achieved. Lead times were reduced which led to better customer service. Processes and procedures became automated and required less human effort. This also improved their inventory management as well.

#### Rosettanet

Rosettanet takes the benefits of XML and EDI while omitting their drawbacks. EDI's strong point is that it consists of strict standards. These standards make it possible to easily program applications that can abide by the rules set forth by the EDI standards. This also makes it possible for generic applications that can be implemented throughout the supply chain. XML's strong points are the fact that it can be deciphered by humans, codes are replaced with descriptive tags, an HTML capable browser can easily read the files, thus allowing for easy transfer over the Internet.

Rosettanet uses dictionaries that contain the standard tag definitions used in XML files. For example, referTo will always mean the partner to which a business document request is being referred. And anytime the partner to whom a business document request is being referred will always be listed in a referTo XML tag. True a tag named address would be easily recognized by the human eye and be deciphered to what it means, however a computer must be programmed to know what address means. By making these dictionary files the computer can comprehend what the data means and how to interpret it. All members of the supply chain agree upon these dictionary standards.

#### Heineken: Implementing Supply Chain Integration

In 1997 Heineken launched a pilot program that took

advantage of the Internet. Heineken had many problems before the new pilot was launched. There was very inefficient communication through out the supply chain. This led to many problems that were associated with the bullwhip effect. Heineken had a police-like relationship with many of its customers and distributors. Lead times were excessive and this led to outdated products being purchased by consumers. Forecasts were inaccurate as it overwhelmed the sales force with paperwork. Inventory management was inconsistent. With these problems in mind, Heineken had decided that they needed a new solution to fix these problems. In 1996 they teamed up with Logility to tackle this problem. The challenge set forth for Logility was to make most processes integrated. This included creating tools that would allow marketing planning and sales planning to communicate. Elimination of data collection by fax needed to become a reality. Inventory management needed to be fixed. Automated processes needed to be installed that would eliminate manual processing.

The plan was based off of creating a central planning organization that was created from the bottom up. This plan would drive the initial forecast for all areas. This way every department would be working with the same numbers and goals. The forecasts were also shared with the distributors, since they have knowledge of their respective markets they could communicate any errors in the forecast. Since computers did the ordering based off the forecast, less human labor would be required and errors could be prevented. The system would also communicate marketing and promotional information to distributors. This would allow the distributors to expect an increase in demand while the promotions were active.

Forecasts were made based off of consumer data. By collecting sales inputs, Heineken would be able to integrate it with marketing plans, financial goals, company objectives, and various strategic plans. Logility designed a pyramid structure that supported forecasting information from remote and distributed sources. It then merges the data and each department can have access to it.

#### Summary of other Benefits

Heineken realized many other benefits as well. Forecasting and planning improved. Customer service improved overall. Self-regulating order planning became plausible. Heineken was able to adjust for inventory variances that were due to forecasting errors. Inventory management improved. Lead times decreased, which in turn also increased customer service. Most processes and procedures became automated reducing the number of manual tasks. Communication became a stronger and more focused tool. It gave the perception that Heineken was a leader.

## Dell Computers and Agile Software

Dell Computers makes customized computers with orders that are fulfilled in a goal of five days. Dell wished to improve margins, market shares, and response to its environment. Dell strived to help ensure rapid, error-free manufacturing and delivery of the exact products specified by the customer using CPFR with their parts suppliers. To accomplish this task Dell used Agile Software Anywhere Software Suite. This software helped ensure that the parts suppliers delivered the correct part at the right time. The Internet is the backbone of this process [1]. “[T]he result has been super-charged growth -- as competitors have lagged.” [11]

Agile Anywhere software suite consists of five software titles that help automate and distribution and synchronization of product information. The first application is called Agile eHub. This program handles storage, web distribution, and administration or product information that is available to all members of the e-supply chain. Agile Product Change Server automates the routing and notification of engineering changes. Agile AML Server links manufacturers with Dell and allows Dell to monitor and approve new products. Agile Product Definition Server provides a web-based environment that manages parts, documents, Bills of Materials, and drawings. [1]. The advantage of the Agile Anywhere software is that Dell and its parts suppliers can easily collaborate over the Internet.

## i2 and Home Depot

Home depot was looking for a way to plan collaboratively with their suppliers to manage truckload capacity. Though there are many economic advantages to this, Home Depot was concerned about improving service. Home Depot enlisted the services of i2 Technologies. By using i2's carrier bid optimizing solution, Home Depot was able to request bids for truckloads as suppose to less-than-truckloads orders. The carriers would then return bids. Home Depot then analyzes the bids and can begin negotiations with the suppliers. This helps Home Depot provide lower prices [6].

Before 1996, Home Depot had a completely manual system used for bidding on lanes. In 1996 they allowed carriers to place their bid on excel spreadsheets. However, even the new system they devised did not allow carriers access to Home Depot's demand. Because of this flaw, a carrier would have to assume that the demand would stay relatively constant throughout the year, thus skewing their forecasting abilities. Another drawback was the fact that carriers could not bid on a group of lanes that they could better optimize. If the carrier had more lanes, they could fill the trucks fuller. However, it would become uneconomical if they did not win the bid on a lane that was in the middle of other lanes that they had won the bid on.

In January 2000, i2 created an Internet based bidding system that allowed important access to some of Home Depot's data. Detailed information about lanes was provided, including exact origin and destination data. Before, only the zip code was provided. Demand forecast were also provided which allowed bidders to better analyze the situation and to better forecast their cost.

By using collaborative management, Home Depot was able to get better rates overall for their transportation needs. The carriers also reported that they were overall happier with the new system. Even though they were charging less, they were able to make more profit because they could manage their business better with informative data that Home Depot provided. The main complaint that the carriers had was that the training was too short, but overall the program was a success.

## Why ERP?

ERP becomes the choice medium for Collaborative Management because it already compromises the data and applications that need to be used. Since ERP vendors such as PeopleSoft have converted to applications based off the Internet it becomes possible to easily augment the ERP software to better cater to Collaborative Planning. By implementing such standards such as Rosettenet and CPFR, an ERP vendor can create a portable application that can be used by all members in the supply chain and still communicate with the ERP software.

It must also be noted that the most important pieces of data include marketing and promotions, inventory levels, sales, and forecasted demand. This list is already handled by ERP software and the data is readily available. To create a stand-alone application would require extra data conversion and may be hindered by software upgrades that can hinder the data communication between the ERP database and the stand-alone application.

## Just In Time

Collaborating can reduce Just In Time cost. If the supplier can better forecast the demand of the manufacture, the supplier can in turn reduce their safety stock requirements and better forecast labor, reducing their cost that can be passed on to the manufacture. Using ERP software to share promotions and historical data, the supplier can create better forecast. Other functions such as purchasing may be handled automatically.

## Problems Associated With Collaborative Management

The biggest issue that arises with collaborative management is trust. Many managers do not wish to share viable information. There is a real concern because a leak of

this information can hurt the company's competitive advantage. To combat this both parties may need to understand the value that will be acquired by this process. A commitment of trust needs to be established. Also, software can be used to analyze actual shipments and shared data to double check numbers that are being shared.

## Conclusion

The future of ERP is defiantly headed into the direction of collaborative planning. This practice allows each member of the supply chain to share the cost of a single process instead of each member having to pay for the exact same process, doubling the total cost. Also many cost advantages appear when each member of the supply chain makes better forecast. It may be concluded that this competitive weapon may beat those firms that do not practice collaborative planning.

## Abstract

We discuss strategic issues related to deploying Enterprise Resource Planning (ERP) systems in terms of their applications, suggested benefits, and proven failures. After this broad explanation of ERP systems as they pertain to today's business world, attention focuses to the difficulties in implementing SAP ERP systems in a Midwestern business. Finally, a review of recommendations for increasing Return on ERP Investment is provided.

## 1. Introduction

Enterprise Resource Planning (ERP) systems are hot issues in today's "costs at a minimum, profits at a maximum" business world. In fact, a recent study predicts that the ERP market will expand at a compounded annual growth rate of 11 percent to reach \$25 billion by 2004 [4]. This is attributed largely to the fact that once a business can get past the kick in the pocketbook they take when implementing the system, ERP provides the business with an integrated suite of computer applications that result in a seamless flow of information across the organization with promises of future cost savings. Post implementation, newfound efficiency, and effectiveness from this "seamless information flow" are some acclaimed ERP benefits that are the drivers of the cost savings [3].

### 1.1. Benefits

While one might view ERP systems as merely improving or updating existing technology (as was the case at the time of Y2K), many business managers believe that ERP systems are implemented for far more significant strategic reasons [1]. Some of these well-known benefits are as follows:

- Cross-functional business processes are brought to the forefront and allow information to be shared horizontally, between functions and business units; and vertically, from the front-line to the strategic levels,
- Operating costs are reduced,
- Production cycles speed up,
- Identification of excess inventories/better management of inventories,
- Improved customer satisfaction by improving late deliveries and customer service resources,

- ERP-enabled business processes and data are standardized and normalized,
- Organizational boundaries dissolve – creating a business where departments are constantly "talking" to one another,
- Independent business units are integrated – forming one business unit,
- Jobs broaden and/or are redefined via expanded information access,
- The availability of information fosters empowerment of employees,
- There is system-wide accountability and visibility that helps to ensure people do things right the first time,
- More accurate demand forecasts are generated.

### 1.2. Who Benefits?

Charlie Rooney, a partner at Orr & Boss, Inc. consulting firm in Plymouth, Michigan identifies the following six major internal factors that determine whether or not ERP should be implemented in an organization [5].

1. If its supply chain includes multiple distribution centers and plants, an ERP system is almost essential.
2. If its manufacturing is capital intensive, ERP will have a larger impact due to its ability to manage peaks of demand by building inventory for forecast sales.
3. With complex production processes that have many levels of intermediate products, ERP systems can help control inventory while avoiding stock outs.
4. Where set up and clean up are a major part of total cost, the ability of an ERP system to aggregate demand and control the number of batches helps minimize cost.
5. ERP systems can cut transportation costs by using Demand Requirements Planning to ensure that warehouses are supplied from the plant that can do so at the lowest total cost. They also minimize freight out by aggregating shipments and enforcing discipline in choice of carriers. This is important in industries like consumer caulk, where transportation cost is a major portion of total supply chain costs, and
6. If the company has built up a fragmented set of legacy systems over the years may be sufficient

reason to upgrade to an ERP package. Modern systems can do so much more, and there are great advantages to working from a common database.

### 1.3. The Failures

While ERP benefits are sought after in today's productivity and efficiency oriented corporate climate, they do come at a price, and sometimes it is more than what the investors were expecting to take on. In fact, the current consensus is that many companies have failed to reap the significant benefits that a massive investment in ERP warrants. The question that arises is why? Below are some reasons are that ERP projects have failed to bring the expected results.

- They represented very large investments for the organizations concerned,
- They have been very painful to implement and left the organization drained and resistant to launching further projects,
- They have not taken into consideration the all the hidden costs in the form of the internal resources deployed and the consequent loss of focus on the business associated with an implementation, and
- They delivered limited business benefits over and above installation of new base systems infrastructure.

The following situations add to the notion that, historically, organizations have not been able to recognize all the benefits ERP has to offer:

- Organizations develop over-ambitious project plans that underestimate the scale and degree of difficulty of implementing ERP. Then when the magnitude of the task becomes clear, the organization scales back and sacrifices benefits,
- There is a bandwagon effect whereby projects are pushed through with flimsy business cases and the claim that, because everybody else in the sector is implementing ERP, it must be the right thing to do, and
- Since ERP is so expensive to implement, many try to minimize cost by reducing the amount of business change involved.

The reality that must be faced now is that organizations must take action – brainstorming solutions that will allow them to realize the benefits of an investment in ERP [6].

## 2. Difficulties and Issues in ERP Implementations

Company XYZ, a Midwestern multi-national company operates five major manufacturing facilities and ten minor facilities worldwide. XYZ elected to implement the SAP Enterprise Resource Planning Software in order to integrate its facilities and improve:

- Their current slow and dysfunctional New Product Development Process,
- Customer Focus (specifically for Large Accounts),
- Operating Systems efficiency: it operated five independent computer systems which required high maintenance,
- Business structure: it had functional silos.

To solve these problems, XYZ decided to assemble a "Customer First" Team to address the future needs of the business. The team was made up of project management and a project team. The objectives of the first phase of the Customer First team were to:

- Identify customer expectations (for external and internal customers),
- Understand the current processes,
- Identify improvement opportunities,
- Determine future process vision, targets, and goals, and
- Develop a Vision

XYZ met these objectives by conducting 220 interviews of customers, vice presidents, departmental directors, middle management, and general staff. The results of the interviews indicated that XYZ would realize significant business benefits via process redesigns. However, these benefits could not be attained without a common vision of how the business would operate and a business that was prepared to make the change.

The team also determined that the current processes and infrastructure could not efficiently support the requirements of increased customer demands following recent business expansion and acquisitions as well as implementing internal growth strategies. To enable the recommended processes to be successful, a new ERP solution was required, since it was key to obtaining the benefits associated with the redesign. The recommended solution consisted of the following elements:

1. XYZ decided to implement the following modules of SAP Enterprise Resource Planning software:
  - Materials Management,
  - Sales and Distribution,
  - Production Planning,
  - Warehouse Management,
  - Human Resources,
  - Business to Business,
  - Advanced Planning Optimizer (Forecasting Tool),
  - Financial Accounting/Controlling,
  - Costing, and
  - Customer Relations Management.

2. XYZ hired consultants from IBM to help with the implementation process. The ERP system was implemented in early 2002 in order to allow XYZ to enter data into the system and test the system before “go live” which was scheduled for July 2002.

The month of July was chosen because it has historically been a relatively slow period for XYZ’s operations, allowing sufficient time and resource capacity buffers for the SAP implementation project. As “go live” date approached, XYZ’s Information Systems and SAP staff, who had performed transactions within a testing environment in the SAP ERP system, wrote procedures. A “Day in the Life” simulation was run in late May 2002. The SAP systems live production environment was turned on for one day and phony manufacturing orders were entered into the system to simulate an actual day of work. Then the data that the system generated was studied for error and corrective action was taken wherever necessary.

The transition to a new system occurred in July 2002. There was a state of confusion and the Production and Inventory Control department, as well as the SAP help desk, and IS department were pummeled with a lot of questions. The disturbance is expected to have a significant effect for several months. After “go live” the following six major obstacles to a smooth SAP system implementation were been identified:

1. There was a lack of tools for generating necessary reports/ the new system wasn’t customized to the business and everyone fumbled to find some way to measure their progresses,
2. There was a lack of knowledge regarding the forecasting module and no back-up plan as well an unacceptable consultant turnover,
3. Data had been overlooked and wasn’t entered into the system causing many errors,
4. The integrity of some of the data entered into the system was poor, once again causing costly errors,
5. There was a lack of time necessary to successfully implement the project. Management pushed for a quick transition to a new system to save money on current system software licenses,
6. Since “go live” XYZ has been making sure that their process goals are in line with the business goals, by setting proper priorities for each process and putting disciplinary measure in place. They have also identified four main implementation issues:
  - Always develop back up strategies and computer infrastructure systems,
  - Review and understand your current processes and need before defining the need for a system (Choose or design a system around your business needs,)
  - Support and drive from executive staff is a must, and

- Training, Training, Training.

We emphasize that training is a critical condition for a successful implementation. The author has witnessed many employees at XYZ having difficulty with utilizing the features of the new system because of a lack of adequate user training program. It is not that the training everyone received was poor, but by the time the system actually went live, most employees forgot what they were supposed to do. Refresher courses were available, but not mandatory, and the reality of the learning curve effect was recognized the hard way.

The early period of the system implementation was plagued with system problems as well as employee mistakes. The consultant turnover was very significant, resulting in a loss of a personal relationship and user confidence that took time to build. Just when one of the consultants was beginning to bring some light to some of the problems, he/she would be reassigned. This is especially evident in regard to the forecasting tool, which is still to generate relatively accurate and usable forecasts to date.

This crisis was partially part of the consulting firm’s plan to keep staff onsite at XYZ for as long as possible (at \$200 per consultant, per day). In addition to the turnover, I learned that the consultants were very tight-lipped about teaching valuable information to XYZ’s support staff, thus prolonging their stay even longer while XYZ’s support staff scrambled to learn what they could. Furthermore, none of this was communicated to upper management for fear that there would be an even bigger slap on the informant’s wrist. Everyone tiptoed around and no one was willing to upset the norm for fear of scrutiny and/or demotion. This is reflective of XYZ’s traditional top-down corporate culture and reflective of the consulting firm’s questionable business ethics. In the end, when project deadlines passed, SAP implementation progress ground to a halt, and the smoke cleared there were an abundance of XYZ executives pointing their fingers at one another.

In order for XYZ to maximize ROI from SAP implementation, they have institute strong leadership that will reinvent the corporate culture, while promoting an increase in data measurement tools, data integrity, and employee knowledge of the system.

### 3. Conclusions and Recommendations

Following Mark Smith, a co-founder of Partners for Change, there are three elements that must be managed in order for an organization to realize more benefit from an ERP implementation [6].

1. The first element is to develop an exploitation strategy. This is primarily concerned with identifying projects that utilize the base infrastructure and deliver the biggest benefits. The challenge is finding people who understand the business and its processes, understand the technology and can identify quickly where a business can change and

improve performance. The types of projects that are emerging in developing these exploitation strategies include:

- Reengineering around existing installed modules,
- Installation of new modules,
- Use of 'new dimension products' from ERP suppliers, or complementary software from niche suppliers, to get more from customer relationship management, supply-chain management, and information management, and
- Internet applications linked to ERP to open up new sales channels or fundamentally change the nature of the business,

The portfolio needs to be shaped into a program that factors in the need for upgrades and the availability of key resources within the organization.

2. The second element is the development of benefit-focused implementation plans. Developing plans that respond to the benefit opportunities available will demand the involvement of the business in identifying the potential changes that could be made and developing business requirements that will underpin those changes. The resulting plan will be more focused on activities that ensure that the business stays involved and to ensure that the changes are made.

The most critical component of this element is the development of detailed business cases. In the past it has been easy to get projects through the investment net on relatively flimsy business cases. This should not be allowed to continue and involving the right users in the development of the cases builds a sense of ownership in the outcomes.

3. The third element is the establishment of recognizable benefit delivery processes, which have been virtually non-existent around ERP projects. A formal process is required that is initiated as part of the development of the business cases and ends well after the systems and processes go live.

At an early stage, the benefits need to be well articulated and evaluated. Accountability for their delivery needs to be clearly allocated and communicated. This accountability often needs to be shared to reflect dependencies on other functions or processes and these dependencies need to be clear so that people do not wriggle out of their commitments at a later date.

Sustaining mechanisms need to be developed, e.g. inclusion of the expected results in budgets or performance measures. Having these results included in a manager's compensation arrangements is a particularly compelling technique.

Around the build-up to going live it is easy to lose sight of the original purpose of the project: it's benefit. Providing the support mechanisms around and after going live are therefore critical to retain

focus on overcoming the inevitable dip in performance after going live, ramping up to a stabilized performance level as fast as possible and then going forward to delivery of the expected benefit. Installing the sustaining performance monitoring mechanisms to encourage continuous improvement also contributes to building a culture of benefit delivery. This helps enormously, as there will always be the next project in the exploitation strategy to manage" [6].

### 3.1. Aligning and Optimizing Processes: Change Management

Additionally, organizations implementing ERP systems should focus on achieving alignment of the organizational team and scope goals. The organization needs to understand why the project is worth the pain of change. Strategic, tangible business benefits should be spelled out and ways to measure success must be well defined and understood throughout organizational ranks. Top management must be firmly and actively united behind the business goals driving the implementation. With adequate direction, the project could be much more successful because potentially resistant employees can change into project pushers.

The purpose of organizational alignment is to align people, work group structures, and the cultural environment with the business flows that are defined from the business case vision and functional design. This is done to enable the organization and the employees to optimize and leverage the ERP system and its supporting processes. This discipline is the key integration point for the teams who design the business processes and configure the systems. Through this discipline, the change management team obtains a deep knowledge of the business processes, which is essential in order to support the change process in a way that will add tangible value to the organization.

The results of an annual CIO survey performed by Deloitte & Touche Consulting in 1998 point to the need for heavy investment in the area of change management. In this survey, one of the questions the executives were asked was what were the major barriers to the successful implementation of a reengineering program. Out of the top 10 issues listed, only the last one pertains to technology; the others relate to cost to people and change management. People and organizational issues were also identified at the top of the list of factors that contribute most to the success of change.

A recent survey of 259 executives in major U.S. corporations conducted by the American Management Association demonstrated a low level of success for all aspects of the change management effort in their organizations. Executives were asked to rate the importance of various aspects of the change management in terms of the success of change initiatives. They were also asked about how successful their firms have been in

actually dealing with these aspects. The results demonstrated the poor performance of change management programs within these corporations. The results show that top management rates the importance of its own role in change initiatives much higher than their actual rate of successful implementation. When asked to pin point the primary reasons why some or all aspects of change management were not successful, respondents most often cited a lack of sufficient attention to and understanding of, change management issues.

Far too often, the change management and training elements are downgraded to the final stages of the project life cycle. For some companies they are even considered low priorities. Nevertheless, research shows that a typical ERP project ends up spending approximately 35% of its overall budget on change management and training.

One of the most challenging responsibilities for any ERP program lies in dealing effectively with the alignment of people, processes, and systems. This can be achieved through a solid change management framework. Strong business ownership is one component of a solid change management plan. It involves having a leadership role assigned for the implementation. It ensures support for the program vision throughout the organization, by enabling the business to support the change at all levels with an active and visible leadership network. It also includes a process for managing the involvement, communications, and commitment of key leaders. Finally, it includes coaching managers and supervisors to better handle employee resistance during the various phases of the change adoption process.

It is also critical that the change management framework provides a combination of predefined processes, which are planned, managed, and measured. Business ownership is a critical success factor for the program; and the change management processes will achieve their goals only if they are “owned” or strategically directed and overseen by the organization affected.

The process ownership structure is linked with specific processes and functions across all business units. It is composed of decision-makers who are responsible for cross-functional processes. The objective is to translate the program vision into new business processes and supported ERP functionalities.

### 3.2. Nuts and Bolts System Solutions

Preventive measures can be taken with respect to the “nuts and bolts” of an ERP system. These measures are considered solutions since they are reducing the likelihood of problems ensuing later on. Some preventative measures that can boost ROI are as follows:

- When selecting a vendor, assess what impact its applications will have on the company’s existing network,

- Work with the vendor to perform a technical audit to help ensure that the company’s database platform will run smoothly with the ERP solution that is chosen,
- Experiment with the data-conversion utilities available in the new ERP system to discover problems early,
- Once it is determined that the utilities are adequate, convert data from the old system early and often,
- Consider the scalability (or storage space of the system) necessary to maintain business. Calculate storage per employee and don’t settle for any less than is needed,

### 3.3. High-Quality Training

Finally, as noted in some of the companies ERP implementations, training is a top priority, and it can’t be left to only to the IT department to carry out. Training resources should have two components: those allocated for IT personnel and those for end users. IT staff must be trained in the technical aspects of the software and how it will interface with the network. They need to understand both their immediate jobs as they pertain to the ERP system and how those jobs affect everyone else. In a well-run implementation, the ERP vendor and its partners train the IT staff directly and the company doesn’t skimp on training the IT staff: allocating at least 4 percent of the total ERP investment to training. Rather than training the end-user employees on the full range of the ERP system’s capabilities, the curriculum should focus only on those modules the employees will use. In addition, it should address employees’ varied skill levels and provide an overview of the system prior to focusing on the specialized functions needed for their jobs [2].

Additionally any training plan should build in post implementation training costs. Refresher courses as well as a training center are two fundamental assets for companies to obtain in order to promote success before, during and after implementation.

## Abstract

There are the following characteristics in decision on lot size in material requirements planning (MRP) systems: multiple time periods, a finite time horizon, discrete demand, and time-varying costs etc. In MRP system there are several different types of lot size techniques, such as the economic order quantity (EOQ), lot-for-lot, periodic order quantity, Wagner-Whitin algorithm, Silver-Meal algorithm and part-period algorithm. Although these lot size approaches focus on controlling the cost of holding cost and order cost, none of them, with the exception of the Wagner-Whitin algorithm, assures an optimal or minimum cost solution for time-varying demand patterns and copes with quantity discount. And Zangwill(1966), Blackburn and Kunreuther (1974) et al extended the Wagner-Whitin algorithm by following demand to go unsatisfied during some period, provided it is satisfied eventually by production in some subsequent period. R. M. Hill (1997), Stanislaw Bylka, Ryszarda Rempala (2001) give dynamic programming formulation to decide lot sizing for a finite rate input process. But the Wagner-Whitin algorithm and its extensions commonly are criticized as being difficult to explain and compute because the algorithms are complicated dynamic programming algorithms. In this paper, we propose a series of inventory models in which backorder and a finite replenishment rate are considered according to the characteristics in MRP ordering and the optimal solutions can be obtained by using general-purpose linear program solver, like EXCEL, LINDO, etc.

## 1. Introduction

It is important to decide the order quantities in the MRP system. MRP ordering has the features such as multiple time periods, finite time horizon, time-varying costs according to the time periods, and discrete demand, etc. There are two research directions to this practical problem: one is the expansion of the classic inventory theory, such as EOQ model; the other gives models or algorithms directly from the characteristics of the MRP system.

The first research direction focus on how to exceed

the two basic hypotheses: fixed cost and infinite time horizon. In recent thirty years, many researches expanded the application of economic order quantity equation by exceeding one or both of the two basic hypotheses. In 1972, Schwarz [17] suggested a model of EOQ with fixed cost and finite demand horizon. In 1967, 1982, 1985, B. Lev, Taylor [19] etc. presented respectively the EOQ inventory model with one cost change and two time horizons. B. Lev [11] concluded the results of former researches systematically and built a fluctuant EOQ model with one cost change (increase or decrease) and two time horizons (one finite time horizon adding one finite or infinite time horizon) in 1989. In 1990, B. Lev and Zhang Jian [22] discussed the problem of EOQ inventory problem with the permission of two cost changes and three equal finite time horizons. And in 1997 Zhang Jian [23] discussed the same problems with multiple time periods and multiple cost changes. Some of these papers also discussed the backorder inventory problem in certain degree, and had important effect on the development of inventory theory. But some of the assumptions such as continuous demand made in regard to classical inventory models (economic order quantity (EOQ), economic production quantity (EPQ), and economic order interval (EOI)) are inappropriate for demand that varies from period to period. In this direction, the EOQ used in MRP ordering is to ignore the variation and apply the EOQ formulation with an average demand rate. The indiscriminate use of these methods can result in larger than necessary inventory costs for these conditions [15].

The other research direction began with a different approach provided by Manne [14] and by Wagner and Whitin [21] in 1958; they divided time into discrete periods and assumed that the demand in each period is known in advance. Since 1958, the Manne-Wagner-Whitin model has received considerable attention, and several hundred papers have directly or indirectly discussed this model; most of these papers have either extended this model or provided efficient algorithms for production problems that arise in it. The references given here and those given by Bahl, Ritzman and Gupta [1] provide only some of the papers related to the Manne-Wagner-Whitin model. Today, even an introductory operations research textbook is likely to

include a chapter on the Manne-Wagner -Whitin model and on some of its extensions (See, for example, Johnson and Montgomery 1974 [10], Wagner 1975 [20], Denardo 1982 [4], Richard J. Terine. 1988 [15], and Hax and Candea 1984 [8]). Because of the immense interest in economic lot size models, a considerable amount of research effort has been focused on establishing the computational complexity of various economic lot size problems. (In particular, see Florian, Lenstra and Rinnooy Kan 1980 [6], Bitran and Yanasse 1982 [2], Luss 1982 [13], Erickson, Monma and Veinott 1987 [5], and Chung and Lin 1988 [3]). As the extensions of Wagner-Whitin algorithm, Zangwill(1966), Blackburn and Kunreuther (1974) et al extended the Wagner-Whitin algorithm by allowing demand to go unsatisfied during some period, provided it is satisfied eventually by production in some subsequent period [18]. R. M. Hill (1997) [16], Stanislaw Bylka, Ryszarda Rempala (2001) [21] give dynamic programming formulation to decide lot sizing for a finite rate input process. But the Wagner-Whitin algorithm and its extensions commonly are criticized as being difficult to explain and compute because the algorithms are complicated dynamic programming algorithms. And many other non-optimal algorithms, such as lot-for-lot, periodic order quantity, Silver-Meal algorithm and part-period algorithm occurred [15, p161-178].

In this paper, we proposed the model that can obtain the economic lot size in MRP ordering systems with backorder and a finite replenishment rate. Then, we transfer the model into linear programming, and deduce three other models, i.e., the model considering a finite time rate, the model considering backorder and the model in which backorder is prohibited and an infinite replenishment rate. Finally, to illustrate the proposed models we give a numerical example.

The models proposed in the paper permit order cost, holding cost, backorder cost, price break points, and item prices varying from period to period. Comparing with the Wagner-Whitin algorithm and its extensions, the models are easier to explain and compute because the models are linearized or linear models and the optimal solutions of them can be obtained easily by using general-purpose linear program solver, like EXCEL, LINDO, etc.

## 2. Mathematical model of the backorder and finite replenishment rate

Assumption:

The planning horizon is finite and composed of several time periods.

The demand is known and occurs at the beginning of each period, but may change from one period from another.

Lead-time is fixed.

Each time period is characterized by finite replenishment rate, which may be caused by a fixed

production capacity or supply capacity from vendors and any interrupt between the replenishment incur setup cost.

The order quantity may not satisfy the demand in time, and the shortages or stockouts are considered. But stockout in the end of the time horizon is prohibited.

Items requirements in a period are withdrawn from inventory at the beginning of the period. Thus, the holding cost is applied to the end-of-period inventory and is only applied to inventory held from one period to the next. Items consumed during a period incur no holding cost.

MRP is a rolling schedule and projected on hand being not zero is considered.

Suppose that there are I periods in MRP system, we introduce the following problem parameters:

$i=\{1, \dots, I\}$ , the index set of periods,

$R_i$  = requirements in units for period  $i$ ,

$OC_i$  = fixed ordering cost or setup cost per order for period  $i$ ,

$HC_i$  = holding cost per unit for period  $i$ ,

$BC_i$  = backorder cost of an item for period  $i$ ,

$S_0$  = stock on hand for period 1 start or for period 0 end,

$M$  = a sufficiently large number.

$P_i$  = replenishment quantity if the replenishment for the whole period  $i$  is continued.

Decision Variables

$X_i$  = whether start to order or not (0-1 variables) for the  $i$ th period,

$Y_i$  = whether to replenish or not (0-1 variables) for the  $i$ th period,

$Q_i$  = lot size or replenish quantity for the  $i$ th period.

$Z_i$  = whether backorder or not (0-1 variables) for period  $i$ .

The problem, denoted by RBP, is to solve:

Problem BDP:

Minimize  $TC =$

$$\sum_{i=1}^I S_0 + \sum_{j=1}^i (Q_j - R_j) [(1 - Z_i) \cdot HC_i - Z_i \cdot BC_i] + \sum_{i=1}^I X_i \cdot OC_i + \sum_{i=1}^I P \cdot Q_i \quad (1)$$

Subject to

$$S_0 + \sum_{i=1}^I (Q_i - R_i) \geq 0 \quad (2)$$

$$S_0 + \sum_{j=1}^i (Q_j - R_j) \leq M \cdot (1 - Z_i) \quad i=1,2,\dots,I, \quad (3)$$

$$S_0 + \sum_{j=1}^i (Q_j - R_j) \geq -M \cdot Z_i \quad i=1,2,\dots,I. \quad (4)$$

$$Q_i \leq P_i \cdot Y_i \quad i=1, 2 \dots I \quad (5)$$

$$X_i = Y_i \quad (6)$$

$$Y_i - Y_{i-1} \leq M \cdot X_i \quad i=2, 3 \dots I \quad (7)$$

$$Q_i \geq P_i - M \cdot (1 - Y_{i+1}) - M \cdot (1 - Y_i) \quad i=1, 2 \dots I-1 \quad (8)$$

In BDP, the objective function, i.e. equation (1) is to minimize the total inventory cost which include holding cost and backorder cost over I time periods, i.e.

$$\sum_{i=1}^I S_0 + \sum_{j=1}^i (Q_j - R_j) [(1-Z_i) \cdot HC_i - Z_i \cdot BC_i], \text{ ordering}$$

cost, i.e.,  $\sum_{i=1}^I X_i \cdot OC_i$ , and item purchase cost, i.e.,

$$\sum_{i=1}^I P \cdot Q_i.$$

Equation (2) denotes any backorder should be fulfilled in the end of Ith period end. When  $S_0 + \sum_{j=1}^i \sum_{u=0}^U Q_{uj} - R_j \geq 0$  stands for plus stock level for period, i.e.,  $Z_i = 0$  can be obtained from equation (3). And in the other case  $Z_i = 1$  from equation (4). Equation (5) means that replenish happen i.e.,  $Y_i = 1$  when  $0 < Q_i < P_i$  for period i and vice versa. For the time period 1,  $Y_1 = 1$  then  $X_1 = 1$  and vice versa which determined by equation (6) and for the period i (i=1, 2, ..., I), the order start to occur for period I i.e.,  $X_i = 1$  if  $Y_i - Y_{i-1} = 1$  and vice versa which is shown in equation (7). Equation (8) mean that replenish quantity  $Q_i$  for period i should be  $Q_i = P_i$  if the replenishment continue through the full period i.

### 3. Discussion on RBP

In the model RBP, it is difficult to calculate the optimal economic replenish quantity since equation (1) is nonlinear. Here, in order to resolve this problem easily we introduce two kinds of nonnegative variables:

$BQ_i$  = the quantity of backorder for period i,

$HQ_i$  = the quantity of inventory for period i.

Then model RBP can be improved as linear programming model, denoted by LRBP is:

Problem LRBP:

$$\begin{aligned} \text{Minimize } TC = & \sum_{i=1}^I BQ_i \cdot BC_i + \sum_{i=1}^I HQ_i \cdot HC_i + \sum_{i=1}^I X_i \cdot OC_i \\ & + \sum_{i=1}^I P \cdot Q_i \end{aligned} \quad (9)$$

Subject to

$$S_0 + \sum_{j=1}^i (Q_j - R_j) \geq 0 \quad (10)$$

$$HQ_i - S_0 + \sum_{j=1}^i (Q_j - R_j) \leq M \cdot Z_i \quad i=1,2,\dots,I, \quad (11)$$

$$HQ_i - S_0 + \sum_{j=1}^i (Q_j - R_j) \geq -M \cdot Z_i \quad i=1,2,\dots,I, \quad (12)$$

$$BQ_i + S_0 + \sum_{j=1}^i (Q_j - R_j) \leq M \cdot (1 - Z_i) \quad i=1,2,\dots,I, \quad (13)$$

$$BQ_i + S_0 + \sum_{j=1}^i (Q_j - R_j) \geq M \cdot (Z_i - 1) \quad i=1,2,\dots,I, \quad (14)$$

$$Q_i \leq P_i \cdot Y_i \quad i=1,2,\dots,I, \quad (15)$$

$$X_i = Y_i \quad i=1,2,\dots,I, \quad (16)$$

$$Y_i - Y_{i-1} \leq M \cdot X_i \quad i=1,2,\dots,I, \quad (17)$$

$$Q_i \geq P_i - M \cdot (1 - Y_{i+1}) - M \cdot (1 - Y_i) \quad i=1,2,\dots,I, \quad (18)$$

Here we explain the equations (11)-(14). When  $Z_i = 0$ , equations (11) and (12) are binding and equivalent to

$$HQ_i = S_0 + \sum_{j=1}^i \sum_{u=0}^U Q_{uj} - R_j > 0. \quad \text{Otherwise } Z_i = 0,$$

equations (13) and (14) are binding and equivalent to

$$BQ_i = -S_0 + \sum_{j=1}^i \sum_{u=0}^U Q_{uj} - R_j > 0.$$

In model BDP, suppose backorder is not permitted in MRP ordering system, i.e.,  $Z_i = 0$ , then

$$\begin{aligned} & \sum_{i=1}^I S_0 + \sum_{j=1}^i \sum_{u=0}^U Q_{uj} - R_j [(1-Z_i) \cdot HC_i - Z_i \cdot BC_i] \\ = & \sum_{i=1}^I S_0 + \sum_{j=1}^i \sum_{u=0}^U Q_{uj} - R_j \cdot HC_i \end{aligned} \text{ in equation (1) and}$$

equations (2), (3) and (4) are equivalent to the constraint

$$S_0 + \sum_{j=1}^i \sum_{u=0}^U Q_{uj} - R_j \geq 0 \quad (i=1,2,\dots,I). \text{ The model RBP}$$

or model LRBP will become a the model of finite replenishment problem, denoted by RP, is:

Problem RP:

$$\begin{aligned} \text{Minimize } & TC \\ = & \sum_{i=1}^I HQ_i \cdot HC_i + \sum_{i=1}^I X_i \cdot OC_i + \sum_{i=1}^I P \cdot Q_i \end{aligned} \quad (19)$$

$$S_0 + \sum_{j=1}^i (Q_j - R_j) \geq 0 \quad i=1,2,\dots,I \quad (20)$$

$$Q_i \leq P_i \cdot Y_i \quad i=1,2,\dots,I, \quad (21)$$

$$X_i = Y_i \quad i=1,2,\dots,I, \quad (22)$$

$$Y_i - Y_{i-1} \leq M \cdot X_i \quad i=1,2,\dots,I, \quad (23)$$

$$Q_i \geq P_i - M \cdot (1 - Y_{i+1}) - M \cdot (1 - Y_i) \quad i=1,2,\dots,I, \quad (24)$$

In model LRBP, suppose the entire order is received into inventory at one time in MRP ordering system. Equations (21)----(24) are equivalent to  $Q_i \leq M \cdot X_i$   $i=1,2,\dots,I$ . Then model LRBP become a backordered problem, denoted by BP, is:

Problem BP:

$$\text{Minimize } TC = \sum_{i=1}^I BQ_i \cdot BC_i + \sum_{i=1}^I HQ_i \cdot HC_i + \sum_{i=1}^I X_i \cdot OC_i + \sum_{i=1}^I Q_i \cdot P_i \quad (25)$$

Subject to

$$S_0 + \sum_{i=1}^I (Q_i - R_i) \geq 0 \quad (26)$$

$$HQ_i - \left[ S_0 + \sum_{j=1}^i (Q_j - R_j) \right] \leq M \cdot Z_i \quad i=1,2,\dots,I, \quad (27)$$

$$HQ_i - \left[ S_0 + \sum_{j=1}^i (Q_j - R_j) \right] \geq -M \cdot Z_i \quad i=1,2,\dots,I, \quad (28)$$

$$BQ_i + \left[ S_0 + \sum_{j=1}^i (Q_j - R_j) \right] \leq M \cdot (1 - Z_i) \quad i=1,2,\dots,I, \quad (29)$$

$$BQ_i + \left[ S_0 + \sum_{j=1}^i (Q_j - R_j) \right] \geq M \cdot (Z_i - 1) \quad i=1,2,\dots,I, \quad (30)$$

$$Q_i \leq M \cdot X_i \quad i=1,2,\dots,I, \quad (31)$$

In model RBP, suppose backorder both are not permitted and the entire order is received into inventory at one time in MRP ordering system. From the analysis in model BP and RP, the model with no permission of backorder and simultaneous replenishment, denoted by P, is:

Problem P:

$$\text{Minimize } TC = \sum_{i=1}^I \left[ S_0 + \sum_{j=1}^i (Q_j - R_j) \right] \cdot SC_i + \sum_{i=1}^I OC_i \cdot X_i + \sum_{i=1}^I P_i \cdot Q_i \quad (32)$$

Subject to

$$S_0 + \sum_{j=1}^i (Q_j - R_j) \geq 0 \quad i=1,2,\dots,I, \quad (33)$$

$$Q_i \leq M \cdot X_i \quad i=1,2,\dots,I, \quad (34)$$

#### 4. Numerical Example

A item has a unit purchase price of \$5, an ordering cost per order of \$100, a unit holding cost per week of \$1, replenishment rate per period of 60 units and a unit backorder cost per week of \$2. Project on hand at period 1 start is 35 units and lead-time for the item is zero. Determine the replenish quantities for each week by model BDP from the requirements in table 1.

By using model LRBP we get the results in table 2.

Table 1 Gross requirements

Period (week)	1	2	3	4	5	6	7	8	9	10
Gross requirements	35	30	40	0	10	40	30	0	30	55

Table 2 The optimized MRP net requirements plan

Period (week)	0	1	2	3	4	5	6	7	8	9	10	Total cost (\$)
Gross requirements	-	35	30	40	0	10	40	30	0	30	55	-
Project on hand	35	0	30	0	0	0	10	0	0	30	0	-
Backorder quantity	-	0	0	0	0	10	0	0	0	0	0	-
Net requirements	-	0	30	10	0	10	50	20	0	30	25	-
Planned-order receipt	-	0	60	10	0	0	60	20	0	60	25	-
Holding cost (\$)	-	0	30	0	0	0	10	0	0	30	0	70
Ordering cost (\$)	-	0	100	0	0	0	100	0	0	100	0	300
Backorder cost (\$)	-	0	0	0	0	20	0	0	0	0	0	20
Total cost* (\$)	-	0	130	0	0	20	110	0	0	130	0	390

\*Here item cost is not considered since the unit purchase price does not change with the time periods, which will not be mentioned in the following tables.

Table 3 The MRP net requirements plan when the backorder cost is \$0.5

Period (week)	0	1	2	3	4	5	6	7	8	9	10	Total cost (\$)
Gross requirements	-	35	30	40	0	10	40	30	0	30	55	-
Project on hand	35	0	0	0	10	0	0	0	0	20	0	-
Backorder quantity	-	0	30	10	0	0	40	70	10	0	0	-
Net requirements	-	0	30	70	10	0	40	70	70	40	35	-
Planned-order receipt	-	0	0	60	20	0	0	0	60	60	35	-
Holding cost (\$)	-	0	0	0	10	0	0	0	0	20	0	30
Ordering cost (\$)	-	0	0	100	0	0	0	0	100	0	0	200
Backorder cost (\$)	-	0	15	5	0	0	20	35	5	0	0	80
Total cost (\$)	-	0	15	105	10	0	20	35	105	20	0	310

In Table 2, the finite replenishment rate i.e., 60 makes that the replenishment quantity for each time can't be replenished in one week, e. g. in the 2<sup>nd</sup> week requirements of 70 units satisfied by 60 units in the 2<sup>nd</sup> week and 10 units in the 3<sup>rd</sup> week. The total cost is \$390.

Decreasing the replenishment rate per week to \$0.5, the results are shown in Table 3.

Comparing Table 3 with Table 2, we can find some changes when the backorder cost per week per unit reduces from \$2 to \$0.5. Apparently, the times of backorder increases from 1 to 5 times and order times from 3 times to 2 times. That causes the order costs changing from \$300 to \$200, the backorder cost rising from \$70 to \$80 and the holding cost decreasing from \$70 to \$30. The total cost decreases \$80 according to the above changes.

By changing the backorder cost per unit per week, we could get Figure 1.

In Figure 1, the total cost has the increase trend with the rising backorder cost per unit per week. When the backorder cost is zero, MRP system will keep the backorder status, ordering all the 235 units in the last four periods by 60 replenishment rate per week, order cost occurring only one time and holding cost being zero. When the backorder is higher than \$3, backorder becomes uneconomic. The MRP system is equals to the system without backorder i.e., the computing results are same between model LRBP and model RP.

Decreasing the replenishment rate per week from 60 units to 70 units, we get the net requirements plan showed as Table 4.

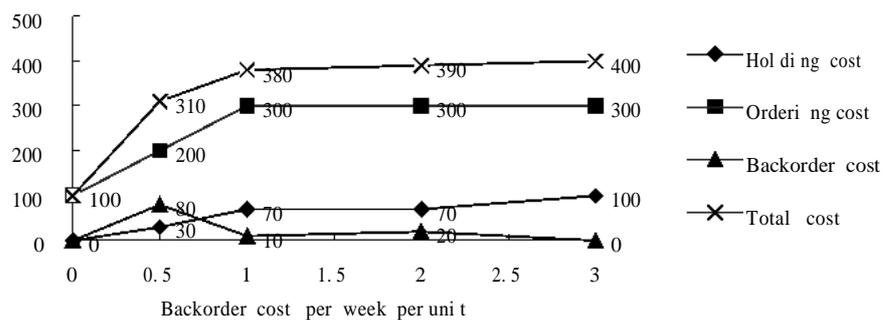

Figure 1 Cost variance with backorder cost per week per unit changing

Table 4 The Optimized MRP net requirements plan when the replenishment quantity per period is 70 units

Period (week)	0	1	2	3	4	5	6	7	8	9	10	Total cost (\$)
Gross requirements	-	35	30	40	0	10	40	30	0	30	55	-
Project on hand	35	0	40	0	0	0	20	0	0	40	0	-
Backorder quantity	-	0	0	0	0	10	0	0	0	0	0	-
Net requirements	-	0	30	0	0	10	50	10	0	30	15	-
Planned-order receipt	-	0	70	0	0	0	70	10	0	70	15	-
Holding cost (\$)	-	0	40	0	0	0	20	0	0	40	0	100
Ordering cost (\$)	-	0	100	0	0	0	100	0	0	100	0	300
Backorder cost (\$)	-	0	0	0	0	20	0	0	0	0	0	20
Total cost (\$)	-	0	140	0	0	20	120	0	0	140	0	420

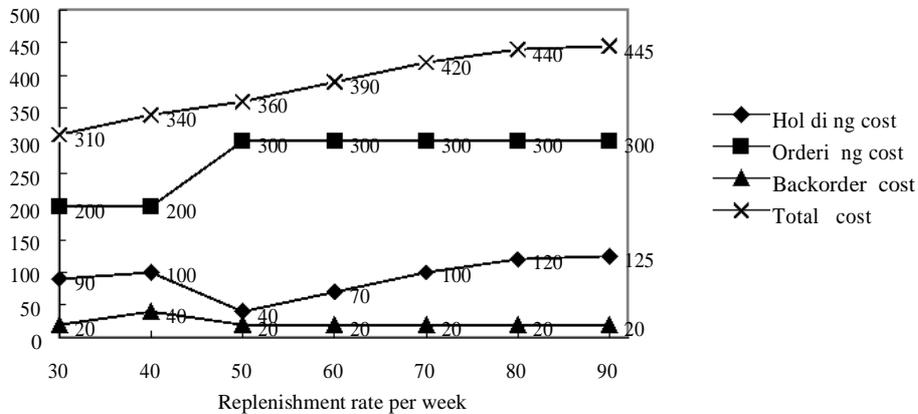

Figure 2 Cost variance with replenishment rate per week changing

From Table 2 and Table 4, when the replenishment rate per week is increased from 60 units to 70 units, only the holding cost enhanced from \$70 to \$100 and the total cost increase to \$420.

By changing the replenishment rate per week, we get Figure 3.

From Figure 2, the total cost rise with the increase of the replenishment rate per week. But since the replenishment rate per week is fixed, when the replenishment rate per week is too lower e.g. 40 units, the MRP system must replenish inventory in the most of the weeks for fear that the requirements can't be replenishment at the end of the 10<sup>th</sup> week and makes the holding cost rise correspondingly. And when the replenishment rate per week is too high e.g. 90 units, the replenishment quantity for each time is fulfilled in a week and the results obtained from model BP and model LBRP are same.

## 5. Concluding remarks

In this paper, firstly we proposed the general model

RBP that can obtain the economic lot size in MRP ordering systems with backorder and a finite replenishment rate. Secondly, the nonlinear programming model RBP is transferred into linear one, and deduces three other models, i.e., the model RP considering a finite replenishment rate, the model BP considering backorder and the model P with no permission of backorder and simultaneous replenishment. Finally, to illustrate the models proposed we give a numerical example. The models proposed can be adapted to such by dynamic change using the idea of rolling horizon, especially in MRP ordering.

However, there are several limitations in the proposed models and research directions as follows.

1) The models proposed assume that all information is known with certainty and is static throughout the planning horizon. This is not always the case, especially when it comes to demand forecasts, since usually a demand realization is not likely to be different from the forecast of that demand.

2) All of the approaches proposed in this paper seek to minimize costs for a single item and do not consider

items as part of a multistage inventory system across the planning horizon; to be specific, none examines the impact of lot size at a higher level in a production structure upon lower items.

3) Aside from the limitation of a finite replenishment rate, a budget that limits the amount of investment in inventory and a warehouse capacity restricting available storage space often confront managers. The model will have more application value if it can combine MRP net requirement plan with CRP (capacity requirements planning) considering these constraints.

4) The lead time in this paper is fixed and quantity discounts is not considered in our model. However, either lead time or item price may change with the order quantities even at the same time point.

# ERP is the Key Point of Supply Chain Management

Xiao Chen Jiahui Cheng  
School of Economics and Management  
Tsinghua University  
Beijing, China  
yqjsj@sina.com

## Abstract

Information technology is changing the mode of customer service, material purchasing, price making in an enterprise. To keep advantage, an enterprise has to take supply chain management. By sharing information and making plans together, an enterprise and its providers, its customers, can improve their whole logistic efficiency through supply chain management. ERP is classic of information management in modern enterprises. ERP manages and controls effectively every node of supply chain inside an enterprise. It's the information flat on which an enterprise manages and makes decision. It is the key point of supply chain management.

## 1. Introduction

Only when an enterprise take full use of its inside resource, and conform its outside resource, can it keep its sales advantage in the furious competition.

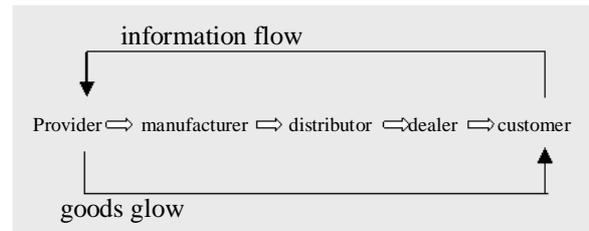

Information technology is changing the mode of client management, material purchasing, price making in an enterprise. Customers now demand to get goods whenever and wherever in the lowest price most quickly. For this, an enterprise has to change its logistics flow, cooperate with its partners (providers, customers) in supply chain management of business affairs.

## 2. The Concept of Supply Chain

The manager of Changan Motor went to Korea for inspection. He saw the motor accessories made in Korea are cheaper than those made in Chongqin, China. If he import the accessories to his company, they cost 40 percent less. But accessories' production and import need a period of time. He don't want to store many accessories, neither does he want the productive speed slowlier. How can the provider in Korea know his company's plan, and supply the accessories on time? This points to the communication and cooperation between two enterprises, not inside an enterprise.

This is a simple case of supply chain management. The concept of supply chain management is, an enterprise and its providers, its customers, are improving their whole logistics efficiency by sharing information and making plans together, by forming a quick responding channel through provider, manufacturer, distributor, retailer and customers.

picture 1 composing of supply chain

Though supply chain management, once the logistics channels that links up several independent enterprises loosely, now manage to work together to improve their whole efficiency and competence. The motive of supply chain is to improve the competence of the logistic channels.

## 3. Supply Chain Management Needs Information Flat to Support

The motivity of supply chain management comes from the request of customers. The goal is quick response, least variance, least inventory and high satisfaction of customers.

Supply chain management emphasizes that an enterprise and its providers, its customers should share information, make plans together and cooperate with others.

Sharing information among enterprises needs information flat to support. Only when information runs in numeric network, can upriver and downriver company get what they need at the first time and make quick response, least variance become possible.

Making plan together can decrease the uncertainty of demand and supply. This makes least inventory, least variance become reality. When an enterprise is making a plan, information flat is required to transfer information that comes from market and strategetic partners. When plans are carried into execution, information flat is required to feedback the variety of demand. So that the enterprise can adjust its plan in time and respond quickly.

## 4. An Efficient Information System of Management Is Required Before Putting Supply Chain Management into Practice

Supply chain management is a reticulation structure formed by many nodes. The adjacent nodes are joined by providing and requirement. They are buckled one by one.

The work of the whole supply chain will be affected whenever a node is in trouble. If the business process of an enterprise is unsuitable, not only the enterprise itself, but the supply chain will work more ineffective.

So we say, the suitable business process and scientific administrant system are required before an enterprise puts supply chain management into practice. If the business process ineffective, the managing troublesome in an enterprise, in the traditional mode, it can be made up for the lost by adjusting the procedure temporarily. Sometimes it won't come to a big lost. But in the mode of supply chain management, enterprises share their resources and restrain the other enterprises. A trouble in an enterprise will enlarge several times into a trouble through the whole supply chain. For example, one day the provider meets a matter. He can't provide raw material on time. Then manufacture will stop without raw material. The manufacturer can't supply goods to the distributor. Then the distributor will have to take a rest because of lack of goods...

This comes to a conclusion. An enterprise should make its business process effective, administrant system scientific by reengineering and standardizing its procedure before supply chain management is put into practice. Further more, the enterprise should ameliorate its inside administrant structure persistently after supply chain management has been carried into execution.

In the supply chain management among a few enterprises, there are goods flow, information flow and capital flow. Supply chain benefits from goods flow mostly. The essential of supply chain is to improve the efficiency of goods flow by the alliance and cooperation among enterprises. It represents as quick response and least inventory. How can we make the goods flow faster, the cost less, deviation smaller? We must depend on the timely and exact information flow. Information flow in the supply chain is what enterprises base on when they make a decision or management. This is to say, information flow is the core of supply chain management. Thus the enterprise with supply chain management must have a data processing system, to collect exact data, analyse the data, organize the data, and support tekecommunications and E-business.

## 5. ERP Is Classic of Information Management in Modern Enterprises

ERP(Enterprise Resource Planning) is a system based on information technology, guided by systemic managing ideology, merged information technology and advanced manage ideology, applied by modern enterprises.

Firstly, ERP is an information system of management guided by modern administrant ideology. The viewpoint of traditional management is to produce right goods and sell them at the right time. The core of ERP is to get the most profit at the right time and on the right place. ERP takes the procedure in an enterprise as a supply chain joined tightly. It divides the enterprise into a few subsystems which cooperate with each other, such as finance system, sales system, manufacture system and else. ERP manages and

controls effectively every node of supply chain inside the enterprise, which includes order, purchase, stock, manufacture, controlling quality, transport and distributing.

With ERP, all information can communicate among departments timely. This ensures the info management and unitary producing. The management and control become more efficient.

Secondly, ERP is correlated with BPR(Business Process Reengineering) tightly. The essential of ERP is sharing resource and cooperation inside an enterprise by using information technology. When ERP is carried into execution, some problems such as the detachment of department management, the difference of managing scale, lots of repeatedly work will be optimized and ameliorated. The amelioration must reengineer the enterprise's business process, information process, and reform the organize. Thus the business process will become more suitable. Producing and managing will become more effective.

Thirdly, ERP is an advanced, systemic data processing system. ERP applies the newest production of computer and communication technology, including GUI, RDBMS, OOT, the fourth language, client/server and DDM. ERP integrates the enterprise's resource and bring the productivity multiplier into effect through information technology. Besides manufacture, purchase, sales, finance, ERP supports storage, transport, OLAP, after service, quality feedback, tekecommunications, E-business, and EDI.

That is to say, ERP is an integrative system of advanced managing ideology, theory and method. ERP integrates the business process and information flow in an enterprise highly. ERP is classic of information management in modern enterprises.

## 6. ERP Is the Key Point of Supply Chain Management

A few national great corporations in our country realize the importance of supply chain management now. Haier, Hisense and Legend are building or have built an automatic, intellectualized modern logistic system which is of international level. But there are still lots of enterprise that don't know what supply chain management is. Neither do they know the status of logistics management abroad. Most enterprises have little information ordinary. They have no information system for management in deed. And their business process is no longer suit the commercial environment and need to be reengineered.

Putting supply chain management into practice is difficult without an effective information system in an enterprise. Supply chain management bases on the cooperation among enterprises. If the management ineffective, amelioration is very complex and hard. However, ERP is an information system of management inside one enterprise. Carrying ERP into execution is easier. Because having a suitable information system and highly integration of managing information, putting supply

chain management into practice is simple with ERP carried out. What needs to do is to decide the symbiosis and duty sharing. ERP will suits the change because it is ameliorating continuous and consummating persistently.

So we can say, ERP is the key point of supply chain management in china. Supply chain management will take full effect only when ERP is carried out. Supply chain management is impossible without ERP.

## 7. Conclusion

The core of logistics in an enterprise is to deliver goods to customers on time and accurately.

supply chain management can enhance the logistic efficiency of an enterprise and ensure the enterprise's sales advantage in the furious competition.

ERP manages every node of supply chain inside an enterprise effectively. It's the information flat on which an enterprise manages and makes decision. It is the key point of supply chain management.

## Abstract

Data warehouse is proclaimed as the latest decision support technology. As data warehouses require a significant amount of organizational resources to develop, more research have been devoted to identifying the critical success factors and the formulas for assured investment return from data warehouses. This study proposes a bi-directional development approach for data warehouses in public sectors. The primary rationale for the proposed approach is the fundamentally different organizational goals of public sector organizations from private sector organizations. Whereas the ultimate goal of private sector organizations is profit making, public sector organizations have a set of conflicting goals including different social and political objectives. The star schema as a dimensional data model for data warehouse is not totally suitable for data warehouses that demand the analyses of both quantitative and qualitative measures. Using the data warehouse in the College of Business Administration at the California State University, Sacramento as a case study, we illustrate how the QQ (Quantitative and Qualitative) data schema accommodates the need of capturing both quantitative and qualitative information. In addition, we show the bi-directional top-down/bottom-up initiative, the formal/informal information collection, and the enterprise data warehouse/subject data mart architecture for the data warehouse.

## 1. Introduction

Inmon [13] defined data warehouse as a subject oriented, integrated, non-volatile, and time variant collection of data for decision support. In the past decade, we have seen the concept and technology of data warehousing evolving from a visionary idea to the mainstream of decision support in corporate culture. It was estimated that the investment in data warehousing will grow from US\$8.8 billion in 1996 to US\$113.5 billion in 2002 [30]. About 85-90% of the Fortune 500 companies have either adopted or plan to adopt data warehouses [25]. The International Data Corporation (1996) reported an average return on investment of 401% in 62 data warehouses, with an average 1.7-year payback period. On the other hand, the failure rate of data warehouses is also very high. While the exact figures are not available, the initial failure rate of data warehouse is estimated to be one-half to two-thirds [31][30]. Following the development path of introduction, proliferation (or growth), control, and maturity, data

warehousing is currently in the stage of proliferation. The accumulation of success and failure experience is generating a wealth of guidance on the application of data warehousing in organizations.

The public sectors are usually slow in adopting new information technology because of their complex organizational structure and project approval process. The past diffusion of information technology follows the path from private sectors to public sectors. In terms of supporting semi-structured or unstructured decision making, the public sectors are as needy as, if not more than, the private sectors. We have seen the application of decision support systems in the areas of resource allocation [15][19][26], admission policies [8], scheduling [9], hazardous waste management [24], and auditing [30]. Data warehousing, the latest development of decision support tools, has been gradually adopted as a problem solver for strategic issues in public sectors. Given the fundamental differences in organizational goals and structure between public and private sectors, the development of data warehouses in public sectors may require different methodologies, tools, and skills. This study attempts to identify the suitable methodology in the planning and design phase of data warehouse in public sectors. The rest of the paper is organized into the following five sections. Section 2 provides a literature review on the data warehousing for the past few years. Section 3 identifies some organizational characteristics in private and public sectors. Section 4 presents the bi-directional approach for developing data warehouses in public sectors. Section 5 illustrates the bi-directional approach using a business school case study. The last section concludes the paper by suggesting some future research directions.

## 2. Data Warehousing in the Literature

Among the seventeen data warehousing research studies we identified from the literature in the past few years, seven are explorative case studies [23][7][21][1][18][25], three are survey studies [6][31][28], three are theoretical analysis without empirical data [20][2][29], two are data warehousing for auditing purposes [11][22], and two are Web-based data warehouses [5][12]. The distribution of our reviewed articles indicates case study as a popular research method in this proliferation stage of data warehouse development. Researchers are observing the development of different data warehouses in different organizations, collecting data about the success and failure factors, accumulating

experience about the planning imperative, design methods, implementation tactics, and operational procedures for data warehouses. We will see the accumulation of case knowledge leading to the development of consolidated theories for the control stage of data warehousing in the coming decade. This section will review some of the recent findings about data warehousing in the literature.

For case studies, Sammon & Finnegan [23] investigated the data warehousing practice of four corporate users. Using semi-structured interviews and document analysis, they identified ten critical success factors for data warehousing. The ten factors are business-driven initiative, executive sponsorship and commitment, funding commitment based on realistically managed expectations, project team with access to cross-functional project management and implementation experience, attention to source data quality, flexible enterprise data model, effective data stewardship, long-term plan for automated data extraction methods and tools, knowledge of data warehouse compatibility with existing systems, and hardware/software proof of concept. Cooper et. al [7] described how the data warehouse technology transformed the First American Corporation from a traditional banking to a customer centric system. The VISION data warehouse at First American Corporation was designed to provide data and analysis to allow the management to know the client better, provide what the client needs, help the client achieve goals, and offer the client preferred channels. First American Corporation managed to re-align the organizational structure with new information technology infrastructure and strategy, which is proved to be a critical factor in enabling the organization to reap benefits from the data warehouse.

Quaddus & Intrapairrot [21] reported the end-user adoption and usage process of data warehouse in the Siam Commercial Bank, a major commercial bank in Thailand. They found that the policies of “increase level of training” and “decrease training delay” can significantly accelerate the diffusion of data warehouse usage. Ang & Teo [1] investigated the data warehouse developed for the Housing and Development Board in Singapore. This is the only case study in public sectors among the seven case studies. The management issues of concern in this case study include identifying the development process, choosing development options, adopting incremental change approach, overcoming resistance, choosing project leader, providing formal and systematic training, and scalability and maintenance. This case study did not focus on developmental differences between private and public sector data warehouses. Marks and Frolick [18] presented the development process of a data warehouse in a home service company. The most important lessons learned from the case study are clear mission, effective business analysis, and top management support. Watson et. al [30] had the question of why some organizations realized

more benefits from data warehouses than others. They traced the development of data warehouses in a large manufacturing company, the Internal Revenue Services, and a financial services company. Their findings show that a successful data warehousing process constitutes the steps of articulating a vision, communicating the vision throughout the organization, and institutionalizing the changes required by the vision. Shin [25] studied the project management issues of a data warehouse project in one of the biggest insurance companies in the US. The study identified the following essential practices for the successful data warehouse project management: (1) process involvement by business units and prospective end-users; (2) manageable project scope; (3) packaged tools for data staging; (4) marketing the new system throughout the project to business customers and target users; and (5) metadata-centric system design and implementation based on conformed dimensions and facts.

For survey studies, Chen et. al [6] developed a questionnaire to investigate the concept of user satisfaction with data warehouses. They identified data accuracy, format, and precision; support provided to end-users; and fulfillment of end-users needs as the three major factors for data warehouse satisfaction. The advice is to provide training and support to end-users, in order for end-users to understand the meaning of data in the data warehouse. Wixom and Watson [31] were interested in the role of implementation in data warehouse success. Their study was a cross-sectional survey from 111 organizations using paired mail questionnaires on implementation factors and success of warehouses. They found that the link between implementation and warehouse success is weak. However, there are significant correlations between data quality and perceived net benefits, and between system quality and perceived net benefits. Watson et al. [28] carried out a survey to explore the topics of sponsorship, architecture, use, costs, and benefits in data warehouse. The 47 usable responses indicate that about 40% of data warehouses were sponsored by vice-president of a business unit, 36% were used in marketing and sales, 32% were of data warehouse only architecture; 58% of the surveyed organizations had an average number of 18.5 users in the information system units, 52% had an average number of 150.5 users in the marketing and sales unit, 41% had an average number of 48.4 users in the finance units, 43% used a prototype approach to develop data warehouses; and 66% of the end-users believed that the data warehouses met their objectives.

Another research direction in data warehouse is to develop theoretical models to describe, explain, and predict the generic phenomenon of data warehousing. Murtaza [20] presented a framework for developing enterprise data warehouses. The framework consists of the stages of business requirements, data sourcing, target architecture, access tool selection, and administration. Ballou & Tayi [2] constructed an integer programming

model to maximize the total value from all projects for improving the data quality in data warehouse environments. The model considers the factors of current data quality, required data quality, anticipated data quality, priority of organization activity, cost of data quality enhancement, and the utility of value added from data improvement projects. Watson et. al [29] described the benchmark variables including data, architecture, stability of the production environment, warehouse staff, users, impact on users' skills and jobs, applications, costs and benefits, and organizational impact for the stages of initiation, growth, and maturity in data warehousing. There are other specific research topics such as incorporating the Web elements into data warehousing [5][12] and the role of data warehouses in auditing [11][22].

The above review of the data warehouse literature in the past few years shows that only a few studies [1][11] have investigated the role of data warehouses in public sectors. It is the purpose of this study to develop an appropriate development approach for data warehouses in public sectors.

### **3. Organizational Characteristics in Private and Public Sectors**

Table 1 summarizes the relevant organizational characteristics for data warehouse development in private and public sectors. One important difference is the organizational goals. Private sector organizations have the ultimate goal of making profit, which can be translated into increasing the share values of investors. On the other hand, public sector organizations (such as federal and state agencies, public educational institutes, and charity organizations) are non profit making, and have multiple social and political objectives. In other words, private sector organizations' goals can be readily quantified whereas public sector organizations' goals have to be measured both qualitatively and quantitatively.

Another difference is the organizational structure. Private sector organizations tend to have clear lines of authorities and responsibilities. Since the goal of profit-making is quantifiable, it is easier to pinpoint the problematic areas when the organizations cannot meet the goals. The numbers speak for themselves showing whether the sales departments do not make enough revenue, the production departments over-spend on raw materials, or the marketing departments do not reach enough potential buyers. If the current structure is not contributive to profit making, private sector organizations are more willing to change the structure. Since structural change is permissible, it is less likely for private sector organizations to rely on informal structure to work around problems. On the other hand, since public sector organizations have to achieve multiple or conflicting objectives, the structure is designed to have a check and balance effect. The lines of authorities and responsibilities are more likely to be overlapping and

vaguely defined. The obscure lines of responsibilities make it difficult to trace the contributions of different organizational units to the organizational goals, which further make it difficult to justify any structural changes for improving organizational effectiveness. As it is difficult to have structural change, ineffectiveness and inefficiencies may be ignored or solved by informal working structure.

As for management style, any styles that can promote profit making will usually be encouraged in private sector organizations. Public sector organizations tend to have management styles that balance different social and political objectives. People who achieve managerial or leadership positions in public sector organizations have very good diplomatic skills but they are reluctant to give commitment and be change agents. As for the working personnel, private sector organizations motivate employees by relatively well-defined monetary reward systems. Private sector employees know very well what they have to do in order to be rewarded. In public sector organizations, personnel are more likely to work by the books in order to avoid being blamed. The reward systems are usually determined by and distributed over different authorities such as the labor union and a multi-level set of ruling units. Public sector employees are in a worse position than their private sector counterpart to control their career destinies. As for change management, since private sector organizations have more competitors, they tend to have more environmental sensors to detect threats and opportunities. They tend to have more formalized systems to respond to crises and carry out required changes. Private sector organizations, on the other hand, usually avoid changes unless they are mandated by top management or their survivals are threatened. In summary, public sectors organizations have quantitative and qualitative objectives, overlapping and vague lines of responsibilities and authorities, top management focusing on balancing, working personnel focusing on maintenance, and intrinsic persistence on status quo. These relative characteristics affect the application process of data warehousing technology. The next section discusses a bi-directional approach for developing data warehouses in public sectors.

### **4. A Bi-Directional Development Approach for Data Warehouses in Public Sectors**

The literature suggests different system development life cycles for data warehouses [17][16][10][4][27][3], and most include the stages of initiation, information requirement, architecture design, data sources, data modeling, end-user interface, implementation, testing, training, and maintenance. Each step has its own methodology, tools, and skills. The bi-directional development approach for data warehouse proposed in this study focuses on the stages of initiative, information requirement, architecture design, and data modeling. Figure 1 summarizes the suggestions of the bi-directional

approach for data warehouse development in public sectors.

For the initiative stage, the bi-directional approach suggests the simultaneous top-down and bottom-up for planning and justification of data warehouses. The hybrid approach can reduce the strong opposition to changes in public sector organizations. The bottom-up direction may be triggered by end-users' dissatisfaction with the current level of information quality and information processing procedure. The top-down direction may be stimulated by external forces that threaten the survival, legitimacy, or status of the organization. The congruency of the two directions provides a fertile ground for data warehouse success. If the data warehouse initiative is mandated by top management without support by end-users, the data warehouse adoption process will be difficult to diffuse. To the extreme, the end-users may sabotage the data warehouse. A data warehouse proposed solely by end-users may not be able to get the multi-level top management's attention in highly bureaucratic public sectors.

For the information requirement stage, the bi-directional approach suggests both the formal and informal channels for requirement identification. As public sector organizations have informal structure performing significant tasks, it is important to collect information requirements from informal channels. Formal channels include interviews, on-site observations, analyses of reports, tables, manuals, and other published strategic papers. Informal channels are unrecorded complaints, grievances, hidden agendas, personal contacts, gossips, and casual discussions.

For the stage of architecture design, the bi-directional approach recommends a combined architecture of enterprise data warehouse and data mart. A pure enterprise data warehouse approach develops one and only one comprehensive data warehouse to support all decision activities in all departments for the organization. A pure data mart approach develops many independent and small data warehouses supporting different organizational units or decision subjects. Given the multiple and conflicting objectives in public sector organizations, the pure data mart approach will not be able to give an overall view of the organizational truth to leaders performing balancing acts. On the other hand, the pure enterprise data warehouse will be too time consuming and complicated to build. The combined approach will first generate a high-level blueprint for the enterprise level data warehouse, then set the priorities for different data marts, and build the most visible, least risky, and most valuable data mart as a proof of concept project. This bi-directional approach has the effect of building the data warehouse incrementally without losing sight of how the data mart pieces will fit together as a seamless entity.

For the stage of data modeling, the bi-directional approach proposes a new data modeling technique QQ schema (first Q for quantitative and second Q for qualitative), capturing both quantitative and qualitative bottom line measures for public sector organizations. The star schema as a dimensional data model for data warehouses [17] is designed to store quantitative data such as sales figures, costs, and budget variances in the center fact table surrounding by multiple dimension tables. Any qualitative data have to be stored in dimension tables, which are used as headers and sub-headers in multidimensional analyses and reports. Once data are stored in dimension tables, they cannot be sliced and diced as in the fact table because dimension tables are usually not inter-related. Given that public sector organizations are not purely figure-driven, it is important to have both qualitative and quantitative measures in the tables that support strategic and tactical analyses. The next section will illustrate the bi-directional development approach using a case study for a business school data warehouse.

## **5. A Case Study Illustrating the Bi-Directional Development Approach for Data Warehouse**

This section describes the data warehousing experience at the College of Business Administration (CBA), California State University at Sacramento (CSUS) in the United States. The data warehouse project started in the Fall of 2001 and is on-going. The CBA at CSUS has about 130 full-time and part-time faculty members, 4000 undergraduate students, and 380 graduate students in Fall 2001. The CBA has four academic departments including Accountancy, Management, Management Information Science, and Organizational Behavior and Environment.

### **5.1 Top-down and bottom-up initiative for data warehouse**

The CBA at CSUS received her re-accreditation from AACSB International (The Association to Advance Collegiate Schools of Business, formerly American Assembly of Collegiate Schools of Business) a few years ago. Amongst the turmoil of leadership transitions from 1995 to 1997, the CBA managed to collect her efforts, engage her faculty members, address issues of AACSB concerns, and finally earned the re-accreditation. The re-accreditation process has taught the administration and faculty members who were involved in the process a lesson of the critical role of information under the new AACSB accreditation guidelines.

Under the California State University System, faculty members have to submit activity reports for the purposes of salary merit increase, tenure and promotion, and post-tenure review. The re-accreditation process also required faculty members to fill in questionnaires for

satisfaction and curriculum surveys, as well as submit faculty data sheets listing their intellectual contributions and professional activities. In total, a faculty member can be requested to submit up to 5 different reports in one year. Many reports have overlapping data that can be consolidated. Faculty members expressed their frustration over filling in multiple reports for the same information. The administration also felt the painful process of collecting data from different sources to satisfy different information requests from the AACSB and other external bodies. In Spring 2001, the Academic Office of the University announced funding availability that was earmarked for strategic information technology and requested proposal for the funding. One proposal for a data warehouse project was submitted from the Management Information Science Department. The Dean of the CBA gladly and enthusiastically approved the data warehouse proposal. The initiative process of the CBA data warehouse is bi-directional, supported by end-users and endorsed by top management.

## 5.2 Formal and informal information requirements

The CBA Dean and the principal investigator of the data warehouse project compiled a list of interviewees for identifying information requirements. The interviewee list included all department heads, all CBA institute directors, the chairperson of Academic Council, the directors of undergraduate and graduate programs offices, and other key decision makers in the College. The question list consisted of the following items:

- i. What tasks in your job involve decision making? What tasks do you need to perform in order to support your immediate supervisor's decision making activities?
- ii. Which tasks you identified in question 1 have very important effect on your overall job performance?
- iii. Do you feel that you have or can obtain enough, timely, and relevant information to carry out the tasks you identified in question 1?
- iv. If your answer to question 3 is no, what other information do you need?
- v. If your answer to question 3 is no, how would you like to improve the information acquisition methods?
- vi. Do you feel that you have enough analysis methods to carry out the tasks you identified in question 1?
- vii. If your answer to question 6 is no, what other analysis methods do you need?
- viii. Do you feel that the current decision making process for the tasks in question 1 is efficient and effective?

- ix. If your answer to question 8 is no, how would like to improve the decision making process?

The information collection process took about three months. There are two factors that facilitated the information collection process. First, being a faculty member and involved in the re-accreditation process, the principal investigator has first-hand knowledge about the information needs of the college. Second, the principal investigator's peer status to the interviewees certainly enhances the trust and open communication during the information collection process. In many occasions, after going through all the formal questions, informal discussions added a lot of insightful requirements to the data warehouse. For example, one department head supported the data warehouse wholeheartedly because it can level the information grounds for all decision makers. That department head had the concern of being unable to access data directly and carry out analyses. Since data can be manipulated and presented in a certain way to support a certain proposition, having access to the same data allows other decision makers to verify the analyses or to present alternative analysis results. The same organizational truth from a data warehouse can streamline the data collection process and avoid locally optimized decisions. The above concern makes it important to allow decision makers to build their customized reports, in addition to pre-defined system reports for general purposes. The information collection process for the CBA data warehouse has been benefited from both the formal and informal channels.

## 5.3 Data warehouse and data mart architecture

The information collection process identified three major subjects for data warehouses, namely, faculty, students, and alumni. For each subject, there are various decision making activities to support. The subject faculty was determined to have the highest priority for implementation. The development strategy is to launch one data mart with high visibility and return as soon as possible, in order to generate confidence from end-users and top management. However, the conceptual blueprint for the enterprise data warehouse will be finished before the first data mart implementation. This is to ensure that the design of each data mart can be consolidated together into the enterprise data warehouse. Individual data marts need to have the suitable conformed dimensions serving as the overlapping tables across different fact tables. Though conformed dimensions can be added later, it will be less disruptive to the warehouse operations if they are built-in rather than added-back. The concurrent design for data warehouse and data marts can produce faster result but not at the expense of losing the overall data warehouse requirements.

