The TextRise is derived from Rise algorithm [8]. In order to process text information, the rule distance is calculated as the text similarity. The TextRise algorithm is shown in Figure 4. The algorithm uses TextAccuracy value to determine whether to terminate the induction process or not. The TextAccuracy is defined as the average accuracy of rule set to the given example set. The algorithm stops when none of rule generalization can improve the TextAccuracy of rule set on given example set.

```

Input: ES is the training set.
Output: RS is the rule set.
Function TextRISE (ES)
RS := ES.
Compute TextAccuracy (RS,ES).
Repeat
For each rule R∈ RS,
    Ê:=arg max Similaity(E,R)
        E∈ES'
    where ES' = { E':E' ∈ES and E' is not covered by R}
    R':=Most_Specific_Generalization(R, Ê)
    RS':=RS with R replaced by R'
    If TextAccuracy(RS',ES)≥TextAccuracy(RS,ES)
        Then RS:=RS'
        If R' is identical to another rule in RS,
            Then delete R' from RS.
Until no increase in TextAccuracy(RS,ES) is obtained
Return RS.
    
```

Figure 4 The TextRise algorithm [8]

We have to remind readers that the size of the produced rule set is smaller than size of the given example set. The new generalized rule may be pruned if there exists identical rule in present rule set.

#### 5. Interestingness measure

The induction rule base produced from the TextRise will be huge when the system processes mass amount of text news reports. We introduce an interestingness measure to help users finding valuable knowledge from our system. Actually, a single rule in the rule base may not be interesting to everybody. We define the proposed interestingness measure as:

$$I(k, \tau) = \frac{|\{b \in D \mid \forall A_i, a_i, \text{sim}(A_i, a_i) \geq \tau, \text{sim}(C, c) \geq \tau\}|}{|\{b \in D \mid \forall A_i, a_i, \text{sim}(A_i, a_i) \geq \tau\}|} \quad (2)$$

where  $k \equiv A \rightarrow C$  is a predicate rule. A is antecedence of the predicate rule k, and C is the consequence. D is the knowledge rule base produced by our system. The  $\tau$  is the user given threshold. The predicate rule k is interesting to user if its interestingness measure is high. Otherwise, the rule is useless to a user.

Figure 5 depicts an interestingness query example. The query result is shown in Figure 6. The example shows query about “information consumer electrical products”. The system returns four related rules from rule base with their interestingness measure.

#### 6. Conclusion

In this study, we propose an automatic knowledge discovery model in Chinese Industrial news with text mining. The proposed model can process mass amount of Chinese text documents and induce them into knowledge rule base. The major contributions are:

1. Define a useful measure, interestingness, to help users find out the useful or unexpected knowledge from our rule base.
2. The system can automatically process mass amount of electronic Chinese text documents. The system induces these documents into knowledge rule base. Such that, the users can easily discover knowledge by query the rule base.
3. Using bag of words has better and complete knowledge representation.

Our approach is not only for industrial news reports. It is also suitable for other field of text documents if we can properly define the bags of words for the specific field. The post-process of the proposed model can be applied other approach to produce better knowledge database. The neural fuzzy might be a possible approach to replace the TextRise algorithm.

## Abstract

This paper introduces the IBM Linux in Academia program and a curriculum development project initiated by the authors for the program. The service of IBM Linux in Academia program is based on the Linux virtual service concept in which a mainframe computer is partitioned into many Linux images supported by IBM's Virtual Machine Operating System. On the IBM S/390 system, each image acts as an independent Linux server. This free service saves the acquisition and management cost of running multiple physically separated servers for participating universities. The curriculum development project intends to create and share curriculum materials for e-Business related courses among participants. The main IBM software used in this project includes DB2 Universal Database and WebSphere. The main objective in the first stage of this project is to develop a data warehouse generator to manipulate a large read-only database obtained from a real world health care application supplied by IBM. Through a web based user interface, an instructor could flexibly create a data warehouse using the Account Data Model developed by some of the authors from the read-only database with the desirable size and attributes to support pedagogical needs. Other aspects of the project are also addressed.

**key words:** Account Data Model, Data Warehousing, DB2, Linux, WebSphere

## 1 Introduction

The objective of the IBM Linux in Academia program is to provide a robust and reliable Linux environment for the university community dedicated to educational and research purposes [2]. The service provided by the program is hosted on an IBM S/390 mainframe computer located at Colorado State University, capable of running hundreds of Linux images (servers) on the same hub server at the same time. The hub server partitions the necessary processing, storage and network capacity for each Linux image. As a result, resources can be allocated flexibly to meet the individual need of an image while maintaining the same level

of separation between images as any physically separated servers would. A commercial service based on the same concept was launched by IBM recently [6]. The Linux in Academia program allows a participating university free accesses to not only IBM software packages but also virtual servers to host those applications. The major benefit to a participating educational institution from this arrangement is that the institution could offer its instructors and students accesses to the state-of-the-art information technologies without heavy investment in IT infrastructure. The service is especially valuable to colleges without adequate financial and human resources to acquire and manage the hardware and software required to support their IT related curricula. In addition to the common open source packages for Linux, the two major IBM software components included in this service are DB2 Universal Database and WebSphere.

Despite the abundant resources provided by the Linux in Academia program, the service does not include instructional resources such as course materials and sample databases. This might not pose a serious problem for a Computer Science program which may require students to build software and network applications on a Linux image from scratch. As the need of a business program, MBA in particular, focuses more on utilizing existing databases for the purpose of training students on analytical skills (marketing research, customer relationship management) and managerial concepts (e-Business strategies), there is a demand for instructional materials, especially those supported by a user friendly interface for students without programming experience. The Business School at the State University of New York at New Paltz (hereafter referred to as SUNY-NP) signed a collaboration agreement with IBM on October 26, 2001, to establish an e-Business Virtual Lab using the service from the Linux in Academia program. As the first business program participating in the Academia program, the authors propose a project to develop course materials for the program. We hope the instructional resources developed from the project could encourage more colleges to join the Linux in Academia program which in turn helps the program develop and test more contents.

The core of the project is to develop a framework

and all associated software so that an instructor could easily extract and build a customized data warehouse from a large read-only database (57 GBytes) for his or her instructional need on the instructor's own Linux image. This read-only database is structured using a popular data model for data warehouses, namely the star schema. As a result, extracting a small portion from the large database is relatively easy. However, we would like to take this opportunity to test a new data model, Account Data Model (see [7] for details), as the data model for warehousing purposes due to its flexibility. The extracted data warehouse is created from the dimensions and attribute values chosen by the instructor. For example, the instructor may select a shorter period of time or a focused subset of geographical regions to control the size of the resulting data warehouse. The instructor has full privilege to the resulting database and could control the privileges rendered to his/her students. The read-only database is provided by IBM from a real world application in health care (medical insurance) industry with all personal and institutional identities removed or disguised. The size of the extracted data warehouse on the instructor's image is targeted at 2 GBytes, which we believe can still give students a flavor of a realistic data warehouse with considerable size. As transmitting 2 GByte data on the Internet can be very time consuming, the Academia program provides a perfect platform for us to implement this project. Although the read-only database is installed on a Linux image which is logically separated and independent from the instructor's image, both are physically located on the same S/390 system. This configuration significantly reduces the download time. Using a web based GUI interface, the process of creating the instructional data warehouse is reduced to clicking on the desired attribute values presented in a tree structure similar to a file/directory navigating system such as Windows Explorer. Additional web based user interface for students to access the data warehouse on their instructor's image is also intended for reducing the level of computer skills needed to query the database. Those user interfaces will be built on common open source software and be organized and managed by IBM's WebSphere.

The following sections provide more detailed introduction and descriptions of the infrastructure of the Academia program and our plan of supporting this service with course contents developed from this curriculum development project.

## 2 Infrastructure of IBM Linux in Academia Program

The service of the Linux in Academia program is based on the "utility computing" concept advocated by major UNIX server vendors including IBM, HP, and Sun Microsystems. They argue that the computing resources do not necessarily need to reside in the user's

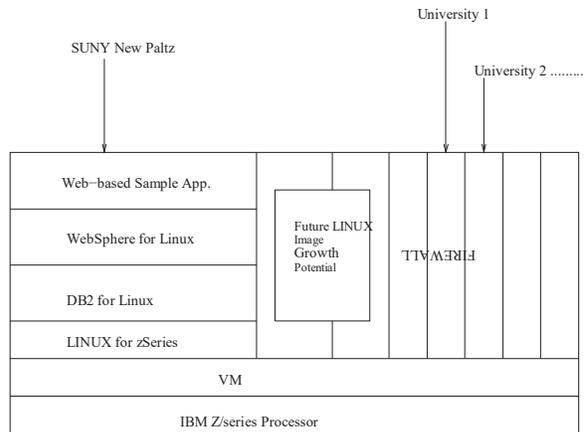

Figure 1: Linux Images on S390

organization. Instead they can be outsourced to a remote server managed by a vendor to save management costs on maintaining system hardware, software, security, and reliability, etc. The organization only needs to maintain lean clients to tap into the utility system. The Academia program has setup its Linux hub at Colorado State University on an IBM S/390 mainframe running a Virtual Machine (VM) operating system which supports the partition of system resources to host many virtual servers (images) each running a Linux (for S/390) operating system. Figure 1 illustrates the architecture of the system. The two layers at the bottom are the zSeries processor and the VM operating system for the S/390. The top four layers on the left demonstrates a sample Linux image created for SUNY-NP. At the foundation of this image is a SuSE version of Linux for S/390 and the middleware includes a DB2 Universal Database Server and a WebSphere Server on which web based applications (top layer) can be built. The other side shows potential future images. These images act like independent servers protected by their own firewalls. For a Computer Networking course, each student may obtain an image of his/her own with small disk space. For an e-Business course offered by a business school to students with limited computer experience, the whole class may share an image having much bigger memory and disk space than those images created for individuals. Thus, an image can be created to serve the need of a course, a user, or an application area with the desired software packages, computing power and storage space.

Accesses to the Linux images are provided via three channels as listed below.

- An end user either on or off campus can connect to the campus LAN which in turn connects to the server through a secure VPN session.
- A user could also access the image directly through an internet Secured Shell (SSH) connection.

- A user can use a browser to access a password protected web sites as a gateway to the resources and applications on various Linux images.

Software packages such as Putty and WinSCP2 are ideal tool to access Linux images through a secured shell (SSH). Both programs are small and do not require installation. This is particularly convenient for students to carry them in a floppy disk and work on different locations. However, the easiest way to access an application for non-computer savvies on a Linux image is to do it through a web browser which is available almost everywhere. As a result, this is the approach we recommend for our business students.

### 3 Potential Curriculum Supports

There are many areas and courses that can utilize the service and its contents. We discuss a few potential areas in this section.

*Data Analysis:* In courses like Marketing Research and Decision Support Systems, students can access a read-only database created by their instructors and retrieve necessary data through a browser on selected dimensions and ranges of attribute values. The interface translates the user's request into a SQL SELECT statement and connect to the data warehouse to get the data which is saved as a file in the user's account. The student can then download the resulting data set to local machines for further analysis. This application is also suitable for covering course subjects such as data mining and customer relationship management. The instructor can observe and discuss the different viewpoints and conclusions generated by students from the same database and demonstrate the benefit obtained from such analysis.

*Virtual Company:* Students create their own small databases with full access privilege to store product, customer, and order information for their virtual companies. This exercise involves students from the design phase of setting up an information system for a company. Students are asked to consider the issues of how their designs can help the organization achieve its strategic goals and manage daily operations. The instructor can address the importance of design issues related to a MIS project and how a well designed information system can facilitate business decision processes, which in turn enhance an organization's competitive advantages.

*Virtual Community:* The first two applications focus more on the database issue which is the building block for other e-Business applications. The virtual community application extends the database built earlier to create an online community by connecting the virtual companies from various students together. For example, a manufacturer wants to purchase materials online from its supplier and a bank handles the payment between the manufacturer and the supplier. Students can team up with Computer Science majors on these web

application projects to develop their first e-Business practice, which handles online transactions and update their databases. This service can be provided either by the Apache web server with CGI supports or from a fully integrated software for e-Business such as IBM WebSphere.

One concern we have at this point is the internet traffic during peak hours. During certain time of the day, the connection to the hub may be much slower. In that case, the instructor may consider installing a local copy of the application to support instructional purposes. For example, the instructor can further extract a 2 MByte data warehouse from the 2 GByte data warehouse on his/her image to a local Linux server (DB2 is available through IBM Scholar program for local installation). Students may practice and prototype their work on the local server during internet peak hours and submit their pretested queries to the 2 GByte warehouse for their project later.

### 4 The Medical Insurance Database

In this section, we introduce the Medical Insurance database used in this project. This database is a database used by IBM for software testing purposes. It is obtained from a real practice at a health insurance company. All sensitive information is either removed or disguised in this database. The database is structured under a popular data model for data warehouses, namely, the *star schema*. As a result, understanding the meaning of attributes and writing queries against it are relatively easy. The data warehouse only contains one year medical insurance claim data which already consumes 57 GByte hard disk space on a Linux image.

At the center of this data warehouse sits a fact table, INS700TB, which records detailed insurance claim history. The metrics in this fact table are dollar amount and frequencies of insurance claims, including measures such as payment amount, deductible amount, coinsurance amount, third party payment amount, and claim utilization counts, etc. This table has 228,221,751 rows. There are 11 dimension tables as follows.

1. INS002TB: Each row in this table represents an individual who enrolled in this insurance policy (1,428,826 rows).
2. INS800TB: This table stores 15,186 different diagnosis categories (15,186 rows).
3. INS801TB: Diagnosis are also classified into 512 diagnosis related groups (512 rows).
4. INS804TB: There are 19 different reasons for discharging a patient from a hospital stay (19 rows).
5. INS805TB: This is a list of states where the patient resides. It covers all fifty states of the United States (50 rows).
6. INS806TB: All claims are classified into 5 different types (5 rows).

7. INS808TB: This table lists the year when services are provided. Since we only have one-year data, this dimension table has no effect on any query results.
8. INS809TB: This table records all month and year combination during the one-year period (12 rows).
9. INS810TB: This table records the month/date/year and month/year combinations for the recorded period (365 rows).
10. INS811TB: There are 4275 different medical procedures (4275 rows).
11. INS812TB: This table records the provider's locations which include the 50 US states, the identification and short name of the state, and some foreign countries or regions (132 rows).

In addition to the main fact table, there are 5 summary tables with higher level of aggregation. Therefore, their sizes are much smaller.

1. INS750TB: This table summarizes the utilization of the insurance policy by patient state, year, month, and claim types (2998 rows).
2. INS751TB: This is a summary of utilization by providers, provider state, year, month, and claim types (2998 rows).
3. INS752TB: This is a summary of service grouped by diagnosis, diagnosis related group, patient state, and primary procedure performed, year, month, and claim types (7,811,520 rows).
4. INS752TB: This is a summary by claim type and year (5 rows).
5. INS756TB: This is a summary by provider state and year. It has 51 rows, one for each of the 50 states and the remaining one for the sum of all non-US countries and areas.

The number of dimensions for those summary tables is also smaller, ranging from two to seven. Due to the fact that we are only given one year data, the year dimension (INS808TB) is irrelevant in this case. Nevertheless, we still retain this dimension to preserve the overall structure of the data warehouse. The main fact table, INS700TB is the most detailed one which has all dimension tables except for INS808TB as its star dimensions. Summary table INS750 has four dimension tables including

1. INS805TB (50)
2. INS806TB (5)
3. INS808TB (1)
4. INS809TB (12)

Numbers in the parentheses indicate the number of rows in each table. Figure 2 shows the dot model for summary table INS751TB. The dot model is centered at table INS751TB, its fact table, and four dimension tables INS806TB, INS808TB, INS809TB,

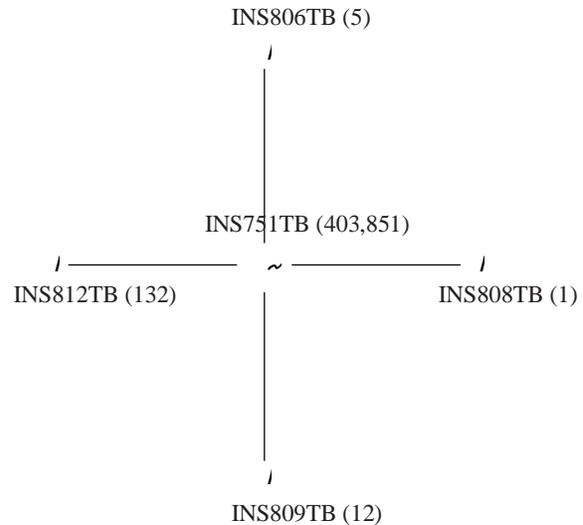

Figure 2: Dot Model for INS751TB

and INS812TB, which maintain one-to-many relationship with the fact table. Summary table INS752TB (7,811,520) has seven dimension tables as shown below.

1. INS800TB (15,186)
2. INS801TB (512)
3. INS805TB (50)
4. INS806TB (6)
5. INS808 (1)
6. INS809TB (12)
7. INS811TB (4,275)

Summary table INS853TB (5) is joined by two dimension tables INS808TB (6) and INS808TB (5). Tables INS808TB (1) and INS812TB (132) are the dimension tables for INS756TB (51) which summarizes the claim amount and frequencies by providers' locations with all non-US locations aggregated into one row.

Those tables and their indices take about 57 GByte of disk space. Table INS700TB alone occupies more than half of that space and due to its size, has to be separated into 30 containers. We also observe that the design of this data warehouse follows a practice suggested by some practitioners, i.e., having a main fact table accompanied by a half dozen summary tables [8] to shorten response time on frequently requested queries about highly aggregated information.

## 5 The Account Data Model

In this section, we briefly introduce the Account Data Model (ADM) used in our data warehousing component of the project. Detailed discussion of the model can be found in Pletch, *et al.* [7]. In most of database implementations, the transaction support

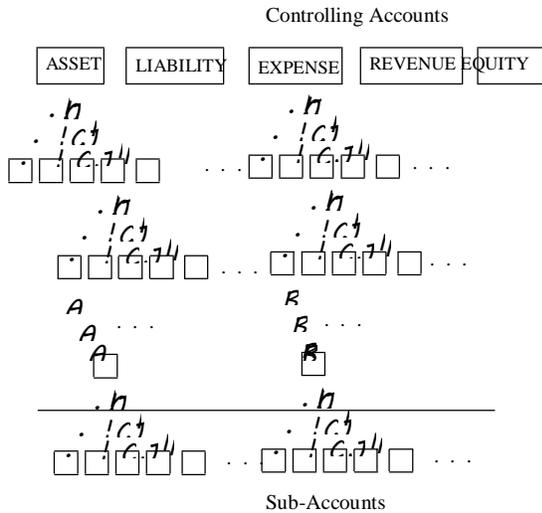

Figure 3: An Account Hierarchy

database and decision support database (data warehouse) are built based on separate data models. The most popular data model for the former is the Entity Relationship (ER) Model [1] and the latter usually adopts a dimensional model with a star schema or a snowflake schema [5]. In our database design, the transactional and warehousing databases are integrated using the same data model, the ADM. From a data warehousing perspective, this data model can be viewed as a special case of a snowflake schema in which there is only one table joined to the fact table that specifies the type of account each row of the fact table belongs to. It uses a hierarchy of accounts to model the information found in an organization's transactional as well as decision support processing. Most of this hierarchy follows standard double-entry accounting practices, i.e. a set of accounts organized in sub-trees rooted in five major accounting categories, namely ASSET, LIABILITY, EQUITY, REVENUE, and EXPENSES. The leaf nodes in Figure 3 represented by boxes below the solid line are called sub-accounts. They are the only accounts which actually participate in transactions and are the ones that link to the fact table from a warehousing perspective. Boxes above the solid line (referred to as controlling accounts) form a type hierarchy and are used as summary accounts, summarizing the activity of the accounts below them in the hierarchy.

Following accounting practices, a transaction is a collection of components that document either debit or credit operations against accounts. Transactions should be *balanced* in that every crediting component is offset by a corresponding debiting component. Ensuring that transactions are balanced before they are accepted pushes some of the data cleansing activity typical of the migration of data from an ER-based database to a data warehouse into the data entry phase. However, unlike the ER model, the design of the hierar-

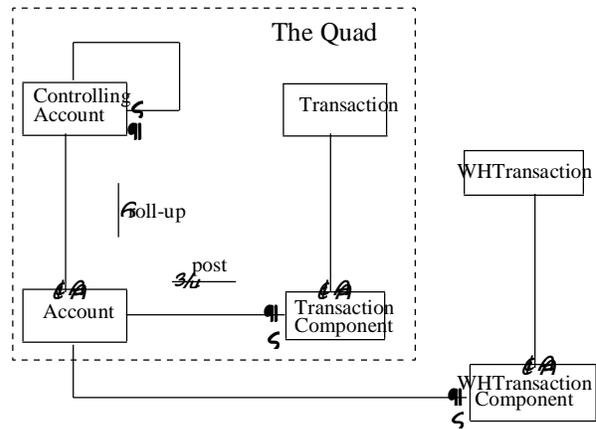

Figure 4: The Quad with Data Warehouse Extension

chical account structure is less intuitive and requires better understanding of the business side of the organization. Nevertheless, a well designed account hierarchy serves as a good managerial tool for companies wanting to practice the principles of the Balanced Scorecard [4] which requires measuring performances from four interrelated categories. This is due to the fact that the design process forces a designer to create accounts which could also represent performance measures. In addition, the double entry system guarantees that an activity is viewed at least from two perspectives. The two entries can also be used to track the links or causal relationship between two performance measures. The pain of designing the hierarchy can somewhat be eased by adopting the standard charts of accounts developed by specific industries.

Part of the justification of our claim that an ADM implementation can be used as a data warehouse is our confidence in the quality of the data stored due to the balanced-transaction nature of the model. Transactions and transaction components along with accounts and controlling accounts eventually come to reside in a standard four-table structure as shown in the dashed box of Figure 4. We refer to this table structure as the *Quad*. Each transaction involves a row in the transaction table and several rows in the transaction component table. A typical transaction can be better described using the following example.

**Example 5.1** A customer, XYZ, orders four units of widget at the unit price of \$15 and unit cost of \$10 on July 15, 2002.

The event in Example 5.1 generates the following accounting entries.

- |   |                                |      |      |
|---|--------------------------------|------|------|
| □ | (a) Account Receivable-XYZ Co. | \$60 |      |
| □ | (b) Sales-XYZ Co.              |      | \$60 |
| □ | (c) Cost of good Sold-widget   | \$40 |      |
| □ | (d) Inventory-widget           |      | \$40 |
- (1)

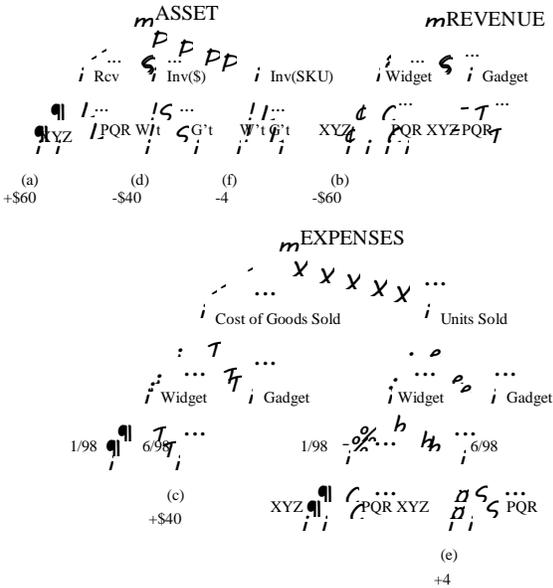

Figure 5: The Components in Accounting Trees

In addition, two inventory entries are also recorded for this event, one debited four units of widgets into customer XYZ's account and the other credited four units from the inventory account of widgets as shown in the following entries.

$\frac{1}{2}$	(e) Units sold -XYZ Co./widget	4	(2)
	(f) Inventory - widget	4	

One row is added to the Transaction table in Figure 4 to represent this transaction. The six accounting entries correspond to six transaction components, half of them debiting accounts and the other half crediting accounts. Hence, six rows are added to the Transaction Component table of Figure 4.

At some point after a transaction has been entered, it undergoes a process called *posting* which updates the sub-accounts in the account table affected by the new transaction. These modifications are further propagated to the controlling accounts (rows in the Controlling Account table) higher up the account hierarchy from the affected sub-accounts by a process called *roll-up*. Both these activities are indicated diagrammatically in Figure 4. When these components are posted, we see the changes in Figure 5 to the balances of the six affected sub-accounts. Note that the negative values under inventory and inventory SKU (Stock Keeping Units) in the figure come from debiting a credit account (or crediting a debit account). Both posting and roll-up become part of the model through automated means - stored procedures, triggers and the like.

The ADM does not support modifying or deleting an existing Quad transaction directly. When a business activity, a sales order for example, is later modified the ADM implements this modification by adding

a totally new transaction. The net effect of combining the components in the new transaction and the original transaction produces new account balances. Thus the original transaction and a corresponding modifying transaction provide a history of the ordering process. From a process point of view, every possible change to an account must be kept for the purpose of process control.

The two tables not in the dashed box of Figure 4 are used specifically for warehousing (decision support) purposes, the WHTransaction and WHTransaction Component tables share exactly the same format as their transactional support counter parts, Transaction table and Transaction Component table. As we use the same data model for the two, they share the same Account and Controlling Account tables. In fact, some of the performance measures from the Financial category of a balanced scorecard may have already been built into the Quad in the transactional support part of the Quad while the performance measures from the remaining three categories (customers, internal business process, learning and growth) are generated for decision support purposes. The warehouse version of the Transaction Component table may choose to keep only the net result of a transaction after it has been fulfilled.

The ADM shows its true strength in its ability to add new information about any transactional and warehousing applications without the need for table redesign. This is achieved by adding new accounts and sub-accounts for the new attributes and entities and then, for each type of affected transaction, additional transaction components are generated to support debiting or crediting the new accounts. In such cases we add more rows to existing tables; never more columns nor more tables. Indeed in the current implementation, transactions saved under an old design schema, which is then redesigned to affect different sub-accounts, will automatically reflect the new design simply by being brought into the user-interface and saved again without change. This is particularly useful if changes of design are needed to reflect new business processes or performance measures. What makes the ADM a viable data warehousing model is the fact that all transactional and decision support components are stored in the same table structures. Adding new types of transactions or even modifying the design of existing transactions becomes a data-entry activity rather than a design endeavor. Thus the line between the transactional database and data warehouse becomes blurry.

## 6 The Data Warehousing Component of the Project

Universities throughout the world often need access to large databases for various pedagogical reasons. In educational programs such as Computer Science where students are simply learning to use SQL or where query

performance or execution are the issues, the kind of data in the database is of little concern. Benchmark databases such as TPC [9] are useful in those situations. Downloading the benchmark database generator written in C/C++ takes almost no time. The generator could install randomly generated databases of various sizes by manipulating the values of some control parameters. On the other hand, in educational programs where the students are more interested in the query results and what they mean, students in a business program for example, it is very difficult to make any real-world sense of the query results from randomly generated databases because these databases contain information that is only marginally realistic. It is nevertheless not reasonable to provide a real database for download, even one of moderate size (a couple of gigabytes) because the download time over the Internet would be unacceptable. The IBM Linux in Academia computing hub provides us with an opportunity to make available to universities a realistic database of considerable size and avoid the typical download time problems. The medical insurance database labelled *insurdb* in Figure 6 plays this role. In order to keep maintenance to a minimum, this install should be read-only.

Although it is possible to allow students to query *insurdb* directly, the result set is usually too large for them to download to their local computers for further analysis using other software packages. In addition, an ill structured query may take hours before a result can be produced. Therefore, we would like to give an instructor control of the size of a customized data warehouse. This project component gives instructors necessary user interface to build their own data warehouses from *insurdb* with the size they deem reasonable for their classes. Since a certain amount of customization would probably be needed we envisage each university/program having its own Linux kernel and own DB2 installed on the same S/390 where the *insurdb* database is installed and that extracts of some size (up to 1 or 2 GBytes) could realistically be made from the *insurdb* database into these user-controlled databases, labelled *WHQuad 1* through *WHQuad n* in Figure 6.

We show how SUNY-NP could use the Linux virtual service environment to support business intelligence course taken by students in our business program and how our own work could be packaged so as to allow other universities to replicate our activities with their own students. We envisage a package that would make it possible for many different users/universities to produce local extracts from the *insurdb* to copies of DB2 running on their own images located on the same S/390 system and into databases we have labelled *WHQuad 1* through *WHQuad n* in Figure 6 using the Account Data Model.

An instructor at university *i* could specify the desired time range, dimensions, and range of attribute values to extract a small portion of *insurdb* and build a customized data warehouse *WHQuad i*. The extract resides in databases controlled by the instruc-

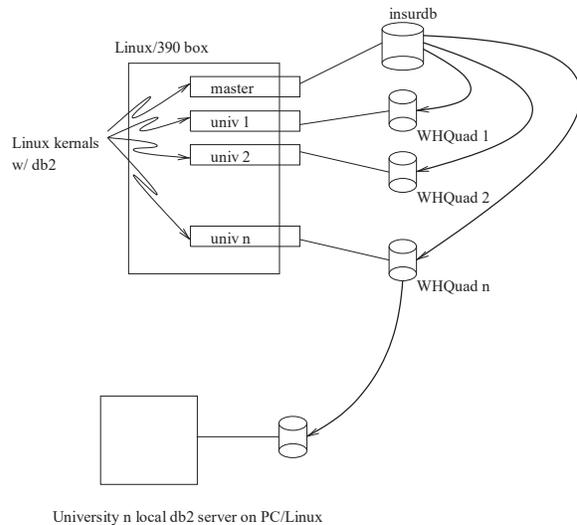

Figure 6: DB2 Structure

tor. In most cases, the instructor may want to make the *WHQuad i* data warehouse read-only to students. The *WHQuad i* databases, although smaller than the *insurdb* database, would still be too large for downloading onto machines that are local to the final users. However they could be used to produce much smaller exports - tables on the order of 2000 to 20000 rows - which would be small enough to download onto local machines (either as files or into a local copy of *db2*) - and it is our intention that these latter tables, looking much like the *fact* tables in a *star-schema* data warehouse but much smaller, could easily be analyzed using local OLAP, Statistics and Data Mining software which, at this time, we do not envisage providing to the user.

Key elements of the package are listed below and explained in Sections 6.1 and 6.2.

- **WHQuad Create :** This script will create the initially empty WHQuad database tables and indices and install various stored procedures and triggers.
- **WHQuad Import :** This program will generate insert statements for the tables in the *WHQuad i* database. The program will proceed from a suitably prepared configuration file and extract data from the *insurdb* database.
- **WHQuad Cube Build :** This program provide the user with a web-based GUI interface from which the user can select *dimensions* and *performance indicators* of interest and build a data cube (typically 2000 to 20000 rows) suitable for analysis using off-the-shelf OLAP tools.
- **WHQuad Export :** This program will export mini-cubes created using the Cube Build software to the user's local copy of *db2*. Although this step is not essential and involves installation and maintenance of a second (local) copy of *db2* by the user,

it will serve as a backup in case the access to the hub server is interrupted.

### 6.1 The WHQuad Databases

We use the Account Data Model (ADM) [7] to build the data warehouse *WHQuad*  $i$ ,  $i = 1, \dots, n$ , due to the fact that ADM is generic and flexible. Once a Linux image and DB2 are available for a university, the *WHQuad Create* program described earlier can be used to install a fresh copy of the *WHQuad* database. This database can be populated with a subset of the information in the *insurdb* database using the *WHQuad Import* program.

A web-based GUI interface, program *WHQuad Cube Build* described in [7], can now be used to extract information from the *WHQuad* tables into mini-cubes or fact tables. A number of OLAP tools such as *Brio* have been developed precisely to present the information in such fact tables.

At this point, the user is able to extract several fact tables containing different dimension/performance indicator configurations. These could be prepared in advance and given to students as source information for data analysis exercises. It is also possible that these *fact tables* could be exported to local copies of DB2 running at the user's university, which we describe next. We should also point out that since *insurdb* adopts a star schema, creating a smaller data warehouse on instructors' images with exactly the same star schema should be straight forward. Thus, we do not include it as a component in this project.

### 6.2 Local Installation of *db2*

We expect the size reduction from

to be in orders of magnitude in general. The *insurdb* database is 57 gigabytes, the *WHQuad* databases as large as a couple of gigabytes but usually smaller than 2 gigabytes and the *fact tables* generated by the *WHQuad Cube Build* software could be as big as 2 megabytes.

Only the latter tables are small enough to be realistically downloaded to machines local to the participating universities. They are just on the edge of being too large to be used on an *ad hoc* basis so we feel the appropriate thing to do is to download them once and use the local copy for conducting classroom activity when the connection to the Linux image is either interrupted or unbearably slow. The program *WHQuad Export* would accomplish this task. It is also possible to use IBM data migration software to do this.

## 7 Other Components of the Project

Next to the applications surrounding DB2 databases is the development of WebSphere applications. There

are several application areas that WebSphere can play a major role.

1. As mentioned earlier, all tools developed for an instructor to generate a data warehouse from the medical insurance database are web based applications. Java Servlets provides a good tool for database intensive applications.
2. The target users of this service are business students who usually do not have profound knowledge in Linux operating system and programming. In order to shield the technical details from the students, a web interface supported by WebSphere as the middleware allows students to focus on analytical and business issues rather than struggling with programming details.
3. We would also like to create some templates for student to easily deploy a virtual company with online transaction capability. This will first link to the database created by students to operate their e-store. Step by step, it can be developed into an online trading community where there are buyers, sellers and transaction facilitating media such as banks and shippers.

The third component in this project covers the area of group decision support, which is a key element in knowledge management. An open source, XML-based software, Jabber [3], can be used as a building block for creating and testing a group decision support environment. Other miscellaneous supporting tasks like developing tools to assist instructors managing student accounts are also intended. This includes programs for setting up the accounts, granting appropriate privileges, and monitoring usage.

## 8 Conclusion

In this paper, we introduce the service offered by the IBM Linux in Academia program and describe a project designed to take advantages of the service provided by the program. The objective of the project is to develop instructional resources including a data warehouse generator using a web based user interface and the Account Data Model. The software allows instructors to carve out a portion of a huge database and create a customized data warehouse for their instructional needs. The data warehouse generator along with other web based resources are designed to facilitate the offering of e-Business and knowledge management related courses in a business program. We hope the software and tools produced from this project can help a business program enhance its capacity and capability to train students on both strategic and analytical issues related to e-Business and knowledge management. We would also like to invite participation from other institutions to contribute to the process of developing and testing more instructional resources.

## Abstract

Past research has hypothesized and empirically supported a model for learners' acceptance of e-learning. To further investigate the influence of gender on e-learning acceptance, data were collected from a sample of 259 Taiwanese undergraduates that were relatively balanced between genders. Comparisons of means and multiple-group Structural Equation Modeling (SEM) with LISREL were used to analyze the data.

Examining *t*-test results indicated that differences in construct means between males and females occurred only for some of the model predictors. Specifically, men have more confidence in using the technology, more Internet experience, a higher perception of system interactivity, and higher beliefs of usefulness and ease of use than women. However there is no significant difference in their intentions to use the e-learning system. In addition, multiple-group SEMs revealed that gender moderated some of the relationships between the hypothesized determinants and intentions to use the e-learning system. In particular, women's adoption intention for distance education purposes is more strongly influenced by system interactivity. Women's perception of e-learning usefulness is negatively influenced by self-efficacy. Some implications for practical purposes are addressed.

## 1. Introduction

E-learning has become an information system market full of growth potential with the computer and Internet steadily gaining popularity [1] [32]. The phenomenon seems to have gone in the direction as Peter Drucker, a noted management professor, has pointed out that the biggest impact of Information Technology (IT) would be on knowledge industries such as education and medicine that were in great need of increased productivity [6]. Corporate training, universities, government, and K-12 education have become four important market segments for e-learning.