## 5.4 Quantitative and qualitative (QQ) data schema

Figure 2 presents a partial QQ data schema for the faculty subject data mart for the CBA data warehouse.

The center of the data schema has two fact tables, one for numbers and the other for text, which are essential information to keep track of for faculty. Surrounding the fact tables are dimension tables including faculty, publication/professional organization, and time. The attribute *CategoryID* representing the classification of each record i.e., instructional development, applied scholarship, basic scholarship, or consulting activities in the Qualitative Fact Table. The relationship cardinality between the two fact tables is (0,\*) and (1,\*) meaning that one record from the qualitative table is associated with 1 or many records from the quantitative table; and one record from the quantitative table is associated with 0 or many records from the qualitative table. The QQ data schema is proposed in this project to support the storage and manipulation of both quantitative and qualitative measures.

## 6. Conclusion

This study proposes a bi-directional approach for data warehouse development in public sectors. The approach focuses on the stages of initiative, information requirement, architecture design, and data modeling for the development process. The initiative stage combines the top-down and bottom-up directions. The information requirement utilizes both formal and informal channels. The architecture design adopts both enterprise data warehouse and subject data marts. The data modeling extends the star schema to capture both qualitative and quantitative measures for organizations that are not purely profit-driven. The bi-directional approach was illustrated using a case study in the College of Business Administration at the California State University, Sacramento. The data warehouse at CBA has been benefited from the bi-directional approach. The data warehouse project is on-going and we expect to expand and fine-tune the bi-directional approach as more experience is accumulated in the future.

## Abstract

Query optimization in OLAP applications is a novel problem. A lot of research was introduced in the area of optimizing query performance, however great deal of research focused on OLTP applications rather than OLAP. In order to reach the output results OLAP queries extensively asks the database, inefficient processing of those queries will have its negative impact on the performance and may make the results useless. Techniques for optimizing queries include memory caching, indexing, hardware solutions, and physical database storage. Oracle and MS SQL Server both offer OLAP optimization techniques, the paper will review both packages' approaches and then proposes a query optimization strategy for OLAP applications. The proposed strategy is based on use of the following four ingredients: 1- intermediate queries; 2- indexes both B-Trees and Bitmaps; 3- memory cache (for the syntax of the query) and secondary storage cache (for the result data set); and 4- the physical database storage (i.e. binary storage model) accompanied by its hardware solution.

**Keywords:** query optimization, OLAP, caching, indexing, MS SQL Server, Oracle.

## 1. Introduction to query optimization

Query Optimization (QO) is a process the success of which affects the entire database (DB) performance [15]. There are basically two types of DB:

1. Archival DB e.g. data warehouse (DW) that is primarily used for query retrievals;
2. Transactional DB e.g. Online Transaction Processing (OLTP) that is primarily used for data maintenance i.e. insert, update, and delete operations.

Efficient QO strategy is a major task in the archival DB types. When a DBMS parses a query it decides the best plan (i.e. strategy) to execute it based on statistics it retains about DB structure, indexes, and number of distinct values. Query optimizer is that part of DBMS that decides which query plan is the best [15]. Relational systems offer the users access to data via high-level

language and it's the responsibility of the system to select efficient plans to execute queries called query evaluation plans (qeps) [6].

## 2. Query optimization mechanisms

There are many query optimization mechanisms. The mechanisms fall into two main categories: hardware (H/W) and software (S/W). *Following is a description of both:*

### 1. The H/W mechanisms:

Currently DB servers make extensive use of multiple processors. DB servers use symmetric multi-processor (SMP) or massive parallel processor (MPP) technology [20]. Some database Management Systems (DBMS) make use of these technologies. DBMS break down a query into parts and process them in parallel by different processors. The most common approach for that is by replicating the query so each copy works against portion of the DB which is usually horizontally partitioned [15] [20]. The same query is to run on each portion in parallel in a separate processor then intermediate results are combined to create the final query set as if the query was running once on the entire DB. A study by [20] reported that the query time was cut by 50% by using parallel processing compared to a table scan ( $T = TW/P$ ; where T is time, TW is table scan time, and P number of processors). The same study [20] indicated that creating an index using parallel processing was reduced to 5 seconds from nearly 7 minutes.

### 2. The S/W mechanisms:

Indexing the DB is one of the best and cheapest methods for improving performance. An index is a data structure that represents a column stored in a certain order [7]. DB optimizers scan the appropriate index to identify any target rows faster than scanning the entire table. If the table is indexed, a binary search for files is carried out on the blocks rather than on the records. A binary search usually accesses  $\log_2(b)$  blocks which is considered an improvement over linear search that is on average accesses  $(b/2)$  blocks when found or b blocks if not found [9]. Caching and physical storage are other two

mechanisms through which queries could be optimized [5] [11] [23].

### 3. Foundations and assumptions

A DB consists of a number of relations. A relation  $R$  contains attributes  $att_1, att_2, \dots, att_n$ .  $R$  is a subset of the Cartesian product  $dom(att_1) \times dom(att_2) \times \dots \times dom(att_n)$ , where  $dom(att_j)$  is a set of values for  $att_j$ . A tuple  $t$  is an ordered list of attribute values which has an associated unique identifier ( $t\_id$ ). An expression  $e$  is used to derive relations and is defined as a group of predicates on some attributes [5]. The length of an expression is the number of attributes involved in the expression. Expressions of length equals 1 are called elementary expressions. For example, an expression of length 2 is like the following:

$\langle price \in [100,200] \wedge type = 'local' \rangle$

An expression  $e_{sub}$  is a sub expression of  $e$  if each elementary expression of  $e_{sub}$  is included in  $e$  and  $length(e) > length(e_{sub})$ . An expression  $e'$  is an extension of  $e$  if  $e$  is a sub expression of  $e'$  and  $length(e') - length(e) = 1$ . An expression  $e'$  is a reduction of  $e$  if  $e'$  is a sub expression of  $e$  and  $length(e) - length(e') = 1$ . An expression  $e'$  is a neighbor of  $e$  if  $e'$  is an extension of  $e$  or  $e'$  is a reduction of  $e$ . A generalization enlarges the range of an elementary expression, whilst a specialization reduces the range of an elementary expression [5].

### 4. Previous work and the research gap

[1] Introduced their query optimization mediator system on which they made no difference between OLTP and OLAP applications. Their contribution resulted in a caching mechanism that allows use of query results of previous queries in case the source is not readily available.

[5] Implemented a framework for query optimization to support data mining applications. The framework proposed concentrated on two main factors; search strategies (hill climber, simulated annealing, and genetic algorithms), and physical DB design.

[6] Proposed a framework for processing a sequence of interdependent queries for which a multi-query optimization is required. Their optimization plan includes: determining on the basis of the dependencies between queries which order they should be specified and which results should we store, then each query is passed separately to the DB optimizer.

[11] Suggested a generalized projections (GP) query optimization technique. GP captures aggregations, group by, projections with duplicate elimination, and duplicate preserving projections. The GP pushes down query trees for select-project-join queries which use any aggregate function. The pushing down technique will result in the removal of tuples and attributes early and consequently

leading to smaller intermediate relations and reducing the query cost.

[23] Focused on optimizing selection queries using Bitmaps. For static query optimization, divide the selection into continuous and discrete ones and suggested algorithms for evaluating discrete selections using bit-sliced indexes including time and space constraints.

Reviewing the previous research work-up to our knowledge- indicates that no efforts have been exerted to introduce QO strategy for OLAP applications. The main contribution of this paper is in proposing a novel QO strategy which will focus mainly on supporting OLAP applications.

### 5. On Line Analytical Processing (OLAP)

Although relational database management systems (RDBMS) are powerful solutions for a wide range of commercial and scientific applications, they are not designed to address the multidimensional information requirements of the modern business analyst, for example forecasting, and classification [3].

The key driver for the development of OLAP is to enable the multi-dimensional analysis [19]. Although all the required information can be formulated using relational database and accessed via SQL, the two dimensional relational model of data and SQL have some serious limitations for investigating complex real world problems. Also slow response time and SQL functionality are a source of problems [3]. OLAP is a continuous and iterative process; an analyst can drill down to see much more details and then he can obtain answers to complex questions.

OLAP represents the use of a set of graphical tools that provides users with multidimensional views of their data and permits them to analyze the data by utilizing simple windowing techniques [15]. OLAP refers to DSS and EIS computing applications [22].

Whilst multidimensionality is the core of a number of OLAP systems available [19], there is a list of elements that determine which OLAP product to purchase:

1. *Multidimensional conceptual view*. The tool must support users with the level of dimensionality needed to enable the required analysis to be carried out;
2. *Transparency*. The heterogeneity of input data sources should be transparent to the users to prevent their productivity decreasing;
3. *Accessibility*. The OLAP system should only access the data required for analysis;
4. *Consistent reporting performance*. As the number of dimensions increases and the database size grows, users will expect the same level of performance;
5. *Client/Server architecture*. The OLAP system has to be compatible with the client/server architectural principles;

6. *Generic dimensionality*. Every data dimension should be in both its structure and operational capabilities;
7. *Multi-user support*. The OLAP system must be able to support a multi-user environment;
8. *Flexible reporting*. The ability to arrange rows, columns, and cells in a way that facilitates visual analysis.

Decision makers should prioritize the previous list elements to reflect their business needs.

Several researchers have stated that OLAP is an independent technique and is as powerful as the data mining process and techniques [2] [10] [13]. [19] stated that in every data mining application the analyst should expect to find some relationships between the variables that describe the data set. These expected relationships need confirmation and any OLAP tool can work well in either confirming or denying these relationships. Because of this, OLAP is one of the data mining techniques applied in the early stages of the data mining process. However, unlike other data mining techniques, OLAP does not learn and hence can not search for new solutions [17] [2].

OLAP involves several basic analytical operations including consolidation, drill-down and statistical techniques [17]:

1. *Consolidation*. Consolidation involves the aggregation of data, e.g. the total number of students at the university, total courses, and average GPA;
2. *Drill-down*. This is the opposite of consolidation and involves more detailed inspection of the underlying data, e.g. the break down of the total number of students into different nationalities that belong to the different majors with different GPA. Drill-down is like adding another attribute to the original report/query [15];
3. *Slicing and dicing*. Slicing and dicing refers to the ability to look at the database from different viewpoints.

## 6. Query optimization techniques in OLAP applications

QO for OLAP applications differ from optimizing queries for OLTP applications in the following areas:

1. OLAP applications are based on data warehouse which is used for READ type transactions;
2. OLAP applications are characterized by complex queries;
3. In OLTP voluminous data are processed as soon as entered;
4. OLAP users are managers and analysts whereas OLTP users are clerks, professionals (non-managers);
5. OLAP activities are generating queries, ad hoc reports, and statistical reports;
6. OLTP are always equipped with SQL, whilst OLAP front-ends include: DSS, visualization techniques, and/or data mining techniques [22]. Data mining

refers to the process of nontrivial extraction of knowledge and discovery of previously unknown information patterns.

Because of the pre-stated reasons this paper is focused on designing strategy for optimizing queries running in OLAP environments. Oracle approach is introduced followed by MS SQL Server approach, and then the details of our suggested approach.

### 6.1 ORACLE approach

Oracle DBMS make use of MPP. Assume that a SALES relation has many records; therefore query processing on that relation will be so slow. To make sure that table scans are executed in parallel using 5 processors:

```
ALTER TABLE SALES PARALLEL 5;
```

Another parallel scanning option happens during query definition.

```
SELECT /*+ FULL (SALES) PARALLEL (SALES, 5)
*/ COUNT (*)
FROM SALES
WHERE SALESPERSON = 'ALY';
```

The /\* \*/ indicate hint to Oracle which overrides any query plan suggested by the optimizer.

In Oracle adjacent secondary memory space may contain records from various tables with different record structures [15]. Records from two or more joined relations may be stored on the same area on disk by declaring a cluster which is identified by the attribute by which the relations are already joined. Clustering reduces the time required to access related records compared to the normal allocation on various scattered areas on disk. Example is the following:

```
CREATE CLUSTER SALE (CLUSTERKEY
(CHAR(10)));
```

```
CREATE TABLE PRODUCT_TYPE (ID NUMBER
UNIQUE NOT NULL, DESC CHAR(20), NAME
VARCHAR(25), CONSTRAINT PK_PROD
PRIMARY KEY(ID)) CLUSTER SALE (ID);
```

```
CREATE TABLE PRODUCT (CODE NUMBER
UNIQUE NOT NULL, LOCATION CHAR(20), ID
NUMBER, CONSTRAINT PK_PROD PRIMARY
KEY(ID), CONSTRAINT FK_PROD_T FOREIGN
KEY (ID) REFERENCES PRODUCT_TYPE (ID))
CLUSTER SALE (ID);
```

Accessing records from the cluster is done via an index on the cluster key. Clustering records is utilized if records are static; if frequent data maintenance occurs clusters create waste space.

An index is a like the structure of a tree that permits direct access to data records in tables [18]. In Oracle indexes are classified by their logical and physical

implementation. From the logical implementation point of view there are:

1. *Single column index* that has only one attribute in the index;
2. *Concatenated columns index* that has composite columns in the index up to 32 or combined size does not exceed 1/3 of Oracle data block size;
3. *Unique index* that guarantees no two rows will have duplicate values;
4. *Nonunique index* on which multiple rows exist for the same value.

From the physical implementation point of view there are:

1. *Partitioned index* is utilized with large table to keep the index entries in several segments which improves scalability and manageability. Partitioned index is used with partitioned tables one for each partition [18];
2. *Nonpartitioned index*;
3. *B-Tree* or balanced tree, on top of which there is the root of the index that has entries which point to the next level of an index. Next level is a branch blocks which also point to the blocks at the next level. Finally, leaf level includes index entries that refer to rows in tables. Oracle also allows the use of reverse key index with B-Tree index structure [18]. A reverse index reverses the bytes of each indexed column whilst retaining the column order. Reverse index is useful for queries which have equality predicates but they never work with range queries.
4. *Bitmap index* is a table of bits such that a row represents the distinct values of a key and each column is a bit which if on implies that the record for that bit column has the associated value [15]. The bitmap index is also organized as a tree but the leaf node stores bitmaps for each value instead of a list of ROWID's in B-Tree. Oracle recommends the utilization of a bitmap index over B-tree in the following cases:
  - a. For attributes with low cardinality;
  - b. The WHERE clause include OR operators;
  - c. Read-Only of low activity attributes.

**Table (1): Bitmap index**

Row ID	Value	B <sub>7</sub>	B <sub>6</sub>	B <sub>5</sub>	B <sub>4</sub>	B <sub>3</sub>	B <sub>2</sub>
1	3	0	0	0	0	1	0
2	4	0	0	0	1	0	0
3	5	0	0	1	0	0	0
4	4	0	0	0	1	0	0
5	6	0	1	0	0	0	0
6	7	1	0	0	0	0	0
7	3	0	0	0	0	1	0
8	2	0	0	0	0	0	1
9	6	0	1	0	0	0	0
10	5	0	0	1	0	0	0

In a very simple form, bitmap index of an attribute is one vector of bits per attribute value, where the size of each bitmap is equal to the cardinality of the indexed

relation. Bitmaps are encoded such that the  $i^{th}$  record of  $v$  value in an indexed attribute iff the  $i^{th}$  bit in the bitmap associated with the attribute value  $v$  is set to 1 and the  $i^{th}$  bit for the other bitmaps are set to 0 [4]. Table 1 provides an example.

Bitmap indexes have been implemented in many DBMS including Oracle, Sybase, and Informix. A major advantage of bitmap index is that bitmap manipulations uses bit-wise operators (AND, OR, XOR, NOT) are efficiently supported by hardware.

Oracle depends on two QO approaches: *rule-based*, and *cost-based* [12]. The rule-based optimizer ranks the qeps by ranking their possible different paths according to the speed of executing each path. It ignores the table size and the distribution of data. This means that the rule based optimizer will always choose to use an index on a small table even though table scan could be more efficient.

The cost-based optimizer depends on the available access paths and statistics stored in the data dictionary e.g. number of rows and cardinality of a table to decide which access path is of least cost. The following statement analyzes the relation student, views could also be analyzed.

```
ANALYZE TABLE STUDENT COMPUTE STATISTICS;
```

Use of the analyze command is done whenever changes made to the DB to ensure that the DB optimizer depends on the most updated contents. Oracle recommends running the ANALYZE command after each data load, and before creating summary table in data warehouses [12].

Join is also optimized in Oracle by choosing the best method for doing the join. A join operation combines tuples from two or more relations based on common attributes (i.e. join condition). The Oracle QO chooses the best join method of the following (sort-merge join, nested loop join, hash join, partition wise join) for more details on join methods refer to [9] [12]. For star queries, each dimension is joined to the fact using the primary key-foreign key relationships. Oracle QO uses bitmap index to retrieve rows from the fact then the result is then join to the dimension tables, instead of computing the Cartesian product of the dimensions. Oracle recommends creating a bitmap index on every attribute on the fact table [12].

## 6.2 MS-SQL Server approach

SQL server 2000 uses memory for its stored procedures, ad hoc and prepared Transact-SQL statements, and triggers. The most significant limitation to SQL server is disk I/O; however, utilizing memory will maximize the advantages of caching and minimize memory swapping.

Memory and lock management are both managed by SQL server not the DB administrator (DBA), the server allocates buffers from the available system memory and releases them when not required [7]. This is also true for the locks, SQL server allocates and releases locks based on the activity level and the expected usage queries will make of the data.

MS SQL supports two index types; clustered and nonclustered to enhance the fast return of result sets [16]. Without indexes a query forces SQL Server to scan the entire table to find matches. A DB index contains one or more column values from tables and pointers to the corresponding record. When performing a query QO uses an index to locate matching records. MS SQL server uses B-Tree structures to store both index types. Microsoft recommends creating index on columns that are frequently used in queries. For instance, query optimizer will use reg\_no index to process the following query:  
 SELECT \* FROM STUDENT WHERE REG\_NO = 1000;

Creating index on every column in the DB tables will negatively affect performance [16]. Insert, Update, or Delete transactions will trigger the index manager to update the table indexes.

Clustered index contains table records in the leaf node of the B-Tree structure. There is only one clustered index per table. When creating PK constraint in a table without clustered index, SQL Server creates clustered index on the PK column, if a clustered index already exist a nonclustered index is created. An attribute defined as unique automatically creates nonclustered index. On most situations, clustered indexes are created before nonclustered. Index information is obtained by the following statement:

```
SP_HELPINDEX STUDENT
```

Following is a create index example in MS SQL Server:

```
CREATE UNIQUE CLUSTERED INDEX INDEX_1
ON STUDENT(NAME, GPA DESC)
WITH FILLFACTOR = 60
```

The fill factor sets up the index so that the leaf node index pages are 40% full, leaving 60% space to include additional key entries.

If a clustered index exists (on table or view) any nonclustered index on the same object uses it as their index key [16]. Dropping a clustered index by the DROP INDEX causes all nonclustered to be rebuilt so they use RID as a bookmark. In case the clustered index is re-created using CREATE INDEX all nonclustered indexes are rebuilt to refer to the clustered index rather than RID.

```
DBCC DBREINDEX (STUDENT, REG_NO, 60)
```

### 6.3 MS® SQL Server™ data retrieval policy

SQL Server language is able to filter data at the server so that only the minimum data required is returned to clients which will minimize expensive Client/Server network traffic.

This means that WHERE clauses must be restrictive enough to retrieve only the data that is required by the application. It is always more efficient to filter data at the server than to send it to the client and filter it in the application (this applies to columns). An application issues SELECT \* FROM... statement which requires the server to return all column data to the client, whether or not the client application has bound these columns for use in program variables. Selecting only the necessary columns by name avoids high network traffic.

This also makes your application more robust in the event of table definition changes, because newly added columns are not returned to the client application. Moreover, performance depends on how the application requests a result set from the server. An application based on Open Database Connectivity (ODBC), statement options set prior to executing a query to determine how the application requests a data set from the server. By default, MS® SQL Server™ 2000 sends the data set the most efficient way.

MS SQL Server assumes that an application will fetch all rows from a default result set immediately. Therefore, an application must buffer any rows that are not used immediately but could be needed later. This buffering requirement makes it necessary for you to specify (using Transact-SQL) only the data needed.

Query analyzer is a graphical tool in SQL Server that provides information about queries in nodes; each node represents a step in the query to execute [8]. For instance, a SELECT statement shows the following information:

- a. Estimated number of rows returned by the statement;
- b. Estimated size of rows;
- c. Estimated I/O cost;
- d. Estimated CPU cost;
- e. The number of times the statement was executed during running the query.

### 6.4 Comparative techniques: ORACLE versus MS-SQL

The following table (20) <sup>1</sup> summarizes the differences between Oracle and MS SQL with regard to QO.

---

<sup>1</sup> Adapted from [21].

**Table (2): Oracle vs. MS SQL Server**

Feature	Oracle	MS SQL
Indexing options	B-Tree and Bitmap index structures Reverse key index	B-Tree only
Partitioning	Range, Hash, List and composite partitioning	Cube partitioning DB partitioning and file groups
Self-tuning	Self-tuning memory, free space, I/O management	Memory management, lock management
Smart advisors	Memory wizard MTTR advisor Summary advisor Virtual index advisor	Cube wizard Query analyzer
Others	Star Schema	Star Schema and Snowflake designs

It is not the intension of this paper to say which of the Servers (i.e. Oracle and MS SQL) outperforms the other, instead to review the QO approaches in both Servers and introduce an integrated suggested approach QO approach for OLAP applications. However, reviewing both servers' mechanisms is useful for people who intent to develop OLAP applications and are not aware of the details of QO supported by each server.

## 7. Suggested QO approach for OLAP applications

Our QO suggested approach for OLAP applications includes:

- The use of intermediate queries. The following procedure is proposed:
  - As a new query ( $q_n$ ) is processed, it is compared to the previous queries in cache;
  - If there is no attribute intersection between  $q_n$  and the previous queries then  $q_n$  is processed from scratch;
  - If there is intersection between  $q_n$  and a previous query  $q_m$  then:
    - If same operator exist:
      - § E.g.  $q_n : AGE > 10, q_m : AGE > 20$ . Then finding tuples that satisfy AGE between 11 and 20 then the result Union  $AGE > 20$  from cache.
      - § E.g.  $q_n : AGE > 20, q_m : AGE > 10$ . Then finding tuples that satisfy AGE greater than 20 as a subset of cache.
    - If different operators:
      - § E.g.  $q_n : AGE > 10, q_m : AGE < 15$ . Then find the intersection between the two queries (i.e. 11, 12, 13, 14) from cache, then find tuples that satisfy  $AGE \geq 15$  and Union them.

- The use of indexes both B-Trees and Bitmap where relevant. Following is a B tree versus Bitmap comparison which helps determines when to use each of which:

**Table (3): B -tree vs Bitmap [Adapted from [18]]**

B-tree	Bitmap
High cardinality attributes	Low cardinality attributes
Inexpensive updates	Expensive
Inefficient for OR queries	Efficient for OR queries
OLTP	OLAP

- The use of memory cache (for the syntax of the query), and secondary storage cache (for the result data set).
  - Physical DB storage and its hardware solution.
- Points 3, and 4 of the suggested QO approach are explained in the following sections.

### 7.1 Pointer-based Binary Storage Model “BSM”

The idea of the binary storage model is to store each attribute with a unique location identifier in a separate table. In [5] if a non-elementary expression is processed each attribute is accessed with its physical address. We propose a modified Binary storage model called Pointer-Based binary storage model. In this model we have to specify the origin table “Table that contains the primary key” This table contains the primary key and a number of pointers equal to  $n-1$  where  $n$  is the number of columns in the virtual table including the primary key. The following example shows the proposed modeling technique.

*Example.* Consider the following student relation (i.e. table):

**Table (4): Student table**

Student ID	Student Name	Student GPA	Student AGE
91131911	Ahmed	2.5	25
95176112	Yehia	2.97	24
98117611	Mohamed	3.68	26
99876511	Ali	3.92	21

We name the last shown table structure ‘*virtual table structure*’ as it is stored in a different way than it appears to the user.

### 7.2 Physical Structure :

Each column will be stored in a table with a pointer that points to the original location.

Student Column

**Table (5): Physical structure**

Physical Location	Student ID Physical Location	Student Name
3000	1101	Ahmed
3001	1305	Ali
3002	2107	Mohamed
3003	908	Yehia

GPA column

**Table (6): Physical structure-1**

Physical Location	Student ID Physical Location	GPA
4000	1305	2.5
4001	2107	2.97
4002	1101	3.68
4003	908	3.92

AGE column

**Table (7): Physical structure-2**

Physical Location	Student ID Physical Location	AGE
5000	1305	21
5001	2107	26
5002	1101	25
5003	908	24

Student Original Table

**Table (8): Student Original table**

Physical Location	Student ID	Name Physical Location	Age Physical Location	GPA Physical Location
908	91131911	3003	5003	4003
1101	99876511	3000	5002	4002
1305	98117611	3001	5000	4000
2107	95176112	3002	5001	4001

Suppose that we want to execute the following query:  
SELECT \* FROM STUDENT WHERE GPA > 2.5

In this case we will search in the GPA table which is sorted, so binary search will be suitable to be applied. After determining the set of tuples that match the selection criterion data tuples are retrieved from the origin table that are stored in physical locations similar to those stored in the pointer attribute.

After determining those tuples data is retrieved from the rest of tables as shown:

**Table (9): Results**

Student ID	Physical Location	GPA
2107		2.97
1101		3.68
908		3.92

Then data exist in physical locations are retrieved from Original table.

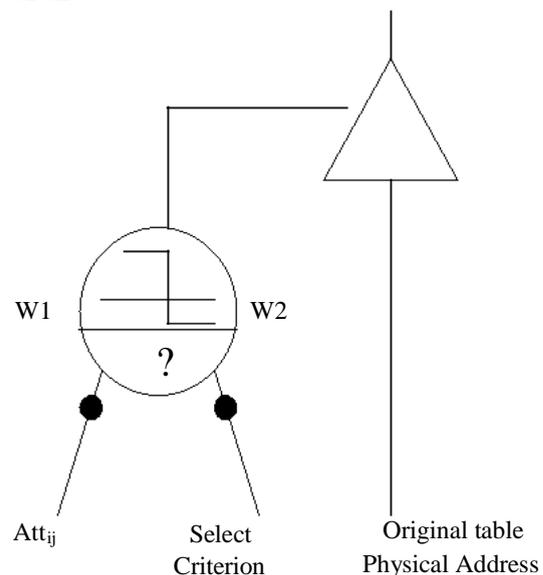

**Table (10): Source table**

Physical Location	Student ID	Name Physical Location	Age Physical Location	GPA Physical Location
908	91131911	3003	5003	4003
1101	99876511	3000	5002	4002
2107	95176112	3002	5001	4001

And then data is retrieved from the locations appear in table.

The above algorithm seems to have considerable cost. In fact this is not true because this pointer point to the physical location so there is no search after retrieving the original table selected rows.

### 7.3 Proposed H/W architecture to speed up search

**Figure (1): Suggested H/W architecture**

The previous Architecture works as follows:

The Att<sub>ij</sub> is feed to the network with the selected criteria, if the where operator is > then W1,W2 equal -1,1 respectively. if the where operator is < then W1,W2 equal 1,-1 respectively. If it is equal then both assumptions are valid.

The activation function is the inverse of the bipolar function. It is defined by:

$$f(x) = \begin{cases} 1 & \text{if } x > 0 \\ 0 & \text{if } x \leq 0 \end{cases} \quad (1)$$

The output of the neuron is feed to a tri-State device in order to either output zero and that means there is no match or outputs the physical address in case of match.

Note that VLSI (very large scale integrated circuits) technology allows the integration of huge number of replicates of this architecture in one chip. And so parallel processing for the query is achievable.

*Assumptions and constraints:*

1. For the technique to be efficient, each table has to be sorted in order to achieve efficient data retrieval “binary search”. Note that we don’t need to use B-tree algorithm as it is too costly for a sorted table.
2. Each group of tables constituting a virtual table must be stored in the same cluster in order to speed up the operation.

## 7.4 Query Result Cashing

Query caching process is divided into two sub tasks “memory cash and secondary storage cash”. We cash the query semantics and its native language transformation into memory whilst the results of the query are cashed in secondary storage i.e. hard-disk.

Since the storage media is limited in space, it is required to develop a replacement technique in order to replace existing queries by newer ones. In this paper we offer a priority-based technique that is based on the following mathematical equation:

$$Q_{IP} = B(Q_i) + H(Q_i)$$

Where  $Q_{IP}$  is the priority of the query number  $I$ . Whenever a new query is executed, it is cashed on disk and it is given a starting value  $B(Q_i)$  where  $B(Q_i)$  is a function that retrieves the base value of the priority and it is calculated as follows:

$$B(Q_i) = \frac{1}{n} \text{Avg}(Query\ Pr\ iorities)$$

and  $H(Q_i)$  is a function that represents the Query Hit Ratio which initially equals 0. Query Hit Ratio is the number of times this query has been used to answer another query.

Note that we formulated  $Q_{IP}$  to include  $B(Q_i)$  in order to give a fair chance for new queries to remain cashed. That is why we do not consider  $B(Q_i)$  a part of the Exact  $Q_{IP}$  Value so each time a new query is cashed the function  $B(Q_i)$  is decremented by 1 for all queries until it reaches 0. Note That If  $Q_2$  is a specification to  $Q_1$  and  $Q_1$  is cashed then  $Q_2$  is not cashed.

Cash Modification:

Any cashed Query that can be considered as an extension of any other cashed query must be removed.

## 8. Conclusion

- o Indexes, memory caches, portioning, clustering, hardware solutions (e.g. parallel processing) are all mechanisms to optimize query performance;
- o Query optimization for OLTP applications is different from QO for OLAP applications;

- o Bitmaps are common indexes for OLAP applications;
- o Both MS SQL and Oracle Servers support optimize queries differently;
- o A suggested QO strategy for OLAP applications should include the following components:
  - o Intermediate queries;
  - o Indexes both B-Trees and Bitmaps;
  - o Memory cache (for the syntax of the query) and secondary storage cache (for the result data set);
  - o The physical database storage (i.e. binary storage model) accompanied by its hardware solution.

## 9. Future work

- o Implementing the suggested QO approach for OLAP applications in ORACLE. *The reasons for which we did not implement our suggested approach in a case study are the following:*
  - o It is very hard to communicate with the DBMS’ query optimizers;
  - o Some DBMS (e.g. MS SQL) do not support some of the suggested techniques like bitmap indexes;
  - o It is costly to implement the suggested hardware (H/W) solution using VLSI (very large scale integrated circuits). But this does not mean that the H/W solution is infeasible, it is feasible for large organizations who store millions of records;
  - o Dumping the cached queries from memory and secondary storage requires adding new module to the existing DBMS.
- o Handling sub queries by using heuristics to determine which intermediate queries to retain.

# User-Based Web Recommendation System: A Case study of the National Museum of History

Kwoting Fang, Jonen Liu  
Department of Information Management  
National Yunlin University Science of Technology  
Yunlin, Taiwan  
jonen@ms19.hinet.net>

## Abstract

With the explosion and the rapidly growing market of the Internet, it is imperative that managers re-think to using technology, especially internet, to deliver services faster, cheaper, and with better quality than their competitors do. The web site provides a communication way that reveals real-time assess data and fruitful information of customers. Therefore, the call for customer with personalized web pages has become loud. To achieve personalized web pages, this study proposes recommendation algorithm of user behavior oriented by using the web log files from National Museum of History. Keywords: Web usage mining, recommendation system, Fuzzy C-means.

## 1. Introduction

The largest web sites are offering an increasing amount of information. However, the World Wide Web is a Computer-Mediated Environment [9] in which uses the hyperlinks to connect related content. Since the hyperlink is a non-linear structure [5][16], most of users waste much time in retrieving information that they do not want and thus result in reducing the number of times web sites are revisited.

Therefore, a web site manager not only need to offer complete information for visitors, users' access behavior also need to be analyzed for increasing competitive advantages. Accordingly, personalized recommendation system is an important issue to provide one-to-one guidance to the users [17] and it's become more and more important for information provider or electronic commerce.

There are two major approaches to provide personalized recommendation: content based approach and collaborative technique approach. In former, it recommends items that are similar to what the user has liked in the past [11]; in collaborative technique approach, it defines other users that have showed similar preference to the given users and recommends what they have liked [19]. [6][15][19] have proposed the earliest and the most successful collaborative recommendation technologies.

Although most of researchers have addressed the development of recommendation systems to share information among interested parties[3][4][11][21][22], there are few researches for applying on actual web page and product recommendations. Accordingly, this study proposed a user-based recommendation system.

## 2. Related Work

Data mining is the process of extracting unknown but useful information from a very large database in order to enable a manager to make a decision [2]. An increasing number of enterprises are trying to understand customer behavior and provide a quality service to increase their competitive advantages using data mining technology. Accompany with the growth of the Internet has resulted in the development of web mining. Web mining extracts the information from an unlabeled and semi-structured dataset. A web site manger can use mining to elucidate and analyze user behavior to set a marketing strategy.

Until now, [4] addresses separated web mining applications into web content mining and web usage mining. In former is based on content, hyperlinks, structure, keywords, and so on, a search engine is an example; the other is based on a web log, user preference, register, clickstream, and so on, in which users access pattern are recorded.

Data that support to web mining are usually stored in a web log which file exists on web server that interacts with the user and the web server [18][15][4]. However, when they were be used, preprocessed at first is necessary. [14] divided the preprocessed procedure into five steps: fire step is data cleaning, followed by how to define user session, web page, completely access pattern and storing.

There are two major approaches to provide personalized recommendation: content based approach and collaborative technique approach. In former, it recommends items that are similar to what the user has liked in the past [11].

Content-based method using the user access pattern or previously purchased products to compute the relevance of other page items or products. Most researchers in this area were use distance to represent the relevance of similarity among page items. The NewsWeeder system is an example [11]; Collaborative technique approach is that products or page items are ranked according to a user's preference then similarities among users are determined. When a customer enters a store, the system refers to the user's preference to find similar users and recommends products or page items in which the new user may have an interest, but which he or she has never bought, GroupLens is an example [8]. These methods depend on users' purchase experience, a user must input preferences among items and specify related items.

Furthermore, [15][18][21] also considered the clustering of users with similar access patterns, using clustering to predict another user's behavior. [15] developed robust fuzzy clustering, applied it to web mining, who used the leader algorithm proposed by [7] to cluster the similar user sessions and thus identify users with similar interests or browsing paths. [21] applied clustering approach to user access patterns, and used a method of web page recommendation developed by WebWatcher [1] and Litzia [12].

### 3. Research Method and Architecture

The study proposes a web page recommendation system. This system with two phases -- offline module and online module. The offline module prepares and preprocesses data and mines usage; the online module is involved with online recommendation and evaluates the accuracy of recommendation.

#### 3.1 Preparing and Preprocessing Data

The original web log used in the experimented was generated from httpd server. The preprocessing includes three parts – cleaning data, identifying user sessions and determining usage behavior. In order to clear the web log, .gif, .jpeg and .cgi et al., but not .html are removed.

#### 3.2 Identifying a user

Identifying a user directly from a web log is difficult. The method of identification used in this paper is to set the 30 min timeout and suppose that an IP represents a single user, to determine the order in which page are browsed.

#### 3.3 User Usage Mining

This paper considers web usage information obtained using the tool WebTrend, developed by Software Inc. Then, Fuzzy C-means clustering is to group users with similar access patterns. Accordingly similarities among users can be computed and related page items recommended to another user. The method of user-based recommendation is collaborative clustering users with similar access behavior. Common characteristics are extracted for sharing. The key steps are as follows:

First, a set of n unique URL is assumed as a vector:

$$\vec{D} = \{url_1, url_2, \dots, url_n\} \quad (1)$$

Next, a user session S is expressed as a bit vector.

$$\vec{s} = \{url_1^s, url_2^s, \dots, url_n^s\}, url_i^s = \begin{cases} 1, & \text{if } url_i \in s \\ 0, & \text{otherwise} \end{cases} \quad (2)$$

Only the click numbers are considered, so the importance of the page cannot be determined. The method is refined using the view number.

$$url_i^s = \begin{cases} \text{count}, & \text{if } url_i \in s, \text{count} ++, \text{initial count} = 0 \\ 0, & \text{otherwise} \end{cases} \quad (3)$$

Then, Fuzzy C-means clustering is used to determine the common characteristics of user behavior on which to base a recommendation. Before the fuzzy clustering is applied, the cosine of the angle between the two users is used to measure the similarity matrix. The element represents the similarity between users. A larger value implies greater similarity.

$$S_{xy} = \frac{\sum_{i=1}^{Nu} S_i^{(x)} S_i^{(y)}}{\sqrt{\sum_{i=1}^{Nu} (S_i^{(x)})^2} \sqrt{\sum_{i=1}^{Nu} (S_i^{(y)})^2}} \quad (4)$$

$N_u$ , the number of unique URL;  $S_i^{(x)}$ , the frequency that user x access;  $S_i^{(y)}$ , the frequency that user y access.

The number of clicks is used to evaluate the relative weighting of the pages,

$$\text{Weight}(url_i, c) = \sum_{s \in c} url_i^s \quad (5)$$

This result directly relates user behavior. The cluster to which each user belongs must be clearly determined. In this paper, the membership degrees of all clusters are compared and each user assigned to the highest.

Not all the work is included in a single phase, to ensure that the online recommendation is efficient. The work is separated into two phases – online and offline. The offline work is processed once a week. When the active user proposes a request, the online work is to trace who was browsed and give the user some feedback in which he may be interested.

#### 3.4 Recommendation Phase

Sliding windows [14] are used to display the most recent web page items in which the active user is very interested. For example, when the number of sliding windows equals 3, the active session is <A, B, C>, and once the user requests page D, the active session becomes <B, C, D>.

No absolute method governs the decision of the appropriate number of page items. In this study, the default value is set to ten. Recommending the related page items for different users. There are three key steps: First, the bit vector is  $S_A$  used to represent the active user's trace.

Next, the similarity between the active user and a group of users is computed.

$$SC_j^s = \sum_{i=1}^n (URL_i^s \times URL_i^A) \quad (6)$$

$SC_j^s$  is the score for each session that are compared with active session  $S_A$ ;

$SC_j^s$  is multiplied by the membership degree in each jth cluster. The formula is following:

$$\text{match}(C_i) = \prod_{j=1}^n (S_j^{\text{deg rec}} \times SC_j^s) \quad (7)$$

Finally,  $\max\{\text{match}(C_1), \text{match}(C_2), \dots, \text{match}(C_i)\}$ , for all  $C_i \in C$ . The result is the cluster has the highest similarity to the active user. From the  $C_i$ , the top ten web page items are recommended according to the relative weights.

### 3.5 Evaluating the Result

Recall and precision [10] are used to evaluate the accuracy of the recommendation system. These indices are generally used in information retrieval. Recording the top ten recommended pages links for each page is difficult. Therefore, only the recall value is considered in the evaluation according to the following formula.

$$\text{Recall} = \frac{\|\text{actually browse recommended page items}\|}{\|\text{actually browse}\|} \quad (8)$$

$\|\text{Knumber of web pages items}\|$

## 4. An experiment and Result

One million web log records were collected from the National Museum History from 1999/7 to 2001/11. A mirror based on the FreeBSD 4.5 platform was used to avoid influencing the original web site. Graphical records and those of clicks of about ten web page in 30 seconds were removed.

Identifying a user is difficult. The timeout was set to 30 minutes. The percentage of users who clicked less than ten pages was nearly 96%. Only the 143 user sessions of browsing of over 20 web pages were extracted.

The web site has a total of 46 web pages, six pages were clicked more than remnant (1327).

Before similar user characteristics can be clustered, the similarity between users must be computed. First, a bit vector is used to identify a user who clicks the page. Secondly, the cosine angle is used to compute the similarity to construct a 143\*143 matrix, which is clustering base. In this matrix, all the elements on the diagonal are 1.

We use Fuzzy C-means is used to cluster similar users and Compactness and Separation Validity Functional [20] are used to measure the clusters' validity.

Figure 1 presents an example of the recommendation result. Frame is used to show the recommended pages dynamically.

52 users were invited to click the web pages and 929 records were recorded. Eight users' clickstreams were under three and 12 web logs may have been created by reloading events, and were removed. Finally, 44 users will with a clickstream of 917, in which 865 were the recommendation page items, the recall value was 865/917=94.32%.

## 5. Conclusion and recommendation

To achieve personalized web pages, this study proposed recommendation algorithm of user behavior oriented by using the web log files from National Museum of History and to evaluate the algorithm according to the recall value.

Some issue and questions remain outstanding: first, obtaining web log information is difficult. Therefore, the suitability of the recommendation system for other web sites cannot be evaluated. Next, the recommendation system involves mining user behavior. In the future, content mining will be included to improve the accuracy of recommendation and fit the users' interests. Then, Scanning the databases many times increases the time taken, extends the computation period, and increases the number of users. Finally, making the algorithms efficient and determining the optimal number of clusters remains important outstanding issues.

Figure 1: The recommendation result

## An Experiment

### Abstract

Document clustering is an important tool for applications such as Web search engines. Document clustering can be defined as the process of organizing documents into groups. The groups thus formed have a high degree of association between members within the same group and a low degree of association between members of different groups. The goal of this paper is to present an experiment on one of the most widely used document clustering algorithms, namely, the agglomerative hierarchical algorithm. In our experiment, two set of graduate theses are clustered based on the key phrases assigned to each document by the author(s). Overall, the clustering results of our clustering scheme are considered to be very good.

Keywords: Document Clustering, Agglomerative Hierarchical Clustering, Complete Link, Data Mining.

### 1. Introduction

Document clustering is an important tool for applications such as Web search engines. The widely application of WEB technology has created a huge amount of web pages and the number of web pages is still increasing. According to an International Data Corporation report, the annual growth rate of storage media is more than 130%. Due to the huge amount of web pages, search engines have to be developed to help web users to search and retrieve information from the web in a timely fashion. As the number of web pages increases, the efficiency of web storage and retrieval becomes an important issue. Since the classification of web contents and the organization of web storage can have critical impacts on the retrieval performance of a search engine, some search engines, such as YAHOO, organize the web storage by means of laborious, time-consuming classification procedures. However, the accelerating influx of new web pages threatens to outpace the ability of human experts to classify the web contents. Therefore, automatic classification (also referred to as cluster analysis or clustering) methods must be developed to help alleviate this burden. Furthermore, search engines may return too many web pages for a particular key word search. Again clustering can be used to generate a category structure and enable users to have a better overview of the information contents [1].

Document clustering can be defined as the

process of organizing documents into groups. The groups thus formed have a high degree of association between members within the same group and a low degree of association between members of different groups. While clustering is often referred to as automatic classification, it is not accurate strictly since the clusters formed are not known prior to processing, but are defined by the items assigned to them [2]. Clustering is useful to provide structure in large data sets, because it is not necessary for the clusters (and often the number of clusters) to be identified prior processing. Thus, it has been described as tool of discovery and also has been an important research area in data mining [3]. There are two major styles of clustering: partitioning (often called k-clustering), in which every document is assigned to exactly one group, and hierarchical clustering, in which each group of size greater than one is in turn consisted of smaller groups [2]. Both had been studied extensively by the mid-1970's, and comparatively less clustering research in the 1980's. However, the widely application of Web technology and the large amount of data thus created have lead to a renewal of interest in clustering algorithms. The goal of this paper is to present an experiment on one of the most widely used document clustering algorithms, namely, the agglomerative hierarchical algorithm.

Clustering can be performed on documents in several ways, such as clustering documents based on the terms that they contain, clustering documents based on co-occurring citations, and clustering terms based on the documents in which they co-occur [2]. In this experiment, two set of graduate theses from Taiwan are clustered based on the key phrases assigned to each document by their author(s).

The rest of the paper is organized as follows: section 2 describes the general agglomerative hierarchical clustering algorithm, section 3 describes the detail of our experiment, section 4 presents some results of the experiment, and the conclusions are given in section 5.

### 2. The Agglomerative Hierarchical Clustering Algorithm

The agglomerative hierarchical document clustering process includes the following three steps:

- (1). Select the attributes for each document to be clustered. In principle, document clustering might involve a direct comparison of words or sentences

used in documents. However, the vocabularies of normal documents show substantial variety and the number of words or sentences included in many documents may be so large that a complete text comparison between different documents becomes impossible. Thus, it is advisable to characterize document by assigning special content descriptions, or profiles, which serve as document surrogates during cluster analysis [4]. The process of constructing identifiers as surrogates for documents is known as indexing. The choice of index terms should consider the degree that all aspects of the subject matter of a document are actually recognized and the index terms can somehow distinguish between different documents. Since indexing is rather a complex task, it was normally performed intellectually by subject experts, or by trained persons with experience in assigning content descriptions. It has been a routine for an author to assign key words for the document he/she has created. Thus, the key words assigned by the author(s) can be served as attributes for a document and used as the basis for cluster analysis.

- (2). Select an appropriate similarity measure from those available. There are a variety of distance and similarity measures, such as Simple Matching Coefficient, Dice Coefficient, Jaccard Coefficient, Overlap Coefficient, and Cosine Coefficient [5,6]. A list of the similarity measures appears in Table 1.

Table 1. The Similarity Measures and Definitions

Similarity Measures	Definitions, $\text{Sim}(D_i, D_j) =$
Simple matching coefficient	$\frac{ T_i \cap T_j }{ T_i \cup T_j }$
Dice coefficient	$\frac{2 T_i \cap T_j }{ T_i  +  T_j }$
Jaccard coefficient	$\frac{ T_i \cap T_j }{ T_i \cup T_j }$
Overlap coefficient	$\frac{ T_i \cap T_j }{\max( T_i ,  T_j )}$
Cosine	$\frac{ T_i \cap T_j }{\sqrt{ T_i  \times  T_j }}$

Where  $T_i$  is the set of terms assigned to document

$D_i$ ,  $T_j$  is the set of terms assigned to document

$D_j$ , and  $|T_i|$  is the number of elements of set  $T_i$ .

The Dice, Jaccard and cosine coefficients are three typical similarity measures, which have the attractions of simplicity and normalization and have often been used for document clustering [2]. The Jaccard is selected as the similarity measure for its simplicity in this experiment to calculate the similarity matrix for the initial data collection.

- (3). Create the clusters or cluster hierarchies. Based on the similarity matrix, the two closet clusters are combined to form a new cluster. Once new clusters are created, the similarity matrix between clusters needed to be recalculated. The clustering process is repeated until a single cluster is obtained or there are no pairs of clusters having a similarity value larger than a predefined threshold. To calculate the similarity between clusters which have two or more members, four commonly used methods, namely, single link, complete link, group average link, and Ward's method can be used [2,7]. The clustering structure resulting from a hierarchical agglomerative clustering is often display as dendrogram as shown in Figure 1.

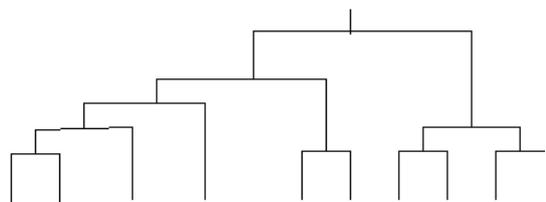

Figure 1. Dendrogram of a Hierarchical Clustering

These four methods are also called maximum distance, minimum distance, group average distance, and centroid distance respectively. Their definitions are as follows:

ò Minimum distance :

$$d_{\min}(C_i, C_j) = \min_{p \in C_i, p' \in C_j} |p - p'|$$

ò Maximum distance :

$$d_{\max}(C_i, C_j) = \max_{p \in C_i, p' \in C_j} |p - p'|$$

Mean distance :  $d_{\text{mean}}(C_i, C_j) = |m_i - m_j|$

Average distance :

$$d_{\text{avg}}(C_i, C_j) = \frac{1}{n_i n_j} \sum_{p \in C_i} \sum_{p' \in C_j} |p - p'|$$

Where  $C_i$  or  $C_j$  represents a cluster, and  $p$  and  $p'$  are points (or members) of a cluster. Among the four typical measures, the complete link method has been shown to be most effective for larger collections [8] and is used for our experiment, since the size of document collection for the experiment is fairly large.

### 3. Experimental Details

The agglomerative hierarchical clustering algorithm used in this experiment can be summarized as the following steps:

- (1). Initially assume that each document item forms a cluster.
- (2). Calculate the similarity matrix for each pair of clusters using Jaccard Coefficient.
- (3). Identify the two closest clusters and combine them in a cluster.
- (4). Recalculate the similarity matrix for the newly created clusters using complete link method.
- (5). If more than one cluster remains and there are some pairs of clusters whose similarity is greater than the threshold, which is set to 0 in our experiment, return to step (3).

The algorithm can be illustrated by example 1.

Example 1:

Step 1: Initially assume that each document item forms a cluster. Consider a document collection consists of ten documents, and the set of key phrases for the documents are  $T_1, T_2, T_3, \dots, T_{10}$  respectively.

The key phrase sets are shown in Table 2.

Table 2. The Key Phrases Assigned to Documents

Documents	Key phrases
$T_1$	K1 K2 K3 K4
$T_2$	K5 K6 K7
$T_3$	K8 K9
$T_4$	K2 K3
$T_5$	K6 K7 K10

$T_6$	K8 K11 K12
$T_7$	K9 K11
$T_8$	K3 K4 K13 K14
$T_9$	K5 K6 K15 K16
$T_{10}$	K8 K11 K17 K18 K19

Let each document forms a cluster by itself, so there are ten clusters, denoted as  $(T_1), (T_2), (T_3), \dots, (T_{10})$ .

Step 2: Calculate the similarity matrix for each pair of clusters. Using Jaccard coefficient, for example, the similarity between  $T_1$  and  $T_4$  is :

$$\text{Sim}(T_1, T_4) = \frac{|T_1 \cap T_4|}{|T_1 \cup T_4|} = \frac{| \{K2, K3\} |}{| \{K1, K2, K3, K4\} |} = \frac{2}{4} = 0.5.$$

Similarly, the similarity matrix,  $M_1$ , for the document collection can be calculated and shown in Figure 2.

$$M = \begin{matrix} & (T_1) & (T_2) & (T_3) & (T_4) & (T_5) & (T_6) & (T_7) & (T_8) & (T_9) & (T_{10}) \\ \begin{matrix} (T_1) \\ (T_2) \\ (T_3) \\ (T_4) \\ (T_5) \\ (T_6) \\ (T_7) \\ (T_8) \\ (T_9) \\ (T_{10}) \end{matrix} & \begin{bmatrix} 0 & 0 & 0.5 & 0 & 0 & 0 & 0.33 & 0 & 0 \\ 0 & - & 0 & 0 & 0.5 & 0 & 0 & 0 & 0.4 & 0 \\ 0 & 0 & - & 0 & 0 & 0.25 & 0.33 & 0 & 0 & 0.17 \\ 0.5 & 0 & 0 & - & 0 & 0 & 0 & 0.2 & 0 & 0 \\ 0 & 0.5 & 0 & 0 & - & 0 & 0 & 0 & 0.17 & 0 \\ 0 & 0 & 0.25 & 0 & 0 & - & 0.25 & 0 & 0 & 0.33 \\ 0 & 0 & 0.33 & 0 & 0 & 0.25 & - & 0 & 0 & 0.17 \\ 0.33 & 0 & 0 & 0.2 & 0 & 0 & 0 & - & 0 & 0 \\ 0 & 0.4 & 0 & 0 & 0.17 & 0 & 0 & 0 & - & 0 \\ 0 & 0 & 0.17 & 0 & 0 & 0.33 & 0.17 & 0 & 0 & - \end{bmatrix} \end{matrix}$$

Figure 2. The Similarity Matrix of  $M_1$

Step 3: Identify the two closest clusters and combine them into a cluster. In this case,  $(T_1)$  and  $(T_4)$  are combined to form a new cluster  $(T_1, T_4)$ , also  $(T_2)$  and  $(T_5)$  are combined to form another new cluster  $(T_2, T_5)$ .

Step 4: Recalculate the similarity matrix for the newly created clusters using complete link method. The similarity matrix,  $M_2$ , for newly created clusters is shown in Figure 3.

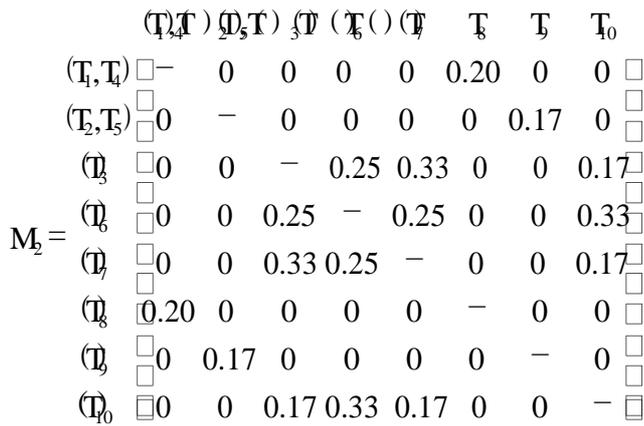

Figure 3. The Similarity Matrix of  $M_2$

Step 5: If more than one cluster remains and there are some pairs of clusters whose similarity is greater than 0, return to step 3. In this case the algorithm returns to step 3.

The process repeats until the condition stated in step 5 is not true and eventually the final similarity matrix,  $M_f$ , is created and shown in Figure 4.

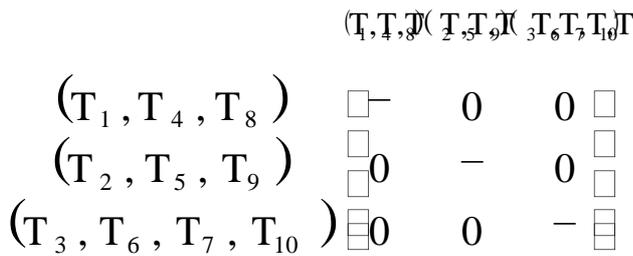

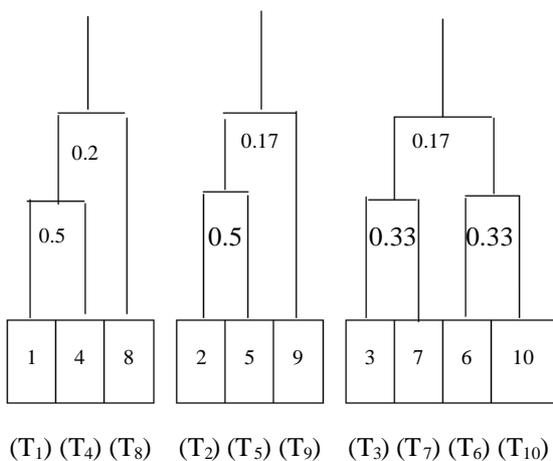

Figure 4. The Final Similarity Matrix of  $M_f$

Finally, the clusters  $(T_1, T_4, T_8)$ ,  $(T_2, T_5, T_9)$ ,  $(T_3, T_6, T_7, T_{10})$  are created and the clustering process is shown in Figure 5.

$(T_1) (T_4) (T_8)$   $(T_2) (T_5) (T_9)$   $(T_3) (T_7) (T_6) (T_{10})$

Figure 5. The Agglomerative Hierarchical Document Clustering Process

## 4. Experimental Results

Two data sets of graduate theses published by universities in Taiwan are used as clustering targets in this experiment. The first data set consists of 411 master theses published by 8 departments<sup>1</sup> from Central Police University. The second data set is the graduate theses published in Taiwan and is a much bigger collection, but due to computation time limit only 1078 master theses published by 5 different departments<sup>2</sup> in Taiwan are used for the experiment. The clustering of the first data set shows that most theses published by an academic department form one single cluster. Only the theses published by the Department of Police Administration are clustered into two different clusters. So totally, 9 clusters are created. Although, the theses published by Police Administration Department form two clusters, 98.56% of them are clustered into one cluster.

The number of clusters created from clustering the second data set is 36, which is much bigger than 5. However, 89.4% of atmospheric science theses, 90.3% of marine biology theses, 89.6% of international economics theses, 90% of plant pathology theses, and 86.7% of electro-physics theses, are clustered into five main clusters respectively. Overall, the clustering results are considered to be very good.

## 5. Conclusions

In this paper, we have described the agglomerative hierarchical clustering method in detail and the experiments to cluster two collections of graduate theses. It is shown that based on the key phrases assigned to documents by the author(s), the agglomerative hierarchical clustering method is able to cluster most (about 90%) of the theses published in one academic area to a single clusters. For theses published by Central Police University, the clustering result is much better, and this may due to that the research area of Police University is more specific and better focused.

Since the academic departments are often used as the categories for classification, we conclude that our clustering scheme is promising for automatic document classification if the clustering granularity is on the academic department basis. For clustering documents on other levels of granularity, terms or individual words besides key phrases and also associated their weights might be used as surrogates for documents. In that case the clustering scheme will be more complex to implement and thus more computation efforts is needed.

<sup>1</sup> They are police administration, fire science, criminal police, traffic administration, information management, crime prevention, forensic science, and law.

<sup>2</sup> They are atmospheric science, marine biology, international economics, plant pathology, and electro-physics.

# The Relationships between Individual Differences and the Quality of Learning Outcomes in Web-based Instruction

Sherry Y. Chen

Department of Information Systems and Computing,  
Brunel University, Uxbridge, Middlesex, UK  
Sherry.Chen@brunel.ac.uk

## Abstract

The use of web-based instruction is becoming widespread in higher education, however much remains to be learned about how different learners perceived such instructional programmes. The study presented in this paper evaluates students' learning performance and their experience in a web-based instructional programme, which was applied to teach students how to use HTML in Brunel University's Department of Information Systems and Computing. Sixty-one Masters students participated in this study. A number of interesting interactions were found. Students' task achievements were affected by the levels of their previous system experience. On the other hand, the Post-Test and Gain scores were positively influenced by their perceptions and attitudes toward the web-based instructional programme. The implications of these findings are discussed.

## 1. Introduction

As one of the most recent developments in learning technology, the web stands to offer significant innovation to the improvement of delivering instructional material. The value of such innovation does not only provide a new way for teaching and learning, but also allows instructors to do traditional things in new ways [1]. This is the probable reason as to there has been an increased growth in the use of the web for teaching and learning. In particular, many institutions in higher education have used the web to support university courses. However, the drawback is that the responsibility for designing learning paths through web-based instructional programmes becomes that of the students. Some students who lack independent learning skills may find it difficult to interact with web-based instruction programmes, so their learning achievement may be disrupted, limiting the outcome of their learning and reducing its effectiveness.

In order to understand the effectiveness of web-based instruction at an individual learner level, it is necessary to see how different people perceive web-based instruction. Therefore, empirical evaluation of learners' preferences becomes paramount because such evaluation can provide prescriptions for developing student-centred learning environments that can match with learners' particular needs. The purpose of this

paper is to reflect the actual student experience of interacting with a web-based instruction programme to present prescriptions for the design of such programmes.

## 2. Web and Individual Differences

Today, many institutes in higher education apply web-based instruction to develop university courses. Web-based instruction utilises hypermedia techniques to provide students with freedom of navigation. Students can control their navigation paths that may help them to develop their own knowledge structure. The development of web-based instruction programmes provides students with many opportunities to explore, discover, and learn in theory according to their own information needs.

On the other hand, the freedom offered by web-based instruction may come with a price. Quintana (1996) states that while students gained the advantage of flexibility in time, pace, and distance with web-based instruction programmes, many students felt isolated, suffered from a lack of motivation, or lack of support, and found that the feedback provided was too limited and consequently dropped out of the course [15]. Hedberg and Corrent-Agostinho (2000) indicate that some students considered web-based instruction to be a difficult learning medium, showing their concern by asking for more incentives, more time, more structure, and more guidance [8]. These studies provide evidence that not all types of learners appreciate being given control over constructing their own knowledge structure. In particular, students who need more guidance through the learning process may meet an increased number of problems in using web-based instructional programmes. Therefore, research that examines the relationships between individual differences and web-based instruction has mushroomed in the past several years. Such differences include cognitive style [18, 4], gender differences [6, 5], system experience [16, 2], and domain knowledge [10].

However, some problems still exist in current studies. For example, most studies measure learning with either theoretical knowledge or practical tasks. Very few studies consider both theoretical knowledge and practical tasks. In addition, paucity of studies integrates the findings of learning outcome with those of perceptions and attitudes. Therefore, there is a need to provide empirical evidence to identify whether there is a close relationship between students' learning

outcome and perceptions to learning environments. The present study attempts to address these problems. The approaches to addressing these two problems in this study are: (a) students' learning outcomes are measured by both theoretical knowledge and practical tasks in a web-based instruction program; and (b) the interactions between students' learning outcomes and perceptions are explored.

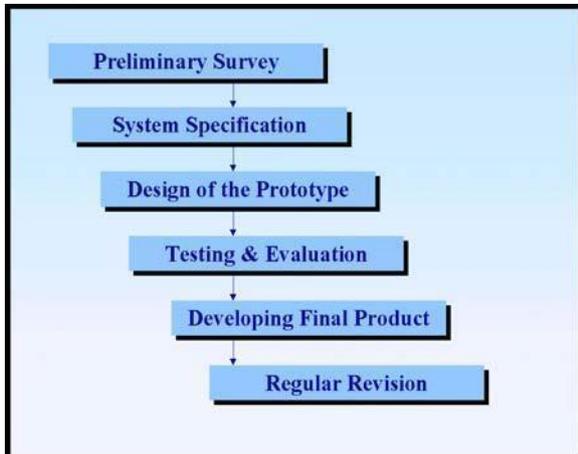

Figure 1: Development process

### 3. Curriculum Design

Curriculum design is a critical issue in the process of implementing web-based instruction. The sections below describe the approaches of the curriculum design in the development of web-based instruction, which include two important elements: creation of instructional material and assessment of learning

outcome.

### 3.1 Creation of Instructional Material

#### 3.1.1 Development Process

Instead of taking a technology-centred approach, the whole development process took a student-centred approach. In other words, the student was central to development process and continually gave input to the improvement of the web-based instructional programme. This approach was to make sure that the web-based instructional programme could meet with the students' particular needs.

As showed in Figure 1, the whole design process included six steps. The preliminary survey, which was the first and most important step, aimed to identify the students' understanding in this subject and to ensure that the level and presentation of the content were matched with their capabilities.

In order to reach this aim, a series of activities were conducted, including:

- f Observation by sitting in the lecture was used to find students' difficulties in studying this subject;
- f Informal discussion was conducted with the lecturers to ascertain their opinions of the students' capabilities;
- f Comprehensive lecture notes and learning materials were collected and analysed in details;
- f An in-depth study of other similar web-based instructional programmes in the relevant subject areas was conducted.

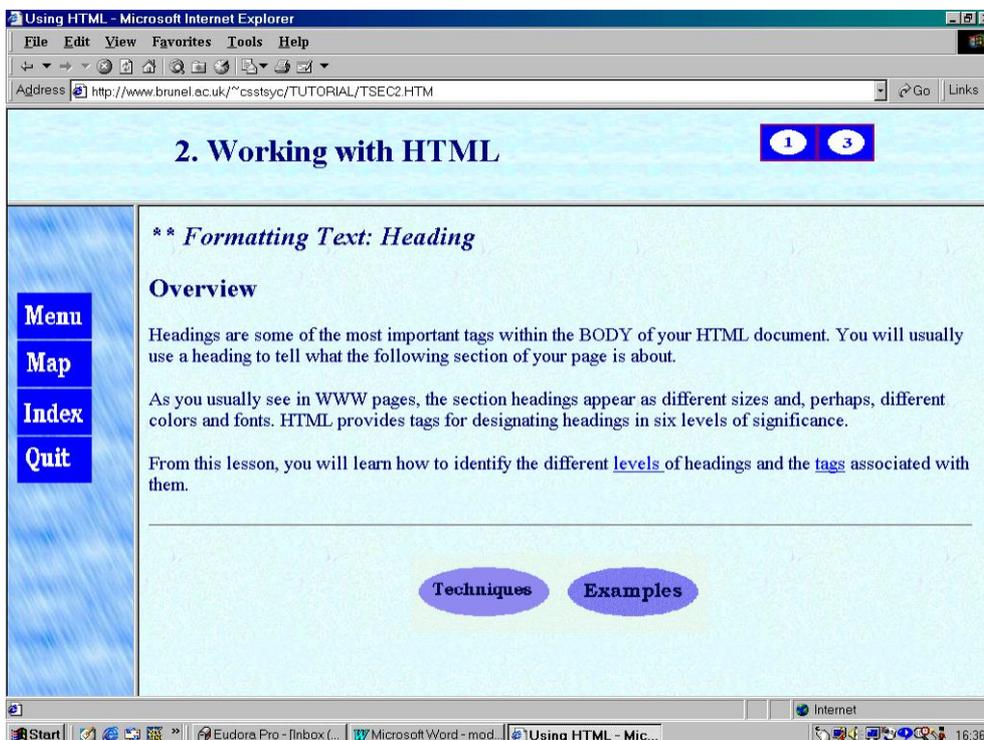

Figure 2: Screen design of the web-based instructional programme

Table 1: Three Types of Navigation Control

Control	Purposes	Tools
Sequence Control	To allow students to decide the sequence of subjects to be learned;	<ul style="list-style-type: none"> <li><i>f</i> Subject Maps: to show all topics and sub-topics in a hierarchical way;</li> <li><i>f</i> Keyword Index: to list keywords in an alphabetical way;</li> <li><i>f</i> Back/Forward: to see the page previously visited;</li> </ul>
Content Control	To allow students to control the selection of the contents they wish to learn;	<ul style="list-style-type: none"> <li><i>f</i> Section Buttons: to choose three sections of the main content;</li> <li><i>f</i> Main Menu: to present main topics;</li> <li><i>f</i> Hypertext Links: to connect relevant concepts;</li> </ul>
Display Control	To allow students to choose one of several display options that cover the same concept.	<ul style="list-style-type: none"> <li><i>f</i> Display Options: to include overview, examples, and detailed techniques, etc.</li> </ul>

According to the results of the preliminary work, a system specification was developed and was employed to define the content, functionality and usability of the web-based instructional programme. A prototype was then designed based on the system specification and the students were invited to test and evaluate its function and contents. Their opinions were summarised and were used to implement the final product. It is important to note that implementing the final product is not the end of the development process. Revising the content on a regular basis is important because it can get students to re-visit the web-based instructional programme frequently.

### 3.1.2 Content Presentation

The subject matter of the web-based instructional programme was related to an introduction to using HTML. The programme began by giving an introduction to the learning objectives and explaining the available navigation approaches provided in the instructional programme. The contents were divided into three sections: (1) What is HTML? (2) Working with HTML, and (3) Relations with SGML and WWW. Section 2, which covers twelve sub-topics of HTML authoring, is the key element of the web-based instructional programme. Each sub-topic was further split into five parts, comprising (a) overview, (b) detailed techniques, (c) examples, (d) related skills, and (e) references. Information was presented in 82 pages using texts, tables, index, and maps. The contents of the web-based instructional programme were divided into seven hierarchical levels.

As shown in Figure 2, the screen was divided using frames. In the top frame was a title bar showing the section name being viewed and the other available section buttons. In the left frame were the Main Menu, Index, Map, and Quit buttons. The right frame displayed the main content for each section, including topic buttons and text-based hypertext links.

### 3.1.3 Navigation Control

The web-based instructional programme took advantage of non-linear learning and provided students with freedom of navigation. Topics and sub-topics could be studied in any order. In other words, students were allowed to decide their own navigational routes through the subject matter. Three types of navigation control were available in this programme as shown in Table 1.

## 3.2 Assessment of Learning Outcome

The objectives of the assessment were to examine the students' learning outcomes and the factors that affect these. Students are required to demonstrate their understanding of the fundamental technologies that underpin HTML authoring and to express their learning experience in using the web-based instructional programme. To achieve these objectives effectively, three types of the assessment were developed:

- f* Pre-Test and Post-test: to reflect students' theoretical knowledge;
- f* Practical Task: to reflect students' real skills of using HTML;
- f* Exit Questionnaire: to reflect students' learning experience.

### 3.2.1 Pre-Test and Post-Test

Examining students' theoretical knowledge was conducted by developing Pre-Test and Post-Test. Students were evaluated with a Pre-Test to examine their levels of prior HTML knowledge and with Post-Test to assess learning achievement. Both these tests were presented in paper-based formats and included 20 multiple-choice questions. There was only one right answer for each question. The formats of the questions were similar, with only the specific subject of the question being modified. The questions covered all three sections of the web-based instructional program from basic concepts to advance topics.

Students were allotted 20 minutes to answer each test and were not allowed to examine the content presented in the web-based instruction at the same time. Students' learning outcomes were assessed by:

- f* Post-Test Score: the sum of each student's score on the Post-Test, ranging from 0 to 20;
- f* Gain Score: score difference between the Pre-Test and the Post-Test in order to ascertain how much knowledge had been gained.

### 3.2.2 Practical Task

Students were assigned to do a practical task, which involved constructing a web page using HTML in order to measure learning outcome on the real skills that they had learnt. The practical task entailed 10 key areas (e.g. creating hypertext links, changing background colours, formatting text, etc.). A printed task sheet that described the detailed features of the web page to be completed was given to the students, who were allowed to decide the order in which they attempted to complete the task activities on the sheet. They were also allowed to look at the content of the web-based instruction programme simultaneously.

One and a half hours were allocated for each student to complete the task. The starting time and the end time for each student were recorded. Students' task achievement was evaluated by:

- f* Task Score: a score consisting of summing items successfully completed, on a 0-10 scale;
- f* Task Time: the total time spent for completing the whole task activities.

### 3.2.3 Exit Questionnaire

The exit questionnaire was divided into two parts. The first part was the assessment of the web-based instructional programme, including (a) levels of understanding, (b) content description, (c) presentation and explanation, (d) functionality and usability, and (e) difficulties and problems. The second part contained information regarding biographical data of students and their experience with using computers, the Internet, and HTML.

The assessment contained three open-ended questions and 47 closed statements. The open-ended questions were related to students' opinions about the strengths and weaknesses of the web-based instructional programme and the barriers that they met. Students were requested to express their opinions in their own words. Enough space was provided for them to write down their opinions. Each closed statement could be classed as either in favour or not in favour of the programme. The numbers of statements in favour was almost equal to those statements not in favour (20 statements in favour and 27 statements not in favour), in an attempt to reduce bias in the questionnaire. All statements used a five-point Likert Scale consisting of: strongly agree, agree, neutral, disagree, to strongly disagree. Students' perceptions and attitudes were measured by

- f* Positive Perceptions: the sum of the scores for all favoured statements of the Exit Questionnaire;
- f* Negative Attitudes: the sum of the scores for all not-favoured statements of the Exit Questionnaire.

## 4. Student Experience

The section below presents the results of how individual differences influence student learning in the web-based instructional programme. The data obtained from Pre- and Post Tests, practical tasks, and exit questionnaires (closed questions) were used to conduct quantitative analyses to identify students' learning experience. Pearson's *r*, which is appropriate to analyse interval level data [21], was applied to find the correlations between students' individual differences and their learning preferences. A significance level of  $p < .05$  was adopted for the study. In addition, the mean scores are employed to describe the learning outcome for each individual group.

### 4.1 Overall Results

Table 2: The distribution of the participants

	Male (N=32)	Female (N=29)	Total (N=61)
<b>Computer Experience</b>			
None	0	0	0
Little	0	0	0
Average	9	11	20
Good	12	10	22
Excellent	10	9	19
<b>Internet Experience</b>			
None	0	0	0
Little	0	0	0
Average	12	10	22
Good	9	12	21
Excellent	10	8	18
<b>HTML Authoring</b>			
None	8	7	15
Little	9	11	20
Average	6	7	13
Good	8	5	13
Excellent	0	0	0

The participants (N=61) consisted of Masters' students at Brunel University's Department of Information Systems and Computing. Despite the fact that the participants were entirely self-selecting, in fact the sample is extremely evenly distributed in terms of gender, and system experience. They were 32 males and 29 females. The computer experience and Internet experience reported by the participants varied from average to excellence. Their familiarity with the subject content, HTML authoring, ranged from none to good (Table 2).

Table 3: Overall learning outcomes

	Post Test	Gain Score	Task Score	Task Time
Mean	10.4	7.7	6.5	46.5
SD	1.8	0.9	1.6	6.8

A majority of the students (78%) felt that the web-based instruction programme was useful and they liked the web treatment of the content. Their actual learning outcomes are described in Table 3.

#### 4.2 Tasks vs. Tests

As indicated in Section 3, students needed to be assessed by both practical task and paper-based tests. It is important to note that both task and tests were markedly different. The distinctions between both of them are similar to those between open-book examination and closed-book examination. The practical task was completed in "open book" examination style, with the students building their Web pages being guided by the task sheet. The practical task could be completed successfully without necessarily recourse to memory, by applying knowledge read from the screen at the particular time it was needed. On the other hand, the Post-Test, which was a multiple choice factual test, entailed recalling knowledge from memory, and completed after learning using the web-based instructional programme, looked like a closed-book examination. These differences can also be associated with those between procedural knowledge and declarative knowledge. Derry (1990) distinguishes between these two, procedural being "knowledge how", and declarative being "knowledge that" [3]. Procedural refers to knowledge of how to do things, while declarative refers to knowledge about the world and its properties [13]. Practical tasks refer to procedure knowledge of how to use HTML, while paper-based tests refer to declarative knowledge about the properties of HTML.

Table 4 Task Score and Prior Knowledge

Task Score		Internet Experience	HTML Authoring
Excellent	Mean	8.2	N/A
	SD	1.9	N/A
Good	Mean	6.9	8.4
	SD	1.6	1.8
Average	Mean	4.3	7.2
	SD	0.7	1.3
Little	Mean	N/A	6.0
	SD	N/A	0.7
None	Mean	N/A	4.2
	SD	N/A	0.3
Significance		r=.4400 p=.006	r=.3459 p=.036

Significant Pearson's correlations showed the students' task scores were affected by the levels of their previous Internet experience and HTML authoring

(Table 4). On the other hand, the Post-Test and Gain scores were positively influenced by their perceptions and attitudes toward the web-based instructional programme (Table 5). In other words, students who had more positive perceptions toward the web-based instructional programme could obtain better Post-test and Gain scores than those who had more negative attitudes toward the programme.

Table 5: Perceptions/attitudes & learning outcomes

	Post Test	Gain Score	Task Score	Task Time
Positive Perceptions	r=.4052 p=.013	r=.4601 p=.004	r=.2979 p=.073	r=.0856 p=.614
Negative Attitudes	r=-.0877 p=.606	r=-.1254 p=.460	r=.0548 p=.751	r=.3053 p=.066

It implied that performance on the practical task of applying procedural knowledge could be promoted by prior system experience in using Internet and HTML authoring, but it would not be affected by the matching or mismatching of instruction with students' preferences. Conversely, the ability to recall declarative knowledge appears to have been mainly facilitated by matching instructional presentation with learners' preferences, but it is not influenced by prior system experience of using Internet and HTML authoring.