An e-learning system is an integrated system as opposed to stand-alone, single-function systems. Recently, more advanced e-learning systems, such as WebCT (<http://www.webct.com>) and Cyber University of NSYSU (<http://cu.nsysu.edu.tw>) have been developed. These systems are specifically designed for teaching and learning purposes and can be used to integrate course development

tools, course material (audio, video, and text), e-mail, live chat sessions, online discussions, and the World Wide Web. With this kind of system, instructional delivery and communication between instructors and students can be conducted either synchronously or asynchronously.

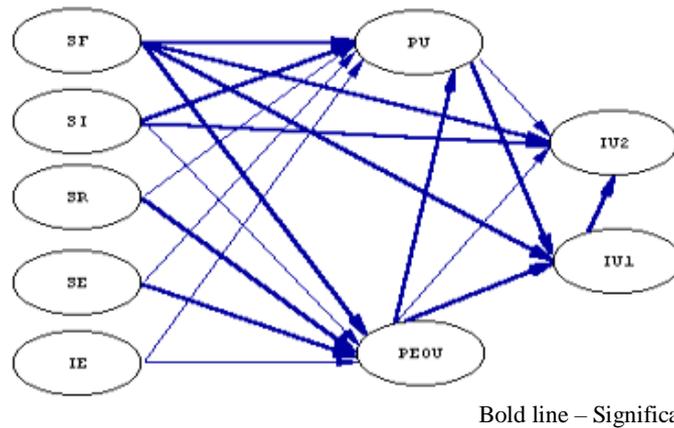

According to the Digest of Education Statistics 2000 [25], between 1988 and 1998, the enrollment growth of key demographic groups has been changing. During that ten-year period, the enrollment in degree-granting institutions for females (16%) was higher than for males (6%). This difference was especially noticeable at the graduate level, as the number of female full-time graduate students increased 60% as opposed to a 17% increase for males. A similar increase of female students has taken place in Taiwan between 1986 and 1999, according to the Ministry of Education [23]. In the adoption of innovation (in this case, e-learning), the factors predicting e-learning adoption may vary across demographic groups. The purpose of this study then is to investigate how gender will influence the acceptance of an e-learning system. In particular, the following research questions guided the study:

1. Do male and female learners have similar perceptions and use intentions regarding e-learning acceptance?
2. Do the relationships between learners' behavioral intentions to use an e-learning system and determinant factors differ for male and female learners?

## 2. Literature Review

### 2.1 Research Model

Lee and Pituch [21] proposed and empirically supported an e-learning acceptance model as shown in Figure 1. The model is derived from the Technology Acceptance Model [10] and Diffusion of Innovation (DOI) perspective [27]. This model uses behavioral intention as a surrogate for IT acceptance of novice learners. The acceptance criteria were categorized into behavioral intentions to use the e-learning system as a supplementary learning tool (IU1) and as a distance education method (IU2). Lee and Pituch found that factors related to IT acceptance included perceived usefulness (PU), perceived ease of use (PEOU), system characteristics (functionality, interactivity, and response), and learner characteristics (self-efficacy and Internet experience). In this study, as well as that of Lee and Pituch, behavioral intention is

**Figure 1. E-learning acceptance model (Lee & Pituch [21])**

interpreted as the strength of one's intention to use an e-learning system either as a supplementary tool for a face-to-face class or as an entire on-line distance education method. Based upon Davis et al. [10], perceived usefulness is interpreted as the prospective learner's subjective probability that using an e-learning system will increase his or her learning performance. Perceived ease of use is interpreted as the degree to which the prospective learner expects the e-learning system to be free of effort.

In addition, Lee and Pituch [21] hypothesized that e-learning acceptance was related to three system factors and two learner characteristics. The system characteristics are defined as follows. System functionality (SF) is a learner's opinion or perception of system functions related to learning and relative advantage as to time and place in learning. Relative advantage, according to Rogers [27, p.212], is "the degree to which an innovation is perceived as being better than the idea it supersedes." System interactivity (SI) is a learner's opinion or perception of the e-learning system's ability in enabling interactions between teacher and students, and among students themselves. System response (SR) is the degree to which a learner perceives whether the system response is fast/slow, consistent, and reasonable in requesting a system service [2]. For the learner characteristics, self-efficacy (SE), based on [7], is defined as one's self-confidence in his or her ability to perform certain learning tasks using an e-learning system. Internet experience (IE) is the extent to which a prospective learner uses the Internet [28].

## 2.2 The Role of Gender

Associations between gender and technology have been reported. An early example of gender differences in technology adoption was telephone use, where women's use of the telephone for socialization purposes helped expand this usage in both residential and business areas [22]. Hopkins [18, p.3] encouraged others to study gender differences, stating, "A significant part of the study of technology and gender is the study of how new technologies are evaluated through the lens of an existing gender system."

Gender differences have also been found with other technology adoption. For example, "computational reticence" [33, p.365] is the resistance to become emotionally and socially involved with computers. It explained women's initially less frequent use of computers. In addition, men and women tend to view the world differently. Men tend to see the real world as a hierarchical structure whereas women tend to view it as an interconnected web of people [16]. From this perspective, computer and communication technology might affect men and women differently because of the different communication patterns adopted. Also, gender is one of the physiological factors influencing knowledge acquisition. For example, men are inclined to be competitive and aggressive and may respond better to competitive games [17]. In addition, a study of knowledge workers in the airline industry found that women and men differed in their beliefs of usefulness and ease of use but not actual use of e-mail [13]. That study also suggested that researchers should include gender in IT adoption models. Another study investigating gender differences in adopting new software systems found that men's technology acceptance was more strongly affected by their perception of usefulness, while women were more strongly influenced by perceptions of ease of use and subjective norms [34].

The e-learning acceptance model (as shown in Figure 1) has been validated in prior research. It provides a sound framework for further exploration of gender differences in technology adoption. In addition, reviewing the literature suggests that construct means and some of the relationships in the model may vary for males and females. Therefore, the focus of the research is on exploring how these groups may differ regarding e-learning acceptance and its determinants.

## 3. Methodology

For this study, data collected from previous research [21] were examined for gender differences. In brief, participants in the study consisted of postsecondary students enrolled in computer classes at a college in

Taiwan. Students were given a 40-minute live demonstration of an e-learning system and 30 minutes to individually practice with it. The e-learning system used is the Cyber University at National Sun Yat-Sen University, Taiwan. It provides Internet users with a guest account. A total of 259 surveys were collected from participants in the demonstration and practice phases. Respondents were relatively balanced between sexes (male 41.7%, female 58.3%) and educational divisions (traditional students 55.2%, non-traditional students 44.8%). The survey instrument that was used in [21] is shown in Appendix 1. Seven-point Likert-type scales were used to measure learners' agreement/ disagreement level for usefulness, ease of use, behavioral intentions, system functionality, system interactivity, and system response. The same scales were used to measure learners' confidence in using the technology as well as the extent to which learners had previously used the Internet. Learners' demographic data were also collected. To address research question 1, separate *t*-tests were used to examine gender differences in the composite means of all nine factors. For research question 2, multi-group Structural Equation Modeling (SEM) [4] [20] [31] with LISREL 8.50 was used to identify the moderating effects of gender on the research model (as shown in Figure 1).

A multi-group SEM is "an SEM extension that permits the comparison of models over multiple populations or groups" [31, p.219]. The main focus of a multi-group analysis is to identify differences in path coefficients between groups [20]. Prior to testing a multi-group path model, researchers typically test the equality of factor structures of the measurement model across groups [19]. In this study, such a factor-loading invariance model was tested by examining the difference in model fit as reflected by chi-square statistics for two opposing confirmatory factor analysis (CFA) models: one with the factor loadings constrained to be the same across groups and the other without such constraints. Second, a test of invariance of the model paths was conducted by constraining the paths to be the same across both groups [4] [20]. Model fit indices were examined. In addition, modification indices were also examined to determine which path, if estimated separately for each group, would result in a significant chi-square decrease reflecting an improvement in model fit. Models were re-specified accordingly and tested. The procedure continued until there were no more modification indices indicating possible improvement in model fit. Covariance matrices for both male and female groups were used as input data for the multi-group SEM. For sample size considerations, researchers using the SEM approach have recommended various minimum sample sizes. A minimum of 100 has been suggested [3]. In addition, the average sample size for MIS studies using LISREL was 249 (minimum 41, maximum 451) [15]. Therefore, the sample size of 108 men and 151 women in this study was considered adequate.

#### 4. Research Findings

As shown in Table 1, male learners had higher mean scores than female learners for each of the nine constructs associated with learners' behavioral intentions to use e-learning. Using an alpha level of .05, significant differences favoring males were found for the constructs perceived usefulness, perceived ease of use, system interactivity, self-efficacy, and Internet experience. With the Bonferroni approach, where .05 was divided by the number of tests (9) or .006, to adjust the significance level to minimize the chances of making a Type I error, male learners had significantly higher means in perceived usefulness, perceived ease of use, self-efficacy, and Internet experience than female learners.

**Table 1. Differences in factor means based on gender**

Factors	Male		Female		<i>t</i> value	Prob.
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>		
PU	5.14	1.03	4.78	0.91	2.996	.003**

SR	4.89	1.09	4.73	0.92	1.303	.194
SE	5.01	1.21	4.49	1.07	3.666	.000**
IE	5.39	1.32	4.90	1.21	3.087	.002**

Note. *N* = 108 for male, 151 for female, *df* = 257 for each factor.  
\* *p* < .05. \*\* *p* < .006 using Bonferroni approach.

A multi-group SEM was conducted to compare the structural equation model over male and female learners. The purpose of this analysis was to identify if gender moderated any of the relationships in the model used to predict learners' behavioral intentions to use e-learning. Prior to testing the differences in path estimates between males and females, measurement models were tested for each group separately. Table 2 shows that the measurement models (single group CFA) for both females and males had adequate model fit. In addition, examining the difference in fit between a baseline model that allowed all factor loadings to vary across the two groups and a factor loading invariance model that constrained the factor loadings to be the same for males and females provides support for the more restrictive model. As presented in Table 2, the difference in the fit of these models is not statistically significant,  $\chi^2_{\text{difference}}(41, N = 259) = 54.29, p > .05$ . In addition, since the overall fit indicators provide support for the invariant factor loading model, this measurement model was used to test the difference in the relationships among constructs for males and females.

Following the establishment of a common measurement model, a series of multi-group SEMs were performed. As suggested by [4] [20], the first model specified that the structural paths, reflecting the relationships among the constructs, were the same for males and females. The analysis of this model indicated an acceptable model fit,  $\chi^2/df = 1.43, CFI = .957, NNFI = .951$ . However, the modification indices indicated that the chi-square would decrease 3.88 if the path from SE to

**Table 2. Test results of multi-group SEMs based on gender**

Model	<i>N</i>	$\chi^2$	<i>df</i>	$\chi^2/df$	$\chi^2_{diff}$	<i>df</i> <sub>diff</sub>	CFI	NNFI
				< 3.0 <sup>a</sup>			> .90 <sup>a</sup>	> .90 <sup>a</sup>
Single Group CFA								
Female	151	311.13*	216	1.44			0.962	0.952
Male	108	316.76*	216	1.47			0.956	0.944
Multiple Group CFA								
Baseline (no constraints)	259	627.89*	432	1.45			0.959	0.948

1. Paths Invariance	259	687.67*	480	1.43			0.957	0.951
2. Free SE->PU	259	683.72*	479	1.43	3.95*	1	0.958	0.951
3. Free SI->IU2	259	679.74*	478	1.42	3.98*	1	0.958	0.952

<sup>a</sup> Recommended values. \* *p* < .05.

PU were estimated separately for each group. A model allowing for this relationship to differ across groups was then specified accordingly and tested. The fit of this model was acceptable,  $\chi^2/df = 1.43$ , CFI = .958, NNFI = .951, and had better fit than the initial model,  $\chi^2_{difference} (1, N = 259) = 3.95$ , *p* < .05. The modification indices for this second model also suggested that the chi-square would decrease 3.90 if the path from SI to IU2 were estimated separately for each group. This third model was specified accordingly and tested. The fit of this model was also acceptable,  $\chi^2/df = 1.42$ , CFI = .958, NNFI = .952, and had better fit than the second model,  $\chi^2_{difference} (1, N = 259) = 3.98$ , *p* < .05. For this third model, a modification index of 4.94 was obtained for freeing the estimation of the path from IU2 to IU1. Since the link was not in the hypothesized model, it was not considered. No other modification indices (the largest was 3.246) indicated that any further improvement in model fit could be achieved by freeing estimation of other paths.

The moderating effects of gender on the relationships in the path model are presented in Table 3. The standardized direct effects found to be the same across gender groups are shown in the common metric column. The values shown in the female and male columns are the standardized path coefficients estimated separately for each group. In particular, system interactivity influenced behavioral intention to use the IT as a distance education method for females (0.213, significant) but not for males (0.042, insignificant). Self-efficacy negatively influenced the perception of usefulness for females (-0.199,

significant) but not for males (0.013, insignificant). The results of multi-group SEMs for gender are illustrated in Figure 2.

## 5. Discussion

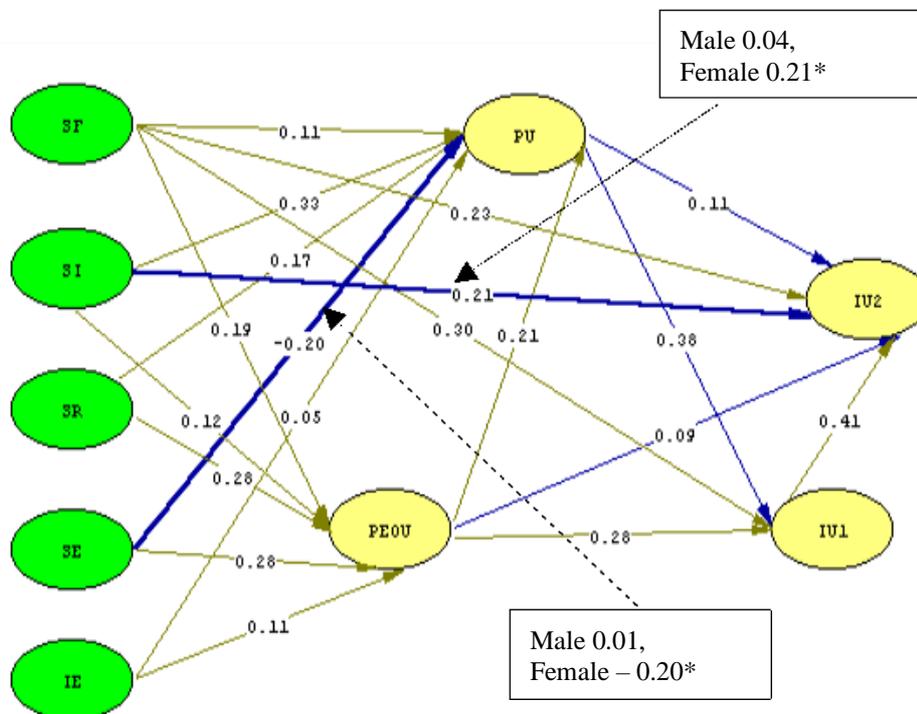

The results of this study indicated that, with regard to e-learning, male learners had more confidence in using the technology, more Internet experience, a higher perception of system interactivity, and higher beliefs of technology usefulness and ease of use. These results are consistent with prior studies [8] [24] [26] [35]. For example, males were found to have significantly higher computer self-efficacy [24]. Females, on the other hand, were found to have significantly less positive attitudes/opinions towards computing than males [8] [26] [35]. In a recent study investigating gender differences in individual adoption of technology, the respective composite means of perceived usefulness, perceived ease of use, and behavioral intention for men were all higher than women's at three different stages (post training, after one month, and after three months), although the difference of perceived usefulness in the post training stage was insignificant [34]. The results of this study as presented in Figure 3 are in accord with those prior studies. Yet one prior research investigating gender differences in e-mail use presented mixed results: men had a significantly higher perception of ease of use than women, but had an opposite results for perceived usefulness [13].

Examining the differences in construct means through

**Table 3. The moderating effects of gender on the research model**

Outcome	Determinant	Standardized Direct Effects		
		Metric	Female	Male
Perceived Ease of Use	System Functionality	0.187*		
	System Interactivity	0.125		
	System Response	0.276*		
	Self-efficacy	0.277*		
	Internet Experience	0.110		
Perceived Usefulness	Perceived Ease of Use	0.215*		
	System Functionality	0.114*		
	System Interactivity	0.334*		
	System Response	0.171		
	Self-efficacy		-0.199*	0.013
	Internet Experience	0.086		
Intention to Use 1 (Supplementary tool)	Perceived Usefulness	0.379*		
	Perceived Ease of Use	0.276*		
	System Functionality	0.304*		
Intention to Use 2 (Distance Education)	Intention to Use 1	0.405*		
	Perceived Usefulness	0.110		
	Perceived Ease of Use	0.090		
	System Functionality	0.234*		
	System Interactivity		0.213*	0.042

Note. N = 259. \* p < .05.

**Figure 2. Multi-group SEM results for male and female learners**

the path model of this study (SE -> PEOU -> PU -> IU1 -> IU2) indicated that gender differences were large for self-efficacy but decreased on the path to IU2 as shown in Figure 3. The p-value for the t-test of these mean differences increased from less than .001 (significant) to a .275 (insignificant). These results are consistent with the finding that gender differences occur in the “the initial expectations for performance” [12, p.106] [13].

In addition, gender showed a moderating effect on some of the relationships in the path model. The relationships in the path model were the same for both female and male learners except for two paths. First, the direct effect of system interactivity on intention to use IT for distance education was present for females but not for males. In other words, system interactivity was more important to female than male learners in determining intention to use the IT for distance education. Considering the many-to-many communications provided by the Web-based learning technology, it enables the networking approach of communication pattern apparently preferred by female learners and, therefore, seems to be more important for females than males. This finding is consistent with the notion as stated by [13] that women tend to adopt a networking approach, using discourse to achieve intimacy, support, consensus, and rapport [30], whereas men tend to adopt a communication pattern based on social hierarchy [29]. These two communication patterns appear to have different implications to learners’ intentions to use the e-learning system.

Second, self-efficacy significantly impacted perceived usefulness for females in a negative direction. This suggests that females with more confidence in using the technology have weaker beliefs in the technology’s usefulness. One possible explanation for this counterintuitive finding is that female learners who have relatively lower initial confidence in using a new technology may be overwhelmed after a brief exposure to the technology and, as a result, may have overly high expectations of its usefulness. On the other hand, females

having a higher confidence level may perceive that the system is not that useful. This phenomenon needs to be further investigated.

In addition, study results indicated that the relationship between perceived usefulness and behavioral intentions were the same for men and women, and the relationship between perceived ease of use and behavioral intentions also did not differ for men and women. Therefore, the findings [34] that men’s adoption decisions were more strongly influenced by their perceptions of usefulness, and women’s were more strongly influenced by perceptions of ease of use, were not supported.

## 6. Conclusions

Theoretically, this study further identifies some of the differences in the perceptions of technology acceptance and differences in the relationships between predictors of this acceptance for males and females. Although male learners have significantly more confidence in using the technology, more Internet experience, a higher perception of system interactivity, and higher beliefs of usefulness and ease of use than female learners, there is no significant difference in their intentions to use the e-learning system. In addition, gender has moderating effects on the relationships between the hypothesized determinants and intentions to use the e-learning system. In particular, women’s adoption intention for distance education purposes is more strongly influenced by system interactivity. Women’ perception of e-learning usefulness is negatively influenced by self-efficacy.

For practical purposes, the results of this study may be beneficial to educators and corporate trainers. The findings in this study suggest that specific factors may be targeted to enhance IT use among the groups. For example, special emphasis can be placed on improving system interactivity in order to elevate female learners’ intention to use the e-learning system for distance education.

## 7. Appendices

### Appendix 1: Operationalization of Constructs

Constructs	Questions	References
Perceived Usefulness (PU)	Using the Web-based learning system will allow me to accomplish learning tasks more quickly. Using the Web-based learning system will improve my learning performance. Using the Web-based learning system will make it easier to learn course contents. Using the Web-based learning system will increase my learning productivity. Using the Web-based learning system will enhance my effectiveness in learning.	[9][14]
Perceived Ease of Use (PEOU)	Learning to operate the Web-based learning system is easy for me. It is easy for me to become skillful at using the Web-based learning system. I find the Web-based learning system easy to use.	[9][14]
Intention to Use (IU1)	<b>The Web-based learning system as a supplementary course tool:</b> I will always try to use the Web-based learning system to do a learning task whenever it has a feature to help me perform it. I will always try to use the Web-based learning system in as many cases/occasions as possible.	[5][11]
(IU2)	<b>The Web-based learning system as an entire distance education method:</b> I intend to take this course and always try to use the Web-based learning system to do a learning task whenever it has a feature to help me perform it. I plan to take this course and always try to use the Web-based learning system in as many cases/occasions as possible.	
System Functionality (SF)	The Web-based learning system offers flexibility in learning as to time and place. The Web-based learning system offers multimedia (audio, video, and text) types of course contents.	
System Interactivity (SI)	The Web-based learning system enables interactive communications between instructor and students. The Web-based learning system enables interactive communications among students.	
System Response (SR)	When you are using the Web-based learning system, system response is fast. In general, the response time of the Web-based learning system is consistent. In general, the response time of the Web-based learning system is reasonable.	[2]
Self Efficacy (SE)	<b>I am confident of using the Web-based learning system ...</b> Even if there is no one around to show me how to do it. Even if I have only the online instructions for reference.	[7][28]
Internet Experience (IE)	<b>Please indicate the extent to which you use the Internet to perform the following tasks:</b> Gathering information Communication (e.g. email, chat) Downloading free software	[28]

# The E-Commerce Application Experience in Selected Asian MBA Programmes

Kin-Yu Cheung     Ping Zhao

School of Economics and Management  
Tsinghua University, Beijing, China  
on926309@netvigator.com

## Abstracts

The objectives of the paper are: (1) to analyse the effects of changing towards a knowledge economy and the development of MBA programmes in selected Asian countries, including Singapore, Malaysia, Hong Kong, China and Taiwan, China; (2) to study how e-commerce applications can be applied to MBA programme studies; (3) to find out what kinds of competitiveness are derived from MBA education with e-commerce facilities; and (4) to conclude lessons learnt from applying e-commerce technology into MBA programmes.

A stakeholders approach has been used to conduct a primary research and a secondary research during the period between April and May 2002. 107 were interviewed, and 174 questionnaires returned.

E-commerce technology has positively affected the rapid growth of MBA programmes, particularly distance learning and online programmes. An e-commerce education model can help to better understand how we can utilize the concepts of supply chain and e-commerce technology in MBA programmes. The supply chain of distance learning and online MBA programmes rely heavily on e-commerce technology. In full-time, part-time, and distance learning MBA programmes, teachers required students to access information from the Internet. Many MBA courses must have university technical support to be successful.

Globalisation of MBA programmes cannot be successful without e-commerce technology. This globalisation knowledge will give MBA graduates a competitive advantage after graduation. In the design of MBA curriculum, teachers must have some knowledge about the technical aspects of e-commerce. In MBA education, speed of information is crucial to students and teachers, and will change their needs and wants.

Online distance learning MBA programme is still unpopular. The combination mode of teaching is dominating the trend in distance learning MBA education. Government regulations on e-commerce can affect information flow, and adversely affect the development of MBA programmes. Security of information is always a concern of the users.

## 1. Introduction

### 1.1 MBA education

The knowledge economy trend worldwide has increased the importance of MBA education where the

practical general management education can adapt more to the real world situation through continuous e-commerce applications. About five years ago, some universities offered more specialised MBA programmes; e.g. The Curtin University of Technology in Australia. However, most leading business schools still only offer the general MBA programme. The Stanford MBA Program is a general management degree. Because of that, you will not be required to specialized in one area, such as finance or marketing, but rather you'll build a program that suits your professional and personal goals.<sup>1</sup>

### 1.2 MBA courses increased globalisation trend

Many business schools recognize the growing importance of globalisation, and pioneer into providing MBA courses that relate to it, e.g. INSEAD. The principal objective of the INSEAD MBA is to provide a solid foundation for your future in general management in a constantly changing global business environment.<sup>2</sup>

To achieve the globalisation objective, some MBA programmes require students to take e-commerce related courses to their core subjects. Tuck School of Business is a good example. Others will encourage students to take international or global related courses that will eventually become a certificate. In the Berkeley MBA programme, students can earn a "Certificate in Global Management". Requirements for the certificate fall into three areas: overseas experience, courses with international content, and language requirement.<sup>3</sup>

### 1.3 MBA education as a tool to build personal competitive advantage

In the past 20 years, there was a clear shift from an industrial organization economics structure conduct performance paradigm to a competence-based competition.<sup>4</sup> Many MBA programmes' designs have shifted to teach courses that relate to generate or improve the competitive advantages of the MBA students. Examples include e-commerce specialization courses,

<sup>1</sup> Stanford MBA brochure, 2002, p3.

<sup>2</sup> INSEAD MBA brochure, 2002, p4.

<sup>3</sup> The Berkeley MBA, Full-Time MBA Program 2002.

<sup>4</sup> Howard Thomas and Timothy Pollock, From I-O Economics' S-C-P Paradigm Through Strategic Groups to Competence-Based Competition: Reflections on the Puzzle of competitive Strategy, British Journal of Management, 1999, Vol. 10, pp127-140.

global concentrations and entrepreneurial electives. In selecting an MBA programme, many potential MBA students actually place great emphasis on what kinds of competitive edge they can derive after graduation.

## 2. The Study Objectives of the Research Paper

### 2.1 Background

In the past 20 years, there were many MBA programmes in various Asian countries, e.g. in Hong Kong, China, Singapore, and Thailand. Most model the American or English MBA programmes, whether full-time, part-time, or distance learning. These MBA programmes help to train international executives with a globalised view and with good personal competitive advantages. There is a need to understand more about various MBA programmes in Asia. Researches into Asian MBA programmes are limited; and Asian regional comparisons, extremely limited.

### 2.2 The objectives

The objectives of the research paper are:-

- (1) to analyse the effects of changing towards a knowledge economy and the development of MBA programmes in selected Asian countries, including Singapore; Malaysia; Hong Kong, China; and Taiwan, China;
- (2) to study how e-commerce applications can be applied to MBA programme studies;
- (3) to find out what kinds of competitiveness are derived from MBA education with e-commerce facilities; and
- (4) to conclude lessons learnt from applying e-commerce technology into MBA programmes and to look ahead challenges facing MBA business schools in the immediate future.

### 2.3 The Approach

To ensure a complete view about the study, a stakeholder analysis will be used. Interest parties related to MBA programmes will be studied.

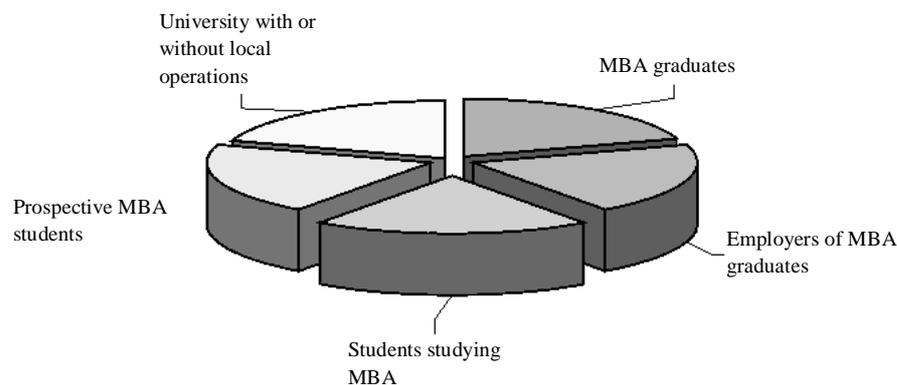

Figure 1: Stakeholder analysis of MBA programmes

The study was conducted in two parts, namely primary and secondary researches during the period between April and May 2002. The data of the primary research was obtained through interviews and returned questionnaires from various MBA stakeholders including university MBA teachers/administrators, local or regional MBA operators, students studying MBA, prospective MBA students, MBA graduates and MBA employers. 107 were interviewed, and 174 questionnaires returned. The secondary research data was collated from various university's MBA brochures, catalogues, facilities, and local and international advertisements.

### 2.4 The limitations

MBA education research is a big research area. Due to limitation in time and personnel, only a very small part of the area is being studied. The findings might not be fully representative of the actual situation. However, it was an introduction into the subject matter. A summary of the responses was outlined below.

	Interviewed	Target	Actual	% Target
1	University offering MBA programmes - Teaching staff	15	12	80%
2	Operators of distance learning MBA programmes - Owners/senior staff of local/regional operators - Administrative staff of local/regional operator	5 5	4 4	80% 80%
3	MBA students - Full-time/part-time - Distance learning	30 20	27 18	90% 90%
4	MBA graduates - Full-time/part-time - Distance learning	20 10	14 7	70% 70%
5	Potential MBA students - Full-time/part-time - Distance learning	10 10	7 8	70% 80%
6	External stakeholders - Employers of MBA students	10	6	60%
	Total	135	107	79%
1	MBA students - Full-time/part-time - Distance learning	150 60	68 41	45% 68%
2	MBA graduates - Full-time/part-time - Distance learning	100 50	36 29	36% 58%
	Total	360	174	48%

The response rate of the primary research was satisfactory; 79% for the interviews; and 48%, for the questionnaires. There were two reasons. First, K Y Cheung had been teaching both full-time, part-time and distance learning MBA programmes for over six years in the Asia Pacific area. Many respondents knew K Y Cheung personally. Second, most of the respondents were used to researches, and welcomed the opportunities to express their views.

## 2.5 The Methodology

### 2.5.1 Interviews

Specific guidelines were given to the interviewers prior to interviewing the target population. Also, all interviewers, total three persons, including K Y Cheung had to attend a 2-hour training session about skills of interviewing, understanding the questionnaires, and how to answer questions raised by the interviewees.

An interview time was around 30 minutes, in a quiet seated environment. The major problem was the interviewees found it difficult to compare various MBA programmes, particular full-time/part-time and distance learning MBA programmes. As a result, we brought along many MBA programmes brochures to assist them in recognizing various MBA programmes. This proved extremely useful.

### 2.5.2 Questionnaires

We designed six types of questionnaires, with both selective and open-ended questions. These included:

- (1) Questionnaire for university MBA programmes teachers/administrators;
- (2) Questionnaire for local or regional operators of distance learning MBA programmes;
- (3) Questionnaire for students studying an MBA programme;
- (4) Questionnaire for MBA graduates;
- (5) Questionnaire for potential students wishing to study an MBA programme, and
- (6) Questionnaires for employers of MBA graduates.

### 2.5.3 Secondary data

Secondary data were mainly collected by reviewing past related literature, by desk researches on magazines and newspapers from USA, UK, Australia, Singapore, and China, including Hong Kong, Beijing and Taiwan. A list of the secondary data was given in Appendix 1. Web sites from the Internet related to the subjects were outlined in Appendix 2.

## 3. The Findings from the Original Research

### 3.1 The MBA Supply Chain Model

#### 3.1.1 The MBA Supply Chain Model

Figure 1 illustrates what constitutes the “MBA Supply Chain Model”. It starts from the supplier, the universities, with or without strategically allied with local

or regional operators to reach the potential students and ended at the employers of MBA graduates.

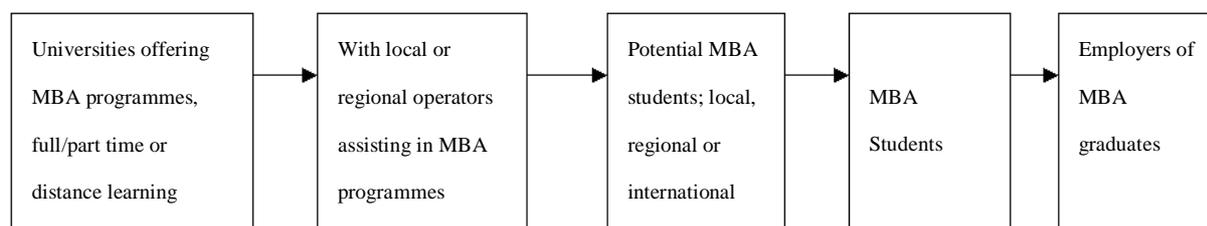

Figure 1: The MBA Supply Chain Model, with local or regional operators

The aim of setting up an MBA Supply Chain Model is to help analyzed where problems occur whilst applying various e-commerce techniques. It pinpoints problems areas, and gives quick answers to questions, where users are generally very time conscious. Also, in case of a breakdown in the system, solutions can be assessed and prioritized.

Each individual member of the MBA Supply Chain can solely determine how various techniques of e-commerce can be applied, as each designs and operates their own e-commerce system. For example, a university can target to have its enrolment procedure 75% electronically processed. Obviously, many of the related administrative work must backup with such an objective.

As there is no control over the degree of specialization and technical advancement in the e-commerce techniques throughout the MBA Supply Chain, often delays and technical problems occur. However, it would up to the individual member within the MBA Supply Chain to solve its own problems. Good co-ordination work among various members of the MBA Supply Chain thus becomes an integral part of operation, if they want an efficient system. This is particularly true for distance learning MBA programmes, where distance is a problem, time zone changes and students' culture varies.

## 3.2 MBA Programmes and E-commerce Techniques

### 3.2.1 Common types of e-commerce techniques

All the interviewed university teachers/administrators of MBA programmes confirmed that their programmes used various e-commerce techniques. The most common types of techniques are:

- (1) EDI for information processing and transmission;
- (2) Own web site/page for information building and dissemination;
- (3) Internet for search of information, particularly for assignments;

- (4) Inter-library information sharing; and
- (5) E-mail for communications.

E-commerce techniques were both important to full/part time and distance learning programmes. Over 90% of the interviewed university teachers now spent over one-third of their time on various e-commerce techniques. Sending, reading and answering e-mails topped their list. For university administrative staff and operators of distance learning programmes, the usage of e-commerce techniques were even higher, 65% of their working time. Same as university teachers, e-mail matters were the most time consuming for university administrators.

### 3.2.2 How e-commerce techniques help increase MBA programmes opportunities?

#### 3.2.2.1 The Opportunities

E-commerce techniques had made it possible for universities to expand their MBA programmes. This was particularly true in UK and Australian MBA business schools interviewed. 75% of the university teachers interviewed admitted that e-commerce techniques had directed helped in creating more MBA programmes, particularly distance learning and online programmes. A university's major consideration in providing more MBA programmes was the costs in administering and developing MBA programmes, whether local or overseas. Different e-commerce techniques had helped to reduce developing and running MBA programmes costs substantially, some even by 80%.

#### 3.2.2.2 Distance learning MBA programmes

A university could either offer a distance learning MBA programme by themselves or in collaboration with local or regional operators. The University of Western Ontario offered their MBA programme in Hong Kong by themselves. In contrast, the University of South Australia offered their MBA programme in Singapore in collaboration with the Asia Pacific Management Institute. With the aid of various e-commerce techniques, distance learning programmes were able to recruit students online,

liaise with students on a regular communication channel, and provide course materials where necessary. Warwick University in UK was one of the pioneers of distance learning MBA programmes with the aids of e-commerce techniques. As a participant on the Warwick MBA by distance learning, you will be required to have Internet access and an email address. We use these technologies extensively for both the academic and the administrative delivery of the programme.<sup>5</sup>

To be successful in distance learning MBA programmes, many universities and local/regional operators held regular video-conferences between students and the universities. These are particularly important before handing in of assignments and prior to examinations. Many overseas students found it necessary to talk direct to the MBA faculty, but without a formal communication channel. Face to face online video-conferences are good use of e-commerce techniques. The University of South Australia used this method for their MBA programmes in Singapore, Malaysia, Hong Kong, China and Taiwan, China.