#### 4.3 Gender Differences

Table 6: Gender Differences in Learning Outcomes

	Post Test	Gain Score	Task Score	Task Time
Female				
Means	12.4	9.3	4.5	35.5
SD	1.9	1.1	0.6	3.8
Male				
Means	8.5	6.2	8.6	56.4
SD	0.8	0.7	1.8	7.8
Significance	r=-.3519 p=.004	r=-.2889 p=.020	r=-.3374 p=.006	r=.3413 p=.005

The students' learning outcomes showed some interesting findings with regard to gender differences. Female students performed better than male students in the Post-Test. Conversely, male students outperformed female students in the practical task (Table 6). As indicated in Section 4.2, the differences between the Post-Test and practical task can be related with those between declarative knowledge and procedural knowledge. It implies that female students are better at acquiring declarative knowledge, rather than procedural knowledge. Conversely, male students are

skilled in gaining procedural knowledge, instead of declarative knowledge.

For learning attitudes, male students were patient in completing the task. On the other hand, female students felt nervous doing the tasks and some of them (N = 10) gave up doing the task in the middle stage. In addition, female students needed more guidance than male students. Female students tended to ask for instruction from the tutor, instead of trying to correct errors by themselves. These findings are in line with previous studies, which found that males showed more interest in using and learning about computers while females reported fear of using computers and feeling helpless around them [17, 9]. For this phenomenon, educators should help female students to build their confidence in facing the challenge of using computers, instead of giving too detailed instructions. In addition, educational settings should ensure that instructional programmes developed should not place any students at a disadvantage due to their gender differences [14].

#### 4.4 Prior Knowledge

Through analysing the students' prior knowledge, one thing seems evident. For doing the practical task, students who had greater experience of using Internet or HTML authoring seemed able to look for relevant information in an efficient way. Conversely, students who were lacking prior knowledge of the subject content needed more time to complete the task by using the web-based instructional programme (Table 7). It seemed that student's existing knowledge did influence their interaction with the web-based instructional programme. These findings arguably supported results from previous studies [18, 7] which found there was a positive relationship between learner control and prior knowledge.

Table 7: Prior Knowledge and Task Time

Task Time		Internet Experience	HTML Authoring
Excellent	Mean	39.2	N/A
	SD	5.5	N/A
Good	Mean	44.5	31.4
	SD	6.1	3.2
Average	Mean	54.4	41.9
	SD	8.1	4.3
Little	Mean	N/A	50.5
	SD	N/A	5.9
None	Mean	N/A	61.2
	SD	N/A	7.3
Significance		r=-.2690 p=.030	r=.2834 p=.022

Expert learners who had an adequate amount of prior knowledge on the subject felt familiar with the interface and the contents of the web-based instructional programme so they were confident about being more active when navigating the web-based instructional system. On the other hand, novice learners might not be aware of the best order to read the material or what the

most important information was. Therefore, it is important to provide novice learners with an initial phase of orientation relating to both interface and domain contents [12]. One of the ways is to provide visual paths, which can be displayed by means of cues to indicate how far students are along a path or by giving some conceptual description for the possible sequences. The alternative way is to providing good labels for the pages. Labels that clearly indicate the role of a particular page may help novices successfully to decide the appropriate coherent path [11].

#### 4.5 Learning by Doing

In this web-based instruction programme, students were asked to do a practical task (i.e. designing a web page with HTML). A significant number of students (44%) reported that doing the task was a useful way of helping their learning in the web-based instructional programme though they felt pressured by the whole process of doing the task. They thought that the task activities could help them set the focus and recall what they had learnt. From these 44% of students, 52% of them could obtain the Post-Test scores above the average (= 10.4) and 63% of them demonstrated more positive perceptions to the web-based instructional programme. These results implied that "learning by doing" could assist some students to set their effective learning strategies. As indicated by Smith and Parks (1997), tasks serve to simulate "goal directed" browsing in such a way that learning performance can be enhanced [20].

On the other hand, a few of them (30%) reported that doing the task hindered their learning. They found that they lost other important information that they needed to learn because they were concentrating on doing the task. From these 30% of students, 58% of them obtained the Post-Test scores below the average and 54% of them showed more negative attitudes toward the web-based instructional programme. This raises some interesting questions for further studies to consider (a) whether task activities can facilitate promoting students' learning performance in a web-based instructional programme; and (b) what the relationships are between students' attitudes and their learning patterns as reflected in a web-based instructional programme with/without setting tasks.

#### 5. Conclusions

The aforementioned findings provide evidence that web-based instructional programmes may not be suitable for all learners as an instructional methodology. Instructors must be aware of individual differences such as gender and levels of prior knowledge possessed. Some learners, e.g. novice learners, may need greater support and guidance from the instructors, while others may be able to follow web-based instructional programmes relatively independently. Thus, instructors should not assume that every student would benefit equally from web-based instructional programmes in

educational settings. There remains the need for guidance to ensure that all learners attain their learning potential.

Implementing web-based instructional programmes is a complex process composed of interactions among students, instructional content, and the features of web-based instructional programmes. It is important for educational settings to have a good plan in advance. Instructors should remain cautious about making a sweeping decision to convert entire curricula onto web-based instructional programmes. The goals of such a process should be weighed against the potential problems (e.g. alienating certain learners). To avoid alienating a certain group, instructors should continue to incorporate a number of different teaching strategies into their lectures. In addition, this transition requires time for the student and time in the classroom to acquaint the students with web-based instructional programmes. This is especially the case for students who have difficulties in independent learning; there is a need to let them have longer time for this shift. With this issue in mind, such innovation in teaching and learning will be more meaningful and valuable.

## Abstract

Many universities have struggled to incorporate Enterprise Resource Planning (ERP) systems into their Information Systems (IS) curriculum. They are now faced with the issue of how best to incorporate e-business. They often treat the two technologies separately without realising the synergy between the two. We propose that IS curriculum can be extended using an ERP system to teach e-business concepts.

Many IS departments have spent much time and resources in modifying their curriculum to incorporate Enterprise Resource Planning Systems. These systems are seen as a tool to reinforce many IS concepts. To facilitate the inclusion of ERP systems into the curricula universities have formed strategic alliances with major ERP vendors. The ERP vendor benefits from these alliances by increasing the supply of skilled graduates that can support their product thereby enhancing its marketability and lowering the cost of implementation, while the university gains access to the software at a greatly reduced cost. Through these alliances universities have made a commitment to incorporate ERP systems into their curriculum and have expended an enormous amount of effort and resources to achieve this. For many of these universities it is important to investigate how they can leverage their current level of expertise in ERP systems curriculum to incorporate many of the ERP's e-business functionality to support the teaching of e-business concepts. Many consider ERP systems as an essential component of any e-business strategy.

Before a university decides to build upon their existing ERP knowledge and resources to teach e-business concepts and skills in the IS curriculum, consideration should be given to a number of factors, including how e-business is covered in the IS curriculum at present; in what ways and to what extent should e-business issues be addressed; and what ERP resources should be extended to support the teaching of e-business concepts and skills.

This paper examines the potential use of ERP systems as a tool to teach e-business concepts. It discusses the different functionality available and its applicability to IS curriculum.

## 1. Introduction

Over a period of 40 years, the Information Systems (IS) discipline has become an essential component in the employment of information technology personnel in business and government organisations in Australia. IS curriculum has undergone rapid and continuous change in recent times. Since its inception as a discipline in tertiary institutions, IS curricula has undergone continual change. The function of IS now, is one of supporting innovation, planning and coordinating resources and systems, rather than one where specialists work in isolation. It has moved from processing data to providing an information infrastructure with applications aligned to organisational strategy [10]. Although it would not be possible to obtain universal agreement on the exact components, Information Systems is oriented towards business, involving the matching of information systems' requirements to an organisation's objectives. IS professionals, to be effective, require formal technical training and a "... sound educational foundation in their discipline so they can keep abreast of new technologies and be responsive to change" [12, p.219].

In recent times there has been concern, what only can be referred to as a panic as IS professionals are considering how to incorporate aspects of electronic commerce into IS curriculum. Initially there was a plethora of new subjects proposed which were primarily existing subjects with "e-" preceding the subject name. It was felt that many universities did this to gain a competitive advantage through the "first mover" principal. As academics began to grasp many of the new concepts of the e-world and their implications, the use of the term e-commerce was slowly replaced by the term e-business. E-business differs from e-commerce in that it relies on the integration of business processes and the supporting technologies to gain competitive advantage across the extended supply chain. It is more strategic in nature and requires greater skill sets than e-commerce due to the front-end back-end integration.

As an academic study, IS needs to educate students in the efficient and effective application of all components of an information system (computer hardware, software and people) to solve business and organisational problems. There have been a number of studies which have attempted to identify IS graduate skills and the resultant curriculum.

The IS'97 Model Curriculum [3] was a collaborative development between industry and academia. The model provided guidelines and resources to facilitate the development of quality undergraduate IS curriculum. Interestingly, this model curriculum, just four years old, makes little mention of electronic commerce or e-business. However the recent revision to this model curriculum (IS 2002) places far more importance on the role of e-commerce.

In the USA, the National Science Foundation [7] sponsored a task force of both industry and academic participants in an attempt to identify the IS skills relevant for the development and use of large information systems. The skills were categorised into Personnel Skills, Interpersonal Skills and Technical Knowledge and Skills. However even though the document acknowledged the importance of enterprise wide systems, it made failed to recognise the extension of these types of systems into the e-business arena and the skill requirements to support this extension. The resultant Information Systems-Centric Curriculum Document [7] recommended an inverted curriculum approach which allows students to experience and analyse real application systems from the beginning of their course [9]. This requires students to take greater responsibility for their learning with academics taking on the roles of mentors. An essential recommendation was the ongoing collaboration with industry to enable meaningful project activities, site experiences, case studies, and assistance in updating the curriculum.

In 2000 the U.S. Departments of Commerce, Labour and Education released the 21st Century Skills report designed to identify skills required by students to work in the "digital age". The report identified a number of broad generic skills but made little reference to specific IT skills [13].

The massive number of IT vacancies around the world, Australia 30,000 (Information Age, 1998), USA 200,000 and Germany 90,000 (The Australian, June 2000) have resulted in governments and industry conducting studies to identify the specific skill shortage areas [13] [2].

The Deloitte [4] report mapped E-skills into 9 super-types:

- Internet & multimedia,
- Application development,
- Web development tools,
- Operating systems,
- Internetworking,
- LAN administration,
- System software and support,
- Database management,
- Communications installation and maintenance.

The National Office of Information Economy reported that 37% of business identified lack of skills as a major barrier to business use of e-commerce [11].

The incorporation of e-business and related issues into university curriculum has been driven by a number of factors:

- Analyst's projections of the enormous growth in this market [1].
- Student's realisation of the potential lucrative job market.
- Industry looking for graduates with the appropriate skill set and
- Academics attempting to keep abreast of current issues in the information technology industry.

The challenge for IS academics is to modify their curricula to embrace the concepts of e-business as to provide graduates with the necessary skills to assist business enterprises in the future.

Many IS departments have spent much time and resources in modifying their curriculum to incorporate Enterprise Resource Planning Systems (ERP) [6] [8] [14]. These systems are seen as a tool to reinforce many of the IS concepts. To facilitate the inclusion of ERP systems into the curricula universities formed strategic alliances with many of the major ERP vendors [5]. The ERP vendor benefits from these alliances by increasing the supply of skilled graduates that can support their product thereby enhancing its marketability and lowering the cost of implementation while the university gains access to the software at a greatly reduced cost. One such alliance is the SAP University Alliance. Through these alliances, universities have made a commitment to incorporate ERP systems into their curriculum and have expended an enormous amount of effort and resources to achieve this. For many of these universities it is important to investigate how they can leverage their current level of expertise in ERP systems curriculum to incorporate many of the ERP e-business tools to support the teaching of e-business concepts. ERP systems are considered by many as essential component of any e-business strategy. This paper examines the potential use of ERP systems as a tool to teach e-business concepts. The paper will focus on SAP's ERP system as they are the market leader and have the largest university partnering program in the Australasian region.

## 2. SAP and e-Business

Since SAP's R/3 Release 3.1, a number of Internet-enabled applications via the inside/out approach have been made available. The Internet applications are developed to add a web user interface to existing SAP transactions. Since then SAP has offered more and more e-functionality especially in its more recent release, mySAP. SAP is now touted as the platform for many companies e-business strategy. Its various components support e-business through the intranet, business to consumer (B2C) and Business to Business (B2B) models. It does this from both a technical and business perspective. The relationships between these components can be summarised in Figure 1.

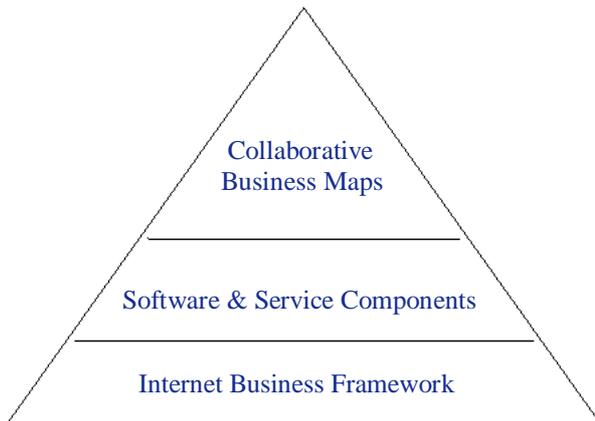

Figure 1: SAP e-functionality

The remainder of the paper will describe the various components contained in the ERP system and how they could be incorporated into an IS curriculum to teach e-business concepts.

### 3. Internet Business Framework

To support the evolving nature of software and particularly ERP systems, SAP developed its Business Framework. This framework facilitates the introduction of new software modules that are incorporated in the ERP system or new components that must interact with the system. This includes non-SAP software that must interact with the ERP system. The Business Framework enables open, integrated, component-based enterprise business application solutions to be produced. For example, using the Business Framework, a company's own IT systems could be coupled with those of customers and vendors. Customers can employ the Internet to shop—their Internet orders are transferred to the order management system and automatically executed through all the processing steps to delivery. Vendors can have access to specific parts of their customers' warehouse management systems, allowing them to independently schedule their deliveries.

The Business Framework adopts a top down approach utilising the following components:

- **Business Components.** These are defined encapsulated business functions such as modules (Human Resources, Logistics, Financials) and functional software (Business Warehouse, Knowledge Management).
- **Business Objects.** An object-orientated approach is adopted to define the objects involved in a particular business process such as customer and invoice.
- **Interfaces.** These provide an open access to business components via standard access methods. This is achieved via BAPIs (Business Application Programming Interfaces), which are the methods or functions assigned to each business object. BAPIs act like interfaces for controlled method calls between SAP business objects and objects of external providers. BAPIs are open interfaces to make certain that when two application systems communicate with

each other, the business-related information such as customer, order or part number, all uses the same semantics. BAPIs form the foundation of SAP's Internet strategy by providing an object-orientated interface between different business components.

- **Integration Technology.** SAP incorporates integration technology that supports industry standards such as CORBA, XML, COM+ and EDI to enable open access to SAP and non-SAP components.

BAPI's provide students, studying IS access to business data and processes following an object-oriented programming model. BAPIs can be called using object-oriented interfacing technologies, such as Microsoft's COM/DCOM (Component Object Model/Distributed Component Object Model), thus enabling software components from SAP and third parties to interact freely.

In addition BAPIs can be accessed from all development platforms that support the SAP Remote Function Call (RFC) protocol. For example, Microsoft's Visual Basic environment supports this protocol. As Visual Basic (VB) is frequently used as the programming language for introductory programming, students are able to use their VB skills as a conduit to accessing an object-oriented programming model within the Business Framework of SAP. For example, we set our students a programming task to write a VB application that incorporates BAPIs, to remotely log into our SAP system and retrieve customer information.

### 4. Software and Service Components

The software and services provided by SAP for e-business are primarily provided by Internet Application Components (IAC). Since SAP R/3 version 4 has contained more than 35 IAC's. An IAC defines a complete internet application consisting of a transaction from the ERP system and the corresponding HTML templates. Traditionally for a user to interact with SAP R/3 they required a reasonable level of training and expertise. This becomes a serious barrier when a company expects customers, potential clients, vendors, business partners and other employees to interact with the system as is the expectation with e-business. Through the use of IAC's, the HTML display is user-friendly and functional providing users with an easy-to-use interface.

IAC's can be broadly categorized into electronic retailing, customer service, purchasing, employee self service and internal services. The OnLine Store is an example of a supplied IAC. The Online Store is a business to consumer (B2C) solution provided to customers in a standard SAP system. It has all the standard features of many online shopping facilities. Its electronic catalogue interacts with SAP's sales and distribution module to display products, descriptions and inventory levels. The online store incorporates the standard "shopping cart" functionality for the identifying of goods to be purchased. It also incorporates various

payment methods for the purchasing of the goods in the shopping cart.

The OnLine Store facility in SAP could form the basis of an e-business curriculum. It enables students to determine and enter the master data which needs to be created to support the products which are to be included in their online store. They can design their product catalogue to display the products available through their store. It would provide students with an understanding of the business process used to support B2C transactions. They could track the placement of online orders sourcing, picking billing, delivery and changes in inventory levels. They can explore the accounting documents that are generated with this type of transaction. From a business perspective they can produce a variety of reports to demonstrate the performance of their store.

The OnLine store provides students with a practical understanding of the business concepts of B2C, students can also explore it from a technology point of view. The IAC's rely of SAP's Internet Transaction Server (ITS) to map SAP R/3 screens to a HTML format. It provides the necessary functional and performance characteristics required to execute R/3 transactions. The application logic remains within the R/3 system thereby providing an "inside-out" approach to e-business. Students in data communications units can use the ITS as a tool which can be configured. They can reinforce security issues, that they have covered, by using the firewalls and encryption capabilities of the ITS.

The architecture of the ITS supports the rapid development of web user interfaces for existing transactions and comes with a PC-based development tool ready for HTML template development - SAP@Web Studio. This development tool is well suited to users who have little technical background and are looking for a simplified way to create web applications. It operates, for the most part, in offline mode and requires almost no specific SAP knowledge. The newer version of SAP R/3 (4.6c) incorporates the Web Application Builder and has the advantages of an online development tool including repository access, reuse and navigation support. It allows for both the inside/out and the outside/in development styles that are used in building common web applications for SAP. Both these tools enable students to create their own applications based on the theoretical concepts they have covered.

At Victoria University we have a group of graduate students who are in the process of installing and configuring SAP's OnLine Store. Once installed this tool will be used throughout the Faculty to reinforce many of the e-business concepts taught in the various schools.

## 5. Collaborative Business Maps

SAP has developed collaborative business maps in an attempt to facilitate the transition of companies to an e-business environment. These maps define the activities, roles, system interfaces, and business documents required for business to business transactions using the ERP system. ERP vendors, in the past have argued that their

systems include "best business practice" and this claim applies equally in the e-world.

The business maps provide three different views of how a company can establish, implement and evaluate their e-business strategy:

- The Interaction View illustrates to companies how their business processes interact with their business partners' processes from an e-commerce perspective. It outlines which users should be involved and what business documents are exchanged.
- The Component View provides information on which technical aspects need to be installed to support the level of interaction as defined in the previous view.
- The Collaboration Scorecard provides a methodology to assess the return on investment for the ecommerce strategy.

The Business Maps provide a company with the necessary tools to develop, implement and assess their e-business strategy from a B2B perspective. This tool would be invaluable in a university setting. It would provide students with what is considered "best business practice" in the B2B environment. They would be able to examine the interaction of business processes between vendors and suppliers. They would become aware of the staff involved and the business documents exchanged. Also they would be exposed to the techniques used to determine return on investment of a B2B strategy. The collaborative business maps could be a foundation for e-business curriculum as they would provide an explanation of the main business processes and the necessary interactions. This teaching tool could be applied to e-business solutions in general.

Also available to students is the Solution Composer, which can be downloaded from the SAP web site free of charge. This tool enables students to modify existing business maps or compose new ones. By editing or creating their own maps, they can analyse and visualize the specific processes from case studies and discover how best to implement and support them in an e-business environment.

The e-business elements discussed above are relatively simple to incorporate into the IS curriculum. There are many other components that can also be used to reinforce e-business concepts but would require considerable effort to configure for student use. These include customer relationship management (CRM), mobile computing, e-procurement, employee self service and enterprise application integration functionality.

## 6. Conclusion

Many universities have struggled to incorporate ERP systems into their IS curriculum. They are now faced with the issue of how best to incorporate e-business. They often treat the two technologies separately without realising the synergy between the two. We have outlined how ERP systems curriculum can be extended to include e-business.

Before a university decides to build upon their existing ERP knowledge and resources to teach e-business concepts and skills in an IS curriculum, consideration should be given to the following questions:

- How is electronic business covered in the IS curriculum at present?
- If electronic business issues are to be addressed, then in what ways and to what extent should this be done?
- Can our existing ERP resources be extended to support the teaching of e-business concepts and skills?

## Abstract

The paper defines Computer-Supported Collaborative Argumentation as a collaborative activity supported by CMC, which focuses on argumentation interactions. CSCA embeds the advantage to eliminate social context cues and provides a direct channel to express one's opinions. In this case, Computer-Supported Collaborative Argumentation (CSCA) becomes a new paradigm supported by Computer-Mediated Communication. CMC facilitates a context for participants within argumentation interactions that embed the advantages of computer conferencing. The goal of our research is to analyse the relationship between knowledge creation and quality of interaction and quality of discussion within an argumentation process. We report data of an experiment in which 120 MIS 2<sup>nd</sup> years students use four communication media settings on knowledge creation. The results suggest that an argumentation-based approach provides an environment not only for creating but also for motivating a community-wide view of information sharing because it enables discussion, mutual engagement and autonomy of knowledge exchanging. Also, in contradiction to media richness theory, this study indicates that structured argumentation-based software results in a better quality of argumentation interaction within the team, and more favourable attitude and participation in interaction, and thus yields the highest level of knowledge creation among four different communication configurations (including face-to-face).

Keywords: Argumentation, Knowledge creation, CSCA, Toulmin, SECI

## 1. Introduction

This empirical study reports the considerations which have to be taken into account in order to understand the

relationship between knowledge creation and communication configurations. Recently, Computer-Supported Collaborative Argumentation (CSCA) becomes a new paradigm of virtual learning and knowledge creation. CSCA is supported by Computer-Mediated Communication (CMC), since CMC facilitates a context for participants within argumentation interactions; in this case, CSCA embeds the advantages of computer conferencing. There are many studies focus on knowledge management but not many detail in knowledge creation neither the influential factors of knowledge creation. Nonaka and Takeuchi [10] state that there are four types of knowledge transformation, in order to achieve the successful outcome of four types of knowledge transformation, participants have to participate in collaborative activity enthusiastically. Due to CSCA embeds the advantage to eliminate social context cues and provides a direct channel to express one's opinions. From knowledge creation aspect, it is possible to infer that because the individual externalises his/her existing knowledge and internalises different opinions and comments from argumentation stimuli, the processes trigger knowledge transformation and knowledge creation. This research attempts to verify in general to understand the relative effects of four communication configurations: face-to-face, email and automated argumentation facilitator software and self study., and in particular the relationship between knowledge creation and argumentation.

## 2. Development of Research Model

Epstein [7] argues that in knowledge sharing, communication skills are more relevant than types of knowledge. In this context, the channels of communication may dominate the processes of knowledge sharing; they may influence knowledge transformation and knowledge creation. In order to

investigate issues relevant to argumentation-based knowledge transformation, the present research seeks answers to the following questions:

1. How does a collaborative argumentation-based setting help or hinder knowledge processing?
2. How does Computer Supported Collaborative Argumentation System (CSCA) help or hinder knowledge processing?
3. Is the CSCA model effective for creating knowledge?
4. How can an Automatic Argumentation Facilitator (AAF) in CSCA model help or hinder knowledge transformation?
5. How effective is the support provided by the Automatic Argumentation Facilitator?
6. What is the relationship between knowledge transformation types and knowledge creation?
7. Which type of knowledge transformation has the most impact on knowledge creation?

We identify *subject knowledge*, *argumentation interaction quality*, *knowledge interaction quality*, *motivation and participation*, *problem solving ability*, and *knowledge transformation types* as the dependent variables. With the characteristics of these variables, we explore the influence of this combination of variables within numbers of combinations of different interaction models, different communication treatments and different argumentation structures. Therefore, we identify *interaction model (argumentation vs. without argumentation)*, *Communication treatment (Traditional vs. CSCA)*, and *argumentation structure (structured vs. unstructured)* as independent variables. Damon [5] states that it is important to know the impact of interaction settings on the individuals. In the present study we look into the effectiveness of different combinations of independent variables as well as the effectiveness within different combinations of independent variables. The former focuses on social, meta-cognitive and the outcome results, for example, subject knowledge and problem solving ability. The latter emphasises the interactions in the processes such as knowledge interactions quality, argumentation interaction quality, and the transitions between different knowledge types. We chose a pre-test/post-test design in order to know how altering the combination of variables changes the outcomes.

However, researchers suggest that when we try to obtain deep understandings of information technology and its uses it is not sufficient just to focus on outcomes; we must also study the processes and interactions within the research [4][5][11]. This study selects quantitative approaches to analyse and categorise unstructured arguments (Email) and structured arguments (F2F and AAF) within the processes.

In Figure 1 we illustrate the experimental configuration, **Self-study** indicates a configuration without argumentation setting; **Email** indicates an unstructured computer-supported collaborative

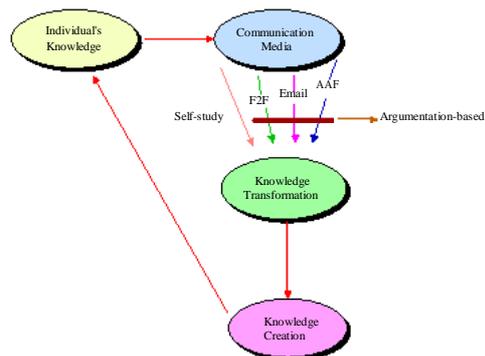

Figure 1. Research Model

argumentation configuration; on the other hand, **AAF** indicates a structured computer-supported collaborative argumentation configuration (automated argumentation facilitator software); and **F2F** (face-to-face) indicates a structured conventional collaborative argumentation configuration. In this experiment we use “structured” to suggest that argumentation interaction applies Toulmin’s model, that is, the participants have to issue their claims followed by the data and the warrant.

According to Media-Richness Theory (MRT), task performance can be improved when task information processing requirements are matched with a medium’s ability to convey information richness (Daft and Lengel, 1984). Face-to-face is considered as the richest medium; it has great potential for carrying information (e.g. emotional, attitudinal, and normative), and is recommended for resolution of an equivocal situation (e.g. negotiation). A lean medium (e.g. a text-base or memo) is always used to exchange unequivocal messages.

Based on McGrath and Hollingshead [8], a CSCA system can be considered a moderate media richness medium between text-base and face-to-face. It is the best fit to intellectual tasks. In this study groups are designed to work in different settings: Self-study, F2F, Email and the AAF system. The principal research framework and relationships from the literatures is shown in Figure 1. The correlation between dependent variables and independent variables is depicted in Figure 2.

### 3. Hypotheses

Computer-Supported Collaborative Argumentation (CSCA) is an avenue for achieving conditions for knowledge creation. For example, because of the advantages of reducing the social anxiety of CMC, individuals may experience less apprehension and may be more willing to share their experience (tacit knowledge). Once individuals are willing to share their knowledge source, collected intelligence is fulfilled. We claim that CSCA facilitates the process of eliciting the knowledge, elaborating the knowledge, amplifying the knowledge and justifying the knowledge. We use this concept to investigate the hypothesis that collaborative argumentation is an approach to the improvement of knowledge transformation; an automatic argumentation

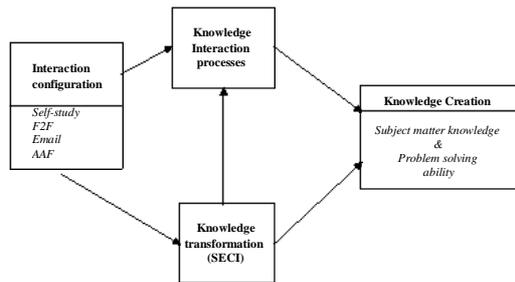

Figure 2. Correlation between dependent and independent variables

facilitator (AAF) in computer-supported collaborative argumentation (CSCA) facilitates a better result of knowledge transformation; the differences in communication configuration influence the type of knowledge transformation, thus affecting knowledge creation.

In order to investigate how different configurations affect subject matter knowledge, three hypotheses were established and tested.

**Hypothesis 1:** Participants in an argumentation-based process acquire more subject matter knowledge compared to the participants without an argumentation-based setting.

**Hypothesis 2:** Participants in a CSCA model acquire more subject matter knowledge compared to the participants in a traditional argumentation-based setting.

**Hypothesis 3:** Participants in a structured CSCA argumentation environment acquire more subject matter knowledge compared to the participants in an unstructured CSCA environment.

One of the potential advantages of CMC is that it allows the application of a spectrum of structured and unstructured techniques and methods to perform a task. We designed two CMC communication configurations in our experiment: the Email setting and the AAF system. The main difference between the AAF system and the Email system is that the Email system is an unstructured argumentation environment; individuals can articulate their opinions and arguments in a text-based format without any style limitation. On the other hand, the AAF system is a structured argumentation context, which provides graphic representation of arguments. Whilst individuals externalise their arguments they have to follow Toulmin's argumentation model. There are a number of advantages of the AAF system setting over the Email setting. Firstly, the AAF system facilitates an argumentation structure. It fosters an environment to direct participants through a sequence which aims to reach consensus. Secondly, the AAF acts as a neutral third party or referee. It provides support for group dynamics, such as maintaining the agenda of argumentation. Moreover, according to certain rules or algorithms, the AAF system manages the conflict and evaluates the strengths of the

arguments. Further, the AAF system can limit the amount of non task-related talk hence it improves argumentation efficiency. Finally, with synchronous WYSIWIS feature, the AAF system presents the arguments in graph structure to both parties spontaneously, it stimulates participants creating as a result a high quality of knowledge interactions. With these advantages we establish the following hypotheses to justify our investigation.

**Hypothesis 4:** Participants in a structured CSCA argumentation environment have a better quality of argumentation interaction compared to the participants in an unstructured CSCA argumentation environment.

**Hypothesis 5:** Participants in a structured argumentation environment have a better quality of knowledge interaction compared to the participants in an unstructured argumentation environment.

**Hypothesis 6:** Participants in a structured argumentation environment have a better perception and higher participation compared to the participants in an unstructured argumentation environment.

Based on the elimination of non task-related talk and the prescribed sequence of process, Hypothesis 7 examines the problem-solving ability in different argumentation-based settings.

**Hypothesis 7:** Participants in a structured CSCA argumentation environment acquire more problem-solving ability compared to the participants in an unstructured CSCA argumentation environment.

## 4. Methodology

**Subjects.** The participants in the experiment were 120 2<sup>nd</sup> year students at the university majoring in management who enrolled on the course in Management Information Systems. The experiment is incorporated into a four weeks workshop which delivers the topic related to the Groupware concept, the participants are required to attend the workshop once a week. The participants are told that the subject knowledge in the workshop will be included in the final examination, and the performance in the workshop is also counted as a partial credit of the final mark. Two groups of 60 students are formed: the treatment group in which, in the argumentation-based model, members are asked to elaborate their arguments within the experiment; and the control group that relies solely on self-study. The group in the argumentation-based setting is further divided into three sessions; each session has 20 students who participate in different settings. According to this design there are four sessions in the experiment: (1) session one neither computer-supported nor argumentation-based model (self-study), (2) session two is an argumentation-based model with traditional F2F (face-to-face) interaction, (3) session three is an unstructured CSCA environment (Email), and (4) session four is a structured CSCA environment (AAF).

**Experimental Task.** The participants in the argumentation-based sessions were asked to perform a collaborative problem solving and decision-making task. It involves ranking 15 desert survival items in a simulation of a desert survival situation [9][2]. We used “The lost kingdom of the Sahara” as the title of the experiment. The desert survival simulation describes a group of four archaeologists who encountered the challenge to rank 15 salvaged desert survival items in the desolate region of the Sahara in the middle of summer (where their plane has crashed). To further understanding, the experiment provides a URL containing the scenario of the task, desert survival knowledge from desert survival experts, and useful dynamic web links, which are relevant to the workshop.

Moreover, the Web page also includes details of the experiment and instructions on how to use the AAF system. The reasons to choose such a task are because (1) the task is open-ended problem solving, (2) the task is “light” to every participant without much “heavy” knowledge, (3) the task embeds an interesting competitive game which can provoke argumentation, (4) the task stimulates participants to search for more information in order to support their arguments, (5) the task requires higher-order skill (analysis, evaluation, synthesis) and deep elaboration, and (6) the task facilitates collaborative learning and collaborative argumentation.

Many studies [6][3][1] show that collaborative problem solving is one of the most effective paradigms to promote learning. We hypothesize that the task has the advantages of provoking argumentation, supporting critical thinking and exploring multiple perspectives which trigger knowledge transformation and enhance knowledge creation.

**Procedure.** The total experimental duration is five weeks; the first meeting takes place before the workshop begins. In the first meeting participants are introduced to the concept of CMC and Groupware as well as the schedule of the experiment and desert survival simulation. A form, which includes a list of 15 desert survival items, is distributed to the participants, and participants are asked to rank the order of survival items within 35 minutes. The forms are collected at the end of the meeting and marked according to the “experts’ ranks”. Participants are required to practice the materials on the Web page, which is designed for the desert survival situation simulation workshop. The Web page contains the details of the experiment, CMC and Groupware concepts, desert survival knowledge, Toulmin’s model and the instructions of how to use the AAF system.

We conclude this section with the summary of research procedure:

- 
- Step 1. Provide desert survival kits ranking form to all the participants.
  - Step 2. Participants rank the survival kits and return the form to the instructor.
  - Step 3. The form is marked according to “experts’

ranks”.

- Step 4. Introduce Groupware concept, Toulmin’s model and the AAF system.
  - Step 5. Participants access the Web page to practice using the materials which are relevant to the desert survival situation simulation workshop.
  - Step 6. Tutoring session for the AAF system and Toulmin’s model.
  - Step 7. Participants engage in experiment under different communication configuration.
  - Step 8. Participants complete problem-solving ability ranking form according to their communication configuration.
  - Step 9. Participants fill the post-experimental questionnaire individually.
  - Step 10. Data collection and analysis.
- 

**Data Collection.** The primary methods of data collection in the present study are; post-experimental questionnaire; problem-solving ability test (desert-survival items ranking); and transcripts of argumentation. The main reason for these methods is because the major part of the study is concerned with the perception of the different communication configuration in argumentation, interaction within the argumentation, and how these perceptions and interactions affect knowledge transformation and further knowledge creation. Pre-test of problem-solving ability can provide the sketch of an individual’s desert survival ability. For the argumentation-based/self-study group, post-experimental questionnaire measures desert survival knowledge, perception of the activity and the interaction within argumentation. Post-test of problem-solving ability assesses the desert survival ability after experiment on a team basis (argumentation-based) or individually (self-study), it presents the strength of collaborative argumentation in different communication configuration.

## 5. Findings

In this study, the participants collaboratively generate the knowledge for problem solving, and then apply the knowledge which they explore from interaction; the score of problem-solving ability is the representation of knowledge application. Of the 120 university students majoring in MIS as study participants, most participants completed their post-experimental questionnaire; but more than half of participants in argumentation-based setting were unable to complete their whole discussion of desert-survival items ranking because of time constraints. However, final valid data in this study is 62: 36 from Self-study group, 8 from face-to-face group (dyads), 10 from the Email group (5 dyads), and 8 from the AAF setting. The data are used to test ten research hypotheses.

The study explores knowledge processing in argumentation-based setting; furthermore, the study investigates the influences of the automatic argumentation facilitator in knowledge transformation and knowledge

creation. From data analyses, we summarise the findings related to each research hypothesis.

Hypothesis 1. We had hypothesized that an argumentation-based setting would be positively associated with subject knowledge gain, but the result shows no support for our hypothesis. The participants in Self-study have a higher mean of subject knowledge compared to the participants in a face-to-face and the Email system and this implies that collaborative argumentation does not guarantee better subject knowledge as a result. Many factors have to be considered in the activity. For example, communication medium selection, time arrangement, dyads arrangement and task characteristics. The fact that the AAF system facilitates diagrammatical argumentation features in the process could be a factor explaining the highest subject knowledge gain.

Hypothesis 2. With information technology, it is reasonable to hypothesise that the participants in the CSCA model gain higher subject knowledge compared to the participants in the traditional model. The data analysis supports our expectation. We found that the participants in the face-to-face setting perceive some degree of social contextual cues, this may affect the motivation in argumentation activity.

Hypothesis 3. As Hypothesis 1, we expect that with computer supported well formatted and well structured process design, participants may acquire more subject knowledge, since the AAF system can provide suitable features to facilitate the argumentation process. The result supports our hypothesis but the result is not significant.

Hypothesis 4. In a structured CSCA environment, participants experience higher motivation and comfort when they use the AAF application, on the other hand, the participants in an unstructured CSCA environment may perceive it to be laborious and cumbersome thus decreasing the quality of argumentation interaction. The data supports our hypothesis but the result is not significant.

Hypothesis 5. Quality of knowledge interaction is one of the important variables in the knowledge process; we hypothesized that the participants in a structured argumentation environment should have better quality of knowledge interaction. The data analysis does not support our expectation. We infer that the relationship between argumentation moves and the communication medium is an important factor; the participants in a structured argumentation environment may perceive constraints while they express their thoughts. For example, in the AAF system, the participants have to follow Toulmin's model to articulate their arguments and in a face-to-face setting, participants perceive some degree of socially contextual cues while they present their opinions.

Hypothesis 6. In a structured argumentation environment, participants may perceive effectiveness of learning in argumentation, and thus may provoke motivation in the activity. The data analysis support this hypothesis but there is no significant result.

Hypothesis 7. The relationship between problem-

solving ability and structured/unstructured CSCA settings is supported and is statistically significant. The data analysis yields an interesting finding that a good quality of argumentation interaction may promise the better outcome of problem-solving ability in negotiation types of task. Even the participants in the Email system have a good quality of knowledge interaction, but they acquire the lowest problem-solving ability score, and this may imply that engaging in argumentation does not necessarily result in good problem-solving.

## 6. Conclusions

We compared the means of subject knowledge, quality of argumentation interaction, quality of knowledge interaction, and the perception and participation between a structured argumentation-based software environment and a traditional argumentation-based environment. We found that the participants in the structured argumentation-based software environment have higher subject knowledge gain, higher quality of knowledge interaction, and higher perception and participation but lower quality of argumentation interaction compared to the participants in the traditional face-to-face argumentation environment. The data reveal that with the advantages of information technology participants experience easy articulation of their arguments and this increase in terms of subject knowledge. The results of this study indicates that the participants in a face-to-face interaction have the highest score of problem-solving ability, and participants in self-study have the second highest score of problem-solving ability.

The task for participants in this study is an open-ended problem-solving task; it can be categorized as a negotiation conflict-of-interest task, and therefore, the face-to-face communication model is the best fit to the task (according to Hollingshad *et al.*, [8]). The results support media-richness theory (MRT) which suggests that if task information processing requirements are matched with a medium's ability to convey information richness then this can improve task performance.

## Abstract

“Scaffoldings” states to let teachers provide a temporary support to help the students developing their self-scaffolding, this temporary support (the scaffolds) might be a kind of teaching facility or teaching strategy, as the capability of the learner advanced, the learning responsibility will shift gradually to the student, finally the student can dominate his/her learning, and through learning he/she shall build up his/her own knowledge. In this study, Internet and the Constructivist Scaffolding Teaching Theories are applied to develop a teaching model based on the “Research Method”- a program for the first year in graduate school, so that information technologies can be applied to make up the teachers’ deficiencies in terms of energy, time and capability. On the other hand, taking the advantages of the traditional teaching model face-to-face communication, and interaction to make up the deficiencies of Internet teaching. To realize the effects of this instructional model, experimentation is adopted in this study. Differences of learning results between constructive scaffolding teaching model with Internet assistance (CSTMIA) and the traditional teaching model (TTM) are analyzed.

The result of the study shows: (1) indeed the performance of the CSTMIA better improves the students’ learning achievement than that of the TTM, but it is not as good as the traditional teaching in terms of the learning performance, learning satisfaction and the growth of learning capabilities; (2) the result of the subsequent evaluation and analysis shows: based on the subjective realization from more than 60% of the students in the CSTMIA, they are positive toward the capability of such CSTMIA in the improvement of learning performance, learning achievement, learning satisfaction, interaction between teachers and the students, and the growth of learning capabilities, this proves that the CSTMIA implemented by this study helps improve the learning effect, strengthen the interaction between teachers and the students in certain extent. The contributions of this study are: (1) Based on the “Research Method” program, to develop that program’s Constructivist Scaffolding Teaching Model supplemented by Internet; (2) Based on the “Research Method” program, to see the influences of the Constructivist Scaffolding Teaching Model supplemented by Internet toward the learning performance, learning achievement, learning Satisfaction, interaction between teachers and

the students, and the growth of learning capabilities.

Key words : Scaffolding theory; Internet; Learning performance; Learning Satisfaction ; The growth of learning capabilities

## 1. Introduction

With the rapid development of technologies, computers can apply in wider areas than before. More and more people use computers on teaching for its convenience of two-way communication, vivid and vigorous media. They hope it can replace the single and dull traditional teaching environment. Moreover, bring about interests of learners to increase their learning effects. This kind of teaching activity with Computer-Based Training is becoming a pedagogical trend (Davis & Davis, 1990). In this study, a teaching model is developed with Internet and constructive scaffolding (CSTMIA) to tie it in the “Research Method” - a program for the first year in graduate school. On the one hand, information technologies can be applied to make up the teachers’ deficiencies in terms of energy, time and capability. On the other hand, taking the advantages of face-to-face communication and interaction of the traditional teaching model to make up the deficiencies of Internet teaching.

The developing technologies change the ways of learning and teaching. New teaching techniques should match up new teaching methods to emerge its specialty. The newly web-based instruction is a modern paradigm about applying new teaching media. Alavi (1995) addressed that use information technologies can increase added value of courses, enhance learning effects of learners, improve the effects of collaborative learning and teaching, and lower teachers’ loading and total teaching cost. Furthermore, students can be provided more integrated and richer learning contents.

Owing to information techniques highly developing and popularizing quickly, it made a great impact on recent education. To strengthen learning effects of traditional teaching and supplement the weakness of lacking face-to-face interaction in web-based instruction, many teachers and scholars believed information technologies can promote education innovation and renovate traditional teaching (Dexter, Anderson, & Becker, 1999; Dias, 1999). Computer integrated instruction and technology integration are often applied

to highlight the importance of teaching with information technologies integrated (Dias, 1999; Ertmer, Addison, Lane, Ross & Woods, 1999). Apply information technologies to curriculums and classrooms are discussed and it was regarded as a critical topic for curriculum integration with technologies. Many researches show that when implementing teaching with information technologies integrated, patterns and types of teaching will change (Dexter, Anderson, & Becker, 1999; Dias, 1999).

In recent years, computers play important roles in teaching for the advanced hardware and software. It also brings about many impacts on traditional teaching model. At the same time, it drives many studies toward distance teaching with the Internet. Scaffolding learning theories are usually discussed the learning effects in elementary and secondary school, or special education in Taiwan. Up to now, studies of learning effects are short of discussing scaffolding learning theories integrated information technologies for specific courses of university level. However, there have been successful researches brought up in other countries in this field (Kao, Lehman, 1997; Oshima & Oshima, 1999; Kao et al, 1996; Weston & Barker, 2001). Based on the mentioned background, applying Internet and ITs as teaching in universities has been gradually shaping. Internet teaching would be applied wider and wider in the future. The functions shall have more flexibilities and variety. The purpose of this study is to discuss and analyze the effects of CSTMIA for learning the Research Method course in graduate school. Teaching activities are designed under the foundation of scaffolding teaching theories. Analyses of teaching effects are preceded after the actual teaching programs, and then CSTMIA is also established.

According to the findings of relevant researches about scaffolding teaching theories, which would indeed improve learning effects. Hence, the purpose of this research does not lie in validating the scaffolding teaching theories. Instead, if learning effects can be enhanced by CSTMIA is the most concern and important discussion in this study. Therefore, there are several objectives would be achieved:

1. Focus on the course of "Research Methods", the constructive scaffolding teaching model is developed with Internet assistance (CSTMIA).
2. Discuss the differences of learning performance, learning satisfaction, interaction between teacher and students, and the growth of learning capabilities between CSTMIA and TTM.
3. Determine that if CSTMIA strengthen more than TTM in aspects of learning performance, learning satisfaction, interaction between teacher and students, and the growth of learning capabilities.
4. Analyze the influences of teachers' loadings as applying Internet on teaching.

## 2. Literature Reviews: Scaffolding Teaching Theories

Any pedagogical approach would have its own

theories basis and background. Scaffolding teaching theories is derivated from the sect of cognitive psychology; what is more, constructionism and collaborative learning are derivated as well form the same domain. Many relevant researches have proved that scaffolding teaching theories is helpful on promote learning effects. Wood et al. (1976) propose the term of scaffolding in 1976 and its main meaning is: growth of learner's psychological abilities rest on assistance from instructors or high-abilities peers, and this kind of assistance should ground on the learner's organization properties of cognition thereupon. Wood et al. (1976) also summed up six supports that scaffolding can offer: 1. Provoked students' learning, 2. Figured out key characteristics of learning objects, 3. Provided relevant examples for students to inspect and learn, 4. Lightened learning loads, 5. Managed directions of learning activities, and 6. Controlled the discouragement in learning process.

The basic concepts of scaffolding originated from the learning theories proposed by the Russian psychologist Vygotsky. He considered that social meanings and experiences of human cognition development process are transformed in personal and inherent meanings with the steps of innerize or action movements (Vygotsky, 1962). Vygotsky divided the levels of cognition development into real level of development and potential level of development. The former means the level that individuals can solve problems independently; the latter means the level that individuals only can solve problems with guidance or collaboration of others (instructors or high-abilities peer). The difference or gap between these two levels has been named zone of proximal development (ZPD) by Vygotsky (1978).

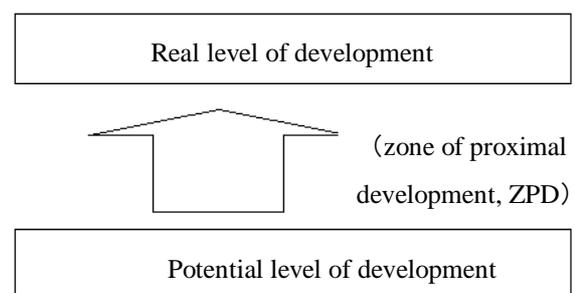

Figure 1: Scaffolding- Zone of proximal development (ZPD)

Scaffolding theory is founded on the concept of ZPD advocated by Vygotsky. Dynamic assessment in teaching, social interactions between learners, and learner's introspection progress are emphasized in this theory. Scaffolding proposes a temporary support to assist students developing their learning capabilities. This temporary support (the scaffolds) might be a kind of teaching facility or teaching strategy, as the capability of the learner advanced, the learning responsibility will shift gradually to the student, finally the student can dominate his/her learning, and through learning he/she shall build

up his/her own knowledge. Therefore, ZPD is regarded as one type of transfer of responsibility in learning processes (Rogoff & Gardner, 1984). Three important conceptions of scaffolding can be summed as follows:

1. In the ZPD, scaffolding supplier (teachers) and receivers (students) have mutually beneficial relationships. The mutually beneficial relationships mean that learning supports of teachers and interaction feedback of students should be decided via negotiation with each other.

2. Teachers ought to gradually shift learning responsibilities to learners, and when is the suitable time will depend on the actual learning states.

3. Communication between teacher and students is the approach that help learners introspect and cognize.

The final purpose of teaching by scaffolding is to achieve learning shifts and self-oriented learning for learners. It would assist learners in developing self-scaffolding for learning. Bickhard (1997) considered that when the scaffolds are defined as simplifying learning background (decrease obsession of choosing) and giving extra supports (guidance of choosing), that will make learners do wise learning. In this moment, learner's self-scaffold is defined that learner can integrate his/her learning content, make extract, and choose it. He/She can also look for outside resource (supports) at the same time. Several points can be concluded as below:

1. Transfer of responsibility: Teaching by scaffolding emphasized that the transfer of teaching will be gradually shifted from instructors to learners.

2. Dialogue of teaching: dialogues in learning progress are strongly stressed, which included instructors to learners and learners to learners.

3. Establish self-scaffolding for learners: The self-scaffolding, learner integration, instructional resource discovery, individual learning, and abilities of evaluating self learning are constructed from teaching by scaffolding.

According to many instruction researches, scaffolding theories is indeed beneficial to learning effects for students. However, teaching by scaffolding are mostly applied to kindergarten level or special education in Taiwan. Up to now, few instructional applications of scaffolding have implemented in university programs, and an instructional model hasn't been designed by using scaffolding with Internet assistance. There are several significant achievements about teaching by scaffolding, which are integrated to instruction media design (Kao & Lehman, 1997 ; Oshima, Oshima & Ritsuko, 1999 ; Kao et al., 1996 ; Weston, Barker & Lecia, 2001). A teaching environment of CAI with scaffolding is used to teach statistic for college students and its teaching effects is proven that scaffolding is helpful and useful. Nevertheless, teaching methods developed by these studies are almost limited in the scope of experimental teaching. Still more, these methods would cost lots of time or efforts and there are only few methods can be effectively implemented in real teaching environment.

This paper would focus on developing a constructive scaffolding teaching model with Internet assistance

(CSTMIA) to actually apply to practical teaching and increase learning effects for students. This CSTMIA teaching model is practically applied to a master degree program of "Research Methods" in graduate school. By using CSTMIA, refining of teaching, adoptive of learning, and improvements of learning effects can be expected.

### 3. Instruction Design

"Research Methods" is an obligatory course in graduate schools, which is also an important tool to train research abilities of students. Therefore, this course depends on deeply comprehension, discussion, and interaction between teacher and students. In the past, many students often felt confused and can't have in hand after learning it. Characteristics of scaffolding teaching focus on mutual discussion and emphasizing teacher's assistance for students' learning, both are suitable for applying it to this course. For these reasons, an instructional model of CSTMIA is developed for this course, and moreover actually implemented in graduate school to find out its effects or influences on teaching in master degree level.

#### 3.1 Implementation Process

In this study, there are two groups of objects. One group has 23 students, and those are full-time graduate students. The other groups are 25 graduate students, and all of them are at work. A 10-weeks experimental instruction would be preceded in this course at autumn semester in 2001.

To avoid Hawthorne effect, students are not informed that they had been observing in the 10-weeks. All of the learning activities and assessments of students are included in grades counting. All sample in this study are departed into two groups resulted from different teaching methods. The experiment group is those 23 full-time graduate students. The control group is those 25 graduate students at work. These two groups have their own class and these two groups can't do inter-communication easily, that would ensure reliability of this experimental instruction. Students of the experiment group would receive CSTMIA approach in this course; the control group would receive TTM approach in this course. All of these objects are students major in department of MIS in NKFUST, so that all of them have basic abilities about using computers and Internet. Simultaneously, most of them have similar intelligence, similar learning situation, and similar background of domain knowledge. They have little inter-difference on the whole.

#### 3.2 CSTMIA System

The CSTMIA system is constructed for applying to

the course of Research Methods in this study. It has three main parts within this system.

1. Homepage functions: 6 items
  - a. Member login: Members can login the learning community, it has a mechanism of password accounting. If someone forgot password, system will e-mail it to him/her.
  - b. Professional's bulletin: Nonscheduled articles of professionals would be posted to share or discuss for learners.
  - c. Hot news: Latest academic information would be provided to learners.
  - d. Top 10: The top 10 warmly discussing articles would be announced.
  - e. Daily term: A scholarly term will be introduced for learners each day.
  - f. Advertisement blocks: Give advertisement chances for business.
2. On-line Learning: This is the key element in CSTMIA system and it has several functional items. Areas for achievements share, knowledge share, and discussion are three sections.
3. Q&A Services: Providing solutions and answers for learners to clear up common problems of using Internet.

### 3.3 Instruction Contents

Based on scaffolding theories and relevant literature reviews, three instruction levels are designed to increase learning effects in this study. CSTMIA is developed to facilitate teaching activities; its contents of the three levels are summarized in table 1.

1. The 2-phase instruction: There are two phases instruction of this course. In the first phase, teacher is the core element. This study adopts a pedagogical approach with TTM and web-based learning to be a temporary support, which would help learners develop their learning capabilities. The second phase aims at transferring learning responsibilities to learners. Learners would complete assignment of research proposal by their own knowledge that learned from the first phase.
2. Dialogue of instruction: In the first phase, the dialogue mainly exists between teachers and students. Teachers guide the instruction and makes brainstorming with students, and students can give opinion freely. In the second phase, the dialogue mainly exists among students. Students guide their collaborative learning, and each one should discuss with others.
3. Instruction activities: To promote students discussing and enhance learning abilities, these instruction activities are integrated with CSTMIA. At the beginning of instruction, students are requested to configure their learning responsibilities and learning target. And then, a temporary support with teaching in classroom and web-based teaching are provided to learners, which is a transfer of learning responsibilities from teacher to students. Finally, learners would establish their own self-scaffolding.
4. Instruction process: Constructive is the major principle, and students are principal part of learning. Knowledge would construct from active cognition of learners, rather than being instill it into learners by instructor. Teacher is just a mediator of knowledge, who merely guides students to construct their own knowledge structure.

Table 1: Contents of scaffolding teaching

Levels of Instruction \ Contents	CSTMIA
Instruction model	... 2-phase instruction and dialogue of instruction ... An instructional approach integrated TTM and web-based learning.
Instruction activities	... Configure learning responsibilities and abilities. ... Transfer of learning responsibilities ... Establish self-scaffolding for learner
Instruction process	... Constructive

### 3.4 Design of CSTMIA

Definition of scaffolding is that the growth of psychological capabilities of learner would rely on assistance of instructor or high-ability peers. This kind of assistance should ground on the learner's organization properties of cognition thereupon. Scaffolding can provide several supports for learning: 1. Provoked students' learning, 2. Figured out key characteristics of learning objects, 3. Provided relevant examples for students to inspect and learn, 4. Lightened learning loads, 5. Managed directions of learning activities, and 6. Controlled the discouragement in learning process (Wood, Bruner & Ross, 1976). Instructors supply a temporary support to assist student inspect and learn. This temporary support (the scaffolds) might be a kind of teaching facility or teaching strategy, as the capability of the learner advanced, the learning responsibility will shift gradually to the student, finally the student can dominate his/her learning, and through learning he/she shall build up his/her own knowledge (Rogoff & Gardner, 1984). According to these explanations, the instruction model in this study would aim at characteristics of the "Research Methods" to develop CSTMIA teaching approach.

Hence, the instruction design in this study would base on the viewpoints of scaffolding supports for learning (Wood, Bruner & Ross, 1976). Most of all, Internet assistance would proceed the design of scaffolding teaching in this study. There are three stages in the whole instruction progress, including configure learning responsibilities and target, proceeding of teaching activities, and analysis of learning results. Practical experiment of instruction is 10-week, which is implemented in the course of Research Methods on students in graduate school. Those research objects are graduate students in their first year major in MIS. Tasks of sequential stages of instruction is described as figure 2.

## 4. Research Methods

### 4.1 Research Model

This paper mainly focuses on discussing the effects of TTM and CSTMIA. Learning performance (subjective part of cognition and objective part of grades), learning satisfaction, interaction between teacher and student, and growth of learning abilities are factors concerned. Furthermore, still discussed whether CSTMIA strengthen more than TTM in aspects of learning performance, learning satisfaction, interaction between teacher and students, and the growth of learning capabilities. Resulting from these purposes and referring theory background, research model of this study is established as figure 3.

### 4.2 Variables

Several variables are determined according to the research model. Independent variables and dependent

variables are summarized in table 2, and each has specific description of operational definition.

#### 4.2.1 TTM: Traditional teaching means

that instructional activities are proceeding in campus or in classrooms. Teacher and students place themselves in the same space. Students have to obey some behavior rules and communication types due to environment conditions. Most teachers still play the roles of teller or disseminator. Learners always passively receive message (Dismuke, 1995).

4.2.2 CSTMIA: The basic concepts of scaffolding originated from the learning theories proposed by the Russian psychologist Vygotsky. Scaffolding states to let teachers provide a temporary support to help the students developing their self-scaffolding, this temporary support (the scaffolds) might be a kind of teaching facility or teaching strategy, as the capability of the learner advanced, the learning responsibility will shift gradually to the student, finally the student can dominate his/her learning, and through learning he/she shall build up his/her own knowledge (Vygotsky, 1962; Wood et al, 1976). In this study, Internet and the constructivist scaffolding teaching theories are applied to develop a teaching model to be applied to make up the teachers' deficiencies in terms of energy, time and capability.

#### 4.2.3 Learning performance:

Learning performance is an indicator that used to evaluate learners' study achievements, and it's also a main item to assess teaching qualities. Learning types, curriculum design, and instruction methods would influence learning performance. In this study, the evaluation of learning performance will be discussed in two parts. One part of evaluation is preceded with investigating the increase of learning performance when students writing down research proposal. It is also equal to evaluate their subjective cognition of learning performance. The other part of evaluation is to investigate total reputation of learning performance by their grades. Assignment grades, behavior of discussion, and representation in class are included in this part. Therefore, the grade is a kind of objective indicator for evaluating learning performance (Doran & Klein, 1996).

4.2.4 Learning satisfaction: Learning satisfaction can be a pleasure feeling, positive attitude, achievement of wishes or requiring, or awareness of abilities enhancing after students participated in learning activities. Learning satisfaction is a feeling or attitude toward learning activities, and it would resulted from students' preference of learning activities or achievement of wishes or requiring (Knowles, 1970; Ridley, Miller & Williams, 1995).

Table 2: List of research variables

Independent variables		Dependent variables
z	TTM	<ul style="list-style-type: none"> <li>• Learning performance (subjective part and objective part)</li> </ul>
z	CSTMIA	<ul style="list-style-type: none"> <li>• Learning satisfaction</li> <li>• Interaction between teacher and students</li> <li>• Growth of learning abilities</li> </ul>

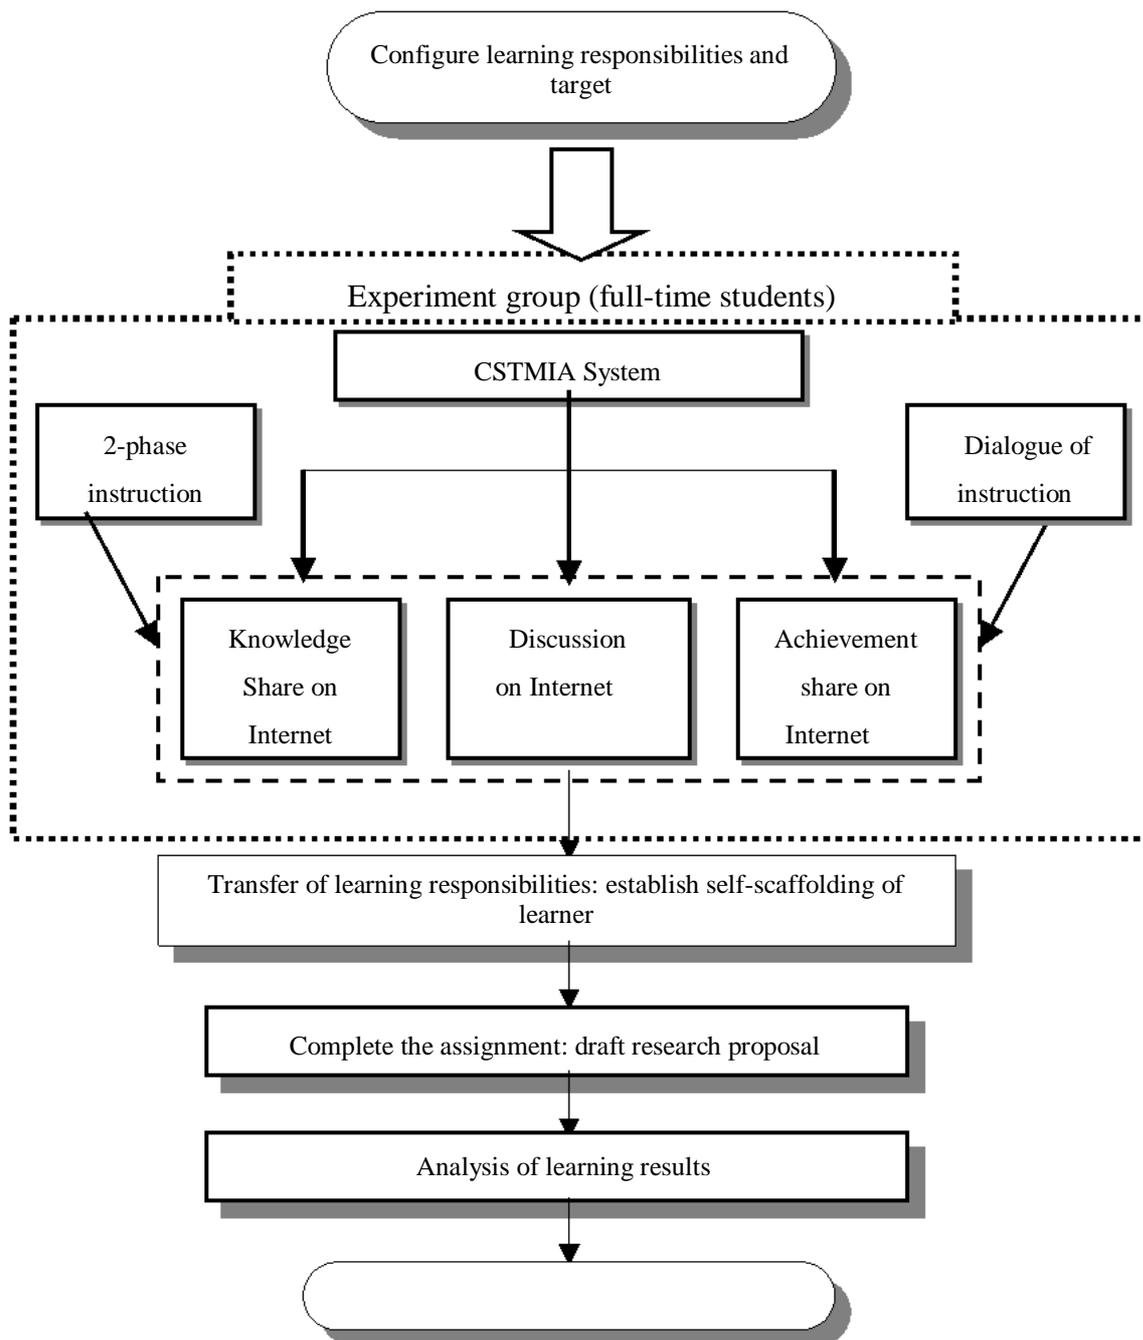

Figure 2: Tasks of sequential stages of instruction

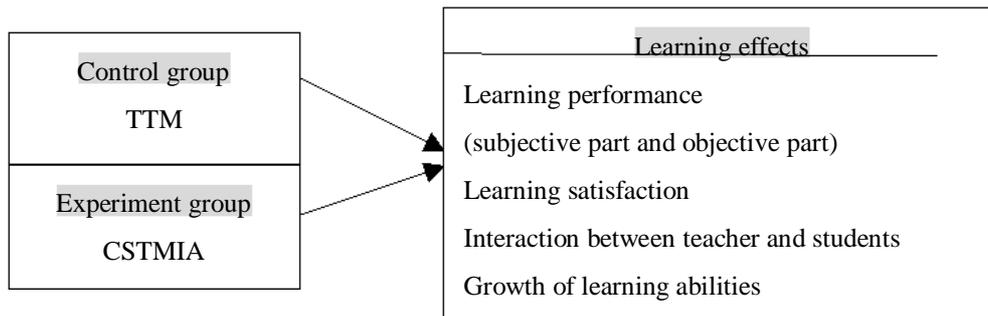

Figure 3: Research model in this study

#### 4.2.5 Interaction between teacher and students:

The process of communication between teacher and students to deliver words or non-verbal with E-mail or discussion areas at class or after class.

#### 4.2.6 Growth of learning abilities:

A set of behaviors or properties for determination, which indicate different level of learners in different attributes. The growth can be used to evaluate learning attitudes, strategy, interest, or the developing states of personality or affection.

There are several hypotheses made and induced from research purposes, reference, and research model in this study.

#### 4.2.7 The prediction of learning effects of CSTMIA and TTM:

Hypothesis 1:

CSTMIA cause better learning effects than TTM.

Hypothesis 1-1:

CSTMIA resulted of better grades of students than TTM.

Hypothesis 2:

CSTMIA cause better learning satisfaction than TTM.

Hypothesis 3:

CSTMIA cause better interaction between teacher and students than TTM.

Hypothesis 4:

CSTMIA cause more growth of learning abilities than TTM.

#### 4.2.8 If CSTMIA enhance more degree of interaction to learning effects than TTM:

Hypothesis 5:

CSTMIA enhance more degree of interaction to learning performance than TTM.

Hypothesis 5-1:

CSTMIA enhance more degree of interaction to learning grades than TTM.

Hypothesis 6:

CSTMIA enhance more degree of interaction to learning satisfaction than TTM.

Hypothesis 7:

CSTMIA enhance more degree of interaction to growth of learning abilities than TTM.

### 4.3 Questionnaires

There are two questionnaires designed to investigation in this study. One questionnaire is to investigate learning effects. This questionnaire refers to certain related questionnaire and it has validated by domain experts. The other questionnaire is to do subsequent evaluation and analysis. It is used to realize if CSTMIA can really enhance more degree of interaction to learning effects than TTM.

Both questionnaires have meet reliability requirement of Cronbach  $\alpha$  (all of them upper are than 0.7). The  $\alpha$  of four constructs of learning effects in the first questionnaire are larger than 0.7 (learning performance 0.9008, learning satisfaction 0.8530, interaction 0.8282, growth of learning abilities 0.7749). The  $\alpha$  of subsequent evaluation in the second questionnaire is 0.8348. Mention-above shows that questionnaires in this study are suitable and reliable.

### 4.4 Experiment design

To achieve the research purpose, experiment method is mainly adopted with static-group comparison in this study. Students in the experiment group adopt CSTMIA and the control group would adopt TTM instead. All of them have a 10-week learning schedule, and data collections in this period are served as empirical analysis. Differences between control group and experiment group are discussed, so do hypotheses validation.

### 4.5 Results

All data of questionnaire are collected and computed by One-way ANOVA method (under .05 significant level) to validate those hypotheses and confirm its effects. The statistic data are arranged in table 3.

Table 3: Statistic results of hypotheses

Hypotheses	p-value	Significance	Validation results
H 1	0.00373	***	Reject H 1
H 1-1	0.000	***	Non-reject H 1-1
H 2	0.000	***	Reject H2
H 3	0.0083	**	Reject H3
H 4	0.0049	***	Reject H4
H 5	0.000	***	Reject H5
H 5-1	0.000	***	Non-reject H 5-1
H 6	0.000	***	Reject H6
H 7	0.000	***	Reject H7

## 5. Discussion and Conclusion

### 5.1 The prediction of learning effects of CSTMIA and TTM:

Learning performance, learning satisfaction, interaction, and growth of learning abilities of CSTMIA have significant difference with TTM. The average grades of TTM are higher a bit than CSTMIA. The fact indicates that research results are just opposite to hypotheses. In order to realize this phenomenon, we've interview the teacher of this course and conclude some findings.

1. Students in the control group have stronger learning motives and positive learning attitudes.
2. Although students in the control learned with TTM, they performed better than comparing with the experiment group. Students in the control group always immediately ask questions they don't know in class.
3. Students in the control group have the courage to express their own opinion and viewpoints. They are able to warm discussions and issues without any guidance from teacher.
4. All students in the control group are at work and at least have 5 years experience of working. Their thinking abilities, representations, and achievement of learning target are indeed practiced well than students in the experiment group.
5. Students in the control group have more tricky attitudes on answering questionnaire because of their social experiences, therefore, more bias might be occurs than students in the experiment group as answering questionnaire. For this reason, the control group may have better effects. The subsequent evaluation and analysis can be deeply discussed the limitation to different learning groups in their learning motives.

In the part of learning grades, CSTMIA and TTM have significant difference in statistic analysis. The average grades of CSTMIA group have higher performance than TTM. We concluded several possible reasons of this result.

1. Students in the control group have more tricky attitudes on answering questionnaire

because of their social experiences, therefore, more bias might be occurs than students in the experiment group as answering questionnaire. For this reason, the control group may have better effects.

2. Learning grades is a total assessment, including daily performance, participation, assignment, etc. Most of all, the assignment of research proposal has largest proportion of grades, and teacher can grade students subjectively. Those would less cause bias than questionnaires.
3. Broadly, if eliminate the influences of objective factor and do subsequent evaluation to analyze results. CSTMIA would be still helpful to increase learning effects.

### 5.2 If CSTMIA enhance more degree of interaction to learning effects than TTM:

The level of interaction has positive correlation with learning performance, learning grades, learning satisfaction and growth of learning abilities. These results indicate that the more degree of interaction, the better learning effects would appear. If we can design certain mechanism that would stimulate students' participation, it would be a critical factor to increase learning effects. For example: apply a director of discussion area. The director would lead discussion, address issues, and make summary. If the director can lead members discuss some questions smoothly, learners will get used to this style of discussion. The discussion area will have its practical effects, and will enhance interaction between teacher and students to increase learning effects.

Although CSTMIA can merely increase learning grades as enhancing interaction to learning effects, learning performance, learning satisfaction, and growth of learning effects are not significant. After further investigation of this event, certain important clues can help to determine these appearances. The two samples of this study have great difference in learning motives, learning wills, learning enthusiasm, and participation. In other word, these two groups have inequality on their learning attitudes, and it will lead to worse results of experimental instruction. But it doesn't mean that CSTMIA is not good in this study, instead, most illnesses come from nature difference of samples.

There are some findings after the subsequent evaluation. Students in the experiment group adopt positive attitudes toward the CSTMIA approach. Therefore, CSTMIA is considered as beneficial tool and it would useful on increasing learning effects and enhancing interaction between teacher and students.

### 5.3 Impacts of teachers' loading as applying Internet to assist teaching:

After interviewing the teacher of this course, we concluded some findings.

1. It would shorten teacher lots of time and efforts on lecture by applying Internet to supports of examples, students can also easily learned key characteristics of learning objects.
2. The discussion area of CSTMIA system provides an on-line space to discuss, interact, and solve problems for teacher and students. They can communicate with each other and

lighten their learning loads of discussion as well. 3. Teacher can notice learning states of each student through discussion area. Teacher can also arrange instruction resource according to students' situation, which will decrease waste of efforts and shorten loads of time.

#### 5.4 Discussion and analyses of the subsequent evaluation:

The subsequent evaluation is quoted to comprehend students' subjective cognition about CSTMIA. We would like to know if CSTMIA could enhance more degree of interaction to increase learning effects after finishing the course of Research Methods. After analysis of the subsequent evaluation, more than 60% students in experiment group adopt positive attitudes toward effects of CSTMIA. They agree with the capability of such CSTMIA in the improvement of learning performance, learning achievement, learning satisfaction, interaction between teachers and the students, and the growth of learning abilities. This proves that the CSTMIA implemented by this study helps improve the learning effect, strengthen the interaction between teachers and the students in certain extent. The worse experiment results come from inequality on their learning attitudes of these two groups, and it will be influenced by man-made factors or subjective factors.

### 6. Contribution and Limitation

1. Establish a constructive scaffolding teaching model with Internet assistance on the course of Research Methods.

Scaffolding learning theories are usually discussed the learning effects in elementary and secondary school, or special education in Taiwan. Up to now, studies of learning effects are short of discussing scaffolding learning theories integrated information technologies for specific courses of university level or other higher education. Still more, these methods would cost lots of time or efforts and there are only few methods can be effectively implemented in real teaching environment. Hence, the first contribution of this study is to develop a CSTMIA pedagogical approach for actual practice to increase learning effects and being a basis for future reference by related courses.

2. Discuss the influence of CSTMIA to learning performance, learning grades, interaction, and growth of learning abilities.

Research Methods is an obligatory course in graduate schools, which is also an important tool to train research abilities of students. Therefore, this course depends on deeply comprehension, discussion, and interaction between teacher and students. In the past, many students often felt confused and can't have in hand after learning it. Characteristics of scaffolding teaching focus on mutual discussion and emphasizing teacher's

assistance for students' learning, both are suitable for applying it to this course. For these reasons, an instructional model of CSTMIA is developed for this course, and moreover actually implemented in graduate school to find out its effects or influences on teaching in master degree level.

3. Provide future reference for related studies

There are still few studies discussing about developing a scaffolding teaching model with Internet assistance in Taiwan. It is trusted that, results of this study can be a foundation of related studies and being a headstone for future complete model. For instance, sample selection ought to be more homogeneous in future days. The records of system logs about students' activities on web may be used to analysis. Adjust the proportion of grades on the part of participation and discussion to encourage students actively learning and discussion. Increase other assessment of performance evaluation in the initial stage and middle stage of semester, which will help to interpret learning curve in the process.

Undoubtedly, there are still some limitations in this study. On sample selection, it doesn't follow the principle of complete random sampling. Because the instruction experiment is practiced with unit of class, external validity may be influenced by the limitation of self-selection. That will make inference incomplete. Furthermore, the length of period of experiment time may influence learning effects too. Two conditions of time may be included for future discussion: Is a 10-week cycle of experiment appropriate? Is on-line time of using Internet resource will influence learning wills? Finally, bias of research data collection may be influenced by subjective factors of students. Those subjective factors can be personality or learning styles of students, or students' identification of teacher or this course. Most of these factors would influence research results.

## Abstract

Creating successful transaction actions to retain customers for future re-purchasing is extremely important in fiercely competitive environments. Moreover, different market strategies should be practiced for customers with different lifetime values and loyalty ratings. This work proposes a method, which combines clustering analysis and multiple criteria decision-making approach to evaluate customer lifetime value ratings, and construct the classification rules for individual clusters in market segmentation. An empirical case involving a hardware retailer is illustrated to show the usefulness for evaluating customer lifetime value ratings.

## 1. Introduction

A number of studies have discussed the evaluation of customer lifetime values (CLV) in terms of RFM (Recency, Frequency, and Monetary) [3][4][5][6][7][14][15][11]. Goodman [3] suggested that RFM method would avoid focusing on less profitable and instead allow these resources to be diverted to more profitable ones. From the behavioral perspective, the RFM measuring method is an important method for assessing the relationship between enterprise and customers.

Hughes [5] proposed a method for RFM scoring, which involves sorting the real data of RFM individual into 5 customer quintiles. Meanwhile, Stone [15] hypothesized that different weights should be assigned to RFM variables according to industry characteristics. To analyze the value of customers who paid using credit cards, Stone suggested placing the highest weighting on the number of purchases, followed by the period of purchase time, while placing the lowest weighting on the amount of purchases. Although various combinations and weightings have been proposed, judging and weighting RFM variables remains subjective.