### 3.2.2.3 Online MBA programmes

With good e-commerce technical backup, many universities pioneered into online MBA programmes. The City University of Hong Kong was a good example. Obviously using various e-commerce techniques were key to success. Although online MBA programmes were still not very common around the world, eventually it would gain importance.

### 3.2.2.4 Full/Part time MBA programmes

Many MBA programmes now introduced in their full and part time MBA curriculum, new courses related to e-commerce. The National Taiwan University MBA programmes had electives in e-commerce, multi-media and networking. Some business schools even pushed the emphasis further to form an e-commerce specialization. Nanyang Business School of the Nanyang Technological University in Singapore was a good example. The specialization focuses on developments in the Internet economy to equip both IT and non IT professionals with conceptual, applied and leadership skills needed for key positions in today's high-tech companies which position the Internet as a strategic resource. Besides learning how to build new Internet companies, participants will also acquire a multi-dimensional perspective in transforming traditional companies into modern e-commerce organizations.<sup>6</sup>

### 3.2.3 The intensity in using various e-commerce techniques

---

<sup>5</sup> Learning Online, Warwick MBA by distance Learning, Warwick Business School, 2002, p 11.

<sup>6</sup> 2002 The Nanyang MBA, Nanyang Business School, Nanyang Technological University, Singapore, p 20.

From the study, MBA students used various e-commerce techniques most. The administrative matters of the MBA programme, the assignments to search information from the Internet, the liaison with fellow students and university teachers, all are via the Internet or the university's intranet, by e-mail or through EDI. For an MBA student, this might be the cheapest, most effective, and highly efficient way of studying. MBA students interviewed and questioned spent over four hours with the computer every day. Even if they were not busy, they still spent two hours per day on various e-commerce techniques, from e-mail to ICQ.

MBA teachers interviewed came second in e-commerce techniques usage, followed by administrative staff. There would be increasing demands for MBA teachers to fully understand, apply and utilize various e-commerce techniques in their teaching and research work.

### 3.2.4 Regional comparison in e-commerce techniques usage

In the study, Hong Kong, China MBA students used various e-commerce techniques most. One of the reasons might be the MBA students interviewed all had their own personal computers. Another interesting finding was on average a Hong Kong, China MBA student had 1.35 computer to use, including their own personal computer. This also suggested that availability of computers was crucial to e-commerce techniques usage. According to the findings of the study, Taiwan, China student came second in e-commerce techniques usage followed by Singaporean and Malaysian MBA students. Another interesting finding was over 80% of the MBA students interviewed used both English and Chinese languages in their computers. We could foresee that multi-languages would become popular in future e-commerce applications.

## 3.3. E-commerce Applications in MBA Programmes

### 3.3.1 Definition

MBA programmes having e-commerce application means during the process of providing MBA education, e-commerce techniques are applied to enhance the supply chain process, e.g. information flow of the MBA programmes. The most important e-commerce techniques encompass electronic data interchange (EDI) systems, value-added networks (VAN), the Internet, hypertext links, web-based technology and security issues.

### 3.3.2 Common e-commerce applications in MBA programmes

From the research findings, we understand that e-commerce applications in MBA programmes are

commonly found in three major areas, namely

- (1) in administration, whether university or local /regional operators;
- (2) in MBA teaching/learning between teachers and students and among students, and
- (3) in the provisions of a secure web-based environment, whether the university's web site/page or the Internet..

### 3.3.2.1 In MBA administration

#### 3.3.2.1.1 University MBA programme administration

To ensure that the programme administration was efficient, different e-commerce applications were introduced. Many MBA programmes constructed their own web sites and hyper-linked with their university main web site. The Melbourne Business School had their own web site, [www.mbs.unimelb.edu.au](http://www.mbs.unimelb.edu.au). This was the easiest method potential MBA students could obtain information from an MBA programme.

All the MBA teachers interviewed admitted that having their own web site/page was the best way to attract potential students, particularly regional and international students, where distance is a problem. Many provide instant email reply services whereby potential students could ask or request for information online, e.g. request for an MBA brochure or an application form. The University of Malaya was a good example.

Other applications included the creation and maintenance of data banks about potential MBA students. Relevant MBA admission materials could be sent to potential MBA students on time and regularly. This actually helped to promote the image of the MBA programme and directly assisted in finding the best students for the business schools. From the study, it was interesting to know that 72% of the potential MBA students actually enquire about an MBA programme via the Internet. 24% actually enrolled on the Internet. Over 90% of the MBA programme admissions staff expected this trend to increase substantially in the immediate future. How to build good web sites/pages and to maintain them became concerns of many business schools, as this would be one of the most popular media for MBA students to find information about their courses.

#### 3.3.2.1.2 Local and regional operators

Local and regional operators who act as an in between for university offering MBA programmes and MBA students used e-commerce applications most. One of the major functions of the operators was to quickly inform university MBA programmes about the feedback of their students. This was particularly important to distance learning MBA programmes. For example, the Hartford Group of Institutions claimed their "MyElearningPortal" was the only online educational platform in Asia to

effectively provide up-to-date information and services for their currently enrolled student's to access their programme information online. Originally, students were encouraged to e-mail the questions to the operators, then onward to the relevant university staff, whether administration or teaching. Now, many universities face students direct, particularly on course questions.

Over 50% of the operators interviewed admitted that their work had been more administrative, as compared with 2-3 years ago. They usually organized video-conferencing meetings on a regular basis, collected assignments before deadline, placed advertisement after approval from MBA programmes, and provided local admission services. Some operators like Global Education also maintained a chat room, whereby students could freely expressed their views. Comments from these chat rooms could be used to improve future administration efficiency.

To ensure quick response with potential and studying MBA students, operators maintained a web site with email address where they could answer queries immediately, e.g. the Informatics Group in Singapore. All operators interviewed claimed that they could handle requests, e.g. application forms, immediately. Potential MBA students could download the information instantly from their web sites.

### 3.3.2.2 In MBA teaching and learning

#### 3.3.2.2.1 MBA teaching

All of the MBA teachers interviewed agreed that e-commerce applications had upgraded the quality of teaching. With a web-based environment, teachers could prepare more up-to-date information for students. The costs for collecting and collating teaching materials were reduced substantially, especially when an electronic library was available. Students could access to reading materials, journals and research work on a 24-hour time frame, thus better utilizing the student's time. MBA teachers in Hong Kong, China particularly liked to put teaching materials on web sites. The Open University of Hong Kong had an electronic library whereby MBA students could link at will.

E-commerce applications could help to enhance the contents of an MBA programme. Teachers could now collect more information via the Internet. During class lectures, demonstration of cases using online Internet technology was a very effective way of teaching. All students interviewed and questionaired regarded the ability to demonstrate a concept online to be a great improvement in teaching. Also for students, seeing was believing. In the study, 75% of the MBA teachers interviewed who taught Marketing courses used many e-commerce applications, some even as much as 30% of the lecture time or more.

In actual MBA course designs, teachers interviewed now

had to consider various types of e-commerce applications in their course curriculum. Some would require students to do presentation work, but with Internet assistance. Others would ask students to collect and collate information from the Internet. All indicated that e-commerce applications were today's trend in MBA course designs. This would be particularly true for MBA programmes that emphasized on recruiting international students and with globalised courses. The University of Singapore MBA programme would be a good example.

Apart from course materials, some MBA teachers allowed their students to hand in their assignments using soft copies. This could be more environmentally friendly, as less paper was involved. This also encouraged the students to use coloured graphics, more appendices and web site references in their assignments. Less administrative work could also be involved. The only drawback could be the argument about whether an assignment had been handed in, if records from the computer could not be traced.

#### 3.3.2.2.2 MBA learning

MBA students benefited most from various e-commerce applications in their study, including lessons preparations, presentations, group work and assignments. If an electronic library facility was available, students could study at will, ignoring the opening and closing hours of a traditional library. In searching for information, the Internet usually had more than enough data for students to collect. How to be selective in data collection would be a skill MBA students had to master. A point of caution was that students had to observe the international copyrights issue when downloading any information. Many universities had strict rules governing the copyrights issues.

Many MBA courses required students to do oral presentations as part of their grading system. The study found that presentation marks could go as high as 40% or more of the course grade. Many students used different computer groupware, e.g. Microsoft Office 2000, in their presentations. Microsoft's PowerPoint was the most commonly used. Together with other software by the same manufacturer, a student could compose a very attractive presentation, with immediate Internet connection, making the presentation very animated and lively. Also, with a coloured screen, the effects and quality of the presentation would automatically be upgraded. Such presentations had become a standard norm in MBA presentations.

Group work was a major characteristic of MBA studying. Students had to liaise with each other on a very regular basis. Emails played the most important role in connecting students, whether living inside or outside the campus. The enclosure of files in emails allowed students to incorporate large amount of data that was not

possible years ago. This helped to prepare large amount of data easily and cheaply. The convenience and low costs encouraged students to search, analyze and use data frequently. The quality of MBA group work had been greatly upgraded. The continual upgrading of transmission speed had directly encouraged the more common usage of various e-commerce applications.

The quality of an MBA assignment had improved tremendously during the past two to three years. Many assignments were liked published works, as the use of coloured diagrams, graphics and enclosures became popular. The settings of the assignments, the quality of printing and the onerous drawing of outstanding diagrams and tables, all showed how e-commerce applications could help to upgrade the quality of an MBA assignment. Students had to master good e-commerce application skills to survive in a very competitive academic environment. This would be particularly true for subjects like Marketing, Economics and Logistics Management where pictures and diagrams helped to express the meanings of theories and concepts. Over 80% of the studying MBA students interviewed and questionnaired admitted that they had to produce high quality coloured assignments.

#### 3.3.2.3 Providing a Secured Intranet System

##### 3.3.2.3.1 Web-based technology

All the university teachers/administrators and local/regional operators interviewed confirmed that they all had their own web sites. The results of the study also indicated that there was an increased risk in web-based electronic commerce. Two universities administrators interviewed said their universities had been victims of information losses. As such, continuously developing and maintaining a high quality secured web-based technology was crucial to the successful development of e-commerce applications in MBA programmes. The limiting factor of most MBA programmes was that they had to be an integral part of their university web site, unless they could afford their own web sites, if approved by their university.

For local and regional operators, they could be more flexible in web sites designs and operation. Installation costs were the major initial concerns. All of the local/regional operators interviewed admitted that ensuring a 24-hour 365-day web-based environment was key to their success, as most of their students would contact them any time of the day, and more frequently after office hours and in holidays. However, this could be a serious problem, if the technological hardware and software between universities and local/regional operators were not commensurable. Also, the level of technical competence of the service providers, local or international, could make a big difference.

##### 3.3.2.3.2 Internet and Intranet Security

Internet and intranet safety had always been a problem in e-commerce applications. Traditional security measures, e.g. firewalls, cryptography and authentication still played the most important role in network protection. Anti-virus operations played a significant role in e-commerce applications like e-mail transmission. As a precaution, some university scanned all incoming and outgoing e-mails as a requirement. As the intranet system would be used by a very huge number of users, e.g. administrators, teachers and students, maintaining a secure system became crucial and difficult.

How to maintain a highly secured intranet system was the major concern of all the people interviewed and questionnaired. Internet security was also extremely important. Protecting the privacy of a user was top priority. Also ensuring 100% of document transmission without being hacked was another priority issue.

### 3.3.2.3.3 Internet and Intranet usage regulations

Depending on locations, different countries had different e-commerce laws. It would be understandable that the control of the Internet would be difficult. Internally, the university's control of its own intranet could be easier. All the university teachers/administrators interviewed confirmed that their universities had guidelines about Internet and intranet usage. Offenders could be easily traced, and disciplinary actions would be taken, if necessary. As such, constant updating of Internet and intranet usage regulations would be necessary to maintain efficient and secured systems.

### 3.3.2.3.4 Operating and maintenance costs

Operating and maintenance costs of the Internet/intranet system were the second major concern of the university teachers/administrators interviewed. University budgets were usually very tight. Constant upgrading of an Internet/intranet system might not be possible, especially when most of the MBA programmes were but part of a university's computer system.

There would be situations where other members of the MBA Supply Chain were technically current; but the source of the MBA Supply Chain, the business schools, lagging behind. This would create many problems, especially when software was not compatible in either old or current systems, e.g. Windows 95 versus Windows 2000. One interesting findings was that all the interviewed or questionnaired remarked they used English and Chinese (either simplified or traditional) as their medium of communication. Microsoft Explorer would be their first choice of the browser, followed by Netscape Navigator.

## 3.4 The Benefits and Problems of Applying E-Commerce Techniques into MBA programmes

### 3.4.1 The benefits

From the research findings, university teachers/administrators remarked the benefits of applying e-commerce techniques into MBA programmes in order of importance are:

- (1) To maintain the image of the business school and the MBA programme,
- (2) To reduce costs substantially,
- (3) To increase the competitiveness of students,
- (4) To provide a regular channel of communication,
- (5) To create programme opportunities, and
- (6) To make their curriculum more globalised and practical.

MBA students interviewed or questionnaired admitted that the most important benefits from their MBA studies were the increase in their personal competitiveness. Globalisation was now the trend. E-commerce techniques and applications were "musts" for executive nowadays. All employers of MBA graduates interviewed considered the e-commerce competitiveness of MBA graduates one of their reasons why they were willing to pay them a higher salary package.

### 3.4.2 Associated costs and problems

#### 3.4.2.1 Associated costs

The benefits from applying e-commerce techniques into MBA programmes had associated costs. First, web sites had to be created, with proper operating and maintenance costs. Second, the opportunity costs involved in ensuring a safe and efficient system were worth considering. Third, future-upgrading costs meant more investments must be allocated. The budget for these costs would become a major concern for all parties in the MBA Supply Chain, as each party would be affected. This would be particularly true for MBA programmes treated as a self-funding project.

#### 3.4.2.2 Related Problems

From the study, the following problems with applying e-commerce techniques into MBA programmes were identified:

- (1) MBA teachers must understand the various e-commerce techniques, and capable of applying them into the curriculum,
- (2) How and who are to ensure that the MBA Supply Chain members had compatible e-commerce application capabilities,
- (3) The technical expertise to backup the hardware and software systems of the Internet/intranet systems of universities and local/regional operators,
- (4) The degree of computerization of the MBA programmes supply and demand countries, and
- (5) The budget situations of different MBA Supply Chain members.

No solutions were found, except that MBA teachers had to self learn to upgrade themselves regularly on various e-commerce techniques and applications to remain competitive. How to solve the abovementioned related problems could be a good future research area.

### 3.4.3 Building MBA student's personal competitiveness

All of the MBA employers interviewed were looking for different competitiveness MBA graduates had acquired. These included good international management giving trained analytical skills; globalised thinking, an ability to handle change; innovation in work process; and entrepreneurial capability. E-commerce applications in MBA programmes had helped to create such competitiveness. Constant exchanges of information and ideas internationally through the Internet made MBA graduates accustomed to the international market. With globalised thinking, the world would be closer together, and more business opportunities.

Over 92% of the students studying MBA programmes interviewed and questioned agreed that e-commerce applications increased their personal competitiveness by giving them the opportunity to create a more practical world and be innovative. The constant involvement in international matters through the Internet made students more accustomed to how to deal with globalised situations and matters. The globalised thinking learning curve effect could be best seen when MBA students

graduated.

The study clearly reviewed that the personal competitiveness of MBA graduates would be a direct result of a carefully designed university's curriculum. From MBA graduates interviewed and questioned, all concluded the course emphasis was key to building their personal competitiveness. These included: (1) trained analytical skills to differentiate their abilities, (2) globalisation understanding to analyse different environmental situations, (3) ability to handle change effectively, (4) entrepreneurial in work attitude, (5) innovative to survive, and (6) networking through their alumni to add value. E-commerce applications in the curriculum played a very major role in building all these competitiveness. We could conclude that e-commerce applications into MBA programmes would be a must for any MBA programme to be highly successful.

## 4. The Findings from Desk Research

### 4.1 Analysis of different MBA brochures in Asia

Many MBA programmes were offered in Asia, including countries like Singapore, Malaysia, Australia, Thailand, Hong Kong, China and Taiwan, China. We had taken 54 MBA programme brochures offered in Asia, and made the following comparisons:-

Comparisons	Australia (Distance learning)	UK (Distance learning)	USA (Distance learning)	Hong Kong, Taiwan, China	Malaysia and Singapore
(1) Coloured brochure	16	12	8	12	6
(2) Introduction about the University and programme	16	12	8	12	6
(3) Clear mission statement	12	10	5	10	4
(4) Building competitive advantage of students	6	8	5	8	3
(5) University and operator information together	10	8	5	4	0
(6) Outline MBA programme structure	16	12	8	12	6
(7) Mention about the research capability of the University	1	1	0	6	2
(8) Entry requirements	16	12	8	12	6
(9) Duration	16	12	8	12	6
(10) Fee schedule	12	5	4	10	3
(11) Application procedure	16	12	8	12	6
(12) Selection procedure	8	7	5	10	3
(13) Rankings by third parties	7	5	0	7	2
(14) Faculty list	6	5	2	5	2
(15) Administrative support	14	10	7	10	5
(16) Academic recognition	12	5	5	12	4
(17) Introducing studying MBA students	0	0	0	6	1
(18) Past student profile	0	0	0	4	1
(19) About graduate employers	2	0	0	0	0
(20) Alumni networking	1	0	0	5	2
Total number of brochures analyzed	16	12	8	12	6

Table 1: An analysis of various MBA brochure

Note: Number inside table is actual counts. The analysis suggested that many of the key selling points of full-time and part-time MBA programmes were not stressed in the brochures. These include acquiring competitive advantage, career services, and alumni networking. Also student profiles were not disclosed.

## 4.2 Review of related MBA literature

There have been very few researches on MBA studies as a research topic. Many business schools do have their perceptions on MBA development, but most of them are confidential and unpublished. Commercial studies on MBAs related mostly to rankings about course evaluations, teacher's background, research capabilities, etc. However, if the business schools chose not to participate in academic and/or commercial assessments, then it would be very hard to compare business schools as a whole.

## 5. Conclusions and Implications of the Research Findings

### 5.1 Conclusions

The conclusions of the research findings were:

- (1) MBA programme in Asia is a rapid growth area, and will continue to grow in the coming decade, especially in countries changing towards a knowledge economy.
- (2) An e-commerce education model can help to better understand how we can utilize the concepts of supply chain and e-commerce technology in MBA programmes.
- (3) E-commerce technology has positively affected the growth of MBA programmes, particularly distance learning and online programmes in selected Asian countries and creates many opportunities worldwide.
- (4) The supply chain of distance learning and online MBA programmes rely heavily on e-commerce technology.
- (5) In full-time, part-time, and distance learning MBA programmes, teachers required students to access information from the Internet. Many MBA courses must have university technical support to be successful.
- (6) Globalisation of MBA programmes cannot be successful without e-commerce technology. Many MBA teachers and students contacts are via the Internet. This globalisation knowledge will give MBA graduates a competitive advantage after graduation
- (7) In the design of MBA curriculum, teachers must have some knowledge about the technical aspects of e-commerce. This can be demanding to some MBA teachers.
- (8) In MBA education, speed of information is crucial to both students and teachers. Information technology will gradually change the needs and wants of both teachers and students.
- (9) Online distance learning MBA programme is still unpopular. The combination mode of teaching is dominating the trend in distance learning MBA education.
- (10) Government regulations on e-commerce can affect information flow, and adversely affect the development of MBA programmes. Security of information is a concern of both teachers and students.

### 5.2 Implications

The conclusions have a number of implications. First, e-commerce technology makes MBA education competition global. Second, understanding the supply chain and local responsiveness in selected Asian countries will affect the design of MBA curriculum. Third, MBA graduates expect their programmes can give them globalisation knowledge to improve their personal competitiveness. Emphasis on an MBA programme will be more global and strategic. Fourth, universities will have to spend more resources on e-commerce technology to remain competitive. This can be a financial burden. Fifth, with plenty of information available through the Internet, teachers need to upgrade themselves at a very quick pace. This can be very demanding to the academic staff. Sixth, development of online distance learning MBA programmes is limited by both hardware facilities and curriculum design. Seventh, different government regulations on e-commerce can affect information flow internationally, and adversely affect MBA development internationally. Finally, Internet security can be a problem in developing distance learning and online MBA programmes.

## 6. A Look Ahead

The MBA programmes in Asia will continue to grow rapidly, e.g. in Singapore and Hong Kong, China, especially when the trend towards a knowledge economy is a natural extension of many economies. The major challenge ahead for business schools in Asia is to design MBA programmes suitable for their local needs in a fast changing technological environment. For countries concentrating on distance learning programmes, the challenge is even more, as both local and regional/international conditions have to be satisfied. More continuous researches into the MBA topic area can help to formulate better strategies for individual Asian business schools searching for their own characteristics; and can create more co-operation among world educators.

## Abstract

The advances in technology today have made the use of the Internet important in almost every discipline. Educators, business people, scientists and those in the criminal justice field all rely on the Internet to help them perform their jobs to the fullest. The Internet is immense and has many uses that can assist student in each discipline. Knowledge of the Internet and the full extent of its capabilities are important to anyone entering the workforce in today's technologically advanced environment. In order to keep their graduates competitive in this environment, it is important that universities offer courses which not only cover the basics of Internet use but also show how the Internet can help them advance and excel no matter which field they enter. The current lack of a course for all students which covers in-depth internet use opposed to the number of fields that utilize the Internet, and the extent to which they use it, exposes the need for a course to better prepare students for the changing environment they will enter after graduation.

## 1. Introduction

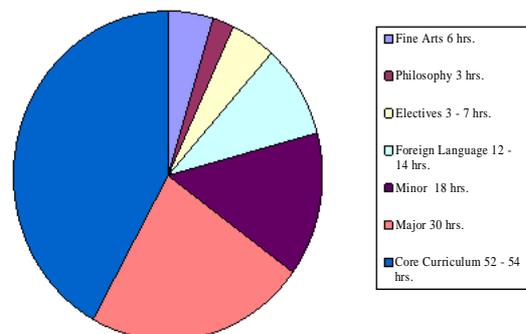

The Internet is "a network of computers interconnected throughout the world operating on a standard protocol that allows data to be transmitted" (Kotabe and Helsen, 2001, 604). The Internet is widely regarded as the greatest invention of the 20<sup>th</sup> century. Since its introduction to the general public in 1990, the Internet has become one of the most widely used tools in many disciplines. The ease of access and amount of information coupled with reduction in prices for both hardware and software has made the Internet invaluable to many professions. Regardless of ones field of study or discipline, the Internet is likely to be used on a regular basis in today's dynamic environment. The Internet is "altering the way companies reach their customers, affecting advertising, shopping, distribution and the way companies communicate with one another and with their staffs" (Cairncross, 1997, 119). Marketing over the Internet is expected to continue to grow, and it is "estimated that even taking into consideration the slowdown of the Internet economy, global business-to-business transactions in 2003 could reach about 6 trillion dollars" (Castells, 2001, 65).

The complexities of this new medium and its growing significance and importance make it especially important

that all university graduates have a full understanding of (which should include not only the opportunities available, but also the limitations and dangers posed by) the Internet. Currently, most US Universities require that all students (irrespective of their major) take a basic computer literacy course (e.g., Introduction to Information Systems, Introduction to Computer Science, Introduction to Library Science, etc.). Most of these courses teach freshman students application software (e.g., Word and Excel), how to send and receive e-mail, and how to use a browser and access the World Wide Web. While a computer literacy course is needed and necessary, such a course only skims the surface of the important and vast uses of the Internet. It is in our opinion that a second mandatory course titled "Introduction to the Internet", which focuses solely on the Internet and related applications (e.g., Intranets and Extranets) would be invaluable to university students pursuing a Bachelor's degree.

The following pie charts show the current breakdown of classes at a state supported institution of higher education (i.e., Sam Houston State University, Huntsville, Texas). The example uses the Bachelor's of Arts degree plan to express the division of hours. While each college may have a slightly different plan of hours, most require the fulfillment of a core, mandatory curriculum, major and minor degree hours and a varying set of electives. This pie chart shows the 128 hours required to graduate as they currently stand (i.e., without an Introduction to the Internet class). The largest section of hours a student takes is clearly the core curriculum, which is intended to give every student, regardless of major, an understanding of each field of study and ability to function in a complete manner in the professional world.

Current Bachelor's of Arts Degree Requirements

Students currently graduating with undergraduate degrees may not have all the skills necessary to be successful in today's competitive environment. Although they have taken the classes designed to make every student competent in a variety of areas, they can be lacking in a field that is quickly growing. Students graduating today must be prepared to utilize the Internet to its full potential. The widespread use of the Internet is quickly placing anyone with only marginal knowledge of its uses at a competitive disadvantage. The creation and utilization of a cross-disciplinary "Introduction to the Internet" class, that every student takes as part of their core curriculum, may help to prepare students better, regardless of their major field of study. The primary purpose of this class would be to introduce all students to the basic principles of the Internet (i.e., posting web pages, validating information downloaded, privacy and security issues, E-commerce transactions, etc.).

In an effort to express the penetration of the Internet into a wide variety of disciplines, the following sections review a few of the uses of the Internet in a selected number of disciplines (i.e., majors) taught at Sam Houston State University. The self-selection of the disciplines was done to provide a representative sample of the types of degrees offered at typical four-year academic institutions in the US. It can be argued that illustrating the importance and uses of the Internet in a selected few disciplines makes it equally important for any student pursuing a degree at a university to be competent in the new technology. The various uses of the Internet by businesses today reflect the need for a required comprehensive course at the university level to prepare students for successful careers. Understanding the various uses of the Internet is also critical from a consumer's perspective so as to make better (more informed) decisions. Next, we will highlight the various applications of the Internet to the following disciplines: Education, Literature, History, Sciences, Criminal Justice, and Business.

## 2. Education and the Internet

The Internet has become a tool used by many educators in classrooms at every level of education (from freshman to post-graduate). College Professors assign online exercises and post their syllabi and course material on their websites. Distance learning courses are offered at most large universities, and some college degrees can now be obtained online with no actual class time required (e.g., University of Phoenix). Educators in grades K-12 are also finding uses for the Internet in their classrooms. Children can communicate with experts and with students in other classes via computers (e.g., <http://www.OnlineClassroom.com>). Even disabled children are able to experience the benefits of the Internet with new advances in software. The Internet is opening up new ways to educate and explore material in and out of classrooms.

All schools, colleges, and Universities have embraced the Internet and use it extensively to maintain a

differential advantage. Almost every University has a web page ([www.shsu.edu](http://www.shsu.edu)), and many offer online classes. Students who work full-time can finish their degrees without having to attend physical classes. University students can also interact with professors through e-mail, virtual chat room, and posting of FAQ on websites. In the 1997-98 school year alone "more than 27,000 college-level courses were delivered over the Internet" (Woolf and Lesser, 2002, 2). Universities that do have actual classes, which meet often, assign research that requires the use of the Internet. Many professors post their class assignments on their personal web pages.

Educators in grades K-12 often use the Internet as more of a teaching tool. Recently a "study by Interactive Education Systems Design found that over 40 percent of high schools already offer online courses or plan to during this year" (CyberAtlas, 2002). Web sites offer lesson plans and online activities in collaboration with cities ([www.thirteen.org/wnetschool](http://www.thirteen.org/wnetschool)). Internet teaching companies like OnlineClassroom offer interactive guides for students and teachers in K-12. Students can interact with other classrooms or ask question of experts in certain areas if they sign on during a demonstration. Students can be exposed to different cultures and fields of study as they gain computer literacy skills.

Teachers in K-12 can teach their students how to use the Internet to their advantage. Students can learn how to quickly obtain quality material as well as how to judge the reliability of the information they discover. Some Universities (e.g., Purdue University) offer online guides and tutorials that teach students how to judge Internet material based on a "basic model emphasizing and integrating topic definition, information seeking, and evaluation" (Brandt, 2002). Teachers can give their students the safety guidelines, utilized by Purdue University and others, which they will need to navigate the Internet on their own through guided in-class instruction. The Internet has a wealth of information, but not all of it is legitimate or appropriate/suitable for everyone (e.g., children).

Teachers may also find that their ability to assist students with disabilities improves with the use of the Internet. Many educational Internet sites are geared toward students who have learning disabilities. The Parent Education Network (PEN) has compiled a database that directs those with disabilities to helpful websites, like *The Boulevard* geared toward those in wheelchairs (PEN, 2001). Software to assist the blind in navigating the Internet is available as well as headphones and captions that assist the deaf. For a student who is physically challenged, the Internet may present an opportunity to interact with others and "see things", which they otherwise would be incapable of experiencing.

The Internet also opens up many possibilities to educators. Distance learning and online classrooms offer new and interesting ways to present material to students. Teachers can now attend online classes, which present them with ways to enhance their students' learning experience through the Internet. It is important that teachers have a comprehensive understanding of the

Internet in order to communicate sound advice to their pupils. Universities now expect their students to be knowledgeable in online research, and many Universities offer classes that take place completely over the Internet. The Internet is quickly becoming a necessary tool in the education system, and soon no child's education will be complete without knowledge of the uses and pitfalls of the Internet.

The importance of the Internet in education is continued in the realm of literature. Literature and education are closely related for all those teaching or interested in teaching. The Internet is a tool that those concerned with or attempting to study literature can use to advance their knowledge. The next section outlines the uses of the Internet in relation to the literary field.

### 3. Literature and the Internet

The use of the Internet has greatly affected the literary field. The speed and ability to reach new customers that the Internet offers makes it an ideal new market for writers and publishers. Research, which traditionally had to be done in a library, can now be achieved online as articles and journals become available electronically. Teaching literature and encouraging children to read using the Internet has also had an impact on the literary field. The use of the Internet is rapidly transforming the literary world and allowing literature to remain current in a quickly changing world.

Both writers and publishers have realized the importance of the Internet as a tool to expose their work to wider audiences and as a new way to market their product. Writers are also taking advantage of the Internet by pursuing a multiple distribution strategy, by giving special offers at online bookstores and publishing seek-peek chapters of their novels to entice readers into purchasing. Novices are grabbing attention by displaying their work online in the hopes that readers will purchase their next work or that publishers will stumble across them and offer them contracts. The *Internet Public Library* and *Bookwire* both offer Reading Rooms in which thousands of complete online texts are available (Flack, 2002). Large publishing houses like Penguin Putnam Inc. are using their home pages as a channel of distribution to display the work of their new writers, offer background information and to sell directly to their readers (PenguinPutnum, 2002).

Other online retailers have realized the benefits of selling directly to their customers as well. While bookstores and libraries were once the only ways to obtain literature, the Internet has opened up an entirely new showcase. Readers can use search engines to find novels or go to any major online bookstore (e.g., Amazon.com or Barnesandnoble.com) to find the book they are looking for and have it delivered. Most online bookstores also sell student textbooks, making it easy for college students to purchase their textbooks online and avoid monopolistic campus bookstores.

Library research has also been greatly affected by the Internet. While research once required a trip to the local

library and hours at the card catalogue, it is now possible to do most research from the convenience of your home or office. Internet websites like the Librarians' Index to the Internet, which offers "more than 10,000 Internet resources selected and evaluated by librarians for their usefulness to users of public libraries," can help researchers evaluate their research material (Schneider, 2002). Professional Literary Journals and many novels are available in full-text on the Internet. Large libraries offer online tours and give readers the option of checking out their books through inter-library loan programs. A reader in a remote region can checkout a book from a major library with the help of the Internet. Most magazines and newspapers also make their material, as well as archives of their past articles, available online. With the use of the Internet, the time necessary to research has decreased as the amount of information available has increased.

As the Internet continues to change the availability of literature and decrease the difficulty of attaining quality work quickly, its use as an educational tool concerning literacy has increased. It has become easier to obtain literature and expose students of all ages to great works for a fraction of the cost of obtaining hard copies of the original literary works. Student Internet literacy programs have increased as schools make Internet access a regular part of their curriculum. Students are now taught Internet researching skills and are exposed to a wider range of material at an early age. The Internet has the ability to make literacy in schools easier to achieve through online programs as well as provide students with a greater range of interesting materials.

In summary, the Internet is having a great impact on the world of literature. Through use of the Internet, literature has become easier to obtain from online bookstores and libraries. Research in the literary field has been made easier by online literary journals and magazines, which offer full-text articles. Even teaching literature in schools and Universities has been affected by the availability of literature and research materials. The literary work has become more easily accessible through the Internet, and anyone training to enter the literary field must be competent in the uses of the Internet.

#### 3.1 Historians and the Internet

The discipline of studying and recording historical events has changed quickly in the last few decades. A major source of this change has been the invention and the increased use of the Internet by historians. Educating students, as well as sharing information between colleges, has been made simpler and faster, thanks to the Internet. There are pieces of visual history that could be viewed by only a few, but can now be downloaded by anyone who has access to the Internet. Children can tour the Louvre "through sixty panoramic views of the museum provided by QuickTime technology" without leaving their school (Louvre, 2001). Architects can also use the Internet to send digital pictures of excavation finds to labs hundreds of miles away within minutes of discovery and obscure

knowledge of historical acts can be found on the web. The ability to record and share historical information has become easier and more readily accessible to the masses thanks to the Internet.

For generation, the only way to learn about historical acts was to research them in books. Professional historians often had to travel miles to gain access to rare books in libraries. Students also had to rely on slow research through books in an effort to learn about acts of historical significance. The Internet changed all this by making large amounts of information available to anyone with Internet access. Large search engines like [www.dogpile.com](http://www.dogpile.com), which uses Altavista, Ask Jeeves, etc. can help students find the information they need quickly (Dogpile, 2002).

Access to visual historical objects has also increased due to Internet technology. Major museums can place all of their paintings, sculptures and other objects on a virtual tour that allows Internet users to view the object from more than just one angle. Many museums now offer similar virtual tours which allow visitors to “visit a virtual museum anytime and from anywhere and see their favorite things long enough without being anxious about other visitors crowding around them” (Kadobayashi, 2002, 212). Students who have never been out of urban neighborhoods in America can be exposed to Greek statues and Roman mosaics. Art and historically significant objects that were once difficult to access can now be viewed by those who might otherwise have never had the opportunity. Digital pictures of discovered artifacts can also be sent across the Internet to be analyzed. Delicate artifacts need not be shipped for other experts to analyze them when detailed digital pictures can be sent in minutes.

Government documents are also more easily available to the masses, thanks to the Internet. Historians can access documents without the hassle of waiting for copies of documents in the mail. Important speeches and legal documents with historical significance are all available through the Internet as are “federal public documents (including slide presentations made by officials)” (Cairncross, 1997, 260). The accessibility of official documents through the Internet and the ease and convenience it offers also increases the ability of those with an interest in genealogy to research their background. Historical documents and artifacts are becoming easily accessible to those who have an understanding of the Internet. Art Historians can find resources at numerous websites (e.g., [www.wisc.edu/](http://www.wisc.edu/)), which has compiled a database of art images and publications ranging from photographs to local artifacts in third world countries (Internet Resources for Art Historians, 2002).

The use of the Internet has changed the accessibility of historical knowledge as well as made it easier to teach history and to more efficiently store historical information. Information, which was once difficult to find, is now available at one’s fingertips. Teaching history in an interesting way with the use of the Internet is now possible as teachers take their students on virtual tours of museums. The use of the Internet has changed

the way we gather and share information, and in so doing has changed the way we view and record our history.

### 3.2 Science and the Internet

The Internet has given the field of science the opportunity to market itself in new ways. A broad range of science-based information is available on the Internet. Many tutorials are available for children who have difficulty with chemistry or physics while interesting sites also display fun scientific discoveries. Pictures from the Hubble satellite can be viewed online, as well as geological information about the earth’s atmosphere. Studies in environmental science are often posted online as many environmental activists have informative websites. The information is more easily available, and the ability to market this industry grows with the expansion of the Internet.