This study uses an analytic hierarchy process (AHP) [12][13] to evaluate the importance (weight) of each RFM variable by the perception of decision makers. The K-means clustering is used to group customers into those with similar lifetime values or loyalty based on the performance value of RFM. Each target market can be further ranked using multiple criteria decision making (MCDM) approach. Finally, classification rules are determined for each cluster using the decision tree

algorithm C5.0. The classification rules are employed to predict other potential customers regarding their groups and loyalty ranking. The case of hardware retailer is used for the sake of illustration.

The remainder of this study is organized as follows. Section 2 reviews related work in evaluating CLV. Section 3 then outlines the methodology used herein. Next, Section 4 presents a case study for evaluation. Section 5 construct rulesets for target market using a decision tree approach. Finally, the conclusion summarizes the contributions of this study and outlines areas for further research.

## 2. Related work

### 2.1. Market segmentation

Chen et al. [2] noted that clustering is one of the data mining tools used to discover knowledge processes. Clustering aims to maximize variance among groups while minimizing variance within groups. In clustering, many algorithms have been developed, such as k-means, hierarchical, fuzzy c-means approaches and so on.

This study applies K-means method to cluster customers based on their CLVs. The K-means method involves iterative improvement that can compensate for a poor initial partition of data. The number of clusters must be predetermined with the K-means method.

### 2.2. Evaluation of CLV

Bult et al. [1] explain the RFM terms as follows: (1) R (recency): time period since the last purchase, and the lower the value is, the higher the probability of the customer making a repeat purchase; (2) F (frequency): number of purchases made within certain time period; higher frequency indicates higher loyalty; (3) M (monetary): the amount of money spent during a certain time period; increasing monetary contribution from customers indicates increased focus on the company supplying the products.

Hughes [5] developed a widely used method for evaluating RFM. Each RFM is divided into 5 quintiles. With the ordering of customers from the top to the bottom, in the increasing order of recency values, the R scores of top 20% customers are set to 1, while those of the bottom 20% customers are set to 5. The F scores and M scores are assigned similarly, using the decreasing order of

frequency and monetary values, respectively. Accordingly, the RFM score of the best customer equals 111, while that of the worst equals 555. Different marketing strategies can thus be developed for different customers. Stone [15] hypothesized that the weights of RFM variables vary depending on industry characteristics. To analyze the value of customers with credit cards, Stone proposed that the frequency should be assigned the highest weighting, followed the recency, and finally, the monetary.

In practical applications, RFM variables need to measure different weights in different industries (e.g., [15]). However, Stone [15] determined the RFM weightings subjectively, without using a systematic approach or evaluation to determine the RFM weightings. This study employs AHP to evaluate each weight (relative importance) among RFM variables, and specifically asks decision makers to make intuitive judgments about ranking order to produce pairwise comparisons.

### 2.3. Decision tree

The earliest decision tree algorithm was extended from Concept Learning System (CLS) – Iterative Dichomizer 3 (ID3), which works by computing a metric known as the information gain ratio [8]. The spirit of decision tree is achieved by maximizing the information gain threshold at each node in the decision tree and the way to evaluate is based on classification validation. The ID3 has been refined into C4.5 by [9]. This study uses the latest C5.0 algorithm proposed in 1998, and the See5 software released by the company Rulequest [10].

## 3. Methodology for evaluating CLV ratings

This study proposes a method that combines clustering analysis and MCDM approach to evaluate the customer lifetime values or loyalty based on weighted RFM. Figure 1 shows the proposed methodology.

(1) Prepare a marketing database from enterprise; and remove nonsensical records such as those of customers who have purchase amount but never create any transactions. Next, the characteristics and purchase behavior of consumers are generated using simple statistics.

(2) Extract RFM variables for each customer to evaluate their lifetime values.

(3) Segment the market according to customer lifetime values by K-means; use the analysis of variance (ANOVA) to test whether RFM significantly discriminates against these market segments; and rank each market by MCDM with two models for comparison: one, without any preference, meaning equal weights among RFM, and the other with preferences, i.e., weight assessment is based on the AHP [12][13].

(4) Construct the classification rules for each market segmentation, and predict another potential customers by See5/C5.0.

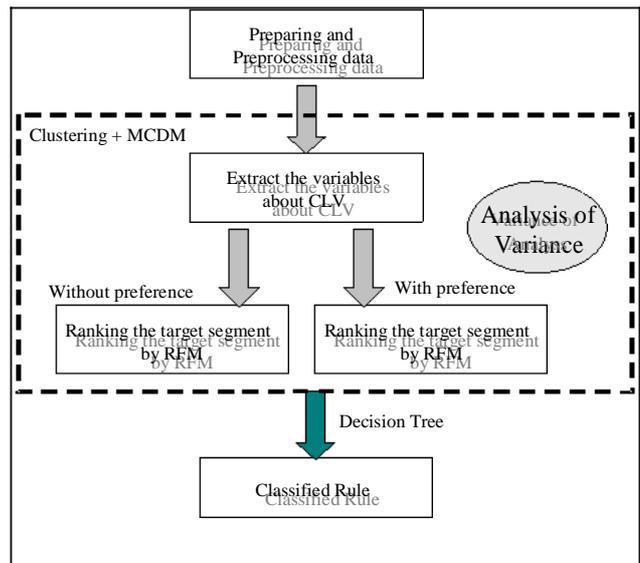

Fig. 1. Methodology for evaluating CLV ratings

## 4. Empirical study

An empirical case is used to show the usefulness of our approach for evaluating CLV ratings.

### 4.1 Preprocessing the data set

The empirical study is conducted using a data set collected from a company that manufactures wheels, casters, platform and hand trucks for industry, medical, hospital equipment and institutional purpose. The data set comprises 7,500 customers and 70,000 purchases records. These data were gathered from 2000/1 to 2002/4. Four related tables of transactions (Product, Transaction, Customer and Customer\_classify) were extracted. After removing unreasonable records, the remaining contains 60,000 records.

Specifically, in the table Customer\_classify, there are 3 types of customers, retailers, assembly industry and end users. Since the purchase records of retailers cover over 50% of all purchase records, this study analyzes the purchase records of retailers, which contains 984 customers.

### 4.2 Extracting the RFM values

Table 1 shows the RFM values for each 984 customers in hardware retailers, which are extracted from the dataset to measure CLV.

Table 1. RFM values for each customer

Customer no.	R	F	M
1108001	65	434	1252430
1108003	411	7	37930
...	...	...	...
1860003	159	87	313763

### 4.3 Evaluating CLV ratings with RFM clustering

#### 4.3.1 Identifying target groups

The K-means method is used to group customers with similar lifetime value or loyalty. Eight possible combinations of inputs pattern (RFM) are made from  $2 \times 2 \times 2$ . Table 2 shows the result. The average RFM variable values for each cluster are then compared with the total average RFM values of all clusters (163.57, 40.38 and 159481.1). If the average exceeds the total average, an upward arrow  $\uparrow$  is given, while if the opposite occurs, a downward arrow  $\downarrow$  is given.

Table 2. The result of K-means clustering

Cluster no.	Total Customers	Pattern
1	19	R $\uparrow$ F $\uparrow$ M $\uparrow$
2	136	R $\uparrow$ F $\downarrow$ M $\downarrow$
3	54	R $\uparrow$ F $\downarrow$ M $\downarrow$
4	30	R $\downarrow$ F $\uparrow$ M $\uparrow$
5	136	R $\downarrow$ F $\uparrow$ M $\uparrow$
6	467	R $\downarrow$ F $\downarrow$ M $\downarrow$
7	94	R $\uparrow$ F $\downarrow$ M $\downarrow$
8	48	R $\uparrow$ F $\downarrow$ M $\downarrow$

Analysis of variance is conducted to test whether RFM variables could discriminate 8 clusters. The analysis result would reject  $H_0$ , because the p-values are significant ( $p < 0.05$ ). Thus, the result confirms that 8 clusters would be discriminated based on recency, frequency and monetary significantly.

Customers in cluster 4 and 5 have the same characteristics, both their average recency are less than the total average; frequency and monetary are greater than the total average (R $\downarrow$ F $\uparrow$ M $\uparrow$ ). Consequently, the customers in cluster 4 and 5 can be considered to be loyal customers who frequently visit and make large purchase.

Cluster 2, 3, 7 and 8 show the pattern of R $\uparrow$ F $\downarrow$ M $\downarrow$ , and are likely to be the clusters with customers of least loyalty. Such customers almost never visit and make transactions. Furthermore, they generally only make purchases during sales. Enterprises can reduce prices to attract these customers, but in so doing will suffer reduced margins. Cluster 6 displays the pattern of R $\downarrow$ F $\downarrow$ M $\downarrow$  and may represent new customers who have recently visited the company to make purchase.

Finally, Cluster 1 displays the pattern of R $\uparrow$ F $\uparrow$ M $\uparrow$ , and represents customers who may once have enjoyed a good relationship with the company, and have higher than average purchase frequency and purchase amount. However, customers in this cluster have not made transactions recently, possibly because of moving their businesses or bankruptcy.

#### 4.3.2 Rating without preference on RFM

This section evaluates the rating on market segmentations, without preference on RFM variables, i.e.,

the RFM criteria have equal weight. Let  $w = [w_R, w_F, w_M]$ , where  $w_R, w_F, w_M$  represent the weight (relative importance) on RFM, respectively. The MCDM approach to evaluate the customer lifetime value ratings is illustrated as follows.

##### (1) Determining the RFM weightings

Herein,  $w_R = w_F = w_M$ .

##### (2) Constructing the normalized performance matrix

The normalized performance matrix  $D$  contains 8 clusters associated with the RFM criteria. The 8 clusters are generated using K-means method based on RFM, as illustrated in Section 4.3.1. Let  $x_{ij}$  be the performance value of the  $i$ th cluster with respect to the  $j$ th RFM criteria in  $D$ .  $x_{ij}$  can be derived via computing the average R, F, and M value for each cluster  $j$ . Moreover, the normalized performance value ( $r_{ij}$ ) of each cluster is derived as follows: the profit form,  $r_{ij} = (x_{ij} - x_j^-) / (x_j^* - x_j^-)$  is used to normalize the frequency and monetary values, since they positively influence CLV or loyalty. The cost form,  $r_{ij} = (x_j^* - x_{ij}) / (x_j^* - x_j^-)$  is used for recency, since it has negative impact on CLV. Notably,  $x_j^*$  is the best performance value of all in  $j$ th criterion;  $x_j^-$  is the worst.

##### (3) Ranking the performance order

The weighted normalized performance value,  $v = [v_1, v_2, \dots, v_8]^T$ , can be derived by multiplying the normalized performance matrix  $D$  and the  $w^T$ , i.e.,  $v = [D \times w^T]$ . The rankings of each market segmentation (cluster) can be determined according to the weighted normalized performance values of clusters, as shown in the right most column of Table 3. For example, the loyalty ranking of market segmentation 4 (cluster 4) equals 1.

Table 3. The rating of clusters without preference on RFM ( $w_R, w_F$ , and  $w_M$  are equal)

Cluster no.	R	F	M	Weighted Performance Value (v)	Loyalty Ranking
1	0.71	0.39	0.47	1.58	3
2	0.81	0.06	0.04	0.91	5
3	0.61	0.02	0.02	0.65	6
4	1.00	1.00	1.00	3.00	1
5	0.99	0.39	0.30	1.69	2
6	0.98	0.09	0.07	1.13	4
7	0.37	0.07	0.07	0.50	7
8	0.00	0.00	0.00	0.00	8
Average	0.68	0.25	0.25		

The fourth cluster displays the highest loyalty (Table 3), followed by the fifth cluster. That appears especially clear for decision makers to know which market segmentation is the main target of a company. Table 3 indicates that cluster 2, 3, 7 and 8 are the disloyal groups of customers, with group 8 being the worst, and thus the

company should pay less attention to these groups and distribute less resource to them.

### 4.3.3 Rating with preference on RFM

This section conducts experiment to determine the ranking of CLV or loyalty for market segmentations (clusters) based on weighted RFM. AHP [12][13] is first used to assess the weightings (preferences) among RFM variables.

Three groups of evaluators exist: (a) 3 administrative department (managers); (b) 2 sales division (business manager, sales) and 1 marketing consultant; and (c) 5 customers who have made purchases. The above groups were invited to evaluate the criteria weightings. Data were gathered by interviewing evaluators, and an interview was conducted via a questionnaire (see Appendix, Table 5), with the answers being expressed in the form of a pairwise comparison matrix (see Appendix, Table 6).

#### (1) Determining the RFM weightings

According to the analytical result of AHP,  $w_R$ ,  $w_F$ , and  $w_M$  are 0.7306, 0.1884 and 0.081, respectively.  $w_R$  has the highest ranking, followed by  $w_F$  and  $w_M$ . The implication of this ranking on the preference of RFM is as follows. Recency is the most important, since the unit price of hardware products is relatively low, and thus evaluators only care about whether customers purchase continuously or not. In addition, customers, without any transaction activities in long periods, could have been lost or have transferred to new vendors.

#### (2) Constructing the normalized performance matrix

This step of constructing the normalized performance matrix D is the same as the step (2) in Section 4.3.2.

#### (3) Ranking the performance order

This step of ranking the performance order is similar to the step (3) in Section 4.3.2, except that  $w_R$ ,  $w_F$ , and  $w_M$  are different, as derived from step (1). Table 4 shows the result of the rating on market segmentations, according to the preferences on RFM variables.

The ranking between cluster 1 and 6 in Table 4 differs from that in Table 3. That seems reasonable. For cluster 1 in Table 4, the frequency (0.39) and monetary (0.47) are higher than the total average F (0.25) and M (0.25). However, the time period since last purchase (recency) is very long, indicating that the customers in this cluster may have been lost or have transferred to other vendors.

For the cluster 6 in Table 4, although the frequency (0.09) and monetary (0.07) were lower than the total average, the recency (0.98) indicates that they have recently been active. Marketers should devote greater effort to retaining customers in cluster 6 than those in cluster 1. However, if individual RFM weightings are not considered, as the result shown in Table 3, cluster 1 ranks ahead of cluster 6. The comparison implies that the proposed approach may be a better method for evaluating

the ranking of CLV, and the result is consistent with decision makers.

Table 4. The rating of clusters with preference on RFM ( $w_R$ ,  $w_F$ , and  $w_M$  are different)

Cluster no.	R	F	M	Weighted Performance Value (v)	Loyalty Ranking
1	0.71	0.39	0.47	0.63	4
2	0.81	0.06	0.04	0.61	5
3	0.61	0.02	0.02	0.45	6
4	1.00	1.00	1.00	1.00	1
5	0.99	0.39	0.30	0.82	2
6	0.98	0.09	0.07	0.74	3
7	0.37	0.07	0.07	0.29	7
8	0.00	0.00	0.00	0.00	8
Average	0.68	0.25	0.25		

### 4.4 Classifying the target groups

See 5 software [10] based on C5.0 algorithm is used to construct decision tree and classification rules for each cluster. These classification rules are used to predict other potential customers belonging to which target market and mapping to which loyalty ranking. This approach can help decision makers to consider relevant marketing strategies. The samples are randomly divided into calibration (70%) and validation (30%) of total customers (984). The calibration samples are used as a training set to construct the classification rules, and then validation cases are classified for testing. The accuracy rate is critical to validating the classification result.

Each rule summarized the performance using the statistics (N/E, lift L) or (N, lift L) where: (1) N denotes the number of training cases covered by the rule; (2) E (if shown) represents the number of training cases covered that do not belong to the rule's class. Meanwhile, the accuracy of the rule is estimated by the Laplace ratio  $(N-E+1)/(N+2)$ ; (3) L is the estimated rule accuracy divided by the previous probability of the rule class. Taking rule 9 as an example, if Recency  $\leq 117$  and Frequency  $\leq 63$ , then cluster 6 contains 325 customers. The accuracy of the rule is estimated to equal 0.997.

Rule 9: (325, lift 2.1)

Recency  $\leq 117$  Frequency  $\leq 63$  class 6 [0.997]

Finally, the classification result of the calibration and validation samples is evaluated. 11 rule sets are produced to classify 8 different clusters. The result shows 3.4% error rate of classification for validation samples.

### 5. Conclusions

In this paper, an analytical approach, combining clustering analysis and MCDM approach, is proposed to evaluate CLV ratings. The analytical result demonstrates that our approach would define the target market more

clearly via AHP weighting and performance ranking than without weighting on RFM. The result helps market practitioners to make more effective strategies for retaining customers.

Moreover, to target potential customers, this study uses the classification approach to predict other potential customers for future purchases. Decision tree algorithm – C5.0 is used to classify these clusters (market segmentations) generated by K-means clustering. Classification rules based on RFM variables are extracted to classify 8 clusters. The result shows 3.4% error rate of classification for calibration samples.

There are two limitations of our study. First, we experimentally evaluate our approach on the data set collected from hardware retailers. Although customer purchase behavior are often available in marketing database, customer privacy and security concerns cause difficulty in obtaining more databases to verify whether our approach would be appropriate to other application domains, such as supermarkets or electronic commerce. Second, we assume that the relationship among RFM variables is linear. In fact, the purchase frequency always affects purchase amounts, and thus further research is required to relax the linear assumption.

## Appendix

Table 5. AHP questionnaire sheet for RFM

Importance degree										
Criteria	9	7	5	3	1	3	5	7	9	Criteria
Recency	9	7	5	3	1	3	5	7	9	Frequency
Recency	9	7	5	3	1	3	5	7	9	Monetary
Frequency	9	7	5	3	1	3	5	7	9	Monetary

Table 6. Retailer’s RFM pairwise comparisons matrix

	Recency	Frequency	Monetary
Recency	1	5	7
Frequency	1/5	1	3
Monetary	1/7	1/3	1

## Abstract

Knowledge Management (KM) is the process of managing organizational knowledge from creating business value that will focus on creating and delivering innovative products or services and managing relationships with existing key stakeholders in the context of Customer Relationship Management (CRM). The value of KM and CRM is well recognized by many leading companies. Application of Knowledge-enabled Customer Relationship Management (KCRM) is a great opportunity to increase the customer value and provides a way to systematically attract, acquire and retain the customers. This study has taken a beauty enterprise as an example and focused on its franchise stores to perform a field study. A strategic knowledge-enabled CRM framework is introduced in order to classify the subjects by customer-oriented perspective. From the responses of the surveyed beauty enterprise, it is demonstrated how the companies can develop their customer connection strategies based on their current and future positions in four dimensions of the value compass model. Moreover, this study presented a conceptual model of KCRM to see how KM can help CRM implementation.

Keywords: Knowledge Management, Customer Relationship Management, e-Business

## 1. Introduction

Electronic Commerce (EC) has changed the traditional focus of Information Technology (IT) and created a fast-changing business environment. Within such a competitive environment, long-term relationship with customers is one of the most important assets in the companies, which can increase their competitive advantages and improve their profitability substantially. E-businesses focus on their marketing efforts on building lasting relationship with customers through CRM and better understand what customer wants and needs becomes obvious [6]. Conducting business through electronic commerce, the handling of transactions over communications networks, continues to grow in a seemingly unabated fashion. Recently, several leading companies have taken advantage of the CRM power to expand their markets sharply [7]. These companies

establish CRM systems to maintain and further create loyal customers. Unfortunately, most of the companies have limited knowledge about CRM and ignore its importance. It is a common sense that the loss of good opportunity to better serve customers may create great opportunity for the competitors to increase their market share. In response to increasingly competitive environments, companies examine how they can better leverage knowledge assets and create added value. Davenport and Prusak [4] have emphasized that KM addresses the issues of creating, capturing, and transferring knowledge-based resources. Taking the beauty industry as an example, the improvement of the customer relationship for a company in the beauty industry can therefore generate great business opportunity. This study has taken the beauty industry as an example to perform a comparative study between Taiwan and China. A strategic KCRM framework is introduced in order to classify the subjects by customer-oriented perspective. In specific, this paper studies four interrelated objectives in order to get a holistic view of customers and their relationship to the entire enterprise as follows.

1. Provide a framework of KCRM.
2. Conduct a comparative study of KCRM between Taiwan and China franchise stores.
3. Discuss opportunities for Taiwan and China beauty Industry to leverage customer knowledge and to create value for customers based on the findings.
4. Help Taiwan and China beauty industry understand the needs of each other and further find the possibility to develop the new market.
5. See how KM can help CRM implementation.

## 2. Literature review of CRM and KM

Tiwana [11] defined Knowledge-enabled Customer Relationship Management (KCRM) as "Managing customer knowledge to generate value-creating lock-ins and channel knowledge to strengthen relationships and collaborative effectiveness, Knowledge-enabled CRM is more of a business model/strategy than a technology-focused solution." He clearly identified knowledge management and customer relationship management for every business decision-maker and IT professional. The availability of large volume of data on

customers, made possible by new technology tools, has created opportunities as well as challenges for businesses to leverage the data and gain competitive advantage. Shaw et al. [10] have presented a systematic methodology that uses data mining and knowledge management techniques to manage the marketing knowledge and support marketing decisions. Lesser et al. [3] have identified four approaches (customer knowledge development dialogues, facilitating the capture of knowledge relevant data, demonstrating enterprise leadership commitment to customer knowledge) that can expand the availability and use of customer knowledge. Lin [5] presents a systemic integrated communications model that may help enterprises identify the potential issues of CRM. Wayland and Cole [12] have presented the Value Compass model which makes explicit connection between what managers know about their customers and how they can leverage that information to create customer value. Arthur Andersen Business Consulting [1] identified that customer knowledge base is one of the ten high performance of KM. So CRM together with Knowledge Management (KM) could be further studied.

As shown from these researches, directly related to and underlying CRM is the emerging discipline of KM. Although a surge in emphasis and interest on both CRM and KM such as popular press reports, books, conferences, the growing number of CRM and KM systems, vendors, consultants and so on. Massey et al. [9] have explored the leading company IBM's first effort to re-engineering the CRM process by leveraging technology and its knowledge-based resources. Moreover, enabling CRM through KM inside IBM represented a full-fledged business approach to the acquisition, assembly, and application of knowledge to the CRM process.

### 3. Research Model

#### 3.1 Problem background

The beauty enterprise in this study has the most franchise stores in Taiwan and most expert Taiwan-based multinational beauty conglomerate. It manufactures a great variety of products in Taiwan and has markets the superb quality products into the world markets in its own brand for a long time. It has further expanded its service for worldwide counterparts in the UK, France, Italy, Germany, the United States, Uruguay and Argentina. In the integral global structure under the brilliant leadership, this beauty enterprise constantly insists on corporate philosophy of research, education, services and promotion; combining research, production, training, marketing, promotion and service into a whole. Unlike conventional marketing of franchises, it features diverse, international, systematic and standard management to assure integration in education, technologies theories, products, equipment, systems, trademarks, ads, marketing and management and, furthermore, develop the world-admired marketing networks. This beauty

enterprise now has around 600 franchise stores in Taiwan and 2000 franchise stores in China. Knowing their customers better is very important especially through KCRM.

In our conceptual model, we will consider strategic analysis of CRM and further see how KM can help the process of CRM implementation successfully. The conceptual model is displayed in Figure 1.

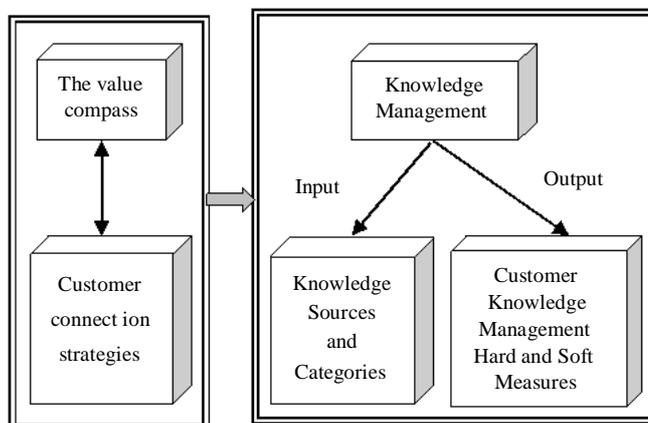

Figure 1 The conceptual model

#### 3.2 Strategic analysis of KCRM

Based on our previous studies [6] [7] [8], Wayland and Cole's [12] value compass model will help to do strategic analysis of CRM. Customer knowledge, customer-connecting technology, and customer economics are the foundations of customer-connected strategy. They make it possible to determine where a business can position itself along each of the four dimensions of the value compass model.

The four dimensions of the value compass model provide ways for business to identify and manage customer relationships, to measure business's contribution to its customer value chain, to decide the position of the company within the industry value-added chain, and to decide, on this basis, which customers and suppliers can create and share better value. A comparative study of KCRM between Taiwan and China franchise stores can evaluate where they are on the value compass model at present and in the future and furthermore get ideas about KCRM strategies.

#### 3.3 How KM can help the process of CRM implementation

Beckman [2] identified 8 steps of KM: knowledge identify, knowledge capture, knowledge select, knowledge store, knowledge share, knowledge apply, knowledge create and knowledge sell. This study took advice from 5 senior managers of the beauty enterprise and select 5 steps: knowledge select, knowledge capture, knowledge share, knowledge create and knowledge store.

Tiwana [11] provided knowledge source and categories such as markets, competitions, customers, orders, contracts, products and services, problems and best practices. Basically, knowledge about these sources and categories must be integrated into a knowledge-enabled CRM strategy. In general, that what can be measured is not always important, and what is important cannot always be measured. The example of hard and soft measures from Tiwana [11] can serve the indicators of the business impact of customer knowledge management (As shown in Table 1). Our concept is to identify how important the knowledge sources and categories and customer knowledge management hard and soft measures are. Moreover, how KM is so important and can further help the process of CRM implementation.

Table 1 Hard and soft measures [11]

Hard	Soft
Cost savings	Customer satisfaction
Customer retention	Customer loyalty
Repeat purchases	Customer and employee productivity
Market share	Employee loyalty
Customer acquisition rate	Employee empowerment
Cost of sales/expense reduction	Defection likelihood
Stock valuation	Market leadership
Bottom-line effects	Organizational stability
Profit margins	Cultural change

### 3.4 Hypothesis development

The hypothesis development is identified as follows and will be explained later.

- H<sub>1</sub>: There is significant different between current and future position of the value compass model in Taiwan.
- H<sub>2</sub>: There is significant different between current and future position of the value compass model in China.
- H<sub>3</sub>: There is significant difference between Taiwan and China in the KM dimension.
- H<sub>4</sub>: There is significant difference between Taiwan and China in the customer resources and categories dimension.
- H<sub>5</sub>: There is significant difference between Taiwan and China in customer knowledge management hard and soft measures dimension.

## 4. Research method and design

This study proceeded in three phases. First, a qualitative approach that included a literature review was

employed. The purpose of this phase was to get basic knowledge about the topic. Secondly, a quantitative approach that included the development of a questionnaire was conducted. Lastly, the deep case study was conducted to validate the research findings, to assist in the interpretation of the results and to see how KM can help CRM implementation. We aimed to ascertain:

- (1) Where are the current and future marketing strategies for the franchise stores of the beauty enterprise in Taiwan and China on the value compass model ?
- (2) How do these franchise stores consider about their customer connection strategies ?
- (3) How KM can help CRM implementation successfully for the beauty enterprise ?

Phase three of this research involved a further case study stage. The purpose of this phase was to discuss the research findings with interviewees of the beauty enterprise in order to explain and validate the findings of the questionnaire.

## 5. Research findings

This field study focused on the selected beauty enterprise and the questionnaires were sent to 35 franchise stores in Taiwan and 70 franchise stores in China. The questionnaires were sent by its headquarter and all returned. There were 30 available responses from 35 franchise stores in Taiwan and 66 available responses from 70 franchise stores in China. An analysis of scale reliability was performed using Cronbach's alpha coefficient. The final scale reliabilities were 69.18% for knowledge management (5 items), 79.69% for knowledge sources and categories (8 items), and 84.68% for customer knowledge management hard and soft measures (2 item).

### 5.1 Strategic analysis of KCRM

The strategic analysis of KCRM will be separated into two parts.

- (1) The value compass

The current and future position for the subject on the value compass in Taiwan and China are shown below in Table 2. As shown below in Figure 2, the franchise stores in Taiwan current stay on market, extended offer, product manager and neutral and will more to market, extended offer, network manager and outcome levels. In the Figure 3, the franchise stores in China current stay on market, extended offer, process manager and performance levels and will stay on market, extended offer, network manager and outcome levels in the future. Clearly, although there is difference between Taiwan and China currently, they have the same future view on the value compass model. According to H<sub>1</sub> and H<sub>2</sub> as mentioned before, Table 3 indicates the results as follows. It seems that there is no significant

difference between current and future position in all dimensions of the value compass model in Taiwan. However, there is significant difference between current and future position in value proposition design, value-added role, and reward and risk sharing dimensions of the value compass model in China. Not surprising, China economics is growing like flying. The people in China expect a lot of progress in the future. So these three dimensions have to be urgently considered to change.

Table 2 The current and future positions on the value compass in Taiwan and China

Dimension		Taiwan		China	
		Current	Future	Current	Future
Customer portfolio management	Market	17	21	41	42
	Group	7	8	21	20
	Individual	6	1	4	4
Value proposition design	Core product	4	2	14	20
	Extend offer	13	15	37	29
	Total solution	13	13	15	17
Value-added role	Product manager	18	9	23	20
	Process manager	7	9	30	19
	Network manager	5	12	13	27
Reward and risk sharing	Neutral	15	10	20	20
	Performance	10	9	31	20
	Outcome	5	11	15	26

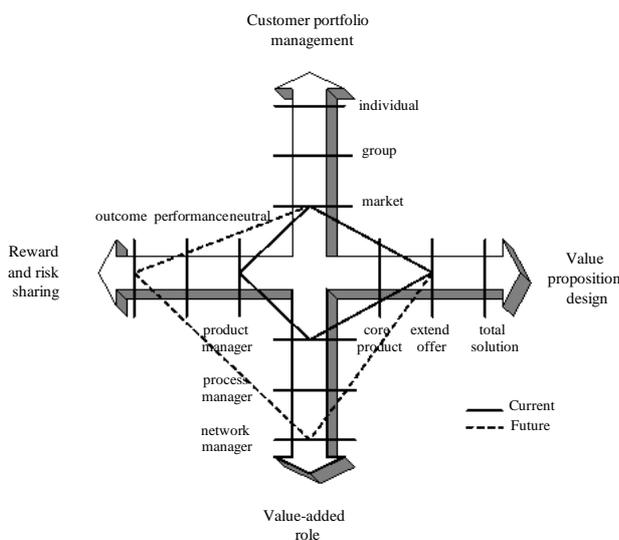

Figure 2 The value compass in Taiwan

Table 3 The significant difference between current and future position in Taiwan and China on the value compass model

Dimension	Taiwan			China		
	$\chi^2$	P-Values	Significant difference	$\chi^2$	P-Values	Significant difference
1. Customer portfolio management	5.835	0.212	No	6.137	0.189	No
2. Value proposition design	8.380	0.079	No	24.041	0.000	Yes
3. Value-added role	6.649	0.156	No	38.657	0.000	Yes
4. Reward and risk sharing	4.186	0.381	No	28.229	0.000	Yes

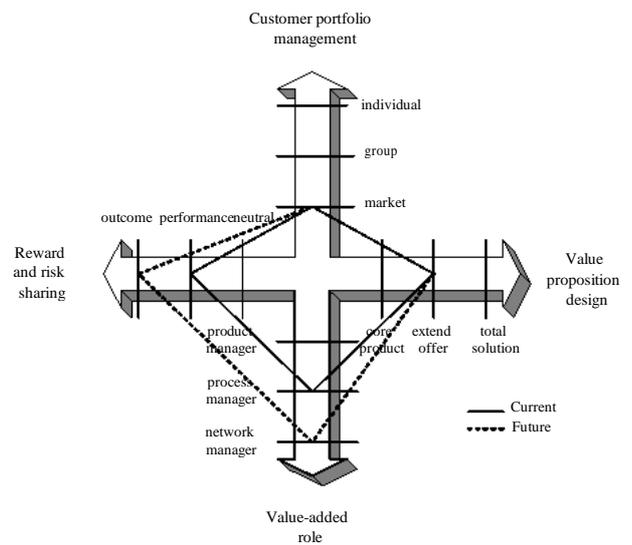

Figure 3 The value compass in China

After doing deep interviews, there were some suggestions coming out in the following.

- (A) Build it and they will come strategy: Adding franchise stores to expand market share and targeting the right market with the right product and image.
- (B) Appreciate the customer's value criteria and decision-making process strategy: Collaborative marketing with the famous brand in European to get into China market.
- (C) Add value for both buyers and sellers by providing a form of connection more efficient than either could achieve by operating independently: Using Application Service Provider (ASP) model to help franchise stores get significant information, search, or transaction costs.

(D) A mutual investment by both the buyer and seller strategy:  
 Expanding in Taiwan and China toward SPA new image stores, with encouragement of franchised beautification stores into franchised SPA chains.  
 (2) Customer connection strategies

In Figure 4, a comparison of how the franchise stores in Taiwan and China consider about their customer connection strategies is shown. Based on the surveyed data, the franchise stores in Taiwan have done the connection for customer knowledge in 64.17%, for customer connective technologies in 70% and for customer economics in 75%. On the contrary, the franchise stores in China have done the connections for customer knowledge in 70.94%, for customer – connection technologies in 65.76% and for customer economics in 64.55%. Interestingly, the franchise stores in Taiwan are doing better for customer connective technologies and customer economics. The franchise stores in China are doing better for customer knowledge. There will be something they can learn from each other and totally make profit for the beauty enterprise.

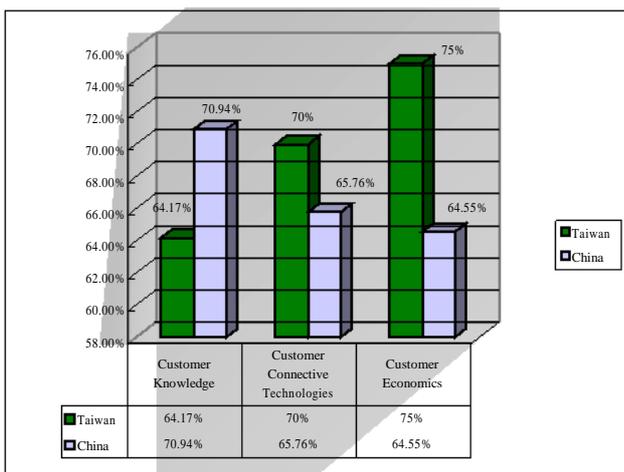

Figure 4 Customer connection strategies in Taiwan and China

## 5.2 Process analysis of KCRM

According to H<sub>3</sub>, H<sub>4</sub>, H<sub>5</sub>, Table 4 has shown responses about the process analysis of KCRM in Taiwan and China. So there is significant difference between Taiwan and China in the KM dimension expect knowledge store. It is important for the franchise stores to focus on knowledge create and share in Taiwan and knowledge store and capture in China.

According to Table 4, there is significant difference between Taiwan and China in the customer resources and categories dimension. It is really needed to take care of sharing knowledge sources and categories. Eventually,

the respondents of the franchise stores in Taiwan want to get more knowledge about best practices and problems. The respondents of the franchise stores in China want to get more knowledge about products and services and markets.

According to Table 4, there is significant difference between Taiwan and China in customer knowledge management hard and soft measures dimension. As shown in Table 5, the respondents of the franchise stores in Taiwan believe that well customer knowledge management is good for repeat purchases, customer retention and market share in the hard measures. The respondents of the franchise stores in China believe that well customer knowledge management is good for market share and repeat purchases in the hard measures. About the soft measures, the respondents of the franchise stores in Taiwan believe that well customer knowledge management is good for customer satisfaction, customer loyalty, customer and employee productive and organizational change. The respondents of the franchise stores in China believe that well customer knowledge management is good for customer loyalty and employee loyalty.

## 6. Conclusion

This research presents application of Knowledge-enabled Customer Relationship Management and takes a beauty enterprise as an example. This paper can be summarized in the following.

- (A) There is significant difference between current and future position in value proposition design, value-added role, and reward and risk sharing dimensions of the value compass model in China.
- (B) In this case study, the franchise stores in Taiwan are doing better for customer connective technologies and customer economics. The franchise stores in China are doing better for customer knowledge. There will be something they can learn from each other and totally make profit for the beauty enterprise.
- (C) Developing the process of KCRM, it is important for the franchise stores to focus on knowledge create and share in Taiwan and knowledge store and capture in China.
- (D) The respondents of the franchise stores in Taiwan want to get more knowledge about best practices and problems. The respondents of the franchise stores in China want to get more knowledge about products and services and markets.
- (E) Well customer knowledge management is good for repeat purchases, customer retention, market share, customer satisfaction, customer loyalty, customer and employee productive, organizational change and employee loyalty.
- (F) KM can enable CRM and help the CRM implementation.

Dimension		Mean <sub>Taiwan</sub>	Mean <sub>China</sub>	t-Values	P-Values	Significant difference

# Analyzing the Functional Frame of eCRM Based on Customer Value

Bing Liang, Bo-Cheng Chen

## Abstract

eCRM ties customer relationship management with the e-business. This paper suggests the functional frame of eCRM should base on the customer value to realize the win-win strategy for both the companies and their customers. The main functions to support these are explained and a functional frame model is proposed.

## 1. Introduction

No other inventions in recent years can have such a deep influence like the Internet to the companies on how to management their customer relationship and how to do business. The use of network has greatly changed a customer's purchase expectation to convenience, speed, price and service. Internet provides totally a new way of doing business in this century.

More and more customers now purchase goods through Internet, but this is not the only influence of Internet to the customer behavior. Customers also search for information's about products, services and other related things through Internet before they make a purchase decision, and enjoy more services that the companies offered on their service web sites. Companies have to rethink about how to tighten the relationship with their customers by creating the e-business strategy.

eCRM ties customer relationship management with e-business. We can expect eCRM may have a rapid growth in the near future. However, what should the eCRM functional frame be? Is it purpose merely to realize the marketing, sales and customer service automation through Internet technology?

We think the automation is the basis for eCRM operation, but the main propose of customer relationship management should be the realization of the customer value. Here the customer value means not merely the value that customers provide to companies, but also the value that companies can provide for their customers. Therefore, when we build an eCRM functional frame, we first should consider how to realize the customer value for both sides. A successful eCRM should effectively support the company to realize the win-win strategy in the Internet Era.

In this paper, we first state the customer value as the core of eCRM. Then the content of customer value is discussed from what customer requires and what customer returns. Third, based on the customer value, the main functions for supporting the realization of customer value

are suggested and a functional frame model is proposed.

## 2. Customer Value: Core of CRM

People usually classify the CRM software products by their main functionalities to three types: the Operational CRM, the Analytical CRM, and the Collaborate CRM. The operational CRM is a customer-orient application, which is something like parts of ERP's function. It not only strengthen the relatively weaken part of sales function in the ERP, but also integrate the marketing and customer service function as a whole. The analytical CRM captures, stores, extracts, processes the customer data and publishes the corresponding paper by using the data warehouse and data mining technology, so to discover the new customer knowledge for the company. The Collaborate CRM provides collaborate working environments across all the customer touchpoints.

Currently there are many CRM softwares available in the market, including the eCRM applications. However, we can see that most of them still function as marketing, sales, and customer service automation and integration tools. Although there are more or less customer management functions in them, those functions looked more like customer information management systems than customer relationship management.

The automation and integration of marketing, sales and customer service contribute to company's front-office automation, and it is the basis to run the customer relationship management, but not the core. We all know that today's market goes from product centric to customer centric, a customer driven business requires a clear knowing to the customer value. Some acknowledged marketing and management theories on CRM suggest CRM bring value to the company through these ways:

First, it should bring the capacity of "one to one marketing" to the companies. Companies should classify their customers base based on the value each customer brings to the company, and provide different service to them.

Second, based on the "80%-20%"rule, to keep an old customer is more profit than to acquire a new customer, so, companies should turn from the focus on opening new marketing to the focus on keep their loyalty customers and make them more profitability

These methods focus on the value that customers bring to companies, but this is not the all, CRM should not merely consider the value that the customers provide to companies, but more important is the value that the

customers need! Customers wouldn't keep relationship with companies if their own value requirement cannot be satisfied; this is more prominent in today's customer centric era. So, a successful CRM should first focus on the value that the customer required, consider what value can the companies provide to their customers, how can these values be provided to their customers. CRM should first manage customer value by providing customers with their required value, and to gain customers' return value. This is the win-win key for a successful CRM. To management customer value and realize it should be the core of CRM.

In the eCRM environment, Internet provides the convenience and flexibility for a customer to browse information, purchase goods and get services, it also provides the companies the power to provide information about products and services quickly to their customers, and to monitor their customers online more effectively. Whereas, Internet also carries a situation that people never meet before, that companies and their customers wouldn't communicate face to face as before, but just through a computer network. How to deal with the changes and how to realize the customer value is the problem that eCRM should face. This problem needs effective functions to meet the customers required value and make a good use of customers return value.

### 3. Customer Value Analysis

To get a clear understand on the contents of customer value, here we analyze customer value based on both customers' required value and their return value to the company.

#### 3.1 The Customer Required Value

The propose that customer buy a product is to get its use value, but this is not the all, customer has requirements during all the process —from product selection, purchase to usage, these requirements form the customer's additional value requirement. We now discuss the customer's value requirement by dividing the customer interaction process into three periods: pre-purchase period, in-purchase period and post-purchase period.

##### 3.1.1 Pre-purchase Value

The diversification of products and the mass of information make it difficult for the customers to make their purchase decisions, customers have to spend considerable quantity of time and energy, sometimes even money to seek and acquire the useful information to help them choose the proper products.

We call the cost arisen during customer's product seeking activities as the seeking cost. It contains the time, energy and money consumed during the product seeking process, besides, the risk cost of choosing wrong product also included. Lower down the seeking cost means the customer can choose product more fit for use while spend much more less time, energy and money in it. So, the value that customer requires during pre-purchase period is to minimize the seeking cost.

##### 3.1.2 In-purchase Value

Once customer makes a choice, the value he requires will transfer to the purchasing process. The common expectations to the purchasing process are: (1) Convenience, that he can place a purchase order through a convenient way, for example, he can buy it on the web, not necessarily going abroad. (2) Simple ness, the purchase procedure won't be so complex. (3) Timeliness and accuracy, means that the product he buys can be sent to him as soon as possible and the product delivered is the right one he wants. (4) Flexibility, which means some flexible payment ways can provide to customer. The value requirement during purchasing period is to maximize the expectation utility.

##### 3.1.3 Post-purchasing Value

Companies appear to know their customers' needs after the products sold, so this is a common scene for companies to provide after service for their customers. After-service is an effort by companies to meet their customers' post-purchasing period value requirements. The post-purchasing period value requirement is to pursue the minimization of risk cost of the product use. The risk cost includes the probability of consumption in the product maintenance and repair, and the lost due to the incapable of product use.

The pre-purchase value requirement, in-purchase value requirement and post-purchase requirement form the process value requirement, here the word process represents the companies' relationship process with their customers. The customer required value includes two important parts: the process value arisen from the relationship and the use value brought by the product. Though the use value is determined by the nature of product, it is apparent that high process value can take a positive improvement to use value. Figure 1 shows the construct of customer required value.

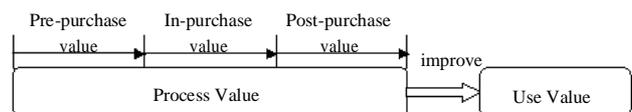

Figure 1: The construct of customer value

#### 3.2 The Customer Return Value

The customer return value is the value that customer contributes to the company after his own requirement is fulfilled. The main value within the return value is, of course, the money value that customer brings to the company. The money value consists of three parts:

- y History value: The value that has been realized until now.
- y Current value: The future value that the customer can bring to the company if his current behavior pattern keeps unchanged
- y Potential value: If customer's purchasing enthusiasm can be raised by company's effective marketing and sales means, he might provides

more value to the company than ever.

Currently more and more companies are prone to care not just the temporary profits that their customers brought to, but the long-term profits through the whole customer lifecycle, which is called the customer lifetime value, abbreviated as CLTV. CLTV is the net value of all the revenue a customer contributes minus all the cost relevant to the customer.

A loyalty customer can bring more value to the company other than the increase in profit, these mainly include the cost saving and the word of mouth. Cost saving is the result of an effective cut down in marketing and transaction cost. While a good word of mouth may grow the company's good will to the society and leave a favorable image to company's prospects.

#### 4. An eCRM functional frame analysis

The eCRM should well support a company to realize its win-win strategy under Internet environments. So its functionality settlement should be based on the customer value that we discuss above.

Based on customer value, the functionality of CRM should include customer support and customer segmentation.

##### 4.1 Customer Support

It is essential for a company to provide more process value for its customer to gain a competitive edge. A well-designed customer support functionality can help to win it. These functions or modules may be as follows:

###### (1) Customer Decision Support

In most cases, customers like to find out a way that can make their seeking cost the lowest, such as asking an experienced friend. Now the information available on Internet is so abundant and easier to access, more and more customers are used to find out information about the products before they make a purchase decision or go out to the street.

The troubles caused by much too many information won't be simpler than those caused by too less information available. Customers have to find out something useful among the huge searching results, which lower the seeking efficiency and make it difficult for customers to make a decision. Therefore, the effective way to lower a customer's seeking cost is to import a customer decision support system into CRM. Here customer decision support means to help customer:

Identify the product range that fits his needs.

Know the advantages of the company's products comparing to the competitors.

Choose a proper product from the company's product list.

This is not a new idea. In fact, there are many resources; especially a lot of web sites on Internet are helping people to make a good purchase decision. The help forms include providing a purchase guide, a comparison among the leading products, and a final purchase solution. This kind of help is actually to make

information collection, classification and analysis for the customer, so that they don't have to waste time and energy to do this work, thus effectively lower their seeking cost.

To give a decision support for the customer is meaningful to a company's marketing strategy. Based on the minimization of seeking cost rule, the probability that a customer comes to buy or inquire is larger if he thinks this company can effectively help him to make a right decision on purchase.

This work may be miscellaneous, but not difficult for the realization in technology. To build a customer decision support system maybe not as complex as a truly decision support system that can help a top manager to make decisions, but actually companies take less notice of it. To give customers help in the pre-purchasing period is an aspiring manifest in concerning the customer's requirement value.

###### (2) Purchase checking and monitoring

There exist many differences between the purchase online and the traditional purchasing patterns, some may bring troubles to customers while some are favorable to them.

If the product that a customer wants to buy is out of stock, then he may want to know when it can be available again. If the customer is doing shopping with a company's sales employee, he could get this information from the employee, but on a web site, often he is just get a notice that this product is OOS. It is the same in the situation while the available quantity of product is less than what the customer wants.

After placing a purchasing order in a web shop, a customer needs to wait for the company delivers. The customer wants to know whether his order is accepted and being processed, when can his product be sent to, is it right on the way?

To meet a customer's purchasing requirement, a purchasing check and monitor system should be incorporated in the CRM system to provide him with these capabilities.

This cannot be done entirely by CRM, actually, it needs a cooperation with company's back end systems, such as ERP or SCM to get the information.

###### (3) Self-service

The Internet can provide a true 24×7 service capacity for the companies. The service web sites can provide such functions as a solution database, FAQs, resource downloads, E-mail answers for questions and so on. The future development of Internet self-service web sites is to cooperate with the customer interaction center so to strengthen the capacity of providing real-time service to the customers.

##### 4.2 Customer Segmentation

The purpose of a company to know its customers value is to segment its customer base based on the value they provide. Then the company can find its most valuable customers through recognize, identify and retain of customers.

The differentiation of service can lower down the

total service cost while ensuring the valuable customers that they can enjoy service that is more valuable. The functions that work through using customer return value can be as follow:

(1) Customer classification

Customer value management suggests viewing customers as an important asset for a company. The method of classifying and managing customers based on customer return value is an application of ABC analysis.

To identify the importance of a customer for the company, customer profitability is an important but not the only measure element. A more comprehensive way is to use the customer loyalty as an evaluate figure.

(2) Customer behavior analysis

Customer behavior analysis is used to analyze the customer's purchasing behavior. Applying the data mining methods to customer data to segment customer base, and define the cross-selling product association rules. We can also use the RFM analysis to optimize the business campaigns.

Customer behavior analysis can also be used to determine customer's churn propensity. Using the data mining methods to analyze the history data and identify which type of customer behaviors often happen frequently before customer leaving the company, and define these behaviors as the alert for customer churning.

(3) Customer intention analysis

Different from the history record based customer behavior analysis, the customer intention analysis is to forecast the customer's future intention. The data that this analysis used comes from the feedback information through proactive customer interaction.

Forecast can help companies to know their customers' latent thought, to know what customer needs in the first time, and put these demands into the product or service development process; or use this information to propose more suitable products to their customers. Through the real-time monitor of customers' attitudes to satisfaction during the customer interaction process, companies can make a more precise evaluate on how their products can be accepted by their customers, and find out the problem during the process in time, then a more accurate forecast to customer churn can be made.

To collect more elaborate customer feedback information through CRM system environment, thereby forecast the customer's intention seems to be a common sense. However, customer intention analysis is still not an emphasis on customer relationship management, at least current developed applications don't think much of it. To integrate the true customer voice into a company's business process is a slow process which a high technology and a plenty of money is required. Consequently, many companies still make their customer analysis and decision based on the past sales data and history records.

In fact, customer intention analysis has existed in other forms for many years. Tools such as customer visit, telephone inquiry and personalized talking are all used to do this task. Internet even provides a strong capability to

monitor customers' activities on line and make responses in time. Therefore, the work is to make a good use of these tools and capabilities through a system ways to build a systematic customer intention analysis system.

(4) Customer group segmentation

Customer group segmentation is a most important way for a company's marketing department to do company's market strategy. The development of data warehouse and data mining technology enables the companies to segment their customer base not simply based on the demographic data, the segmentation based on the customer behavior analysis and the customer intention analysis can be more precise and valuable.

(5) Personalized configuration

The customer master data together with the customer classification information and the customer analysis result can form a comprehensive customer profile. The personalized configuration is to provide different service solutions for different customer profiles, such as product-combined suggestion, pricing discount strategy and after-sales promise.

4.3 A Functional Frame Model

From a general prospect, the frame of an eCRM still takes the automation and integration of marketing, sales and customer service as its operation base. Working in the Internet environment, the feature of this model is to provide both customer support and customer segmentation functions for the customer required value and the customer return value. Figure 2 shows this model.

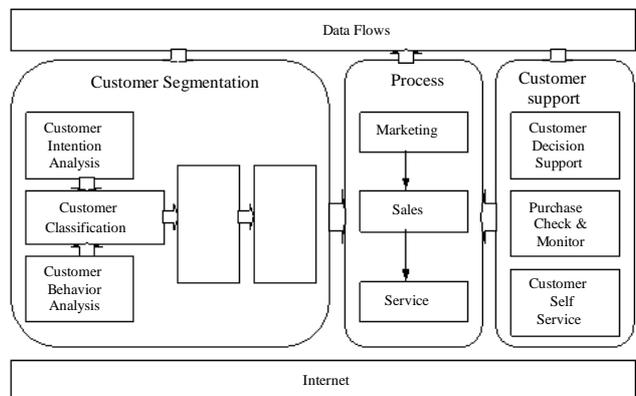

Figure 2: A functional frame model of eCRM

5. Summary

In this paper, we suggest the customer value should be the basis when we consider the function frame of eCRM. The first we should do is to realize the customer values by using it. The customer values include both the customer required value and the customer return value. Based on the content of these values, the main functions of customer support and customer segmentation operating on the Internet environment are explained and a function frame model is proposed. It is a way of thinking in an attempt to realize the win-win strategy for both the companies and their customers through Internet under the e-business environment.

## Abstract

Marketing managers in the telecommunication sectors are confronted with considerable complexity. They have to make decisions about the optimum combination of products or offerings, customer groups and the means of interacting with potential customers. Further, in saturated markets such as mobile telephony, it is increasingly important to retain customers potentially to churn.

On the optimal campaign planning, this research describes how the customer survey was conducted for those potentially churning customers based on which an optimal campaign planning was followed. This research engages with the subjects of customer retention from the perspective of a major mobile operator in Taiwan. Customers' preferences with C&C (campaign offer and communication channel) were predicted and input for further analysis for target selection optimization. These models were proved novel in an organizational prototype project suggesting that the use of the hybrid of data mining and optimization approaches can be effective for target selection.

## 1. Introduction

According to the ITU world telecommunication indicator database [1], the mobile telephone penetration rate in Taiwan had reached 97% at the end of 2001. This is the second highest level in the world and has resulted in a highly competitive market place for providers. It is both difficult and costly for the operators to acquire new customers when a market demand is so highly saturated. So, one of the key success factors for the operators is their ability to retain high value customers. To do this they need to understand, in depth, the behavior of customers and to use this information effectively to support successful retention campaign activities.

Artificial Intelligence (AI) technologies offer a way of achieving this knowledge. These have a number of underlying reference disciplines such as biology, neurology, psychology, statistics, and computer science, and have increasingly been applied to various types of problems. Because of advances in IT technologies, the power of AI approaches has increased dramatically.

These techniques offer the business community a

broad set of tools capable of addressing problems that are much difficult, or impossible, to solve using the more traditional technologies from statistics and operations research. However, these AI technologies are not commonly employed in business generally, largely because many organizations are not adequately prepared to capitalize on a technology driven environment.

This paper focuses on customer retention from the perspective of the major mobile operator. Its purpose is to explore the applicability of AI techniques in the customer retention campaign design process. A hybrid of data mining and optimization techniques is developed for target selection in order to retain valuable customers. The paper has five following sections. The first provides a brief review of the literature on customer retention, customer equity, customer data analysis approach, target selection and budget allocation, artificial intelligent techniques and genetic algorithms. The second describes the background of the decision problems of the mobile operator. In the third, the methodology used to is described and this is followed by the results, a discussion including limitations of the study and suggested areas for future research.

## 2. Literature Review

### 2.1 Customer Retention

A traditional marketing approach advocates the quest for market share dominance through mass marketing techniques and focuses on new customer acquisition. This approach has guided managers for decades in planning and implementing their marketing strategy. However, attention is drawn by some researchers to the inadequacies of the traditional marketing approach, and this has led to the birth of relationship marketing (RM). RM advocates supplier-customer interaction and the maintenance of long-term relationships with a focus on customer retention. Based on their consulting experience, Reichheld and Kenny [2] claimed that a 5% increase in retention rate led to profit swings of 25% to 80%. Ahmad and Buttle suggest that practitioners need to move beyond gaining a larger market share, to satisfying market segments and developing brand preference in order to secure lasting customer patronage and profitability [3]. They believe that firms should consider integrating customer retention into

their strategic market planning processes and set it as one of their primary goals .

## 2.2 Measurement of Customer Equity in Retention

Even after having accepted the importance of customer retention, managers are left with the issues of which customers to retain and what is the appropriate metric on which to base decisions. Some researchers stress the importance of customer value as a measurement of customer retention [3][4]. Others take a more long term view and have proposed the “Customer Lifetime Value” (CLV), also referred to as Customer Equity [5], as a method of measuring customer value. The basis of a CLV approach is the “excess of a customer’s revenues over time over the company costs of attracting selling, and servicing that customer” [6]. Berger and Nasr [7] present mathematical models for determination customer lifetime value and their models have been often referenced by researchers [3][8]. Although in theory CLV is a useful form of measure, in practice it is difficult to implement. The difficulty lies in the lifetime construct because lifetimes are variable. In this study, the customer value measurement was based on the literature and additionally according to our domain manager’s experience and data availability. For example, an age variable was used instead of estimating a lifetime for each customer.

## 2.3 Approaches to Analysing Customer Data

Demographic and behavioral data are very useful in describing customers and have an important place in direct marketing decisions but they provide little insight into understanding the needs that motivate and shape the purchase process [9].

As Compared with the more ‘objective nature’ of demographic and behavioral data, needs-based data reflects more psychologically abstract dimensions of consumer segmentation. The use of buying motive and benefit data are appropriate inputs for segment-specific product decisions, promotion decisions, and target marketing decisions [10]. Segmenting markets by consumption patterns can be quite insightful for understanding the customer mix, as by classifying customers into usage categories; management can design appropriate strategies for each market segment [4]. In the current study, the needs-oriented data about consumer preferences on different retention offers and communication channels were obtained by survey. The experimental framework (Figure 2) was designed using two approaches in building C&C models, with and without segmentation. Then the prediction performance of two approaches was compared.

## 2.4 Target Selection and Budget Allocation

Most of the literature on target selection focuses on the issues of response model of direct mail. This study focuses

on target selection of multiple channels . The process of target selection in our experiment is defined as a prior process before building the response model of direct mail. In our experiment, direct mail target customers were determined by the C&C prediction model and target selection model. However, a customer who prefers a specific channel does not necessarily mean he/she will respond to the content delivered by the channel. If a response model is expected, it can be built after finishing the target selection process. Related research on response models can be referenced in [11-13].

In general, target selection in customer retention tends to maximize customer equity under resource restriction. This resource restriction associates with the retention process lies in promotion budgets, call center labor capacity, or other medias channel capacity. Berger and Nasr present a model focusing on promotional budget allocation decisions between acquisition and retention in an organizational level. They assume that a promotional budget has been already set, and they address the optimal allocation of this preset budget [14].

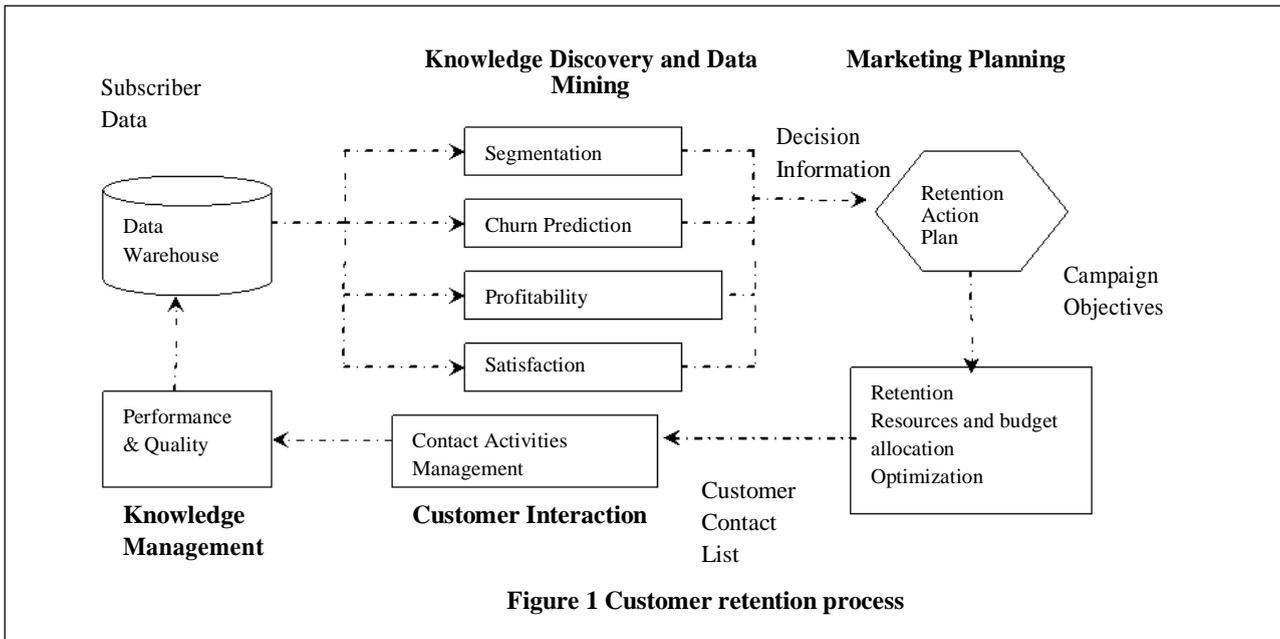

In the current study the decision problems were being made where the retention promotion budget was either undetermined or determined; and the goal was to optimize the budget allocation in an individual level.

## 2.5 Artificial Intelligence Techniques

Increasingly, work is becoming “knowledge oriented”, with a growing number of “knowledge workers” in organizations required to work with information- gathering, summarizing and interpreting - in order to make decisions. AI can play an important role as a powerful analytical tool to this knowledge oriented working environment.

With the improvements in storage and processing capacity of computers in recent years, artificial intelligence (AI) derives its power to offer the business community a broad set of tools capable of addressing problems that are much harder to solve using traditional techniques from statistics and operations research [15].

Another terminology related with AI technique is data mining. Data mining brings together ideas and techniques from a variety of fields that are similar to AI. Statisticians, artificial intelligence researchers, database administrators, and marketing people used different words to mean the same thing and the same words to mean different things [16]. Data mining frequently uses a variety of AI and statistical techniques for solving problems, but the approach of data mining is more grounded in the methodology than just in the techniques. Data Mining, or AI, is good at solving tasks related with classification, estimation, prediction, affinity grouping, clustering and description. Typical examples of these techniques are Genetic Algorithms, Neural Networks, Decision Trees, Automatic Cluster Detection, Fuzzy Logic, Market Basket Analysis, Memory-Based Reasoning, and Rule-Based

Reasoning [15] [16].

Companies use information in their customer relationship management (CRM) strategies. Data warehouse and data mining techniques allow companies to collect, store, analyze and manipulate enormous volumes of data. This can be important for marketers trying to provide better service to retain more customers than competitors. A survey of 40 companies in UK [17] shows that few companies are adapted in using such approaches and that there is a need for more applied research using AI techniques in business.

### 2.6 Genetic Algorithms and Target Selection

Roberts and Berger [18] discuss the most frequently used models to select targets for direct mail. Among these are multiple regression analysis, multiple discriminate analysis, log-linear modeling, and chi-square regression automatic interaction detection (CHAID). More recently target selection has used a neural network model [13].

Hurley et al. [19] suggest some potential marketing research can employ genetic algorithms. Targeting and optimization of distribution channels are among them. Bhattacharyya [20] presents a genetic algorithm-based approach for obtaining models in the area of direct mail. This paper is unusual in its application of genetic algorithms to the process of target selection although doing so is still within the scope of a response model to direct mail.

Traditional use of optimization methods assumes that a 'best solution' can be generated. These methods are not well suited to less structured problems, where the desired objectives are not known in advance [21]. Many real world decisions problems are unstructured. In less structured problems, the conditions indicating the existence of problems are not defined; there is no best methodology to solve these problems, and the criteria for choosing the optimized decisions are not clear [22].

desired characteristic of a decision support approach is to provide diverse alternatives for consideration. A Genetic Algorithm (GA) is good at generating diverse alternatives in such unstructured problems. GAs can also deal with problems that incorporate nonlinearity, discontinuity, uncertainty, complexity, and other demands which make the application of traditional search and optimization methods inappropriate [21]. In this study, target selection in customer retention is characterized by searching for alternatives of budget allocation in offer-channel-customer combinations to achieve the optimization of objectives under multiple constraints.

In the current study, the target selection is achieved by genetic algorithm that involves decision making with a budget allocation and offer-channel combinations.

### 3. Background of ABC Company

Six operators provide mobile service in Taiwan. Table 1 shows that the number of Taiwan mobile users grew tremendously between 1998 and 2002 - almost 500%. Over this period, average revenue per user (ARPU) has fallen by 33%, minutes of use per user (MOU) grew for the first two years, and has been steady for the last three years. Obviously, this is a demand-saturated market. As for the past several years, mobile operators have competed for market share, that is, the acquisition of new customers has been the major market strategy.

**Table 1 Market data in Taiwan mobile service industry\*\***

	1998	1999	2000	2001	June, 2002
Penetration Rate %	21.46	52.24	80.24	96.55	102.69
MOU	689	828	884	883	415
APRU	11725	9118	8492	7892	3838

\*\*Penetration Rate = Total number of mobile users / Total number of population in Taiwan  
 MOU = Minutes of use per user  
 ARPU = Average revenue per user, measure unit = Taiwan Dollar (NT)

complex because of different offer-channel combinations.

The company initiated a prototype project to explore solutions to the above issues.

## 4. Methodology

### 4.1 Research Experiment Framework

The research framework adopted the steps in Figure 2:

However, the competitive environment has forced the ABC to adjust their marketing strategies and refocus their business strategies on retaining - rather than acquiring - customers.

In order to understand the defection status of their customers, the ABC company has implemented a churn prediction model based on the framework for Customer Retention process shown in Figure 1[23]. The process shows that data in data warehouse can be used to analyze customer behavior from several perspectives, including segmentation, profitability, satisfaction, and defection (churn). A churn prediction model is a logical output as it is important to understand which customer is likely leaving, and why, so that retention initiatives can become more focused. A churn prediction model aims to aid in the development of more accurate estimate information for use in subsequent retention campaigns. The focus in this paper is on the next step process - retention action plan.

The company intends to retain customers identified as having a high likelihood of churn. To do this the following considerations have to be met:

1. The output name list of churn prediction model, normally around 5000 customers, is too large to be managed and needs to be reduced. The basis for the reduction is unclear.
2. A retention offer which meets customers' preferences and hence achieves a higher retention needs to be formulated.
3. The desire is to announce the retention offer through the communication channel which mostly meets customers' preferences.
4. Budgetary allocation for the retention program is

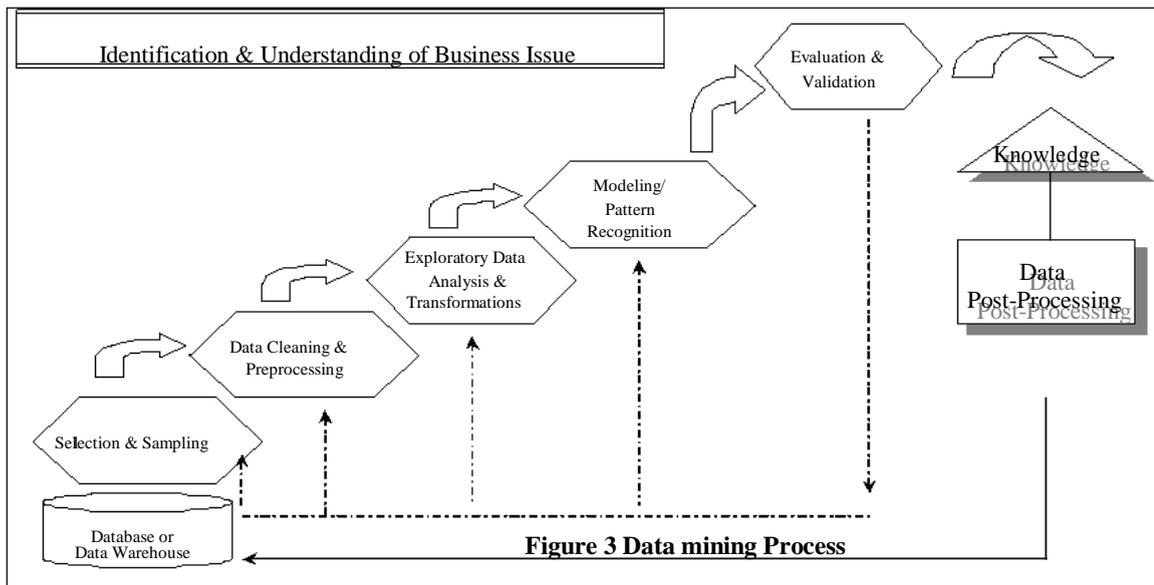

1. A survey to collect information on customers' preferences on campaign offers and communication channels.
2. The integration of customer preference data from survey, and customer data from data warehouse, to build a customer C&C predictive model.
3. Two approaches were designed. Approach I involved building a segmentation model first and then building C&C models for each segment. The major premise behind this needs-based segmentation approach was that by segmenting customers into various user groups, management could develop appropriate strategies for each market segment [10]. Approach II involved building the C&C model without considering segmentation. This is a much quicker way to build C&C model.
4. Comparison of the predicted performance of the models, and choosing the model with best performance.
5. Application of the models to a customer population to provide a prediction of the preference C&C for each customer.
6. Using data predictions, to build a target selection model to evaluate and differentiate budget-offer-channel combinations. The model will search for a series of good (optimal) solutions under resources constraints, and optimize some presetting business objectives.
7. To take action on retention campaign programs targeting customers selected from the target selection model.
8. Evaluation of the campaign performance from data in data warehouse.

Steps 7 and 8 were not undertaken in this study.

## 4.2 Campaign Offer and Communication Channel(C&C) Mode 1

### 4.2.1 Data Mining Methodology

Fayyad's process [24] was followed as shown in the Figure 3.

### 4.2.2 Data Collection and Preprocessing

A population of 4481 (February, 2002) customers with a high churn propensity were provided by ABC company. Six hundred (600) customers were randomly surveyed by mail. Three main questions were asked:

- Which retention offer do you prefer?
- Which communication channel do you prefer to receive our notice of promotion activity?
- What are potential reasons will cause you to decide to leave your current operator?

Five retention offers were designed by the company. These offers are related with handset subsidies, free traffic minutes, prepaid discounts, special gifts. Four communication channel options were presented including email, DM mailing with monthly invoice, short message, and outbound call from sales representatives. Two hundred and sixty one (261) questionnaires (43.5%) were returned within fifteen days of mailing.

Customer data were extracted from data warehouse, Details for individuals included demographic information (age, geographic code, etc.), rate plan, transaction apply items, tenure, credit record, churn score, complaint records and usage information.

A preliminary statistical analysis was performed to enhance familiarity with the data and to detect and remedy any missing values or outliers that might distort the

subsequent analysis .

### 4.2.3 Data Mining Approach

With the initial analysis completed, knowledge discovery algorithms were applied to the data. The aim was to statistically identify the relationship between variables and dependent variables so that significant variables could be selected, derived and transformed, and

input into next modeling process. The total number of independent variables used for C&C modeling was 61 while one dependent variable (preference on retention offers or communication channels) existed.

The data was then divided into a training set and a testing set. This was done because it was important to ensure that our models do not merely memorize the patterns in the training set. The testing set confirms findings are valid and can be generalized to enable predictions to be made on new data. In the modeling process, decision tree and neural network training was applied to the prediction model.

In the modeling Approach I, the clustering algorithm - k means was used. Before the C&C modeling for each subgroup, the relationship of clusters with retention offers by independence test was examined. The purpose was to test if customer preference of retention offer was significantly different between subgroups. If so, the attributes of customers between subgroups is different and hence their preference of retention offer is different from other subgroups. If this was the case it would be appropriate to build a C&C model for each subgroup. If not, then a segmentation approach was not necessary, and Approach II was more appropriate.

The model performance of the decision tree and neural network methods was assessed and the superior approach retained. Then, the developed model was applied to the population to predict the preferred campaign offer and

communication channel for each customer. These predicted values will be used as input data of the optimization process for target selection.

### 4.3 The Optimization Model for Target Selection

With thousands of high churn propensity customers, the selection of retention targets is a difficult problem in practice. However, a GA can be used to optimize objective functions within constraints, and select retention targets under the following situation:

- (1) When the budget is undetermined, to provide several budget allocation alternatives with combinations of offer-channel-customer.
- (2) When budget is determined, provide several alternatives with combinations of offer-channel-customer.

#### 4.3.1 The Genetic Algorithm

GAs are good for solving optimization problems. The basic goal of optimization tasks involves finding one, or a series, of very good (optimal) solutions from among a very large number of possible solutions. Optimization problems involve three components: a set of problem variables, a set of constraints, and a set of objectives. These components can be transformed and operated by a GA.

GAs solve problems by borrowing a technique from nature evolutions. GAs use Darwin's basic principles of survival of the fittest, mutation, and cross-over to create solutions for problems. A GA consists of five main components:

The chromosomal representation, initial population, fitness evaluation, selection, cross-over and mutation.

A simple GA operation cycle is:

1. Generate initial random population
2. Evaluate fitness of current population
3. Select chromosomes based on fitness for reproduction
4. Perform cross-over and mutation give new improved population
5. Repeat 2-4 until stop criteria is met, the stop criteria may be set by number of trials, minutes of running time, a stop formula function or else.

A GA searches intelligently through the possible permutations. This is much more practical than searching through all possibilities. A GA allows a good solution to a problem quickly rather than waiting for the absolute best solution. Unlike many mathematical techniques, solution times with GA are usually highly predictable. Solution time is usually not radically affected as the problem gets larger, something which is not always so with the more traditional techniques. However this heuristic technique does not guarantee optimal solutions, users must often settle for "near optimal" solutions. [15]

#### 4.3.2 Problem Formulation

##### 4.3.2.1 Chromosome Representation

Each chromosome represents a possible solution for a selected group of customers. The individual genes with each chromosome are represented by a binary alphabet; 0 indicates that a particular customer is not selected, whereas a 1 would indicate that a particular customer is selected. To illustrate this, assume we have five existing customers, then the chromosome

11010

represents where customer 1,2,4 are selected and customer 3, 5 are unselected. In a case of one thousand customers, our chromosome will have a length of 1000 genes.

##### 4.3.2.2 Fitness Function

Fitness evaluation involves defining an objective or fitness constraints against which each chromosome is tested for its fitness, a high fitness value would indicate a better solution than a low fitness value. In this study, the fitness function was formulated as follows:

Maximize CVS (customer value score)

$$\sum_i \sum_j (W_1 * q_{CLV} + W_2 * q_{Tenure}$$

$$+ W_3 * q_{Payment\_Overdure} + W_4 * q_{Age\_Now}) X_{ij} \dots \dots (1)$$

Subject to the following constraints :

$$Tcost \leq MaxBudget$$

$$CusNum_i \geq MinCusNum_i$$

$$\sum_i PcusNum_i \leq MaxPcusNum$$

$$Tcost \leq \sum_i \sum_j (f(y) + f(z)) X_{ij}$$

$$0 \leq X_{ij} \leq 1, X_{ij} \text{ is an integer}$$

Where

$q_{CLV}$  Customer lifetime quantile value of  $X_{ij}$

$q_{Tenure}$  Tenure quantile value of  $X_{ij}$

$q_{Payment\_Overdure}$  The quantile value of the average invoice payment overdue days last six months of  $X_{ij}$

$q_{Age\_Now}$  The age quantile value of  $X_{ij}$

$W_1, W_2, W_3, W_4$  The weight value assign to each variable

$X_{ij}$  The customer  $j$  in the area  $i$ , it is the selection index of  $X_{ij}$  to retention program, if  $X_{ij}$  is selected as target then  $X_{ij}$  is set to 1, Otherwise,  $X_{ij} = 0$

$Tcost$  The total cost to execute retention program

$f(y)$  The cost function of retention offers

$f(z)$  The cost function of communication channels

$MaxBudget$  Maximum budget allocated to retention program

$CusNum_i$  Number of customers were selected in the area  $i$

$MinCusNum_i$  Minimum customers need to be selected as targets in area  $i$

$PcusNum_i$  Number of customers targeted through personal contact channel in area  $i$

$MaxPcusNum$  Maximum number of customers can be targeted through personal contact channel by call center

In summary, the objective of the target selection was to optimize Equation 1 the customer value score (CVS), subject to budget and resource constraints.