Professionals in the field of science can access the web to hunt for jobs and display their own research with ease. Many websites are focused on finding opportunities for those exclusively in the science field. Students can also access science information and use Internet tutor programs to help them advance in the field of science. There are numerous websites dedicated to assisting students like *Chemistryweb*, which is an “annotated directory of Internet resources for students, educators and researchers” (Lawal, 2000). Students from primary school to post-graduate college can utilize tutor programs provided by chemistry organizations online.

Major chemical businesses also utilize the Internet to market their products. Large oil companies, like Shell, show off their products online and encourage investors as they exhibit new uses for their products. Other major science based companies have interactive websites, which increase interest in their product while improving their image. Government based science programs also display Internet information as well as accept applications online. NASA’s website gives information about their location, launch dates, and offers information about applying for positions online (NASA, 2002, website).

The realm of environmental science on the Internet has also increased in the past few years. Interest in endangered species and the effects of pollution on the environment are just two reasons why the Internet has been used to display information concerning environmental science. Databases, which can be easily accessed and searched, hold large amounts of information concerning all aspects of the environment. Scientists interested in this field can find information quickly, and those interested in conservation of natural resources can also use these databases.

The Internet has made it easier for those in the field of science to share and gather information concerning many different areas of the Internet. This quick exchange of information and expanded resources make it important to be prepared for the high-tech environment. An understanding, coupled with an ability to fully utilize, the Internet will be a necessary task in the future for anyone planning to enter the field of science.

### 3.3 Criminal Justice and the Internet

In the field of criminal justice, the Internet represents an enormous challenge as well as a tool that can be utilized to educate and assist in crime prevention and solution. The use of the Internet has opened up entirely new avenues for criminals while providing them with anonymity. The challenge of tracking down criminals and prosecuting them on existing laws has become increasingly difficult for those in the criminal justice field. In order to prevent crime and prosecute criminals, knowledge of the Internet has become necessary for those entering the criminal justice field.

The Internet has allowed the criminal justice field to expand and become more easily accessible than ever before. Government websites provide full text documents that include previously difficult to obtain case transcripts. Lawyers are finding it easier to research for court cases due to the amount of information on the web that they can utilize.

Another aspect of the changes that the Internet has brought about in the criminal justice field is the entirely new avenue it has created for criminals to commit crimes. Criminals can invade the privacy of those who use the Internet and commit fraud that is difficult to trace in the physical world. Anyone with a computer can attempt to access the personal information that is stored in large databases on the Internet. Hackers can destroy large amounts of information online and are hard to detect. A Pentagon report stated, "a staggering 96 per cent of security breaches were found to have been detected" (Barrett, 1998, 40). Although they are protected by firewalls, credit card numbers from online purchases, banking information, and social security numbers are also accessible to hackers through the Internet. Child pornography rings have also become a crime perpetrated on the Internet. Criminals find the secrecy of the Internet the perfect medium to exploit children without exposing themselves unduly. These crimes are becoming more prevalent as the Internet grows, and those entering the criminal justice field will have to determine actions to control this behavior.

The new and faceless crimes on the Internet can be difficult to prosecute for several reasons. Existing laws often do not cover this relatively new medium, and the slow pace of passing legislation does not keep up with the lightning pace of the Internet. The international aspect of the crimes committed often-complicate matters considerably. For example, if a criminal in England steals American credit card numbers off of the Internet and uses them to make purchases in Japan, the issue of who has the right to punish the criminal comes into question. Fear of greater Internet crimes, like terrorism, is forcing those in the criminal justice to overview our current laws and pass new ones. The Patriot Act is an act that "permits federal investigators to use more-powerful tools to monitor phone calls, e-mail messages, and even Web surfing" (Kandra, 2002, 38). The changes in local laws may mean less privacy in order to achieve safety. Internet legislation varies widely from country to country

and those in the Criminal Justice field will be forced to deal with international issues when encountering the Internet due to its very nature of having no tangible geographic boundaries.

Those who plan to enter the Criminal Justice field will obviously be forced into dealing with the Internet. Those who neglect its research abilities will fall behind as more and more information concerning the Criminal Justice field becomes available online. The new opportunities available to criminals also make it imperative that those in this field have adequate knowledge of the Internet in order to discover and fight the crimes being committed on the Internet. The need for legislation that covers the criminal actions on the Internet and the international aspects on the Internet is also obvious. Anyone planning to enter the Criminal Justice field will obviously be left at a disadvantage without adequate knowledge of the Internet.

### 3.4 Business and the Internet

The Internet has also affected the diverse field of business tremendously. The Internet has opened up an entirely new way to run a business and market goods to the public. Obtaining consumer information is easier than ever thanks to the Internet. One-to-one marketing is feasible even for small and medium size businesses. Consumer convenience has increased due to this new medium as has acceptable product standards. Small and medium size businesses are able to compete with large multinational corporations. International trade and sales are increasing due to the ease, accessibility, and cost transparency created by the Internet. Studies show that "Large companies implementing Internet technologies already are realizing improvements of 13% to 21% in financial performance measures" and "small companies...can achieve even greater benefits" (Anderberg, 2001, 4). Anyone entering the business world in the future will surely encounter the Internet and experience the changes the Internet has brought about in the marketplace. The importance of a full comprehension of the power and effects of the Internet, as well as ability to use it to ones advantage, is necessary in today's market.

The Internet has allowed a new way of marketing products. Retailers can be removed in many instances as wholesalers and manufactures use websites to sell directly to their customers for minimum cost to the company (commonly referred to as dis-intermediation). Even small businesses can compete on an international level using the Internet if they have set up an appropriate infrastructure to handle their orders. The playing field has been leveled to a certain extent as small companies enter the market alongside business giants.

The importance of the Internet as an emerging and growing market cannot be ignored by business people. The Internet is a desirable marketplace since it is both measurable and sizeable. The Internet is certainly a growing market as "the rate of growth of Internet use in the United States is currently two million new internet users per month" (Anonymous, 2002, 4). Government

studies also show that “in September 2001, 143 million Americans were using the Internet – an increase of 26 million in 13 months”(Anonymous, 2002, 4). The number of global users is expected to almost double in the next two years, making the Internet market an increasingly desirable place to conduct business. An understanding of this growing market and the ability to compete in this new and expanding market will be a requirement for all who are entering business fields in the future.

Marketers can also gather information from this growing market with greater ease than ever before. Every click of the mouse that an Internet surfer makes can be monitored to discover their habits and preferences. Cookies, which are “digital markers automatically placed by websites in the hard disk of the computers that connect to them, so that internet sites like Amazon.com can keep track of their customer preferences and can design personalized sales techniques for each customer and market to them more efficiently” (Castelles, 2001, 171). Internet based marketing research is also popular and relatively inexpensive, thereby making it easy to obtain information from the consumer. The wealth of information makes it easier to market to each customer more efficiently.

The Internet does present several difficult issues that those in the business field must be aware of and be prepared to face. The global aspect of the Internet means that language and cultural barriers will almost certainly be encountered by anyone using this medium. The language of a website can effect its ability to be effective in an international market. Customers are three times more likely to buy a product off a site if the site is in their native tongue. If Internet entrepreneurs plan to be successful internationally, they must provide their site in multiple languages to appeal to all customers. The use of the Internet may vary from culture to culture as well. Some cultures prefer to interact in person and do not like to give out their credit card information, which makes it difficult to perform online transactions.

Business people must realize the difficulties presented when selling over the Internet, but even those who do not must confront the changes the Internet is making in the global society. Price transparency is becoming more prevalent all over the world as people in every country become aware of the prices that are being paid in other countries due to the Internet. Consumers in England are not willing to pay double the price of Americans when they can see the price difference on a website. International trade is changing due to the Internet, and those who neglect becoming involved may be left behind. Customers can find convenience and speed on the Internet through quick delivery. Even local retailers must compete with the Internet as any customer with a computer and Internet access can be lured away from the local market into the Internet market.

In the future business people may find it impossible to succeed without a full understanding and use of the Internet. Online banking and shopping are creating new ways to do business in the marketplace. The ease of

collecting consumer data is changing the way customers can be marketed to on the net and the ability to establish more one-to-one marketing situations. The very way that businesses interact internationally is changing as the Internet makes it easier and more productive to sell internationally than ever before. The incentive to fully understand the Internet and be prepared to tackle the barriers encountered in the Internet is great for anyone entering the business field. The Internet is quickly changing the way the world does business, and in order to keep up, an understanding of the Internet is required.

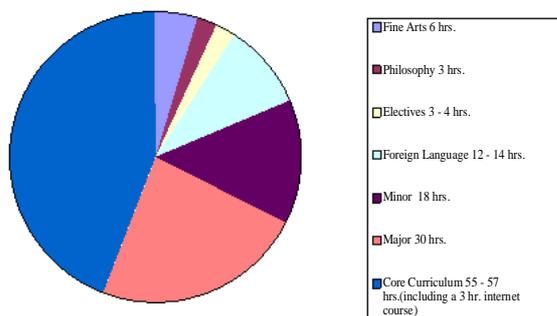

#### 4. Conclusion

In conclusion, the Internet has become a necessary tool for all disciplines today. The Internet is used by educators, business people, scientists, and historians alike. The Internet has changed the global market as well as the way we share information, communicate, and educate. The information available on the Internet is immense and it is important to be able to decipher the reliability and accuracy of all information collected.

It is therefore important that all students with hopes of entering professional fields have a complete understanding of the Internet and its uses. Currently there is not a comprehensive Internet course offered as a part of the core curriculum at Sam Houston State University, but the need for such a course is obvious. The use of the Internet continues to expand, and the opportunities that the Internet provides are vast. Every professional in the future will likely encounter the Internet and be able to enrich their professional experience through intelligent use of the Internet. The role of the Internet in society is only likely to increase, and anyone entering the workforce without a complete understanding of the Internet is entering with a disadvantage. Universities have a responsibility to prepare their students for the field that they choose to enter, and without providing courses that adequately cover the use of the Internet, universities are falling short in their responsibilities.

It will only benefit students to require a mandatory class, which will teach the basics of Internet practices. As the pie chart below illustrates, the addition of an “Introduction to the Internet” course in the core curriculum section of the degree plan will have little effect on the overall dispersal of hours. However, this class will provide students of every major the knowledge of current technology that is now necessary in order to succeed as a student and advance as a professional. By removing 3 hours from the electives category and adding them to the core curriculum minimal hour shifting is needed to achieve the hours required for an Internet course. Electives hours change from college to college while the core curriculum stays basically the same across the board. With these minor changes to the existing core curriculum, an important addition to the University learning process can be achieved.

**Bachelor's of Arts Degree with the Addition of Required Internet Course**

The information disseminated through an "Introduction to the Internet" course will benefit students immensely as they learn to research, create web sites, and decipher the reliability of information available to them over the Internet. Every student regardless of their discipline of study could benefit from such a class. The class would be taught in such a way as to provide the basics of Internet use without becoming too specific in any field of study.

The following syllabus is an example of one that may be used in an Introduction to the Internet course (see Appendix). The syllabus avoids being too "major" specific while being sure to cover the most important aspects of the Internet that effect students and professionals today. A short course schedule is included at the end of the syllabus and direction for the syllabus was taken from lesson plans on OnlineClassroom.com.

**5. Research Limitations**

Any research into a topic has limitations and the very nature of the Internet increases the likelihood of limitations. The Internet is constantly changing and expanding. The number of people using the Internet and the things that they use the Internet for are also constantly changing. This constant change makes all material gathered reliable for only a short period of time. When this paper is finished it will already be behind in its ability to relate the current status of the Internet.

It is extremely difficult to find up-to-date information about the Internet as a classroom focus. Since many resources on the use of the Internet are also found on the Internet, there is the issue of quality control. It can be difficult to choose material that is valid in the vast amount that is available on the Internet. Relying on print sources where the publisher has hopefully analyzed the material for quality control is tempting, but print materials quickly become outdated due to the time it takes to print them. Finding current materials that are of high quality can be complicated, and even the best research will quickly be outdated.

**6. Future Research**

Future research of this topic will be a requirement for anyone interested in the importance of educating college students in the use of the Internet. The quickly changing world of the Internet will make it important to have current material. A study of the newest resources and journals on the topic available on the Internet as well as the latest publications on the uses of the Internet will be helpful. Hundreds of new journals and books are published each year on the Internet and most are out of date within a year or two of their publication. Future research could also include field studies that were unable to be completed here due to time and resource constraints.

Research that reveals the number of Universities that offer a course that covers only the uses of the Internet, and how many of these courses are mandatory would be of use in determining the standards of other Universities concerning the Internet. Surveying students at Sam Houston could also be conducted at a future date and may prove very useful in establishing students' willingness to take such a course. Surveying students to discover how often they use the Internet and how comfortable they feel using it may help to establish a need for the class. Another survey of University professors may be of use in determining the need for such a class. Professors could be asked questions that determine how often they assign work that requires their students to use the Internet and how well they feel their students utilize the Internet.

A pilot study could even be conducted in which a sample of students would actually take the course in place of the current required computer course if they already feel skilled at basic computer knowledge. This group of students would be surveyed at the end of the course to determine if they found the course useful and if they felt that their Internet skills had improved their studies. At the same time, the group of students who completed only the computer class could complete a questionnaire to relate their feeling of competence on the Internet and ability to complete basic Internet functions, creating web pages and searching for quality information. After both groups are evaluated, their answers could be compared to determine if the current class adequately prepares students for Internet use or if an Introduction to the Internet class is needed.

Other research could also be based on the importance of Internet experience to agencies and corporations, which may hire from the Sam Houston State University pool. Is it important to these businesses that students be able to use the Internet with ease. Also, how many of these corporations allow or encourage telecommunication and what percentage of their employees telecommunicate? How many of these businesses hire employees from online applications and what percentage of their applications are online? These questions will help to reveal the importance of the Internet in the businesses that come into direct contact with Sam Houston State University students and regularly hire from the Institution.

Future research may also include creating a budget for such a class. Projecting a budget cost for starting an "Introduction to the Internet" class at Sam Houston State University and maintaining it. Will the computers and

Internet connections at the University be adequate to support a mandatory Internet class or will it be necessary to expand the computer materials now on campus? Will current computer fees from students cover this cost or will it be necessary to raise the cost of attending the University through increased Internet fees?

All future study into the uses of the Internet and the importance of the Internet to University students should be made as close to the date that the information is needed in order to ensure that the information is current. The ever-changing world of the Internet makes it important that future research is done when evaluating the subject. The importance of surveying students, professors, and businesses to determine the desire and need for an Internet class will be invaluable to those trying to reveal a need for such a course. Creating a projected budget is also invaluable in revealing whether such a class is possible at this time. The cost of such a class may outweigh the benefits of making it mandatory, and creating a budget for the course will reveal this. Regardless of the cost though, an Introduction to the Internet course is needed as the world changes and Internet skills become requirements in every profession.

## 7. Appendix

*Sam Houston State University  
Introduction to the Internet - Course Syllabus*

*Course Description:* This class will focus on the uses of the Internet and on gathering information on the Internet. Students will have hands-on experience in gathering information that is reliable and utilizing it to complete class projects. Every student will be responsible for creating their own website, creating links to other sites, using electronic mail and researching their subject online.

*Course Objectives:* To familiarize every student with the uses of the Internet. Make students comfortable with the research and quality control aspects of the Internet. Teach each student to create their own website and how to best utilize the Internet regardless of the field of study they plan to enter.

*Contents of Class:*

1. Surfing the Internet
2. Compare/contrast commercial and educational homepages
3. Set up e-mail; read, write, save e-mail and send attachments
4. Use Internet news resources; Register with a listserv/discussion group
5. Find answers to questions posed on your web-page topic
6. Compare/contrast search engines
7. Create and publish your own website

## Course Schedule

- Week 1:** Course Orientation. Introduction to class and review of syllabus. Internet basics and begin surfing the Internet.
- Week 2** Send and receive e-mail. Set-up e-mail account and send attachments. Complete exercises and e-mail attachments to professor. Cover e-mail privacy and dangers of viruses and spam.
- Week 3** Discussion Groups. Learn how to send and read e-mail from discussion groups.
- Week 4** Begin Electronic research. Learn how to use the Internet for research purposes.
- Week 5** Search Engines. Learn about different search engines and how to judge them.
- Week 6** Announce website topics and begin research for website using skills learned in class.
- Week 7** Learn how to judge material found on the Internet.
- Week 8** Website Construction. Learn how to develop web pages using information learned in class, Dreamweaver.
- Week 9** Learn how to create links to other websites and how to gauge the validity of the site to which you are creating a link.
- Week 10** Present websites in class and score the pages of other students for 10% of project grade.

# Considerations for Computer Ownership Policies

Elena Salas

California State Polytechnic University of Pomona  
Pomona, CA United States  
ellebbs@aol.com

## Abstract

The introduction of Internet technology is changing the way people communicate, work and live. In business environments, individuals are using electronic networks instead of the traditional methods to accomplish their goals. Furthermore, as more industries implement new applications of technology, the pressure on employees and consumers to acquire new skills increases. The result is an urgent need for higher learning institutions to adopt computer and technology protocols that leverage network resources to deliver on demand services. As an option, institutions are turning to the capabilities of wireless technology to create wireless network campuses. Although it appears to be an ideal solution, both the challenges and the opportunities require careful consideration.

## 1. Introduction

On a national level, academic institutions, recognizing the demand for graduates capable of succeeding in a technology driven economy, are developing and implementing computer ownership policies and standards. Currently, California State Polytechnic University of Pomona is considering the development of a notebook requirement for undergraduate e-business students in the College of Business Administration. The question then becomes what type of computer ownership program or policy to implement. Should students be required to own a desktop computer or a notebook computer, similar to the University of Florida policy? Should academic institutions offer a recommendation only, such as that offered by University of Indiana? To answer these questions, various issues must be explored.

There are various issues to consider when developing computer ownership standards and policies, for example, student demand, faculty willingness to incorporate new tools into existing curriculum, and what is the availability of technology and resources. For example, are the students willing to accept the use of new technology to facilitate learning when the current methods have previously been successful? Would students from other degree programs accept a computer or notebook requirement? Another, item to consider, involves the current and expected use of wireless technology? These are just a few of the questions that require careful attention when considering implementing a computer

ownership policy. The following takes a closer look into the struggle of one university to provide quality education in an ever-changing environment. Lastly, similar policies currently implemented at other institutions, such as the University of Florida, University of Indiana, and Georgia Tech University, serve as a comparison model for California State Polytechnic University of Pomona to develop their own computer policy.

## 2. California State Polytechnic University of Pomona seeks to establish Policy

California State Polytechnic University of Pomona is constantly anticipating the demands of the economy. The College of Business Administration is especially interested in changes in business practices. In the fall of 2001, Cal Poly, Pomona launched a new concentration within the Bachelor of Science in Business Administration. The E-business Concentration developed in response to today's evolving business environment, which demands graduates be equipped with a thorough understanding of e-business theory and practice.

The E-business Concentration (EBZ) is responsive to the markets' increasing emphasis on the use of technology related skills. In addition to technical skills, the field of e-business requires that professionals be equipped with interpersonal abilities. To support the development of these skills, students work in teams with an extensive emphasis on group collaboration. The College of Business Administration practices a "learn by doing" approach to management education, which encourages the support and development of programs that facilitate the learning process.

In keeping with this philosophy, Dean Eduardo Ochoa of the College of Business Administration sought to utilize available resources in technology to facilitate learning. In particular, Ochoa saw the usage of notebook computers as a viable tool to accomplish the objectives of CBA and the EBZ Concentration. Courses in the curriculum involve a structure based on team collaboration. Therefore, a notebook computer is an excellent tool because it offers mobility and the ability to access learning anytime and anywhere.

## 3. Earlier Notebook Requirement for Cal Poly, Pomona's MBA/MSBA Program

Currently, the College of Business Administration at Cal Poly, Pomona has a laptop requirement for their MBA/MSBA program. However, the laptop requirement policy encountered unexpected obstacles once implemented. The initial proposal overlooked how the new requirement would be incorporated into the curriculum. The CBA faced an enormous dilemma because, at the time, the majority of the Faculty lacked sufficient computer and Internet knowledge to incorporate such a requirement into existing curriculum. In addition, there was little incentive for the faculty to incorporate the use of notebooks in their course outlines.

Soon, the MBA/MSBA students expressed resentment towards the requirement. Their primary complaint revolved around the fact that Instructors were not incorporating the use of the notebooks in the classroom. To address this issue, in the summer of 2001, Ochoa, "provided faculty with the opportunity to apply for support to develop innovative and creative ways to incorporate an instructionally relevant component of their classes, which would use the notebooks in a meaningful way (McLaughland, 2001)." Of the proposals submitted, 5 stipends were approved and implemented during the following quarter.

#### 4. Gathering Support for Notebook Requirement Policy

New policies or initiatives typically involve gathering feedback from those affected most. When Georgia Institute of Technology began their student computer policy implementation in 1995, the President G. Wayne Clough appointed a Student Computer Ownership Committee ("STUDENT COMPUTER OWNERSHIP," 2002). The committee brought together students, faculty, and staff, to study the various trends and attitudes toward a proposal to require computer ownership of all enrolled students. Once the review process was finalized, a student computer ownership policy was recommended by Georgia Tech faculty requiring all students with the class of 2002 to have their own computer.

In keeping with a similar concept, Cal Poly of Pomona and the College of Business Administration initiates the process by incorporating student and faculty feedback. Due to a lack of enthusiasm from both the faculty and the MBA/MSBA students, there are additional feelings of apprehensive about implementing such a program for undergraduate students, without sufficient evidence of both student and faculty support. As a result, during winter term 2002, Dean Ochoa suggests to first determine how receptive EBZ students are of a notebook requirement.

In February 2002, the E-Business Society, a professional student organization, initiates to assist the CBA with the notebook requirement project, by

conducting a survey. Dr. Robert Schaffer, Professor of International Business and Marketing and E-Business Society, Faculty Advisor, and John Tang, E-Business Society member, develop a questionnaire to administer to a sample size of approximately 200 students enrolled in EBZ courses. The survey objective is to determine the attitudes and level of cooperation from Cal Poly E-business students to a laptop requirement. Secondly, the survey gathers the student perspective on purchasing options. The results of the survey, supports the hypothesis that E-business students favor having a laptop requirement.

See exhibit 1 and 2.

#### 5. Available Resources: Hardware Requirements

The results from the survey show sufficient evidence to conclude Cal Poly of Pomona undergraduate students are supportive of a notebook requirement. The following recommended step is to establish minimum configuration standards for hardware and software. The E-Business Society collaborates with students in the EBZ program to compile a list of the minimum specifications required of the e-business concentration, utilizing informal email surveys. Prior to completion of this list, the Society sought input from Richard Van Lommel, Senior System Administrator Consultant for the College of Business Administration of Cal Poly, Pomona. Van Lommel plays a significant role because of his involvement in implementing the notebook requirement for the MBA/MSBA program (Personal communication, August 9, 2002). After careful evaluation, he recommended for the minimum configuration to be offered as a baseline standard and provide the more robust configuration model as the recommend configuration. (See exhibit 3).

#### 6. Wireless Access

Wireless access is available to students, in building 6, on the Cal Poly, Pomona campus. To connect to the network students will require a computing device capable of using a wireless adapter card and a wireless adapter that supports the IEEE 802.11b standard. Previously, the University was undecided on which wireless card brand to use (L. Turner, personal communication, July 17, 2002). There were issues of security and concerns with longevity of Cisco cards. In a recent development, the concerns and issues were resolved and the decision to use Cisco is confirmed (R. Van Lommel, personal communication, August 9, 2002). The Cisco Aironet 350 wireless client adapter (AIR-PCM352), is available through the Bronco Bookstore for \$120.00. Although there are also older 340 series adapters available and possibility available at a lower price, the newer cards have a higher power output capability and more advanced performance features.

## 7. Evaluation of Other Computer/Notebook Policies

Cal Poly of Pomona is committed to the professional development of its' students. A portion of the research complies samples to better understand what was meant. I Part of the process evaluate various other models of existing standards. The following are the current computer/notebook policies and recommendations for Indiana University and Florida University. They serve as an example of different ways to implement such policies within the College of Business Administration.

### 7.1 Case 1 Indiana University, Kelley School of Business

<http://www.bus.indiana.edu/ugrad/compinfo.html>

The University of Indiana currently does not require undergraduate students within the Kelley School of Business to own a computer. However, they recognize that various undergraduate programs in the Kelley School of Business expect to incorporate the use of networked (wired/plug-in) classrooms over the next three to four years. In addition to the use of wired/plug-in classrooms, all undergraduate dormitories are wired for network connectivity.

The University of Indiana considers a computer to be a wise investment. Although, notebooks provide mobility and may connect to the UI network from various academic buildings, the Kelley School of Business encourages undergraduate students to consider purchasing the less convenient and less expensive hardware choice. Their recommendation is for students to purchase a decent desktop system for no more than \$1,500. The University, also, provides suggested minimum hardware guidelines in order to use all the technology services available at IU. (See exhibit 4) To accommodate their recommendation, the University has negotiated various pricing plans with numerous vendors. Students have access to the vendor links from the IU website. The vendors include Apple, Dell, Gateway and the IU Bookstore. For an example of a recommended laptop configuration, (see exhibit 5).

### 7.2 Case Study 2: University of Florida, Warrington College of Business

<http://www.cba.ufl.edu/programs/computer.asp>

The University of Florida has an official policy on the student computer requirement. Their policy stipulates beginning summer term 1998 all junior level and new incoming students must purchase computer hardware and software appropriate to his or her degree program. Students may not graduate unless computer proficiency is demonstrated. The policy continues with the expectation that all students will purchase or lease a computer capable of accessing the Internet, through dial up or network

connections, and posses' productivity programs for spreadsheets and various calculations.

The University provides the minimum computer configurations for all students. (See Exhibit 6). Individual colleges may have additional requirements or recommendations for lower division, upper division, graduate and professional students.

The Warrington College of Business stipulates that all junior, senior and master level students must have a notebook computer. For an example of these requirements, see exhibit 7. The College of Business has also established negotiated prices from Dell and IBM. The links are available online.

## 8. Available Models for California State Polytechnic University of Pomona

The decision to implement a computer/notebook policy or standard is relatively difficult because there are numerous models available. However, with student support, wireless network standard established, as well as vendor support, the decision is less complex.

The first option for Cal Poly Pomona is to delay implementation of any computer standard/policy. One benefit to the University is in cost savings, in the event a new technology for wireless networks is developed, making the existing infrastructure obsolete. The drawback to the University is the loss in revenue due to lower enrollment. Students will prefer to attend other universities because they offer innovative programs demanded by the market.

The second option available to Cal Poly, Pomona is to approve a minimum configuration standard to offer as a recommendation only for students. The policy resembles the policy adopted by Indiana University. The university benefits because it will be perceived by others an innovative campus with extensive knowledge of the inner workings of technology. In addition, the campus will benefit with a slight increase in enrollment once the policy is added to the CBA web site. Furthermore, students will appreciate the opportunity to access the current negotiated discounts available to all faculty, staff and students within the California State University System. However, since this model is offered as a recommendation, the drawback for students requiring financial assistance is that financial aid is not offered.

The third option available is a model similar to the University of Florida, Warrington College of Business. The College of Business offers a recommendation only for hardware and software configurations to all concentrations. The Cal Poly Pomona policy would offer a notebook requirement to junior and senior level EBZ students. However, the College may offer to extend the requirement to CIS students since their use of computing

tools is extensive and would also benefit from these policies. If a laptop requirement is implemented, those students in financial need will have access to financial aid monies. Furthermore, the College of Business will benefit from an increase in enrollment as a result of the laptop requirement.

The fourth option available to Cal Poly, Pomona is a model similar to the California State University of Bakersfield. Their model offers information resources information as a means to increase the knowledge and understanding of the students. The University Web site provides recommendations for both PC and Mac computers. Students may purchase software at students' prices from the information resource page.

## 9. Conclusion

The status of Cal Poly of Pomona's Notebook Initiative is currently undergoing further consideration. The objective is to take all possible scenarios into account before imposing such a costly requirement upon the students. Although careful consideration is recommended, each day that passes without a computer/notebook policy

implemented, is a disservice to the students. Students are at a disadvantage when they do not receive the skills, nor the education demand by the new Internet technology enabled economy.

## Appendix

### Exhibit 1 Survey Questionnaire Excerpt

#### E-Business Society

The E-Business Society is collecting data so that we might make recommendations to the college administration concerning the possibility of either requiring or encouraging EBZ majors to have laptop computers. Thank you for your time in completing this survey.

1. What is your Major? \_\_\_\_\_  
 What is your Career \_\_\_\_\_  
 Track within this major? \_\_\_\_\_
2. Gender
  - Female
  - Male
3. Approximately, what is your annual household income?
  - 0-\$10,000
  - \$10,001-\$20,000
  - \$20,001-\$30,000
  - \$30,001+
4. On average, how often do you check your e-mail?
  - Continuously (DSL, LAN or network connection)
  - 3-4 times
  - At least once
  - Perhaps once every 2-3 days
  - Once a week or less
5. Excluding e-mails, about how many hours each week, on average, do you spend on line?  
 \_\_\_\_\_ hrs/week

Thank you for your time.

## Exhibit 2 Excerpt from Results of the Survey

### E-Business Laptop Survey

#### Background

**Management Decision Problem:** E-business graduates are going to enter a high technology job environment. In order to succeed in an environment such as this and meet the necessary challenges E-business graduates will need to have all the necessary tools, giving them the best opportunity for success.

**Research Objectives:** To determine the attitudes and level of cooperation from Cal Poly E-Business students to a possible laptop requirement. As well as attitudes toward laptop purchasing options.

**Hypotheses:** The majority of e-business students will show more favoritism toward a laptop requirement. E-Business students are using computers and the Internet a great deal in their classes and surely will see the need to become better acquainted with hardware and software tools.

**Significance of the Study:** This study will show that students are serious about the need for technology in their education. It will also show teachers the importance of implementing these technologies into the educational process. Corporations may also find through this survey that Cal Poly students have a high level of technical proficiency and a great desire to maintain and increase that through their education. Laptop vendors will also find that Cal Poly students will respond to the laptop requirement with full cooperation.

**Information Needs:** The following information was taken for this study:

Major	Amount of time on the internet
Gender	Current computer
Income	Importance of PC
Frequency of E-mail usage	Pricing
Monthly payment Requirement	Financial Aid
	Payment options

#### Descriptive Results

Question 1: What is your major?

		MAJOR			
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1.00	49	24.5	24.5	24.5
	2.00	26	13.0	13.0	37.5
	3.00	50	25.0	25.0	62.5
	4.00	18	9.0	9.0	71.5
	5.00	37	18.5	18.5	90.0
	6.00	6	3.0	3.0	93.0
	8.00	3	1.5	1.5	94.5
	9.00	1	.5	.5	95.0
	10.00	1	.5	.5	95.5
	11.00	1	.5	.5	96.0
	14.00	4	2.0	2.0	98.0
	15.00	2	1.0	1.0	99.0
	16.00	1	.5	.5	99.5
	17.00	1	.5	.5	100.0
	<b>Total</b>	200	100.0	100.0	

Question 2: Gender

		GENDER			
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1.00	82	41.0	41.0	41.0
	2.00	118	59.0	59.0	100.0
	<b>Total</b>	200	100.0	100.0	

Question 3: Approximately, what is your annual household income?

INCOME					
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1.00	53	26.5	26.5	26.5
	2.00	36	18.0	18.0	44.5
	3.00	23	11.5	11.5	56.0
	4.00	88	44.0	44.0	100.0
	Total	200	100.0	100.0	

Question 4: On average, how many times do you check your e-mail?

TIMES					
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1.00	73	36.5	36.5	36.5
	2.00	62	31.0	31.0	67.5
	3.00	43	21.5	21.5	89.0
	4.00	19	9.5	9.5	98.5
	5.00	3	1.5	1.5	100.0
	Total	200	100.0	100.0	

Question 6: What type of computer do you currently own?

COMPTYPE					
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1.00	134	67.0	67.0	67.0
	2.00	9	4.5	4.5	71.5
	3.00	49	24.5	24.5	96.0
	4.00	8	4.0	4.0	100.0
	Total	200	100.0	100.0	

Question 7: Do you feel it is important to have your own personal computer?

Importance of PC					
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	4.00	6	3.0	3.0	3.0
	5.00	11	5.5	5.5	8.5
	6.00	21	10.5	10.5	19.0
	7.00	162	81.0	81.0	100.0
	Total	200	100.0	100.0	

Questions 8: Notebooks are available from many different sources, with many features, at several prices. Considering the features that you want, about how much will that computer cost?

PRICE					
		Frequency	Percent	Valid Percent	Cumulative Percent

	50.00	1	.5	.5	.5
	100.00	3	1.5	1.5	2.0
	200.00	6	3.0	3.0	5.0
	400.00	2	1.0	1.0	6.0
	500.00	6	3.0	3.0	9.0
	600.00	3	1.5	1.5	10.5
	700.00	2	1.0	1.0	11.5
	800.00	3	1.5	1.5	13.0
	900.00	7	3.5	3.5	16.5
	999.00	1	.5	.5	17.0
	1000.00	20	10.0	10.0	27.0
	1099.00	1	.5	.5	27.5
	1100.00	2	1.0	1.0	28.5
	1200.00	18	9.0	9.0	37.5
	1300.00	8	4.0	4.0	41.5
Valid	1400.00	7	3.5	3.5	45.0
	1500.00	32	16.0	16.0	61.0
	1599.00	1	.5	.5	61.5
	1600.00	2	1.0	1.0	62.5
	1700.00	7	3.5	3.5	66.0
	1800.00	3	1.5	1.5	67.5
	1900.00	2	1.0	1.0	68.5
	2000.00	39	19.5	19.5	88.0
	2200.00	1	.5	.5	88.5
	2400.00	2	1.0	1.0	89.5
	2500.00	10	5.0	5.0	94.5
	2800.00	1	.5	.5	95.0
	3000.00	8	4.0	4.0	99.0
	3500.00	1	.5	.5	99.5
	7000.00	1	.5	.5	100.0
	Total	200	100.0	100.0	

Question 9: Considering the computer you envisioned above, about what monthly payment would you expect to make?

MONTHLY					
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	.00	9	4.5	4.5	4.5
	6.00	1	.5	.5	5.0
	8.00	1	.5	.5	5.5
	10.00	6	3.0	3.0	8.5
	15.00	3	1.5	1.5	10.1
	20.00	9	4.5	4.5	14.6
	25.00	10	5.0	5.0	19.6
	30.00	12	6.0	6.0	25.6

	35.00	4	2.0	2.0	27.6
	40.00	4	2.0	2.0	29.6
	45.00	2	1.0	1.0	30.7
	50.00	46	23.0	23.1	53.8
	60.00	5	2.5	2.5	56.3
	70.00	4	2.0	2.0	58.3
	75.00	4	2.0	2.0	60.3
	80.00	3	1.5	1.5	61.8
	100.00	45	22.5	22.6	84.4
	125.00	1	.5	.5	84.9
	150.00	14	7.0	7.0	92.0
	200.00	10	5.0	5.0	97.0
	300.00	4	2.0	2.0	99.0
	500.00	1	.5	.5	99.5
	750.00	1	.5	.5	100.0
	Total	199	99.5	100.0	
Missing System		1	.5		
Total		200	100.0		

Question 10: Would you be interested in applying for financial aid funding towards the purchase of a notebook computer?

Financial Aid Funding					
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1.00	41	20.5	20.5	20.5
	2.00	5	2.5	2.5	23.0
	3.00	6	3.0	3.0	26.0
	4.00	19	9.5	9.5	35.5
	5.00	17	8.5	8.5	44.0
	6.00	7	3.5	3.5	47.5
	7.00	105	52.5	52.5	100.0
	Total	200	100.0	100.0	

Question 11: Assuming that the college provides a variety of payment options, do you feel it is reasonable to require all business students to have a notebook computer?

Laptop Requirement					
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1.00	26	13.0	13.0	13.0
	2.00	12	6.0	6.0	19.0
	3.00	23	11.5	11.5	30.5
	4.00	24	12.0	12.0	42.5
	5.00	24	12.0	12.0	54.5
	6.00	27	13.5	13.5	68.0
	7.00	64	32.0	32.0	100.0
	Total	200	100.0	100.0	

Results with respects to relationships

ANOVA was used to determine if there were any significant relationships between variables. All the relationships at .10 or greater are presented below.

Frequency that student checks their e-mails:

- Students that frequently check their emails were more likely to feel that it is important to have their own computers. (sig.= .03)
- Students that frequently check their e-mails are not as price sensitive to laptops as students that don't check their e-mails as frequent. (sig.=.061)
- Students that check their e-mails frequently are more favorable towards having a laptop requirement. (sig.=.001)

Types of computers students own:

- Students that own laptops are more favorable towards having a laptop requirement. (sig.=.058)

Majors:

- EBZ and MHR students are more likely to feel that it is important to have their own computers. (sig.=.071)
- EBZ and Marketing students are more favorable of having a laptop requirement. (sig.=.000)
- EBZ students are more likely to check their e-mails than other four majors. (sig.=.018)

Gender:

- Females are more likely to pay higher monthly payments on their laptops. (sig.=.026)
- Males are more favorable toward having a laptop requirement. (sig.= .075)

Income:

- Females are more likely to check their e-mails more frequent than do males. (sig.=.073)
- Students that have higher incomes are more likely to consider personal computers to be important. (sig.=.048)

Conclusion

The conclusion supports the hypothesis of E-business students being more favorable towards having a laptop requirement. We can infer that E-business students are different in some ways, and one those ways are, they are more likely to support and accept the laptop requirement. E-Business students are more likely to appreciate and support a laptop requirement. E-business students see the need for laptops in their education, and in the event of a laptop requirement, E-business students will be more willing to support this initiative.

**Exhibit 3 Minimum Requirements**

**Laptop Requirements**

Hardware Standards:

In order for students to complete their degree programs successfully, on-going use of a computer is required. The specifications listed as baseline are the minimum standards that all notebook computers should meet.

Students are encouraged to upgrade or purchase a notebook computer to meet or exceed the recommended specifications. The principle behind the recommended specifications is that these laptops will be usable for three years from the date of purchase.

Baseline (Minimum)/ Recommended Laptop Requirements:

	Baseline	Recommended
<u>CPU</u>	Pentium III,1.1 GHz Processor (Celeron/ AMD is ok)	Pentium 4, 1.6 GHz Processor or higher, (AMD is ok)
<u>Memory</u>	128MB SDRAM	256MB SDRAM
<u>Screen</u>	14.1" Viewable, capable resolution 1024x768 or higher	14.1" Viewable, capable resolution 1024x768 or higher
<u>Hard Drive</u>	20 Gig HD	30 Gig HD

Modem	Integrated 56k Fax/Modem v.92	Integrated 56k Fax/Modem v.92
Network Card	Integrated 10/100 NIC	Wireless PCMCIA card (CISCO Aironet 350) available at bookstore \$120 (optional)
Multimedia	32MB DDR nVidia GeForce4 AGP 4X Graphics Integrated CD-ROM Drive Integrated Sound Card	64MB DDR nVidia GeForce4 AGP 4X Graphics Integrated DVD - CD-RW Combo Drive Integrated Sound Card
Software	Windows 98/ME, NT, 2000, XP Microsoft Office 2000, XP (standard) Option of no software	Windows 98/ME, NT, 2000, XP Microsoft Office 2000, XP (Pro) Option of no software
Other Misc. Items	Built-in floppy drive Lithium Ion-Battery 2 USB Ports, 1 Serial Video output Carrying case Weights 8lbs or less Warranty Plan (1 year std)	Built-in floppy drive Lithium Ion-Battery 2 USB Ports, 1 Serial Video output Carrying case Weights 8lbs or less Warranty Plan (3 year optional)

#### Exhibit 4 Indiana University, New Computer Hardware Recommendations

<http://computerguide.indiana.edu/buying/index.html>

In order to use all the technology services available at IU, we suggest the following minimum hardware components if you are purchasing a new computer.

	<u>Minimum PC Requirements</u>		<u>Minimum Mac Requirements</u>
Processor:	1.2GHz or higher	Processor:	500MHz PowerPC G3
Memory (RAM):	256 MB SDRAM	Memory (RAM):	128 MB SDRAM
Hard Drive:	20 GB Ultra ATA hard drive	Hard Drive:	20 GB Ultra ATA hard drive
Video Card:	Direct-X compatible video card with 32 MB Video RAM	Video Card:	Not Applicable
Sound Card:	SoundBlaster compatible sound capability with two speakers	Sound Card:	Not Applicable
CD-ROM:	48x DVD/CD-ROM drive (or 16x CD-R/W)	CD-ROM:	48x DVD/CD-ROM drive (or 16x CD-R/W)
Removable Storage Media:	Internal Floppy, Internal Zip250 Zip Drive	Removable Storage Media:	Internal Floppy, Internal Zip250 Zip Drive
Ports:	2 USB ports	Ports:	2 USB & Fire Wire ports
Operating System:	Windows XP Professional	Operating System:	Mac OS 9.2.2 or OS X (Requires 128 MB RAM)

Service:	Type 3 Contract - Next Business Day Parts & Labor On-Site Response 2YR Extended	900-6232

## Exhibit 6 University of Florida, Sample computer configurations for University

<http://www.circa.ufl.edu/computers/>

For students acquiring a computer in spring through fall 2002, the following are recommended minimum configurations. These minimum specifications are not necessarily available in new computer configurations currently on the market and are provided as a reference for a minimally configured computer. Some colleges have specific requirements more restrictive than the general campus recommendation; see the [college requirements](#) section below for more details.

- 300 MHz or faster CPU (e.g., Intel Pentium/Celeron family, AMD K6/Athlon/Duron family, or compatible processor)
- 64MB or more RAM for Windows 98, NT, or Me operating systems, 128MB or more for Windows 2000, and 256MB or more for Windows XP operating systems is recommended. For other operating systems and software applications, check the minimum requirements of the operating system and application software you will be using for the necessary RAM for your needs.
- 4 GB or larger hard drive
- 10x or faster CD-ROM drive
- High-resolution graphics adapter with at least 2 MB video RAM, supporting at least 24-bit color at 800 X 600 resolution. Laptops should have an external monitor port for connection to an external monitor or classroom projection system.
- High-resolution color display (at least 800 X 600 resolution, 24-bit color. Laptop displays should be at least 12" diagonally, and use active-matrix technology. Desktop displays should be at least 15" diagonally.)
- Sound support, including speakers or headphones
- 56kbps V.90 modem (avoid any modem labeled "win modem" or "modem for Windows")
- Laptops should have PCMCIA or PC-Card slots
- A high-quality printer (ink-jet or laser) is recommended, although limited printing facilities are available in campus labs.
- Bundled software should include either Corel or Microsoft office suite.<sup>1</sup>

<sup>1</sup>The office application suites come in several varieties and combinations of programs. You should evaluate your choice of office productivity suite based on the needs of your intended coursework. Word processing and spreadsheet applications are used in almost all disciplines. Presentation applications are highly recommended since they are used in many courses and many fields. Database applications may be needed in some disciplines. Remember that you can always add the missing applications later, if you discover an unforeseen need.

## EXHIBIT 7 University of Florida, Warrington College of Business Computer Requirement for Masters and Undergraduate Students

<http://www.cba.ufl.edu/programs/computer.asp>

Junior / Senior / Masters (Enrolling Summer 2002 through Spring 2003)

If you do not own a notebook computer meeting the following standards, upgrade or buy a notebook computer to meet or exceed the following minimum standards:

### Hardware Specs:

- 500 MHz processor
- 10 gigabyte hard drive
- 256 megabytes or more of RAM
- 10X CD ROM with sound support including speakers and/or headphones
- Lithium Ion battery
- A 10/100 Network adapter (for Ethernet and/or cable modem access)
- 56Kbps V.90 Modem (for dial-up access)

### Software Specs:

- Windows 2000 OR XP - Professional Edition (Millennium Edition and XP Home Edition is not recommended nor supported.) Compare the features - <http://www.microsoft.com/windows/>
- Microsoft Office 2000 OR XP Professional with Access. Microsoft Office 2000 Small Business Edition (SBE) bundled with many computers is not adequate. It lacks PowerPoint and Access. Microsoft Office Premium Edition is an acceptable and superior alternative as it includes all the features of Professional plus FrontPage and PhotoDraw - <http://www.microsoft.com/office/>
- Microsoft Internet Explorer - <http://www.microsoft.com/windows/ie/>
- Microsoft Outlook Express - <http://www.microsoft.com/windows/oe/>

# An Empirical Study of the Impact of IT Intensity and Organizational Absorptive Capacity on Customer Relationship Management Performance

## Abstract

In recent years, e-Business has emerged as a mainstream business practice. Engaged in highly-competitive Internet-enabled markets, many business organizations have turned to customer relationship management (CRM), a computer-based information system that allows them to gain greater insight into their customers' needs, to gain a competitive advantage. Consequently, CRM has risen to become a key e-business issue. Yet, many critical organizational factors underlie the success and performance of CRM. This study examines the impact of information technology (IT) intensity and organizational absorptive capacity on CRM practices and performance, and presents a research model. Data collected through a survey of Taiwan financial service institutions suggest that CRM practices mediate the effects of IT intensity and organizational absorptive capacity on CRM performance.

## 1. Introduction

As more businesses transition to e-business, competition in the Internet-enabled marketplace becomes keener. Many have turned to information technology (IT) for solutions that provide a competitive advantage. One such IT-based solution that has gained popularity in recent years is customer relationship management (CRM), frequently defined as an information system to assist the customer retention process or a methodology that extensively employs information technology (IT), particularly database and Internet technologies, to enhance the effectiveness of relationship marketing practices. Generally, greater investments in IT provide CRM with greater capabilities. As a formidable strategic weapon, CRM tunes the organization into listening to its customers, and allows it (organization) to develop customized products and services that cannot be easily duplicated, substituted or imitated by their competitors, and consequently more precisely fit their needs [29], [30], [34], [39]. Given this context, the primary objectives of CRM involve attracting, developing and maintaining successful customer relationships over time [2], [6], and building customer loyalty [20] through efficient and

effective two-way dialogues [39]. As the customer-business relationship flourishes, both the customers and organization benefit [40].

An important factor that may critically affect CRM performance lies in the organization's ability to leverage and exploit its knowledge toward innovating new products and services. Past studies [4], [5], [16] suggest that an organization's ability to link its knowledge to its innovativeness (i.e., ability to innovate) depends upon its absorptive capacity, the ability to recognize and assimilate new information, and apply the ensuing knowledge to commercial ends (i.e., exploitation) [5]. Therefore, differences in CRM practices and performance may be attributed to differences in absorptive capacity. Greater investments in developing organizational learning may lead to more successful results of CRM.

The purpose of this paper is to examine the effects of IT intensity, an organization's commitment to its IT infrastructure and IT applications, and organizational absorptive capacity on CRM practices and performance. This study proposes that organizations with stronger IT intensity and greater absorptive capacity will reap greater benefits from CRM, and be inclined to develop and produce more innovative products and services for their customers and as a result deepen their relationships. Hence, IT intensity and absorptive capacity should affect the CRM practices (i.e., customer insight) and CRM performance (i.e., organization and customer benefits). This study expands upon earlier research that examined the relationship between organizational absorptive capacity and CRM performance, and seeks to conceptually and empirically validate the relationship through a review of supporting studies and survey data collected from Taiwanese financial institutions, respectively.

## 2. The Impact of IT Intensity on Marketing Practices and Customer Services

Because CRM is an IT-enabled system, its performance hinges on the resources and investments an organization commits to it. IT intensity refers to the IT infrastructure and applications that allow the organization to benefit from its IT investments and apply them toward their best interests. The

infrastructure ensures access to and the availability of computing resources (i.e., hardware, software, data), and facilitates information sharing and communication throughout the organization. Henderson and Venkatraman [13] suggest that an organization's IT infrastructure has two components: (1) a technical IT infrastructure, and (2) a human IT infrastructure. Duncan [10] sees the technical IT infrastructure as a set of tangible, shared, physical IT resources that form a foundation for various business applications. Tangible IT resources include hardware and operating systems, network and telecommunications technologies, data, and core software applications.

In contrast, the human IT infrastructure addresses the necessary individual skills and knowledge required to develop, maintain, manipulate and support end-users in their abilities to leverage the technical infrastructure. Osterman [28] discusses the importance of developing and acquiring individual skills and roles to enable an organization's investments in IT. Without an adequate human IT infrastructure, the organization will realize very little benefit from its IT infrastructure and investments. In essence, the human IT infrastructure must shadow the development of a technical IT infrastructure.

With increasing emphasis being placed on organizational IT, the impact of IT on marketing practices and customer services has become more apparent over the past several years. As a major driving force, IT has permitted organizations to introduce continual improvements to their marketing practices in their quest to secure competitive advantages. These improvements fall into two general categories: (1) marketing process automation and (2) marketing intelligence. While marketing process automation helps link marketing activities to facilitate information sharing (i.e., efficiencies), marketing intelligence aims to enhance decision making through tools that provide greater insights. In many cases, the continual advances in IT have led to more sophisticated applications of IT. For example, the results of a survey conducted by Stone and Good [37] on computerization aids in the assimilation of tactical and strategic marketing activities strongly indicate that marketers are applying IT in new ventures, including tactical and strategic marketing activities such as the application of EDI to strategic supply chain [24]. Li et al. [23] found that many marketers are becoming more familiar with information and Internet technologies, and actively engaging in the development of computer applications that meet their specific information needs. The impact of IT on marketing practices has been an enabler of greater efficiencies (i.e., faster responses to satisfy information needs) and market intelligence.

IT also opens many new business opportunities in the customization of products and services, and development of customer loyalty. In particular, the migration of many businesses from traditional *bricks and mortar* operations to e-business has refocused the market's competitive orientation from product-centric to

customer-centric. Thus, the emphasis now lies in understanding each customer's needs in contrast to targeting a group or market segment with similar needs. In their discussion of IT enhancement to customer service, Walsh and Godfrey [38] suggest that e-tailers hold greater opportunities to offer better customer service than their *bricks and mortar* counterparts through customization, and add greater value to their products and services through personalized sites.

Along with the ability to gain greater insights into their customers' needs, organizations also now possess the capability to leverage their knowledge toward developing customer loyalty. Past studies reveal that the greatest leverage comes from investments in the retention rather than the generation of new customers [35], [32], [36], [39]. In their examination of e-loyalty and the unique economics of e-business customer loyalty, Reichheld and Scheffer [34] state that building loyalty involves first gaining the customer's trust, and not the application of technology and the Internet. Even though the Internet is a powerful tool for strengthening relationships, the basic laws and rewards of building loyalty have not changed. A study of Karimi et al. [19] that gauged IT management practices to determine whether they differed among firms seeking a competitive advantage with IT when it was linked to their customer service lends further support to this. The proposed relationship between customer value and positions on the product and process structure of Heim and Sinha [12] also reflects the value of developing customer loyalty.

### 3. Organizational Absorptive Capacity

Another organization factor with significant influence on CRM performance is organizational absorptive capacity. The absorptive capacity of an organization results from the cumulative learning activities of its individuals and the transfer of knowledge within the organization through a common language [5]. Learning activities occur with new experiences directed toward exploration (i.e., research), routine experiences and training. These activities help develop knowledge that can be used to recognize, acquire, assimilate and apply new knowledge. The more frequent learning occurs, the greater the accumulation process, which in turn reinforces prior knowledge, increases the capacity to retain new knowledge and yields the application of knowledge to new scenarios [3]. Thus, continuous learning builds over time a repository of knowledge that allows the organization to recognize and solve new problems with innovative solutions. The knowledge structures resulting from learning form a wealth of knowledge that eventually becomes available to the entire organization as a shared resource.

Absorption capacity allows organizations to leverage this knowledge (i.e., recognize and assimilate new information, and apply knowledge) in the form of innovative responses to benefit from their insights

garnered through their customer relationships. The greater the knowledge possessed and shared throughout the organization, the more the organization will be inclined to *absorb* new knowledge, and apply it toward innovative, creative and effective products and services. Thus, leveraging becomes greater as knowledge becomes pervasive in the organization.

## 4. CRM Practices: Market Orientation and Customer Service

### 4.1 Market Orientation

Various issues of market orientation have been widely discussed since the 1990s, including performance implications [17], [21], [25], [26], [27], measurement [7], [14], [22], and antecedents and performance outcomes [17], [27]. Market orientation can be defined as the organization-wide generation, dissemination and responsiveness to market intelligence, and involves information sharing among multiple departments engaged in activities directed toward meeting customer needs. In contrast to product-driven marketing, which focuses on pushing end products into markets while promoting lower prices and good quality, market-orientation concentrates on detecting customer needs and quickly fulfilling them. Market -orientation practices have positive impacts on an organization's performance and new products, and promote customer-centric values.

### 4.2 Customization and Loyalty Programs

The objective of customization is to provide tailor-made products/services that appeal to and more precisely fit the individual customer's needs. This requires soliciting customers for their feedback and integrating this information into production processes such that it provides the organization with its greatest competitive advantage [31]. However, customization incurs costs, and sacrifices flexibility and speed [8]. Mass customization attempts to customize products and services for the individual customers to reach a one-to-one marketing level. It can be seen as an extension of traditional product differentiation which strives toward changing the product's characteristics to competitively distinguish it from another business' offering. In contrast, mass customization achieves differentiation through targeting the product's or service's benefits toward satisfying the customer's specific needs. The advances in IT makes mass customization more feasible as it allows individual customer behavior to be traced and analyzed through data warehouses and data mining techniques, all of which make customer service easier and solution-oriented [18].

Through the analysis of their collected data, organizations can capitalize on future opportunities through the development of loyal programs. Loyalty programs behoove organizations to develop since they often lead to increases in repeat-purchase rates and

usage frequency, and raise barriers of entry into the market by making it difficult for new entrants to court customers away from existing businesses [36]. The market research studies of Hughes [15], and Reichheld and Sasser [33] strongly suggest that loyalty programs can increase business revenue and total customer market share. Similarly, Dowling and Uncles [9] conclude that loyalty programs can introduce many benefits to their promoters.

## 5. Research Model and Test of Hypotheses

Figure 1 illustrates this study's research model. The model proposes the impact of IT intensity and organizational absorptive capacity on CRM practices and performance. IT intensity and organizational absorptive capacity represent the independent variables, while CRM practices a mediator variable, and CRM performance represented by business benefits and customer benefits the two dependent variables. Based on a review of the literature, previous related case studies and field experiences shared by industrial experts, the following hypotheses and sub-hypotheses are presented:

- H1: There is a positive relation between IT intensity and CRM practices
  - H1a: There is a positive relation between IT intensity and market orientation
  - H1b: There is a positive relation between IT intensity and customer service
- H2: There is a positive relation between absorptive capacity and CRM practices.
  - H2a: There is a positive relation between absorptive capacity and market orientation.
  - H2b: There is a positive relation between absorptive capacity and customer service
- H3: There is a positive relation between CRM practices and CRM performance.
  - H3a: There is a positive relation between market orientation and firm benefits.
  - H3b: There is a positive relation between market orientation and customer benefits.
  - H3c: There is a positive relation between customer service and firm benefits.
  - H3d: There is a positive relation between customer service and customer benefits.
- H4: There is a mediating effect of market orientation on IT intensity, absorptive capacity to CRM performance.
  - H4a: There is a mediating effect of market orientation on IT intensity, absorptive capacity to firm benefits.
  - H4b: There is a mediating effect of market orientation on IT intensity, absorptive capacity to customer benefits.

H5: There is a mediating effect of customer service on IT intensity, absorptive capacity to CRM performance.

H5a: There is a mediating effect of customer service on IT intensity, absorptive capacity to firm benefits.

H5b: There is a mediating effect of customer service on IT intensity, absorptive capacity to customer benefits.

## 6. Research Methodology

### 6.1 Data Collection and Sample

Survey questionnaires with accompanying cover letters were mailed to 542 Taiwanese financial service companies. The cover letter briefly explained the purpose of this research project, which received funding from the National Science Council (NSC) of Taiwan, and contained general instructions for completing the survey. The recipients were restricted to CRM and marketing managers, and customer service department heads. Two weeks after the initial mailing, 99 responses were received. Follow-up telephone calls were made a week later, urging non-response recipients to complete and return their surveys by either mail or fax. In total, 173 responses were returned for a response rate of 30 percent. Among the returned surveys, nine were incomplete and discarded; this reduced the sample size to 164. The final sample covers a broad cross-section of firms in the banking, insurance and trading industries as well as many others.

### 6.2 Measures

A standard psychometric scale development procedure [11] was followed to generate multiple-item scales based on a review of the literature and interviews with IT and marketing professionals. Measures with single- and multiple-item formats and conceptualized multiple-items scales as formative or reflective in nature were formulated. The questionnaire was pre-tested and refined following the comments of the IT and marketing managers. All items were operationalized using five-point Likert-type scales. Table 1 provides the operational definitions of each variable. Table 2 contains the results of the reliability test while Table 3 shows the summary statistics of all constructs and the variance-covariance matrix.

A comparison between respondents and the population on four variables (number of employees, capital, industries, and age of the firm) was conducted to examine the data for potential non-response bias. None of these four t-tests for differences between the sample and the population means was statistically significant at a 0.05 level. Moreover, no significant differences between earlier and later respondents on the scores of each question item were detected. The absence of differences supports the contention that no response bias is present in the sample [1].

## 7. Results

Eight hierarchical regression models were developed to test the hypotheses. Firm capital (CAPITAL) and the number of employee (EMPLOYEE) were set as the control variables. Tables 4 through 11 provide summaries of the statistical results. The p-values for IT-intensity (IT\_NESS) and absorptive capacity (ABSRPTVE) (Tables 4 and 5) both indicate significance ( $p < .01$ ). The VIF values show no sign of colinearity. The first model (Table 4) suggests that IT intensity and organizational absorptive capacity are positively related to market orientation (MK\_ORNT), one of the elements of CRM practices. Therefore, H1a and H2a are supported. The second model (Table 5) also suggests that IT-intensity and absorptive capacity are positively related to customer service (CS), the second element of CRM practices, and thereby lends support to H1b and H2b.

The regression models shown in Tables 6 and 7 suggest that the relationships between customer service (CS) and firm benefits (F\_BENEFI, Table 6), and customer service and customer benefits (C\_BENEFI, Table 7) are both significant ( $p < 0.01$ ) and positive, and support H3c and H3d. Market orientation practice is also positively related to firm benefits (Table 6,  $p < .01$ ) and customer benefits (Table 7,  $p < .05$ ). Therefore, both H3a and H3b are supported. The VIF values indicate the presence of no collinearity.

Several regression models were developed to test the mediating effects of CRM practices (market orientation and customer service). The results are summarized in Tables 8 through 13. Tables 8 and 9 reveal that both absorptive capacity and IT intensity have direct effects on CRM performance ( $p < .01$  and  $.05$ , respectively) as measured against customer and firm benefits. When market orientation is included (Tables 10 and 12), the models suggest market orientation's mediating effect on customer benefits (market orientation,  $p < .01$ ; IT-intensity,  $p > .05$ ; absorptive capacity,  $p > .05$ ), and a partial mediating effect on firm benefits (market orientation,  $p < .05$ ; IT-intensity,  $p > .05$ ; absorptive capacity,  $p < .05$ ). Partial mediating effects were also found between customer service and firm (customer service,  $p < .01$ ; IT-intensity,  $p > .05$ ; absorptive capacity,  $p < .05$ ) benefits (Table 11), but a mediating effect between customer service and customer benefits (customer service,  $p < .01$ ; IT-intensity,  $p > .05$ ; absorptive capacity,  $p > .05$ ) (Tables 13). The models support H4b and H5b, but not H4a and H5a due to the partial mediating effects.

## 8. Conclusion

This paper investigated the impact of IT intensity and absorptive capacity on CRM practices and CRM performance, and the mediating effects of CRM practices. Based on the data collected through a survey of financial institutions in Taiwan, the analyses indicate that (1) IT intensity and absorptive capacity are

positively related to CRM practices (i.e., firm benefits, customer benefits), and (2) CRM practices (i.e., market orientation, customer service) are positively related to CRM performance. Furthermore, (3) CRM practices can be treated as mediators since they can influence the impact of IT intensity and organizational absorptive capacity on CRM performance.

Adopting CRM has been a top priority for many business organizations. To ensure a successful CRM implementation, the results of this study suggest that organizations need to enhance their IT intensity, such as investing in their IT infrastructure, and improving and fully utilizing their IT applications. More importantly, they need to develop their absorptive capacity through

enhanced training programs and knowledge transfer capabilities. Nevertheless, improving IT intensity and enlarging absorptive capacity are important for all organizations engaged in e-business and CRM. Organizations that maintain a market-oriented strategy, adopt customization approaches and place greater emphasis on customer service will promote customer benefits and eventually retain their customers and increase revenue and profits.

### Abstract

How to more efficiently and effectively enhance service performance is an on-going challenge to any service team. A new service model, Proactive-Service-Center (P-S-C), is developed since Feb'01. As a result, the service performance results are improved in terms of same day issue closure rate, issue response time and system uptime. The P-S-C is not only an innovative way to enhance service performance but also a systematic way to build-up engineers' trouble-shooting capability.

In the old service situation, the information flows randomly among customer engineers, customer section managers, AMT engineers, and AMT site managers. The average time spent is around two hours from Issue Happened to Dedicated Engineer on site. Customer and AMT engineers are running around like a chicken without head. The information flows inefficiently and ineffectively among customer engineers, section managers, AMT engineers and site managers. The detailed solutions are not documented and remained in the engineers' heads.

In the PSC model, the information flows automatically from the system which is down to the customer Server then to the PSC Server and the dedicated AMT engineer is automatically informed. The information flows efficiently and effectively. The actions

done are then systematically entered and documented in PSC and a monthly analysis report is generated and provided to customers.

The cost savings of PSC can be estimated indirectly. The issue response time is reduced from 2 hours to 58 minutes (reduced by 62 minutes). This translates to the increase of system uptime by 62 minutes. This will bring cost savings. In addition, the issue closure rate is improved from 50% to 85% (improved by 35%). This also translates to the increase of system uptime. The system uptime enhancement is cost savings.

Three areas which need improvement are identified to be Technology, People and Process. Technology: Internet is used and many auto functions (for example, reminding, reporting) are built-in to enhance the capability. People: Dedicated Engineer Matrix is built-in PSC and the right engineer can be reached at the right time in the most efficient manner. Process: Process is real time and systematic with clear R&R defined to ensure efficiency and experience build-up in the future.

Data : Original work performed

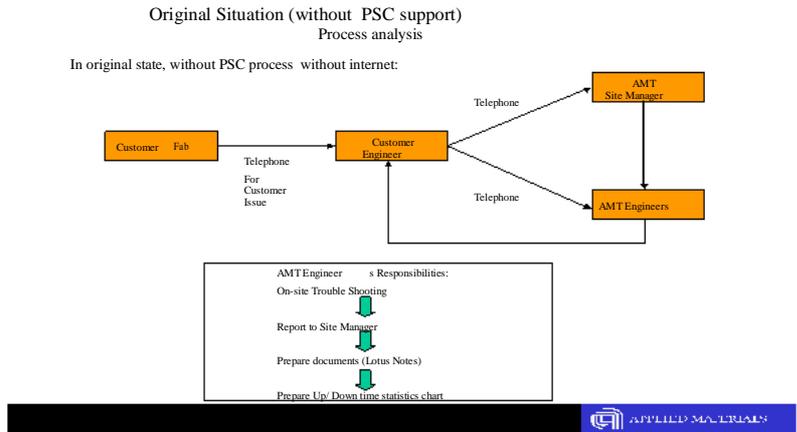

Figure 1: Original Situation (without P-S-C support)

### 1. Solutions

As indicated in Fig. 1, the original service situation is not real time, no service record, and no standard format to collect field trouble-shooting experience.

The customer decides when to make the phone call of any issue and there is no service record of the time involved trouble-shooting for any issue. In addition, after the issue is solved, the experience remains inside the engineer's head.

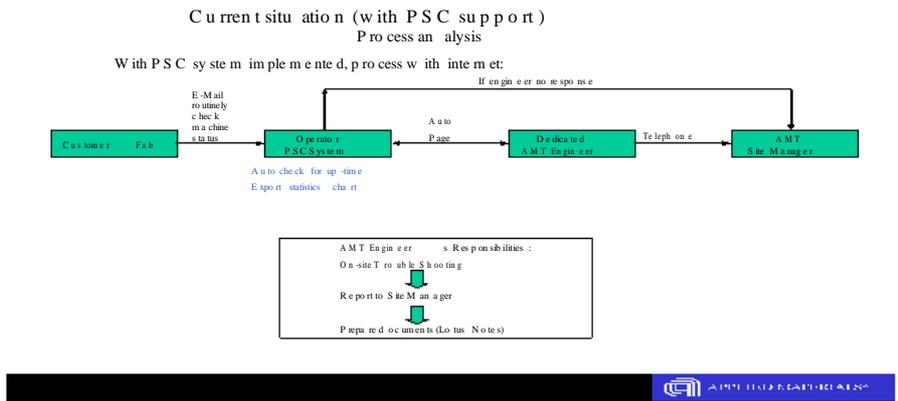

Figure 2: Current situation (with P-S-C support)

Table 1: Benefit Analysis of Original Service Situation v.s. Proactive Service Center (P-S-C)

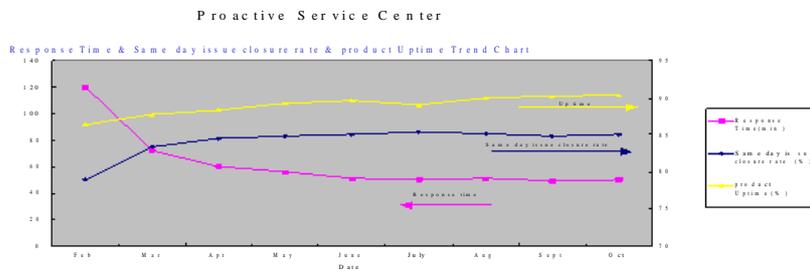

Category	Original Service Situation	Proactive Service Center	Benefit
Mechanism	Reactive	Proactive	The support mechanism is now proactive instead of reactive to wait for issue to happen. Research can be done for each issue before discussing with customers. This has shortened the issue cycle time.
Issue	Delayed	Real Time	Issue cycle time is shortened since there is no time delay in waiting for each issue to be reported.
Satisfaction Index (Same Day Issue Closure Rate)	N/A	Available	Same day issue closure rate is recorded in the P-S-C database and can be calculated regularly. This meaningful index can be monitored to enhance customer satisfaction.
Satisfaction Index (Issue Response Time)	N/A	Available	Issue response time is calculated automatically in the P-S-C database and this meaningful index can be monitored to enhance customer satisfaction.
System Uptime	Maintain	Maximize	Since the issue cycle time is shortened, the system uptime performance is maximized.
Troubleshooting Guide	N/A	Systematically Build-Up	Troubleshooting guide is built up systematically from engineers' service report which enhances engineering capability and improve system uptime.

As indicated in Fig. 2, the current service model is real-time with service record in the PSC system. In addition, the software is written to include auto checking and alarming functions for low uptime systems and it systematically collects field trouble-shooting actions done by engineers.

In short, when there is a variation in system normal condition, then the system automatically sends out the abnormal message to the customer server. The AMT server receives the message and page the system's dedicated engineer automatically. The engineer

responsible for the system response to the operator at the P-S-C, acknowledge receiving the pager and with on-site arriving time. After the issue is resolved, the engineer will fill out the service report with actions done.

The new service model, P-S-C, is real-time in issue feedback with service record and the engineer's trouble-shooting experience is systematically documented for future reference. The PSC solution is proven sustainable over time as indicated in the results trend chart. Fig. 3: Results Trend Chart.

## 2. Product Excellence

The benefit of P-S-C is summarized in Table 1. The P-S-C mechanism is proactive and shorten the issue cycle time. The issue is real time acknowledged to shorten cycle time. The customer satisfaction index previously not available such as same day issue closure rate and issue response time are now available to enhance customer satisfaction. In addition, the system uptime is now maximized since the issue cycle time is shortened. The P-S-C process is systematically collecting engineers' service report which serves as the base to build up the field trouble-shooting guide. The field trouble-shooting guide can be used to enhance engineering capability and improve system uptime.

In addition, the PSC has accumulated historical data on each system. Data analysis are done and included in the Monthly Report. The data analysis includes top 3 root causes for downtime and actions done which can be used to forecast future manpower arrangement and materials allocation. This means the

data analysis from PSC can be used proactively for future manpower or materials planning.

## 3. Model of Proactive Service Center

The model of P-S-C is shown in Fig.4 and management theory framework of P-S-C is documented in Fig. 5 and it includes the Infrastructure, Methods and Theories and Application of P-S-C. In addition to Internet, the infrastructure is based on Knowledge Management. P-S-C is a systematic way to document engineering field knowledge. During P-S-C implementation, it is crucial the customers fully understand the security and technology of P-S-C. The application of P-S-C can be shown in Fig. 4 to be Cycle Time Enhancement, One-to-One System Historical Record, Engineering Trouble-Shooting Build-Up, Proactive Service Provider and finally customer satisfaction leverage to create Win-Win-Win situation among AMT, customers and customers' customers.

# Quality Management for an E-Commerce Network Under Budget Constraint

Yi-Kuei Lin

Department of Information Management

Van Nung Institute of Technology

Chung-Li, Tao-Yuan, Taiwan

[yklin@cc.vit.edu.tw](mailto:yklin@cc.vit.edu.tw)

## Abstract

In general, several types of information data are transmitted through an E-Commerce network simultaneously. Each type of information data is set to one type of commodity. Under the budget constraint, this paper studies the probability that a given amount of multicommodity can be transmitted through an E-Commerce network, where each node and each arc has several possible capacities. We may take this probability as a performance index for this network. Based on the properties of minimal paths, a simple algorithm is proposed to generate all lower boundary points for  $(d^1, d^2, \dots, d^p; C)$  where  $d^i$  is the demand of commodity  $i$  and  $C$  is the budget. The probability can then be calculated in terms of such points.

## 1. Introduction

The capacity of each arc (the maximum flow passing the arc per unit time) in a binary-state flow network has two levels, 0 and a positive integer. For perfect nodes case, Aggarwal et al. [1] computed the system reliability, the probability that the maximum flow of the network is not less than the demand, in terms of minimal paths (MPs). A MP is an ordered sequence of arcs from the source  $s$  to the sink  $t$  that has no cycle. Lee et al. [10] and Rueger [15] extended the system reliability problem to the case that nodes and arcs have a positive-integer capacity and may fail. A stochastic-flow network is a multi-state network in which each arc has several states or capacities. The system reliability is the probability that the maximum flow of single-commodity through the network is not less than the demand  $d$ . Without the budget constraint, several authors [11,12,14,19,21] had presented algorithms to generate lower boundary points for  $d$  in order to evaluate the system reliability for perfect node case. Lin [13] and Yeh [22] extended the problem to the more general case that nodes have several capacities as arcs do.