Equation 2 is the customer lifetime value (CLV) based

on Berger and Nasr's definition applied in this research:

$$CLV = C \sum_{i=0}^{n-1} \frac{r^i}{d^{i+1}} + M \sum_{i=0}^{n-1} \frac{r^i}{d^{i+0.5}} \dots \dots \dots (2)$$

where

$C$  = Yearly gross contribution

$M$  = Promotion cost per customer per year

$n$  = The length in years of period

$r$  = The yearly retention rate

$d$  = The yearly discount rate

Because the difficulties in defining  $n$  for each customer, for simplifying purpose, it was assumed that  $n = 0$ , thus

$$CLV = \sum_{ij} (C_{ij} + M_{ij})$$

and if  $M_{ij}$  is equal in each of  $X_{ij}$ , therefore,

$$CLV = \sum_{ij} C_{ij}$$

$C_{ij}$  = The yearly invoice contribution of  $X_{ij}$

Consequently a customer was judged only on current value with the yearly invoice contribution; however, the *Age\_Now* variable was set to reflect a customer's future value.  $W_1 = 1, W_2 = 0.4, W_3 = 0.2, W_4 = 0.1$  were assigned according to the company domain experts' experience. Negative values were assigning to  $W_3$  and  $W_4$  to represent the negative impact to the customer value score.

#### 4.3.2.3 Simple illustration

To illustrate the application of GAs to a target selection problem with a simple example, a population of five chromosomes is first randomly generated,

- $C_1$  11000  $C_4$  01100
- $C_2$  10001  $C_5$  10100
- $C_3$  10100

If the customer value score (CVS) calculated is,

- Customer 1 963 Customer 4 945
- Customer 2 953 Customer 5 605
- Customer 3 370

The fitness values (value of objective function) of chromosomes are:

- $C_1$  10000 fitness = 1916  $C_4$  01100 fitness = 1323
- $C_2$  10001 fitness = 1568  $C_5$  10100 fitness = 1333
- $C_3$  10101 fitness = 1938

Chromosome  $C_1$  and  $C_3$  are the fittest, so they would be

more likely to be selected for cross-over and mutation. If a one-point cross-over was used at a randomly chosen position, say position 3, the following offspring would be produced:

$$C_1 \ 11000 \ \square \ C_6 \ 11100$$

$$C_3 \ 10100 \ \square \ C_7 \ 10000$$

Their respective fitness values calculated are  $C_6 = 2891$  and  $C_7 = 963$ . Therefore, a new and better solution represented by chromosome  $C_6$  has been found.

The advantages in using a GA approach are:

- (1) An optimal or near-optimal solution is established in a predictable time.
- (2) The good alternatives can be accessed easily.
- (3) It is easy to apply, all that is needed is the ability to describe a good solution and provide a fitness function that can rate a given chromosome. This means that you can use a GA to solve problems that you don't even know how to solve!

## 5. Experiment and Results

### 5.1 The Survey Result

#### 5.1.1 Preference of retention offer

Table 2 shows the preference distribution of the retention offer and Table 3 the  $\chi^2$  values for independence tests for age, education and revenue factors. In Table 3, all the  $\chi^2$  values are smaller than  $\chi^2_{0.05}$  and  $\chi^2_{0.01}$ . This means that there is insufficient evidence to say that the preference retention offers differ on the basis of education, age, or revenue. However, from Table 2, it is obvious that the 'free minutes offer without prepaid' is the most favored retention offer overall.

**Table 2 The distribution of retention offer preference**

Retention offer type	%
Handset subsidies	20
Free minutes offer with prepaid	17
Free minutes offer without prepaid	56
Free mobile internet minutes offer	2
Special designed gift	5

**Table 3 The independence test**

Factors	$\chi^2$ value	$\chi^2_{0.05}$	$\chi^2_{0.01}$
Age	15.7	31.4	37.6
Education	25.0	26.3	31.9
Revenue	4.9	26.3	31.9

#### 5.1.2 Preference of Communication channel

Table 4 shows the preference distribution of communication channels and Table 5 the  $\chi^2$  values for the independence test with age, education and revenue. The preference of communication channel significantly depends on age at both  $\chi^2_{0.05}$  and  $\chi^2_{0.01}$ , and on education at  $\chi^2_{0.05}$ . Younger people (under 20) preferred only 'short message' and 'email', while for older people (above 50), these two forms were least preferred. The preference for personal phone contact increased with age. Also, people with higher education showed a greater preference for

'short message' and 'email' than people with lower education levels. From Table 4, 'DM with invoice' is the channel most often preferred, followed by 'short message'.

**Table 4 The distribution of communication channels preference**

Type of contact channels	%
Email	8
DM with monthly invoice	45
Short message	33
Personal telephone contact	14

**Table 5 The independence test**

Factors	$\chi^2$ value	$\chi^2_{0.05}$	$\chi^2_{0.01}$
Age	38.2	24.9	30.6
Education	24.7	21.0	26.2
Revenue	10.5	21.0	26.2

### 5.1.3 Potential Reasons to Churn

Communication quality and price were the top two issues that impact customer's potential churn behavior (Table 6).

**Table 6 Distribution of potential reasons to churn**

Type of reasons	%
Unsatisfied mobile communication quality	32
Cheaper tariffs with friends and relatives within same operator's network	15
Unsatisfied service quality	12
Better handset discounts from other operators	10
Price is higher than other operators	31

### 5.2 C&C Preference Model

In Approach I, before building the C&C modeling for each segment, the relationship of clusters with retention offers by independence test was examined, that is:

$H_0$  : Cluster is independent from retention offer preference

$H_1$  : Cluster is dependent with retention offer preference

However, the  $\chi^2$  value of 10.61504 was smaller than the critical value of  $\chi^2_{0.05} = 21.06$ , and so the  $H_0$  was accepted. Hence, it was decided not to build C&C model for each subgroup. This means that Approach II is applied to building the C&C model in this study.

By integrating the preference data from the survey with customer data in the data warehouse, and discarding some records with important missing data, the C&C model was built. Lift [25] was used to measure the prediction performance of the model. Lift values in Table 7 show that the prediction rate was improved using the models.

The next step was the application of these models to the remainder of the population, and the prediction of preference retention offers and communication channels to each customer.

After discarding records with missing data, the number of records available were 2247. This 'predict list' was used for target selection.

**Table 7 Lift of C&C model\*\***

	(A)	(B) =(A)/ Total	(C)	(D)= (C)/ (A)	Lift (E)= (D)/ (B)
<b>Retention Offer:</b>					
Handset Subsidies	24	0.18	11	0.46	2.56
Free minutes offer with prepaid	24	0.18	15	0.63	3.49
Free minutes offer without prepaid	78	0.58	73	0.94	1.61
Free mobile internet minutes offer	1	0.01	0	0	0
Special designed gift	7	0.05	2	0.29	5.47
Total	134	1.00			
<b>Communication Channel:</b>					
Email	11	0.09	6	0.55	6.39
DM with monthly invoice	53	0.41	38	0.72	1.75
Short Message	41	0.32	38	0.93	2.92
Personal telephone Contact	24	0.18	12	0.5	2.69
Total	129	1.00			

\*\* 1.(A) : Survey Result

3.(C) : Model Predict Result  
4.(D) : Model Hit Rate  
5.(E) : Lift

### 5.3 Target Selection Optimization Model

The GA approach was applied to the optimization problems when:

Y When the amount of budget is undetermined

Y When the amount of budget is determined

Table 8 presents the solutions obtained for an undetermined budget situation. Four alternatives were provided with budgets from 200000 to 500000. Mutation rate was set to 0.15 and the cross over rate to 0.5. The objective function aimed to maximize the customer value score (CVS). The stop criterion was set at the objective value of not improving 0.1% in the last 3000 trials.

The ability of GA to find good solutions within a limited time is shown in Table 8. Resource constraint criteria were set for budget limit, personal phone contact capacity, DM with invoice capacity and minimum geographic customers needed to select. All the optimal solutions according to different budgets are shown in the Table 8. Alternative III generates the highest value per dollar. Managers can modify constraints to meet their specific business needs, and make their optimal decision based on the information suggested.

**Table 8 Alternatives when budget amount is undetermined\*\***

Budget alternatives	I	II	III	VI
CVS	200000	300000	400000	500000
Retention Cost	137249	222259	390056	453986
Value per cost dollar	199421	298674	396426	497524
Time to generate this CVS	0.68824	0.74415	0.98393	0.91249
Numbers of customer selected	461	239	435	918
Retention offer mix	A=32 B=118 C=250 D=0 E=2	A=44 B=165 C=421 D=0 E=4	A=39 B=315 C=681 D=0 E=6	A=64 B=351 C=739 D=0 E=15
Communication-on Channel mix	A=19 B=161 C=43 D=179	A=24 B=248 C=74 D=288	A=35 B=426 C=100 D=480	A=35 B=439 C=135 D=560
Geographic mix	T=106 N=41 C=117 S=104 E=34	T=158 N=53 C=184 S=185 E=54	T=281 N=82 C=287 S=293 E=98	T=296 N=99 C=328 S=332 E=114

- \*\*1. We set constraints: maximum personal phone contact capacity  $\square$  35, DM with invoice capacity  $\square$  500, minimum targets per area  $\square$  20.
2. Initial population is generated by random; population size is set to 200.
3. The objective function is to maximize CVS; an initial random CVS is 100633.
4. We set mutation rate = 0.15, and cross over rate = 0.5.
5. The stop criterion is the objective value without improving 0.1% for the last 3000 trials then stop.
6. The measure unit of time to generate this CVS is second.
7. The measure unit of budget and cost is Taiwan dollar (NT).
8. Retention offer mix: A is handset subsidize, B is Free minutes offer with prepaid, C is Free minutes offer without prepaid, D is Free mobile internet minutes offer, E is special designed gift.
9. Communication Channel mix: A is personal telephone contact, B is DM with invoice, C is email, D is short message.
10. Geographic mix: T is great Taipei area, N is northern area, C is central area, S is southern area, E is eastern area.

Table 9 presents solutions when fixed budget of \$400,000 Taiwan dollars. A better value per dollar (1.004485) was generated in alternative III when the call center capacity constraint was released to 50. The stop criterion for alternatives II and III was not at least a 0.1% improvement over the last 3000 trials. However, a stop criterion was not set for alternative I, and it was stopped manually after a relatively good (optimal) value was generated. A comparison of time taken to reach the optimal CVS values between I and II, a better objective value was achieved as more time were taken, 702 seconds to 1037 seconds. However, more CPU resources are needed to generate the better solution. All the alternatives solutions presented in this table all started from an initial value of 100633 and achieve to the optimal solutions within reasonable time

This is likely to only be a 'good' solution and not necessarily 'optimal'. The mutation rate and cross over rate could have been adjusted to speed up the searching for optimal solution.

**Table 9 The alternatives with the determined budget\*\***

	I	II	III
CVS	392542	390056	399109
Retention cost	399922	396426	397327
Value per cost dollar	0.981546	0.983931	1.004485
Generations to get this value	85.16	46.575	71.37
Time to get this CVS	1309	702	1089
Numbers of customer selected	1037	1041	1073
Communication channel mix	A=35 B=338 C=110 D=504	A=35 B=426 C=100 D=480	A=42 B=403 C=126 D=502

- \*\*1. Communication Channel mix: A is personal telephone contact, B is DM with invoice, C is email, D is short message
2. Capacity constraint of personal telephone contact for alternative I and II is  $\square$  35, for alternative III is  $\square$  50.
3. We set mutation rate = 0.15, and cross over rate = 0.5
4. An initial random CVS is 100633

## 6. Conclusion and Suggestions for Future Research

One of the major implications of target selection in customer retention is its ability to provide marketing decisions information to evaluate different alternatives' impacts on customer equity. In this paper, a methodology for the optimization of target selection based on customer preferences, using a genetic algorithm and where the objective was to maximize customer equity is described.

The study demonstrates the potential of AI technologies for the customer retention process in the mobile industry. This study used a customer needs-based approach to predict the C&C preference of customers, and a different way of applying genetic algorithm to target selection and budget allocation.

While most traditional techniques provide a single best solution, multiple solutions with high performance levels can be advantageous, especially if coupled with a faster solution search time. A genetic algorithms can be useful in such contexts in providing multiple alternatives obtained from independent runs with different random number seeds, crossover rates, mutation rates, or from explicit use of varied fitness criteria. Because genetic algorithms only use an encoding of the solution and its associated fitness value and do not utilize auxiliary information, such as derivatives or assumptions about continuity in the solution process, they can be applied efficiently to a wide range of marketing optimization problems with only minor changes to parts of the algorithm.

One limitation of the current work is the insufficient

data to segment customers due to small scale of sampling in survey and missing data problems in the data warehouse. These problems should be avoided in a formal project implementation. Another important limitation of the work is that it did not empirically investigate the validity of models in real world, taking action on the results of models by carrying out an experiment of treatment group and control group is planned in the future work.

Further empirical investigation is needed to evaluate the effectiveness of the proposed GA method as compared with the traditional methods. Application to retention programs in other industry is needed to demonstrate the broader applicability of this methodology.

### Acknowledgement

The authors would like to thank the Managing Director of the Call Centre of the ABC Company for access to data used in the study.

## Abstract

The rapid development of Internet technology has made inter-organisation connectivity much easier and cheaper than ever before, hereby providing an opportunity for companies, both large and small, to realise the true value of the Internet. Despite the huge investment and complexity of implementing e-procurement, there is little empirical research to provide managerial guidelines for developing effective procurement strategies and for successfully implementing e-procurement. This paper attempts to fill this gap by reporting an Australian case study on the adoption of e-procurement. The findings offer detailed, varied and practical strategic insights into organisational redesign, critical factors, and challenges. The implications are also offered.

## 1. Introduction

Using e-business to enhance an organization's channel has been considered as a starting point for implementing e-business for many organizations in a business-to-business context [3]. The rapid developments in Internet technology have made the inter-organization connectivity much easier and cheaper than ever before, thereby providing opportunities for many companies, large and small, to real the real value of the Internet.

Implementing e-procurement is of strategic, rather than tactical, importance. It should be regarded as an integrated part of an organization's overall e-business strategy because of its enormous expenditure and potential savings. Many companies spend as much as 30 per cent of their revenue for indirect procurement, that is, non-production materials and services [3, 5]. Traditionally, indirect procurement is a costly pen and paper process that may require more than \$100 dollars just to issue a purchase order. Further, decisions of purchasing many moderated-price goods and services have been at the discretion of individual employees. Finally, as business environment become increasingly competitive, many companies are striving to improve their profitability. Every cent saved in procurement goes straight to the bottom line.

Many organisations, both public or private, are adopting e-procurement programs to reap the benefits of Internet technologies. A recent survey of more than 500 managers in six West European countries by IDC

[4] found that 38 per cent of businesses have used the Internet for procurement.

Despite its huge investment, complex implementation process, and the involvement of multiple functions and departments, little empirical research has been conducted to provide managerial guidelines on developing effective procurement strategies and to successfully implement e-procurement. This paper attempts to fill this gap by presenting a case study of an Australian organization. Specifically, it aims to address the following questions:

- 1) How does it successfully implement e-procurement in order to fully tap the potential of the Internet technology and the emergence of e-marketplace?
- 2) What benefits does the organisation attempt to reap from e-procurement?
- 3) What are the critical factors in implementing e-procurement? and
- 4) What challenges does the organisation face in implementing e-procurement?

## 2. Literature Review

### 2.1 What is E-Procurement

The meaning of procurement is much broader than purchase. Conceptually, it includes such activities as purchasing, transportation, warehousing, and inbound receiving [5].

Functionally, e-procurement can have three approaches: e-procuring non-production goods and services, e-sourcing and e-auction [3]. The non-production goods and services procured are variously known as operating [2], or indirect materials [7]. They can further be broken down into three categories: office and computer supplies, or ORM (Operating Resource Management, mainly office products), maintenance, repairs, and operations (MRO) supplies; and travel and accommodation [5]. MRO is the most important of these three categories one. Because MRO typically includes mission critical overhaul and maintenance, its procurement processes usually involve much higher levels of complexity, cost and volume than ORM and travel and accommodation [7].

Table 1 A Brief Summary of Benefits in Implementing E-Procurement

Studies	Benefits
[3]	Employees compliance with pre-negotiated contracts; Improved leverage with suppliers, and Process improvement
[5]	Efficiency improvement, including: <ul style="list-style-type: none"> <li>ò low procurement costs,</li> <li>ò faster cycle times,</li> <li>ò reduced maverick or unauthorized buying,</li> <li>ò more highly organized information,</li> <li>ò tighter integration of the procurement function with key back-office systems.</li> </ul> Effectiveness enhancement, including <ul style="list-style-type: none"> <li>ò increased control over the supply chain</li> <li>ò proactive management of key procurement data, and</li> <li>ò higher-quality purchasing decisions within organizations</li> </ul>
[2]	Operational benefits: <ul style="list-style-type: none"> <li>ò reducing the administrative costs of the whole procurement process by two third.</li> <li>ò improved expenditure control.</li> </ul> Strategic benefits: <ul style="list-style-type: none"> <li>ò increased procurement control (better coordination between users and purchasers and greater control over sources of supply, purchase price, and inventory policy from adopting a centralized purchasing function),</li> <li>ò better supplier management (reducing supply base and thus increasing leverage over suppliers)</li> </ul>

2.2 Benefits and challenges in implementing e-procurement

Many publications have reported the potential benefits of implementing e-procurement. Some are summarised in Table 1.

The level of saving possible in implementing e-procurement partly depends on the amount of indirect spending that is e-procurable [3]. For example, service is hard to purchase online.

While the benefits to procurers have been well identified and documented, only several publications have reported how suppliers can benefit from e-procurement from a descriptive perspective. By participating in e-supply, suppliers can have several benefits, including sales increase, expansion of market reach, reduction of costs for sales and marketing activities, shorter selling cycle, improved sales productivity, and streamlined bidding process [2, 3, 9].

2.3 Challenges in implementing e-procurement

Given the level of complexity in redesigning procurement processes, integrating multiple functions within the organization, and engaging key suppliers in participating in e-supply, several challenges have been identified and described. In a recent survey of procurement managers in 13 European countries, IDC [4] has reported a number of challenges in implementing e-procurement, including internal

resistance to change (27%), system too difficult to use/understand (11%), e-procurement system integration with existing IT systems (11%), employee training (11%), and supplier migration to the Internet (11%).

Croom [2] reported that management has three major concerns in implementing e-procurement: concern for the management of service supply, such as facilities services, e.g., clearing and catering, particularly with its quality measurement because services are hard to e-procure; concern for security, particularly payment; and concern for supply database maintenance, which may involve a central supply database containing information about process concerns (authority levels for order-placers, supplier details, product/service details), and pricing scheme. The questions are where is this database located and who should be responsible for maintenance.

2.4 The evolution and implementation processes of e-procurement

The development of e-procurement has so far undergone three stages [1]: 1) large companies such as General Motors and Wal-Mart established Internet buying hubs for reducing costs and speeding supply; 2) independent firms created third party exchanges that attempt to bring many buyers and sellers in e-marketplace; and 3) horizontally dominant industry players joined in e-procurement consortiums, such as Covisint in the automobile industry.

With regard to the e-procurement implementation processes, Kalakota & Robinson [5] suggested that a seven-step guideline. These seven steps are to: 1) clarify the company's e-procurement chain goals. Such goals may include automating the selection and purchase of goods, cutting costs, reporting companywide purchasing patterns timely and accurately, or eliminating purchasing by unauthorized employees; 2) conduct a procurement process audit; 3) establish a business case for e-procurement; 4) develop a supplier integration matrix, which helps determine the best type of individual vendor relationship. The type of individual vendor relationship depends on the uniqueness and scarcity of the products or services procured; 5) select an e-procurement application; 6) integrate e-procurement with other applications; and 7) train employees involved.

### 3. Research Methodology

**Research design.** Case study as a research method has been increasingly accepted in social sciences and management studies. Yin [10] has defined case study as "an empirical inquiry that investigate a contemporary phenomenon with its real-life context; when the boundaries between phenomenon and context are not clearly evident; and in which multiple sources of evidence are used" (p. 23). Many e-business applications are still new and not well researched. Therefore, case study is considered to be very appropriate for this stage of e-business application development.

**Case selection.** Many companies use e-procurement based on Internet technologies as a strategy to improve competitive advantages. Therefore, it is expected that the decision to adopt e-procurement is made at head office given the quantity of money invested and the number of functions and departments involved. Moreover, the potential significant benefits that can be reaped from implementing e-procurement often dictate that large manufacturing firms are more likely at the forefront of companies rushing to exploit e-procurement. Thus, these companies tend to be large and in manufacturing sector, and they are targeted for this study.

Woodside, a large Australian oil and gas exploration company, has some characteristics that apply to an e-procurement study. First, Woodside has learnt much from Shell, its significant shareholder and an early adopter, in implementing e-procurement through their close relationship. Therefore, what Woodside has done in implementing e-procurement could be more solid than that of early adopters. This means it can offer a good pathway to e-procurement for other companies.

Second, Woodside is a major player in the Australian oil and gas industry. It not only can exercise considerable power in engaging suppliers in e-supply,

which is crucial to the success of e-procurement, but also is able to initiate other e-procurement programs, such as e-sourcing and e-auction, for its industry. Hence, this case study can also shed light on how e-procurement impact on the firms involved and the whole industry.

Finally, Woodside not only has large procurement expenditure (about A\$1.3 billion annually) and many supply chains, but also has many geographically dispersed plants and groups. This requires effort in coordinating a range of activities other than mere procurement, such as transportation, warehousing and inbound receiving. All these can provide a large and complete picture about e-procurement at the organizational level.

**Data collection and analysis.** Multiple sources were used to collect data, including interview with two senior procurement managers, compilation of information from the company's Web site and media reports, and collection of the materials and booklet about e-procurement at Woodside and Shell during the interview. The interview was conducted at Woodside headquarters in Perth using a semi-structured approach. Specifically, a list of questions was prepared based on literature review. These questions covered four major areas: the implementation processes, benefits and challenges, integration of e-business applications and other IT-related issues, and critical factors. However, we also kept an open mind during the interview to ensure that other important issues would be captured. The "funneling approach", as suggested by Minichiello et al [6], was used. The interview lasted about two and half hours and was tape-recorded. The recorded tape was then transcribed. Although several computer software packages, such as NUDIST or Nvivo, developed by Qualitative Solutions and Research Pty Ltd [8] could be used to facilitate qualitative data analysis, we have decided to analyse the data manually for two reasons. First, most of these software packages for qualitative data analysis require much time and effort to set up the project. Second, this research only involved one case.

The information and materials collected from the company's Web site, promotional materials, and media reports were used to further complement or triangulate the findings from the interview.

### 4. Background Information of the Company

Based on Perth, Woodside Energy is a leading Australian resources company. Its main business is in the exploration, development, and production of hydrocarbon products, such as oil and natural gas.

Woodside was founded in 1954 to search for oil. Its major expansion came in 1963 when it secured exploration permits over 367,000 square kilometres off

the Western Australian coast. In the early 1970s, it successfully discovered the several gas fields in Western Australia's harsh Pilbara region. These fields were eventually to form the basis of Australia's biggest energy resource development: the North West Shelf Venture, which is the biggest and one of the most important natural resource developments ever undertaken in Australia.

Delivery of North West Shelf natural gas to customers in Western Australia (WA) began in 1984. With deregulation of the domestic gas market in WA, it now sells directly to major energy consumers in WA.

Another Woodside product is condensate, a light oil produced in association with gas. The first crude oil development was produced in the late 1980s. Production from the Floating Production, Storage and Offtake facility (FPSO) began in 1995. The following month it also began exporting Liquefied Petroleum Gas (LPG). In late 1999, under Woodside's operatorship, the Northern Endeavour FPSO began producing oil in the Timor Sea. This was its first operations outside the North West Shelf Venture.

Woodside is also actively exploring for oil and gas in WA, Victoria, the Timor Sea, and several overseas sites. In 1999, Woodside has implemented ERP developed by a Tier One ERP developer.

In 2001, Woodside production included 7.2 million barrels of crude oil and 1.25 tons of liquefied natural gas. It employed about 2500 people and generated annual revenue of A\$2.34 billion. The annual procurement expenditure is about A\$ 1.3 billion. There were approximately 9000 procurement invoices to process per month.

## 5. Implementing E-procurement at Woodside

### 5.1 Redesign organizational structure based on the product and service market

The e-procurement program was initiated on 1<sup>st</sup> April 2000. As the first step, a new division, Shared Services, was established based on a detailed analysis of the goods and services it procures, its procurement spending, and existing procurement processes. The two guiding principles used for this organizational restructuring are market of goods and services procured, and e-procurement process. This division now covers most important functions and activities involved in the procurement processes. It employs 90 people and consists of nine teams or groups.

The first team, Business Development, is responsible for research and development in procurement. Its specific tasks include redesigning the e-procurement processes, monitoring new development,

and planning the directions for e-procurement. Another important task for this team is to communicate with suppliers and to get them involved in e-supply.

The second team is Communication and IT. It controls expenditure in telecommunications and other IT related areas, such as the purchase of software and hardware, and license and contract management in IT areas. The company has 1500 personal computers. So its expenditure in communication and IT is very substantial.

Another team is Contracts and Services. Its responsibilities cover legal, insurance, financial, and logistic issues in dealing with suppliers. This team manages all the contracts and services required to sustain other parts of the Shared Services division.

The next group is Plant that is physically located in a natural gas treatment plant that is about 1,300 kilometres away from Perth. This is essentially a virtual team. The team's tasks include the procurement of MRO for the plant, management of a warehouse, and logistics and inventory management.

Topsides is another team. It provides all of the support in procuring goods and services for the company's entire offshore asset, mainly the platforms and the Floating Production and Storage Offload Facility (FPSOs). These goods and services include a maintenance contract, paints, and any spare parts for rotating equipment and inventory management.

Procurement Support Group deals with two major functions: Account Payable Management and Cataloguing. Accounts Payable was part of the company's finance organization before implementing e-procurement. When the e-procurement management team mapped out the supply chain, they suddenly realised that accounts payable is the back end of its supply chain because any relationships associated with vendors and contractors can be impacted by the lack of payment of their invoices. Therefore, Accounts Payable was included in the Shared Services division. According to the interviewees, this has so far worked very well because it facilitates the communication between account payable and procurement. The Catalogue team is mainly responsible for maintaining and updating the catalogue centrally. It also requires some research effort to ensure that the new items added will fit the technical specifications and safety requirements. There are now about 8000 line items in the company's catalogue. Another important task for Cataloguing team is to search for Original Equipment Manufacturers (OEM) in purchasing MRO to cut off the middlemen, or dis- intermediate channels, in order to drive the costs down.

The Drilling team (exploration), as its name indicates, is the team that supports the well engineering

part of the company's businesses. Drill has to be made through the sea-bed in order to find gas or oil. The goods this team procures include drill bits, casting, modules, all the chemicals associated with drilling, and the mobile drilling rigs that are used to charter in to initiate the drilling.

The last group within Shared Services division is sub-sea and exploration group. In order for the company to initiate drilling, a 3D or 2D seismic survey of the sea-bed need to be conducted to determine whether the geographic strata of the sea-bed lends itself to a drilling program. The Group manages all MRO for all sub-surface needs, including all chartering seismic vessels, and the sub-sea components.

## 5.2 Intended benefits for implementing e-procurement

After conducting business analyses, Woodside considers that it can benefit from implementing e-procurement in the following five ways:

Capturing and reducing rogue spending. By 'rogue spending', it means that those spending is outside of its procurement contracts. As the manager of the Shared Services Division pointed out that there are many people, particularly when they weren't associated with a central group, were actually spending money outside of contracts. This problem has been addressed by implementing e-procurement.

Better analysis, better spending tracking, and better contracting prices. The implementation of e-procurement can facilitate the collection and analysis of spending data. This can ensure better tracking of procurement spending. Thus, company can consolidate spending and leverage such aggregated purchase volume to get a better deal from the suppliers. This can enable the company to have more robust contracts. Therefore, the bottom line of the company can be improved by extracting much overheads out of its procured goods and services through e-procurement.

Cutting out distributors to drive down prices. Another benefit the company expects from implementing e-procurement is to lower the prices of goods purchased by cutting out some of its distributors and the middle men. E-procurement provides opportunities for the company to go straight to the source of manufacture. Currently, it is unable to do that and many of the suppliers force it to go through an agent who typically "puts on his 10% or his 15%". Because e-procurement doesn't recognise any international boundaries, it enables the company to go right back to the source of the manufacturer and to negotiate better prices by cutting out some of the middle people

Optimising logistics to reduce transportation costs. Before implementing e-procurement, the company was able to rely upon a network that funnelled everything through to its distribution depot. Because of implementation of e-procurement, a layer of middlemen or distributor has been taken out. Hence its distribution channel could become wider. This seems to create challenges for the company to coordinate its procurement activities. However, the logistics aggregation can be made within the terms and conditions of the purchase order that e-procurement can send out electronically. Although the logistic carriers the company used would still be the same and the method of delivery or transportation would not be changed, the company could simply optimise it. This could leverage the movement of the materials purchased and thus reduce the logistics costs.

Logistics costs can also be further reduced by collaborating with other companies, particularly those that have branches located in the same remote areas. For example, Woodside has developed some sharing agreements with BHP, another Australian major player in oil and mineral industry. Because both companies work in the same industry and need to transport goods procured to the same remote areas, aggregating materials procured for transportation can make Woodside to get an economy of scale. The implementation of e-procurement can make such inter-firm collaboration much easier, particularly with the recent establishment of the online industry's supplier database, Supplybase Vendor Registration System ([www.supplybase.com.au](http://www.supplybase.com.au)), where Woodside is a major player.

Facilitating advanced planning for maintenance by integrating e-procurement with ERP and other e-business applications. With the installation of ERP and PM (preventive maintenance) within the company, the installation of e-procurement software EBP (Enterprise Buyer Professional) can enable the company to undertake advanced planning and maintenance. With the plant maintenance module, it can plan plant maintenance and shutdown anywhere up to 7 years in advance. The integration of e-procurement with ERP and PM enables the company to automatically place the orders and generate requests on suppliers or vendors for the goods and parts, particularly critical items. One advantage for having one integrated system is in the plant maintenance. The system can facilitate planning, calculate the lead-time, and flag the critical items for maintenance.

### 5.3 Critical factors in implementing e-procurement

Having implementing e-procurement for nearly two years, Woodside has identified some critical factors as follows.

1. Ensuring e-procurement is compatible with the back end ERP system, including the maintenance system. Woodside is a manufacturing firm and the maintenance of its operation and exploration is critical to its success. Therefore, it is crucial that the e-procurement package should be compatible and complementary to its ERP system.
2. The second critical factor, as the interviewee stressed, is good preparation and active monitoring and learning. As he stated that “you should allow yourself plenty of time and to move around the world and see how it is going in other parts of the world. So that you can bring in the lessons learnt.” This is very important, particularly in selecting the software for e-procurement.
3. Undertaking a good detailed analysis of procurement spending is another critical factor. It is not good jumping on the e-procurement bandwagon if it is not going to deliver the benefits. Only after a detailed spend analysis, can the benefits of implementing e-procurement be determined.
4. Communicating both internally and externally is also a critical factor for successfully implementing e-procurement. Also, competent people are needed who can implement the process.
5. The last, but not least, critical factor is to adopt a gradual approach. Start small and then make big. Because implementing e-procurement is a complex process, such a gradual implementation process can ensure that project can be properly controlled and lesson can be learned quickly. At the beginning, it is better to involve four or five key suppliers in e-supply.

### 5.4 Challenges in implementing e-procurement

Several challenges have been also identified in implementing e-procurement at Woodside, including issues in human resource management, technology integration, and supplier's involvement.

One challenge in implementing e-procurement is the redeployment and training of employees. Because e-procurement can automate significantly many processes, some existing employees have to be redeployed. Also the skills required for its employees need to be changed, specifically, from putting together purchase orders to putting procurement deals together. This shift in skill

requirements demands employees equip with more negotiation skills.

Revamping IT system and integrating IT with other applications, such as ERP, and Preventive Maintenance are also challenges the company face. The compatibility, or interoperability, of various e-business applications is a problem for the company. Although the company purchased all the software (ERP, PM, EBP) from the same software developer, they were not compatible in data communication in their standalone package. The software developer has been working for solving this problem. Nevertheless, it had presented as a stumbling block and the project had to be delayed until EBP is installed and tested.

Finally, how to involve its suppliers in e-supply is another challenge. The manager is cognizant of this issue and intends to adopt a staged approach to engaging suppliers in this area. Several large hardware suppliers who the company has already dealt with in e-procurement in other parts of Australia would be selected first. Then each quarter the number of suppliers will be increased until it has achieved what it believes the critical mass in terms of its high-volume and low value spend.

## 6. Summary and Implications

This paper attempts to explore several important issues in implementing e-procurement. To do so, a case study on the e-procurement implementation practice in an Australian organization was conducted. This has shed much light into several strategic issues and provided guidelines for other firms that wish to implement e-procurement in their own organizations. Several important results have been presented in this paper and can be briefly summarized as follows.

First, implementing e-procurement may need to redesign organization. Such organizational restructure should be based on the e-procurement processes. It also needs to ensure avoiding the overlapping of functions. The overall objectives are to simplify the e-procurement process and to provide “total” services both to the organization itself and the suppliers involved. In doing so, Woodside has established a new division, Shared Services that includes all important functions in procurement. The division itself has been structured based on the market of goods and services procured.

There are four areas that the company can potentially reap the benefits in implementing e-procurement. They are: 1) making employees comply with the prenegotiated contracts to improve procurement effectiveness; 2) leveraging the consolidated spend data to get better prices from suppliers; 3) dis-intermediating distribution channels to cut out middlemen, thereby lowering the prices of goods purchased; and 4) collaborating with other

players in aggregating goods procured to drive down logistics costs.

Like other e-business application, implementing e-procurement entails challenges. For Woodside, it faced three challenges: employee redeployment and training, integration of e-procurement with other e-business applications, and supplier involvement.

Finally, conducting a detailed business case analysis of procurement spending, well preparation, gradual implementation, and internal and external dialogue can pay off in implementing e-procurement.

The above findings have a number of important implications for managers. First, implementing e-procurement is very complex and can involve many functions and departments within the company, such as IT, HR, Finance, and Legal Services. Therefore, securing commitment from top management can be very important for successfully implementing e-procurement.

The second implication is that compatibility of various e-business applications should be considered thoroughly. It is a strategic issue given the amount of investment in these applications. Many firms may want to adopt a staged approach in implementing e-business applications. However, a critical question to ask in selecting a software package is: Can it inter-operate with other e-business applications that are potentially adopted by our organization in the future?

The findings in this paper also imply that e-procurement should be considered in a broad sense in order to fully tap its potentials. E-procurement involves much more functions than simply purchasing, including warehousing and transportation. Thus, in conducting business case analysis for e-procurement and redesigning organization structure, activities and benefits or costs incurred from these functions should be considered for streamlining e-procurement processes and generate a more 'realistic picture' about the consequences or outcomes of e-procurement.

# Performance Evaluation for 59 Listed Electronic Corporations in Taiwan

Chien-Ta Ho

Department of International Trade

Lan-Yang Institute of Technology

I-Lan, Taiwan

brucedaa@ms26.hinet.net

## Abstract

Most previous studies concerning company performance evaluation focus merely on operational efficiency. Operational effectiveness, however, which might directly influence the survival of a company is usually ignored. As a result, this paper presents a study which uses an innovative two-stage data envelopment analysis (DEA) model that separates efficiency and effectiveness to evaluate the performance of 59 Listed corporations of the electronics industry in Taiwan. The empirical result of this paper is that a company with better efficiency doesn't always mean that it has better effectiveness. There is no apparent correlation between these two indicators.

Key Words: Performance Evaluation; Data Envelopment Analysis (DEA); Electronic Industry

## 1. Introduction

Data envelopment analysis (DEA) is a mathematical programming approach for characterizing the relationships among multiple inputs and multiple outputs. There is a wealth of literature on both basic and applied research in DEA. Since the DEA model was proposed by Charnes, Cooper, and Rhodes in 1978[3], it has been widely used in non-profit organizations. Since then, numerous applications have appeared in profit organizations, such as the banking industry (see [21] [17] [6]), securities (see [12]), insurance (see [13]), medical services (see [10]), real estate brokerage (see [4]), construction (see [5]), the mutual fund industry (see [22] [14]), the airline industry (see [11] [18]) and so on. But, most previous studies concerning company performance evaluation focus merely on operational efficiency. Operational effectiveness, however, which might directly influence the survival of a company is usually ignored. As a result, the paper attempts to evaluate the company performance in terms of efficiency and effectiveness.

This purpose of the paper is to construct a conceptual framework, based on the return on assets, a ratio commonly discussed in financial analysis, to define the meanings of performance. Besides, the paper uses a recently developing model of data envelopment analysis

proposed by Cooper, Seiford and Tone in 2000 [7].

The remainder of the paper is organized as follows. Section 2 defines the meanings of efficiency, effectiveness and performance and its evaluation process. Section 3 describes the DEA methodology. Finally, a case study is conducted using the example of Taiwan's 59 listed corporations of electronics industry.

## 2. Evaluation Process

### 2.1 The Meanings of "Efficiency", "Effectiveness" and Performance"

Most scholars define performance as the degree of achievement towards the set goal. However, some suggest differently. The following are some suggestions on the meaning of performance from a variety of literature:

- (1). Management guru Peter Drucker (1963) [9] uses efficiency and effectiveness in analyzing performance, defining efficiency as "doing things right" and effectiveness as "doing the right thing". If a manager maximizes the output for a given level of input, we could say that he has achieved efficiency. On the other hand, we could say that he achieves no efficiency. Effectiveness refers to the degree of achieving the set goal of the organization. In order to avoid "doing the right things using the right method or the wrong method", enterprises need to distinguish between effectiveness and efficiency. In principle, effectiveness should be set as the primary goal, from which efficiency is enhanced.
- (2). Venkatraman and Ramanujam (1986) [23] look into the issue from the perspective of strategic management. They suggest that business performance is a part of organizational effectiveness, and proposed three levels of performance evaluation, namely: (i) financial performance; (ii) financial + operational performance; and

- (iii) organizational performance.
- (3). Sailaggyi, A. D. (1984)[20] holds that performance evaluation is a global concept, representing the result of organizational activities.
  - (4). Traditionally performance measures have been seen as a means of quantifying the efficiency and effectiveness of action [15].
  - (5). Nanni et al. (1990) [16] use the analogy of a thermostat to explain how performance measures are part of a feedback loop, which control operations against a specific value.
  - (6). Berliner and Brimson (1988) [2] state that performance evaluation is a key factor in ensuring the successful implementation of a company's strategy.
  - (7). Appropriate performance measures are those which enable organizations to direct their actions towards achieving their strategic objectives [8].

The above summary of literature indicates that different researchers define performance differently, depending on the focus of their study. However, there is also inconsistency in the use of the terms "efficiency", "effectiveness" and "performance". For the purpose of allowing readers to distinguish the meanings of the three terms, the author explains the distinction of the three in terms of Return on Assets, a topic commonly discussed in financial analysis:

$$\text{Return on Assets (Performance)} = \frac{\text{Earning Before Taxation}}{\text{Total Assets}}$$

(This can be broken down into 2 equations)

$$= \frac{\text{Earning Before Taxation}}{\text{Net Sales}} \times \frac{\text{Net Sales}}{\text{Total Assets}}$$

$$= \frac{\text{Profit Ratio (Effectiveness)}}{\text{Total Assets Turnover (Efficiency)}} \times$$

Return on Assets (Performance): It assesses the profitability of total assets before taxation, and could be treated as performance in this study. It contains two elements, efficiency and effectiveness.

Profit ratio (Effectiveness): It assesses the net profitability before taxation during the current accounting period. It could be treated as the element of effectiveness in this study and is defined as the ability to achieve the expected goal (result or output).

Total Assets Turnover (efficiency): It assesses the ability of the firm to use its assets and it could be treated as efficiency in this study. It is defined as the output generated by given resources under the influence of the environmental factors.

$$\text{Performance} = \text{Effectiveness} \times \text{Efficiency}$$

The above analysis shows that performance is indeed the product of multiplying efficiency by effectiveness.

## 2.2 A Two-Stage Evaluation Process

Based on the above definition of performance, this paper evaluates the performance of Taiwan's 59 listed corporations of electronics industry via a two-stage evaluation process that separates efficiency and effectiveness.

Figure 1 is an introduction of a two-stage evaluation process. The process is divided into two stages and the six factors are expressed as inputs and outputs at each stage. The first stage (Stage 1) measures efficiency, i.e., a company's ability to generate the sales in terms of its capital, asset, and employee. The second stage (Stage 2) measures effectiveness, i.e., a company's profit and operating revenues by the sales it generates.

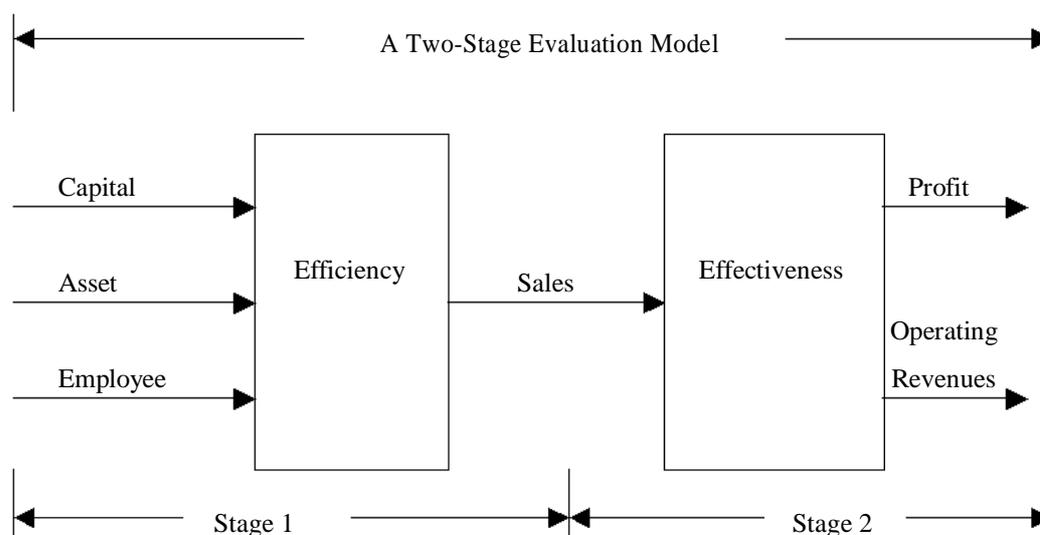

Figure1: A Two-Stage Evaluation Model

### 3. Methodology

DEA, a mathematical programming approach for characterizing the relationships among multiple inputs and multiple outputs, has proven itself as a metric for measuring company performance. The concept of Pareto Optimality in economics is used to measure efficiency, and is the core of DEA. This method was proposed by Charnes, Cooper and Rhodes in 1978. Based on the concept of envelopment in economics, the three projected the input and output of all units subject to evaluation (Decision Making Unit, DMU) on a geometric map to find the limits. If both the input and the output fall above the efficiency margin, then the DMU is efficient. Likewise, if the input and output fall within the efficiency margin, then the DMU is inefficient. The basic idea of DEA is to identify the most efficient DMU among all DMUs. The most efficient DMU is called a Pareto-optimal unit and is considered the standard for comparison for all other DMUs. The Pareto-optimal unit is the one such that any change that makes some people better off makes other worse off.

The most widely used models for DEA are the CCR and the BCC. The former was proposed by Charnes, Cooper and Rhode in 1978 based on the concept of “two inputs and one output” originally spelled out by Farrell in 1957. The three scholars have modified the concept to “multiple inputs and multiple outputs” in order to meet the needs of the complex production procedure of today. The fundamental premise is that under fixed scale of return is used to measure the overall technological efficiency of DMU. The latter was proposed by Banker, Charnes and Cooper in 1994, with the purpose of extending the concept of the CCR model and scope of application. The fundamental premise of the latter is that where scale of return is changeable, the overall technical efficiency of the CCR model could be compartmentalized into pure technical efficiency and scale efficiency.

In this study, the author will use the revised CCR model proposed by Cooper, Seiford and Tone in 2000 to evaluate the performance of Taiwan’s 59 listed corporations of electronics industry. The model is demonstrated below:

Assuming that there are  $n$  decision units and each  $DMU_j$  uses  $m$  input  $X_i$  to produce  $S$  output  $Y_r$ , we find the CCR model from the following equation if the scale of return is constant:

$$\text{s.t. } X_{io} = S + \sum_{j=1}^n X_{ij} \lambda_j$$

$$\Phi_0^t Y_{ro} = -S_r^+ + \sum_{j=1}^n Y_{rj} \lambda_j$$

$$\lambda_j, S_r^+, S_i^- \geq 0 \text{ for all } j, r, i$$

$$r=1, \dots, s$$

$$i=1, \dots, m$$

$$j=1, \dots, n$$

$$t=1 \text{ is stage 1; } t=2 \text{ is stage 2}$$

$$X_{ij} \text{ is the } i\text{th input of the } j\text{th DMU}$$

$$Y_{rj} \text{ is the } r\text{th output of the } j\text{th DMU}$$

$$S^- \text{ is the difference input variable}$$

$$S^+ \text{ is the difference output variable}$$

$$\lambda_j \text{ is the } j\text{th DMU weight value}$$

$$\epsilon \text{ is the Archimedes value, usually set as } 10E-4 \text{ or } 10E-6$$

In Stage 1, we have  $n = 59$  DMUs (corporations);  $i = 3$  inputs: capital, asset, and employee; and  $r = 1$  outputs: sales.

In Stage 2, we have  $n=59$  (corporations);  $i = 1$  inputs: sales; and  $r = 2$  outputs: profit and operating revenues.

## 4. Case Study

### 4.1 Data and Sample

59 listed Corporations of electronics industry in the Taiwan Stock Exchange Corporation (TSEC) for Year 1999 will be measured. All input and output data of these companies are obtained from Taiwan Stock Exchange Corporations (as shown in Appendix 1).

### 4.2 The Software for Calculating DEA Efficiency Value

The data from all DMU in this study is subject to the calculation of the Frontier Analyst software based on the revised CCR model in order to obtain the DEA efficiency value. If the DEA efficiency value is equal to 1, it means it is the best efficiency and hence the unit is the most efficient unit.

### 4.3 The Correlation Coefficient Between the Input and Output Variables

The Pearson Product Moment Correlation Coefficients of all input and output variables calculated by the Frontier Analyst software are shown in Table 1 and Table 2. From the both tables, we find out that all input and output variables chosen for this study are strongly correlated.

$$\max \Phi_0^t + \epsilon \left( \sum_{i=1}^m S_i^- + \sum_{r=1}^s S_r^+ \right) \quad t = 1, 2 \quad (1)$$

Table 1 The Pearson Product Moment Correlation Coefficients of All Input and Output Variables of the Stage 1 Efficiency Model.

Input Output	Capital	Asset	Employee
Sales	0.96	0.99	0.98

Table 2 The Pearson Product Moment Correlation Coefficients of All Input and Output Variables of the Stage 2 Effectiveness Model.

Output Input	Profit	Operating Revenues
Sales	0.91	0.95

#### 4.4 The Evaluation Result of 59 Listed Corporations

Table 3 report the CCR efficiency scores, only nine corporations, namely POTRANS (2378)<sup>1</sup>, EMC (2383), AVISION (2380), Q-RUN (2354), ACER (2353), HON HAI (2317), SYNEX (2347), QCI (2382) and ACER (2306), are CCR-efficient in the stage 1 efficiency model. Five corporations, namely, TMC (2338), POE (2370), ABILITY (2374), RITEK (2349) and TSMC (2330), are CCR-efficient in the stage 2 effectiveness model. Table 3 also reports the total performance scores of the two models and the rank of 59 listed electronic corporations. The top 5 performing companies are as follows. AVISION (2383) (score = 71.42%) ranks first, next is TSMC (2330) (score = 57.03%), ABILITY (2374) (score = 54.67%) is third, ASUSTEK (2357) (score = 46.95%) is fourth, QCI (2382) (score = 34.66%) is fifth.

Note the relation between both models (efficiency and effectiveness). In our case, within 59 Listed corporations of electronics industry, the company with best efficiency doesn't always mean having best effectiveness. For example, TMC (2338) ranks first in effectiveness but ranks last second in efficiency. There is no apparent correlation between these two indicators. Further, from the efficiency distribution of 59 corporations, we find that only 15.25% (9/59 DMUs) of the companies were efficient for the stage 1 and 8.47% (5/59 DMUs) of the companies were efficient for the stage 2.

#### 4.5 Process Improvement

The analysis of the previous section indicated which electronic companies were efficient and which are inefficient. For each stage, inefficient electronic companies are able to improve their performance and the DEA projections provide a prescription for improvement. For example, 2383(EMC) was CCR-efficient in stage 2 effectiveness model; however, it can move its performance to best-practice by either (1) increasing its profits and operating revenues, or (2) decreasing its sales. Thus, inefficient electronic companies are able to improve the overall performance via the stage 1 or the stage 2.

#### 4.6 The Relation between Efficiency and Effectiveness

The author employs the business strategy matrix derived by Boston Consulting Group (BCG matrix) to illustrate the individual evidence in the relationship between efficiency and effectiveness (see Table 4). It has been observed that 4 (EMC, TSMC, ABILITY and ASUSTEK) of 59 companies are in the "super star" group which is characterized by high efficiency and high effectiveness. Conversely, 25 (BTC, FIC, SOLOMON, TECOM, PICVUE, SILITEK, ASKEY, DELTA, LITE-ON, Q-RUN, TATUNG, AURORA, LPI, BENQ, MTI, WUS, COMPEQ MFG, YAGEO, MXIC, GCE, CHIN-POON, D-LINK, RECTRON, MIC) of 59 companies are characterized by low efficiency and low effectiveness and placed in the "problem child" group. The author can argue that the 25 problem child companies should rearrange input to improve their performance.

<sup>1</sup> The numbers stand for the stock-number code of the company in Taiwan Stock Exchange Corporation (TSEC).

## 5. Conclusions

This paper uses a recently developing model of data envelopment analysis proposed by Cooper, Seiford and Tone in 2000 to evaluate the performance of 59 Listed corporations of the electronics industry in Taiwan. The estimated results show that for the stage 1 efficiency model only nine corporations, namely, POTRANS (2378), EMC (2383), AVISION (2380), Q-RUN (2354), ACER (2353), HON HAI (2317), SYNEX (2347), QCI (2382) and ACER (2306), are efficient, and for the stage 2 effectiveness model only five corporations, namely, TMC (2338), POE (2370), ABILITY (2374), RITEK (2349) and TSMC (2330), are efficient. The inefficient companies can effectively promote resource utilization efficiency by better handling their labour and capital operating efficiency. The result also indicates that the corporation with better efficiency doesn't always mean that it has better effectiveness. There is no apparent correlation between these two indicators.

## Abstract

This is a case study based on an online skincare and markup products retailer, e-beauty. The raw materials for the authors' analysis come from a close observation of its marketing tactics, operating environment, as well as comments from online free speakers, some "offline" female interviewees, and reported public spoke made by managers of the company. From a neutral perspective, the authors draw conclusions on the integration of various aspects of the facts with the aid of some well-established marketing principles and theories. Findings suggest that online retailers might go profit by taking the virtues of both "online" and "offline." In specific, instead of tirelessly pursuing totally virtualization, some traditional non-electronic and traditional marketing practices can be used to strengthen the area where "Internet" is weak. In practice, the authors suggest that judging from a consumer's perspective, or customer orientation, is the rule of thumb for the choice of appropriate marketing strategy and tactics.

## 1. Introduction

Online shopping, a prosperous business area which attracted great interests even several years ago, has undergone significant drawback. People's dream on Internet giant was dashed to the ground overturn with the astonishing decline of the NASDAQ's stock index. In recent years, many online retailers shut down one by one, so that people almost forget some of them are once famous or panegyricized. Amazon, once the most successful online bookstore, has also felt into the situation of struggling for survival.

As the e-business is surrounded in a worldwide stagnant environment, an online retailer, e-beauty, shows lights on a new avenue for B2C online business. e-beauty (<http://www.nicebeauty.com>), founded in Taiwan, April 2000, is an online retailer which offers electronic commerce platform selling women makeup and skincare products, providing health and fashion suggestions. It operates nearly 200 products from seven brands including Dr. Bella, Serene, Roberta di Camerino and KyuBuTo ReDinGu etc., among which Dr. Bella is the most important one. Only half a year later, the company reached balance and every dollar turned into profit since that. Until now, it has more than 180,000 members in Taiwan, monthly sales of more than HK\$5,000,000. On 8 October 2001, it established new business in Hong Kong (<http://hk.nicebeauty.com>).

How can e-beauty be so successful in online B2C practice? What's the difference between e-beauty and most flat online retailers? The implications under its success need to be dug up to guide online enterprises that are struggling on the edge of survival and those that intend to step into this

area. A detailed investigation of this case was conducted to answer these questions. The raw materials for the authors' analysis came from comments from online free speakers, some "offline" female interviewees, and reported public spoke made by managers of e-beauty.

This case study reaches the conclusion that the extraordinary success of e-beauty ascribes to its splendid combination of online virtues with traditional business advantages, with the two complementary with each other. The combination effectively lowers consumers' perceived risks on online retailing, builds strong brands by providing various concrete and psychological benefits, targets and segments consumers implicitly while efficaciously. These measures adopted help reduce running expenses, induce tryout intention, and protect security. In turn, they lead to increased sales and profits. In the following section, the author first provides an overall description and analysis of e-beauty's practices in every main aspect. Then, synthetic remarks are provided based on the former work.

## 2. The Characteristics of the Products e-beauty Sell

It is said that among every \$1000 spent on makeup and skincare products, \$600 flow into the pockets of ad-agents and middlemen. This industry is a highly profitable business and the high costs are eventually born by end consumers. Li Junyan, senior manager of e-beauty in grant China area, said: "Through Internet, e-beauty makes possible for manufactures to face mass consumers directly, which significantly reduces the intervention from distributors and retailers, and thus increases cost efficiency. Therefore, e-beauty can charge competitively attractive prices for good-quality skincare and makeup products from Europe, America and Japan." Liang Yangming, the senior manager of e-beauty emphasized: "e-beauty help consumers to realize 'spend every penny on your own beauty'."

For every product, e-beauty provides colorful product photo as well as detailed description of its intergradient, function, usage and application, which make prospective consumers knowledgeable of all fundamental aspects of the product. "It is not enough, however. On the condition that I'm not familiar with a skincare brand, no matter how splendid it is boasted by the seller, I'll be hesitate to buy one unless I have a tryout in person" expressed by many interviewees. So, how to induce probation seems the first critical step toward profit, especially for e-beauty since it sells unknown brands. In addition, creating strong brand reputation is equally vital in personal care industry as well.

### 3. Brand Building

With the help of Internet, it is possible for e-beauty to charge low prices. "Price is one thing. I care more about the brand itself." "Using products of prestigious brands like Lancome, Shiseido or H<sub>2</sub>O makes me feel younger, safe and psychologically fulfilled." Given that consumers know nothing about Dr. Bella, how to make a brand in obscurity well known is the biggest challenge to gain consumers' belief.

To make consumers appreciate the brands sold by e-beauty, a photo of Wang Zuxian, a famous female actress known by Chinese, published on the website. If you click on the photo, a shortvideo in which Wang Zuxian advertises for e-beauty and its products will show. Advertisement by a celebrity increases the credibility of the contents of the website and raises the admiration for brands associated with the advertising. Somewhat, it can also be taken as a kind of warranty. In addition, compared with TV ad, ad on Internet is much cheaper, can be published for a longer time and can be accessed whenever you want. So the ad can be accepted more actively than those that are released through traditional media.

The openness and freedom of Internet make it possible to separate building a strong brand with expensive agent fees, advertising fees and rents.

### 4. Induce Probation

The website also promotes extensively for its free gifts to induce probation. Every month, e-beauty provides 3 to 5 free skincare or makeup products with prices ranging from HK\$300 to HK\$500 for members (free membership). To cover the material and transportation costs, e-beauty charges HK\$45 or NT\$180 for every free gift.

"The volume and quality of free gifts are parallel to normal products on shelf. We turn the money that is traditionally spent on advertising and special shelves lease into products for consumers to have a tryout." Critique from competing websites responds that e-beauty's so called "free gift" is just a kind of "extensive promotion ploy". Anyway, the charge of "HK\$ 45" cannot be set equal to "free" apparently. The authors think that the success of this measure can be contributed to the following reasons.

From the viewpoint of consumers, different from in other circumstances, consumers can get a so called "gift" in normal volume, they have free membership and unlimited right to ask for "gifts", and the price is cheap even for normal products, especially when the retailer makes fantastic utilization of reference price effect. In specific, the regular prices of "gifts" are labeled up to several hundred of dollars, which are comparable to high-level skincare products. Perhaps no rational consumers will buy from e-beauty at these prices. In other words, the prices are unauthentic and thus be suspected. However, extensive literature on reference price shows that consumers are affected by exaggerated advertised prices even though they do not trust them fully and this effect can be embodied on purchase behavior. In this case, consumers unawares take the high advertised "regular" prices as reference, based on which "HK\$ 45" is judged and perceived to be very cheap. This altered price perception will lead further to increased

purchase intention and even real purchase behavior. Responses from Internet free speakers show that they are apt to take the risky (or chance). "While it is priced so low, I don't mind to be cheated and would like to have a try." The low prices also lower consumers' expectation on the performance of the products. So, consumers are more easily satisfied. "It's astonishing, I didn't expect products with so high quality" an Internet user gave comments after she got her free gift. In addition, lower price can greatly reduce consumers' perceived monetary lost and make consumers' curiosity affordable.

From the retailer's perspective, on the other hand, its operations costs and advertising expenditures can be controlled within a low level with the help of Internet. Also, its brands are not worth so much to be charged as famous brands. These grant that it could be profitable even at the price for "free gifts", since many middlemen and associated costs are saved.

Some research showed that if products are mainly judged by searchable attributes, e.g., price, intergradient, Internet is a good choice to sell this kind of products; on the contrary, if non-searchable attributes, e.g., smell, handle, of products are significant for consumers' buying decision, selling solely online is not a wise option. Skincare and makeup products can be roughly categorized into the later type. Thus, inducing probation is a countermeasure to tackle the limitation of Internet.

e-beauty website absorbed 30,000 members by the end of the first month after its setting up. During the first three months, it sent out 40,000 gifts. Now, e-beauty sends out 80,000 gifts every month. In August 2001, it even created a record of sending out 40,000 gifts within two days and a half.

### 5. Payment and Logistics

Instead of solving the biggest headache in B2C electronic commerce, logistics and payment, along the prevailing thinking, e-beauty cooperates with "offline" convenient chain stores, 7-eleven.

7-eleven, the biggest retailing network in Hong Kong, is composed of 441 convenient chain stores and located almost everywhere in Hong Kong. It provides clean, comfortable and kind shopping environment, fresh, quality products, as well as speedy and convenient service. Every month, there are more than 20,000,000 capita buy from 7-eleven. To finish their orders online, consumers are required to indicate which 7-eleven store they would like to draw their ordered products. After a consumer makes order or asks for free gifts online, she/he will receive a confirmation email assuring the product ordered or gifts asked, time period to draw product, the place to draw etc. Consumers need to pay in cash as soon as they get their ordered. Although consumers can't enjoy the convenience of getting goods while staying at home, it is almost equivalently convenient to drop by 7-eleven in Hong Kong. The cost would be much higher if goods were sent by post or FedEx, and consumers sometimes complaint they can't wait for the products at home in the daytime.

It is also preferable that consumers can pay by cash. According to many online surveys, privacy and security are

the most serious concerns preventing consumers from shopping online. The payment security is especially concerned. "I'll never give out my credit card number online." "It's too dangerous to give out my credit card information on the Internet." Consumers show their distrust on Internet when they need to pay and therefore they are hesitant to provide their credit card number. Cooperating with traditional convenient store seems a wiselolution.

## 6. Loose Shopping Environment

e-beauty also raises the freedom of consumers' choice by: 1) providing a relative long time period for consumers to draw the products (normally 6 days); 2) if consumers fail to draw the products, there is no monetary punishment, except that they will never get the chance to order free gifts if they fail three times. These measures free consumers from compulsory action, instead they create a loose and trustful environment, give room for consumers to "regret" and consider more. They can help to raise consumers' favor on e-beauty and appreciate its consideration. "We make consumers moved continuously," said Liang Yangming.

## 7. Targeting and Segmentation

While e-beauty takes advantages of various means, it doesn't forget the basic concept in marketing, targeting and segmentation, especially in this highly competitive industry, or you might lose the whole market.

The idea segmentation can be embodied everywhere. It emphasizes that its products are designed according the Eastern skin type. The websites are written in Chinese characters, the celebrity chosen are highly famous among Chinese, it distributes goods just locally, and consumers need to pay on domestic or local currency. For most online retailers, with the help of Internet, they try to reach consumers globally. While for e-beauty, it seems somewhat "myopic". In Taiwan, there is <http://www.nicebeauty.com>, while in Hong Kong, there is <http://hk.nicebeauty.com>. e-beauty targets to Taiwan people and Hong Kong people respectively. All the above facilitate the transaction process in the target market, reduce the risks from extraordinary factors, e.g., exchange rate, product performance failure, and make the shopping experience more convenient and enjoyable.

e-beauty is also aware that although loyal consumers are surely important and crucial to the company, a great proportion of skincare or makeup users are always switching and apt to take bargains, especially in a highly competitive industry. To well grasp this segment, the "free gift" program is always in operation, with the products offered varied every month.

## 8. Conclusion

Overall speaking, we think the success of e-beauty lies mainly in its combination strategy, in specific, it takes the advantages of Internet media; at the same time, it retains benefits of traditional business practices, e.g., paying in cash, as a supplementary. In other words, each works to strengthen the area where the other is weak. Compared with online retailers that tirelessly pursue being totally virtualized and take great efforts and investment to catch up

in logistics, e-beauty abandons such efforts, instead it adopts seemingly lagged manner, something between modern and tradition.

It is easy said than done. The case manifests that thinking from consumers' perspective is a useful device in guiding detailed measures or practices. No matter how advanced a technology or practice is, whether consumers perceive it favorable or unfavorable is the theme. An online retailer must see through its consumers' eyes to judge what advantages of Internet and traditional business practices respectively should be retain. Some traditional marketing concepts, e.g., target, segmentation, brand reputation, are still useful or even fatal for online retailers.

In practice, the author thinks that e-beauty's practice can be best used for reference when setting up online retail stores selling high value-added unknown consumption brands in high population areas having developed offline retailing network charged by just a few holders.

# Payment Barriers in China's B2C Business

## Abstract

With the entry into the WTO, China has made a lot of progress in its e-business. However, there are still some barriers that limit the development of e-business in China. One of the most difficult hurdles might be the fragile online payment system. According to The first DHL Global E-commerce Report, in mature Internet countries, online payment is no longer a problem. For instance, six out of 10 companies in the US (60%), Australia (61%) and Finland (58%) say payment is not a barrier to e-commerce. But less mature markets including China consider payment a barrier. This paper mainly discusses the payment barrier to B2C Business in China, and then forwards some suggestions on how to remove those barriers on the basis of analyzing the case of BOLChina—A successful B2C model from Germany. Also, some conclusions are given to make it more clear that China should break the ice of payment barriers on the way to the bright future of its e-business.

## 1. Current Situation of China's Internet Users

Since a certain number of Internet users are the foundation of e-business especially the base of B2C business, it's quite imperative to discuss the current status of Internet users in China and the main characteristics of their online buying behaviors. This section describes the population of Chinese Internet users and their basic online shopping behaviors.

### 1.1 Growing Online Population

The China Internet Network Information Center (CNNIC) in January 2002 claims that the number of Internet users in China has reached 33.7 million, with 6.72 million using leased lines and 21.33 million using dial-up connections. The "Statistical Report on Internet Development in China" said that the number of users accessing the Internet via both means was only 5.65 million. Additionally, another 1.18 million people are connected through appliances such as mobile telephones and various home information appliances. According to the reports made by CNNIC in the past four and a half years, we can see clearly the development of Internet in China (see Exhibit 1 and Exhibit 2)[3].

Exhibit 1: The Increase of the Computer Hosts in China (in Thousands)

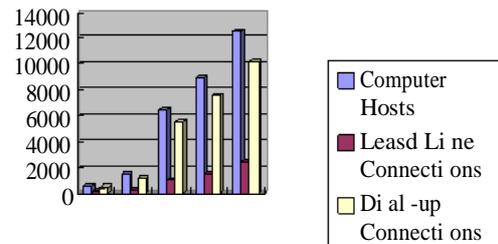

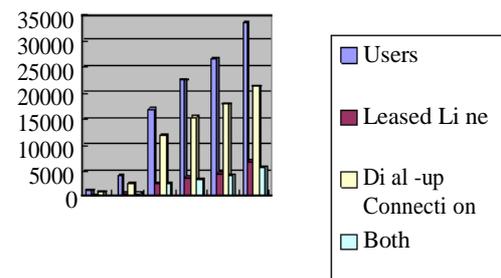

Exhibit 2: The Increase of the Internet Users in China (in Thousands)

With 1.3 billion potential e-consumers, it is likely that the Chinese market will have a ramatic effect on world e-commerce. However, Internet penetration rate in China is currently low when compared to the U.S., but is growing at a tremendous rate. Citing research by CNNIC Semiannual Surveys, the report said that Internet penetration is currently only 2.6 percent in mainland China which reflects the fact that China's e-business is quite fledgling.

Even though many mainland Chinese do not have Internet access at home, Internet penetration rates for mainland China were once doubling every six months from October, 1997 to July, 2000, though the speed slowed down in recent two years, the absolute number of Internet users still increased at a quick pace, and this has laid a solid foundation for China's B2C business.

### 1.2 Favorite Items Bought Online

Only 31.6% of Chinese Internet users have had some experience of buying online. The most popular goods for Chinese online shoppers are books and magazines,

purchased by 58.0% of those who shopped online at least once. Computer appliances(33.7%) were ranked the second item that Internet users bought. The rest popular items are: Photographic Equipment 3.6%, Communication Appliance 15.5%, AV Equipment 34.4%, Living and Housing 11.6%, Clothing 4.4%, Family Electrical Appliance 5.6%, Sports Equipment 4.4%, Medical Care Services 3.1%, Present Delivery 14.7%, Financial and Insurance Services 2.6%, Ticket Ordering 9.7%, Educational Services 11.8%, Others 3.1%.

### 1.3 Reasons to Buy Online

48.3% of Chinese Internet users bought online because they thought it can save time by buying online, and “Easy to Operate For Fun and Curiosity (31.5%)” and “Reduce Costs(38.8%)” are the reasons next to “Saving Time”. Interesting is the following reason of “For Fun and Curiosity (31.5%)”, which was ranked the 4<sup>th</sup> purpose for users to purchase online.

## 2. Payment Barriers to B2C Business in China

### 2.1 Barriers in China’s Banking System

Credit cards are very inconvenient to use in China because banks don’t share a centralized settlement system. Different banks issue their own credit cards and the cards can only be used in certain shops and restaurants and hotels, etc. Each bank has its own territory and they don’t talk to each other. Cash, instead of credit cards, is the dominant payment method.

Besides, banks don’t have a complete network among all of their branches, so they don’t promote credit card usage. Trying to own a credit card in China is a difficult process. And, very often, consumers are given very little credit lines so that a credit card virtually works as a debit card.

Therefore, online payment is a big bottleneck to e-commerce. A Web site has to establish settlement with different banks before they can accept all different cards from its users. Most B2C sites are actually using the Web as a catalogue only, while collecting the money offline at the time of purchase at a consumer’s home or office.

### 2.2 Online Shopping Barriers

Just as elsewhere in the world, the Chinese online shoppers have their trouble regarding every aspect of online shopping behavior. Concerns about security and quality of goods are cited as primary online shopping barriers: (see Table 1) [2]

Inconvenient payment ranks the third place in online shopping barriers, but the value and attitude of Chinese people towards credit cards attributes partially to this barrier. According to a research made by China Women Journal and Mastercard, among the banking card holders, 62% of them possess 1 to 3 cards, 36.6% of them possess

3 to 6 cards, and the rest of them even hold more than 6 cards. However, only 34% of them use credit cards occasionally, 15% of them never use any card [5]. The trouble is that few Chinese people trust the Internet for business. A Chinese saying goes that one should “never let out your hawk until you see the hare.” So, frankly speaking, providing a more effective way of paying online will not solve the “attitude” problem of Chinese online purchasers.

**Table 1 :Online shopping barriers in China**

Online shopping barrier	Percent
Security can not be guaranteed	31.0%
Inconvenient Payment	11.8%
Quality of products, after service and credit of the producer can not be guaranteed	30.2%
Delivery is time wasting, the channel is not expedite	13.9%
Unattractive Price	6.3%
Unreliable Information	6.3%
Others	0.5%

Source: Jan, 2002 CNNIC

### 2.3 Trust Issues

Many surveys made both domestically and abroad showed that most Chinese online shoppers were also distrustful of companies that exist only in cyberspace without a brick-and-mortar counterpart. According to the surveys, few Chinese would make a purchase from an e-tailer that they had never heard of before [4].

Since the Chinese online market is just in its infancy, Steve Diller, partner and head of eBusiness and Media Strategy at Cheskin thought that it's even more critical to pay attention to online trust, as technology penetrates global markets, access to e-commerce won't be the issue, creating loyal relationships through service, authenticity, and trust will be key.

### 2.4 Other Related Barriers

Other related barriers include distribution of online shopped goods, the application of state-of-the-art technology in China’s e- business, etc.

As to the logistic system, which is another serious problem of e-commerce development in China, the successful online shops in China adopts a pragmatic method—to order online, to pay offline. Such a strategy is based on such a logic of trying to avoid much

involvement of delivery and transaction infrastructures. In fact, the development of delivery and transaction infrastructures is out of the reach of internet companies in China. The worst situation is that internet companies invest a lot of money to develop infrastructures that are supposed to be done by the government and other industries. When the infrastructures are not available, e-commerce companies should focus on building up information platform to make that part electronic and seek more physical solutions for delivery and transactions which is called partial e-commerce models. Unlike in the U.S., delivery function of online shops is contracted out to major courier firms such as UPS, FedEx, etc., the only viable delivery system to both business and homes is the state-owned Post Office. But the Post Office is notorious for being slow and mishandling goods. Foreign competitors, such as DHL and EMS are starting to have presence in large cities of Shanghai, Beijing and Nanjing, but they are targeting office buildings and the cost they charge is excessively high for an ordinary online shopper. So, a lot of Chinese online shops together with foreign ones are taking advantage of cheap labor resource in China to combine with electronic solutions. Physical solutions in delivery and transaction are not necessarily second best solutions in China since labors are still very cheap in China.

### **3. Some Suggestions on How to Remove Payment Barriers in China**

#### **3.1 Establish a far-reaching, well-organized payment system**

Dotcoms and B2C business in China could only achieve ideal growth after entered into long-term agreements with banks.

China lacks central credit clearing corporations, making the proliferation of credit cards difficult -- although debit bank cards number is over 350 million[4]. The tool that has transformed American on-line purchasing is therefore rare in China. Companies selling merchandise depend on cash-on-delivery and nascent debit card accounts for their commerce. Recognizing this obstacle, the People's Bank of China and the leading state-owned commercial banks are actively engaged in setting standards for secure payment through the establishment of certification authorities. Companies such as Capital Electronic Center are already filling the gap by facilitating on-line payment for any of 12 debit or credit cards issued by the major commercial banks. After such efforts, the off-line cash payment which is currently quite popular as a substitute is to be soon outmoded and replaced by a modern online payment

#### **3.2 Increase communication with global e-commerce outfits, publicize knowledge about e-commerce and Internet usage, and merge the modern Internet economy with the traditional business model.**

Any commerce model involves three infrastructures: information infrastructure, delivery infrastructure and transaction infrastructure. E-commerce models in western countries take big advantage of well-developed delivery infrastructure and transaction infrastructure and try to manage information flow, goods flow and payment flow as much as possible with electronic solutions (complete e-commerce models). The internet strengthens information infrastructure and catalyzes E-commerce development.

#### **3.3 Establish A Strict Credit System Throughout the Country**

The credit system is also linked to popular perception. In the U.S., bad credit brings you lots of trouble. In China, wrongdoers are left too much leeway to correct things. How can we establish a credit system under such cultural views? So, it's necessary to set up such a credit system so that the questionable practice online will be punished.

#### **3.4 Establish An Efficient Delivery System**

Delivery is another serious problem to e-commerce development in China. The only viable delivery system to both business and homes is the state-owned Post Office. But the Post Office is famous for being slow and mishandling goods. Foreign competitors, such as DHL and EMS are starting to have presence in key cities of Shanghai, Beijing and Guangzhou, but they are targeting office buildings and the cost they charge is prohibitively high for an ordinary consumer.

How to get goods out to a consumer's door in time before he or she gets irritated is a huge problem. Or is there an alternative solution? Web sites in Japan are using Seven-eleven convenient stores as the distribution channel. Consumers purchase goods online but go to a Seven-eleven store to pick them up. But China should develop a more practical model of e-distribution since there is no such a chain store system like 7-11.

### **4. BOLChina—A Successful Case in China's B2C Market**

Bertelsmann is a Germany-based company offering books and other media products. Since its entry into China in 1995, Bertelsmann contributed to many cultural exchanges between Germany and China and today it strives to further develop the Chinese media industry through its products and services.

During Chancellor of Germany Kohl's first visit to China in 1993, Bertelsmann set its foot in China as a member of the German delegation. Bertelsmann then started negotiations with competent government authorities in Shanghai concerning the possibility of media cooperation. After a series of negotiations the Science and Technology Book Corporation under the Shanghai Press and Publishing Bureau and Bertelsmann Germany Holding GmbH signed a joint-venture contract

in July 1994. Subsequently, in February 1995, Shanghai Bertelsmann Cultural Industrial Company Limited was founded [1].

As a result Bertelsmann, one of the leading media groups in the world, entered China and opened a new chapter in its adventure in China: promoting cultural exchanges between Germany and China, sharing its successful experience with its Chinese counterparts, and providing a wide variety of media products to the Chinese consumers. At present, Bertelsmann's operation in China is not only based on the traditional book market, but also pervasively participates in the progress and further development of the Chinese cultural industry and advanced multi-media and e-commerce, shaping its unique professional service in the market.

While China's dotcoms are bruised by the heavy blow from the recent Nasdaq crash, Bertelsmann AG, the third largest media conglomerate in the world, is moving its China businesses onto the Web.

Aimed at exploring China's fledging multimedia market, Bertelsmann has launched an online media arm under the global brand umbrella of BOL.com.

BOL China ([www.bolchina.com](http://www.bolchina.com)), functioning as a platform to retail media and entertainment products in China, claims to be capable of dispatching 100,000 book titles throughout the country on a daily basis.

To run an online bookstore is nothing new in China and many firms have so far struggled in the industry.

Ekkehard Rathgeber, vice-president of Bertelsmann Direct Group East Asia and General Manager of Shanghai Bertelsmann Culture Industry Co Ltd, is upbeat about the online business for one reason: the strong brand of Bertelsmann and its traditional media businesses.

The initiative in China is part of Bertelsmann's global strategy of transferring its established business onto the Web.

Thomas Middelhoff, chairman and chief executive officer of Bertelsmann AG, declared the corporate strategy to focus on development of core content services together with e-commerce. The success of this company's online business is partially due to the pragmatic way of using the traditional COD payment pattern and the cooperation with Post Offices in delivering its books to customers.

The company introduced its first book club to China in 1997. The club has been a great success in other parts of the world. The club's registered members in China have hit 1.5 million.

In 2000, Bertelsmann's revenue in China was 140 million yuan (US\$16.87 million).

## 5. Conclusion

(1)China's e-commerce and dotcoms will only switch to a rapid and healthy growth track after the establishment of a sound basic infrastructure base especially the payment system.

(2)Now is not the proper time for the explosion development of B2C business and dotcoms because China's dotcoms are merely castles in the air, for they

have no fundamental support. Some experts say that "The highway of Internet is supported by weak pillars like paper pokers." Maybe this is not exaggeration.

(3) A logistics and distribution system is another barrier that has hindered the growth of B2C business. After more than 50 years of development, a State-owned comprehensive logistic and distribution system has been set up with the participation of department stores, grocery stores, book stores and post office. The dotcoms could utilize the delivery capability of traditional businesses instead of setting up a new system by themselves.

(4) China's infrastructure including payment system is poor but improving. For example, China's big four commercial banks - the Industrial and Commercial Bank of China, the China Construction Bank, the Agricultural Bank of China and the Bank of China - have yet to reach every corner of the country, once they realize that online payment system can bring huge profits to them, they are bound to take part in the improvement of online payment system proactively.

## Abstract

Electronic Commerce (E-Commerce, EC) is thoroughly changing business models of organizations (governments, corporations, and communities) and individuals the way of living and working. However, the major success will accrue to those companies that are willing to transform their organizations and business processes, which is the scope of e-Business. An Enterprise Information Portal (EIP) provides real time information and integrated applications to knowledge workers, employees, customers, business partners and the general public as well. Effective applications of EIP facilitate high quality strategic decisions. That is, an EIP can enhance an organization's productivity, improve the collaboration to facilitate E-Commerce and gain competitive advantages. However, the EIP solutions are usually too expensive to small businesses. With Enterprise Application Integration (EAI) approach, this paper presents an economic way to design a low-cost EIP that leverages existing systems. Moreover, a prototype is implemented to show the feasibility.

For the external data access, the web mining technology is utilized to mine some relevant and valuable web contents from the Internet and put these contents into the document warehouse. By combining the textual information inside the document warehouse and the numeric data from the data warehouse, competitive advantages can be provided over those who work with just the numbers.

Keywords: Enterprise Application Integration (EAI), Enterprise Information Portal (EIP), E-Commerce, Workflow, XML, Web Mining, Document Warehouse

## 1. Introduction

Intel Corporation president and CEO Craig Barrett said that if the Taiwanese industries want to speedup Internet growth and E-Commerce cooperation that are the first an imperative duty. He thinks that the ASPs don't exist after 5 years because all companies become ASPs. Figure 1 shows a prediction of E-enterprise's growth by IDC. Taiwanese businesses could survey outsourcing of IT and businesses refocus on overarching business objectives such as customer satisfaction, the core of competition ability and increased competitive advantages, as it controls only the

technologies critical to those programs. July, 2002. According to the IDC report, the EIP solution software not only increases, but also tendency of obvious growth. It estimates that the investment from five hundred million to three thousand million between 2001 and 2006. The growth of Internet technologies has unleashed a wave of innovations that change the way business is conducted. These shows demand immediate attention for E-Commerce.

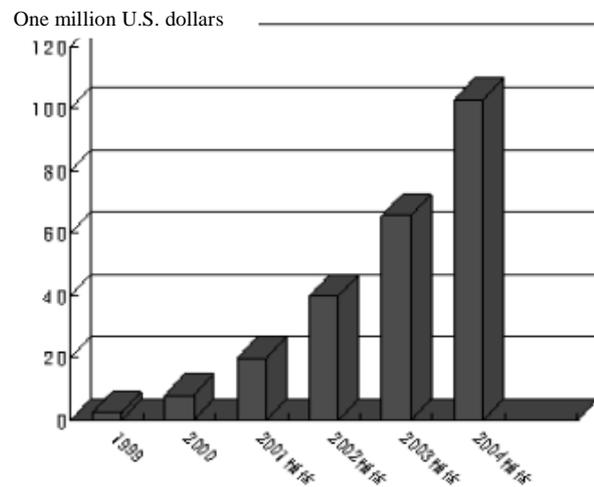

Figure 1 A prediction of e-enterprise's growth by IDC  
source: IDC

A corporate portal, also called an EIP, is generally defined as a personalized, single point of access through a Web browser to critical business information located inside and outside an organization. Some refer to a "Web top," rather than browser, to include handheld devices, mobile phones, PDA, ad-hoc network devices and other Internet appliances [21]. Portals gather information from one or more servers, as well as from the Internet, and deliver that information through a single, consistent interface. This gives users one interface to access all the required documents, e-mail, Web sites, competitive information, databases, and so forth for their jobs. It's also important to view the portal not only as an internal tool in an enterprise, but as one used by the extended enterprise, including partners, suppliers, investors, and customers. The portal is a basis of any e-business strategy. The EIP

\* The Graduate School of National Defense Information, National Defense management College, National Defense University, Chung h o, Taipei Taiwan

solution provides a single point of access to all structured and unstructured enterprise data. It is a concept for a Web site that serves as a single gateway with a company's information and knowledge base to employees, customers, business partners, and the public as well. The EIP effectively connects users to content in context, enabling true enterprise agility [1, 17, 20].

There are two key concepts to define an EIP: access and integration. Moreover, there are two problems of information management: "Isolate of Information" and "Island of automation". Thus EIP plays a critical deployment role in reengineering legacy systems. No matter systems reengineering or business reengineering can play complementary roles when performed in an integrated. They have been stereotypically and perhaps unfairly described as existing software systems whose plans and documentation are either poor or nonexistent. Generally, legacy systems are large and/or complex; developed using unstructured data with little programmatic support. A business has to handle several kinds of issues in building brand new systems or integrating some legacy system into an EIP system [12]:

- an efficient communication and project management among teams and organizations;
- Encouraging "contextual collaboration" or ad-hoc team communication around specific data sources;
- Defining, illustrating and managing the complex interactions among the players;
- Capturing and archiving the knowledge and interactions of all players in an enterprise such that it can be used as essential data in a knowledge management/decision support mode

In the backend, data mining technologies provide analysis data tools for knowledge workers, employees, customers and business partners.

The goal of this paper is to integrate all of the legacy system into a web-based interface, the prototype is provided to preview related technology, identify open issues, and demonstrate how to convert existing client/server systems into the Web. It is therefore organized as follow. In Section 2, some of the related features of the system description are described. A brief introduction of our prototype is in Section 3. The prototype implementation for Taiwanese small business is presented in this section. The contribution of this research, technical challenges, and future work are summarized in Section 4. Finally, conclusions are made in Section 5.

## 2. System description

The best way to embark on an EIP system is to select the target users and understand what information they need. The information can fall into a number of categories, including:

- unstructured content (documents, hypertext content, etc.)
- structured content (data stored in relational or other types of databases)

- news (either free or for-fee)
- groupware application data (such as Lotus Domino or Microsoft Exchange)

With EIP, information can be easily organized, searched and packaged, users can friendly select what they want to access.

Our EIP system provides recommendation engines. Even if you aren't familiar with this term, you might have already experienced the functionality on E-Commerce sites like Amazon. At Amazon, after a selection you made, a recommendation list of best sale books, CDs, or movies are provided for you. This recommendation function is a useful feature to stimulate users' purchases [13].

### 2.1 Enterprise Information Portal (EIP)

Comparing with the MyYahoo!, a primary function of an EIP is to aggregate content from disparate sources [14]. As most companies have an environment of disparate legacy systems, application, processes, and data source, which typically interact by a maze of interconnections that are poorly documented and expensive to maintain. An EIP has quickly become important business infrastructure as they aggregate disparate data sources and attempt to unify and organize information for decision support. The integration of EIP and collaboration technology allow the organizational communication processes to be unified into single information source creating a complete and usable archive of all transaction, including the data, discussion about the data, and the decision-making process.

In addition to creating a knowledge archive, the chaotic and ad-hoc nature of B2B communication demands definable, demonstrable, and repeatable processes which companies can use to conduct business models.

### 2.2 Web Mining and Business Intelligent

How does user deal with gargantuan information repositories for every bit of business trivia? Moreover, the sources of data were of the old realm of business: point-of-sale terminals, inventory databases, transaction records. Attempting to understand the data, several analysis tools are used: statistical tools, OLAP systems, and Data Mining. Data Mining is the best of these tools. It is natural for one would want to analyze this data with the best data mining techniques available. The results of the data mining - the rules which say which customers are likely to buy what products at the same time, or who is about to switch to your competitor [4, 8, 9,11].

When customers visiting a web site, they provide their information based on the content of the web site. There is so much information is interesting, such as: which links customers click, what kind of web site contents they stop by longer, which terms they use to search, and when they browse. Some customers might fill out a lifestyle survey or provide names and addresses information to the visiting web site. Complex content also contains important information, such as words in articles, job descriptions and resumes, and features of competitive or complementary

products. Usually, all information is stored in a database. This results in a lot of information available on Web sites, but web users probably can not use it in a best way. To solve this problem, web-mining techniques can be used to find buried patterns in databases, and report or act on those findings.

### 3. System architecture

Our primary goal is to implement a web-based portal, called MyPortal, with a web-mining technique. Basically MyPortal would integrate business's legacy systems, personalized interface, and existing heterogeneous database [19]. Figure 1 shows the system architecture of MyPortal.

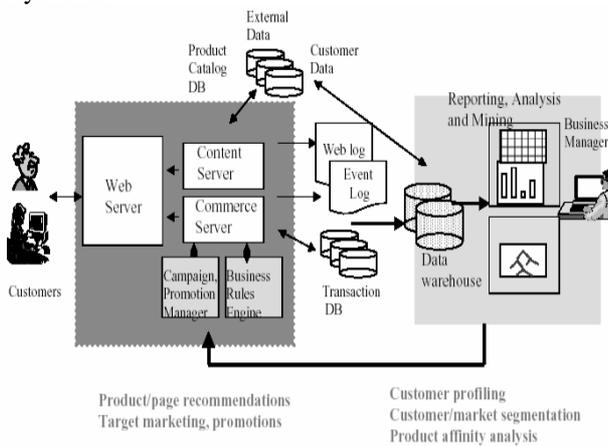

Figure 2 MyPortal system architecture

Figure 3 depicts a mapping of N-tier architecture and its implementations in MyPortal. N-tier architecture would simplify the system development environment and maintain the system easily.

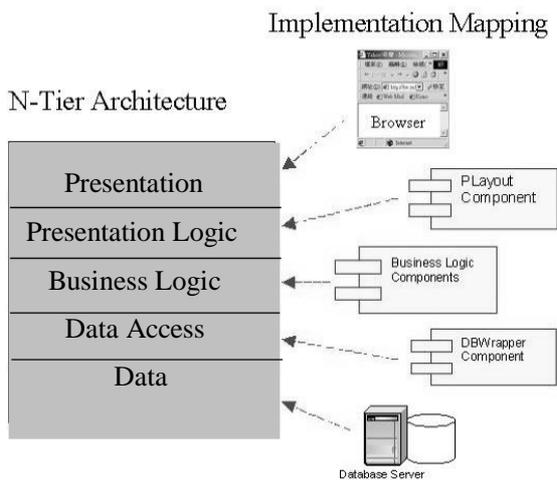

Figure 3 MyPortal mapping of N-tier architecture and its implementation

#### 3.1 System Environment

The implementation platform is MS-window-based personal computer. In MyPortal, programming tools cost around one hundred thousand NT dollars that is affordable to most Taiwanese small businesses. System configuration

is listed as the following:

- System Environment:
  - ◊ Operation System: MS Windows 2000 Server or later
  - ◊ Web Server: MS IIS 5.0 or Apache HTTP Server
  - ◊ MS SQL Server
- Application Environment:
  - ◊ Integrated Development Environment: MC C++, ASP
  - ◊ MS FrontPage 2000
  - ◊ Java Server Page
  - ◊ JAVA 2

#### 3.2 System Implementation

Figure 4 shows the prototype of MyPortal application. There are two major parts of the whole MyPortal: The portal and WMIS (Web-Mining Information System). MyPortal provides a personalized web-based environment and supports a web-mining technique. The WMIS provides general contents and news contents [6].

Figure 4 shows the prototype of MyPortal application

#### 3.3 WMIS Application

The major function of WMIS is to provide interfaces for user to input keyword data and find the related information. In WMIS users have to create “personal information needs profile” first, there are two major methods: Input Keyword and Online Help Document. Online Help is txt-format file for supporting Chinese punctuation [5, 7, 10].

When the user profile created their profile then web document-agent can retrieve, analyze and converge web pages for user. The query interface further provides searched results based on request of keyword, author's name, title or publishing date. Furthermore, user can recommend other valuable browsed homepages or provide “Negative Feedback” to WMIS system that can filter non-related homepages. Figure 5 shows results of user query and figure 6 shows advanced query interface in WMIS [2, 3].

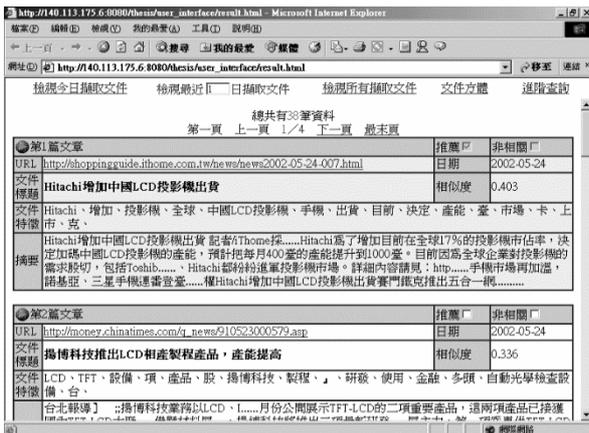

Figure 5 shows results of user query

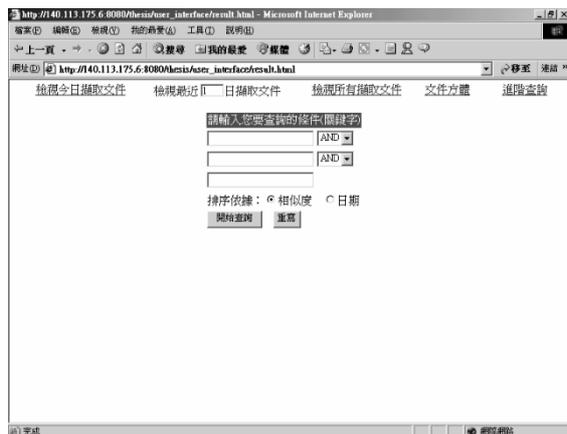

Figure 6 shows advanced query interface

Web mining agent: This is core of WMIS application there are five modules: pre-process document, retrieval web pages, document-related analysis, auto-retrieval abstract and process multi-dimension document. The detailed features of each module are described in the following paragraphs [18].

- Pre-process document module includes HTML tag omission, Chinese punctuation and feature retrieval.
- Retrieval web pages, this module can retrieve homepages through URL using existing net package of JAVA.
- Analysis document-related module uses “Vector Space Model” implement the module through “similarity object”.
- Auto-retrieval abstract module can automatically generate an abstract of retrieved document, let users easily understand web pages of contents and save storage space.
- Process multi-dimension document module converges every dimensions (including URL, title, publishing date, abstract) store in the document warehouse.

Especially mentioned, the words adopt “Tsai’s List of Chinese Words” of Chih-Hao Tsai<sup>1</sup> at University of

1 Words source: Chih-Hao Tsai  
<http://casper.beckman.uiuc.edu/~c-tsai4/chinese/tsaiword.zip>

Illinois.

### 3.4 MyPortal Application

Most companies have an IT environment with disparate legacy systems, applications, processes, and data sources. The system we proposed provides a single interface to access to all structured and unstructured enterprise data. Four design models, business user case model, use case model, analysis model, and design model, are available in MyPortal.

The basic schema of MyPortal is to utilize a web server and applications as the middle tier in a N-tier client/server architecture. With such a schema, it is easily to put existing business model over the Internet. The middle tier is then responsible for accepting the requests for database access initiated at Web browsers, initiating proper database transactions, and returning them to users through the Web server. Based on the idea, the N-tier solution can be designed and maintained more efficiently [15, 16].

### 4. Discussions

The approach presented in this paper can be enhanced in several aspects: First, The WMIS application can be extended to a multilingual support and enhanced to deal with all kinds of unstructured information. Second, query result cache and paging support can be added to improve data retrieving performance and resource utilization. Third, using middleware component technology, each of these distributed object components can interoperate smoothly in an integrated system. Moreover, there are several object-oriented and component-based development technologies, such as XML, CORBA and EJB (Enterprise JavaBeans), are available. These technologies would be helpful to develop a web-based system, such as WMIS Fourth, SSL, client-side authentication and a single sign-on should be supported in an EIP. Especially, the single sign-on can be integrated with the Windows logon, or it can be extended to support logon to back-end systems after a user has been authenticated to the EIP. A possible approach for achieving the above enhancement is to develop integrated application in the future work.

### 5. Conclusion

The employee can either use the desktop, notebook, PDA or ad-hoc network devices to access business databases simultaneously and browse the information with a web browser. This paper is a good entry for CIO, one in an organization's IT decision-making team and other interested in IT to understand an EIP solution for organizations. It integrates efficient information of all business intelligent by MyPortal application and provides quickly information search by WMIS application.

The enterprise collaboration portal can be available for every kind of businesses. It also becomes the source of a company’s most valuable asset: the collective knowledge from its employees, suppliers and customers. The “Myportal” prototype is based on the cost-saving

conception, it is especially to fit Taiwanese small business. With “Myportal”, it becomes possible to overcome the physical boundaries of existing organizations.

# Atomicity Implementation in E-Commerce Systems \*

Lars Frank and Uffe Kofod

Department of Informatics, Copenhagen Business School, Howitzvej 60, DK-2000 Frederiksberg, Denmark.  
frank@CBS.DK

## Abstract

Distributed databases with high performance and availability do not have the traditional ACID properties (Atomicity, Consistency, Isolation and Durability) because long duration locks will reduce the availability and the write performance. The problems of the missing ACID properties may be avoided by using approximated ACID properties, i.e. from an application point of view; the system should function as if all the traditional ACID properties had been implemented. The distributed approximated atomicity property manages the workflow of a transaction in such a way that either all the updates of the global transaction are executed (sooner or later) or all the updates of the global transaction are removed/compensated. In this paper, we will describe a flexible algorithm for implementing distributed approximated atomicity. Frank and Zahle [1] have described how to implement the other global approximated ACID properties.

We will illustrate our algorithm with E-commerce examples. If one of the partaking subsystems fails in a system for E-commerce, the approximated atomicity property will ensure that when an order is accepted, the payment and stock levels are managed automatically in the locations of the partaking banks and product stocks. Even logistics and/or production may be managed by using approximated atomicity.

We have cooperated with one of the major ERP (Enterprise Resource Planning) software companies in designing a distributed version of the ERP system with local autonomous databases in the different sales and stock locations.

*Keywords:* ACID properties, approximated atomicity, distributed systems, electronic commerce, ERP systems.

## 1. Introduction

In the transaction model described in this paper, the approximated atomicity property is implemented by using retrievable, pivot and compensatable subtransactions. The global consistency property does not exist in our transaction model. However, the concept *asymptotic consistency* can be used to create a consistent database state for e.g. datawarehousing [10]. The approximated isolation property is implemented by using countermeasures [1] to the isolation anomalies that occur when transactions are executed without isolation. The

global durability property is implemented by using the durability property of the local DBMS systems.

Our algorithm for approximated atomicity implementation is a transaction pattern with all the necessary types of database accesses, but without the application logic. This transaction pattern must be used by all distributed transactions. By using our transaction pattern, the development costs for new applications may be reduced.

By means of examples, we will illustrate how to implement the approximated atomicity property in E-commerce systems. There are many different workflow architectures for E-commerce systems [12] and our transaction pattern cannot cover them all. However, our transaction pattern can manage the distributed workflow needed in most E-commerce systems [13].

The paper is organized as follows:

Section 2 will describe an extended transaction model that provides approximated ACID properties. Section 3 describes a general transaction pattern (algorithm) for implementing the approximated atomicity property. In this section, we will also illustrate by examples how to implement the approximated atomicity property in practice. Concluding remarks are presented in section 4.

*Related Research:* The transaction model described in section 2 is *The Countermeasure Transaction Model* [1]. This model owes many of its properties to e.g. Garcia-Molina and Salem [2], Mehrotra [3], Weikum and Schek [4] and Zhang [5]. Frank and Zahle [1] describe in detail the countermeasures used against the isolation anomalies in the E-commerce examples of section 3.

An early version of the pattern described in this paper has been developed for atomicity implementation in CSCW systems [14].

## 2. The Transaction Model

A *multidatabase* is a union of local autonomous databases. *Global transactions* [7] access data located in more than one local database. In recent years, many transaction models have been designed in order to integrate local databases without using a distributed DBMS. The countermeasure transaction model [1], has, among other things, selected and integrated properties from these transaction models in order to reduce the problems of the missing ACID properties in a distributed database not managed by a distributed DBMS. In The Countermeasure Transaction Model, a global transaction

---

\* This project was in part supported from 'Udviklingscenter for e-business' – UCEB.

consists of a *root transaction* (client transaction) and several single site *subtransactions* (server transactions). The subtransactions can be nested transactions; i.e. a subtransaction may be a *parent transaction* for other subtransactions.

All communication with the user is managed from the root transaction, and all data is accessed through subtransactions. A subtransaction is either an execution of a *stored procedure* that automatically returns control to the parent transaction or an execution of a *stored program* that does not return control to the parent transaction.

All remote subtransactions are accessed through one of the following types of tools:

#### *Remote Call (RC)*

From a programmer's point of view, a RC functions like a remote procedure call or submission of a SQL query. RCs have the following properties, which are important from a performance and an atomicity point of view:

- If a parent transaction executes several RCs, the corresponding subtransactions are executed one at a time.
- A stored procedure or SQL submission has only local ACID properties.
- The stored procedure or SQL submission can automatically return control to the parent transaction.

#### *Update Propagation (UP)*

In this context, UP is used in the general sense of propagation of any update (not just replicas). The UP tool works in the following way:

The parent transaction makes the UP "call" by storing a so-called *transaction record* in persistent storage at the parent location. The following information must be stored in the transaction record:

The parent transaction id, the id of the subtransaction, the id of the location where the subtransaction should be executed, the id of a stored procedure (or the SQL code) and the parameters of the subtransaction.

If the parent transaction fails, the transaction record will be rolled back, and consequently the subtransaction will not be executed. When the parent transaction is committed, the transaction record is secured in persistent storage, and we say that the UP has been *initiated*. After the initiation of the UP, the transaction record will be read and sent by the UP tool to the location where the subtransaction should be executed. UPs may be implemented by using either push or pull technology as described in Frank and Zahle [1]. UPs have the following properties, which are important from a performance and an atomicity point of view:

- If a parent transaction initiates several UPs, the corresponding subtransactions may be executed in parallel.

- A subtransaction initiated from a UP has atomicity together with the parent transaction, i.e. either both are executed or none are.
- A subtransaction does not automatically return control to the parent transaction.

In the following, we will give a broad outline of how approximated ACID properties are implemented in the Countermeasure Transaction Model.

## 2.1 The Atomicity Property

An updating transaction has the *atomicity property* and is called *atomic* if either all or none of its updates are executed. In The Countermeasure Transaction Model, the global transaction is partitioned into the following types of subtransactions that are executed in different locations:

- The *pivot* subtransaction that manages the atomicity of the global transaction, i.e. the global transaction is committed when the pivot subtransaction is committed locally. If the pivot subtransaction aborts, all the updates of the other subtransactions must be compensated or not be executed.
- The *compensatable* subtransactions that all may be compensated. Compensatable subtransactions must always be executed before the pivot subtransaction is executed to make it possible to compensate them if the pivot subtransaction cannot be committed. Compensation is achieved by executing a *compensating* subtransaction.
- The *reliable* subtransactions that are designed in such a way that the execution is guaranteed to commit locally (sooner or later) if the pivot subtransaction is committed. A UP tool is used to automatically resubmit the request for execution until the subtransaction has been committed locally, i.e. the UP tool is used to force the reliable subtransaction to be executed.

The global atomicity of the pivot transaction models is implemented by executing compensatable, pivot and reliable subtransactions in that order.

RCs can be used to call/start the compensatable subtransactions and/or a pivot subtransaction, because the execution of these subtransactions is not mandatory from a global atomicity point of view. (If any problems occur before the pivot commit, we can compensate the first part of the global transaction).

After the commit decision of the global transaction, all the remaining updates are mandatory. Therefore, UPs are always used to execute the reliable subtransactions, which are always executed after the global commitment.

If the pivot fails or cannot be executed, the execution of all the compensating subtransactions are mandatory. Therefore, UPs are always used to execute the reliable compensating subtransactions.

### Example 2.1

Let us suppose that an amount of money is to be moved from an account in one location to an account

in another location. In such a case, the global transaction may be designed as a root transaction that calls a compensatable withdrawal subtransaction and a retrievable deposit subtransaction. Since there is no inherent pivot subtransaction, the withdrawal subtransaction may be chosen as pivot. In other words, the root transaction executed at the user's PC may call a pivot subtransaction executed at the bank of the user, which has a UP that "initiates" the retrievable deposit subtransaction. If the pivot withdrawal is committed, the retrievable deposit subtransaction will automatically be executed and committed later. If the pivot subtransaction fails, the pivot subtransaction will be backed out by the local DBMS. In such a situation, the retrievable deposit subtransaction will not be executed.

In our transaction model, subtransactions may be nested, i.e. a subtransaction may call another subtransaction, etc. In *The Open Nested Transaction Model* [4], the subtransactions of a compensatable subtransaction must be compensatable. (Otherwise, the parent transaction cannot be compensatable). This idea has been generalized and integrated into our transaction model in the following way:

- Subtransactions of a compensatable subtransaction must be compensatable. Please notice that sometimes the subtransactions of a compensatable subtransaction may also be designed as retrievable, which simplifies the application program and reduces the response time.
- Subtransactions of a retrievable subtransaction must also be retrievable. (Otherwise, the parent transaction cannot be retrievable).
- Subtransactions of a pivot subtransaction must either be compensatable or retrievable. Compensatable subtransactions must be executed before the commit of the pivot subtransaction and retrievable subtransactions must be executed after the commit of the pivot subtransaction.

Furthermore, a non-committed transaction should be subject to changes. This implies that a retrievable subtransaction, which more or less compensates a compensatable subtransaction, may be executed before the commit of the pivot subtransaction.

## 2.2 The Consistency Property

A database is *consistent* if the data in the database obeys the consistency rules of the database. If the database is consistent both when a transaction starts and when it has been completed and committed, the execution has the *consistency property*. Transaction *Consistency rules* may be implemented as a control program that rejects the commitment of transactions, which do not obey the consistency rules.

The definition above of the consistency property is not useful in multidatabases with approximated ACID properties because such a database is normally always inconsistent. However, a distributed database with

approximated ACID properties should have *asymptotic consistency*, i.e. the database should converge towards a consistent state when all active transactions have been committed/compensated. Therefore, in distributed databases with approximated ACID properties, we want the following property:

If the database is asymptotically consistent when a transaction starts and also when the transaction is committed, the execution has the *approximated consistency property*.

Frank [10] has described how to make a consistent database state for datawarehousing on top of a distributed database with approximated ACID properties.

## 2.3 The Isolation Property

A transaction is executed in *isolation* if the updates of the transaction only are seen by other transactions after the updates of the transaction have been committed.

If the atomicity property is implemented, but there is no global concurrency control, the following isolation anomalies may occur [7] [8]:

- *The lost update anomaly* is by definition a situation where a first transaction reads a record for update without using locks. After this, the record is updated by another transaction. Later, the update is overwritten by the first transaction. In the countermeasure transaction model the lost update anomaly may be prevented, if the first transaction reads and updates the record in the same subtransaction using local ACID properties. Unfortunately, the read and the update are often executed in different subtransactions, as we do not recommend locking a record across a dialog with the user. Therefore, it is possible for a second transaction to update the record between the read and the update of the first transaction.
- *The dirty read anomaly* is by definition a situation where a first transaction updates a record without committing the update. After this, a second transaction reads the record. Later, the first update is aborted (or committed); i.e. the second transaction may have read a non-existing version of the record. In our transaction model this may happen when the first transaction updates a record by using a compensatable subtransaction and later aborts the update by using a compensating subtransaction. If a second transaction reads the record before it is compensated, the data read will be "dirty".
- *The non-repeatable read anomaly* or *fuzzy read* is by definition a situation where a first transaction reads a record without using *long duration locks* [7]. This record is later updated and committed by a second transaction before the first transaction is committed or aborted. In other words, we cannot rely on what we have read. In our transaction model this may happen when the first transaction reads a record that is updated by a second

transaction, which commits the record locally before the first transaction commits globally.

- *The phantom anomaly* is not relevant in this paper.

In the following, we will only describe the countermeasures that are used in the e-commerce examples of section 3. We will first describe a countermeasure against the lost update anomaly, because it is the most important anomaly to guard against.

#### *The Commutative Updates Countermeasure*

Adding and subtracting an amount from an account are examples of commutative updates. If a subtransaction only has commutative updates, it may be designed as commutable with other subtransactions that only have commutative updates. This is a very important countermeasure, because retrievable subtransactions have to be commutable in order to prevent the lost update anomaly.

#### **Example 2.2**

A deposit may be designed as a retrievable commutative subtransaction, where the subtransaction reads the old balance of the account by using a local exclusive lock, adds the deposit to the balance and rewrites the account record. After this the retrievable commutative subtransaction will commit locally. This deposit subtransaction is commutable with other deposit and withdrawal subtransactions.

#### *The Pessimistic View Countermeasure*

It is sometimes possible to reduce or eliminate the dirty read anomaly and/or the non-repeatable read anomaly by giving the users a pessimistic view of the situation. The purpose is to eliminate the risk involved in using data where long duration locks should have been used. A pessimistic view countermeasure may be implemented by using:

- Compensatable subtransactions for updates which limit the options of the users.
- Retriable subtransactions for updates which increase the options of the users.

#### **Example 2.3**

When updating stocks, accounts, vacant passenger capacity, etc. it is possible to reduce the risk of reading stock values that are not available ("dirty" or "non-repeatable" data). These pessimistic stock values will automatically be obtained if the transactions updating the stocks are designed in such a way that compensatable subtransactions (or the pivot transaction) are used to reduce the stocks and retrievable subtransactions (or the pivot transaction) are used to increase the stocks.

### **2.4 The Durability Property**

The execution of a transaction has the durability property, if the updates of a transaction cannot be lost after the

transaction has been committed. The updates of transactions are said to be *durable* if they are stored in stable storage and secured by a log recovery system. In case a global transaction has the atomicity property (or approximated atomicity), the global durability property (or approximated durability property) will automatically be implemented, as it is ensured by the log-system of the local DBMS systems [9].

### **3. A Transaction Pattern for Atomicity Implementation**

In this section, we will describe a general transaction pattern that can simplify the atomicity implementation. In order to implement the atomicity property, the transaction pattern must follow the rules of our nested transaction model described in section 2. After the presentation of the transaction pattern, examples will illustrate how to use the transaction pattern.

The following figure illustrates a UML statechart diagram for a global transaction. The syntax for a transition has tree parts, all of which are optional: *Event* [*Guard*] / *Action*. In the diagram, all the events are either subtransactions submitted by the user or subtransaction aborts. All the event actions and state activities of the diagram must be designed with "subtransaction atomicity". In the diagram, we do not deal with subtransaction aborts that do not change the state of the global transaction, because the user without problems can resubmit these subtransactions. All the event guards coming from the same state in the diagram are mutually exclusive, and, therefore, the diagram does not have loose ends.

The description of the event actions and state activities is a pattern without application logic, i.e., only the necessary database access types of the actions/activities are described. It is important to distinguish between two types of locations for each subtransaction:

- The "execution location" is the location where a subtransaction is executed. For example, the "root location" is the execution location of the root transaction, and it is normally the user's PC. The "pivot location" is the location where the pivot subtransaction is executed.
- A "log location" is the location where the parameters of a subtransaction are stored. If an event corresponding to a subtransaction changes the state of the global transaction, the new state is also stored in the log location.

Often, the log location of a subtransaction is not the same as the execution location, and, in such a situation, it is important to make the updates in the two locations atomic (or approximated atomic). Otherwise, recovery will be much more complex.

If a subtransaction fails and/or the user does not get an answer, it is important for the user to know the state of

the global transaction. Therefore, a State record must first be created in the log location of the root transaction. Later, a new State record is created in the log location of the compensating subtransactions, and finally, a State

record is created in the log location of the pivot subtransaction. By reading these State records it is always possible to find the state of the global transaction.

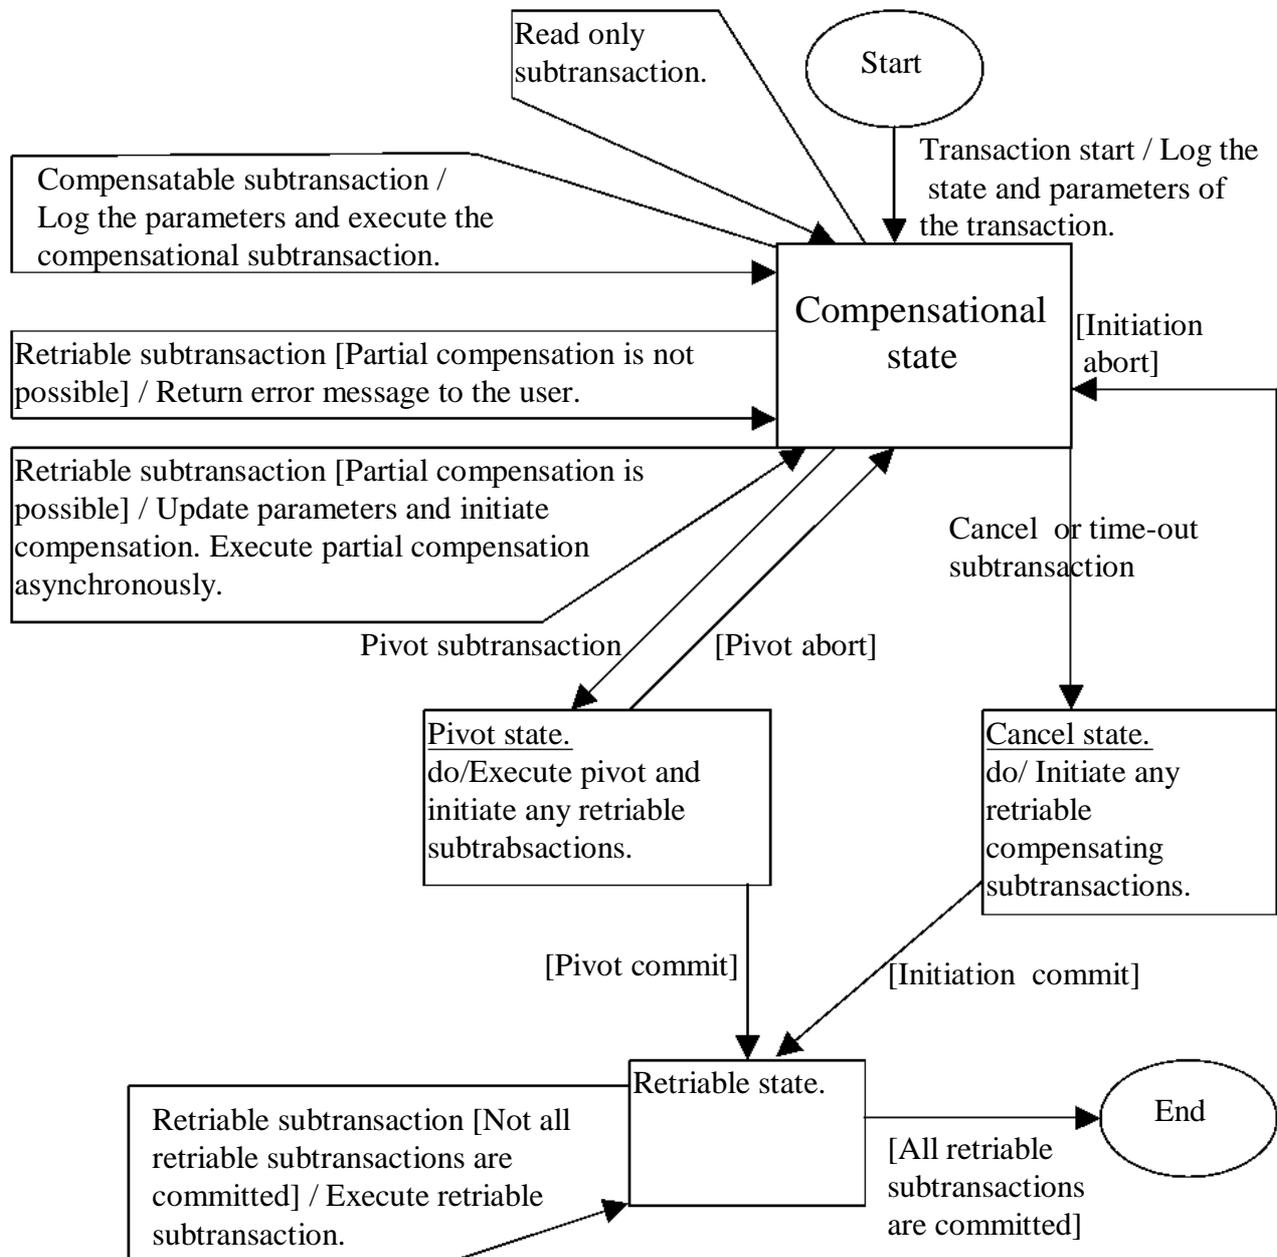

Figure 3.1. Statechart diagram for a general global transaction.

In the following, we will illustrate how to use our nested transaction model in E-commerce systems. The first example outlines how business-to-business E-commerce transactions may be designed by using our transaction model. The second example describes a more complex business-to-consumer E-commerce transaction.

In contrast to the business-to-consumer segment, business-to-business E-commerce may anticipate trust between the customer and seller. Hence, global transactions need not involve a third party, such as the

bank of the customer or seller. This simplifies the global transaction in Example 3.1 compared to Example 3.2, which describes the global transaction of a retail customer.

### Example 3.1

In this example of business-to-business E-commerce, we will assume that the seller has a customer file with the names, addresses, account balances and credit limits for all his customers. Therefore, the banks of the customers

are not involved in the following description of the order transaction. In this example, we choose the local server of the seller as both pivot location and log location for all the subtransactions. The root location is the user's local PC. Other locations are any remote stock servers of the seller.

At first, the customer reads the offers made by the seller. If the customer wants to make an order, the root transaction in the location of the customer calls a compensatable subtransaction at the location of the seller. This subtransaction creates an order record with relationship to the customer record at the same location. A new State record with the value "Compensatable state" is created for the transaction. Now, the customer can make order-lines. For each new order-line made by the customer, the root transaction starts a compensatable subtransaction, and this subtransaction creates an order-line at the location of the seller. For each order-line, a compensatable sub-subtransaction updates the local (or remote) stock of the product ordered in the order-line. If the first stock cannot fulfill the quantity ordered in the order-line, another stock may be accessed by using another compensatable sub-subtransaction. If an order-line cannot be fulfilled, the field "quantity-delivered" in the order-line is updated. Please notice that only *short duration locks* are used, and, therefore, distributed deadlock cannot occur. When the order form has been completed, the pivot subtransaction is executed at the location of the seller where it updates the account balance of the customer. If the credit limit of the customer is not violated, the pivot subtransaction initiates a retrievable sub-subtransaction that is sent to the customer to confirm the deal. The pivot subtransaction also changes the State record to "Retriable state" before all the updates are committed. Alternatively, the global transaction will be rejected or the customer asked to reduce the amount of the balance in order to avoid violating the credit limit.

By executing a retrievable subtransaction that reduces the quantity ordered in an order-line, the amount in the order-line may be reduced. For each reduced order-line, a retrievable sub-subtransaction increases the local (or remote) stock of the product that is reduced in the modified order-line. Finally, the customer can retry to execute the pivot subtransaction.

### Example 3.2

In this example, we will describe the atomicity implementation of a business-to-consumer E-commerce transaction where the global transaction also involves the banks of the customers and the seller. In the example, the bank of the customer is used as the pivot location. The server of the seller is the log location of all the subtransactions. The PC of the user is the root location. When the retail customer wants to make an order, the first compensatable part of the global transaction may be the same as in the previous example, where the order and order-lines were created. However, the seller may not know the customer, and, therefore, a compensatable customer record should also be established. Before the pivot subtransaction is executed, the balance of the

customer is updated by a compensatable subtransaction and the State record changed to "Pivot state". The pivot subtransaction is executed at the bank of the customer, where payment of the customer may be accepted/committed and a retrievable subtransaction to the seller initiated. When the retrievable subtransaction of the pivot is received in the location of the seller, the State record of the global transaction is changed to "Retriable state", and the account of the customer updated. A retrievable sub-subtransaction may also be initiated in order to confirm the deal for the customer.

## 4. Conclusions

Normally, distributed systems do not have the traditional ACID properties because they will reduce availability and write performance. In this paper, we recommend using approximated ACID properties, i.e. from an application point of view the system should function as if all the traditional ACID properties had been implemented.

The distributed approximated atomicity property manages the workflow of a distributed transaction in such a way that either all the updates of the transaction are executed (sooner or later) or all the updates of the transaction are removed/compensated. In this paper, we have described in detail how distributed approximated atomicity may be implemented. That is, we have described a nested transaction pattern (algorithm) designed for updating multidatabases with approximated atomicity. The transaction pattern can be used for all types of distributed updates, and, therefore, it may reduce time for design and programming. Our transaction pattern makes it possible to nest all types of subtransactions to any depth. In addition, the root location (normally the PC of the user), the log location (the location where the recovery information is stored) and the pivot location (the location where the global transaction is committed) may be different locations or grouped in any combination. Another feature is that our transaction pattern allows retrievable subtransactions to be executed before the global commit if the retrievable subtransactions more or less compensate compensatable subtransactions that have already been committed locally but not globally.

We have illustrated how to use the transaction pattern in E-commerce systems. For example, if one of the partaking subsystems fails in a system for E-commerce, the approximated atomicity property will ensure that when an order is accepted (the global commit), the stock levels, payment etc., are managed automatically in the locations of the partaking product stocks and banks. Even logistics and/or production workflow may be managed by using approximated atomicity.

We have cooperated with one of the major ERP software companies in designing a distributed version of the ERP system with local autonomous databases in the different sales and stock locations.

# English as the Infrastructure Language for a Multilingual Internet

Garry White

Computer Information Systems Department  
Southwest Texas State University  
San Marcos, Texas U.S.A.  
gw06@business.swt.edu

## Abstract

English has been the dominant language of the Internet for users and infrastructure development. This is changing due to the increasing number of non-English speaking Internet users. While the Internet community will eventually become a multilingual environment; the development of the Internet infrastructure source will still be English. This will have an impact on global businesses and government's education systems in non-English speaking countries. Eventually, English will be the global language for Internet developers and professionals of global businesses.

## 1. Introduction

In 1999, less than 10% of the world's populations spoke English as their primary language. The majority (56.5%) of Web users use English as the language of choice [4]. This is changing. Global Reach has indicated that one half of Internet users are from non-English speaking nations. By 2003, this will reach 70%. The majority of Web page content will be in languages other than English [11]. There is more and more evidence of the adoption of non-English use of the Internet. Evidence of this growing trend are the emergence of translation services, multilingual domain names, Unicode, and the use of icons [17]. It is clear that Web pages are becoming multilingual for users and business customers. However, the infrastructure and Internet development are still in English. This is due to the need for global standards in programming and technical communication.

## 2. The English Internet

The Internet began with ARPANET, a research project by the U.S. Department of Defense, to allow military computers to communicate through dynamic paths of communications. If one path failed, another path was used. Later the U.S. government divided this network into a military subsystem and a civilian subsystem. It was the civilian network that became today's Internet. In 1992, the U.S. government allowed businesses to link to the Internet. [16, p. 243]

The character set used by this new network was American Standard Code for Information Interchange (ASCII). This has been the coding scheme for computer communication. Like the Internet, it too originated in the United States. The text characters used consisted of the English alphabet. E-mail and web page source code use

this character set.

As expected, since the development of the Internet originated in an English speaking country, the technical infrastructure and web pages (interface for users) all have used English. English has been the lingua franca of the Internet [15].

## 3. Need for Multilingual Web Pages for Customers

The Internet has created one global market. Those who understand the technical and cultural issues have a head start on capturing new audiences and helping their businesses forge a worldwide market [22]. There is a need for a multilingual Web. By having Web sites in local languages, more businesses and opportunities can be established. People are more comfortable with e-commerce when the product is in their native language [24], even if English is their second language. Those companies that only have English version of their Web sites or just their local language versions stand to lose their existing or potential international clients to their competitors who communicate in the native language of the customer [17].

Several Information Technology trade periodicals indicate that English has been the dominant language on the Internet and most of the revenue generated inside the U.S.A. However, this is changing. The Internet is moving from English to multilingual [7][5][14][20][22][25][26][29]. For example, English is a second language in Thailand. However, Thai language content web is increasing [6]. The use of the Internet has become more and more popular among non-English speaker, especially for people in the countries like Japan, Germany, China, and Korea [21].

Companies have awakened to that trend of the Internet becoming multilingual and are developing country-specific and language-specific Web sites for individual markets [12]. Some examples of these corporations are IBM, Gap, McDonald, VISA, and Coca-Cola. International firms such as Sony, Mercedes Benz, Kodak are very international focused as well [17]. For global businesses to be successful, they have to become multilingual [2]. The localization of the Web culturally, geographically, and linguistically is a trend that will continue [20]. The result will be non-English speakers occupying more than half of all Web traffic in

their respective native languages [21]. English will NOT be the online lingua franca for long [1].

#### 4. The Multilingual Internet

The Internet is moving to multilingual web sites. This is due to web page text written in the native language. The result of having the Web sites written in the users' native language brings a sense of familiarity that helps bridge the language gap [17]. To facilitate this, a new coding scheme for the user interface had to be developed.

ASCII is the coding scheme of the Internet. ASCII, American Standard Code for Information Interchange, was defined by the American National Standards Institute (ANSI) in the United States and by the International Organization for Standardization (ISO) worldwide [10]. The character set consists of the English alphabet. To resolve this limited character set, Unicode was developed. It is a multi-byte character representations system for computers, and provides for the encoding/exchanging of all the text of the world's languages [3]. Unicode uses 16 bits, which means that it can represent more than 65,000 unique characters [23]. Unicode allows programmers to provide software that ordinary people can use in their native language" [3]. Unicode is a character coding system designed to provide the ability to display text of the world's languages on web pages.

Internet users want domain names in their native language instead of today's English-language domain names. Unicode can also be used for domain names. This would require no changes to the DNS protocol or servers [13]. Multilingual domain name is still under implementation because the languages other than English do not use ASCII-based characters. There are several organizations working toward solution to implement non-English domain names on the Web [17]. The current solution involves converting foreign language characters into Unicode. Then encoding them in ASCII for transmission over the Internet as is currently done. It creates a presentation layer to display domain names to end users in their native languages [28].

#### 5. English as the Source Language for Multilingual Web Pages

A web page consists of two parts: text content and source code. Text content is the text displayed on the web page. Unicode is used here to display the different characters of the variety of world languages. Examples of source code components are XML, Java, JavaScript, and HTML. By dividing the web page into these two parts, a company can extract all language and cultural specific elements, making the source code language-neutral and easily tailored for a local language by adding translations of text messages, icons, and cultural data. Hence, the web page is easily made multilingual.

Such a web page is able to run with any localized text content, without requiring source code changes or recompilation. It is this source code that incorporates

English into the infrastructure. Web developers write English "source code" to support multilingual web page "content." When you view the source code for any multilingual web page, the HTML, XML, Java, and JavaScript are in English.

Such software allows web pages for multilingual users to display the text in the correct local language and character set. For example, XML uses Unicode by default, which allows end users to encode text in their preferred language and character set [18].

Because ASCII is used by the Internet, the domain names are also in English. As stated earlier, the user interface will use Unicode, making domain name services multilingual. However, as noted, the Unicode domain names from the user interface will be changed to the English version of ASCII.

Considering the source code and domain names, English will continue to remain the most widely used language in the technical arena of the Internet.

#### 6. English as the Global Language for Internet and other Information Systems Professionals

The language used at international Internet conferences and by international Internet journals is English. Table 1 shows some of the Internet related conferences for the year 2002. Research papers, Proceedings, official web site, and/or language of these conferences used English, and in some cases, along with the host country's native language. Table 2 shows some of the international journals relating to the Internet that are also in English.

#### 7. Implications for Governments and Global Businesses

What appears to be developing on the Internet, as far as spoken languages are concern, is a distinction between local and global languages. The Internet will be multilingual due cultural pride and that people are more comfortable with e-commerce when the product is in their native language [24]. Local web interfaces will be in the local language. This includes operating systems and web development tools. Sun's Solaris 7 operating system is a fully internationalized. It uses a single global binary that allows for the use of different language versions [19]. Microsoft, IBM, and Sun are also developing their software systems in multi-languages [9].

When dealing on a global scale, there has to be a common language for all to understand. English is the language of international commerce/business and science [8][15][27]. European businesses are making English their official language. Companies are looking at the whole continent as their domestic market. [8]. English is becoming the common language for a multilingual continent. It appears that global developers and global users of the web are following this trend. To be able to

function on a Global/International scale via the Internet, Internet professionals and business executives will have English as a second language.

Table 1. Internet related conferences for the year 2002

<p>15th Bled Electronic Commerce Conference eReality: Constructing the eEconomy  <a href="#">Bled, Slovenia</a>, June 17 - 19, 2002.</p> <p>7<sup>th</sup> Association Information Management Conference to be held in Hammamet, Tunisia, May 30 to June 1, 2002.</p> <p>2<sup>nd</sup> International Conference on Electronic Business (ICEB 2002), Taipei, Taiwan, Dec 10-13, 2002.</p> <p><a href="#">The 7th Asia Pacific Decision Sciences Institute (APDSI) Annual Meeting</a>, Bangkok, Thailand, 24-27 July, 2002.</p> <p>The 3rd International Conference On Web Information Systems Engineering (WISE 2002): 12-14th Dec 2002, Singapore.</p> <p><a href="#">The International Conference on Information Technology, Communications &amp; Development</a>, Kathmandu, Nepal, 1-3 December 2002.</p> <p><a href="#">11th European Conference on Information Systems</a>, Naples, Italy, 19-21 June, 2003.</p> <p><a href="#">The First International Conference on Information and Management Sciences</a>, Xi'An, China, 24-28 May, 2002.</p> <p><a href="#">Internet &amp; Investments Forum</a>, St. Petersburg, Russia, 25-26 April 2002</p> <p><a href="#">Second International Workshop on Electronic Commerce (WELCOM'01)</a>, Heidelberg, Germany, 16-17 November, 2001.</p> <p>Global IPv6 Summit in Korea July 11-12, 2002, Seoul, Korea.</p>
--

Table 2. International Journals relating to the Internet

---

The impact is that computer curriculum in non-English speaking countries will have to incorporate English. Global businesses will have to provide English training to their international computer personnel.

## 8. Conclusion

The majority of Web page content will be in languages other than English [11]. Evidence of this growing trend can be seen through the emergence of the tools such as translation services, multilingual domain names, Unicode, and the use of icons [17]. It is clear that Web pages are becoming multilingual for users and business customers. However, the global infrastructure of the Internet will still in English because of the need for global standards in programming and technical communication. English will be the global language for Internet developers and global businesses professionals.

cls@mail.dyu.edu.tw\*; E9002015@yahoo.com.tw\*\*

## Abstract

*This research not only describe convenience of e-business system but also point out the key techniques to construct Internet system of medical history related technique – JSP, SQL, JDBC, ODBC, Javascript, Oracle Database, Internet techniques and so on. The doctor and the staff who use this Internet system can access, delete, update, and modify the Internet database. Furthermore, they can download and upload images and documents via Internet. This system can garner the security and convenience when you use this system.*

**Keywords:** JAVA, JSP, JavaBean, Oracle Database, Servlet, JavaScript, Telemedicine, hospital's Internet and Intranet, medical image process via the Internet.

## 1. Introduction

The web server of jakata-tomcat [3,4] and the technique of JSP [4] implement this JSP Internet patient medical history database system. Also we connect the Internet Oracle database [6] with JDBC and ODBC [4] [5] [6] drivers to the JSP server. When you initially browse the JSP file, the JSP file will be compiled to the servlet file [3]. The servlet file is a byte code file, which can be executed in a more efficient way when a client demands this file. When client requests a demanded servlet, the servlet will be translated into HTML file in server and return this HTML file to client. Thus the client can only see traditional language of HTML; therefore the secret information can be hidden.

Since JSP was based on framework of JAVA [1], thus we suggest someone who wants to program the JSP language should had experiences in JAVA programming. Moreover, our technique not only includes server side issue, but also includes client side issue. We use component of HTML input-box and JAVASCRIPT [2] to simplify the

input process. Furthermore, JSP files another function is the JSP can include javabeen program code. The implementation concept of Javabeen is similar to active X. Using JSP has the following advantage: (1) JSP is a freeware language. (2) JSP can be executed in different platforms. (3) JSP is a faster language.

## 2. Access and Process the Patient's medical history by the Internet Technique

### 2.1 The doctor's login system

Figure 2.1.1: Doctor login and confirm page

Figure 2.1.1 shows when a doctor keys in the login ID and password and presses login button, the system will save the login ID and password in the session object automatically. Each time when doctor login to the system, the system will take login ID and password to check against the permit-account automatically. If he or she is the legal user, he or she then can login this system; otherwise, the system will cut the usage to the user. The Java Saver Pages is operating on the server side; in the client side, the client can't see the Java Server Pages source code. Thus the web server can hide information form the client.

### 2.2 Add a record to system

病歷號碼	e9002016	性別	男 <input type="radio"/> 女 <input type="radio"/>
病患姓名	陳秀美	電話	04-2234567

病歷號碼	性別	病患姓名	電話	生日
e9002001	男	曾建羸	04-7654321	1968/6/6
e9002013	男	黃宏楠	05-5998992	1974/1/21
e9002015	男	洪松男	04-7561019	1976/10/27
e9002016	女	陳秀美	04-2234567	1970/10/30

Figure 2.2.1: Add a new patient's record to the system

Figure 2.2.1 shows add a new patient's record to the system. The user can type in the necessary data and press the transmit button to send the typed message to the web server. By checking figure 2.2.1, one can find the following advantage:

1. Using HTML text-input-box can reduce mistakes and increase inputting efficiently. For example, we can use combo button to reduce times of input and increase efficiency.
2. For the client side, by using the java text-input-box one can prevent mistakes happened too. For example, when one user types the date-field with the wrong date-type, the system will give a warning to the user to avoid mistakes.
3. Javabeen can simplify the writing-process of JSP and reuse them. For example, in this case, when you have many files need to upload or download, you can use java bean to pack program and reuse them.

### 2.3 Delete a record from system

**Before**

病歷號碼	性別	病患姓名	電話	生日
e9002001	男	曾建羸	04-7654321	1968/6/6
e9002013	男	黃宏楠	05-5998992	1974/1/21

e9002001	男	曾建羸	04-7654321	1968/6/6
e9002015	男	洪松男	04-7561019	1976/10/27
e9002016	女	陳秀美	04-2234567	1970/10/30

Figure 2.2.1: Delete a patient's record from the system

Figure 2.2.1 shows that the user can input a patient number

that the user want to delete and press the enter button to delete a record from the system. The server will execute SQL command inside the server and delete the record. Although most machines implement the SQL command by SQL-92 protocol, but some components are not clear defined in this protocol. Thus each company has its dedicated rules to execute the SQL commands. Therefore you shall use oracle dedicated SQL command for oracle database.

### 2.4. Query a record from system

病歷號碼	文件代碼	圖片檔名(before)	圖片檔名(after)

Figure 2.4.1: query a patient's record from the system

Figure 2.4.1 shows the Java Server Page's Search function. One can input a patient number and press the search button to pick the patient data from the database and display the patient data in the Internet page.

### 2.5 Modify a record from system

Figure 2.5.1 shows the Java Server Page's update function. One can input a patient number and fill in the necessary data and press update button to update the data.

## 3. Results and conclusion

The technique of JSP and the server of Tomcat implement this Internet system. The patient can access, update, and delete information from the hospital mainframe computer by the JSP technique. Furthermore, the patient can even download and upload the files via the JSP technique. Since JSP is inherited from Java, JSP can be executed in different platform too. Each time when a JSP file is execute, an attached class-file will be compiled. If the same JSP page were executed again, the JSP file will not be compiled again. The server can simply execute the previous compiled class-file; thus, the execution speed will be faster.

By the usage of the reuse of the class-file, the efficiency of JSP can be superior to ASP. Furthermore, there are many web server support JSP and most of them are freeware.

## Abstract

This paper introduces a model for Internet adoption, namely: level 0 – e-mail adoption; level 1 – Web presence; level 2 – prospecting; level 3 – business integration; and level 4 – business transformation. Two broad Web site categories can be identified: informational Web site and transactional Web site. The competitive advantages in terms of differentiation, cost reduction, innovation, growth, and alliance that are affected by Internet adoption are examined.

A questionnaire survey of 553 firms was conducted, of which 159 usable responses were received, resulting in an effective response rate of 28.8%. The results show that proactive business strategy, firm size and competitive advantage are found to be positively related to Web adoption level. Implications of the results for researchers and practitioners are discussed, and directions for future research are proposed.

## 1. Introduction

In this decade, the Internet has become a new profit-enhancing tool for firms, and the adoption of Internet technology is especially important for firms if they are to do business on the Internet. However, there is a paradox in this mode of profit-enhancement since Internet adoption itself does not necessarily lead to financial growth. The role of Internet Web technology is more like a long-term strategic tool than a short-term profit generator. To what extent should firms adopt the Internet? How could Internet adoption enhance firms' competitive ability? These are the research questions that this paper attempts to answer.

## 2. Model for Internet Adoption

An extensive literature review is conducted pertaining to research streams on Internet-based commerce, technology adoption, and competitive advantage. A model of Internet adoption is proposed, namely: level 0 – e-mail adoption; level 1 – Web presence; level 2 – prospecting; level 3 – business integration; and level 4 – business transformation.

**Level 0 – No Web Site, Only E-mail Account:** A firm at adoption level 0 is one that has an e-mail account but does not have a Web site. The term "level 0" is used because the firm has not actually adopted the Web. The inclusion of level 0 is based on research done by Teo et al.

[8]. They classified Internet adoption into three groups: non-adopters (those without Internet account), adopters without Web sites but with Internet account, and adopters with Web sites. Through an extensive examination of Web sites in Singapore, we found that some firms do not have independent domain names and Web sites. These firms normally have an Internet e-mail account that they use to establish connectivity with customers and business partners. These firms are not strictly adopters because they do not have Web sites; hence they are classified as level 0 adopters.

**Level 1 – Web presence:** The first adoption level is Web presence. At this level, the firm has made the adoption decision but the implementation is still in process [6,7]. The purpose of adoption may be to occupy a domain name or simply to have Web presence. Generally, Web sites at this level provide mainly information and brochures, and tend to be non-strategic in nature.

**Level 2 – Prospecting:** The second level of adoption is named as prospecting. This is the limited use of the Internet without exploring the potential commercial opportunities provided by the Internet. Usually, Internet adoption initiatives at this stage are spearheaded by individual departments. Thus, they are with low strategic value and not tied to business strategy [4]. Most firms at this level establish Web sites to provide customers with product information, news, events, interactive content, personalized content, e-mail support, and simple search. This strategy is helpful in providing potential customers with access to the firm's products with minimal information distributing cost.

**Level 3 – Business Integration:** Business integration is the third level of adoption. At this level, Internet adoption is incorporated into the business model and integration of business processes is taking place. The value proposition is usually cost reduction and business support, and there are cross-functional links between customers and suppliers [4]. Moreover, Internet strategy is integrated with firm's business strategy.

**Level 4 – Business Transformation:** The fourth adoption level is business transformation. This is the highest level of adoption. At this level, Internet adoption will transform the overall business model throughout the organization. The focus is on building relationships and seeking new business opportunities.

### 3. Method

The sample was selected from the Singapore 1000 and SME500 directories. Only firms with Web sites and/or e-mail addresses were selected. Two rounds of pretests were conducted with students, faculty members and practitioners, and modified accordingly. The questionnaires were then sent by mail to IT managers or top executives (for firms without IT managers). A second mailing was carried out three weeks later. The final usable response was one hundred and fifty nine, resulting in a response rate of 28.8%.

The questionnaire captured data relating to Internet adoption level, impact of Web adoption level on competitive advantage, business strategy and demographic data.

### 4. Results

#### 4.1. Respondents' Profile

About 40% of respondents came from the manufacturing industry (23.3%) and the retailing and trading industry (15.7%), followed by the architecture and engineering industry (11.3%), the finance, banking and insurance industry (10.1%), and the business services industry (8.8%). Nearly 50% respondents are either IT Managers or Managing Directors, followed by General Managers/ Vice Presidents/ Directors (12.6%) and Finance/ Accounting Managers (10.7%). The average number of years they have served the company is 6.6, and the average number of years they have spent in the industry is 11.1. The high hierarchical level of the respondents coupled with the years of tenure in the company and industry further strengthens the validity of the sample since management level respondents are more likely to be knowledgeable about the use and impact of the Internet.

More than 40% of responding firms have average annual revenues of S\$100 million to S\$600 million, while about one-third have average annual revenues of less than S\$100 million. About 65% have less than 600 employees. Data show that establishing a Web site is relatively easy and inexpensive, because 44% of the participating firms spent less than S\$30,000 when they first created their Web sites. However, the maintenance of a Web site is more expensive compared with its establishment. About 45% of the participating firms invest up to S\$100,000 into Internet technology annually, and another 18% invest S\$100,000 to S\$300,000. Interestingly, it seems that a Web site can be easily maintained, because 60.4% of the participating firms have less than ten IT/ IS employees. One possible reason is that firms may have outsourced their Web sites maintenance to specialized Web service providers rather than increase the number of IT/IS employees.

#### 4.2. Adoption Level

Among the 159 respondents, the distribution of Web adoption levels is as follows: twenty-seven in level 0, forty-eight in level 1, fifty-two in level 2, eighteen in level 3, and fourteen in level 4.

#### 4.3. Firm Size and Adoption Level

A post hoc test was conducted using Tukey procedures on mean scores of the three indicators of firm size (number of employees, number of IT employees and revenue turnover) among the five adoption levels (Table 1). The results show that there is no significant difference on number of employees, number of IT employees and revenue turnover among adoption levels 0, 1 and 2, as well as among adoption levels 3 and 4. However, significant differences exist between pairs of Web adoption levels, i.e., levels 0, 1 and 2 from levels 3 and 4. These results indicate that there is a relationship between firm size and adoption level. It seems that two different types of adoption activities exist between larger and smaller firms, with larger firms being more involved in adoption levels 3 and 4, and smaller firms being more involved in adoption levels 0, 1, and 2.

#### 4.4. Business Strategy and Adoption Level

In the questionnaire survey, data of an organization's business strategy were collected in relation to whether it is a proactive strategy or a reactive strategy. Chi-square test ( $\chi^2=23.24$ ,  $df=4$ ,  $p < .005$ ) indicates that Internet adoption level is related to business strategy (Table 2). The results indicate that there are nearly equal number of proactive strategies and reactive strategies in this study, with frequencies of 84 and 75 respectively. In adoption levels 0 and 1, 66.7% and 64.6% of the organizations are reactive strategy takers respectively, while in adoption levels 2, 3, and 4, proactive strategy takers emerge as the dominant party, with proportions reaching 61.5%, 72.2%, and 92.9% respectively. This suggests that the more proactive an organization's strategy is, the higher the adoption level it will have.

#### 4.5. Firm Size and Business Strategy

Results show that except for the number of employees, both revenue and the number of IT employees are significantly correlated with business strategy, indicating that higher revenue turnover and more IT employees are more related with proactive business strategy (Table 3). This is consistent with Kowtha and Choon's [2] findings that firm size substantially influence the strategic commitment of a firm to e-commerce.

#### 4.6. Adoption Level and Competitive Advantage

The relationships between adoption levels and various dimensions of competitive advantage were assessed using one-way ANOVA and post-hoc Tukey procedures. Results indicate an increasing trend across adoption levels (Figure 1). As expected, the competitive advantage at adoption levels 3 and 4 are greater than levels 1 and 2. Results indicate that alliance, differentiation, innovation and growth advantages are affected more than cost advantages.

### 5. Discussion and Implications

The results indicate that there exist some relationships between Internet adoption level and firm size as well as firm's business strategy. Larger firms are

involved more in transactional Web site adoption, i.e., in adoption levels 3 and 4, while smaller firms are involved more in informational Web site adoption, i.e., in adoption levels 0, 1, and 2. This could be that to support transactional Web site, more technology investment, including capital and personnel, is required, which could be quite challenging to small businesses with relatively lower revenue income and resources. At the same time, firm size is positively related to business strategy, implying that larger firm size, which is represented by higher revenue turnover and more IT employees, tend to advocate a more proactive business strategy, and thus be related to higher adoption levels. In contrast, firms with relatively low revenue turnover, tend to prefer a reactive business strategy, leading to lower adoption levels. This result is important in terms of relating firms' Internet adoption activities with their strategic positions. Further research can be done to examine the relationship between business strategy and the two Web site categories. Moreover, researchers can use Miles and Snow's [5] typology of organizations, and examine the relationships between different strategic postures and adoption levels.

The results also indicate significant relationships between Internet adoption level and the five dimensions of competitive advantage. This is consistent with Lederer et al.'s [3] findings that the Web and electronic commerce improves firms' competitiveness. Among the five dimensions, alliance, differentiation, innovation and growth are affected the most by Internet adoption level. This suggests that the Internet offers an interactive channel for direct communication with customers and business partners thereby facilitating the formation of alliances and enhancing differentiation and growth. Further, firms have used the Internet for innovation and knowledge transfer rather than simply as a mechanism to lower costs [1]. Cost advantages appear to be least affected by Internet adoption level probably because cost advantages can be offset by high development costs of Web sites. Future research can further examine the sustainability of these competitive advantages resulting from Internet adoption. In addition, researchers can also examine whether predominant competitive advantages associated with different Internet adoption levels exist.

This study also has important implications to practitioners. Top management of firms should realize that the most basic function of a Web site is communication. It is a new channel to establish effective interactivity with customers and business partners. A firm deciding to adopt this technology should remember to provide their contact information on the Web site at least.

In addition, the positive relationships between Internet adoption level and competitive advantage should provide some assurances to practitioners that Internet investment is worthwhile. While firms may hesitate to invest in Internet technologies due to fear of rapid technological obsolescence, such firms may also risk losing their competitive edge by failing to leverage Internet technologies in their business strategies.

## 6. Conclusions

This study proposes a model of Internet adoption with five levels: level 0 – e-mail adoption; level 1 – Web presence; level 2 – prospecting; level 3 – business integration; and level 4 – business transformation. Higher Internet adoption levels tend to provide more extensive information and more transactional functions. The high extent of information and transaction features require technological support for advanced Web site features such as detailed and personalized information, advanced customer services and online business transactions. Thus possessing an advanced technology infrastructure could facilitate higher level Internet adoption.

Further, high level adoption is more prevalent among larger firms and those with a proactive strategic posture for the Web. This implies that as firms grow and become more familiar with the Internet, the features found on Web sites are likely to evolve over time, reflecting their changing objectives of Web sites.

The results also show that firms adopting Internet technology view innovation, alliance, differentiation and growth as more salient benefits than cost reduction. To achieve competitive edge, a firm needs to integrate its business activities with Internet adoption. In other words, the Web site's functions should be consistent with the firm's business strategy. Firms adopting Internet technology should view Web sites as a strategic move rather than a simple Web presence in order to derive greater benefits from Internet adoption.

## Abstract

In recent years, most studies in the Attitude toward Web Site ( $A_{web}$ ) literature have been empirically scoped in shopping or commerce contexts and lack of systematic perspectives in investigations, therefore offered limited insights on guiding the knowledge for non-shopping web contexts, such as the online content industry. The purpose of this study is to choose the content attribute perspective to construct and empirically test a research model incorporating the antecedent and consequence variables of the  $A_{web}$  construct for the online content industry. After an extensive review on related literature, we propose 3 content attributes - informativeness, entertainment, and organization as the antecedent variables driving the  $A_{web}$  construct, which in turn explains the consequence variable set formed by intention to revisit, loyalty toward web site, and intention to future online commerce. For further testing the research model, a controlled survey methodology under laboratory environment is used. After collecting and analyzing 62 observations of psychological experience questionnaire for freely-browsed e-News sites on graduate student samples, all the research hypotheses are tested by using regression analysis and significantly supported. Encouragingly, this study successfully justifies the rationale that manipulating web site content strategies could lead to the formation of web users' attitudes and thus in turn explain and predict their subsequent online behavior.

Keywords: attitude toward web site ( $A_{web}$ ), content strategy, e-News site, online content industry

## 1. Introduction

### 1.1 Research Background

With the proliferation of WWW over the internet, both managerial academics and practices are eager to investigate why and how people like to visit certain sites, for keeping visitors means huge potential commerce benefits [26]. Responding to these managerial questions, there has been an emerging area concerning such issues in internet research. That is a concept termed as "Attitude toward web site" ( $A_{web}$ ), which is an academic construct that reflects a web surfer's predisposition of responding favorably or unfavorably to web content [5]. Studying the antecedent and consequence variables for the  $A_{web}$  construct can provide behavioral rationales for explaining

web surfers' web site preferences and related online behavior [2].

However, most studies in the literature have been empirically scoped in shopping or commerce contexts and therefore offered limited insights on guiding the knowledge for non-shopping web contexts, such as the online content industry. As a matter of fact, under shopping contexts, people exhibit more involvement and mental efforts for the information processing of consumer choice decision [4][23] and thus behave differently from non-shopping contexts like freely-browsed content sites. Therefore, a formal empirical study on the  $A_{web}$  construct for the online content industry is needed. Such a research will not only bridge the gap in the literature but also provide insights for the formation of web site strategies to help online content companies attract more visitors and enhance their web site performances. Aiming on attempting to step forward for the literature of internet research, this study is positioned as constructing and testing a research model incorporating the antecedent and consequence variables of the  $A_{web}$  construct for the online content industry.

### 1.2 Research Purpose and Questions

Previous studies concerning the  $A_{web}$  construct are fragmented and short of a specific perspective to systematically investigate the antecedents and consequences. Aiming on acknowledging such a deficiency in the literature, with the recognition that content strategy is one of the core competencies of content sites [11] [10], the purpose of this study is to choose the content attribute perspective to develop the research model for the  $A_{web}$  construct under the online content sites contexts.

Specifically, the research questions of this research are set as: (1) For online content web sites, what would be the appropriate set of antecedents determining the  $A_{web}$  construct from only the web site content attribute perspective? (2) And in turn, what consequences with business implications might be caused by the  $A_{web}$  construct?

### 1.3 Organization of This Study

The flow of this study is organized as follows. First, we briefly review related literature of the internet behavioral research,  $A_{web}$  research, respectively and then

give an overall commentary on the deficiencies of the body of literature. Second, a systematic research model with hypotheses is developed through the perspective of content attribute. Third, we propose a research design to empirically test our research model. Finally, we discuss the implications based on the findings of this study for both academics and practices and conclude with general recommendations for the online content industry.

## 2. Literature Review

### 2.1 Internet Behavioral Research

World Wide Web (WWW) has been considered as the emerging medium for marketing communication [3]. In recent years, innovation diffusion and consumer internet adoption have attracted many academic attentions [12] [19][18][28]. Also, with certain product categories, consumer buying has been modeled [20]. Another popular internet research topic is the web site effectiveness, where researchers have been focused on web site design features and content [10][27], profiling effective web sites [17], and the features that make a "good" web site [22] [9] [14].

### 2.2 Attitude toward Web Site

Attitudinal research has already been fruitful in the literature of behavioral science and marketing research [21]. Attitude is an important factor that determines human behavioral intentions and thus in turn drives

further actual behavior [1].

After the recognition that viewed WWW as a powerful medium for marketing communication, the attitudinal research concerning the web site inherit much knowledge from the literature of attitude toward the advertisement to study its causes and outcomes for electronic commerce strategies [5]. Understanding why and how people develop positive attitude toward the web site would be a great help to enhance the commerce performance for web sites. After comprehensively reviewing the empirical studies of the  $A_{web}$  literature, we can tell that there have been many factors associated with the  $A_{web}$  construct. It shows that the knowledge on  $A_{web}$  has started to accumulate and is waiting for further integration. For the purpose of sketching the whole picture of the  $A_{web}$  literature, we select antecedents, outcomes, empirical context, research methodology, and testing method as important attributes to profile each empirical reference. The descriptive findings are represented as Table 1 below.

### 2.3 Deficiency of the literature

After reviewing related literature, we can learn that the  $A_{web}$  construct has been drawing many attentions from the researchers. Many variables have been found associated with it, from both antecedent and consequence sides. Through the empirical validations of the linkage between  $A_{web}$  construct and web users' behavioral variables such as intention to revisit or shop, the  $A_{web}$  literature justifies its importance and business implications for the electronic

Table 1: Empirical literature concerning the  $A_{web}$  construct

Reference	Antecedents of $A_{web}$	Outcome of $A_{web}$	Web context	Methodology	Testing method
[29]	Convenience(+) Navigation(+) Economic incentive(+) Entertainment(+) Informativeness(+)		Book shopping	survey	correlation
[5]	Informativeness(+) Entertainment(+) Organization(+)		General	survey	Regression

commerce industry. Although we agree the  $A_{web}$  knowledge has begun to accumulate, we can observe that a systematic investigation of the  $A_{web}$  construct with both antecedent and consequence sides for the online content industry is still absent. Most studies are lacking specific perspectives and are thus fragmented, in addition, they are also empirically scoped under shopping or commerce web contexts, therefore providing limited insights for the  $A_{web}$  knowledge of non-shopping contexts.

Motivated by such a deficiency in the literature and acknowledging the practical importance to introduce the  $A_{web}$  research for the online content industry in order to understand the causes and outcomes of web users' psychological attitudes, this study is planned to adopt specific perspective suitable for the online content industry to systematically investigate the research model incorporating the antecedent and consequence variables of the  $A_{web}$  construct.

### 3. Research Model Development and Research Design

#### 3.1 Perspective selection

Previous studies concerning the  $A_{web}$  construct are fragmented and short of a specific perspective to systematically investigate the antecedents and consequences, and are not yet reaching into the non-shopping context domain. As a matter of fact, this study believes that choosing content attribute as the perspective to study the  $A_{web}$  construct would be a suitable cutting point for the online content industry.

Up to date, the profit source of the online content industry is still mainly stemmed from the traffic visited by web users. Most content web sites like e-News sites though pushing to their limits to explore profitable revenue models, however, web users' intentions to pay for online content remain poorly low [11]. Therefore manipulating content strategies to let web site favorable for web users and keep them revisiting to generate advertising revenue is the most important issue for the online content site managers [10].

Therefore, though there have been many antecedent factors shown in the literature, especially those individual characteristics like involvement, knowledge, and experiences, we believe that investigating content-related variables would mostly contribute to the formation of web site strategies. Because individual characteristics are usually not applicable for the web site holders, only studying content-related variables can be directly linking to the web design method and thus providing a more favorable site to create massive web traffic for generating huge advertising revenues.