However, in real world, many stochastic-flow networks allow multicommodity to be transmitted from  $s$  to  $t$  simultaneously. Assuming the flow network is deterministic (i.e., the capacity of each arc is a constant), many authors [3,4,8,17,18] studied the multicommodity minimum cost flow problem, which is to minimize the total cost of multicommodity. The purpose of this paper is to extend the system reliability problem to a

multicommodity case, named multicommodity reliability here, for a stochastic-flow network with node failure under budget constraint. Then a MP is an ordered sequence of arcs and nodes from  $s$  to  $t$  that has no cycle. The system reliability is the probability that the given demand  $(d^1, d^2, \dots, d^p)$  can be transmitted through the stochastic-flow network under budget  $C$ , where  $d^k$ ,  $k = 1, 2, \dots, p$ , is the required demand of commodity  $k$ . A simple algorithm is proposed to generate all lower boundary points for  $(d^1, d^2, \dots, d^p; C)$ , then the multicommodity reliability can be computed in terms of all lower boundary points for  $(d^1, d^2, \dots, d^p; C)$ .

## 2. Multicommodity Model Under Budget Constraint

$G = (A, N, M)$  is a stochastic-flow network with source  $s$  and sink  $t$  where  $A = \{a_i | 1 \leq i \leq n\}$  the set of arcs,  $N = \{a_i | n+1 \leq i \leq n+r\}$  the set of nodes and  $M = (M_1, M_2, \dots, M_{n+r})$  with  $M_i$  the maximal capacity of  $a_i$ . Let  $x_i$  denote the (current) capacity of  $a_i$  and it takes values from  $\{0, 1, 2, \dots, M_i\}$  with a given probability distribution.

### 2.1 Assumptions and Nomenclature

1. All commodities are transmitted from  $s$  to  $t$ .
2. The capacities of different arcs are statistically independent.

$\lceil x \rceil$  the smallest integer such that  $\lceil x \rceil \geq x$

$Y \geq X$   $(y_1, y_2, \dots, y_{n+r}) \leq (x_1, x_2, \dots, x_{n+r})$  if and only if  $y_i \geq x_i$  for  $i = 1, 2, \dots, n+r$

$Y > X$   $(y_1, y_2, \dots, y_{n+r}) > (x_1, x_2, \dots, x_{n+r})$  if and only if  $Y \geq X$  and  $y_i > x_i$  for at least one  $i$

### 2.2 Multicommodity Flow

Suppose  $P_1, P_2, \dots, P_m$  are MPs from  $s$  to  $t$ . The multicommodity flow model for  $G$  is described in terms of the capacity vector  $X = (x_1, x_2, \dots, x_{n+r})$  and the flow assignment  $(F^1, F^2, \dots, F^p)$ , where  $F^k = (f_1^k, f_2^k, \dots, f_m^k)$  with  $f_j^k$  denoting the flow (integer-value) of commodity  $k$  through  $P_j$ ,  $j = 1, 2, \dots, m$ ,  $k = 1, 2, \dots, p$ . Such an  $(F^1, F^2, \dots, F^p)$  which is feasible under  $X$  satisfies the following condition:

$$\sum_{k=1}^p (\varpi_i^k \cdot \sum_{a_i \in P_i} f_j^k) \leq x_i \text{ for } i = 1, 2, \dots, n+r, \quad (1)$$

where  $\varpi_i^k$  (real number) is the weight of commodity  $k$  on  $a_i$  i.e., the consumed amount of capacity on  $a_i$  per commodity  $k$ . For convenience, let  $\Phi_X$  denote the set of  $(F^1, F^2, \dots, F^p)$  feasible under  $X$ . Similarly,  $(F^1, F^2, \dots, F^p) \in \Phi_M$  if it satisfies

$$\sum_{k=1}^p (\varpi_i^k \cdot \sum_{a_i \in P_i} f_j^k) \leq M_i \text{ for } i = 1, 2, \dots, n+r. \quad (2)$$

Let  $c_i^k$  denote the transportation cost of each commodity  $k$  through  $a_i$ . Under  $X$ , the network  $G$  satisfies the given demand  $(d^1, d^2, \dots, d^p)$  under the budget  $C$  if there exists an  $(F^1, F^2, \dots, F^p) \in \Phi_X$  satisfying constraints (3) and (4);

$$\sum_{j=1}^m f_j^k = d^k, \quad k = 1, 2, \dots, p \quad (3)$$

$$\sum_{i=1}^{n+r} \sum_{k=1}^p c_i^k \cdot \sum_{a_i \in mp_j} f_j^k \leq C. \quad (4)$$

Let  $\Omega = \{X \mid \text{there exists an } (F^1, F^2, \dots, F^p) \in \Phi_X \text{ satisfying constraints (3) and (4)}\}$ . The multicommodity reliability  $R_{d^1, d^2, \dots, d^p; C}$  is thus

$$R_{d^1, d^2, \dots, d^p; C} = \Pr\{\Omega\} = \sum_{X \in \Omega} \Pr\{X\}$$

Each minimal one in  $\Omega$  is named a lower boundary point for  $(d^1, d^2, \dots, d^p; C)$  throughout this paper i.e.,  $X$  is a lower boundary point for  $(d^1, d^2, \dots, d^p; C)$  if and only if i)  $X \in \Omega$  and ii)  $Y \notin \Omega$  for any capacity vector  $Y$  such that  $Y < X$ . Hence,

$$R_{d^1, d^2, \dots, d^p; C} = \Pr\{Y \mid Y \geq X \text{ for a lower boundary point for } (d^1, d^2, \dots, d^p; C) \mid X\}.$$

### 2.3 Generate All Lower Boundary Points for $(d^1, d^2, \dots, d^p; C)$

Let  $\Phi = \{(F^1, F^2, \dots, F^p) \mid (F^1, F^2, \dots, F^p) \text{ satisfies constraints (2) - (4)}\}$ . For each  $(F^1, F^2, \dots, F^p) \in \Phi$ , generate the capacity vector  $Z_{F^1, F^2, \dots, F^p} = (z_1, z_2, \dots, z_{n+r})$

via

$$z_i = \sum_{k=1}^p (\varpi_i^k \cdot \sum_{a_i \in P_i} f_j^k) \text{ for } i = 1, 2, \dots, n+r. \quad (5)$$

For convenience, let  $\Psi = \{Z_{F^1, F^2, \dots, F^p} \mid (F^1, F^2, \dots, F^p) \in \Phi\}$ .

We will first see that  $\Psi$  contains all lower boundary points for  $(d^1, d^2, \dots, d^p; C)$  in the following lemma.

**Lemma 1.** Let  $X$  be a lower boundary point for  $(d^1, d^2, \dots, d^p; C)$ . Then  $X = Z_{F^1, F^2, \dots, F^p}$  for each  $(F^1, F^2, \dots, F^p) \in \Phi_X \cap \Phi$ .

**Proof:** For each  $(F^1, F^2, \dots, F^p) \in \Phi_X \cap \Phi$ , constraint (1) says that  $Z_{F^1, F^2, \dots, F^p} \leq X$ . Suppose that  $Z_{F^1, F^2, \dots, F^p} < X$ , then  $Z_{F^1, F^2, \dots, F^p} \notin \Omega$  as  $X$  is minimal in  $\Omega$ . This is a contradiction. Hence,  $X = Z_{F^1, F^2, \dots, F^p}$ .  $\square$

The following lemma further shows that  $\Psi_{\min} \equiv \{X \mid X \text{ is minimal in } \Psi\}$  is the set of lower boundary point for  $(d^1, d^2, \dots, d^p; C)$ .

**Lemma 2.**  $\{X \mid X \text{ is a lower boundary point for } (d^1, d^2, \dots, d^p; C)\} = \Psi_{\min}$ .

**Proof:** Firstly, suppose that  $X$  is a lower boundary point for  $(d^1, d^2, \dots, d^p; C)$  (note that  $X \in \Psi$  by lemma 1) but  $X \notin \Psi_{\min}$  i.e., there exist a  $Y \in \Psi$  such that  $Y < X$ . Then  $Y \in \Omega$ , which contradicts to that  $X$  is a lower boundary point for  $(d^1, d^2, \dots, d^p; C)$ . Hence,  $X \in \Psi_{\min}$ .

Conversely, suppose that  $X \in \Psi_{\min}$  (note that  $X \in \Omega$ ) but it is not a lower boundary point for  $(d^1, d^2, \dots, d^p; C)$ . Then there exists a lower boundary point for  $(d^1, d^2, \dots, d^p; C)$   $Y$  s.t.  $Y < X$ . By lemma 1,  $Y \in \Psi$  that contradicts to that  $X \in \Psi_{\min}$ . Hence,  $X$  is a lower boundary point for  $(d^1, d^2, \dots, d^p; C)$ .  $\square$

### 3. Algorithm

As those approaches of [11,13,14,19,21,22] we suppose all MPs have been pre-computed. Minimal paths can be efficiently derived from those algorithms discussed in [2,9,16]. The algorithm of Al-Ghanim [2] showed an approximate linear time response versus the number of network nodes. Kobayashi and Yamamoto [9] showed that to generate all minimal paths for a random network with 30 nodes and 100 arcs takes no more than 1300 seconds.

**Step 1.** Obtain all  $(F^1, F^2, \dots, F^p)$  with  $F^k = (f_1^k, f_2^k, \dots, f_m^k)$ ,  $k = 1, 2, \dots, p$ , of the following constraints:

$$\sum_{k=1}^p (\varpi_i^k \cdot \sum_{a_i \in P_i} f_j^k) \leq M_i \text{ for } i = 1, 2, \dots, n+r \quad (5)$$

$$\sum_{j=1}^m f_j^k = d^k, \quad k = 1, 2, \dots, p \quad (6)$$

$$\sum_{i=1}^{n+r} \sum_{k=1}^p c_i^k \cdot \sum_{a_i \in mp_j} f_j^k \leq C \quad (7)$$

**Step 2.** Transform each  $(F^1, F^2, \dots, F^p)$  into  $X = (x_1, x_2, \dots, x_{n+r})$  according to

$$x_i = \left\lfloor \sum_{k=1}^p (\omega_i^k \cdot \sum_{a_j \in P_j} f_j^k) \right\rfloor \text{ for } i = 1, 2, \dots, n + r \quad (8)$$

Step 3. Suppose  $\Psi = \{X_1, X_2, \dots, X_v\}$ .

- 3.1)  $I = \emptyset$  ( $I$  is the stack which stores the index of each non-minimal  $X$  after checking. Initially,  $I = \emptyset$ .)
- 3.2) For  $i = 1$  To  $v$  and  $\notin I$
- 3.3) For  $j = i + 1$  To  $v$  with  $\notin I$
- 3.4) If  $X_i \geq X_j$ ,  $I = I \cup \{i\}$  and go to step 3.7) Elseif  $X_j > X_i$ ,  $I = I \cup \{j\}$
- 3.5)  $j = j + 1$
- 3.6)  $X_i$  is a lower boundary point for  $(d^1, d^2, \dots, d^p; C)$
- 3.7)  $i = i + 1$
- 3.8) End.

#### 4. A numerical example

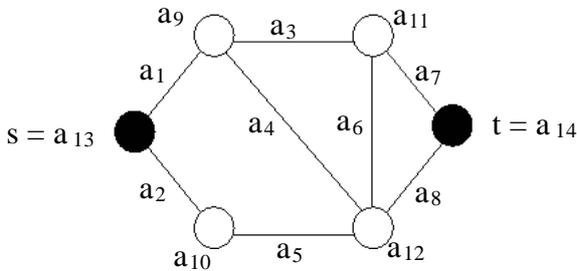

Figure 1. A benchmark [14,20]

We use the benchmark [14,20] in Figure 1 to illustrate the proposed approach. There are 7 MPs:  $P_1 = \{a_{13}, a_1, a_2, a_3, a_{11}, a_7, a_{14}\}$ ,  $P_2 = \{a_{13}, a_1, a_2, a_3, a_{11}, a_6, a_{12}, a_8, a_{14}\}$ ,  $P_3 = \{a_{13}, a_1, a_2, a_4, a_{12}, a_8, a_{14}\}$ ,  $P_4 = \{a_{13}, a_1, a_2, a_4, a_2, a_6, a_{11}, a_7, a_{14}\}$ ,  $P_5 = \{a_{13}, a_2, a_{10}, a_5, a_{12}, a_6, a_{11}, a_7, a_{14}\}$  and  $P_6 = \{a_{13}, a_2, a_{10}, a_5, a_{12}, a_4, a_2, a_3, a_{11}, a_7, a_{14}\}$ . The data of arcs and nodes for 2-commodity case are shown in Table 1. We assume the source and the sink both have infinite capacity and are perfect. If the demand  $(d_1, d_2)$  is set to be  $(3,3)$  and  $C = 810$  US dollars, then the multicommodity reliability  $R_{3,3;810}$  can be calculated by the following steps.

Step 1. Obtain all  $F^1 = (f_1^1, f_2^1, f_3^1, f_4^1, f_5^1, f_6^1, f_7^1)$ , and  $F^2 = (f_1^2, f_2^2, f_3^2, f_4^2, f_5^2, f_6^2, f_7^2)$  of the following integer-programming:

- (9)  $a_1: \begin{cases} f_1^1 + f_2^1 + f_3^1 + f_4^1 + 2f_5^1 + 2f_6^1 + 2f_7^1 \\ 2f_5^2 + 2f_6^2 \leq 5 \end{cases}$
- $a_2: f_5^1 + f_6^1 + f_7^1 + 2f_5^2 + 2f_6^2 + 2f_7^2 \leq 5$
- $a_3: f_1^1 + f_2^1 + f_7^1 + 2f_2^2 + 2f_5^2 + 2f_7^2 \leq 5$
- $a_4: f_3^1 + f_4^1 + f_7^1 + 2f_3^2 + 2f_4^2 + 2f_7^2 \leq 5$
- $a_5: f_5^1 + f_6^1 + f_7^1 + 2f_5^2 + 2f_6^2 + 2f_7^2 \leq 5$
- $a_6: f_2^1 + f_4^1 + f_6^1 + 2f_2^2 + 2f_4^2 + 2f_6^2 \leq 5$

- $a_7: \begin{cases} f_1^1 + f_4^1 + f_6^1 + f_7^1 + 2f_5^2 + 2f_6^2 + 2f_7^2 \\ 2f_5^2 + 2f_6^2 \leq 5 \end{cases}$
- $a_8: f_2^1 + f_3^1 + f_5^1 + 2f_2^2 + 2f_3^2 + 2f_5^2 \leq 5$
- $a_9: \begin{cases} f_1^1 + f_2^1 + f_3^1 + f_4^1 + f_7^1 + 2f_2^2 + 2f_3^2 + 2f_5^2 + 2f_6^2 + 2f_7^2 \\ 2f_5^2 + 2f_6^2 + 2f_7^2 \leq 9 \end{cases}$
- $a_{10}: f_5^1 + f_6^1 + f_7^1 + 2f_5^2 + 2f_6^2 + 2f_7^2 \leq 9$
- $a_{11}: \begin{cases} f_1^1 + f_2^1 + f_4^1 + f_6^1 + f_7^1 + 2f_2^2 + 2f_3^2 + 2f_5^2 + 2f_6^2 + 2f_7^2 \\ 2f_5^2 + 2f_6^2 + 2f_7^2 \leq 9 \end{cases}$
- $a_{12}: \begin{cases} f_2^1 + f_3^1 + \dots + f_7^1 + 2f_2^2 + 2f_3^2 + \dots + 2f_7^2 \\ \leq 9 \end{cases}$

$$(10) \begin{cases} f_1^1 + f_2^1 + f_3^1 + f_4^1 + f_5^1 + f_6^1 + f_7^1 = 3 \\ f_1^2 + f_2^2 + f_3^2 + f_4^2 + f_5^2 + f_6^2 + f_7^2 = 3 \end{cases}$$

$$(11) \begin{cases} 10(f_1^1 + f_2^1 + f_3^1 + f_4^1) + 20(f_1^2 + f_2^2 + f_3^2 + f_4^2) + \{20(f_5^1 + f_6^1 + f_7^1) + 30(f_5^2 + f_6^2 + f_7^2)\} + \{30(f_1^1 + f_2^1 + f_7^1) + 40(f_1^2 + f_2^2 + f_7^2)\} + \{20(f_3^1 + f_4^1 + f_7^1) + 40(f_3^2 + f_4^2 + f_7^2)\} + \{10(f_5^1 + f_6^1 + f_7^1) + 20(f_5^2 + f_6^2 + f_7^2)\} + \{20(f_2^1 + f_4^1 + f_6^1) + 30(f_2^2 + f_4^2 + f_6^2)\} + \{30(f_1^1 + f_4^1 + f_6^1 + f_7^1) + 40(f_1^2 + f_4^2 + f_6^2 + f_7^2)\} + \{20(f_2^1 + f_3^1 + f_5^1) + 40(f_2^2 + f_3^2 + f_5^2)\} + \{20(f_1^1 + f_2^1 + f_3^1 + f_4^1 + f_7^1) + 30(f_1^2 + f_2^2 + f_3^2 + f_4^2 + f_7^2)\} + \{20(f_5^1 + f_6^1 + f_7^1) + 30(f_5^2 + f_6^2 + f_7^2)\} + \{20(f_1^1 + f_2^1 + f_4^1 + f_6^1 + f_7^1) + 30(f_1^2 + f_2^2 + f_4^2 + f_6^2 + f_7^2)\} + \{20(f_2^1 + f_3^1 + \dots + f_7^1) + 30(f_2^2 + f_3^2 + \dots + f_7^2)\} \leq 810 \end{cases}$$

Seven  $(F^1, F^2)$  are obtained:  $(3, 0, 0, 0, 0, 0, 0)$ ,  $(0, 0, 1, 0, 0, 0, 0)$ ,  $(2, 0, 0, 0, 0, 0, 0)$ ,  $(0, 1, 0, 0, 0, 0, 0)$ ,  $(0, 0, 1, 0, 0, 0, 0)$ ,  $(1, 0, 0, 0, 2, 0, 0)$ ,  $(2, 0, 0, 0, 1, 0, 0)$ ,  $(0, 0, 1, 0, 2, 0, 0)$ ,  $(2, 0, 0, 0, 1, 0, 0)$ ,  $(0, 0, 0, 0, 3, 0, 0)$ ,  $(2, 0, 0, 0, 1, 0, 0)$  and  $(0, 0, 0, 0, 2, 1, 0, 2, 0, 0, 0, 1, 0, 0)$ . And the corresponding costs are 790, 790, 780, 780, 780, 770 and 810, respectively.

Step 2. Transform all  $(F^1, F^2)$  into  $X = (x_1, x_2, \dots, x_{12})$  according to

$$x_1 = \begin{cases} f_1^1 + f_2^1 + f_3^1 + f_4^1 + 2f_5^2 + 2f_6^2 + 2f_7^2 \\ 2f_5^2 + 2f_6^2 \end{cases}$$

$$\begin{aligned}
x_2 &= [f_5^1 + f_6^1 + f_7^1 + 2f_5^2 + 2f_6^2 + 2f_7^2] \\
x_3 &= [f_1^1 + f_2^1 + f_7^1 + 2f_2^2 + 2f_5^2 + 2f_7^2] \\
x_4 &= [f_3^1 + f_4^1 + f_7^1 + 2f_3^2 + 2f_4^2 + 2f_7^2] \\
x_5 &= [f_5^1 + f_6^1 + f_7^1 + 2f_5^2 + 2f_6^2 + 2f_7^2] \\
x_6 &= [f_2^1 + f_4^1 + f_6^1 + 2f_2^2 + 2f_4^2 + 2f_6^2] \quad (12) \\
x_7 &= [f_1^1 + f_4^1 + f_6^1 + f_7^1 + 2f_2^2 + 2f_4^2 + \\
&\quad 2f_6^2 + 2f_7^2] \\
x_8 &= [f_2^1 + f_3^1 + f_5^1 + 2f_2^2 + 2f_3^2 + 2f_5^2] \\
x_9 &= [f_1^1 + f_2^1 + f_3^1 + f_4^1 + f_7^1 + 2f_2^2 + \\
&\quad 2f_3^2 + 2f_4^2 + 2f_7^2] \\
x_{10} &= [f_5^1 + f_6^1 + f_7^1 + 2f_5^2 + 2f_6^2 + 2f_7^2] \\
x_{11} &= [f_1^1 + f_2^1 + f_4^1 + f_6^1 + f_7^1 + 2f_2^2 + \\
&\quad 2f_4^2 + 2f_6^2 + 2f_7^2] \\
x_{12} &= [f_2^1 + f_3^1 + \dots + f_7^1 + 2f_2^2 + 2f_3^2 + \\
&\quad \dots + 2f_7^2]
\end{aligned}$$

We obtain  $X_1 = (5, 4, 5, 0, 4, 0, 5, 4, 5, 4, 5, 4)$ ,  $X_2 = (5, 4, 4, 1, 4, 0, 4, 5, 5, 4, 4, 5)$ ,  $X_3 = (4, 5, 4, 0, 5, 0, 4, 5, 4, 5, 4, 5)$ ,  $X_4 = (5, 4, 5, 0, 4, 0, 5, 4, 5, 4, 5, 4)$ ,  $X_5 = (5, 4, 4, 1, 4, 0, 4, 5, 5, 4, 4, 5)$ ,  $X_6 = (4, 5, 4, 0, 5, 0, 4, 5, 4, 5, 4, 5)$  and  $X_7 = (4, 5, 4, 0, 5, 1, 5, 4, 4, 5, 5, 5)$ .

Step 3. Check each  $X_i$  whether it is a lower boundary point for (3,3;810) or not.

- 3.1)  $I = \emptyset$
- 3.2)  $i = 1$
- 3.3)  $j = 2$
- 3.4)  $X_1 \not\geq X_2$  and  $X_2 \not\geq X_1$ .  $I = \{\emptyset\}$ .
- 3.3)  $j = 3$
- 3.4)  $X_1 \not\geq X_3$  and  $X_3 \not\geq X_1$ .  $I = \{\emptyset\}$ .
- 3.5)  $j = 4$
- 3.4)  $X_1 \geq X_4$ .  $I = \{1\}$ .
- 3.2)  $i = 2$

M

After further checking,  $X_4$ ,  $X_5$ ,  $X_6$  and  $X_7$  are all lower boundary points for (3,3;810). Let  $B_1 = \{X|X \geq X_4\}$ ,  $B_2 = \{X|X \geq X_5\}$ ,  $B_3 = \{X|X \geq X_6\}$  and  $B_4 = \{X|X \geq X_7\}$ . Hence, the multicommodity reliability  $R_{3,3;810} = \Pr\{B_1 \cup B_2 \cup B_3 \cup B_4\} = 0.61623376$  can be computed by the inclusion-exclusion method.

## 5. Conclusions

This article extends the system reliability problem to the multicommodity reliability for a stochastic-flow network with node failure under budget constraint. The multicommodity reliability is the probability that the demand  $(d^1, d^2, \dots, d^p)$  can be transmitted through the stochastic-flow network under budget  $C$ . Based on the properties of minimal paths, we propose a simple algorithm to generate all lower boundary point for  $(d^1, d^2, \dots, d^p; C)$ . Then the multicommodity reliability can be calculated in terms of lower boundary points for

$(d^1, d^2, \dots, d^p; C)$  by applying the inclusion-exclusion method. In our model the transportation cost  $c_i^k$  is not assumed to be linear in  $\omega_i^k$ . The main reason is that the transportation cost is not only dependent on the dimension of commodity but also on other attributes of commodity. For example, poison, vulnerable, fragile, etc. For the case that the transportation cost is only charged in terms of consumed capacity,  $c_i^k$  is linear in  $\omega_i^k$ . However, this condition is a special case of the proposed model.

# Customers' Acceptance of a Web Site for Product Information Search

Ling-Ling Wu\* and Shi-Yi Su

National Taiwan University, Department of Information Management  
No. 50, Lane 144, Keelung Road, Sect. 4, Taipei, Taiwan  
[llwu@mba.ntu.edu.tw](mailto:llwu@mba.ntu.edu.tw)

## Abstract

A theoretical model of consumers' acceptance of a website to search for product information is constructed and empirically assessed in this study. The results suggest that, besides perceived usefulness and perceived ease of use, the concepts of perceived costs and perceived risks should be incorporated into the technology acceptance model to account for information search behavior on the new media. Moreover, the causal relationship between use intention and its antecedents is significantly different for search goods and experience goods. To support the task of product information search on a website, product categorization and consumers' evaluation of product quality information should be taken into consideration for website design. That is, the WWW technological applications employed to support product information search for search goods should be different from those used for experience goods.

## 1. Introduction

The Internet has become a popular communication tool between organizations and consumers since its commercial applications in mid 1990's. Among various marketing functions that are possibly supported by the Internet, informativeness is reported as the most important function of the net (Palmer and Griffith, 1998; Chen & Wells, 1999; Keeney, 1999). Supporting product information search is still one the most prominent purposes for many commercial web sites.

However, many of the Web sites are not effectively managed for supporting customer's information search

(Dutta, Kwan & Segev, 1998). In particular, many commercial web sites suffer from low acceptance from consumers (Lin & Lu, 2000). The following crucial questions are yet to be answered: What factors lead consumers to use a commercial web site to search for product information? How information technology on the Internet can support consumers to search information more effectively? Should websites offer the same or different technological features to support different kinds of products? The purpose of this paper is, hence, to construct a theoretical model to account for web site acceptance as product information tool in order to explore the answers to the above questions.

As proposed by Palmer and Griffith (1998), an effective commercial web site must address two issues: technical characteristics (i.e. audio, video, hyperlinks, and etc.) and

marketing functions (i.e. information, promotion, online sales and services). In the context of product information search, the corresponding issues are product information content and the technology used to support information search. These two components are complementary and essential for using Web sites. A glitzy web site without relevant information will not satisfy consumers' needs for reducing product quality uncertainty. Similarly, a web site with ample content needs advanced information search technology to facilitate consumers to process the information. Therefore, this study assesses consumers' evaluations of a web site on these two dimensions. The theoretical model proposed in this paper will hence incorporate theories concerning both issues.

## 2. Theoretical Bases and Research Model

In the research model investigated by this paper, customers' acceptance of a web site will be described in terms of (a) consumers' perceptions of the information search technology utilized on the web site and (b) consumers' evaluation of the product information provided on the web site. Given that web sites are applications of the new technology of the Internet, the technology acceptance model (Davis, 1998; Davis, 1993; Davis, Bagozzi & Warshaw, 1989) is appropriate to serve as the theoretical basis to account for web site acceptance. As for consumers' evaluation of product information, the well-acknowledge cost-benefit framework will be employed in the research model of this study.

### 2.1. Technology Acceptance Model

In the literature of MIS, technology acceptance model (abbreviated as TAM hereafter) proposed by Davis (1998; Davis, 1993; Davis, Bagozzi & Warshaw, 1989) has been widely used to account for user acceptance of new technology. In this theory, acceptance of new information technology (IT) is measured by use intention and use behavior of IT. According to TAM, perceived usefulness (abbreviated as PU) and perceived ease of use (abbreviated as PEOU) are the central beliefs leading to use intention towards IT. Some researches have recently extended this theory to the use of the Internet and found results congruent with previous studies (Agarwal & Prasad, 1997; Lin & Lu, 2000; Teo, Lim and Lai, 1999). Given that product information search on web sites is a common usage of the Internet, user's PU and PEOU of the web site should also account for intention of product information search on the site, as stated in hypotheses 1a and 1b.

Moreover, PU is also positively influenced by PEOU, as stated in the hypothesis 1c.

Hypothesis 1a: Use intention of a web site to search for product information is positively influenced by perceived usefulness of the web technology.

Hypothesis 1b: Use intention of a web site to search for product information is positively influenced by perceived ease of use of the web technology.

Hypothesis 1c: Perceived Usefulness is positively influenced by perceived ease of use in the context of WWW.

In addition to assessment of web technology, consumers' assessment of the product information provided on the web site is also critical for reuse and acceptance of it. The cost-benefit framework is discussed to explore the product information search behavior on WWW.

## 2.2. Cost-Benefit Framework and Product Quality Information

Marketing researches of product information search suggest that perceived benefits and perceived costs affect external product information search conducted by consumers (Beatty & Smith, 1987; Srinivasan & Ratchford, 1991; Newman, 1977). In the context of product information search, the perceived search costs refer to mental efforts, time and financial costs (Claxton, Fry & Portis, 1974; Bettman, 1979) and the perceived benefits refer to reduction of perceived risks (Taylor, 1974; Dowling & Staelin, 1994; Kaplan & Jacoby, 1974). The concept of perceived risks is defined as the uncertainty associated with purchasing a product. Perceived risks, first proposed by Bauer (1960), are used to explain for various stages of consumers' behavior, especially pre-purchase product information search (Mithell, 1992). Consumers are uncertain about the consequences of purchasing a product such that they engage in active information search from various information sources in order to reduce the uncertainty, namely perceived risks.

Nevertheless, the benefits of perceived risks reduction calls for costs of information search, which includes mental efforts, time and money as mentioned in the previous text. Stigler (1961) argued that consumers would seek for product information until the cost of doing so exceeds the benefit of further information. That is, a consumer's search for information is guided by a trade-off between the perceived costs of additional search and the expected benefits of that search.

However, perceived risks and perceived costs are different for different kinds of products and hence the trade-off relationship between perceived risks and perceived search costs might depend upon the category of the product. Products can be classified as search goods and experience goods. In the case of search goods, perceived risks are low and perceived costs are high as opposed to experience goods, for which perceived risk are high and perceived costs are low.

According to Nelson, products can be categorized by the time when product quality information is acquired. When the attribute claims can be verified through pre-purchase search activities, those attributes are called search attributes. And when the most important attribute of the product is search attribute, the product is called search product. On the other hand, when the attribute claim can only be verified after the product has been purchased and consumed, the attribute is called experience attribute. And experience products are those products whose most important attribute is experience attribute. The distinction of search vs. experience products is statistically reliable because people can reliably categorize products into search and experience (Ford, Smith & Sway, 1988).

When consumers search external information about experience qualities, they try to decrease perceived risks through information sources with low search costs. People are less willing to search for experience qualities than for search qualities (Maute & Forrester, 1991; Newman, 1977; Beatty and Smith, 1987; Jacoby, 1984; Ratchford & Gupta, 1987). perceived risk is positively related to use of informal information sources, such as word-and-mouth, opinion leaders, which usually requires lower search costs (Seth & Parvatiyar, 1995; Dowling & Staelin, 1994). In another word, in the case of information search for experience goods, perceived risks are high and perceived costs are low. It follows that to reduce perceived risks should be the major concern for consumers when searching product information for experience goods. On the other hand, in the case of search goods, people are more willing to search and more factual information is provided through advertising. This phenomenon implies that search costs are high for consumers who are engaged in searching information for search goods. Moreover, search qualities can be verified before purchasing the product and people are less skeptical of search qualities claims such that perceived risks for search goods should be low, at least lower than experience goods.

Based upon the above argumentation, it is proposed in this study that the importance of perceived risks and perceived costs are different kinds of products. That is, categorization of product plays a role as moderator for the causal relationship between perceived risks, perceived costs and use intention of WWW as an information search tool. This proposed moderator role of search and experience goods is in alignment with the findings of Maute & Forrester (1991), which have suggested that search and experience goods served as moderators of the relationship between search determinants and external search effort. Therefore, it is proposed that for search goods, reduction of perceived costs (abbreviated as RPSC hereafter) should thus positively influence use intention, as stated in hypothesis 2a. On the other hand, for experience goods, reduction of perceived risks (abbreviated as RPR hereafter) should thus have positive effect on use intention, as stated in hypothesis 2b.

Hypothesis 2a: For search goods, use intention of a web site to search for product information is positively

influenced by perceived search costs reduced through using the web site.

Hypothesis 2b: For experience goods, use intention of a web site to search for product information is positively influenced by perceived risk reduced through using the web site.

Given that to reduce perceived risks is an important reason to use WWW to search product information for experience goods, RPR should have positive effect on perceived usefulness of the used website in the context of experience goods. Similarly, RPSC should have positive effect on perceived usefulness of the website for searching product quality of search goods.

Hypothesis 2c: For search goods, RPSC positively influence perceived usefulness of the website.

Hypothesis 2d: For experience goods, RPR positively influence perceived usefulness of the website.

Some empirical researches have reported that TAM could be extended by adding the construct of task-technology fit to serve as the antecedent of IT perceptions (Dishaw & Strong, 1999). In the following text, the task-technology fit theory will be discussed and incorporated into the theoretical model of this study.

### 2.3. Task-Technology Fit theory

The concept of task-technology fit is defined as ideal profiles of task/technology alignment between characteristics of task and technology (Zigurs & Buckland, 1998; Venkatraman, 1989). In another word, the construct of task-technology fit refers to the degree of match between the two variables: task and technology. Various empirical results suggested that effect of task-technology fit could be mediated through user's beliefs and attitudes onto use intention and behavior (Goodhue & Thompson, 1995; Dishaw & Strong, 1999). The Internet as a new technology possesses various characteristics that can help people to perform the task of information search effectively and efficiently. The empirical results of Dishaw & Strong (1999), task-technology fit should be the direct antecedent of perceived usefulness and perceived ease of use. Therefore, it is proposed that task-technology fit should be the direct antecedent of perceived usefulness and perceived ease of use for using website to search product information of both search goods and experience goods, as stated in hypotheses 3a, 3b, 3d and 3e. Moreover, match between searching task and supporting technology should also have influences on reduction of perceived risks for experience goods and on reduction of perceived costs for search goods, as stated in hypotheses 3c and 3f.

Hypothesis 3a: For search goods, task-technology fit influences PU of the web site for product information search.

Hypothesis 3b: For search goods, task-technology fit influences PEOU of the web site for product information search.

Hypothesis 3c: For search goods, task-technology fit influences RPSC of the web site for product information

search.

Hypothesis 3d: For experience goods, task-technology fit influences PU of the web site for product information search.

Hypothesis 3e: For experience goods, task-technology fit influences PEOU of the web site for product information search.

Hypothesis 3f: For experience goods, task-technology fit influences RPR of the web site for product information search.

In the following text, we will explore how WWW technology can be used to support these different tasks for search goods and experience goods in order to achieve desirable level of task technology fit.

### 2.4. Technological Characteristics of WWW

The task of product information search could vary upon different kinds of products. Marketing researches suggest that verifiability of product quality lead people to focus on different aspects of information. When the product quality claims are easy to verify before purchase, consumers tend to search for so-called hard information which are the well-defined standard attributes of the product. That is, product quality information can be acquired through vast information search for search attributes, such as color of clothes, smell of perfume. On the other hand, people tend to look for soft information when search product quality information for experience goods. Soft information refers to the attributes of the product provided through personal opinion and impressions, such as good taste of foods, durability of computer. Given that product quality information for experience goods can not be acquired before use of the product, people resort to the opinions of those who have used it. Based upon the concept of task-technology fit, the website needs to provide the technology characteristics that help people to search for hard information in the situation of search goods, and soft information in the situation of experience goods.

WWW possesses many powerful technological functions that can support information search. Many researches have addressed on the technological characteristics of the Internet. For instance, Newhagen and Rafaeli (1996) asserted that

the characteristics idiosyncratic to the Internet media are multimedia, hypertext, interactivity and personalization. Kenney (1999) also proposed that the characteristics of the Internet that can satisfy customers are large amount of information, time saving, privacy, personalization and interactivity. Hoffman and Novak (1996) emphasized that interactivity is the feature that distinguish old media and the new media of Internet. Moreover, some large-scale surveys have been done to describe what technological functions attract people to use the Internet. Large information quantity, personalization and privacy are reported as the most important features to account for use of this new media (Ernst & Young, 1999; GVU, Forrester research).

Among the prominent features of the Internet are its temporal and spatial characteristics, which enable information searchers to overcome the limitations of time and space. For instance, people can search for timely information on the Internet 24 hours a day, connecting to the web sites all over the world through the function of hyperlink, even without walking out of his/her own house. At the same, the information searcher can keep his/her privacy about the action of search by keeping anonymous. The three characteristics, temporal characteristics, spatial characteristics and privacy are effective for information search.