The purpose of this study is to choose the content attribute perspective to develop the research model for the  $A_{web}$  construct under the online content sites contexts. After comprehensively examining the reference base, we believe informativeness, entertainment, and organization factors defined and measured by Chen and Wells could be a great framework to capture major conceptual nature of those content-related variables shown in the literature [5]. We firstly propose the research model depicted as Figure 1 below and then provide hypothesis derivations successively.

#### 3.2 Hypothesis derivation

The set of hypotheses of this study can be divided into two different parts, the confirmatory paths and exploratory paths. Confirmatory ones means they are derived with stronger theoretical basis and empirical supports, on the other hand, exploratory ones are those relationships that are incorporated into the model for the purpose of exploring the possibilities of empirical linkage among variables. We propose them as follows.

##### 3.2.1 Confirmatory Paths

In their important research findings, Chen and Wells have factor-analyzed 76 items pooled from an extensive review of attitudinal antecedent literature related to the WWW environment. They finally have extracted three meaningful dimensions formed by 16 items, and termed as the informativeness, entertainment, and organization

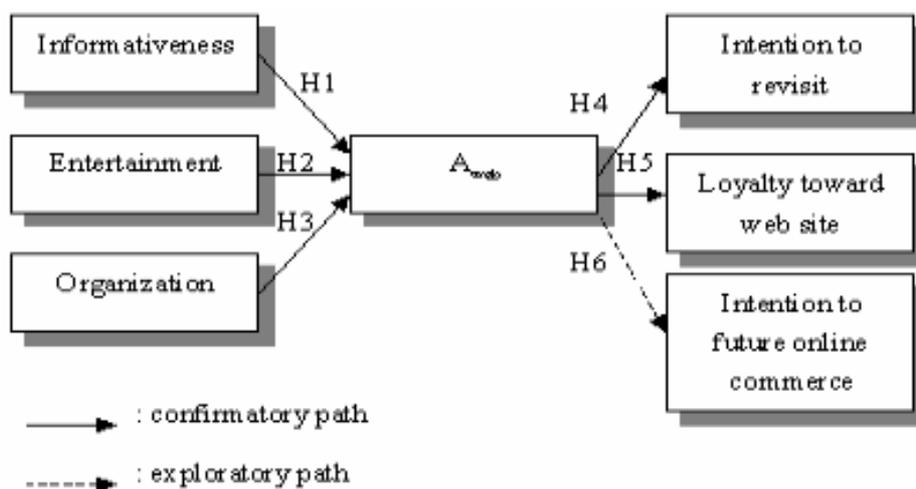

Figure 1 : Research model

respectively. These three dimensions reflect the content attributes perceived favorably by web users or not. Therefore, they can be described as the scores rated by web users in informational, recreational, and interfacial ways to judge the overall evaluations of a web site. Informativeness, entertainment, and organization have also been put into the regression model as the independent variables to explain and predict the  $A_{web}$  construct. In their empirical results, these three factors significantly account for 63% variation of the  $A_{web}$  Construct [5].

This is the most important literature that has formally verified these three factors in explaining the  $A_{web}$  construct. As a matter of fact, there have also been related literature providing more theoretical arguments and empirical supports. Childers et al. [6] have adapted the TAM theory [8] to propose the usefulness, ease of use, and enjoyment of web site content as the three antecedents for  $A_{web}$  and found to be positively significant. Similarly, Wu has also empirically validated that browsing convenience, navigational pleasantness, content entertainment, and content informativeness are significant factors associated with  $A_{web}$  positively [29][30].

We can observe that these factors are all close or similar to the three antecedent variables in this study, however, their empirical contexts are mostly scoped under shopping environment (please referencing Table 1). In responding to our research questions, for the online content industry, we expect that web users are not necessarily behaving the same as in the shopping web sites. Thus we are going to re-test the antecedent paths composed by informativeness, entertainment, and organization respectively to explain the  $A_{web}$  construct. The hypothesis 1-3 is proposed as below.

- ò H1: The perceived informativeness of web content will be positively associated with web users'  $A_{web}$ .
- ò H2: The perceived entertainment of web content will be positively associated with web users'  $A_{web}$ .
- ò H3: The perceived organization of web content will be positively associated with web users'  $A_{web}$ .

Intention to revisit has been empirically found to be positively influenced by the  $A_{web}$  construct. The more positive web users'  $A_{web}$  are, the more intentions they will exhibit to revisit that web site [26][16]. But this relationship has not been validated in non-shopping site contexts yet. Considering this variable is an important index for web site effectiveness and the need to re-test the consequence relationship for the online content industry, in addition, we are also attempting to even extend the explanatory ability of  $A_{web}$  to the loyalty level, thus we propose the hypothesis 4-5 as below.

- ò H4: The web users'  $A_{web}$  will be positively associated with web users' intention to revisit.
- ò H5: The web users'  $A_{web}$  will be positively associated with web users' loyalty toward web site.

### 3.2.2 Exploratory paths

In the exploratory part of the research model, though we are lack of theoretical support and empirical supports

for this path, we are going to verify this linkage between variables in order to explore more relationships for providing empirical basis of future substantive relationship development.

From the interviews of the CEOs of e-news site in Taiwan, we can observe that, being one sector of the online content industries, they are now more impatient with poor revenue statistics of web site. In their future strategic planning for web site business, they are going to explore more profitable business models including experimenting online transactional commerce which is still absent in their web site business scopes.

However, they are actually very concerned with the acceptability of their online users (<http://ceiba.cc.ntu.edu.tw/online/wwwboard/homework/index.html>). For the purpose of investigating that if it will also somewhat increase web users' intentions for future online commerce after they develop positive attitude toward web site, this study incorporates this exploratory path. We hope to answer this important managerial question for online content industries. Hypothesis 6 is proposed as below.

- ò H6: The web users'  $A_{web}$  will be positively associated with web users' intention to future online commerce.

## 3.3 Research Design

### 3.3.1 Measurement

All the research variables shown in the research model can be operationalized through referencing the well-developed instruments in the literature. We tabulate the variable name, number of items, scale type, and literature reference for each research variable as Table 2 below.

Table 2: Measurement of this study

Variable name	Number of items	Scale type	Source
Attitude toward web site	6	Metric, 5-point Likert Scale	[5]
Informativeness	6	Metric, 5-point Likert Scale	[5]
Entertainment	6	Metric, 5-point Likert Scale	[5]
Organization	4	Metric, 5-point Likert Scale	[5]
Intention to return	2	Metric, 5-point Likert Scale	[7]
Loyalty toward web site	2	Metric, 5-point Likert Scale	[26]
Intent to future commerce	2	Metric, 5-point Likert Scale	This study

### 3.3.2 Data Collection and Analytical Methods

The methodology of this study is positioned as a controlled survey, which is a questionnaire survey on subjects under specific task environment. We recruit 21 graduate student samples in university campus and invite them to participate this study in campus internet environment in order to rule out the interference effect of network quality.

The web context for the online content industry is set as the e-news sites, for their representativeness in the content provider industry [11]. The news sites held by the top three publishers in the newspaper industry in Taiwan are sampled as the stimulus to anchor the perceptions of research subjects (tabulated as Table 3). Because each site has its features and strategies somewhat differently, we

expect these sites could create sufficient variations in web users' perceptions and therefore better than a single-site empirical design.

Table 3: e-News site pool of this research design

Newspaper publisher	e-News site
The China Times	http://news.chinatimes.com/
The United Daily News	http://www.udnnews.com/
The Liberty Times	http://www.libertytimes.com.tw

The researchers of this study will adopt a systematic rotating technique to produce the site visiting list for each subject in order to avoid the systematic perception bias caused by fixed visiting orders of web users. The procedure is to let subjects follow their given lists of visiting news sites and freely browse each site for a certain period of time. After finishing browsing a site, he/she will be asked to complete the questionnaire for that site. Therefore, a total sample size of twenty one graduate students is planning to create 3X21=63 observations for further data analysis.

Besides basic descriptive analysis of the sample data, for all the variables collected by the instruments are metric scales, this study uses the factor analysis to validate the measurement models and then multiple regression method to test the substantive relationships of the research model [13]. After analyzing the empirical data set by SPSS 8.0 for Windows, all the confirmatory and exploratory paths are verified and thus provide the empirical testing results for the hypotheses within the research model.

#### 4. Data analysis

##### 4.1 Descriptive Analysis of Samples

After examining the data set, a data set containing 62 effective observations of questionnaire is obtained. We tabulate gender, age, internet usage in Table 4-6 for the sample subjects to sketch the sample characteristics.

Table 4: Gender profile of samples

	Frequency	Percent	Valid Percent	Cumulative Percent
Valid Female	8	12.9	12.9	12.9
Male	54	87.1	87.1	100.0
Total	62	100.0	100.0	

Table 5: Age profile of samples

	Frequency	Percent	Valid Percent	Cumulative Percent
Valid 23.00	15	24.2	24.2	24.2
24.00	12	19.4	19.4	43.5
25.00	20	32.3	32.3	75.8
26.00	3	4.8	4.8	80.6
27.00	6	9.7	9.7	90.3
29.00	3	4.8	4.8	95.2
39.00	3	4.8	4.8	100.0
Total	62	100.0	100.0	

From these descriptive tables above, we can observe the sample features to assess the sample quality of this study. They are mainly male, young, and are internet expert users with at least 3 years of internet usage experiences. Therefore collecting convenient sample for the purpose of adopting the controlled survey methodology turns out to receive a too homogenous

sample pool and thus severely threatens the external

Table 6: Internet usage profile of samples (in years)

	Frequency	Percent	Valid Percent	Cumulative Percent
Valid 3.00	3	4.8	4.8	4.8
5.00	9	14.5	14.5	19.4
6.00	27	43.5	43.5	62.9
7.00	17	27.4	27.4	90.3
8.00	3	4.8	4.8	95.2
10.00	3	4.8	4.8	100.0
Total	62	100.0	100.0	

validity of this study.

##### 4.2 Instrument Validation

In this study, totally 28 5-point scale variables for measuring 7 factors shown in the research model are collected. Although these measurement models are mostly introduced from well-developed instruments in the literature, in order to ensure the construct validity under the empirical context of this study, principal component factor analysis is used to validate the measurement models. All the factor solutions with reliability Alpha are provided as Table7 below. We can observe that each measurement model produces one-factor solution and acquires the Alpha value in the interval of 0.77-0.95. It shows the measurement model quality of this empirical study is extremely desirable and free from the concerns of construct validity and reliability.

##### 4.3 Hypothesis testing

###### 4.3.1 The Antecedent Model of A<sub>web</sub>

In hypothesis 1-3, we propose the antecedent model for the A<sub>web</sub> construct. These paths are verified simultaneously with a multiple regression model incorporating 3 independent variables. The A<sub>web</sub> construct is regressed on informativeness, entertainment, and organization of the web content. As depicted in Figure 2 below, it shows that these paths are all corroborated in this study. They pass the F-test and t-test of regression analysis at 0.000 significance level and explain nearly 80% variance of the A<sub>web</sub> construct (R<sup>2</sup>=0.797). Therefore, hypothesis 1-3 are supported in this study.

###### 4.3.2 The Consequence Model of A<sub>web</sub>

In hypothesis 4-6, we propose the consequence model for the A<sub>web</sub> construct. These paths are verified separately with 3 simple regression model incorporating only the A<sub>web</sub> construct to explain the consequence variables. The A<sub>web</sub> construct is used to regressing intention to revisit, loyalty toward web site, and intention to future online commerce separately. The results show that these paths are all corroborated in this study. They pass the F-test and t-test of regression analysis at 0.000 significance level. And the A<sub>web</sub> construct can explain 72.5%, 38.6%, 52.6% variation for intention to revisit, loyalty toward web site, and intention to future online commerce respectively. Therefore, hypothesis 4-6 are supported in this study as well.

Table 7: Measurement model validations with reliability estimates

Attitude toward web site, Alpha = .9077		Informativeness, Alpha = .8929	
Item	Factor Loading	Item	Factor Loading

Variance extracted	95.31%		

## 4.4 Discussions

### 4.4.1 For antecedent variables

From the empirical findings of this study, we can observe that in online content industry context (e-news web sites), the explanatory capability of 3 content attribute factors is even stronger than in shopping context investigated empirically in the literature. Chen and Wells have ever reached the 0.63 level of R square and concluded with the emerging opportunity of the  $A_{web}$  prediction theory [5]. In this study, we are interested in the non-shopping context and re-test the content attribute antecedent model for the e-news site industry. By using the controlled survey methodology, we amazingly achieve the 0.797 level of R square toward explaining the  $A_{web}$  construct. Therefore we find that the antecedent structure is more suitable for explaining  $A_{web}$  in digital content industry, and we also develop a more robust basis of the  $A_{web}$  prediction theory for the academic literature from the web content attribute perspective. Although there have been many variables shown in the  $A_{web}$  literature (please referencing Table 1), now it can be claimed that content-related variables, namely, informativeness, entertainment, organization are the most major explaining

system for the  $A_{web}$  construct and therefore provide the rationale for people's preference of web sites.

Besides that, we also observe that the influencing effects of 3 content attribute factors are different from those empirically explored in the literature. For e-news web sites, entertainment factor is the most important factor influencing  $A_{web}$  (Standardized beta coefficient: entertainment 0.42, > informativeness 0.40 > organization 0.30). Compared to the Chen and Wells' study [5], the influencing effect of informativeness is much decreased in strength, and the effect of organization factor is remained the weakest (in their findings, Standardized beta coefficient: informativeness 0.57 > entertainment 0.34 > organization 0.22).

The possible explanations of the findings above may be attributed to the motivational factors of web users and the information quality of online content providers. According to the annual internet surveys conducted by one of the largest portal sites in Taiwan, in recent years, seeking for recreational entertainment source of digital content has been one of the major activities performed by web users of e-news sites (<http://survey.yam.com/index.html>). Therefore from the view point of motivational reasons, being satisfied by the entertainment attributes of a web site is going to generate the most positive experiences for web users and thus develops the most favorable attitudes toward a site.

On the other hand, online content providers today are facing channel conflict dilemma among content delivery vehicles. Being driven by fearing the decline of physical material sales, they are reluctant to offer high quality information online. This leads to lower the average level of expectations of web users for acquiring knowledgeable information on news sites and thus might dilute the effect of informativeness on  $A_{web}$ .

### 4.4.2 For consequence variables

From the testing results of the consequence model of the  $A_{web}$  construct we can learn that  $A_{web}$  can both significantly affect intention to revisit and loyalty toward web site, however, the  $A_{web}$ -Loyalty relationship is much weaker.  $A_{web}$  accounts for 72%, 38% variation for intention to revisit and loyalty toward web site respectively. This finding may be not so good for web site managers, for putting huge efforts to develop and

Model Summary

a. Dependent Variable: AWEB

Figure 2: Regression analysis for testing the antecedent model of  $A_{web}$

implement web content strategies may just only well pay off on attracting people to come back to site in the future but not on receiving sufficient loyalty from their web users. Site managers have to face the reality that in internet business, if other sites provides stronger incentives, then their online users may just switch easily and quickly. Although  $A_{web}$  affects loyalty significantly, the site managers are still obviously risky at relying on the content strategies to develop user loyalty. Seeking for other more effective means of web site strategies to combine with or replace content strategy still challenges the site managers.

However, surprisingly, we find  $A_{web}$  does build a relationship with intention to future online commerce.  $A_{web}$  accounts for over 50% variation of it ( $R^2=0.52$ ). We can now confirm the conjecture that striving for  $A_{web}$  will also pay off on the electronic commerce perspective. News site users tend to be willing to transact with sites responded favorably in the future. Although this relationship means little in theoretical contributions, however, it is going to greatly inspire online content providers for already offering the confidence for future strategic planning of entering electronic commerce. This study creatively and successfully relates the  $A_{web}$  construct to intention to future online commerce. Of course it's only an exploratory finding and thus needs to be validated with better research design by future studies.

## 5. Conclusion

The purpose of this study is to choose the content attribute perspective to develop and test the antecedent and consequence model for the  $A_{web}$  construct under the online content sites contexts. By using the controlled survey methodology with graduate student samples, all the research hypotheses are supported. The main empirical results can be summarized and depicted by mapping back to the research model as Figure 3 below.

### 5.1 Contributions and Implications

Selecting the content-related variables as the perspective to construct the research model for the  $A_{web}$  construct with online marketing variables provides an point of view that links the content strategies of web sites

to web users' psychological attitude and behavioral outcomes. With the derivation and empirical testing these relationships among research variables, we justify the rationale that manipulating web site strategies could lead to the formation of web users' attitudes and thus in turn explain and predict their subsequent online behavior.

It is certainly that such a research model should be taken into further empirical validation for clarifying the substantive relationships. However, this study already provides both the logical derivations of model building and feasible operationalization approach of empirical research design to verify hypothetical relationships among variables and thus contributes to the theory building and testing for the electronic commerce literature. Besides, linking the web content strategies to web site business-related outcomes via the attitudinal construct helps us to successfully cope with the most urgent managerial issues for the online content industry.

From the empirical testing of such a research model, we can tell the influencing effect of every single model path and thus develop the knowledge for the impact of web site content strategies on  $A_{web}$  and those important indices of web site effectiveness, such as intention to revisit and loyalty toward web site. It can directly help the web site managers to adjust their ways of web site design. Based on the empirical findings, for the e-News site industry, we recommend to pursue entertainment strategy first in order to directly meet most web users' expectations and satisfy their online motivations. Compared to informativeness and organizational factors, providing interesting and attracting recreational content will contribute most effectively to develop web users' favorable attitudes.

We also put important online marketing variable like future online commerce intentions into the model. Such an attempt is even beyond the web site business scope and therefore facilitating the formation of the corporate level strategies to explore the potential of entering into the transactional online commerce activities for the newspaper industry.  $A_{web}$  is found to be significantly associated with web users' intentions to future online commerce thus providing a good message for the online content providers to bravely attempt building transactional relationships with their web users.

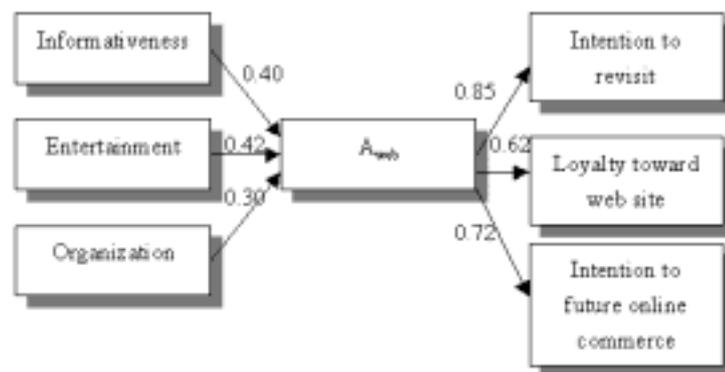

Figure 3: Research finding summary of this study (paths are labeled with standardized beta coefficients obtained by regression analysis )

## 5.2 Limitations and Recommendations

Although variables shown in the research model provides significant implications for both the managerial research and practices of the electronic commerce, readers ought to pay attentions to the interpretations of the findings in this study. What we claim and focus for the model building is via the web content-related perspective and thus offering limited scope for the explanation and prediction toward the  $A_{web}$  construct and subsequent dependent variables. As a matter of fact, there have been fruitful in the exploration of explanatory variables for the web site attitudinal research. Individual characteristics such as involvement, internet knowledge, and experiences have also found to be empirically associated with the  $A_{web}$  construct [2]. In addition, other web site attracting strategies such as providing economic incentives for web users also identify the utilitarian rationale for developing positive attitude toward sites [29][30].

In other words, there are still lots of potentials in this area of research. Future studies should attempt to explore more antecedent views with more business outcomes of online marketing for the  $A_{web}$  construct to enrich the theoretical systems of the web attitudinal research, and thus continuing to uncover the phenomenon of people's preference to stick with certain web sites and its possible behavioral outcomes as well. And certainly, the sample quality concern that threats most severely to the external validity of this study has to be relieved by future studies. Larger sample size and more heterogeneous sample characteristics are more desirable to effectively estimate the real pictures of internet user population.

Individual psychological constructs are very popular and playing important roles in the consumer behavior literature, however, they are still relatively unexplored in the web site effectiveness literature. This study puts lots of efforts into the preliminary attempt to investigate the phenomenon of why people respond to certain web sites favorably and explore its potential online marketing outcomes. We hope to introduce an innovative perspective and thus inspire more future studies to enrich the electronic commerce management literature.

### Abstract

This paper presents taxonomy of operations priorities using data collected from 175 companies in China. The taxonomy of operations priorities in China are found to be quite different from what was observed in previous studies (Miller and Roth 1994; Kathuria 2000; Frohlich and Dixon 2001). The result of this study supports the view that the types of the operations strategies used by companies are different in different parts of the world and are influenced by the competitive environment (Frohlin and Dixon 2001).

This paper also compares the use of the competitive strength and importance rating of the operation priorities to develop the taxonomy and found that competitive strength measures are more reliable and can better explain company's performance and their emphases on management programs. The paper advocates the use of competitive strength rather than importance in future research on operations strategy.

xske@center.njtu.edu.cn

## Abstract

Many enterprises all over the world plunge into developing ecommerce in recent two or three years, but don't attain their expectant goals. Taking Chinese enterprises as the example, through analyzing the individuating trend of consumption and the operating status of ecommerce, this paper emphasizes that only the enterprises develop client-centered ecommerce considering their practice conditions can they fit the individuating trend of consumption and ecommerce, and puts forward some proposals for the individuation of this client-centered ecommerce for enterprises in new century.

## 1. Introduction

Internet brings one world-shaking change for people's daily life and economic activities. The enterprises worldwide trade with others on Internet, which is called ecommerce, this raises the producing efficiency and decreases the cost of the management, but also enlarges the production market and enhances the enterprise's strength. The traditional trade mode is receiving more and more challenges from this new trade mode on Internet. Chinese enterprises also plunge into ecommerce with great ardor in recent two or three years, but don't attain the expectant goals with the further development of ecommerce and Internet economy. Some new problems are appearing too such as the individuation of consumption and ecommerce. More and more enterprisers and scholars are analyzing these problems and trying to find some good methods which can help the enterprises do better and client-centered ecommerce and get better return. Some solutions are put forward such as cooperative business, synergic business and etc. Most of these solutions base on the theory demand and prefabricate some fixed stencils, but are not practical enough to fit the current practical condition of all enterprises from different countries. So the proper development strategy of client-centered ecommerce for meeting the individual needs of clients is needed very much by many enterprises, especially for Chinese enterprises.

## 2. Individuating Trend of Consumption and Ecommerce

There are enough and almost all kinds of commodities in human society now through more than 100 years' industry revolution, adding the fast

development of information technology with computer as a representative, these can gradually meet the individuation needs of consumers which are upswing, such as individuated cars, individuated houses, individuated home appliances, individuated clothes and individuated computers. Thus the individuated productions and individuated services have become the leading tide of our new age with client-centered concept. When one enterprise is regarded individuated, this means larruping and can get more consumers' more attention and consider more from the side of clients. Now almost all enterprises worldwide are in pursuit of their individuation. For instance, the famous retail enterprise of USA, Roudster-Rom Corp., makes one management tenet that the enterprise will satisfy any consumer's needs. When one consumer does business with this enterprise, besides the commodities, he will also be received a series of services such as the consultation and being run after. The relation between the consumer and the enterprise isn't ceased with the end of shopping and will continue for a long time, maybe the whole life of the consumer. This strategy gives the consumer one comfortable family feeling.

The consumer feel more convenient and save money by the means of doing shopping on Internet, but he also lose the satisfaction which is full of the milk of human kindness offered by traditional trade way, what he can see and get is infinite information on Internet and formatted service by the silent machine. For the enterprise, the lead of technology is temporal, the predominance is no longer easy to be acquired by the lead of technology now. Whenever and wherever Internet directly push the enterprise to the front of consumers and let the enterprise face more and more individuated demands. So, only the enterprise can provide characteristic services aiming at kinds of consumers by combining some traditional marketing means and Internet technology, it will be a simon-pure winner. The individuation of ecommerce comes forth following this demand, that is client-centered and providing the individuated services and products on Internet. It has the following two contents:

First, the custom-tailored service and merchandise full of individuation. Because of the difference of individual conditions, the clients' demands are different too. For the commodity with higher content of technology, the consumer no longer receives it just passively while the businessman no longer only provides many selections, he will take part in the processes of the commodity's design and production with his individual

love. Now whether the enterprise can provide more individualized services or not comparing with traditional companies becomes the key factor for a successful or a failed ecommerce.

Second, the custom-tailored information full of individuation. Internet makes it possible to custom-tailor information following the consumer's wish, this means huge business chances. The personal electronic newspaper provided by New York Times early is a good example. The best characters of Internet is real time and dynamic exchange, in virtue of this, consumers can enjoy the function of VOD, but also can take part in the design and production of the TV programs.

### 3. Analysis of Chinese Ecommerce

Internet is influencing almost all the fields of Chinese society and culture deeply like it does in other countries. In the end of the year 2001, the total number of Internet users in china has exceeded 30 million and is increasing at a double surprised speed every year, the number of Chinese websites has more than 800000 while the number of government internet websites reach 3000. In addition, more than 1 million small companies, 10000 moderate and 100 large enterprises have connected to Internet. With a good Internet environment comes into being in china, doing ecommerce on internet is increasingly becoming one important way for one enterprise changes to be more competitive in new century. The representative door websites like Sina, Sohu, Tom, Capital Online develop ecommerce one after another; the traditional IT products manufacturers and sellers state their ecommerce development strategies and ecommerce productions early or late; the professional ecommerce websites including more than 100 thousand kinds of merchandises like 8848 and DangDang develop very quickly. In general, all kinds of enterprises want to expand themselves by this new business way of doing ecommerce.

But Chinese enterprises are changing from planned economy system to market economy system and haven't enough market experiences, so, many of them just imitate the ecommerce mode of foreign enterprises simply, establish Internet website, issue information and do business on Internet, etc. They have not enough experiences or time or skills to make one analysis that whether the practical conditions of the enterprises fit for doing ecommerce or not and how to do first. The result is disappointed. Chinese enterprises' current status of developing ecommerce is: ecommerce has been developed vigorously and busily on the surface in recent two or three years, but the result is the little proceeds comparing the huge investment, some even deal losing money in business now; the total amount of ecommerce is so small and less than RMB5000 million in the year 2001; the development level of ecommerce is still resting on one lower level and the ecommerce upsurge like in America don't emerge in china.

There are many reasons causing this result, the main factors are described as following:

First, imitate the ecommerce mode of foreign

enterprises simply while not considering the practical condition of the enterprise carefully and insist on having done all things by one step excessively and seek to set up one complete and consummate ecommerce platform. Such as whether the products are fit to do ecommerce or not, whether the quality of the employees and departments fit to develop ecommerce or not, etc.

Second, the ecommerce contents are very finite and the marketing means are simple and bald, lack of individuality, so these still can't arouse and stimulate the consuming appetite of Chinese people and change their traditional consuming conception which formed for a long time.

Third, there isn't one enough and full estimate about the influences for china's incomplete ecommerce environment, such as relative poor Internet establishments, more expensive Internet fee, not too reliable security technology of Internet and information, shortage of the organizations for ecommerce's notarization and arbitration, etc.

Forth, the management, establishment and technology of physical distribution in China is very poor, the advanced third-party system is lacked very much. This situation make it very finite of the ecommerce developing area for one enterprise and can't ensure providing in-time service of sending the goods, say nothing of sending goods spanning areas. It is unimaginable if one enterprise can develop ecommerce fast in a large scale and get one good repay in this condition.

Last, Chinese enterprises are still not used to accept the concept of client-centered for their long history of the planned economy system.

### 4. The Proposals for the Individuation of Client-Centered Ecommerce

According to the ecommerce developing status of Chinese enterprises and the individuating trend of ecommerce, many project providers have put forward a lot of ecommerce solutions, such as cooperative business, synergic business and etc. Most of these projects base on the theory demand and prefabricate some fixed stencils. For example, some providers emphasize beginning with ERP of the enterprise inside, some pay stress on the visualization of the enterprise. Analyzing these projects carefully, we can find out that these stencils lacking flexible, which can not reflect the peculiarity of each enterprise and can not accommodate to new circumstances. In order to improve the efficacy of ecommerce and adapt to the individuating trend of ecommerce, Chinese enterprise should consider comprehensively the circumstance of capital, the operation trait and economy environment so as to plan the individualized ecommerce strategy suited to each enterprise.

4.1 Analyze the latent customers of enterprise's products, their consumption ability, the ecommerce possibility of products and the

investment risk through decision adviser consulting, find out one appropriate entry to begin with and ascertain the development direction of ecommerce. Notice the key point.

Ecommerce is investment, not consumption. The enterprise should evaluate the situation of present competitor and the character of its products carefully, according to own limited financial and material resources, find one appropriate entry to begin developing ecommerce instead of doing with all-sides. Each kind of merchandise has specific user group. Each group has the preference, consuming ability and consuming habit, the enterprise should analyze the market fully in order to find accurate product location. For example, Shanghai Maydeal Science and Technology Corp. set up one nationwide professional medical electronic market: www.maydeal.com in June 2000. The company adopts the strategy which meeting enterprises' demand, selects medical consumable goods as an entry to do ecommerce, offers a professional medical ecommerce platform for professional buyer and medical product supplier which has definite classification and complete kinds of goods. Although Maydeal website was set up only one year ago, now it has been beginning to establish its leading market position in China.

4.2 Begin from demand chain, combine BPR and Client-Centred concept, pay more attention to use social resources and explore one series of flexible business processes that suits ecommerce development.

The business process of ecommerce is other than that of traditional business, which also differs from each other because of different trade and different enterprise. When designing the business process of ecommerce, the enterprise should consult experts and customers, consider problems from the demand chain, accord with the individuated demands of consumers as far as possible, give fast feedback and notice to evaluate the work efficiency of the process and adjust it in time. For example, the operation process developed by Qingdao Haier Group which can make fast feedback on network offers the individuated service that the distributor can custom made refrigerators. This gets warm welcome of dealers, and helps Haier and numerous dealers get better return together.

4.3 According to the development trend of ecommerce and the characters of business process, purchase the ecommerce technical platform or unite to develop one. When implementing, perfect each module step by step, pay attention to the cooperation with traditional commercial pattern and prevent from pursuing success immediately or just at one step.

The enterprise should go to consult the experts who can make careful analysis about the management scale,

the trade and business characteristics, and give good proposals according to actual circumstances to the enterprise. If condition permitted, it is a good idea to develop the corresponding ecommerce technical platform by uniting other professional companies, and perfect it modularly step by step. By this way, the technical solution of ecommerce can suit the customers better, provide and add peculiar services for the clients in time.

4.4 In place of establishing the ecommerce platform solely at one huge cost, develop net cooperative business between enterprises actively, construct and support a harmonious and uniform market environment for sharing the resources and benefits. This also can meet the individuated needs of customers better and realize the enterprise's durable development of ecommerce.

Since Chinese enterprises contact market economy lately, they lack enough understanding of market risk and market competition. They always like to do business by themselves and do not pay attention to the cooperation between the enterprises and the use of social resource, so as to increase operation cost and market risk. So does in the field of ecommerce. For Instance, not long ago, some name brands domestic companies, such as Chunlan, Haier, Midi and so on, throw huge capital respectively on internet and build each ecommerce platform, in order to construct one B to B and B to C system which has the capacity to realize the functions such as sales online, delivery online and purchasing online in global scope. But the results may not as their hope. On the contrary, considering the construction and maintenance of common market environment, the long-term development of market and the long-term benefit of customers, three famous world-class corporations, General Motor, Ford and Daimler-Chrysler, decide to give full cooperation to found and run one common online B to B website instead of building the competitive and independence B to B website each. Besides, about the management of physical distribution in support ecommerce development, according to the facts of low profits in Chinese transportation enterprises, lot of assets leaving unused and growing unemployment, the enterprise can use these social resources fully, organize and manage them efficiently, design one work process of physical distribution to satisfy the customers and cooperative partners just at low cost.

4.5 Explore the marketing strategy of ecommerce actively. Maintain some operating ways of traditional business to meet the need of the continuity of customer habits, but also combine the characteristic of Chinese culture, be positive to adopt the new technologies and new methods according with the new century concept. Notice the combination of the social benefit and the commercial benefit to cultivate one good

individuated ecommerce image.

One good individuated and client-centered ecommerce image with the individuated marketing strategy of ecommerce can help the enterprises to maintain a long-term relatively regular customers, but also attract new user to join the consumption chain of the enterprise continuously. For example, environmental protection has become the hot and important topic of the 21<sup>st</sup> century. That the enterprise collects discarded batteries or presents one environmental can for collecting discarded batteries incidentally When delivering goods may be one nice peculiar marketing method which accords with new century concept. It can consider both social public welfare and the commercial benefit too. Another, when implementing electronic payment, we can retain some traditional payment means, such as cash payment on the spot, which accords with the long-term consumption culture of most Chinese people and satisfies some consumers by continuing their payment habit.

## 5. Conclusion

When one enterprise or one Internet website or one kind of service is client-centered, this always is regarded individuated and means larruping and will get more consumers' more attention. Individuated productions and individuated services have become the leading tide of ecommerce age. That Chinese enterprises construct their individuated ecommerce platform and develop individuated ecommerce is the effective strategy which replies the challenge aroused by the individuating trend of consumption and ecommerce, help the enterprise to bring into full play of ecommerce while avoiding venture and bring back one material repay. This also is one feasible way which helps Chinese enterprises subsist, develop, boost up in the more and more competitive market and gain one preponderant position. One good news is that some Chinese enterprises have begun to do some works in pursuit of developing client-centered ecommerce for adapting to the individuating trend of consumption and ecommerce with the client-centered concept. For example, when the consumer logon the ecommerce system which is set up by Digital-china Corp. of Legend Group, one characteristic homepage will come forth. If the consumer is a registered user, the ecommerce system will display the peculiar homepage made just for this user and provide him individuated one to one services. This also shows Digital-china Corp. is establishing the fundamental strategic concept which consumers are first and the center.

On the other hand, the enterprise shouldn't go from one extreme to the other too. This is said that the enterprise shouldn't pursue the individuality blindly and regard it as the target, the key point is client-centered and suit for clients' demands.

## Abstract

Traditional time series methods are designed to analyze historical data and develop models to explain the observed behaviors and then predict future value(s) through the extrapolation from the models. The underlying premise is that the future values should follow the path of the historical data analyzed by the time series methods, and as such, these methods necessitate a significant amount of historical data to validate the model. However, this assumption may not make sense for applications, such as demand forecasting, where the characteristics of the time series may alter frequently because of the changes of consumers' behavior and/or cooperate strategies such as promotions. As the product life cycle gets shorter as it tends to be in today's e-business, it becomes increasingly difficult to make a forecast using traditional time series methods. In response to this challenge, this paper proposes a novel pattern matching procedure to decide whether one or combination of several patterns actually represents the development of the time series and then to use the patterns in forecasting. Several pattern transformation algorithms are also proposed to facilitate a flexible match. Rematching through dynamic reevaluation of the new data may be needed until the true development of the time series is discovered. Initial evaluation indicates superior performance in predicting the demand of a new product.

## 1. Introduction

Demand forecasting has attracted increasing attention because an accurate prediction of future demand dictates the success of supply chain planning. Various forms of demand forecasting techniques have been proposed in the literature including statistical approaches, decomposition methods and approaches borrowed from artificial intelligences. Statistical techniques, such as moving average (MA), autoregressive (AR) or integration of both methods i.e., auto regressive intergraded moving average (ARIMA) [2] regard times series as stochastic processes. Decomposition methods, such as Fourier transformation, convert the original time series into components in both time and frequency domains, and then predictions are applied to the individual components. In practice, simple methods such as moving average and exponential smoothing are frequently used due to their simplicity. Ironically, these simple methods might occasionally lead

to more accurate forecasting results than sophisticated or complex methods. Recently, techniques in the area of artificial intelligence, such as neural networks and genetic algorithms [4, 5, 7], became popular in time series forecasting. However, all the traditional time series forecasting methods are established under the assumption that certain "behavior" exists in the time series that can be modeled systematically with past history. Even though researchers claim neural network as a "model-free" approach, the technique still relies on selected time series data to predict future events. Such methods would not be able to predict the "turning point", or detect sudden behavioral changes.

Almost all the methods require a significant amount of past historical data to build or "train" the model. The validity of the model would be doubtful when only very short history of time series is available. A good example is that, the life cycle of consumer products has become much shorter than ever before due to changes in business paradigm from mass production to semi-customization. As a result, a lot of products did not have long historical records to make a demand forecast with traditional forecasting methods.

The paper presents a pattern-matching algorithm for time series forecasting, especially in demand forecasting when very short history of time series is available. The objective is to take advantage of new methodologies in the field of temporal data mining and apply them to forecasting. Section two presents the new pattern-matching algorithm. Section three presents an experimental evaluation in demand forecasting of a new product using the pattern-matching algorithm. Section four presents the conclusions and future research.

## 2. Pattern Matching in Time Series Forecasting

A vast amount of literature exists on detecting meaningful patterns in data mining and other domains. Both technical analysis and programming generated methods of detecting patterns have been proposed. However, the purpose of pattern matching in those studies is to find a good match of specific patterns "inside" a time series. Examples of researches in pattern matching include pattern recognition [8] and the similarity measurement [1, 3, 6]. While the basic concept of the proposed pattern-matching algorithm for forecasting is

that the meaningful patterns would repeat itself in the future of the time series. Therefore we only consider if a certain pattern is developing at the end of the time series. In other words, we treat the patterns not in the context of discovering higher-level relations of what they mean but use the patterns as possible representations of future values for the time series. The main purpose our pattern matching is to decide whether a pattern would actually represent the development of an on-going time series.

The idea of the proposed forecasting method originates from the concept that humans use available patterns to predict the future. Hence, we consider the followings steps as possible procedures for pattern matching in time series forecasting:

- (1) Match patterns at the end of the time series only. The purpose is to predict future value. The way the patterns exist in the (past) times series is not important;
- (2) Start by guessing and matching “partial” patterns. Only the front part of the patterns, which represents the portion of the pattern that has already occurred, is matched into the time series. The remainder or the “unmatched” portion of the pattern is used as forecasts of future values.
- (3) Consider several candidates before a good match is completed. There might be several candidates of patterns at the beginning of the forecasting process. The true, or closest pattern that represents the on-going time series may not be revealed at the beginning but will be identified as the process is continued. In some cases, a combination of several patterns may be the best way to characterize the on-going time series. Hence, a weighting scheme would be necessary to make an overall forecast from different patterns. Re-evaluation is needed as the new data of the time series arrives.
- (4) Adjust patterns to fit the time series. Transformations of pattern may be needed to increase the precision of the pattern matching as well as the forecasting accuracy.

Note that it is not obligatory to obtain the patterns directly from the historical data of the same time series. For example, in the case of demand forecasting of a new product or the life cycle of the product is too short to extract meaningful patterns and assuming that the company had produced similar items in the past, the demand patterns of the old products might be very good indicators for the new product. This suggests a way to forecast a short time series in such a special case (i.e., use patterns found in other time series).

An important assumption of the proposed matching algorithm is that the current time series is developing into a trend that is equal or similar to an interesting pattern and we have several possible candidates of the pattern at hand. The problem is then reduced to find which pattern or combination of patterns will be best to represent the immediate future of the time series.

Based on the above analysis, we propose the following algorithm:

Pre-condition: time series  $x$ , candidate patterns  $y$ .

Post condition: forecasted future values  $x\hat{c}$ .

1. Apply the matching algorithm to each pattern. (Matching algorithm is stated in section 2.1)
2. Decide the candidate set of patterns and the weights for each pattern (Weighting scheme is stated in section 2.2). The overall forecast is the weighted sum of forecasts from the patterns.
3. Update mean square error (MSE) for each pattern when new data arrives. If the updated MSE's indicated a better match or one or more of the candidate patterns were exhausted, repeat step (1) and iterate Step (2). Otherwise, advance the time index, report the new forecasts with the same set of patterns and their weights.

## 2.1 Matching Algorithm

From the discussion in the previous section, we propose the matching algorithm in this section. For us to find the best matching for the pattern, we need to define how well the patterns will fit at the end of the time series. The similarity measure used in this study is mean square error (MSE). MSE was chosen in this study because patterns may not match to the same depth for each pattern. If measures such as total sum of square were used to estimate the forecasting accuracy, the result would be biased by the length that individual pattern matched to the time series. The objective of the proposed matching algorithm is to find the best match with the minimum MSE. The pattern-matching algorithm is described as follows.

Given: Time series  $x = \{x(0), x(-1), x(-2), x(-3), \dots\}$   
 /\*  $x(t)$  indicate the past history at time  $t$ . \*/  
 /\*  $t=0$  indicates current time \*/  
 Pattern:  $\{y(0), y(1), y(2), \dots, y(n)\}$

Output:  $optm$ , number of period used in the pattern that generate the best MSE;  $opt$  = the best MSE, and forecasts  $\{x'(1), x'(2), x'(3), \dots, x'(n-optm)\}$

```

begin
  optm= 3;      /*starting with a 3-point match to
                avoid over-fitting*/
  opt = 10000; /* initializing with a large
                number*/

  for m= 3 to n-1 do
    /* m indicates the matching depth */
    begin
      mse=10000; /* initializing with a large
                  number*/
      for k = 1 to m do
        mse=(x(-k+1)-y(m-k))^2;
        mse=mse/m;

        if mse <= opt;
          begin
            optm=m;
  
```

```

    opt=mse;
  end
end

for j=1 to (n-optm) do
  x'(j) = y(optm+j);
  /* reporting the remainders of the */
  /* pattern as forecasts*/
  output optm, opt, x';
end

```

An example of matching depths (m) 4 and 5 of a pattern into a time series is illustrated in Figure 1. The matching depth of 4 indicated the first 4 data points in the pattern ( $y_0, y_1, y_2$  and  $y_3$ ) which are compared with the last 4 data points in the time series ( $x_{-3}, x_{-2}, x_{-1}$  and  $x_0$ ). The MSE of matching depth of 4 is calculated as the average of the squared difference of the 4 paired data points. The construction of the MSE for matching depth of 5 would follow a similar definition. As shown in Figure 1,  $m = 4$  has a smaller MSE than  $m = 5$ . If  $m = 4$  has the smallest MSE,  $y_4, y_5, \dots$  will be reported as forecasts of the future values. In the next iteration, i.e. when new data arrives, the MSE will be updated. If the updated MSE is within the threshold,  $y_5, y_6, \dots$  will be reported as forecasts. Otherwise, a "rematch" will be performed for this pattern by using the proposed matching algorithm.

obtain an overall forecast. In the literature on combining forecasts, researchers proposed various ways of assigning weights to different forecasting methods. However, most of the methods employ mathematical procedures such as quadratic programming that requires all the methods to be examined over the same period of time. In the proposed pattern matching forecasting, the matching depths of patterns may not be the same; hence the quadratic programming is not applicable. Instead, we proposed a simple weight-assigning procedure in order to decide how well the pattern fit into the time series.

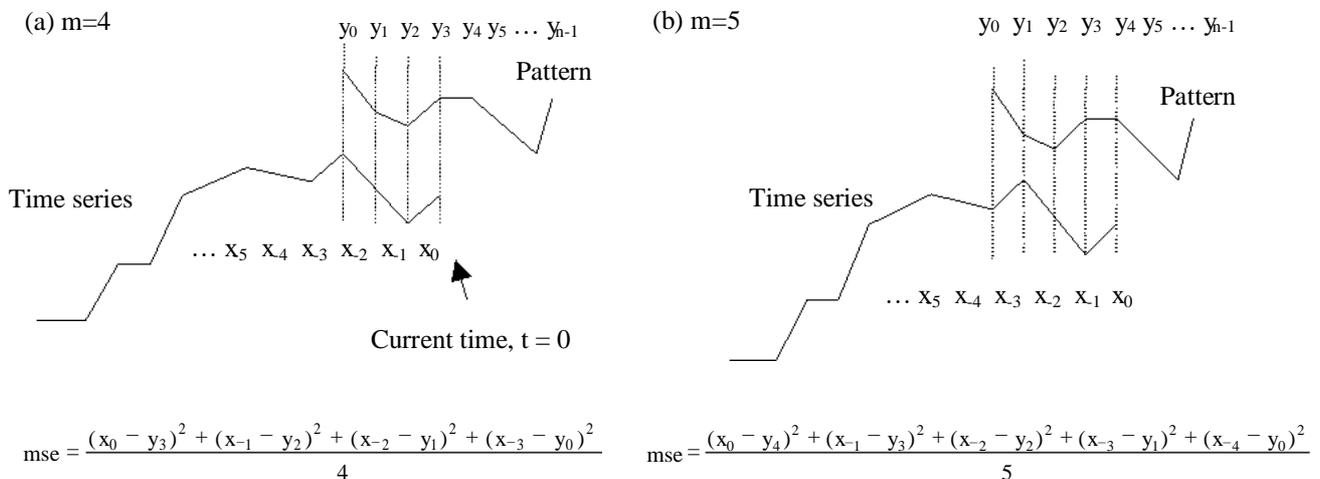

The MSE for each pattern is used to evaluate the performance of the pattern, and thus, will be used to decide the weight assigned to the pattern. Not all of the patterns are included in the overall forecast. A threshold value  $m^*$  is first determined to select the candidate patterns. A candidate pattern is the one whose minimum MSE is less than  $m^*$ . The weight assignment for each pattern is then proposed as follows.

$$w_i = \frac{m^* - mse_i}{\sum_{i \in C} (m^* - mse_i)} \text{ for all } i \in C;$$

$$w_i = 0 \text{ otherwise.} \quad (1)$$

where  $w_i$  is the weight for candidate pattern  $i$ ,  $mse_i$  is the MSE for candidate pattern  $i$  and  $C$  is the index set for the candidate patterns.

For example, assume that we choose the threshold,  $m^*$

Where  $x$  = time series data at time  $t$  with current time  $t$  equal to 0  
 $y_i$  = pattern data in a relative time index  $i = 0, 1, 2, \dots, n$ .  
 $n$  = length of the pattern

Figure 1. Illustrated calculation of mse with pattern matching depth  $m= 4$  and  $5$ . (Patterns were lifted for better demonstration).

## 2.2 Weighting Scheme

In the case of using several candidate patterns to perform the forecasting, a weighting scheme would be necessary to combine the forecasts of the patterns and

$= 5$ , the MSE's are 6, 4, 2.5, 7, and 1 for patterns  $i = 1, 2, \dots, 5$ , respectively. Then patterns 2, 3 and 5 will be the candidate patterns since their MSE's are lower than 5. Their weights can be calculated as follows:  $w_2 =$

$1/(1+2.5+4)=0.1333$ ,  $w_3 = 2.5/(1+2.5+4)=0.3333$ ,  $w_5 = 4/(1+2.5+4)=0.5333$ . Weights  $w_1$  and  $w_4$  will both be zero because the MSE's for patterns 1 and 4 are larger than  $m^*$ . Note that pattern 5 has the largest weight for having the smallest MSE among the patterns. If the reported forecasts are 45, 36, 47, 52, and 67 from the five patterns, the overall (weighted) forecast would be  $45 \times 0 + 36 \times 13.33\% + 47 \times 33.33\% + 52 \times 0 + 67 \times 53.33\% = 56.2$ .

The weights are adjusted dynamically to improve forecasting accuracy. Since the MSE for each pattern will likely be different when the new data arrives, the candidate set and the assigned weights need to be re-evaluated to reflect the best combination of the overall forecast. In the above example, we will still keep patterns 1 and 4 and their predictions because there might come a time when they would make a better forecast. In other words, once their MSE's become smaller than  $m^*$ , they can be included in the candidate set. This dynamic re-evaluation of weights makes the proposed pattern-matching algorithm possible to facilitate potential changes in characteristics of the time series.

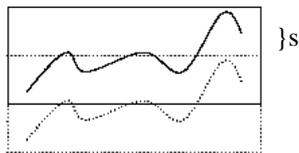

### 2.3 Transformation of Patterns

Transformation of a pattern are needed to lower the MSE for the reason that the time series may be developing similarly to but not exactly the same as the pattern. We would like the pattern-matching algorithm to be flexible and able to deal with scaling and time axis distortion problems. Techniques such as dynamic time wrapping (DTW) have been used in regular pattern matching inside a time series [1, 6]. However, they are not applicable to the forecasting algorithm proposed in this study. The reason is that only a partial pattern is used in our matching algorithm, while DTW requires two full patterns. Hence, the following pattern transformations are proposed.

(1) Vertical Shift --

$$y'_i = y_i + s, \quad (2)$$

where  $s$  is the displacement in the vertical direction. ' $s$ ' could be either positive or negative to represent a shift up and/or down respectively. Horizontal shift is not required because of the way pattern fits into the time series covers the horizontal shift.

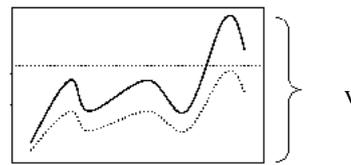

(2) Vertical extension/compression --

$$y'_i = \min_i y_i + v \left( \frac{y_i - \min_i y_i}{\max_i y_i - \min_i y_i} \right), \quad (3)$$

where  $v$  is the ratio the whole pattern extends vertically. (See appendix A for detailed derivation) If  $v < 1$ , this indicates a compression whereas if  $v > 1$ , indicates an

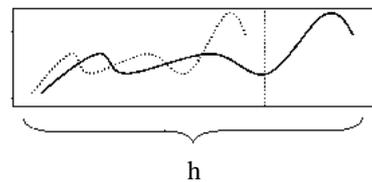

extension.

(3) Horizontal extension/compression – the way to calculate a horizontal extension is more complex than the calculation for a vertical one. First, we need to reconstruct a new time index  $i' = 1, 2, 3, \dots [nh]$  where  $h$  is the ratio of the whole pattern extending horizontally,  $n$  is the length of the pattern, and  $[nh]$  is the largest integer less than or equal to  $nh$ .

$$\begin{aligned} \text{Then } y'_{i'} &= \text{Interpolation of } y_i \text{ and } y_{i+1} \\ &\text{where } h i' \leq i' < h(i+1) \\ &= y_i + (i' - hi)/h \times (y_{i+1} - y_i) \end{aligned} \quad (4)$$

(See appendix B for detailed derivation)

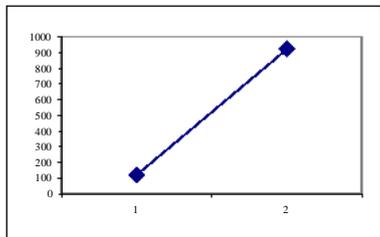

(4) Combination of the above transformations

Transformation(s) should be applied to the pattern prior to the matching algorithm. The optimal transformations ( $s$ ,  $v$  and/or  $h$ ) may be decided by using mathematical programming. In demand forecasting, the transformation in horizontal direction may not be much realistic because of the seasonality issue of product sale. Therefore, the combination of shift and vertical extension/compression will be the two main transformations in the application on of demand forecasting. A heuristic procedure to find  $s$  and  $v$  is (1) shifting the pattern so that the mean value of the selected data points in pattern is equal to the mean value of the matched data points in time series; then (2) finding  $v$  that generates the minimum MSE.

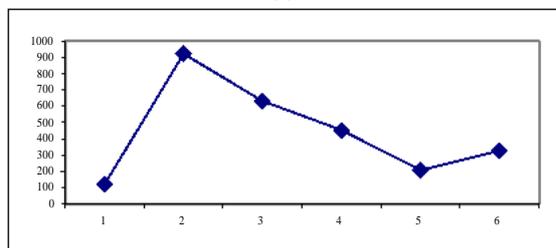

### 3. Experimental Evaluation

As mentioned in the previous section, the transformation of today's business focus from mass production to semi-customization shortens a product's life cycle and makes demand forecasting difficult. This is especially true when a new product enters the market, because there is no historical data available to make a forecast. However, the proposed pattern matching procedure still generates reasonable predictions since patterns were extracted from the past sales of similar products and/or predictions from human experts.

To demonstrate the usefulness of the proposed pattern matching procedure, we use a real world data set. All data are obtained from the same company where the demand forecasting of a new product X is desired. In particular, the sales data of the first two months of product X is collected (Figure2 a). The past sales data of four similar products (products O, Q, R and U) are used as patterns (Figure3) to predict the future demand of product X.

(a)

(b)

Figure 2. The actual demand of product X during (a) first two months (b) the first 6 months.

As shown in Figure 3, most of the sale patterns consist of an immediate surge of sales shortly after the products were introduced to the market due to their promotion, then the demand subsides soon after the new product's introduction. Those patterns look similar, but have their own characteristics. What differentiates the patterns are the customers' reaction to the promotion of the new products and how the products were accepted by the customers. The purpose for this case study is to examine if the development of product X is similar to those patterns, in fact, we use the combination of those patterns to predict the future demand of product X.

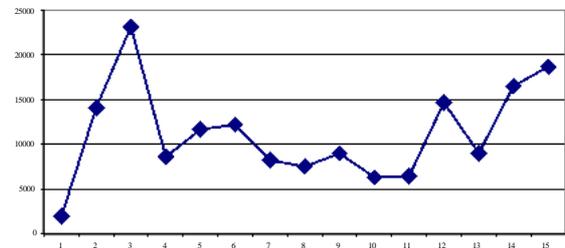

In our example, month 2 will be the current time, which is noted as  $t_0$ . We attempt to predict month 3 ( $t_1$ ), 4 ( $t_2$ ), 5( $t_3$ )... etc. Forecasted and actual values will be denoted as  $x_i'$  and  $x_i$ , respectively, with an appropriate time index.

Notice that we only have two data points of product X (120 and 921) at the beginning of the experiment, almost all the existing forecasting methods is not applicable to such a short time series. One can only "guess" that the value for the third month will either follow the linear trend from the first two months, i.e.  $x_1' = 921 + (921 - 120) = 1722$ , or average the sales of the first two months i.e.  $x_1' = (120 + 921) / 2 = 520.5$ . Apparently, neither would be a reasonable forecast because judging from the sale patterns of products O, Q, R and U, there might be a turning point in month 2 ( $t_0$ ) or 3 ( $t_1$ ). But, we will apply the matching algorithm and let the procedure decide what the turning

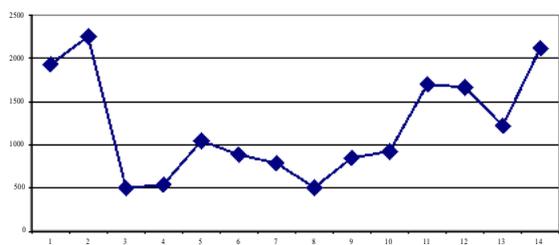

point should be, by finding the best matches using the matching algorithm.

The result of the matching is shown in Table 1. As

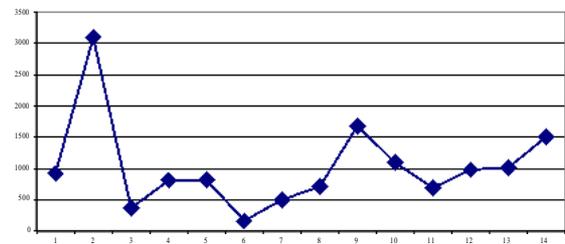

Product O

Product Q

Product R

Product U

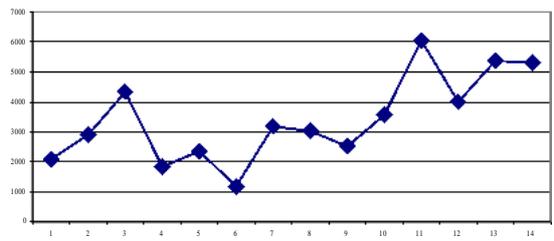

Figure 3. Sale patterns of products O, Q, R and U that were used to predict the future demand of product X

shown in Table 1, the weights were assigned equally at the first month, because there were no historical performance evaluations for the patterns. Starting at month 4 and continuing to month 8, the weights for patterns of products O and R are heavier than the other two products. If we examine the patterns and the overall development of product X (Figure 2(b)), we can easily tell that product X's on-going sale pattern is more comparable to products O and R than those of products Q and U. In other words, the patterns of two products that show more closer resemblances to product X receive heavier weights.

Table 1. Forecasts with patterns of past sales products, corresponding weights and over all forecast for product X

	Month					
	3	4	5	6	7	8
Forecast						
product O	1320.4	339.69	395.49	374.80	245.23	222.23
product Q	0	451.41	428.61	344.43	313.20	277.36
product R	0	260.63	319.63	161.00	209.35	222.30
product U	2121.4	677.57	366.71	107.26	450.10	382.78
Weights						
product O	25%	59.94%	33.04%	29.70%	28.11%	28.95%
product Q	25%	4.24%	14.05%	14.90%	17.23%	18.56%
product R	25%	21.46%	29.94%	31.11%	29.95%	30.97%
product U	25%	14.36%	22.97%	24.28%	24.72%	21.52%
Overall Forecast	860.44	375.97	370.82	238.79	296.83	267.03

The comparison of predictions and the actual demand for up to month 8 are listed in Table 2. In Table 2, we also compare our result with the predictions made by the exponential smoothing method. The exponential smoothing method was selected because all the other methods, such as ARIMA and neural networks, would require much more data to create or train a model. Exponential smoothing and simple moving averaging are the only two choices available for such a short past history. Exponential smoothing is preferred over the simple moving averaging method in terms of better forecasting accuracy. The values shown for months 3-7 for the exponential methods are fitted value; the only forecast value is the one for month 8. The RMSE (root mean squared errors) of the forecast for both methods are listed. The graphic representation of how the two systems performed in predicting product X is depicted in Figure 4. Apparently, the proposed pattern matching procedure has outperformed exponential smoothing, which is the only traditional forecasting method available to predict a time series with such a short history.

Table 2. Comparison of forecasts with pattern matching and exponential smoothing.

	Month					
	3	4	5	6	7	8
Actual	632	453	208	327	220	374
Forecast: Pattern Matching	860.4	376.0	370.8	238.8	296.8	267.0
Exponential Smoothing	395.5	425.1	428.6	401.0	391.8	370.3
Note	RMSE for Pattern Matching is 140					
	RMSE for Exponential smoothing is 281					

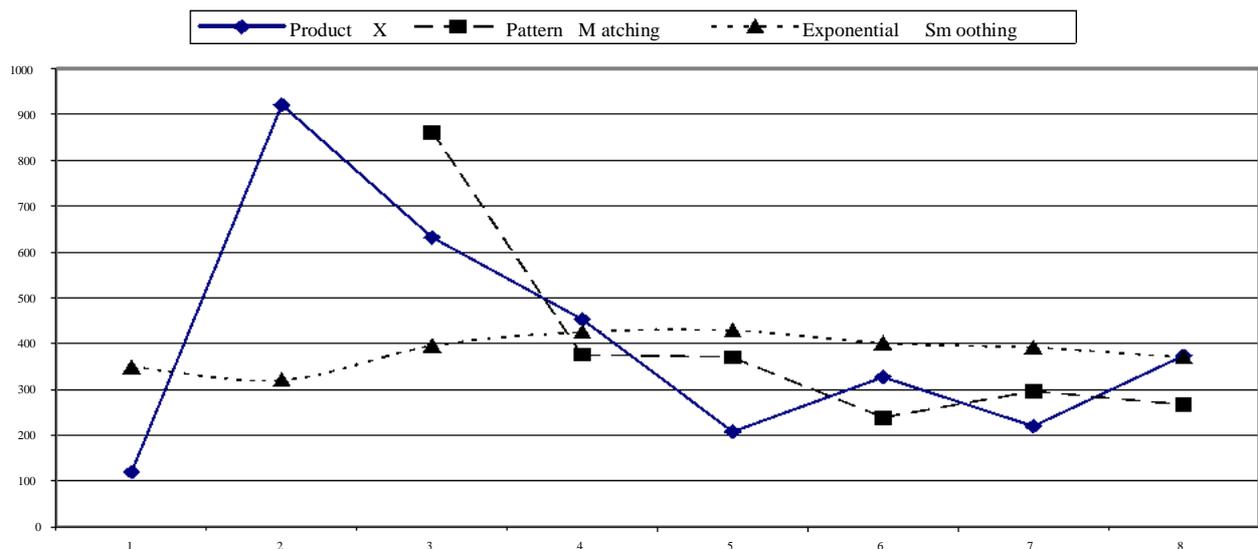

Figure 4. Comparison of pattern matching and exponential smoothing.

#### 4. Conclusion

This paper has presented a novel approach to demand forecasting that is designed for pattern matching. Patterns could be defined by human experts or extracted from various data mining techniques. In our example, instead of creating models from the immediate past history to predict future values, the past sales of similar products were used as predictors of the sale of the product examined. Initial evaluation indicates superior performance in predicting demand of a new product. With little demand data available for the new product, most existing methods are not even applicable to create valid models for demand forecasting.

Although it is not the focus of this study, the presence of “quality” patterns to forecast is essential for this approach. Nevertheless, the approach provides an alternative way of forecasting and beefs up some weakness of the traditional methods. It may be used in conjunction with other forecasting methods to improve overall forecasting results and to apply the pattern matching procedure to a wide range of forecasting problems. In fact, the proposed dynamic pattern-matching algorithm is part of the architecture of an agent-based forecasting system [10]. The purpose is to capture the uncertainty that exists in temporal data sets and apply advanced data mining technique to improve forecasting accuracy.

#### Appendix - Derivation of Transformation Equations

##### A. Vertical extension/compression

let  $y_i$  denote the original pattern at time  $i$ ,  $y'_i$  denote the transformed pattern at time  $i$

let  $v$  be the ratio of the whole pattern extends vertically from the bottom of the pattern

$$\Rightarrow \min_i y_i \text{ remain the same, i.e. } \min_i y'_i = \min_i y_i,$$

while  $\max_i y_i$  extend up to a ratio of  $v$  i.e.  $\max_i y'_i =$

$$\min_i y'_i + (\max_i y_i - \min_i y_i) \times v$$

$\Rightarrow$  for any  $y_i$ ,  $y_i$  extend up to a ratio of  $(y_i - \min_i y_i)$

$$/(\max_i y_i - \min_i y_i) \times v$$

$$\text{i.e. } y'_i - \min_i y'_i = (y_i - \min_i y_i) / (\max_i y_i - \min_i y_i) \times v$$

$$\Rightarrow y'_i = \min_i y'_i + (y_i - \min_i y_i) / (\max_i y_i - \min_i y_i) \times v$$

##### B. Horizontal extension/compression

let  $y_i$  denote the original pattern at time  $i$ ,

$y'_i$  denote the transformed pattern at time  $i$   
 $n$  denote the length of the pattern.

let  $h$  be the ratio of the whole pattern extends horizontally from the beginning of the pattern

$\Rightarrow y_i$  will map to the new domain set of  $\{h, 2h, 3h, \dots, nh\}$

Since the element of the new domain set may not necessary be integer, which is not eligible to be a time index set, a new time index set  $I'$  will be defined as  $\{1, 2, 3, \dots, [nh]\}$ . Where  $[nh]$  is the largest integer that less than or equal to  $nh$ .

$\Rightarrow y'_i$  will become the new range set that the time index set  $I'$  maps into.

$$\Rightarrow y'_{i'} = \text{Interpolation of } y \text{ and } y_{i+1} \\ \text{where } h \leq i' < h(i+1)$$

$$\Rightarrow (y'_{i'} - y_i) / (y_{i+1} - y_i) = (i' - ih) / ((i+1)h - ih)$$

$$\Rightarrow y'_{i'} = y + (y_{i+1} - y_i) \times (i' - ih) / h$$

## Abstract

Most conventional data-mining algorithms identify the relationships among transactions using binary values and find rules at a single concept level. Transactions with quantitative values and items with taxonomic relations are, however, commonly seen in real-world applications. Besides, the taxonomic structures may also be represented in a fuzzy way. This paper thus proposes a fuzzy multiple-level mining algorithm for extracting fuzzy association rules under given fuzzy taxonomic structures. The proposed algorithm adopts a top-down progressively deepening approach to finding large itemsets. It integrates fuzzy-set concepts, data-mining technologies and multiple-level fuzzy taxonomy to find fuzzy association rules from given transaction data sets. Each item uses only the linguistic term with the maximum cardinality in later mining processes, thus making the number of fuzzy regions to be processed the same as the number of the original items. The algorithm therefore focuses on the most important linguistic terms for reduced time complexity.

## 1. Introduction

Machine-learning and data-mining techniques have been developed to turn data into useful task-oriented knowledge [20]. Deriving association rules from transaction databases is most commonly seen in data mining [1][2][6][9][10][11][13][14][27][28]. It discovers relationships among items such that the presence of certain items in a transaction tends to imply the presence of certain other items.

Most previous studies have concentrated on showing how binary-valued transaction data may be handled. However, transaction data in real-world applications usually consist of quantitative values, so designing a sophisticated data-mining algorithm able to deal with quantitative data presents a challenge to workers in this research field.

In the past, Agrawal and his co-workers proposed several mining algorithms for finding association rules in transaction data based on the concept of large itemsets [1-2, 28]. They also proposed a method [27] for mining association rules from data sets using quantitative and categorical attributes. Their proposed method first determines the number of partitions for each quantitative attribute, and then maps all possible values of each

attribute onto a set of consecutive integers. Other methods have also been proposed to handle numeric attributes and to derive association rules. Fukuda et al. introduced the optimized association-rule problem and permitted association rules to contain single uninstantiated conditions on the left-hand side [11]. They also proposed schemes for determining conditions under which rule confidence or support values are maximized. However, their schemes were suitable only for single optimal regions. Rastogi and Shim extended the approach to more than one optimal region, and showed that the problem was NP-hard even for cases involving one uninstantiated numeric attribute [23][24].

Fuzzy set theory is being used more and more frequently in intelligent systems because of its simplicity and similarity to human reasoning [18]. Several fuzzy learning algorithms for inducing rules from given sets of data have been designed and used to good effect with specific domains [3-4, 8, 12, 15-17, 25, 29-30]. Strategies based on decision trees were proposed in [7, 21-22, 25, 31, 33], and Wang et al. proposed a fuzzy version space learning strategy for managing vague information [29]. Hong et al. also proposed a fuzzy mining algorithm for managing quantitative data [14].

In [18], we proposed a data-mining algorithm able to deal with quantitative data under a crisp taxonomic structure. In that approach, each item definitely belongs to only one ancestor in the taxonomic structure. The taxonomic structures may, however, not be crisp in real-world applications. An item may belong to different classes in different views. This paper thus proposes a new fuzzy data-mining algorithm for extracting fuzzy multiple-level association rules under given fuzzy taxonomic structures. The proposed algorithm adopts a top-down progressively deepening approach to finding large itemsets.

## 2. Review of Fuzzy Set Concepts

Fuzzy set theory was first proposed by Zadeh in 1965 [34]. Fuzzy set theory is primarily concerned with quantifying and reasoning using natural language in which words can have ambiguous meanings. This can be thought of as an extension of traditional crisp sets, in which each element must either be in or not be in a set.

Formally, the process by which individuals from a universal set  $X$  are determined to be either members or non-members of a crisp set can be defined by a

characteristic or discrimination function [34]. For a given crisp set A, this function assigns a value  $\mu_A(x)$  to every  $x \in X$  such that

$$\mu_A(x) = \begin{cases} 1 & \text{if and only if } x \in A \\ 0 & \text{if and only if } x \notin A \end{cases}$$

Thus, the function maps elements of the universal set to the set containing 0 and 1. This function can be generalized such that the values assigned to the elements of the universal set fall within specified ranges, referred to as the membership grades of these elements in the set. Larger values denote higher degrees of set membership. Such a function is called the membership function,  $\mu_A(x)$ , by which a fuzzy set A is usually defined. This function is represented by

$$\mu_A : X \rightarrow [0,1],$$

where  $[0, 1]$  denotes the interval of real numbers from 0 to 1, inclusive. The function can also be generalized to any real interval instead of  $[0,1]$ .

A special notation is often used in the literature to represent fuzzy sets. Assume that  $x_1$  to  $x_n$  are the elements in fuzzy set A, and  $\mu_1$  to  $\mu_n$  are, respectively, their grades of membership in A. A is then represented as follows:

$$A = \mu_1 / x_1 + \mu_2 / x_2 + \dots + \mu_n / x_n.$$

An  $\alpha$ -cut of a fuzzy set A is a crisp set  $A_\alpha$  that contains all elements in the universal set X with membership grades in A greater than or equal to a specified value  $\alpha$ . This definition can be written as:

$$A_\alpha = \{x \in X \mid \mu_A(x) \geq \alpha\}.$$

The scalar cardinality of a fuzzy set A defined on a finite universal set X is the summation of the membership grades of all the elements of X in A. Thus,

$$|A| = \sum_{x \in X} \mu_A(x).$$

Among operations on fuzzy sets are the basic and commonly used complementation, union and intersection, as proposed by Zadeh.

The complementation of a fuzzy set A is denoted by  $\neg A$ , and the membership function of  $\neg A$  is given by:

$$\mu_{\neg A}(x) = 1 - \mu_A(x), \quad \forall x \in X.$$

The intersection of two fuzzy sets A and B is denoted by  $A \cap B$ , and the membership function of  $A \cap B$  is given by:

$$\mu_{A \cap B}(x) = \min\{\mu_A(x), \mu_B(x)\}, \quad \forall x \in X.$$

The union of fuzzy sets A and B is denoted by  $A \cup B$ , and the membership function of  $A \cup B$  is given by:

$$\mu_{A \cup B}(x) = \max\{\mu_A(x), \mu_B(x)\}, \quad \forall x \in X.$$

The above concepts will be used in our proposed

algorithm to mine a set of fuzzy interesting association rules under fuzzy taxonomic structures.

### 3. Data Mining with a Fuzzy Taxonomic Structure

Previous studies on data mining focused on finding association rules on a single-concept level. Mining multiple-concept-level rules may, however, lead to discovery of more general and important knowledge from data. Relevant taxonomies of data items are thus usually predefined in real-world applications. An item may, however, belong to different classes in different views. When taxonomic structures are not crisp, hierarchical graphs can be used to represent them. Terminal nodes on the hierarchical graphs represent the items actually appearing in transactions; internal nodes represent classes or concepts formed by lower-level nodes. A simple example is given in Figure 1.

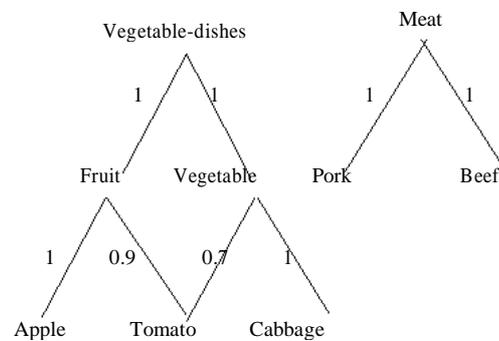

Figure 1. An example of fuzzy taxonomic structures

In this example, vegetable dishes fall into two classes: fruit and vegetable. Fruit can be further classified into apple and tomato. Similarly, assume vegetable is divided into tomato and cabbage. Note that tomato belongs to both fruit and vegetable with different membership degrees. It is thought of as fruit with 0.9 membership value and as vegetable with 0.7. The membership value of tomato belonging to vegetable dishes can be calculated using the max-min product combination. Since both fruit and vegetable belong to vegetable dishes with membership value 1, the membership value of tomato belonging to vegetable dishes is then  $\max(\min(1, 0.9), \min(1, 0.7))=0.9$ . Only the terminal items (apple, tomato, cabbage, pork and beef) can appear in transactions. The membership degrees of ancestors for each terminal node are shown in Table 1.

Wei and Chen proposed a method to find generalized association rules under fuzzy taxonomic structures [32]. The items to be processed in their approach are binary. Their mining process first calculated the membership values of ancestors for each terminal node in the manner mentioned above. Han and Fu also proposed a method for finding level-crossing association rules at multiple levels [13]. In that method,

Table 1. The membership degrees of ancestors for each terminal node in this example

Terminal node	Membership values of ancestors
Apple	1/Fruit, 1/Vegetable-dishes
Tomato	0.9/Fruit, 0.7/Vegetable, 0.9/Vegetable-dishes
Cabbage	1/Vegetable, 1/Vegetable-dishes
Pork	1/Meat
Beef	1/Meat

each item only belongs to one ancestor in the preceding generation. A top-down progressively deepening search approach is used. Their method finds flexible association rules not confined to strict, pre-arranged conceptual hierarchies and exploration of “level-crossing” association relationships is allowed. Candidate itemsets on certain levels may thus contain other-level items. For example, candidate 2-itemsets on level 2 are not limited to containing only pairs of large items on level 2. Instead, large items on level 2 may be paired with large items on level 1 to form candidate 2-itemsets on level 2.

Wei and Chen’s concepts of fuzzy taxonomic structures and Han and Fu’s top-down progressively deepening search approach were used in our approach to mine fuzzy generalized association rules from quantitative transaction data. The rules mined are expressed in linguistic terms, which are more natural and understandable for human beings.

#### 4. Notation

The following symbols are used in our proposed algorithm:

- $n$ : the number of transactions;
- $D_i$ : the  $i$ -th transaction,  $1 \leq i \leq n$ ;
- $x$ : the number of levels in a given taxonomy.
- $m^k$ : the number of items (nodes) at level  $k$ ,  $1 \leq k \leq x$  ;
- $I_j^k$ : the  $j$ -th item on level  $k$ ,  $1 \leq k \leq x$ ;  $1 \leq j \leq m^k$ ;
- $h_j^k$ : the number of fuzzy regions for  $I_j^k$  ;
- $R_{jl}^k$ : the  $l$ -th fuzzy region of  $I_j^k$ ,  $1 \leq l \leq h_j^k$  ;
- $v_{ij}^k$ : the quantitative value of  $I_j^k$  in  $D_i$  ;
- $f_{ij}^k$ : the fuzzy set converted from  $v_{ij}^k$  ;
- $f_{ijl}^k$ : the membership value of  $D_i$  in region  $R_{jl}^k$  ;
- $\text{count}_{jl}^k$ : the summation of  $f_{ijl}^k$ ,  $i=1$  to  $n$ ;
- $\text{max-count}_j^k$ : the maximum count value among  $\text{count}_{jl}^k$  values,  $l=1$  to  $h_j^k$  ;
- $\text{max-R}_j^k$ : the fuzzy region of  $I_j^k$  with  $\text{max-count}_j^k$  ;
- $\alpha$ : the predefined minimum support value;
- $\lambda$ : the predefined minimum confidence value;
- $C_r^k$ : the set of candidate itemsets with  $r$  items on

level  $k$ ;

$L_r^k$ : the set of large itemsets with  $r$  items on level  $k$ .

#### 5. The Multiple-level Fuzzy Data-mining Algorithm

The proposed mining algorithm integrates fuzzy set concepts, data mining and multiple-level fuzzy taxonomy to find fuzzy association rules in a given transaction data set. The knowledge derived is represented by fuzzy linguistic terms, and thus easily understandable by human beings.

The proposed fuzzy mining algorithm first calculates the membership values of ancestors for each terminal node as Wei and Chen’s method did. It then adopts a top-down progressively deepening approach to finding large itemsets. Each item uses only the linguistic term with the maximum cardinality in later mining processes, thus making the number of fuzzy regions to be processed the same as the number of original items. The algorithm therefore focuses on the most important linguistic terms, which reduces its time complexity. A mining process using fuzzy counts is performed to find fuzzy multiple-level association rules. Details of the proposed fuzzy mining algorithm are stated below.