In addition, some technological characteristics of the Internet can help providing hard information, such as information capacity, multi-media. On the other hand, search of soft information can be supported by the functions of personalization and interactivity. In conclusion, characteristics such as temporal, spatial, privacy, multimedia and information quantity are crucial to support task-technology fit in the context of search goods, as stated in hypotheses 4a-e. For experience goods, characteristics such as temporal, spatial, privacy, personalization and interactivity, as stated in hypotheses 4f-j.

Hypothesis 4 a-e: For search goods, task technology fit is influenced by the following technological supports: information quantity, multimedia, privacy, temporal characteristics, and spatial characteristics.

Hypothesis 4 f-j: For experience goods, task technology fit is influenced by the following technological supports: personalization, interactivity, privacy, temporal characteristics, and spatial characteristics.

### 3. Research Methods

#### 3.1. Operationalization of theoretical constructs

The measurement indexes of all the theoretical constructs in this research are adapted from relevant studies, to fit the situation of product information search on web sites. Please see Table 1 for related sources of constructs.

Table 1: Literature sources of the theoretical constructs

Construct	Measurement sources
Perceived Ease of Use (PEOU)	Davis (1989)
Perceived Usefulness (PU)	Davis (1989)
Use Intention	Chau (1996)
Reduction in Perceived Search Costs (RPSC)	Claxton, Fry & Portis, 1974; Bettman, 1979
Reduction in Perceived Risks (RPR)	Kaplan & Jacoby (1974)

Product quality information	Nelson (1986)
Task-Technology Fit	Goodhue & Thompson (1995)
Information quantity	Keeney (1999); Peterson, Balasubramanian & Bronnegger (1997)
Multimedia	Keeney (1999); Hoffman & Novak (1996); Daft & Lengel (1984)
Temporal characteristics	Richmond (1996); Schillewaert, Langerak & Kuhamel (1998)
Privacy	Keeney (1999); Richmond (1996)
Spatial characteristics	Schillewaert, Langerak & Kuhamel (1998); Keeney (1999)
Personalization	Daft & Lengel (1984)
Interactivity	Peterson, Balasubramanian & Bronnegger (1997)

#### 3.2. Sample

The respondents of the survey questionnaire are students randomly recruited from five university campuses in Taiwan, during January and March in 2000. In total, 272 questionnaires were distributed, and 264 of them were returned, with the response rate of 97.6%. Among the 264 returned questionnaires, 19 of them were invalid. So, the sample size was 245. Given that product quality information is hypothesized to be a moderator in our research model, the sample was split into two sub-samples: the search goods sub-sample and the experience goods sub-sample, according to how the respondent judged the assigned product. Respondents were randomly assigned to one of the six products (described in the next section of research material) chosen for this survey and were asked to judge the given product on a rating scale, from 1 to 7, with 1 referring to search goods and 7 to experience goods. The responses higher than average are categorized as experience goods and lower than average are categorized as search goods. Consequently, among the 245 valid responses, 125 were categorized into the search goods sub-sample, and 120 were categorized into the experience goods sub-sample. In order to see if other factors than product quality categorization distinguish the two sub-sample, the demographic data were analyzed. The results showed that these two sub-samples do not differ from each other in terms of the distributions of gender and age (Gender:  $\chi^2_{1} = .64, p < .20$ ; Age:  $\chi^2_{5} = 4.40, p < .42$ ). The result of this analysis suggests that these two sub-samples are demographically similar to each other.

### 3.3. Research Material

Six products were chosen to serve as the test products in this study, as demonstrated in Table 2. There were three criteria for choosing the products. First, the products have to be familiar to our respondents because people might not know what attributes are important for unfamiliar products. Secondly, the price of the products must be among the affordable range for our student respondents. Thirdly, the prices of products were controlled as close as possible because the price might affect respondents' perception of search costs and risk cost.

For each of the six products, two web sites were used for the survey. One web site is presumed to fit for supporting search goods and the other web site is presumed to fit for supporting experience good. In total, there were twelve websites chosen for this survey, and all respondents were randomly assigned to one of the website. The survey questionnaire involved two stages: pre-search section and post search section. The pre-search section includes three components: demographic information of the respondent, categorization of the assigned product and perceived search cost and risk cost of the product. The measured perceived search costs and perceived risk costs in the pre-search section will be compared against the perceived search costs and perceived risk costs of the same product measured in the post-search section, which measured the perceptions associated with website information search.

The post-search section involved measurements of the theoretical constructs in this study: product categorization, perceived usefulness, perceived ease of use, perceived risks, perceived search costs, intention to use, task technology fit and characteristics of the Internet. The construct of RPSC is measured by perceived search costs of post-search section, deducting the measurement of perceived search costs of pre-search section. The construct of RPR is measured by the same way.

### 3.4. Survey procedures

The task of respondents was to gather product quality information on the website to facilitate buying decision and also to evaluate the assigned web site for future visit. Every respondent was randomly assigned one of the above 12 web sites as the virtual space to search for shopping information. Before search, every respondent was asked to fill out the pre-search section of the questionnaire. Then, respondents searched for the product information on the assigned web site in their pace. When the search was complete, respondents were asked to evaluate the website by filling out the post-search section.

### 3.5. Data analysis

The data of both sub-samples were analyzed in the same way through Lisrel 8, developed by Joreskog & Sorbom (1993). Lisrel 8, as confirmatory factor analysis,

involves two stages: measurement model and structural model. The analysis of measurement model was first evaluated against three criteria: item reliability, composite reliability and discriminant validity. As for the structural model, the various indexes of goodness of fit were analyzed to test if the hypothetical models discussed in the previous text were suitable to describe the collected data. Moreover, direct, indirect and total effects of the independent variables on the dependent variables were analyzed.

## 4. Results Discussion and Conclusions

### 4.1. Measurement model analysis of Search Goods and Experience Goods

The assessments of both measurement models of search goods and experience goods indicate that reliability, convergent validity and discriminant validity of the hypothetical constructs are considerably adequate.

Three measures were used to examine reliability and validity of the measurement indexes: item reliability, construct reliability and average variance extracted. Those measurement indexes that did not fulfill the criteria (Bagozzi & Yi, 1988) were all deleted from further analysis. For the construct of perceived difference in search cost (abbreviated as RPSC), only one index was left, which is difference in search time. Therefore, in the following analysis, the construct of RPSC was replaced by reduction of perceived search time.

Composite reliability and the average variance extracted are calculated to assess convergent validity. The minimum value of composite construct is .60, and that of average variance extracted, .50, for evidence of convergent validity. The composite reliabilities of all the theoretical constructs are all above .60, and average variance extracted, all above .50, showing that the convergent validity of those constructs in the measurement models of both search goods and experience goods were adequate. Nevertheless, for the constructs of perceived difference in search cost, temporal characteristics, only one measurement index was left and hence the composite reliability could not be calculated.

Most of the inter-correlations of the items between constructs are smaller than the correspondent average variance extracted (89% for search goods, and 80% for experience goods), indicating high discriminant validity for both measurement model. Beside adequate convergent validity, the discriminant validity for the measurement model of experience goods is considerably fair.

### 4.2. Structural Model analysis of Search Goods and Experience Goods

The difference between the structural models of search goods and experience goods was statistically significant by using multiple sample analysis ( $\chi^2_{103} = 221.48, p < .001$ ). That is, the causal relationships of the variables discussed

are different among search goods and experience goods. Therefore, the data of search goods and experience goods were hence analyzed separately.

The goodness-of-fit of these two structural models are measured by seven index,  $\chi^2/df$ , GFI, AGFI, RMSR, NFI, NNFI and CFI to assess if the collected data could be described by our models. For both search goods and experience goods, some goodness-of-fit measurements of the original structural models do not fulfill the minimum requirements. Therefore, the structural models are modified according to the suggestions provided by LISREL such that all the values of the seven indexes fulfill the minimum requirements. The results of the data collected in this research are examined to see if the hypotheses are supported.

### Effects on Use Intention

The results show that the construct of PU significantly affects use intention ( $\beta=.60$ ,  $p<.01$  for search goods,  $\beta=.57$ ,  $p<.01$  for experience goods). However, there is no direct effect of PEOU on use intention. Nevertheless, PEOU affects use intention indirectly through perceived usefulness. PEOU directly affects PU ( $\beta=.32$ ,  $p<.01$  for search goods and  $\beta=.17$ ,  $p<.01$  for experience goods), which further mediates the effects of PEOU on use intention ( $\beta=.19$ ,  $p<.01$  for search goods and  $.10$  n.s. for experience goods). Hypotheses 1a and 1c are supported by hypothesis 1b is partially supported by our data. In another word, use intention of WWW is directly affected by PU and indirectly affected by PEOU.

Moreover, use intention is also predicted to be affected by RPSC in the context of search goods, and to be affected by RPR in the context of experience goods, as stated by hypotheses 2a and 2b. In the context of search goods, perceived difference in search time affects use intention ( $\beta=.14$ ,  $p<.01$ ) although the effect is indirectly mediated through PU. As for experience goods, perceived difference in risk costs directly affects use intention ( $\beta=.13$ ,  $p<.05$ ). Hypotheses 2a is partially and 2b is fully supported by our data. In conclusion, use intention is affected by different factors for search goods and experience goods.

---

### Effects on the Perceptions

According to the hypotheses 2c, 2d, and 3a-f, the precedents of the perceptions of WWW are also different for search goods and experience goods. The construct of PU is affected by PEOU ( $\beta=.32$ ,  $p<.01$ ), RPSC ( $\beta=.24$ ,  $p<.01$ ) and TTF ( $\beta=.67$ ,  $p<.01$ ) for search goods. On the other hand, the construct of PU is affected by PEOU ( $\beta=.17$ ,  $p<.01$ ) and TTF ( $\beta=.58$ ,  $p<.01$ ) for experience goods. As for PEOU, it is not affected by TTF for search goods, but affected by TTF for experience goods ( $\beta=.54$ ,  $p<.01$ ). Hypotheses 2d, 3a, 3e and 3d are supported by the results, but hypothesis 2c and 3b are not supported. Moreover, the perceptions of both risk costs and search costs are not affected by TTF for both kinds of products. Hypotheses 3c and 3f are not supported by the results.

### Effects on Task-Technology Fit

Task-technology fit can be achieved by technological characteristics supporting “hard information” search in case of search goods, such as large information quantity, multimedia, privacy, spatial and temporal characteristics, as predicted by hypotheses 4a-e. On the other hand, task technology fit can be achieved through technological characteristics supporting search of “soft information”, such as personalization, interactivity, privacy, spatial and temporal characteristics, as stated in hypotheses 4f-j. The construct of task-technology fit is determined by different sets of technological characteristics for search goods and experience goods. For search goods, information quantity, privacy and spatial characteristics are in effect ( $\beta=.68$ ,  $p<.01$ ;  $\beta=.33$ ,  $p<.01$ ,  $\beta=-.17$ ,  $p<.01$ ). Hypotheses 4a, 4c and 4e are supported, whereas hypotheses 4b and 4d are not supported by the data. For experience goods, two more characteristics besides those three are in effect (information quantity:  $\beta=.84$ ,  $p<.01$ ; privacy:  $\beta=.14$ ,  $p<.05$ ; spatial characteristics:  $\beta=-.47$ ,  $p<.01$ ), namely personalization and multimedia ( $\beta=.50$ ,  $p<.01$ ;  $\beta=-.27$ ,  $p<.01$ ). Hypotheses 4f, 4h and 4j are supported, but hypotheses 4g and 4i are not supported by the data. Out of 23 hypotheses proposed, 15 hypotheses were supported by the data.

There are three important results found in this paper: First, use intention of a website as product information search tool is influenced by, besides PU and PEOU, perceived risks and perceived search costs of the product. Second, product categorization moderates the causal relationship between use intention and its direct and indirect determinants. Third, task technology fit plays an important role in mediating the effects of technological characteristics and product information categorization onto perceptions of a Website.

# The Customer Resource Management in the Internet Age

Minxue Huang      Yinfeng Song

School of Business  
Wuhan University  
Wuhan, China  
hmxlmh@public.wh.hb.cn

## Abstract

The fiercer and fiercer competition and the change of competition model make the customer more vital than before. In order to keep up with the changing situation, the competition-orientation turns from “product-center” to “customer-center” and there appears subsequently some new ideas such as “relationship marketing”, “customer relationship management” and etc. The customers’ status has been enhanced in the web age and the old ideas about customer management become out of date. So the author presents a new idea of customer management ----- customer resource management, which requires the enterprises take the customer as their own resource and make use of this resource to get competition advantage. The paper mainly discourses the following three aspects: the evolution of customer management ideas, the strategic analysis of customer resource and the strategic value of customer resource management.

## 1. Introduction

The customers’ status is promoted gradually during the fiercer and fiercer commerce competition. Meanwhile, the competition focus turns from products to customers and what is the key—point of a enterprise’s success is the manage-skill on those recognizable customers who buy a large amount of goods at one time and transact more times. Especially when there comes the web age, the economic-running model and the competition methods both changes greatly. The main cause is consumers’ demand going quickly on that way of individuality and diversity. Internet entitles consumers the dominant power----they can get much information by means of modern technology. So, companies can’t gain the leading position unless they can satisfy consumers’ demand fastest and best. This capability is the most important competition advantage in the e-commerce. Therefore, companies must put enough emphasis on the consumer (especially those customers) study and try to improve customer management level. It is of strategic meaning to each company.

There is close connection between the development of marketing theories and customer management ideas. In 1985, Babala.Jackson put forward the concept of “Relationship marketing”. This new idea discarded the traditional idea of “transaction marketing” and denoted the marketing aim should be “trying to get、establish、maintain” the close and long-term relationship with customers. Once presented, the idea of “Relationship marketing” is popularly accepted and applied in a quite

wide range.

When time comes into 1990s, the internet-economy makes consumers a more important and active role in the e-commerce. We even can say it is consumers, not enterprises, that is the dominator now. Only trying to maintain the good relationship with customers with traditional tools (such as good product and other marketing endeavors) is hard to obtain customers or their praises, the current competition advantage is built on the capability of meeting customers’ personality-and-differentiation-demand fastest. In the web age, the unique method to gain long-time competition advantage is satisfying customers with high accuracy and rapidity; those who can’t do this will come to failure certainly. For this, there comes the new idea of “Customer relationship management” Which is based on the database technology and guided by the “one-to-one marketing” theory. “Customer relationship management” acquires demand information of customers by means of many kinds of web technology and other modern tools, such as the Emails, call-center, automation sale system and etc. Through analyzing the information having been collected by so many channels and combined with the traditional marketing instruments, “Customer relationship management” strives to supply the most rapid and excellent individualized service.

Compared to the marketing ideas based on the products and brands, “Relationship marketing” and “customer relationship management” both have great progress, but there is still much weak points in them. “Relationship marketing” regards customers as a fixed and passive factor and the quality of the “enterprise---customer” relationship which is decided by the enterprise’s endeavor in building relationship, what the customers have done and what they are doing have little influence. In other words, “Relationship marketing” treats customers as a passive receiver of all the enterprises activities; only the enterprise’s behavior can influence the relationship. This is the distinctive defect of “Relationship marketing”.

Although “customer relationship management” realized it is of great importance that customers imitatively show their demands in the process of relationship maintaining. Customers are still treated as a external factor----they are seen independent or even against to enterprises Both sides intend to gain more benefit: customers wish to meet their demand at the least cost, and enterprises wish to gain the greatest profits from customers. Obviously, the relationship built on this thought is quite unstable. Once either side can’t meet it’s own needs, it’ll be entirely hopeless in relationship

maintaining. Then, what the enterprises have done is in vain.

Furthermore, whether “Relationship marketing” or “Customer relationship management” regards the customer-satisfaction-level as a important index in evaluating the enterprise-customer relationship, and almost all the enterprises that directed by these two ideas take great endeavor in improving the customer-satisfaction-level. However, chasing only the high customer-satisfaction-level might lead enterprises to a wrong direction---there is huge difference between customer-satisfaction and customer-loyalty, and what is vital to enterprise is customer-loyalty. Firstly, the satisfied customers may not purchase from the same company again. The consumer habits, income, location and other factors will impact their consumer decisions. Secondly, enhancing the customer-satisfaction-level will expend much money and labor, but the possible end is the investment and output is more unbalanced. So, enterprises should know that the satisfied customers aren't equal to the loyal customers, and only the loyal customers are the resource of their long-term profits--they even help enterprises build their core competition advantage.

Another problem of “Relationship marketing” and “Customer relationship management” is they both think the money customers pay for the goods or serve is the most meaningful even the unique value that customers bring to them, so they ignore customers' great contribution on the many other sides.

All in all, it's necessary to put forward a new idea of customer-management in the web age. Customers should be regard as a resource and even the critical resource (or call it strategic resource) that can determine the enterprises' fate in competition, and enterprises should comprehend customers' value comprehensively and manage customers based on this. We name this new idea as “customer-resource-management”.

## 2. The strategic analysis of customer resource management

### 2.1 The strategic value analysis of customer resource basing on the resource-based theory

The resource-based theory founded by Barney, Rumelt and Peteraf is the linkage of Porter's competition advantage theory and Prahalad&Hamel's core capability theory. Resource-based theory regards the enterprise as an ensemble of all kinds of resources, including the capital, capabilities, organization process, the enterprise's characters, information, knowledge and etc. Only the critical resource but not the common resources can gain competition advantage for enterprises. The critical resource is the fountainhead of the core capability and it uplifts the enterprise to a more high revenue level (Penrose,1959).The critical resource must be of the following five characters: being valuable, being scarce, can not be completely cloned, can not be substituted by other resources、 must be obtained at a price lower than its

value(Barney,1991).The study structure of the resource-based theory is “resources → strategic → achievement”, which shows the core notion of this theory: the difference of enterprises capabilities is resulted from their strategies or furthermore , and determined by their different resources. The resources influence an enterprise strategic first, and then the competition ability. Obviously, it is just the owned resources that determine an enterprise's capability.

In the e-commerce, the material resources are easy to get, the technique can be cloned easily and its life cycle is shorter and shorter. So, it's difficult for enterprises to build the core capability on these two factors.

Contrary to these, as a resource, customer-resource totally fits for the requirement demanded by Barney and furthermore, it has more value than the common strategic resource and contribute much to the core-capability's forming and improving. So, treating customers as a critical resource and making strategies, the enterprises will do better in competition surely.

### 2.2 The strategic character of customer resource

The strategic resources are those resources, which can't realize its expected purpose unless it enhances the enterprise's capability at some sides (HengLi&YiLiu, 1996). To make full use of customer-resource, the enterprise must grasp the following strategic characters of customer quite well.

#### 2.2.1 Stability and specialty

The good relationship between customers and enterprises will erect a transferring-barrier. Customers must undertake high cost if they transfer to another enterprise. For this, customers, especially those loyal customers, once generate trust to an enterprise; they'll be the most stable resource. Study has proved that if the loyal customers increase 5%, in different industries, the profit will increase 25-95% (Reichheld, 1996). Meanwhile, except for buying repeated, the loyal customers also provide much valuable information timely. And the stability transforms into specificity in long run. It builds an entrance-barrier against the latent antagonists, which ensures the company to get the monopolized profits coming from loyal customers. It also sets a quitting-barrier to hold back the enterprise's quitting from that industry, or else it'll lose the profits could be gained from current customers and expend more on acquiring new customers. The stable customer resource also can stimulate employers to work hard for the enterprise's aim.

#### 2.2.2 Can be used repeatedly

Once be used, the majority resource's value is completely excavated and can't be used again, or their value in repeated-use is quite limited. Compare to them, the customer-resource can be used again and again, and most important, acquiring more knowledge about the whole enterprise in utilization, the customer-resource's value is added at the same time. It can generate greater

effect in the next time utilization.

### 2.2.3 Network-effect

A resource often has a single utility and can be used at one method only, but the customer-resource gives more contribution to the enterprise, in other word, we can say it has the network-effect

Customers not only bring enterprise money, they also bring much information and by which, enterprise can meet customers' need quickly and exactly. The mouth-recommendation brings many customers and even the customers' customers can become the enterprise's customers. Furthermore, forming cooperate-partnership with their customers, enterprise in finance difficulty might obtain capital from its customers. They are willing to pay for the goods beforehand, even lend money to the enterprise. Except for this, the customer-resource can be shared with other companies and the sharers all can benefit from other' customer-resource. For example, the combined sale of Coca-Cola and Pint can be seen as sharing the two companies' customer-resources, or we can call this the repeated-selling of customer-resource. So, we can say the customer-resource will generate network revenue for the enterprises.

### 2.2.4 Driving-force

Driving-force means that besides its core-value, customer-resource can push other resources turning towards strategic resources (See Figure 1). From the chart, we know that the critical resources might come from some scattered resources or innovated by modern techniques or purchased from outside. The sources' features never are unchangeable, with time flying; even the strategic resources might be less useful and turn into common resources. Customer-resource lies in all departments and all manufacture-processes, it can help enterprises evaluate, select resources and optimize its business process. Directed by customers information, the human resources, capital, materials all can be allocated effectively and realize their greatest value. Meanwhile,

the inferior resources will be discarded. In fact, the pushing-force really improves the resources' using-efficiency and then, enhances the enterprise's long-time competition capability.

### 2.2.5 Virtuality

Now, many enterprises have treated customers as their capital and evaluated it with the index of "customer-lifetime-value", which is the profit customer bringing during the whole consume-lifetime. The total profits need to be reappraised into the current value. Because the customers' consumer behavior isn't fixed in future, what we estimated now is quite possibly to change, so, the customer-capital only can be seen as artificial capital.

The same problem lies in the idea of customer-resource. First, customers' personalities, consumer-habits, interests, income, knowledge is changing continuously, especially the predilection. Second, whether the customers have the willing of offering information or not is influenced by their mentalities and technology conditions. Third, considering the ownership, the feature of virtuality is especially distinguishable. Once having got them, enterprises have the ownership of the general resources. However, similar to the human-resource, only the usufruct of customer-resource can be gained, the ownership is still belonging to the customers themselves.

Thinking of these, what the enterprise can do is treating customer-resource as an artificial resource and put enough emphasis on its changeability and virtuality.

## 3. The strategic value of practicing the customer-resource man

### agement

#### 3.1 Optimizing the organization structure and business process

Customer-resource management will help enterprise

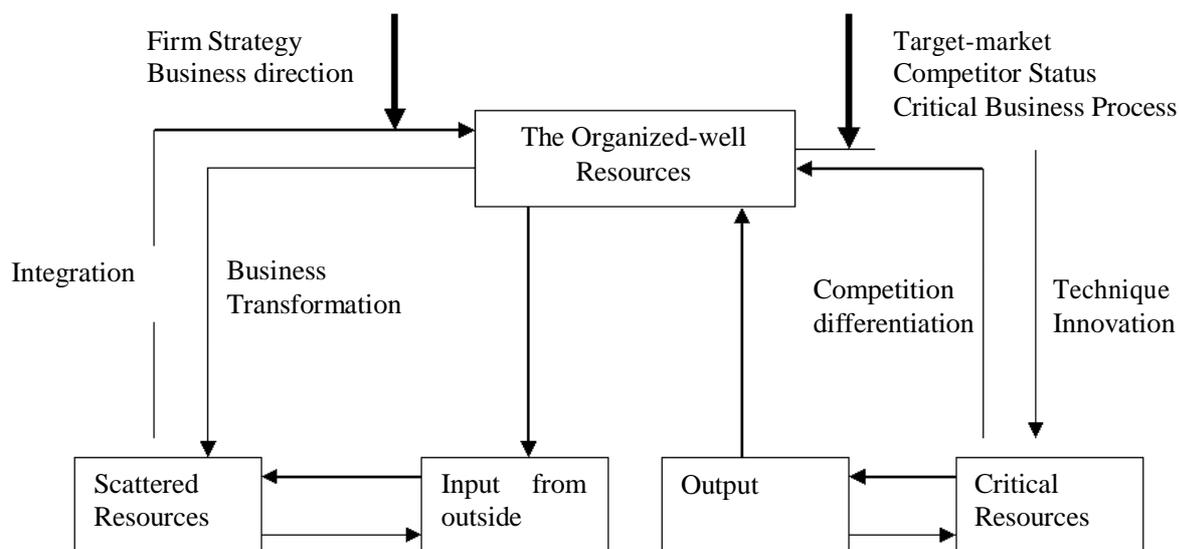

Figure 1. The process of common resources turning into critical resources

optimize its structure and business processes, and make it react to the market fast. In order to include customers into their resources and form close customer-enterprise relationship, enterprises must have the capability of collecting customers' information timely; which requires them provide convenient communication channels. So, except for realizing the manufacture and management automation, enterprises must do some adjustment to become a new flexible organization. According to this, the traditional line-produce and line-information-transferring are outdated. Manufacture and information communication should be accomplished simultaneously now, and all departments can cooperate and share information synchronously. This will improve the manufacture efficiency and management level, and most important, which will induce the beneficial circulating between structure optimizing and efficiency-improving in long-time.

### 3.2 Building and enhancing the core competition capability

The resources which can't enhance the enterprise' capability neither can generate monopoly profit nor build core competition advantage in the free competition. As a strategic resource, customer-resource has unequalled benefit on innovating technology and optimizing resources-allocation. It's useful in selecting premium resources and pushes them into valuable critical resources, which does great contribution to strengthening the core capability. Just as saying before, customers can provide market information, help resources selecting, allocating and technology innovation, optimize structure and manufacture process and etc. All these are the fountain of building and improving the core capability. Furthermore, because customer-resource is renewing and adding value to itself continuously, it causes all the activity above be carried out persistently. In this meaning, customer-resource not only from the core capability, it also improve it on and on, so, the core capability is strengthening screwing, which is the most precious situation that each enterprise chases after.

### 3.3 Strengthening the general competition advantage

The applying of customer-resource can improve the enterprise's general competition capability. Customer-resource brings direct and indirect benefits to each company. Direct benefits mainly mean customers' consume-behavior will provide money and profit. The indirect benefits are as the following: First, the information provided by customers is the most critical factor for forming competition advantage. Second, the mouth-recommendation has great influence, especial, the

loyal customers' opinions and behaviors will provide a learning-model and enlarge the customer-group (or call it customer extension). One research on 7,000 consumers in seven Europe countries has proved that relations or friends influenced more than 60% purchases (Kiely, 1993). In fact, each company can enlarge its customer-group by means of this mouth-recommendation. Third, the collaboration-relationship between customers and enterprises will prevent customers' output to other companies, or it will cost them a lot. And in order to get more from the relative enterprise; customers might be willing to help enterprise cope with all kinds of crisis, besides the finance-crisis mentioned above. For example, when enterprises are in crisis for their own mistakes, customers are easier to forgive them and the expenditure of compensating on loyal customers is much less than on the common consumers.

## 4. Conclusion

Above all, we can know that customer-resource have huge contribution to the new-product development, products (sever) sale, customer extension, enhancing intangible assets (mainly referring the brand-equity and the enterprise's image-value), collecting money, saving marketing expenditure, overcome crisis and etc. So, if any enterprise can manage and handle the customer-resource well, it'll erect a secure-effective-all-round-barrier against the antagonists, which is the source of the general competition advantage for long-time.

# The MTO-Framework for Implementation of E-Business Models

Michael Holm Larsen, Heller Zinner Henriksen & Niels Bjørn-Andersen

Department of Informatics  
Copenhagen Business School  
DK-2000 Frederiksberg, Denmark  
{mhl, hzh, nba}.inf@cbs.dk

## Abstract

Venture capitalists typically require that you can explain the business model in the time it takes the lift to get to the tenth floor. Implementation typically takes years. There is a disproportionate large amount of focus on what constitutes an innovative new business model compared to implementation since most e-business failures are attributed to failures in implementation. Obviously, there is a significant lack of knowledge of factors leading to successful implementation among those responsible for practical implementation of e-business models. E-business models or IT-systems for inter-organizational purposes cannot be implemented exclusively following the traditional guidelines in the IS/IT literature. Development methods are very different from earlier, there are many more stakeholders, and the environment is much more dynamic.

The paper suggests a framework highlighting important implementation factors derived from four different disciplines; venture capitalist experiences, business process reengineering, diffusion theory and system development.

The contribution of the paper is a classification of implementation factors in a framework that identifies the technological, the organizational, and the market related factors relevant for implementation of e-business models.

## 1. Introduction

The purpose of the paper is to develop an integrated approach for implementation of eBusiness models based on a taxonomy including four very different approaches to eBusiness implementation/adoption. These approaches are:

- ¾ Traditional IS/IT implementation insights especially as these was conceived until the late 80'ies.
- ¾ Business process reengineering guidelines for implementation dating from the early to mid 90'ies.
- ¾ Technology diffusion and adoption theory starting with the earlier work of Rogers, but updated in the late 90'ies with Rogers (1995), Grover et al. (1995) and Gottschalk (1999).
- ¾ Venture capital guidelines for eBusiness ventures.

It is quite clear that these approaches are very different.

There is also evidence that none of them is sufficient to secure a successful implementation. But it is our contention that each of them holds a piece of the truth.

Accordingly, the paper will contrast the four bodies of knowledge and develop a multi-perspective taxonomy for implementation of eBusiness. This will provide a basis for the development of an integrated approach in later research.

Earlier research on IT implementation is used to identify a coherent framework for eBusiness implementation factors. A number of researchers (Riggins and Mukhopadhyay, 1999; Galliers, 1999; Walsham, 2001) have pointed at the appropriateness of using past experiences from other technologies in the process of understanding new technological and managerial concepts such as eBusiness. That is especially the case for those technologies that are transferable from one environment to another (Riggins & Mukhopadhyay 1999). From a technological point of view the lessons learned from implementation of IT demonstrate similarities in relation to those challenges managers face when implementing eBusiness models in an organization. The humans inhabiting the organization do typically not change as fast as technologies and managerial concepts (Walsham 2001). The lessons learned from other research disciplines might therefore offer valuable insights to similar phenomena.

In order to present a holistic approach to implementation research, a cross-disciplinary approach is taken to illustrate those factors that have been found to influence implementation of IT in organizations.

The specific research questions that are investigated in this paper are:

- ¾ What are the key IT implementation factors in the different perspectives?
- ¾ How could the key IT implementation factors be classified in order to provide a coherent framework for eBusiness Model implementation?

The delimitation of this research is that the number of perspectives investigated are limited focusing on four specific schools of thought, and that the research takes an organizational perspective.

The organization of the paper is as follows. In Section 2 definitions of the two key terms, eBusiness models and implementation, are presented. Section 3 presents our design approach for the implementation framework. Section 4 outlines the key implementation factors derived from reviews of literature from venture capitalist sources, BPR, diffusion theory, and finally

system development. Section 5 presents our implementation framework for eBusiness models. Section 6 provides an illustrative case related to eBusiness model implementation. Section 7 is a discussion of the validity and applicability of the eBusiness implementation framework. Section 8 presents the conclusion and recommendations for future research.

## 2. Basic Definitions

This section presents our basic understanding of eBusiness models and implementation.

### 2.1 e-Business Models

Whether the company is a new venture or an established player, a good business model is essential to every successful organization (Magretta 2002). Although, a business model is regarded differently by different groups of researchers and practitioners, e.g. Mahadevan (2000), Amit & Zott (2001), Afuah & Tucci (2001), Applegate (2001), Weill & Vitale (2001), and Elliot (2002); most people regard a business model as a description of the business system identifying all essential business processes, products, services and information related to these. Moreover, a business model describes the actors contributing to the value creation of the product to the end user or customer and identifies roles and responsibilities, relationships, interactions and transactions of and between the value network actors.

In this paper we adopt the following definition of an eBusiness model: “An architecture of product, service, and information flows, including a description of the various business actors and their roles; as well as a description of the potential benefits for the various business actors, and a description of the sources of revenues”, cf. Timmers (1998:4). This definition frames the discussion of implementation factors and initiatives.

An underlying assumption of this paper is that the characteristics of eBusiness models call for research on the rethinking of the basis of implementation. Compared to earlier information systems, there are a number of reasons why traditional implementation models, theories, and methodologies do not hold any longer and a multi-perspective is called for:

- ¾ New stakeholders. Venture capitalists rather than internal business management make decisions about new systems, and their decisions are based on very different criteria from the traditional business unit manager due to limited knowledge of market, wish for fast exit strategies, etc.
- ¾ Interorganizational nature of eBusiness. eBusiness systems are inter-organizational covering multiple organizations where there are no ultimate decision maker. This requires much more

comprehensive analyses of competition, markets, value chains and networks, collaboration etc. It is not enough to have the commitment of a dedicated member of top-management.

- ¾ Time compression. Traditionally it could take years to develop IS/IT systems. Today many eBusiness systems are developed in time-slots of weeks or months.
- ¾ Iterative systems development. Waterfall and modified versions of waterfall models have given way to much more iterative systems development relying a lot on prototyping, testing and continuous development.

An illustration of the need for multi-perspective business analysis and that more stakeholders may influence the decision making of the implementation process is presented in the figure below.

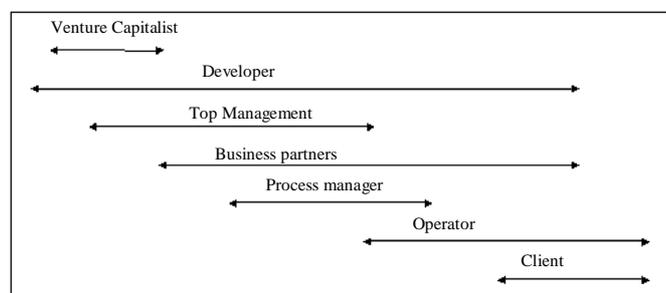

Figure 1: Overview of implementation actors during the life-cycle of an eBusiness system

Assuming that the horizontal axis represents a time scale, the figure also illustrates that the different actors in principle have different and/or overlapping time-periods in which they are actively involved in the design and implementation process.

### 2.2 Definition of Implementation

Rogers (1995) argues that the implementation stage ends when the new idea becomes an institutionalized and regularized part of the adopters ongoing operations. Any systems development project may be seen as consisting on three rather different sets of activities, requirement specifications, design and implementation. But implementation is not a particular stage occurring after a design stage. Instead we subscribe to the view that implementation is a set of activities starting almost at the very beginning of any eBusiness project and continues as Rogers suggests above, until the solution has been adopted and fully integrated not just in the target organization developing the eBusiness solution, but also for everybody else in the value network related to and affected by the solution. This is illustrated in the figure below.

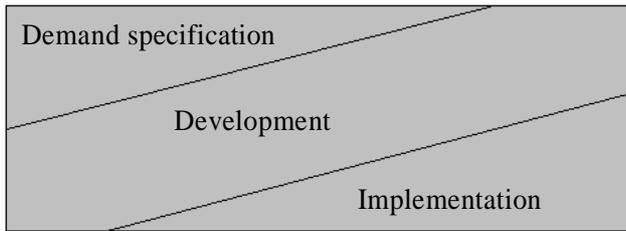

Figure 2. The Process of Organizational Implementation

The horizontal axis represents development in time, whereas the vertical axis represents the amount of efforts dedicated to particular activities, i.e. demand specification, development and implementation.

Common for almost all conceptualizations of the term implementation is that some degree of organizational action has taken place. This requires different degrees of commitment and large variety actions until the intended benefits are being realized as a successful implementation (Gottschalk, 1999).

Inherently we assume that the outcome of implementation is successful (for a thorough literature review on implementation success measures see Linton, 2002) and that it is possible to identify dependent variables for successful implementation as frequently done in the requirement specification stage. DeLone and McLean (1992) found that the most common IS implementation success factors were system usage and user satisfaction, but these are clearly too limited when considering eBusiness systems, where adoption by other organizations in the value network is of key importance. Indicators like number of visits to web-sites, revenue, execution etc. are other key performance indicators crucial to implementation success in relation to eBusiness models.