The fuzzy mining algorithm using taxonomy:

INPUT: A body of  $n$  quantitative transaction data, a set of membership functions, predefined fuzzy taxonomic structures, a predefined minimum support value  $\alpha$ , and a predefined confidence value  $\lambda$  .

OUTPUT: A set of fuzzy multiple-level association rules.

STEP 1: Set  $k=1$ , where  $k$  is used to store the level number being processed.

STEP 2: Calculate the membership values of ancestors of each terminal node from the given fuzzy taxonomic structure.

STEP 3: Calculate the quantitative value  $v_{ij}^k$  of each ancestor item  $I_j^k$  in transaction datum  $D_i$  ( $i=1$  to  $n$ ) as:

$$v_{ij}^k = \sum_{v_{ij}^x \text{ in } D_i} v_{ij}^x * \mu_{I_j^k}(I_{ij}^x)$$

where  $I_{ij}^x$  is a terminal item appearing in  $D_i$ ,  $v_{ij}^x$  is the quantitative value of  $I_{ij}^x$ , and  $\mu_{I_j^k}(I_{ij}^x)$  is the membership value of item  $I_{ij}^x$  belonging to ancestor  $I_j^k$  .

STEP 4: Count the number of occurrences of each ancestor item  $I_j^k$  in the transactions and remove the each ancestor item  $I_j^k$  with their counts less than  $\alpha$  .

STEP 5: Transform the quantitative value  $v_{ij}^k$  of each transaction datum  $D_i$  ( $i=1$  to  $n$ ) for each  $I_j^k$  into a fuzzy set  $f_{ij}^k$  represented as:

$$\left[ \frac{f_{ij1}^k}{R_{j1}^k} + \frac{f_{ij2}^k}{R_{j2}^k} + \dots + \frac{f_{ijh}^k}{R_{jh}^k} \right]$$

by mapping  $v_{ij}^k$  form the given membership functions, where  $h$  is the number of fuzzy regions for  $I_j^k$ ,  $R_{jl}^k$  is the  $l$ -th fuzzy region of  $I_j^k$ ,  $1 \leq l \leq h$ , and  $f_{ijl}^k$  is  $v_{ij}^k$ 's fuzzy membership value in region  $R_{jl}^k$ .

STEP 6: Calculate the scalar cardinality of each fuzzy region  $R_{jl}^k$  in the transaction data:

$$\text{count}_{jl}^k = \sum_{i=1}^n f_{ijl}^k.$$

STEP 7: Find  $\max - \text{count}_j^k = \text{MAX}_{j=1}^{m^k} (\text{count}_{jl}^k)$ , for  $j=1$  to  $m^k$ , where  $h_j^k$  is the number of fuzzy regions for  $I_j^k$  and  $m^k$  is the number of items (nodes) on level  $k$ . Let  $\max - R_j^k$  be the region with  $\max - \text{count}_j^k$  for item  $I_j^k$ , which will be used to represent the fuzzy characteristic of item  $I_j^k$  in later mining processes.

STEP 8: Check whether the value  $\max - \text{count}_j^k$  of a region  $\max - R_j^k$ ,  $j=1$  to  $m^k$ , is larger than or equal to the predefined minimum support value  $\alpha$ . If a region  $\max - R_j^k$  is equal to or greater than the minimum support value, put it in the large 1-itemsets ( $L_1^k$ ) at level  $k$ . That is,

$$L_1^k = \{ \max - R_j^k \mid \max - \text{count}_j^k \geq \alpha, 1 \leq j \leq m^k \}.$$

STEP 9: If  $L_1^k$  is null, then set  $k = k + 1$  and go to STEP 4; otherwise, do the next step.

STEP 10: Generate the candidate set  $C_2^k$  from  $L_1^1, L_1^2, \dots, L_1^k$  to find "level-crossing" large itemsets. Each 2-itemset in  $C_2^k$  must contain at least one item in  $L_1^k$  and the other item may not be its ancestor in the taxonomy. All possible 2-itemsets are collected in  $C_2^k$ .

STEP 11: For each newly formed candidate 2-itemset  $s$  with items  $(s_1, s_2)$  in  $C_2^k$ :

- Calculate the fuzzy value of  $s$  in each transaction datum  $D_i$  as  $f_{is} = f_{is_1} \wedge f_{is_2}$ , where  $f_{is_j}$  is the membership value of  $D_i$  in region  $s_j$ . If the minimum operator is used for the intersection, then  $f_{is} = \min(f_{is_1}, f_{is_2})$ .
- Calculate the scalar cardinality of  $s$  in the transaction data as:

$$\text{count}_s = \sum_{i=1}^n f_{is}.$$

- If  $\text{count}_s$  is larger than or equal to the

predefined minimum support value  $\alpha$ , put  $s$  in  $L_2^k$ .

STEP 12: Set  $r=2$ , where  $r$  is used to represent the number of items stored in the current large itemsets.

STEP 13: If  $L_r^k$  or  $C_{r+1}^k$  is null, then set  $k=k+1$  and go to STEP 3; otherwise, do the next step.

STEP 14: Generate the candidate set  $C_{r+1}^k$  from  $L_r^k$  in a way similar to that in the apriori algorithm. That is, the algorithm first joins  $L_r^k$  and  $L_r^k$ , assuming that  $r-1$  items in the two itemsets are the same and the other one is different. The different items must also not have a hierarchical relationship. That is, items may not be ancestors or descendants of one another. Store in  $C_{r+1}^k$  all itemsets having all their sub-  $r$ - itemsets in  $L_r^k$ .

STEP 15: For each newly formed  $(r+1)$ -itemset  $s$  with items  $(s_1, s_2, \dots, s_{r+1})$  in  $C_{r+1}^k$ :

- Calculate the fuzzy value of  $s$  in each transaction datum  $D_i$  as

$$f_{is} = f_{is_1} \wedge f_{is_2} \wedge \dots \wedge f_{is_r},$$

where  $f_{is_j}$  is the membership value of  $D_i$  in region  $s_j$ . If the minimum operator is used for the intersection, then:

$$f_{is} = \text{Min}_{j=1}^r f_{is_j}.$$

- Calculate the scalar cardinality of  $s$  in the transaction data as:

$$\text{count}_s = \sum_{i=1}^n f_{is}.$$

- If  $\text{count}_s$  is larger than or equal to the predefined minimum support value  $\alpha$ , put  $s$  in  $L_{r+1}^k$ .

STEP 16: If  $L_{r+1}^k$  is null and  $k$  reaches the level number of the fuzzy taxonomic structures, then do the next step to find association rules; otherwise, set  $r=r+1$  and go to STEP 13.

STEP 17: Construct the fuzzy association rules for all large  $q$ -itemset  $s$  containing items  $(s_1, s_2, \dots, s_q)$ ,  $q \geq 2$ , as follows.

- Form all possible association rules as:

$$s_1 \wedge \dots \wedge s_k \wedge s_{k+1} \wedge \dots \wedge s_q \rightarrow s_k,$$

$k=1$  to  $q$ .

- Calculate the confidence values of all association rules using the formula:

$$\frac{\sum_{i=1}^n f_{is}}{\sum_{i=1}^n (f_{is_1} \wedge \dots \wedge f_{is_{k-1}}, f_{is_{k+1}} \wedge \dots \wedge f_{is_q})}$$

STEP 18: Keep the rules with confidence values larger than or equal to the predefined confidence threshold  $\lambda$ . Output the rules with their support measures and confidence measures larger than or equal to the predefined  $\lambda$  and  $\alpha$  threshold to users as generalized association rules.

The rules output from Steps 18 can then serve as meta-knowledge concerning the given transactions.

## 6. An Example

In this section, an example is given to illustrate the proposed data-mining algorithm. This is a simple example to show how the proposed algorithm generates association rules from quantitative transactions using fuzzy taxonomic structures. The data set includes the six transactions shown in Table 2.

Table 2. Six transactions in this example

Transaction ID	Items
1	(Apple, 3) (Tomato, 4) (Beef, 2)
2	(Tomato, 7) (Cabbage, 7) (Beef, 7)
3	(Tomato, 2) (Cabbage, 10) (Beef, 5)
4	(Cabbage, 9) (Beef, 10)
5	(Apple, 7) (Pork, 9)
6	(Apple, 2) (Tomato, 8)

Each transaction includes a transaction ID and some purchased items. Each item is represented by a tuple (item name, item amount). For example, the fourth transaction consists of nine units of cabbage and ten units of beef. Assume the predefined fuzzy taxonomic structures are as shown in Figure 2. For convenience, the simple symbols in Table 3 are used to represent the items and groups.

Table 3. Items and groups are represented by simple symbols for convenience

Items	Symbol	Groups	Symbol
Apple	A	Fruit	T <sub>1</sub>
Tomato	B	Vegetable	T <sub>2</sub>
Cabbage	C	Vegetable dishes	T <sub>3</sub>
Pork	D	Meat	T <sub>4</sub>
Beef	E		

Also assume that the fuzzy membership functions are the same for all the items and are as shown in Figure 3.

In this example, amounts are represented by three fuzzy regions: Low, Middle and High. Thus, three fuzzy

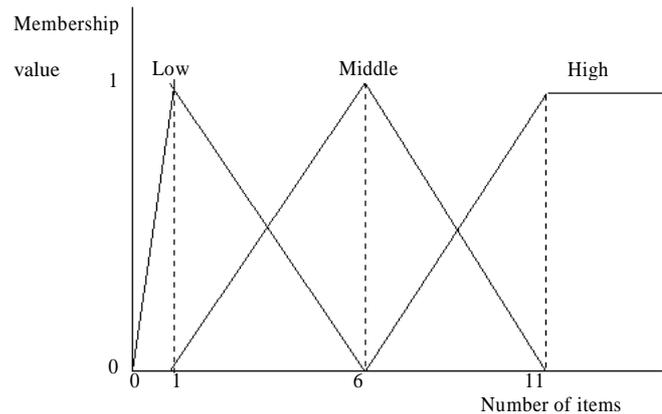

Figure 3. The membership functions used in this example

membership values are produced for each item amount according to the predefined membership functions. Assume in this example, the support threshold  $\alpha$  is set at 1.5 and the confidence threshold  $\lambda$  is set at 0.7. For the transaction data in Table 2, the following three rules are mined from the proposed algorithm:

1. If E = Middle, then T<sub>3</sub> = High, with a support value of 1.8 and a confidence value of 0.9;
2. If E = Middle, then T<sub>3</sub> = High, with a support value of 1.92 and a confidence value of 0.96;
3. If T<sub>4</sub> = Middle, then T<sub>3</sub> = High, with a support value of 2.12 and a confidence value of 0.82.

These three rules can then serve as meta-knowledge concerning the given transactions.

## 7. Discussion and Conclusions

In this paper, we have proposed a fuzzy multiple-level data-mining algorithm that can process transaction data with quantitative values among them. The rules thus mined exhibit quantitative regularity on multiple levels and can be used to provide suggestions to appropriate supervisors.

Although the proposed method works well in data mining for quantitative values, it is just a beginning. There is still much work to be done in this field. Our method also assumes that membership functions are known in advance. In [15-17], we proposed some fuzzy learning methods to automatically derive membership functions. We will therefore attempt to dynamically adjust the membership functions in the proposed mining algorithm to avoid the bottleneck of membership function acquisition. We will also attempt to design specific data-mining models for various problem domains.

## Abstract

Recently, the integration of data warehouses and data mining has been recognized as the primary platform for facilitating knowledge discovery. Effective data mining from data warehouses, however, needs exploratory data analysis. The users often need to investigate the warehousing data from various perspectives and analyze them at different levels of abstraction. To this end, comprehensive information processing and data analysis have to be systematically constructed surrounding data warehouses, and an on-line mining environment should be provided. In this paper, we propose a system framework to facilitate on-line association rules mining, called OMARS, which is based on the idea of integrating OLAP service and our proposed OLAM cubes and auxiliary cubes. According to the concept of OLAM cubes, we define the OLAM lattice framework that exploit arbitrary hierarchies of dimensions to model all possible OLAM data cubes.

## 1. Introduction

Over the past few years, data warehouse has been recognized and widely adopted as a platform for storing integrated, detailed, summarized, and historical data. Nowadays, most data warehousing systems are designed to accomplish On-Line Analytical Processing (OLAP), the process of creating and managing multidimensional data for analysis. But with the rapid growth of various requisitions, the OLAP-like tools that provide aggregation charts or tables to visualize data cannot supply further exploration of requisition from different levels of business management. This heralds the development of data mining techniques to discover implicit knowledge from a huge collection of data. One of the predominant techniques in data mining community is association rule mining, which refers to the discovery of associations from a list of database transactions. An example association rule is that "80% of customers who buy product 'A' also buy product 'B'". Such rules reveal customers' buying behavior and can be used in various decision strategies, such as catalog design, cross-sale, customer classification and product layout.

In real world applications, data are featured in multidimensional attributes. The decision makers usually want to analyze the data from various aspects to inspire new insight to achieve competitive advantage. To date,

though many researchers have proposed various methods to discover associations from data warehouses [1][2][3][4][6][10][11][12], many problems remain unsolved. Some of them are

- 1) Nowadays, most data warehouses adopt the star schema to organize the stored data, which allows the users to explore the data from diverse aspects. Current association mining methods, however, fail to exploit all possible patterns hidden in the star schema. This would restrain an expert from discovering new insight.
- 2) It is well-known that the techniques of data preprocessing and view materialization widely used in query processing and OLAP analysis also could favor on-line re-mining task. For example, the work in [3][4][12] suggested using the OLAP data cube to employ on-line data mining such as association, sequential patterns, classification, etc. However, an inappropriate cube definition cannot fit the on-line mining environment. First, the OLAP-like aggregated cube cannot exploit all of the item relationships such as intra-dimensional or hybrid associations. Mining associations from OLAP cubes still requires a lot of computations. Second, the OLAP cube based paradigm is unfeasible when users want to change the constraints such as support threshold and employ a sequence of re-mining tasks. Each re-mining requires executing the whole procedure to generate frequent itemsets.

To this end, we propose a system framework for on-line association rules mining, called OMARS (Online Multidimensional Association Rules mining System), which adopts the idea of pre-computing and materializing cube like OLAP, and integrates the OLAP cubes and our proposed OLAM cubes and auxiliary cubes to realize on-line association mining environment.

The remaining of this paper is organized as follows. In Section 2, we introduce some background material. The previous work related to our research is described in Section 3. Section 4 explains our OMARS framework and details each constituent. Finally, we conclude with suggestions and future work in Section 5.

## 2. Background

### 2.1 Data Warehouse and Data Model

The term ‘data warehouse’ was first coined by W. H. Inmom as a “subject-oriented, integrated, time-variant and nonvolatile collection of data in support of management’s decision-making process” [7]. Although the data stored in data warehouses have been cleaned, filtered, and integrated, it still takes much time to translate the data into the strategic information because of massive amounts of data. To improve the performance, most data warehouses adopt some preprocessing tools like OLAP service. The term ‘OLAP’ is the acronym of ‘On-Line Analytical Preprocessing’, which refers to the process of creating and managing multidimensional data for analysis and visualization. Typical OLAP operations include roll-up (increasing the level of abstraction), drill-down (decreasing the level of abstraction), slice and dice (selection and projection) and pivot (re-orienting the multidimensional view of data) [5].

In the world of decisions making, managers tend to view the analyzed data from different business perspectives. As a primary repository for decision support, the data warehouse has to model the data multi-dimensionally. The most popular dimensional modeling of data warehouse is star schema [8]. A star schema consists of a central table, called fact table, and several dimension tables. The fact table consists of numeric measures and some foreign keys. Each dimension table contains a set of attributes that represent the user’s business perspectives and are often organized in the form of a hierarchical relationship. Figure 1 shows an example star schema for sales data.

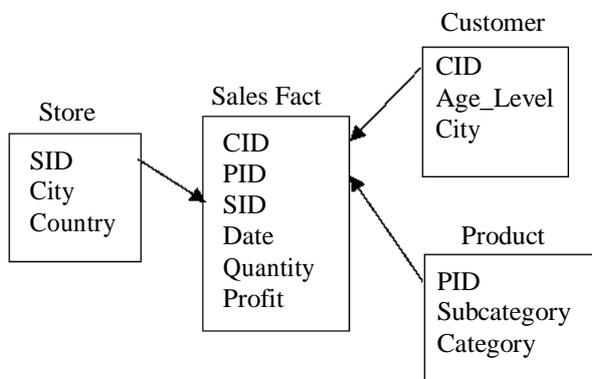

Figure 1. An example star schema for sales data.

## 2.2 Association Rules Mining

One of the predominant techniques used in data mining is association rule. An association rule,  $A \rightarrow B$ , denotes the relations between itemsets A and B, which means itemset B tends to appear together with itemset A. For this rule being interesting, the support of A and B, i.e., the number of transactions containing both A and B, denoted as  $\text{sup}(A \cup B)$ , should be more than a user-specified minimum support, called minsup ( $\text{sup}(A \cup B) \geq \text{minsup}$ ), and the confidence, measured as the conditional probability  $P(B|A)$ , should also be more than a user-specified minimum confidence, called minconf ( $P(B|A) \geq \text{minconf}$ ).

In general, the work for mining association rules can be decomposed into two phases:

- 1) Frequent itemsets generation: find all itemsets whose supports sufficiently exceed the minsup.
- 2) Rules construction: from the discovered frequent itemsets, generate the association rules. More precisely, for each frequent itemset X, construct the rule  $(X-Y) \rightarrow Y$ , if  $P(Y|X-Y) \geq \text{minconf}$ , where Y is a proper subset of X.

## 2.3 Multi-Dimensional Association Rules

The association mining is originally motivated by discovering frequently purchased patterns from a list of supermarket transactions. Traditionally, only one attribute, e.g., Product, is concerned in the association mining.

In real life, data often involves several tables and a table usually contains multiple attributes. For example, a data warehouse fact table may involves multiple dimension tables with multiple hierarchies. When mining from this kind of multidimensional data sets, users may want to observe the inter relations among the values of dimensions, i.e., a multi-dimensional view of the associations. We call such kind of association rules the multidimensional association rules. In [12], Han, Chee, and Chiang defined three different types of association rules involved multidimensional attributes.

- 1) Inter-dimensional association rule: This kind of rules reveals the associations between a set of dimensions.
- 2) Intra-dimensional association rule: This kind of rules exploits the associations between different items within only one dimension.
- 3) Hybrid association rule: This kind of rules also exploits the associations between a set of dimensions, but allows some items in a rule are from one dimension. It can be regarded as a combination of inter-dimensional and intra-dimensional rules.

According to the above description, intra-dimensional association rules, indeed, correspond to single-dimensional association rules, which can be defined as follows:

Definition 1. Consider a transaction table composed of k dimensions  $\{d_1, d_2, \dots, d_k\}$ . An intra-dimensional association rule can be expressed as

$$(d_i, "x_1"), (d_i, "x_2"), \dots, (d_i, "x_m") \rightarrow (d_i, "y_1"), (d_i, "y_2"), \dots, (d_i, "y_n"),$$

where  $x_j$  and  $y_j$  represent the values of dimension  $d_i$  and  $1 \leq i \leq k, 1 \leq m \leq j, 1 \leq n \leq j$ .

For example, an intra-dimensional association rule

$$(\text{Product}, \text{"diet coke"}) \rightarrow (\text{Product}, \text{"pretzels"})$$

says that most of customers who buy product “diet coke” also buy “pretzels” at the same transaction time. We thus say this kind of rules reveals the intra-relation among

products in the same dimension “Product”.

Following the concept in [12], we can define the multi-dimensional association rules, inter-dimensional or hybrid, as follows:

Definition 2. Consider a transaction table composed of  $k$  dimensions. Let  $x_{im}$  and  $y_{jn}$  be the values of dimensions  $X_i$  and  $Y_j$ , respectively. The form of a multi-dimensional association rule is:

$$(X_1, "x_{1m}"), (X_2, "x_{2m}"), \dots, (X_i, "x_{im}") \rightarrow (Y_1, "y_{1n}"), (Y_2, "y_{2n}"), \dots, (Y_j, "y_{jn}")$$

For example, an inter-dimensional rule

$$(City, "Taipei"), (Gender, "Female") \rightarrow (Product, "pretzels")$$

says that female customers living in “Taipei” tend to buy “pretzels”. And a hybrid association rule

$$(City, "Taipei"), (Gender, "Female"), (Product, "juice") \rightarrow (Product, "pretzels")$$

says that female customers living in “Taipei” that buy “juice” tend to buy “pretzels”.

### 3. Related Work

Without any pre-computation, the authors in [2] proposed an algorithm, called Carma, to realize on-line computation of frequent itemsets using only two database scans. In the course of the first database scan, the algorithm continuously constructs a lattice of potential frequent itemsets, displays the result, and allows users to adjust the threshold at any time. At the second scan, it determines the precise support of each set of lattice and then removes all infrequent itemsets. We observed that

- 1) The performance of Carma is better than Apriori or DIC when the support threshold is much small. However, it cannot defeat Apriori or DIC when the support threshold is larger than a critical value.
- 2) The performance of Carma is worse than on-line mining with preprocessing technique, because the whole mining procedure is carried out repeatedly. If the data is so large that it cannot be handled in real-time, the performance may be much worse.
- 3) It ignores the fact that in real world most data have diverse characteristics. The users may want to explore the associations from multi-dimensional viewpoints.

Aggarwal and Yu [1] considered the on-line rules generation and provided a lattice-based approach, called adjacency lattice, to pre-fine and pre-store the primary itemsets. They analyzed the on-line queries and proposed several adjacency lattice based algorithms. Users working with their on-line mining framework are free to launch different queries at different thresholds. Their approach, however, may suffer the following problems:

- 1) If the adjacency lattice is complex and large, the preprocessing time for constructing the lattice will become unacceptable.

- 2) It is difficult to trade off the amount of pre-stored data against the query time.

Recently, a promising direction for realizing on-line data mining has been proposed. The basic idea is to combine OLAP and data mining, called OLAP Mining [3][4][6][12]. However, we observe the following problems about this approach.

- 1) In most cases, inter association rules and hybrid association rules appear simultaneously in multi-dimensional OLAP mining. For example, if we group ‘Customer’ into transactions and choose ‘Product’ and ‘Store’ as mining attributes, the rules may be:

$$\text{Store("Mexico")} \rightarrow \text{Product("Berry")}$$

or

$$\text{Store("Mexico"), Product("tents")} \rightarrow \text{Product("Berry").}$$

Thus, it is hard to differentiate hybrid association rule from inter association rule in multi-dimensional association mining.

- 2) Because of lacking support for on-line re-mining, one has to invoke the whole mining procedure, and so cannot discover the frequent itemsets in real-time when the data cube is very large.

In [11] the authors proposed the concept of using materialized itemsets for fast mining of association rules. The approach divides the database into a set of non-overlapping partitions according to some attributes, e.g., education type of customers, store location, product category, and generates the frequent itemsets in each partition according to the local threshold. Then, the positive borders corresponding to the frequent itemsets in each partition are computed. Finally, all positive borders are combined to re-mine the new frequent itemsets with supports greater than the global threshold.

The FARM framework presented in [10] addressed the problem of mining associations from multi-attribute databases. Their framework particularly concentrates on exploring the mining spaces without specifying what attributes are used to group records into transactions and what attributes are used to define items. The method for counting support, however, is different from the existential aggregating functions. They also proposed three different types of downward closures and used them to implement an efficient Apriori-like mining algorithm. The FARM framework, however, ignores the following issues:

- 1) Lacking interaction: Users cannot perform the queries with different thresholds.
- 2) Costly for virtuous refinement: Like OLAP mining, FARM needs to discover the frequent itemsets by repeating the whole mining process whenever the threshold is increased or decreased.

### 4. The OMARS Framework

In this section, we describe the proposed framework for integrating data warehouse, OLAP processing and our OLAM cubes and auxiliary cubes to build an on-line multidimensional association mining environment.

Through this system, the users can interactively change their viewpoints, refine the constraints according to the observed result, and perform further exploration.

#### 4.1 Panorama

Figure 2 depicts the OMARS framework, which is deployed to meet the following characteristics of on-line multidimensional association mining.

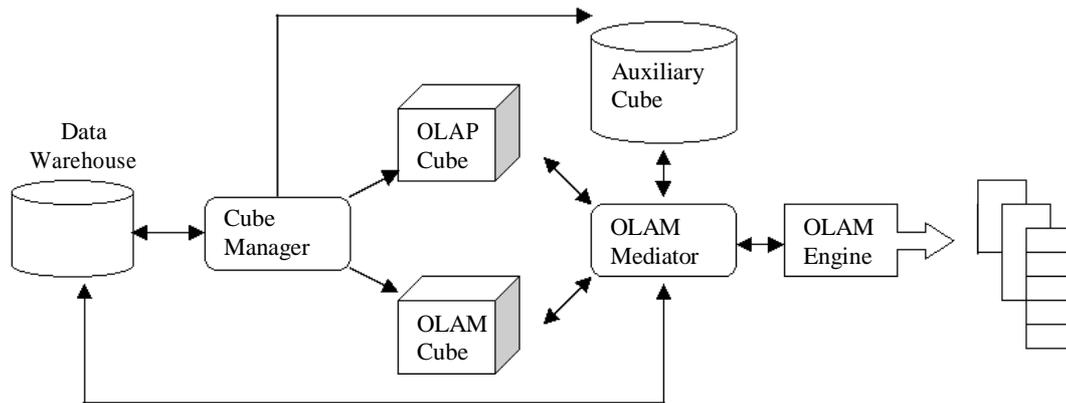

Figure 2. The OMARS framework.

To this end, we propose the concept of OLAM data cube, which stores the frequent itemsets with respect to various groupings of dimension attributes. We also make use of the OLAP service supported by most data warehousing systems, and integrate the OLAP cube and our OLAM cube to meet simultaneously these two different analyses. Our intention is to develop an add-on service instead of a stand-alone system to commercial data warehousing products. The task of on-line association mining is employed through the following two phases:

- 1) Off-line preprocessing phase: This phase concerns the construction of the data cubes. The data in data warehouses are preprocessed and stored in different repositories, including OLAP Cube, OLAM Cube and Auxiliary Cube. The Cube Manager component is in charge of the cube construction and maintenance, either regularly or irregularly.
- 2) On-line mining phase: Once the itemsets with supports above a presetting threshold, prims, in the preprocessing phase are materialized, the OLAM Engine forwards the user query to the OLAM Mediator, which then searches for the most appropriate cube to answer the association query. However, if the threshold of the query is lower than the presetting threshold specified in the preprocessing phase, the OLAM Engine will make use of the auxiliary cubes and re-scan the database to answer the query.

The critical design issues for these two phases are:

- 1) Off-line preprocessing phase: how to define the presetting minimum support, and how to construct the OLAM cube and the auxiliary cubes that store

- 1) Users can perform OLAP-like explorations. That is, users can interactively change the dimensions that comprise the associations.
- 2) Users can refine the constraints such as minimum support and minimum confidences, and see the response in no time.

the frequent itemsets with supports greater than prims and the infrequent itemsets with supports less than prims, respectively.

- 2) On-line mining phase: how to re-use the existential information stored in OLAM, OLAP and auxiliary cubes to facilitate the on-line association mining from various perspectives.

The first phase involves Data Warehouse, Cube Manager, OLAP Cube, OLAM Cube and Auxiliary Cube, while the second phase involves OLAM Engine, OLAM Mediator, OLAP Cube, OLAM Cube and Auxiliary Cube. In the following sections, we will elaborate each constituent of the framework.

#### 4.2 Cube Manager

As stated previously, Cube Manager is responsible for cube generation and maintenance. More precisely, the work of Cube Manager consists of three different parts.

- 1) Cube selection: This part concerns the problem of how to select the most appropriate set of data cubes for materialization in order to minimize the query cost and/or maintenance cost under the constraint of limited storage.
- 2) Cube computation: This part deals with the work for efficiently generating the set of materialized cubes selected by the cube selection module.
- 3) Cube maintenance: This deals with the task of how to maintain the materialized cubes when there are updates to the data warehouse.

### 4.3 OLAM Mediator and OLAM Engine

The primary task of OLAM Engine is to generate the association rules. It accepts various queries from users and invokes the most appropriate algorithm according to the dimensional attributes and the minsup of the query. After receiving a query, the OLAM Engine first analyzes the query and forwards the necessary information to OLAM Mediator, and then waits for the most relevant cube from OLAM Mediator to generate the qualified association rules.

On the other hand, when OLAM Mediator receives the messages about the user query from OLAM Engine, it will look for the most matching cube. First, OLAM Mediator

judges whether the input minsup is greater than primsup or not. If the input minsup is smaller than primsup, it has to coordinate and communicate with Auxiliary Cube and data warehouse, and return the matching jointed table to OLAM Engine. Otherwise, it will check that whether the required cube exists in OLAM Cube or not. If not, it will search for OLAP Cube and return the matching cube to OLAM Engine. In the worst case, when in OLAM Cube and OLAP Cube no cube matches the query, it will re-scan the data warehouse and notify OLAM Engine to execute the whole mining procedure afresh.

Figure 3 depicts the cooperation between OLAM Mediator and OLAM Engine.

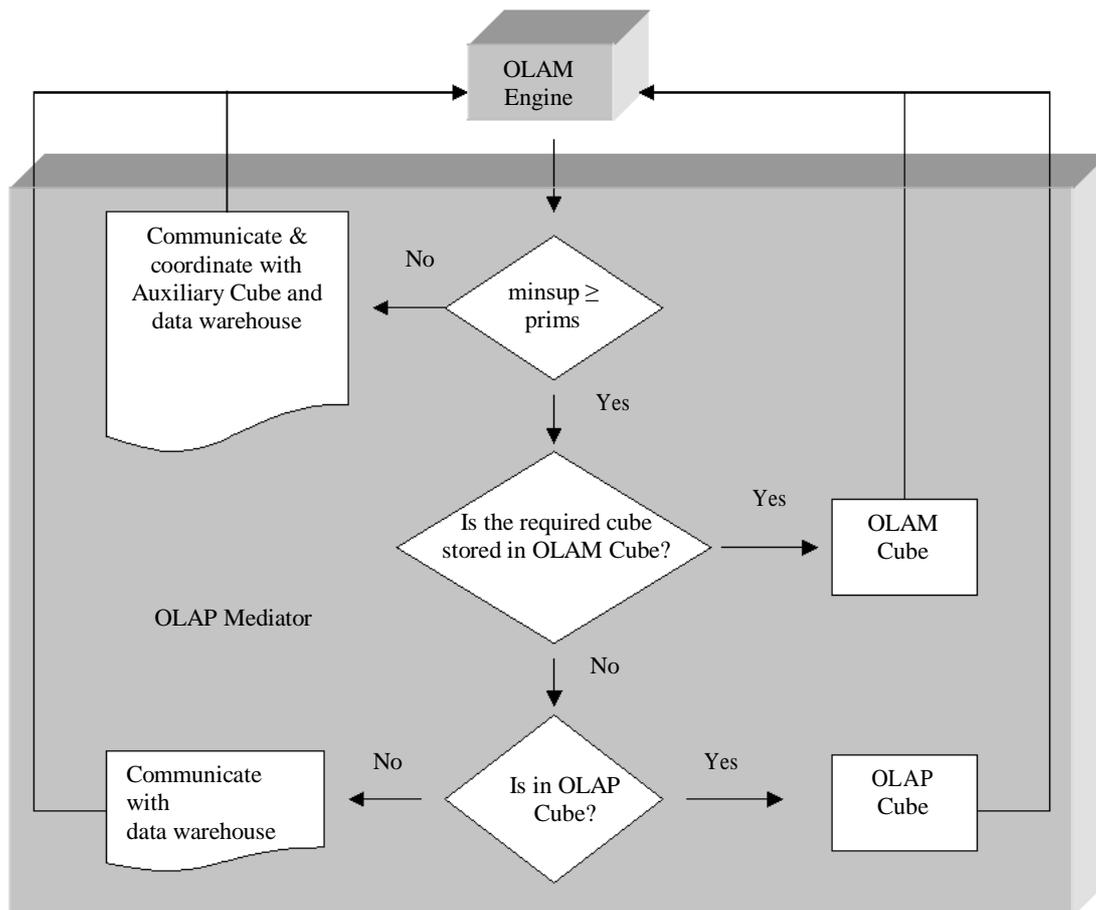

Figure 3. Flow diagram of OLAM Mediator and OLAM Engine.

### 4.4 OLAM Cube and OLAM Lattice

The concept of OLAM data cube is used to store the frequent itemsets with supports greater than the pre-setting support threshold primsup, in the off-line preprocessing phase. The intuition is to accelerate the process of association mining by utilizing these materialized frequent itemsets. To clarify the structure of OLAM cubes, we first specify the form of multidimensional association query, which is defined as a four-tuple mining meta-pattern.

Definition 3. Consider a star schema  $S$  containing a fact table and  $m$  dimension tables  $\{D_1, D_2, \dots, D_m\}$ . Let  $T$  be a jointed table from  $S$  composed of  $a_1, a_2, \dots, a_r$  attributes, such that  $\forall a_i, a_j \in A(D_k)$  there is no hierarchical relation between  $a_i$  and  $a_j$ , and  $1 \leq i, j \leq r, 1 \leq k \leq m$ . A meta-pattern of multidimensional associations from  $T$  is defined as follows:

$$MP: \langle t_G, t_M, ms, mc \rangle,$$

where  $ms$  denotes the minimum support,  $mc$  the minimum confidence,  $t_G$  the group of transaction attributes,  $t_M$  the

group of mining attributes,  $t_M \subseteq \{a_1, a_2, \dots, a_r\}$  and  $t_G \cap t_M = \emptyset$ .

Note that this meta-form specification of multi-dimensional association queries can present three different multidimensional association rules defined in [12], intra-dimensional, inter-dimensional, and hybrid associations.

For example, consider a jointed table T involving three dimensions from the star schema in Figure 1. The content of T is shown in Table 1. If the mining attribute set  $t_M$  consists of only one attribute, then the discovered rules present the intra-association. For example, if  $t_G = \{Cid, Date\}$ ,  $t_M = \{Category\}$ , we may have

$$(Category, "B"), (Category, "D") \rightarrow (Category, "E")$$

Otherwise, if  $|t_M| \geq 2$ , then the resulting associations will be inter-association or hybrid association, e.g.,  $t_G = \{Cid, Date\}$ ,  $t_M = \{Category, Age\_level, C.City\}$ , we have

$$(Age\_level, "21-30"), (C.City, "Taipei") \rightarrow (Category, "B"),$$

which is an inter-association, and

$$(Age\_level, "31-40"), (C.City, "New York"), (Category, "C") \rightarrow (Category, "D"),$$

a hybrid association.

Table 1. A jointed table T from star schema.

Tid	Cid	Date	Category	Age_level	City
1	C1	2001/01/12	B, C, D, E	21-30	Taipei
2	C1	2001/01/23	A, B, C	21-30	Taipei
3	C2	2001/02/01	B, C, D	31-40	New York
4	C4	2001/03/16	A, D	below 20	Toronto
5	C3	2001/03/16	A, B, D	41-50	Seattle
6	C2	2001/08/09	C, D, E	31-40	New York
7	C4	2001/08/09	D	below 20	Toronto
8	C3	2001/09/25	B, C, E	41-50	Seattle
9	C1	2001/09/26	B, D, E	21-30	Taipei
10	C2	2001/10/12	B, C, D, E	31-40	New York

\* A: Magazines, B: Electrical, C: Hardware, D: Drinks, E: Paper Products

We now proceed to clarify the OLAM cube structure.

**Definition 4.** For a meta-pattern MP with transaction attributes  $t_t$  and mining attributes  $t_m$ , and a presetting minsup, prims, the correspondent OLAM cube,  $MCube(t_G, t_M)$ , is the set of the frequent itemsets with supports larger than prims.

**Example 1.** A hybrid OLAM cube: Let  $|t_M| = 3$ ,  $t_G = \{Cid, Date\}$ ,  $t_M = \{Category, Age\_level, City\}$ , and prims = 3. The resulting OLAM cube is shown in Table 2.

Note that in an OLAM cube, an attribute value is viewed as an item and a tuple containing k-items represents a frequent k-itemset. For example, the last tuple represents a frequent 4-itemset, where the "Category" dimension of

the tuple contains several values, such as "C" and "D". An association rule derived from the last tuple will be

$$(C.City, "New York"), (Age\_level, "31-40") \rightarrow (Category, "C"), (Category, "D")$$

This rule reveals that the customers whose age is between 31 and 40 and who live in New York tend to buy product category "C" and "D".

Table 2. An example hybrid OLAM cube expressed in table.

Age_level	City	Category	Support
-	-	A	3
-	-	B	7
-	-	C	6
-	-	D	8
-	-	E	5
21-30	-	-	3
31-40	-	-	3
-	Taipei	-	3
-	New York	-	3
21-30	-	B	3
31-40	-	C	3
31-40	-	D	3
-	Taipei	B	3
-	New York	C	3
-	New York	D	3
21-30	Taipei	-	3
31-40	New York	-	3
21-30	Taipei	B	3
31-40	New York	C	3
31-40	New York	D	3
31-40	New York	C, D	3

**Example 2.** An intra-dimensional OLAM cube: Let  $|t_M| = 1$ ,  $t_G = \{Cid, Date\}$ ,  $t_M = \{Category\}$ , and prims = 4. The resulting OLAM cube is shown in Table 3.

Table 3. An example intra-dimensional OLAM cube expressed in table.

category	Support
B	7
C	6
D	8
E	5
B, C	5
B, D	5
B, E	4
C, D	4
C, E	4

In this example, the attributes "Cid" and "Date" are grouped into transaction attributes and the "Category" is viewed as the mining attribute. There are 10 transactions in this table. Again, a tuple containing k-items represents a frequent k-itemset. From the last tuple that represents a

frequent 2-itemset, we can derive the following association rule:

$$(\text{Category}, \text{"C"}) \rightarrow (\text{Category}, \text{"E"}).$$

This rule says that those customers who buy category “C” tend to buy category “E”.

To allow the users mining associations from various perspectives, we have to exploit all possible OLAM cubes. Indeed, according to the definition of OLAM cube, all of the possible OLAM cubes generated from a given star schema can form an OLAM lattice. To provide a hierarchical navigation and multidimensional exploration, we model the OLAM lattice as a three-layer structure. The 1<sup>st</sup> layer lattice exploits all of the dimensional combinations.

The 2<sup>nd</sup> layer then further exploits the inter-attribute combinations for the selected dimensions in the 1<sup>st</sup> layer. Finally, the 3<sup>rd</sup> layer exploits all of the possible OLAM cubes corresponding to the meta-pattern that can be derived from the chosen subcubes in the 2<sup>nd</sup> layer. Note that the first two layers only serve the purpose for hierarchical navigation and dimensional exploration. The real OLAM cubes are stored in the 3<sup>rd</sup> layer.

For example, consider the star schema shown in Figure 1. We obtain eight possible dimensional combinations and construct the 1<sup>st</sup> layer lattice as shown in Figure 4. Each node in the 1<sup>st</sup> layer lattice represents a possible dimensional combination.

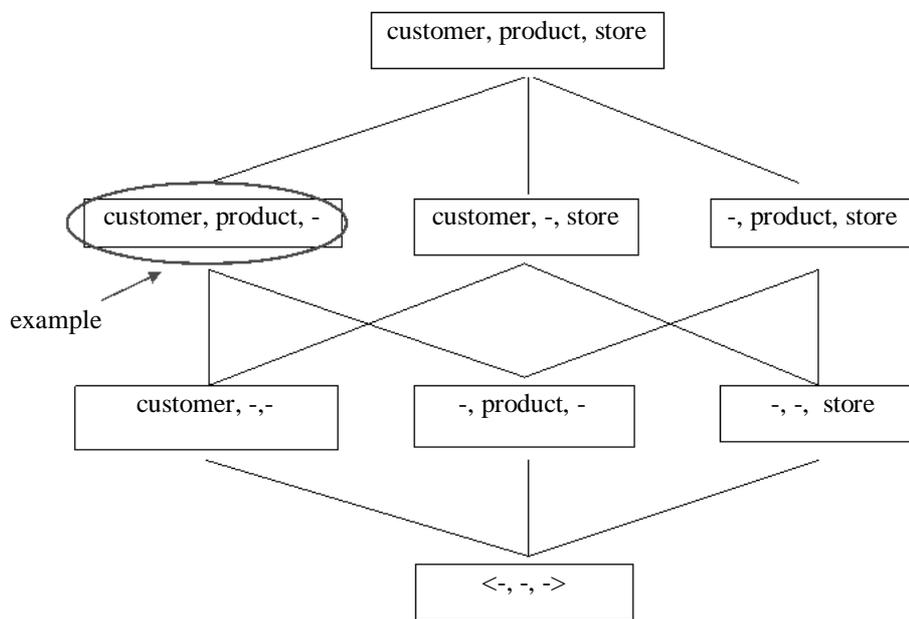

Figure 4. The 1<sup>st</sup> layer OLAM lattice for the example star schema in Figure 1.

Any node in the 1<sup>st</sup> layer lattice then can be extended to form a 2<sup>nd</sup> layer lattice. For example, consider the node composed of “customer” and “product” dimensions. Figure 5 shows the 2<sup>nd</sup> layer lattice derived from this node. Each node of the 2<sup>nd</sup> layer lattice is constructed by attaching any attribute chosen from the selected dimensions and the attributes are added one by one as traversing down the lattice. The traversing stops when all attributes of the selected dimensions appear in this bottom node.

Similarly, any node of the 2<sup>nd</sup> layer lattice can be further extended to form a 3<sup>rd</sup> layer lattice. Consider the <(City, Age\_level), (Category)> node in Figure 5. Figure 6 shows the 3<sup>rd</sup> lattice by extending <(City, Age\_level), (Category)>. There are eight different nodes in this lattice, where each

node represents an OLAM cube. As Figure 6 shows, the nodes can be divided into two different categories:

- 1) Intra-association cubes: These refer to at the 3<sup>rd</sup> level the nodes that contain only one mining attribute.
- 2) Inter- or hybrid association cubes: These include at the 1<sup>st</sup> level the nodes that contain no transaction attribute and at the 2<sup>nd</sup> level those that contain one transaction attribute.

Note that not all of the OLAM cubes derived in the lattice have to be materialized and stored. Indeed, the concept hierarchies defined over the attributes in the star schema provide the possibility to prune some redundant cubes.

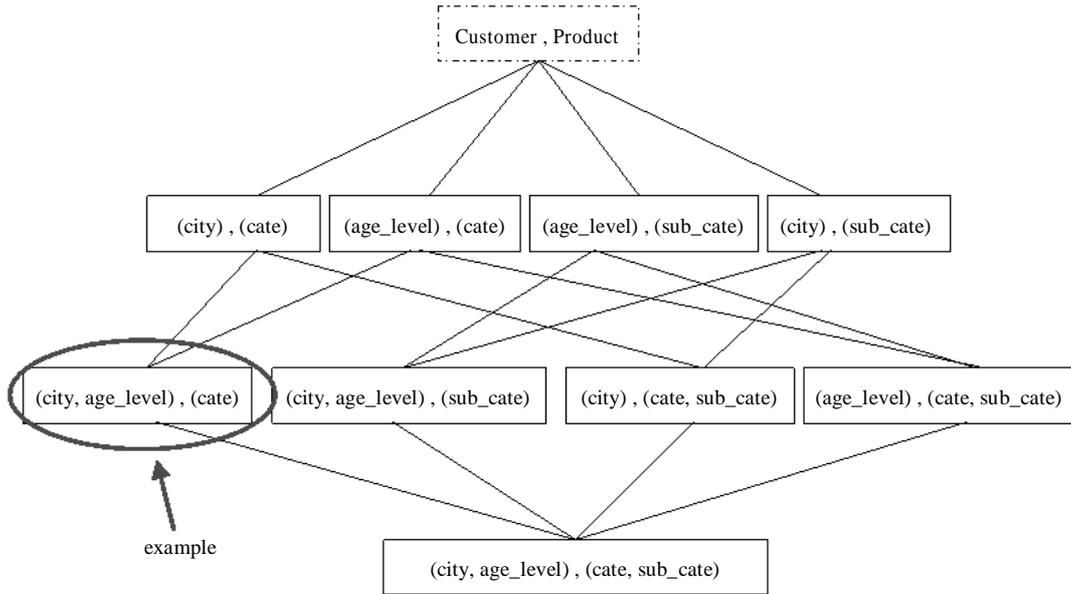

Figure 5. The 2<sup>nd</sup> layer lattice derived from <customer, product, -> in the 1<sup>st</sup> layer.

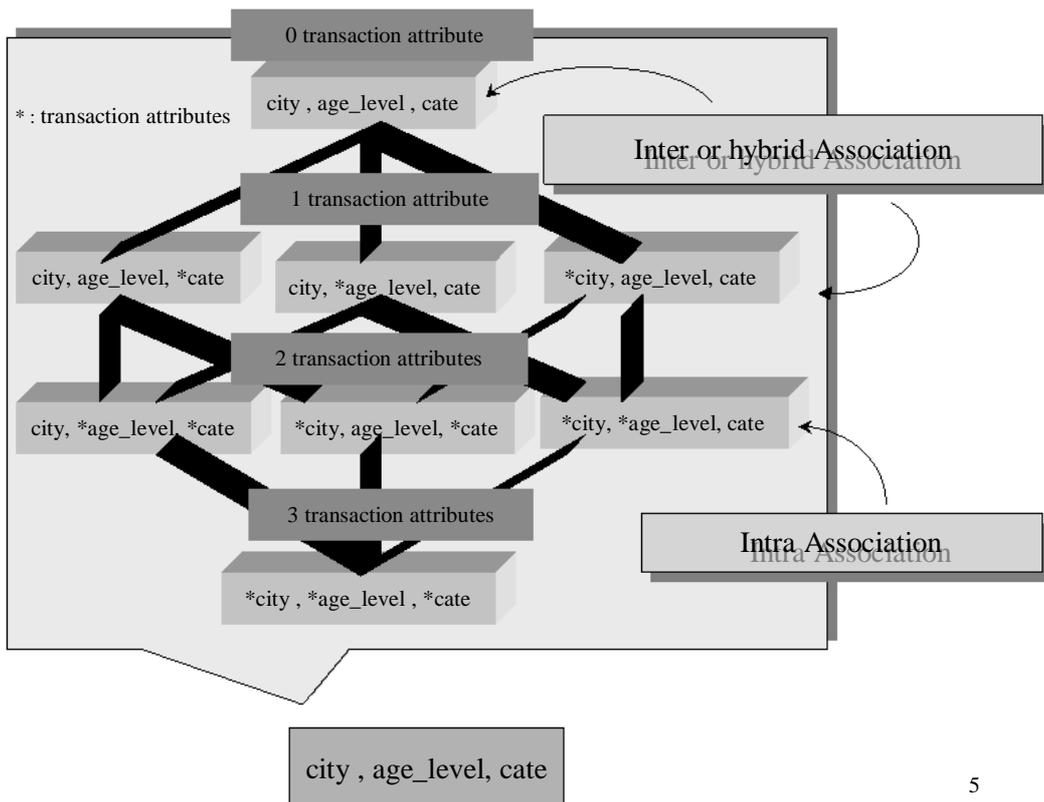

Figure 6. The 3<sup>rd</sup> layer lattice derived from the subcube <city, age\_level> in the 2<sup>nd</sup> layer.

Consider an OLAM cube,  $MCube(t_G, t_M)$ . We observed that there are two different types of redundancy.

Observation 1. Schema redundancy: Let  $a_i, a_j \in t_G$ . If  $a_i, a_j$  are in the same dimension and  $a_j$  is an ancestor of  $a_i$ , then  $MCube(t_G, t_M)$  is a redundancy of cube  $MCube(t_G - \{a_j\}, t_M)$ .

Example 3. Consider the jointed table in Table 4. Let  $|t_M| = 1$  and  $t_M = \{\text{Subcategory}\}$ . The resulting table by grouping “City” and “Country” as transaction attributes is shown in Table 5. Note that this table is the same as that by grouping “City” as the transaction attribute, as shown in Table 6. Thus, the resulting cube  $MCube(\{\text{City}, \text{Country}\},$

{Subcategory}) is the same as  $MCube(\{City\}, \{Subcategory\})$ .

PC, Printer	Ink_Jet	2
PC, Printer	Notebook	2
PC	Notebook, Ink_Jet	2
Printer	Notebook, Ink_Jet	2
PC, Printer	Notebook, Ink_Jet	2

Observation 2. Values Redundancy: Let  $a_i, a_j \in t_M$ . If  $a_i, a_j$  are in the same dimension and  $a_j$  is an ancestor of  $a_i$ , then  $MCube(t_G, t_M)$  is a cube with values redundancy.

Example 4. Consider the jointed table in Table 4. Let  $|t_M| = 2$ ,  $t_G = \{Cid\}$ ,  $t_M = \{Category, Subcategory\}$  and  $prims = 2$ . The resulting OLAM cube is shown in Table 7. We observe that the tuples with gray area in this table are redundant patterns. Therefore, it satisfies the values redundancy. Note that if it holds the values redundancy, we must prune the redundant patterns during the generation of frequent itemsets.

In addition, we observe that any OLAM cube is useless if it satisfies the following property.

Observation 3. Useless Property: Let  $a_i \in t_G$  and  $a_j \in t_M$ . If  $a_i, a_j$  are in the same dimension and  $a_j$  is an ancestor of  $a_i$ , then  $MCube(t_G, t_M)$  is a useless cube.

Example 5. Let  $|t_M| = 1$  and  $t_M = \{Category\}$ . The resulting table by grouping {Subcategory} as transactions is shown in Table 8. The cardinality of every transaction in this table is 1. Therefore, we cannot find any association rule from this table.

Table 8. The resulting table by grouping {Subcategory} as transaction attribute for Table 4.

#### 4.5 Auxiliary Cube

Though the OLAM cube is useful to generate associations for minsup larger than the pre-setting threshold, it becomes useless when the minsup is less than the threshold. In that case, we have to perform the mining task afresh, which probably will not satisfy the on-line demand.

To alleviate this problem, we propose the concept of auxiliary cube, which is used to store infrequent  $\alpha$ -itemsets generated in the off-line preprocessing phase, where  $\alpha$  denotes the cutting-level. For example, consider Table 1 and let  $\alpha = 3$  and  $prims = 4$ . Table 9 shows the auxiliary cube with respect to the intra-dimensional association, where "Cid" and "Date" are grouped as transaction attributes while "Category" is regarded as mining attribute. All tuples containing three items present infrequent 3-itemsets.

Though auxiliary cube can speed up on-line mining when  $minsup \leq prim$ , it consumes a lot of cube scanning time to locate the qualified itemsets when the auxiliary cube is very large. To prevent this problem, we partition the auxiliary cube into several sub-cubes to reduce the I/O cost. The structure of the partitioned auxiliary cube is shown in Figure 7. Assume  $prims = 0.5\%$ . We partition the auxiliary cube into three sub-cubes, with respect to three different ranges of thresholds, "0.5%-0.2%", "0.2%-0.1%" and "0.1%-0.0%". Next, we judge which sub-cube can answer the query. Because most of the infrequent itemsets appear

in “0.1%-0.0%” sub-cube, the I/O cost of scanning the other sub-cubes would be much low. For example, if the input threshold is between 0.5% and 0.2%, it just needs to scan the “0.5%-0.2%” sub-cube instead of scanning the whole auxiliary cube.

## 5. Conclusions

In this paper, we have proposed a system framework for on-line association rules mining, called OMARS. The goal of this framework is to provide an on-line mining environment to facilitate multidimensional exploration of association rules from data warehouses. To reach this goal, we adopted the concept of preprocessing, and proposed the concept of OLAM cubes and auxiliary cubes to store the frequent itemsets over a presetting minsup and the infrequent itemsets. We also proposed a three-layer OLAM lattice to organize all of the possible OLAM cubes in a systematic way. Through this three-layer lattice, users can carry out OLAP-like multidimensional exploration of association rules.

This paper present a preliminary result of our project on building a real on-line multidimensional association mining system. There remains much work, theoretical or

implemental, to accomplish to realize the proposed ORMAS on-line mining system.

## Abstract

This paper demonstrates a quick and efficient method of assessing the ideation structure for a group of people via the Internet and text mining. Data collection using the Internet is increasing; although the Internet has made access easier figuring out what people think is still a challenge. Email was used to contact and then direct survey respondents to a web site. At the web site, open-ended questions requiring text (type written) responses were asked. Conceptual (ideation) structure was obtained via an algorithm similar to that suggested by Quillian [7] and Bonnet [1]. To discover ideation structure, a modified Hopfield neural network based text-mining algorithm was used to obtain the statistical weights of ideas and concepts and the weights of the joint occurrences of the ideas and concepts with other ideas and concepts. Applying neural network technologies to text allows the analysis of open-ended responses without incurring the expensive, time-consuming and error-prone task of manually reading the open-ended comments. The Internet via email contact and web-based survey input dramatically speeds the process.

## 1. Introduction

Data are typically collected through surveys conducted by phone or through the mail, consumer interviews in malls, and focus groups. The increasing use of the Internet for data collection has made access easier; however, figuring out what people think is still a challenge. This paper demonstrates a quick and efficient method of assessing the ideation structure for a group of people.

This paper uses a combination of electronic methods to measure the ideation (concept) structure of university faculty interested in developing communities. Email was used to contact and the direct faculty to a web site. At the web site, open-ended questions requiring text (type written) responses were asked. Conceptual structure was obtained via algorithms similar to those suggested by Quillian [7], Bonnet [1] and Chung, Pottenger, and Schatz [3]. The goal of the application of methods was

to gather “collective wisdom” as quickly and efficiently as possible.

The content of the survey focused on thoughts, suggestions, and opinions regarding the startup and operation of a community development center at a major U.S. University. The survey focused on four textual questions; only one of these is reported in this paper: The faculty and staff’s suggestions on how to encourage community development activities on campus and local community. This study used E-mail and a Web site to conduct a survey, designed to capture via open-ended (text) responses, the structure of ideas and semantic concepts.

Faculty (and administrative and support staffs) were contacted by email and directed to a web survey site. The survey contained four open-ended (text) questions including current projects and activities related to community development, projects planned for the next year, interests in community housing projects, and suggestions regarding the promotion of community development activities. Specifically, this last question asked for suggestions about how to encourage/promote community development activities on the university campus.

## 2. Electronic Data Collection

Four weeks before the end of the spring term 2002, an email message was sent to all faculty and administrative staff introducing the respondents to the survey topic and then directing them to a web page, the survey’s URL. Two weeks later a reminder email was sent. One hundred and forty faculty and administrative staff responded to the survey request. The responding faculty and staff, of course, do not provide a representative sample of the entire faculty; however, they do represent those faculty and staff whom are highly interested in community development activities.

## 3. Discovery of Ideation Structure

Implementation of the analysis was accomplished via Text Analyst 2.0; the general idea of applying a modified Hopfield network to text is given in Chung, Pottenger, and Schatz [3].

The goal of the text analysis is to filter out meaningless elements, process the significant information, and identify the key semantic concepts contained within the text. Important concepts and word combinations from the text are identified by their frequencies of occurrence and joint occurrence with other concepts. The text is taken as a sequence of ideas organized by sentences into words. This sentence-string of words is moved through a window of variable length of text fragments. The goal is to discover ideation structure of the text. A modified Hopfield neural was used to obtain the statistical weights of ideas and concepts and the weights of the joint occurrences of the ideas and concepts with other ideas and concepts. The Hopfield network evolves by changing the weights assigned to the nodes and links between them into a stable configuration corresponding to the minimum of an energy function characterizing the semantic network. The ideation structure represents a conceptually accurate and concise map of the key ideas contained in the input text.

The modified Hopfield neural network is used to obtain a graph-like structure of statistical weights of concepts and the weights of the joint occurrences of these concepts with other concepts. The Hopfield network evolves by changing the weights assigned to the nodes and links between them into a stable configuration corresponding to the minimum of an energy function characterizing the semantic network. The semantic network represents a linguistically accurate and concise picture of the analyzed text. Applying neural network technologies to text allows the analysis of open-ended responses without incurring the expensive, time-consuming and error-prone task of manually reading the open-ended comments.

### 3.1 Modified Hopfield Algorithm

The Hopfield network is a neural network that may be viewed as a content-addressable memory structure. Knowledge and information is stored in single-layered interconnected neurons (or nodes) operating as memories representing patterns stored in the network. Algorithmic steps for the general application of a modified Hopfield algorithm to semantic networks are presented in Chung, Pottenger, and Schatz [3]. Their method is used below to illustrate the operations of Text Analysis 2.0.

#### 3.1.1 Preprocessing

Preprocessing is a language dependent activity. It involves removal of all ancillary and commonplace words, words that carry no semantic meaning. It also involves the identification of stems of the words, while separating prefixes and suffixes. Additional preprocessing includes pooling words with common stems, "mean" and "meaningful" for example.

#### 3.1.2 Assigning Synaptic Weights

Similarity of any two concepts is given by their co-frequencies of usage relative to individual frequencies, similar to an index of statistical covariance. The concepts generated by similarity analysis serve as the trained network. The concepts represent nodes in the network and the similarities, computed based on co-occurrence analysis, represent asymmetric semantic weights between ideas or concepts (nodes). The synaptic

weight from node  $i$  to node  $j$  is denoted as  $w_{ij}$ . The

relationship between each pair of ideas (nodes or neurons) is expressed as the real-valued asymmetric similarity associated with each pair of ideas. Materially, this is the Hopfield network equivalent of a semantic space.

#### 3.1.3 Initialization

The initial set of recurrent ideas (including repetitive phrases) extracted from a text comments serves as the input pattern. Each node in the network matching one of the extracted concepts from the text comment is initialized to have a value of 1 (i.e., the node is activated), with the rest deactivated, assigned 0 weight, summarized in Equation 1 below:

$$u_i(t_0) = x_i, \quad 0 \leq i \leq n-1 \quad [1]$$

$u_i(t)$  is the output of node  $i$  at time  $t$  and  $x_i$  indicates the input pattern for node  $i$ .

#### 3.1.4 Activation

The nodes contain all important concepts and word combinations from the text. Concurrently, the same network assesses frequencies of occurrence and joint occurrence of different semantic elements within certain structural text units, for example sentences. The resulting graphical structure however does not provide an accurate semantic picture of the analyzed text. An adjustment of the individual statistical weights of the words and relations between them to provide a consistent text representation is needed. The weights of those concepts, strongly related to other frequent concepts in the text should be increased. This is accomplished by assigning the statistical weights of individual concepts to the nodes in the one-dimensional Hopfield with all neurons completely interconnected.

During the activation phase, the statistical weights of relations between concepts are assigned to the links between individual nodes in the semantic network and are permitted to settle. The modified Hopfield network

advances by changing (the weights assigned to the nodes and links between them) to a stable configuration corresponding to the minimum of the Hopfield energy function.

The goal is to obtain the weights  $w_{ij}$  once the network reaches a stable state.

$$u_i(t+1) = f_s \left( \sum_{j=0}^{n-1} w_{ij} u_j(t) \right) \quad [2]$$

$$0 \leq i \leq n-1$$

$f_s$  is the continuous sigmoid transformation function,

$n$  is the number of nodes in the network, and  $net_i$  is the weight computation formula:

$$f_s(net_i) = \frac{1}{1 + \exp\left(\frac{-(net_i - \theta_i)}{\theta_0}\right)} \quad [3]$$

$\theta_i$  is the threshold or bias parameter, and  $\theta_0$  is modifies the shape of the sigmoid function.

$$net_i = \sum_{j=0}^{n-1} w_{ji} u_j(t), \quad [4]$$

The term  $net_i = \sum_{j=0}^{n-1} w_{ji} u_j(t)$  creates a unique feature of the Hopfield net algorithm in that each activated node computes its new weight (output state) based on the summation of the products of its neighboring nodes' weights and the similarity weight between its neighboring nodes and itself.

### 3.1.5 Convergence:

Activation continues until the network reaches a stable state, i.e., there is negligible change in the value of the output states between two time steps. To measure the stability of the network, the difference in activation level between two time steps is computed and compared to a predetermined convergence threshold,  $\epsilon$ :

$$\sum_{i=0}^{n-1} \left| u_i(t+1) - u_i(t) \right| \leq \epsilon \quad [5]$$

The parameter  $\epsilon$  is a threshold used to indicate whether there is a non-negligible overall difference between two consecutive steps, across all network nodes. The final result is the set of concepts having the highest activation level, when the network converges. The resulting concepts (ideas or noun phrases) are considered most relevant to the concepts contained in the semantic space.

## 4. Results and Findings

Eighty-one of the 140 respondents gave input to the question regarding suggestions about how to encourage/promote community development activities on the university campus. The total word count for this file is 2,622 words. Text Analyst 2.0 was applied to the text of word-sentences via as described above. Graphically, the key semantic concepts addressed by the respondents are presented in Figure 1 below.

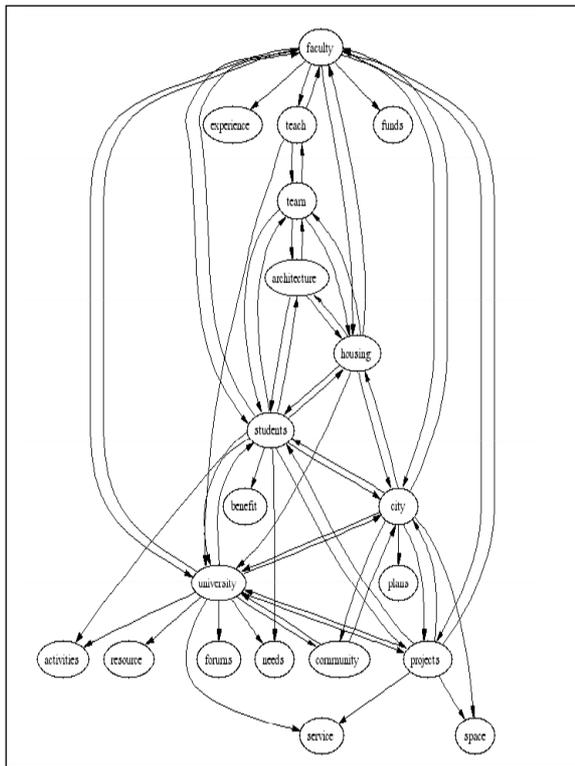

Figure 1: Semantic Map: Ideation Structure For Encouraging Community Development Activities

The above semantic map presents the key concepts contained in the collective text responses to the question regarding suggestions about encouragement and promotion of community development activities by the university community. It is important to note, this map does not necessarily represent any one person, but

rather, represents the collective or group of respondents. The renormalized weights of words and relations between them are called semantic weights and the resulting reshaped graph-like structure is called a semantic network (which is a list of the most important words and word combinations from the text and relations between them).

A 261-word summary of the total set of text responses is presented below. Note this summary yields highly actionable managerial information:

“The university should interact more with the city to reach mutually beneficial solutions to employment, housing for faculty and students and community development. Continue to provide a forum for discussion of issues between the university community and the city community at large: Outreach projects, which have visible impact. Volunteers who perform services for the needy, university learning projects which enhance quality of life for community, Opening up university resources to community. Allow more local businesses to have commercial activities on university.

I would be interested in team teaching a collaborative course with business, architecture, city and Regional Planning and Landscape architecture students and Faculty on investigating housing design for families, elderly and students.

I would like to develop team-based senior projects (ideally jointly between College of Business, and [local research park] and college of architecture students) to study housing options for the elderly, for instance, and develop viable proposals for housing facilities which will fill the gaps in the current market.

We need a lecture series that brings California and Western practitioners to university to share their experiences with the faculty.

We need a 'faculty brown bag' series that allows faculty and students to come together and share local experiences

University needs to hold forums on relevant topics. Perhaps these initiatives could be tied together with a multidisciplinary forum on community development where university faculty and staff as well as outside speakers could be invited to share their experience and expertise on issues related to community development.

Extended Studies is a logical resource for promoting community development activities on our university.”

#### 4.1. Managerial Implications

To encourage community development activities on campus and local community, the content of the survey focused on thoughts, suggestions, and opinions regarding the startup and operation of a community development center at a major U.S. University. The key relational ideas expressed in the group’s responses are presented below.

University and city interaction regarding

- Housing for faculty and students
- Services for the needy
- Quality of community life
- Opening university resources
- More local business activities on campus

Actions within the university to focus on

- Team teaching
- Investigation of housing for the elderly and students populations
- Increased relations with local research park
- Encouraging practitioners to share experience with faculty and students
- Lecture series
- Faculty “brown bag” seminars
- University sponsored forums
- Use of extended studies programs

## Abstract

With prevalence of Internet, users can easily retrieve the information what they want from Internet. Information explosion shows that efficient information summarization is aspired to all users. Therefore, an efficient knowledge management methodology becomes very important. Some technologies, such as text mining, for acquiring knowledge from huge amount of electronic documents are recognized as important technology in this field.

This work focuses on text-mining applications on Chinese industrial news and knowledge discovery. We use information extract method to extract news into companies, event keyword, time, location, and person categories based on the characteristics of news. The set of five extracted categories is called information template. The templates are summarized by rule induction. We can discover unexpected knowledge from these summarized rules. We built an integrated industrial news text-mining model by using induction rule learner. This model is suitable to manipulate rules in bag-of-word form. Furthermore, we proposed interestingness to measure interesting strength of rules. The users can analyze the discovered rules based this measure. These are helpful to discover unexpected knowledge. It is meaningful to commercial activities if we can discover valuable rules. Besides industrial news application, we believe this model is suitable for knowledge discovery application in other fields.

## 1. Introduction

With prevalence of Internet, users can easily retrieve the information what they want from Internet. Unfortunately, people could not promptly acquire knowledge from this information source without computer processing technology. Therefore, an efficient knowledge extraction technology becomes very important. Text mining is recognized as one of the most important technologies for discovering knowledge from huge amount of electronic documents. In recent years, the technologies of knowledge discovery from database (KDD) have been well developed. Most researchers proposed text-mining

models based on well-developed data mining technologies [7]. The purpose of knowledge discovery is to extract implicit, unknown, and unexpected information [2].

Figure 1 depicts a text-mining model extended from data mining. In order to transform ordinary text document into predefined database, an information extraction (IE) process is developed to extract necessary information from text documents. IE process involves natural language process technologies [3]. After transforming unstructured text documents into structured information database, the system applies suitable data-mining technologies to post-process the extracted information for completing knowledge discovery.

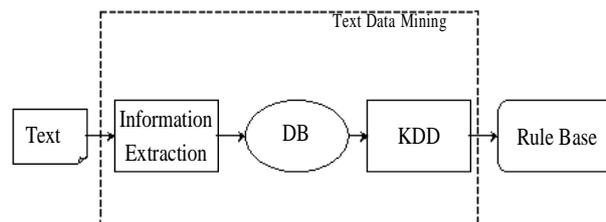

Figure 1 Text-mining model extended from data mining [7]

Text mining is to discover useful information pattern from huge amount of electronic documents. The discovered information pattern can be transformed into specific knowledge presentation form. Once the extract information can be transformed into knowledge presentation database, we achieve the knowledge discovery purpose. In this study, we focus on industry related news report. We applied mutual information (MI) technology to segment Chinese text document into phrases and statistical method to select keywords of the text documents. The extracted information is transformed into predefined rule templates to represent the extracted knowledge fact. The extracted rule templates are stored in database and we applied knowledge discovery technologies, namely rule learners, to discover unexpected knowledge rule form the database. The produced knowledge rules are stored in database. As a result, our knowledge

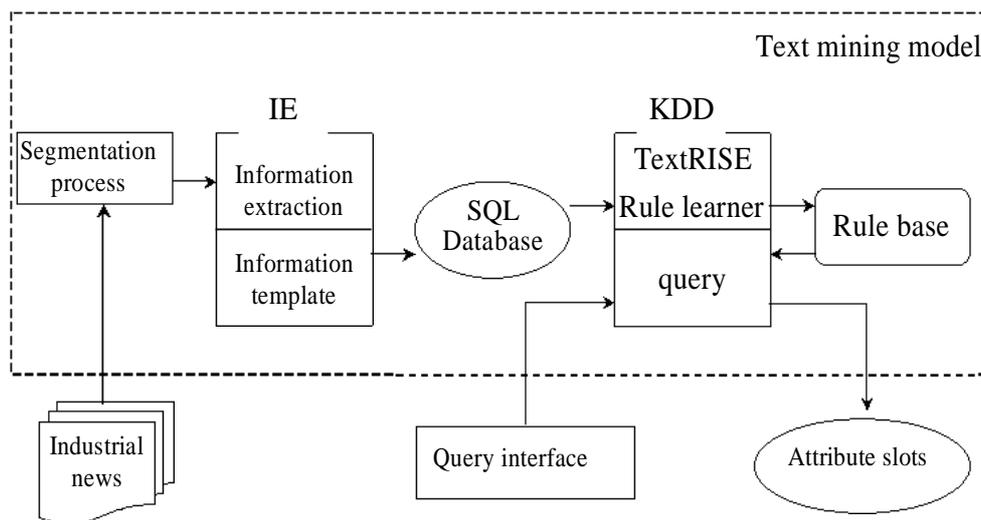

Figure 2 The knowledge discovery model in Chinese Industrial News

database is created and offers convenient query interface for knowledge rule querying. We have to remind readers that not every minded knowledge rule is interesting to all users. Furthermore, we introduced a measure, interestingness, to help users find out the knowledge rules what they are interested.

In Section 2, we introduce our Knowledge Discovery model in Chinese industrial news with text-mining. The globalview of the proposed model is discussed. The detail discussion of the text preprocess is shown in Section 3. In section 4, we discuss the rule learner algorithm TextRise what we use in our model in detail. We introduced the interestingness measure in Section 5.

## 2. The Knowledge Discovery Model in Chinese Industrial News

In this section, we give the global view of the knowledge discovery model in Chinese industrial news. Our knowledge discovery model is derived from the general text data mining model which is discussed in previous section. As shown in Figure 2, the model is divided in two parts: pre-process and post-process. The pre-process part takes the Chinese news reports are input data. The pre-processes include Chinese segmentation and information extraction. The extracted information is stored in predefined format database to represent the knowledge template. The post-process, KDD, part is applied a rule learner, named TextRise, to induce the knowledge templates into a set of rule base. The users find out the interesting or helpful knowledge rules aided by a proposed measure, interestingness, from the rule set. In such a way, the users can easily find out useful knowledge or information without reading huge

amount of text documents from Internet or other sources.

Unlike pre-process for English text documents, Chinese text documents are composited from Chinese characters without spaces. The process to divide Chinese text into segments, or phrases, are called segmentation process. There are three major approaches for Chinese segmentation. The first approach is dictionary-base with maximum matching. That is, the process segments Chinese text by looking up a pre-defined Chinese dictionary. In general, the process takes the phrase with maximum length from all candidate phrases. The second approach is based on statistical methodology. The system uses a pre-produced characters mutual information database to divide Chinese text into proper phrases. The character mutual information is a statistical information from an exist corpus. The third approach integrates the first two approached to have both advantages of these two approaches. We use the third approach as part of our Chinese text segmentation process. We will discuss the segmentation in detail in next section.

The information extraction categorizes the segmented phrases into pre-defined bags of words, or BOWs, and stores the extracted information into database. We called the set of categories as knowledge template. The post-process of our model uses a rule learner TextRise to induce the knowledge template into knowledge rule base. The TextRise is suitable to process rule representation we use. The rule learner is designed for BOW-base rule learning. Actually, the users are not interested to all mined rules. We introduce a measure interestingness to help users find out knowledge rules what they are interested. We shall discuss this part in Section 4.

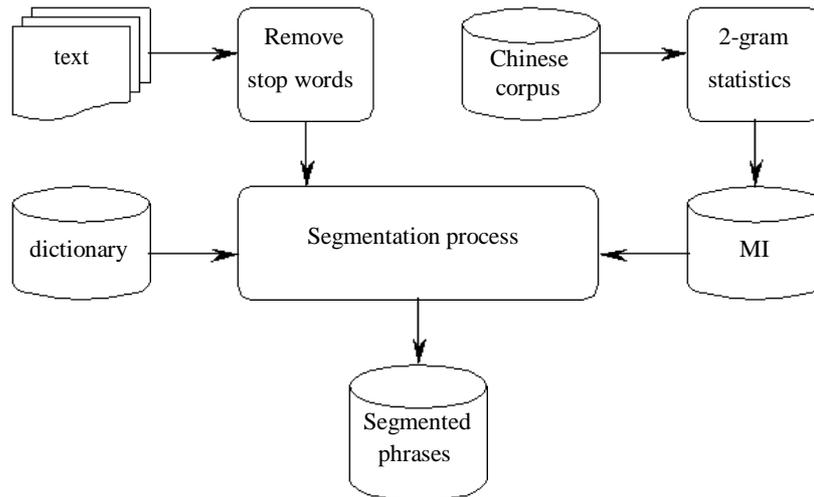

Figure 3 The integrated Chinese segmentation process

### 3. The Chinese segmentation and information extraction

Figure 3 depicts our integrated Chinese segmentation process in the proposed model. We prepared Chinese character mutual information from huge amount of Chinese corpus. We also prepared a Chinese stop word list for removing meaningless Chinese stop words first. In the segmentation process, we use dictionary-base and MI-base to segment the same text. The segmentation process takes the longest phrase as a result.

We use Sporat and Shih’s approach [9] to calculate the Chinese mutual information (MI). The MI measure represents the concatenation strength of two Chinese character a and b. The MI value is calculated by equation (1):

$$MI(ab) = \log_2(N) + \log_2 \frac{f(ab)}{f(a) \times f(b)} \quad (1)$$

where Chinese character b appears after character a.  $f(ab)$  represents the times what character b appears after character a.  $f(a)$  and  $f(b)$  represent the appearing times of character a and b respectively. N is the total number of Chinese characters in the corpus. Chinese phrase ab could be a Chinese phrase if their MI value is high. Chinese character sequence abc could be highly possible a true Chinese phrase if both  $MI(ab)$  and  $MI(bc)$  are high. In such a way, we can possibly find a new n-gram phrase. This approach solves the deficiency of phrase-base segmentation approach for new phrase. For example, we find that

the both  $MI(\text{范巽})$  and  $MI(\text{巽綠})$  are high, 15.9 and 14.4 respectively, and 3-gram “范巽綠” is not in our dictionary. Due to the high MI values of both bi-gram “范巽” and “巽綠”, our segmentation process can successfully segment the present Taiwan vice-minister of education “范巽綠”.

Table 1 Example of finding new Chinese phrase

bi-gram	MI value
長范	4.8009
范巽	15.9413
巽綠	14.4544

After segmentation process, information process categories all segmented phrases into pre-defined BOWs and form rule templates. The definition of BOWs is based on the characteristics of processed text documents. In this work, we are interested in text-mining application of industrial news reports. We categorize the phrases into five BOWs, namely people, company, location, time, and event. Table 2 shows such an possible template example which is extracted from an industrial new report.

Table 2 The template example

Bag of words	Contents
Company	文化公司
Event	股票上市、開高走高
Time	民國89 年第3 季
Location	文化資訊公司
People	王財得、林大義