Linton (2002) found in his review of ten years of implementation literature that implementation success could be traced back to five factors: organizational structure, technology, project management, divisibility, and social interactions. The interaction perspective is especially important and has been center stage for many implementation researchers. For example Tornatzky and Fleischer (1990) claim that implementation success can be assessed by the degree of interaction with other technologies within the organization. That is especially the case when considering implementation of eBusiness models in existing organizations where the integration of eBusiness models with existing ERP-systems are of great importance if organization are to derive benefit from their eBusiness solutions. Furthermore, the integration with systems in other organizations and between organizational units in the different organizations is absolutely necessary for the success of an eBusiness.

### 3. Methodology for developing the implementation framework

The purpose of this section is to present how factors are

derived from literature, how the factors are selected and clustered, and finally how the framework is constructed.

The overall research task of this paper is, as previously mentioned, a cross-disciplinary analysis of implementation factors. The relevant implementation factors are derived through a literature review of the four influential areas of expertise/research: Venture capitalists experiences, business process reengineering (BPR), diffusion theory, and systems development. From articles within these four areas, the individual implementation factors are selected if they have been suggested as normative implementation characteristics, and are cited within the body of knowledge of the specific expertise/research area.

The implementation factors are then compared across the four areas and identical factors are eliminated and only presented once. All factors are then clustered into groups of factors with similar characteristics in order to provide an overview.

Hence, the factors are presented in a matrix presenting the various expertise/research areas. This matrix provides the basis for the resulting implementation framework where technological, organizational and market clusters represent our clustering of the factors. This framework is provided in Section 5 and show the four reference disciplines side by side and structured according to the three clusters.

### 4. Contributions of implementation factors from the literature review

This section investigates literature and practice that provides evaluation aspects of eBusiness models.

#### 4.1 Contributions of implementation factors from venture capitalists experiences

The contribution from venture capitalists to eBusiness projects has flourished especially during the dot-com period and have increased dramatically in numbers during the last 5 years. Venture capitalists (VC) have always belonged as an integrated part of the financial sector which is reflected in the implementation factors they emphasize.

Little research literature prescribe the prerequisites demanded from the venture capitalists, although general guidelines on what incubators and venture capitalists may offer of services is found in literature, cf. Hansen et al. (2000). Hence, insight from venture capitalists are found from alternative sources.

A typical example of a VC inspired insight was provided by T. Forcht Dagi (2001), MD of Cordova Ventures and professor at The Georgia Institute of Technology who shared a seminar at the Global e-Management MBA Program. The main focus of this was management, other investors, and the board. In addition to this, products/services, the market, the revenue model, the sustainable competitive advantage, the organizational structure, and the exit potential opportunities influenced this decision to invest.

Mr. Dagi argued that the pitfalls that led many start-up

companies to fail were numerous and caused by wrong interpretations and insufficient planning and analysis of the eBusiness model. Among others the true costs of starting and running business were not understood, especially since the eBusiness market suffered from weak barriers to entry. The Internet does not per se provide any sustainable competitive advantage, and customers may to a large extent be reluctant to purchase due to security issues, over-exposure, and the non-pleasant customer experience. Furthermore, revenue models were often flawed, cash flow from financing eclipsed cash flow from operations, and business plans had poor strategic vision. Hence, the success factors of an eBusiness plan promising a successful implementation are that the basic principles of business do not change, since:

- ¾ Cash flow determines survival management
- ¾ Strategy and vision are key attributes
- ¾ Growth is to be obtained organically or by acquisition
- ¾ A solid understanding of what really drives customer value is necessary
- ¾ A rational revenue model is required.

Noble (1999) suggests a model that divides an implementation into four stages. The stages are pre-implementation, organizing the implementation effort, managing the implementation process, and maximizing cross-functional performance. The focus of the model is on cross-functional issues and dynamics. This is why it is relevant to consider in relation to implementation of eBusiness models, which contain the same characteristics. The research of Noble (1999) provides critical success factors (CSF's) for each implementation stage from a managerial point of view. The "managerial levers", cf. Noble (1999:25), as the CSF's are named, provide insight from a research conducted through executive interviews and middle manager surveys with respect to goals, organisational structure, leadership, communications, and incentives. The learning point of the framework provided is that the management of these factors changes through the implementation stages.

Lazer & Livnat (2001) suggest a five-step evaluation process of eBusiness models that is materialised in specific questions regarding the economic viability of the eBusiness model. These are:

- ¾ What market failures and transaction costs are addressed by the business model?
- ¾ How effective can the e-commerce firm be in reducing the market failures or transaction costs?
- ¾ Will the e-commerce company be able to expropriate benefits from customers?
- ¾ What are the necessary resources to conduct the business?
- ¾ Can competitors erode profits?

The transaction costs address in particular seller's

transactions costs of order taking costs, recording costs, display costs, mailing costs, and marketing costs; buyer's transactions costs of transportation costs, timing of transactions, information gathering costs, information processing costs; and other benefits as personalization, price transparency, market making, and network externalities.

De et al. (2001) suggest a micro economic perspective on evaluating eBusiness models emphasizing traditional areas as transaction costs, switching costs, network externalities and product versioning. In addition to this the authors suggest that successes and failures of eBusiness models also need to be evaluated based on infrastructure investment models, user experience models, and models for revenue generation in order to reveal the inherent complexity of conducting electronic business.

#### 4.2 Contributions of implementation factors from BPR

The concept of Business Process Reengineering (BPR) was originally coined by Hammer (1990). The focus here was very radical emphasizing radical organizational changes through obliteration of activities instead of (or before) automating the activities. The approach was later softened and changed focus from radical redesign to process focus as the driving force in reengineering projects, cf. (Hammer 1996, Hammer 1999). The reengineering activities have during the early years primarily addressed intra-organizational initiatives, cf. e.g. Hammer & Stanton (1995) and Keen (1997), but has later extended the scope to network redesign by focusing on inter-organizational redesign projects, e.g. Keen & McDonald (2000) and Hammer (2001).

One of the key issues in implementing BPR projects according to Hammer & Champy (1993) is that reengineering success depends on getting all the way around the business system diamond (Hammer & Champy 1993; Champy 1995) meaning that not only design decisions must be taken, but also that deployment must be conducted. The business system diamond identifies the relationship between business processes, jobs and structures, management and measurement systems, and values and beliefs. When restructuring the business process, the content of jobs and of organisational structures changes for all employees. Changing jobs and structures require changes in management principles and performance measurement systems. These new management principles and performance measurement systems induce change in values and beliefs, which in turn enable the new business processes. Consequently, reengineering is not complete until all elements of the business system diamond have been changed and aligned (e.g. Larsen & Leinsdorff 1998), which is a process that may be undertaken iteratively in order to gain the buy-in, acceptance and appreciation from the employees involved (Larsen & Bjørn-Andersen 2001)

Moreover, alignment of the business processes with the business strategy is considered important (Tinnilä 1995;

Clemons et al. 1995; Sarkis et al. 1997; Lockamy & Smith 1997) as well as alignment with the information technology strategy. Hence, recruitment of the necessary skill-base and training are vital for BPR-project success, cf. Bashein et al. (1994) and Martinez (1995). In addition to this, scoping the BPR-projects (Hall et al 1993) and assuring learning processes (Galliers 1997) and shared values (Grover et al. 1995) are crucial for obtaining radical results. Finally, change management emphasizing communication and training and handling of political controversies are important in order to maneuver in a highly political landscape which a BPR project often turns into, are recommendations from researchers as well as practitioners (McElrath-Slade 1994; Taylor 1995; Davenport 1995; Homa 1995). Finally, most authors agree that all BPR efforts are unlikely to reach success unless the top management is committed, supported and engaged in the activities (e.g. Davenport & Short 1990; Bashein et al. 1994; Willcocks & Smith 1995).

#### 4.3 Contributions of implementation factors from diffusion theory

The traditional diffusion of innovations theory as represented by Rogers (1995) assumes that implementation is the final destination of a sequential process departing from initiation of a given idea. The IT diffusion process is characterized by different behaviors. Whereas the adoption stage is claimed to represent rational behaviors, the implementation stage is argued to reflect social learning and political behaviors (Cooper & Zmud, 1990). The final stage in the implementation process is routinizing. This routinizing is characterized by a combination of individual and organizational learning where individual insights and skills become embodied in organizational routines (Attewell, 1992).

The diffusion theory is not specifically targeted at adoption, implementation, and diffusion of IT. The theory is relevant to any technological innovation, which is implemented among individuals and organizations. Researchers within MIS (e.g. Premkumar et al., 1994; Ramamurthy et al., 1999; Ramamurthy & Premkumar, 1995; Cooper & Zmud 1990) have however often used the perspective when defining normative guidelines for successful implementation of IT. These sources are used as guidance for description of the key factors influencing successful IT implementation in organizations from a diffusion perspective.

According the diffusion school of thought implementation is when a new practice is put into use (Marble, 2000). Implementation therefore involves behavior change in the organization (Rogers, 1995). A more specific definition targeting organizational IT implementation is given by Kwon and Zmud who claim that organizational IT implementation is “the managerial concerns focusing on the effective diffusion of information technologies into organizations, business units, and work groups” (Kwon & Zmud, 1987). Cooper and Zmud (1990) defined IT implementation as “an organizational effort

directed toward diffusing appropriate information technology within a user community.” The means for “the diffusion of information technology” according to this line of thought are presented in the following.

The factors influencing implementation represent a broad variety of themes. Researchers within diffusion theory have presented useful classifications of the numerous factors (e.g. Kwon & Zmud, 1987; Tornatzky & Fleischer 1990; Premkumar & Ramamurthy, 1995). In this context the Kwon and Zmud (1987) taxonomy is used as a classification scheme. The reason for using this particular classification of contextual factors influencing implementation is that a broad scope of factors influencing organizational implementation is included. Five types of factors are identified in the Kwon and Zmud taxonomy: 1) Characteristics of the user community influencing implementation, e.g., commitment to change, education, social approval, degree of understanding of the technology. 2) Characteristics of the organization influencing implementation, e.g., organizational structures, management support, organizational compatibility. 3) Characteristics of the technology influencing implementation, e.g., degree of complexity, compatibility, standards. 4) Characteristics of the task to which technology is applied influencing implementation, e.g., task uncertainty, responsibility, task variety. 5) Characteristics of the organizational environment, e.g., uncertainty, dependence, and power.

#### 4.4 Contributions of implementation factors from system development

The system development perspective sees implementation as the last step in the development life cycle. It is “the conversion and installation of newly developed systems” (Marble 2000). From the system development perspective systems success can be measured by four parameters (Coe, 1996): Use of the system measured by intended or actual use of the system; Favorable attitudes toward the system on part of users; Degree to which the system accomplishes its original objective, and; Payoff to the organization. These measures are closely related to successful implementation. However, as pointed out by Coe (1996) numerous implementation efforts related to information systems are technical successes but at the same time organizational failures.

In the systems development perspective the development process is the focal point rather than the outcome and ultimately an organizational implementation success. However, at the end of the day “[Computer professionals] develop and maintain computer systems for others to use” (Dahlbom & Mathiassen, 2000). In this context we are more interested in the use than the development and maintenance of the eBusiness applications. Therefore, focus is on those factors which systems development literature identifies as important parameters for use and/ or implementation.

An organizational oriented view on systems development is put forward by Eason (1988) and by

Tornatzky and Fleischer (1990). According to them focus is on the organizational change caused by information technology. The organizational perspective to system development suggests that issues such as: testing and validating the technical system; organizational change; acceptance of change; integration with other systems and, training and support are crucial in implementing IT in organizations. These aspects indicate that implementation of IT is an organizational adaptation and learning process where the significance of technology is de-emphasized in favor of human/organizational aspects. This is in line with suggestions from other researchers, e.g. Attewell (1992). Regardless of the six steps an implementation strategy has to be considered. Basically the implementation strategy ranges from revolution to evolution (Eason, 1988). Eason argues that adaptation tends to be more difficult the less evolutionary the implementation strategy is.

Another view on implementation from a system development perspective, which is more focused on the system, is presented by (Dahlbom & Mathiassen 2000). Dahlbom and Mathiassen suggest that a set of quality parameters concerning the fulfillment of users objectives are necessary for implementation. These parameters include: Correctness, reliability, efficiency, integrity, and usability. This view of system efficiency as a parameter for successful implementation is also suggested by (Coe 1996) who argues that system failure can be avoided by observance of five efficiency measures related to systems delivery; implementation process owner, training, front line support, explication of efficiency measures, and effective communications. Finally, Iversen et al. (2001) advocate the importance of risk management during the implementation process.

## 5. Construction of the implementation framework

This section describes how the factors of the different perspectives are clustered and the basis for this clustering.

Based on the literature reviews of the four reference disciplines all factors were individually put on a blackboard in order to get an overview. Then identical factors within the same reference discipline were eliminated. A clustering of the factors were then undertaken through a iterative process of trying to identify a common denominator of the clusters. The final clustering process resulted in three clusters, i.e. Technological factors, Market factors and factors Organizational – in short the TMO-framework. The table below is the result of the clustering process.

As illustrated in Table 1 do all four disciplines have strong emphasis on organizational factors. Some of these factors which are represented in all four disciplines is management support and organizational structure, directly related to commitment to change. The diffusion theory and systems development literatures do not focus on marked factors in particular. This has been source to recent criticism (Lyytinen & Damsgaard, 2001; Kurnia & Johnston, 2000) since it narrows the scope of diffusion

theory in relation to IOS. The technological cluster is represented in all four disciplines. However, focus is very different depending on the school of thought. Whereas diffusion theory and system development literature focus on manifest attributes of the technological artifact, VC and BPR focuses on more abstract characteristics related to the capabilities of the technology.

Implementation factors from the four perspectives are clustered or related to technology, market, or organization – see appendix.

## 6. The HABURI.COM case

The case presentation of HABURI.COM is provided to illustrate the broad range of implementation issues businesses are confronted with when applying an eBusiness model in their business practices. The presentation of HABURI.COM is mainly based on Bjorn-Andersen (2002).

HABURI.COM is a virtual factory outlet mall for fashion clothing and accessories on the Internet. The HABURI site was first launched by April 2000 and by the end of year 2000 the company was present in fifteen European countries. Before the launch of the virtual factory outlet mall the three founders investigated the characteristics of physical factory outlets. They found that the virtual outlets had a number of advantages compared to the physical outlets. These advantages included elimination of distance to outlet for customers and critical mass among customers due to a general increase in the number of factory outlets. Taking the critical situation at that time into consideration HABURI was fortunate to get the necessary financial support when they searched for investment capital in beginning of year 2000. It took the founders 180 days from the strategy formulation and till the web-site was launched. The founders reason this successful entry by their professional preparations, operations and well-stated business plan.

Prior to the launch of the web-site the three founders of the company made a rough draft of HABURI's business strategy. Part of the business strategy was to meet the customers' expectations rather than to present the ultimate eBusiness solution from day one. The strategy for the web-site was to create a web-site without any complex user-intrusive technologies. Next, part of the business plan was, as explicitly pronounced in the firm's mission statement, to stick to one of the old business virtues: Placing the customer in focus. Another strategic consideration was to differentiate HABURI from traditional online retailing shops. Two features distinguish HABURI from traditional online retailing shops. Firstly, HABURI sells the most exquisite brands on the market through their web-site. By year 2000 DKNY, Calvin Klein, Cerrutti, and Valentino were some of the organizations supplying products to the HABURI web-site. The online retailing clothing store thereby differentiates it from for example landsend.com or dressforless.com. Secondly, instead of selling from stock as the traditional online clothing shops HABURI decided to prosper from their

competitors' failure in estimating demand. The primary approach is to clear the its suppliers' stock. It is traditionally critical for producers of exclusive brands to sell their stock through clearance sales in the traditional channels since those customers, which bought their clothing do not like to see their luxury goods being offered in less exclusive environments.

HABURI did from day one decide to outsource several activities. Though the three founders had business backgrounds and experiences in the Internet environment they realized it was crucial to obtain expert knowledge in different areas. McKinsey & Company contributed with knowledge in the pre-launch phase by giving input to the business strategy. IBM Denmark and ProActive A/S delivered the technical eBusiness platform to the web-site. Proffice Communication Center A/S designed and composed the HABURI web-site. It was made as customized as possible in order to increase the customer service level. Proffice Communication Center A/S was also in charge of the call-center functions and information services. Finally, did the SAS Institute provide a business intelligence system, Balanced Scorecard, which was implemented in order to assist the decision-makers in establishing strategic decisions. The Balanced Scorecard solution was used to prepare distribution, logistics and customer contact.

It was HABURI's strategy to create a reintermediating link in the supply chain. This strategy has far proven to be successful. Downstream in the supply chain HABURI has created a window of opportunities for customers to make a good bargain on exclusive clothing and accessories. Upstream in the supply chain HABURI has created a safe market-place for the exquisite brand names to clear their stock. HABURI is as such an example of a successful implementation of an eBusiness model.

## 7. Discussion

The validity and applicability of a framework is of particular importance as it is suggested to serve as recommendations and guidelines for future ventures implementing eBusiness models either as click-and-mortar or pure-e-play initiatives. Hence, the robustness of the proposed framework is discussed in the following.

Depending on the choice of eBusiness model definition, variations of relevant factors may change. However, as the majority of the definitions referred to in the eBusiness model section are comparable with the selected definition of Timmers (1998), the likely variations in the proposed framework are expected to be moderate. Similarly, the choice of relevance criteria for selecting implementation factors may provide some variation in the final outcome of the framework.

Literature, either providing prescriptive recommendations or descriptive experiences, suggests a huge number of factors that likely may affect implementation of information systems and eBusiness models in particular. In our presentation of relevant factors we have aimed at selecting factors the commonly were

agreed as important, although this selection process may be influenced by subjective opinions. We did find that an implementation model for eBusiness models should include three clusters of factors: technology, market, and organization – the TMO-model. Depending on the theoretical perspective emphasis varied on the three dimensions. However, given our multi-disciplinary approach it is concluded that a feasible model for eBusiness model implementation should embrace the three dimensions.

The framework may have leveraged other categorization schemes, which could have altered the final presentation of the implementation framework. E.g. Earle & Keen (2000) identify six value drivers that are crucial for long-term profitability of eBusiness models. The value drivers that are derived from field research and the authors' experience in companies (as president of Hewlett-Packard E-Services Solutions and Chairman of Keen Innovations) are logistics, relationships, channels, branding, capital and cost structures, and intermediation. Through these drivers the authors claim that the primary goal of any business, which is to create customer value and generate profits over the long term, may be obtained.

As mentioned in Section 3, this work is considered to be conceptual in nature. Based on a review of four relevant research disciplines we have outlined a theoretical framework, which we find broadly applicable for eBusiness model implementation. One way of validating a theoretical framework is to validate the strength of the theoretical contribution. Whetten (1989) has outlined four guidelines for assessment of theoretical contributions: 1) A description of which elements logically should be considered as part of the explanation of the social or individual phenomena of interest; 2) A description of the relationship between the elements; 3) An explanation of the underlying psychological, economic, or social dynamics that justify the selection of elements and the proposed causal relationships, and; 4) A description of the range of the theory. These four "building blocks" will be discussed to demonstrate the strength of eBusiness model implementation framework.

The first building block defined by Whetten reflects the factors, which are part of a given model. In our TMO-model we argue that technology, market, and organization are the factors which should be considered as parts of the phenomena. Our phenomenon, which is to be embraced by the TMO-model is eBusiness model implementation success. The just described example of HABURI.COM illustrates the validity and applicability of the model. The three founders paid interest to the development of the web-site and the technical platform. They argued that technology had to be efficient and user friendly. The founders also paid attention to market factors. HABURI.COM focused on customers and they did at the same time provide an optimal solution for their suppliers by creating a reliable outlet for their potential suppliers. The organizational factors are indirectly represented in the HABURI.COM case. It is evident that the management supported the adoption and implementation of the

eBusiness model since they were the designers of the concept. It is also evident that there would be no resistance to change in the organization since no rigid structures had been established in the start-up venture. However, aspects related to e.g. organizational learning and competence building did get attention from the founders. HABURI.com did explicitly engage Proofoffice Communication Centre A/S to manage these tasks.

The second building block, which focuses on the relation between the elements, is also well illustrated in the HABURI.COM case. The founders integrated the three dimensions technology, market, and organization in their business-strategy. Whetten suggests that some causality should be probable from the relationships between the included dimensions of the model. The founders of HABURI.COM realized that the technological dimension had to include certain attributes in order to support their market relations and at the same time support organizational structures.

The third building block is concerned with the underlying logic of the model. As described in Section 2.1 do we find that eBusiness models are characterized by attributes, which go beyond the organization. Value is created in networks and the market dimension is therefore an important aspect, which has to get attention when outlining normative guidelines for implementation. Inherent in eBusiness models is technology (Timmers, 1998). It is therefore inevitable to include the technological dimension in a framework, which aims at supporting successful implementation of eBusiness models.

The fourth building block, which can be used to assess the validity of the theoretical contribution, is concerned with the range of the theory. Those eBusiness models which are based on business-to-business relations and market structures (versus hierarchical structures) make a natural scope of the model.

## 8. Conclusions and Future Research

The paper argues that the prerequisites for implementation of eBusiness models compared with traditional information systems are changed due to causes as new stakeholders, need for multi-perspective business analysis, time compression of development time and changed development methods. Hence, it is relevant to suggest a framework highlighting important implementation factors derived from various relevant disciplines.

The specific research questions investigated in this paper are: What are the key IT implementation factors in different perspectives? And: How should the key IT implementation factors be classified in order to provide a coherent framework for eBusiness Model implementation?

The key IT implementation factors of each of four influential areas of expertise/research, i.e. venture capitalists experiences, BPR, diffusion theory, and systems development, were presented based on a literature review.

The implementation factors were classified in a framework – the TMO-model - that identified the technological, the organizational, and the market related factors relevant for implementation of eBusiness models.

The framework may be extended in various ways. More perspectives may be investigated and searched for contributing eBusiness model implementation factors. Also development direction of the research is that the framework may be tested under different conditions. For example, case studies may be performed using the framework as a diagnostic tool or surveys covering a larger number of business models may be conducted. All initiatives will add to the development and robustness of the framework by increasing the validity of the framework. Moreover, research will be conducted in development of assessment criteria for evaluation of eBusiness models, systems and application in order to assure the implementation process. Empirical testing of the framework is optimally performed on a sample of eBusiness models from different organizations that will provide statistically validated results. However, at the research is in its embryonic stage such a high validation level have not been possible to reach.

# The Invisible Borders in Internet Transactions: An Empirical Study of eBay's Auction System

Ruth L. Wang    Chien-Hua Li    Mike Lee

Department of Management  
California State University, Sacramento  
Sacramento, CA 95819-6088  
wangr@csus.edu

## Abstract

The popularity of auctions handled through eBay's website demonstrates the marketing power of the Internet. This study examines the influences of price, quality, reputation, and country-of-origin effects on buyers' repeat purchase decisions of jade products listed on eBay. Lower price, although promotes higher volume of bidding, tends to have negative impacts on quality perception. Repeat purchases and reputation differs significantly depending on the country of origin.

## 1. Introduction

One of the most researched Internet transactions in recent years is eBay's reputation system. These studies tend to focus on the sellers' perspective such as how to maximize the final auction prices and what factors lead to sales and premium prices. The results are, however, somewhat conflicting due to the nature of product categories examined in their data sets. Many believe that the seller's reputation, not buyer's, matters in high-priced goods. Studies also find that higher starting bid prices reduce the bid volumes, but lead to a high final sales price; given a successful sale. Others argue that reputable sellers enjoy no boost in price, though their auctions are more likely to be sold; or that the seller's reputation is no longer significant in the case of specific low-priced commodity goods. Additional elements investigated include whether seller is made better or worse off by setting a reserve price. There are also studies that investigate bidding behavior.

## 2. Variables

The purpose of this study is to address issues and information which might be useful to buyer's decision making in Internet transactions. Data are collected from feedback information of sellers who have been listing items under the "jade" category of eBay from the beginning until April 2002. The variables analyzed in this research range from price (not auction price realized, but the starting bid price), relative quality, feedback information, rate of repeated purchase, eBay history, percentage of jade items in the seller's listing,

and origin (country/location) of the seller. In addition to the statistical tests based on quantitative data extracted from eBay, qualitative analysis of item descriptions is performed to understand potential national differences. This is a judgment sample by nature. For instance, sellers who are relatively new, or list under this category occasionally because they happen to have a jade piece or two, are excluded from our sample. As a result, there are 75 valid sample subjects included in this research. Since the researchers of this study have had years of experience with this particular gemstone and have also purchased from most of these sellers in the sample, we have the advantage in evaluating the quality and business practices of these sellers in Internet transactions.

TABLE 1 Variables

Variables	Description
Quality	4-point scale, highest to lowest
Feedback	Number of feedbacks (positive, neutral, and negative)
History	Number of months listed on eBay
COO	Country of origin (US, HK/Singapore, China, and other)
Price	4-point scale, highest to lowest
Repeat Rate	Number of repeat purchase from the same seller
Reputation	Number of net positive or negative feedbacks

## 3. Analysis

The statistical analysis of our data indicates that there is a negative correlation between price and quality. But neither one factor plays a key role in repeated purchase, nor do they have anything to do with the seller's reputation. For this exotic product, lower starting bids also indicate poorer quality. Although low price promotes bid volume and generates more positive feedbacks, it does not enhance the seller's reputation. Generally speaking, sellers experienced with this category tend to offer quality items.

TABLE 2 Influences of Country of Origin

	Rep. Pur	Quality	Price	Reputat.
US	1.81	2.80	2.47	0.9969
HK/S	1.99	2.59	2.88	0.9954
China	2.60	3.25	2.00	0.9867
Other	3.12	2.75	4.00	0.9954

Table 2 indicates a significant relationship among the country-of-origin effect, repeat purchase rate, quality, starting bid price, and reputation. Internet transactions are supposed to be borderless, but invisible borders such as national and cultural differences remain significant. Seller's location matters very much in sources and quality of the items, communication and shipping methods, and consequently buyer satisfaction. Both of the two key variables in this study, reputation and repeat purchase, are significantly influenced by only the seller's location. Another intriguing result is that although US sellers enjoy the highest mean score

in reputation, they generate the lowest repeat purchase rate.

This paper also examines the cultural differences in a seller's item description, including the accuracy of period dating and authentication of so-called "archaic jades". The researchers find US sellers to be the most conservative in this regard. The shipping fees may be high, but shipping methods and auctions terms tend to be described more explicitly. Sellers from China, on the other hand, appear to be quite the opposite. Their descriptions are fuzzy and at times exaggerated. However, their seemingly endless supply of many newly manufactured replicas gives them an unmatched advantage. In a way, these also explain why US sellers score high on reputation, but fail to attract repeat customers.

# Adaptive Inter-Organizational Workflow Management for E-Business Integration

Han-Seup Kim and Sungjoo Park

Graduate School of Management  
Korea Advanced Institute of Science and Technology  
Seoul, Korea

[kimhs@isir.kaist.ac.kr](mailto:kimhs@isir.kaist.ac.kr), [sjpark@kaist.ac.kr](mailto:sjpark@kaist.ac.kr)

## Abstract

As the collaboration between companies is facilitated in e-business environment, inter-organizational workflow management becomes an important issue. Because the inter-organizational workflow consists of autonomous organizational workflow, the coordination of these autonomous processes is required. In this paper, a local viewed inter-organizational workflow model is proposed, in which an inter-organizational workflow is defined as a set of block activities. Exception handling rules for internal process are defined with pertinent block activities. Based on the suggested model, a multi-agent system and a coordination algorithm are proposed. For the illustration of the suggested model, an example inter-organizational workflow about book order process is presented.

## 1. Introduction

The workflow management as a technology that automates business process is widely used for organizational process. As the collaboration between companies is facilitated in e-business environment, the integration of organizational workflows becomes an important issue. But there are many obstacles for the integration. Ideally, details of each participating company's workflow should be opened and linked tightly. But each participating company reluctantly opens details of its process and hands over the authority of control to other companies. Moreover, various heterogeneous systems are used in participating companies. So in reality each participating company executes its own work independently and passes the results. This type of collaboration cannot manage the frequent changes or exceptions in the e-business environment appropriately [1].

There are several approaches for dealing with the inter-organizational process. WfMC suggests the standard inter-workflow interface in their reference model in order to link workflows [19]. It supports the exchange of limited control messages including queries and changes [20]. Recent approaches for web service propose the interface standard in order to link services provided in the web [4]. They support the invocation of other company's process and the returning of the results of that service. But they don't consider the characteristics of inter-organizational process. Existing researches cannot be applied directly to the real situations of the inter-organizational process.

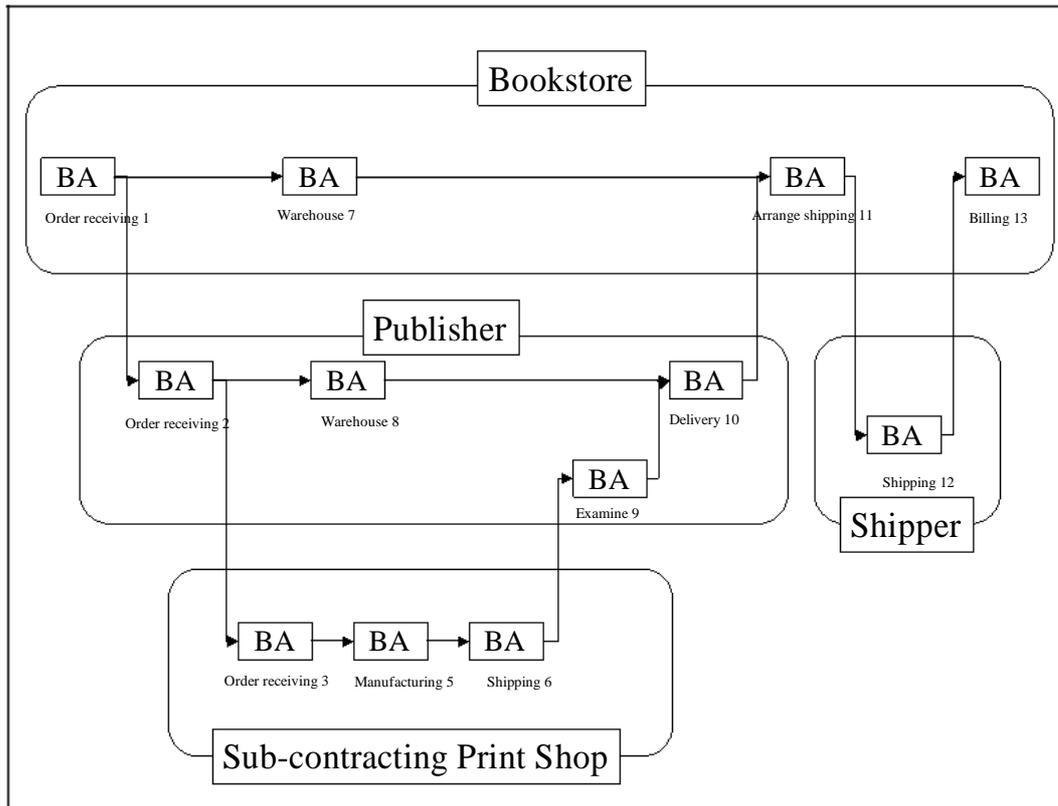

In this paper, the concept of 'block activity' is proposed for modeling autonomous participating workflows. Block activity is the unit of inter-organizational workflow and is the boundary where independent execution is guaranteed. Block activity refers internal activity set of external sub flow. Internal activity set contains applicable exception handling rules. External sub flow contains the information of pertinent company. The criterion of internal and external is depending on who the owner of the workflow is, so proposed inter-organizational workflow model only captures partial view of the whole process in perspective of each company.

To implement the adaptive inter-organizational workflow, multi-agent system is used. This multi-agent system is laying on the existing legacy process management systems and determining the exception handling process. The agent layer communicates with legacy systems using standard XML messages, so the heterogeneity problem can be overcome. To resolve the effects of invoked change or exception on the inter-organizational workflow, software agents coordinate about the requirements for exception handling to attain the common goal. One agent per each company infers the exception handling rules and determines the effecting boundary. Change propagation is invoked when the effect of exception handling is over the boundary of the block activity.

This paper is organized as follows. In section 2, the characteristics of the inter-organizational workflow are described with an example process. Section 3 briefly reviews related works. Section 4 presents the suggested inter-organizational workflow model and its components. Section 5 presents the multi-agent system for adaptive inter-organizational workflow and the coordination mechanism between participating agents. Section 6 presents the detailed description of example inter-organizational process and the usage of the proposed model for some probable exception cases. Finally, section 7 presents a conclusion and further research issues.

## 2. Inter-organizational Workflow

Inter-organizational workflow can be defined as the shared process where several companies are involved in [17]. In this section, an example of inter-organizational workflow is described in some detail. This example will be used later to illustrate our approach. [Figure 1] is a supposed book order process in the e-business environment.

[Figure 1] Inter-organizational process of book order

Consider that a customer places an order for books with Internet bookstore, such as Amazon.com. The bookstore checks the stock of ordered books and in turn places orders for shortage of books with the publishers. At this time, the control of the whole inter-organizational process is handed over to the publisher. The publisher checks its own publishing schedule and updates the publishing schedule. The update of publishing schedule includes placing orders for required raw materials, such as printing paper. After finishing the publisher's internal process, the control is returned to the bookstore. The bookstore determines the shipper and requests delivery. The shipper then coordinates the delivery according to its schedule. Finally, the completion of delivery triggers the last of internal process of bookstore.

This simple example describes the normal process of book order. Of course there is no problem if the process is followed the process just as described above. But there is no means to deal with any situations of unexpected exceptions. For example, the customer may cancel or change his issued order when the order is conveyed to the publisher. The publisher may not be able to print the books as committed or the shipper may not be able to deliver on time. Actually considering cancellation policy of Internet bookstores, they allow cancellation only before the process control is handed over to outer companies, such as publishers or shippers. In the customer's perspective, the cancellation for the perceived single book order process is limited because the process is performed by multiple participating companies.

This limitation wastes customer's time and money and increases customer's dissatisfaction. In the bookstore's perspective, this limitation increases the returning rate and diminishes the profit. So the cancellation option should be possible until the cancellation cost is smaller than the returning cost (including the wasted time value).

The characteristics of inter-organizational workflow are summarized as follows. First of all, the participating companies are autonomous and decentralized. It differs from the established assumption that one main process and other subsidiary processes join the master/slaves relationship. Any company has no right to verify or to control other's processes. Each participating company can control only its own internal process and inter-links outer process via limited messages equally. As seen above example, bookstore cannot directly order publishers or shippers to cancel their internal processes.

Next, participating companies use heterogeneous models and systems for internal process management. This characteristic makes the inter-organizational workflow a very troublesome and difficult issue. The standardization organization, such as WfMC, tries to define a common reference model and interface standards. But this effort is limited because of variety of legacy systems and newly supported services.

For all that, participating companies collaborate with each other for common goal. They are not in a competitive mood, but cooperate for the common goal such as order fulfillment. The inter-organizational workflow should be functioned as a seamlessly integrated

workflow. In order to attain this requirement, the inter-organizational workflow should be adaptive and flexible to the various exceptions and changes that are brought by customers or external environment.

As seen above, the current situation of inter-organizational workflow is just a linking of autonomous workflows for normal execution. The inter-organizational workflow defines the mapping relationship of input/output information and signals between workflow. There is no way to handle abnormal situation. Especially in the e-business environment, exceptions and changes occur frequently and the effect of them is not only on the process of origin but also on the other companies' processes. Even though the current situation is only an intermediate stage, the ultimate goal should be a virtual enterprise that is the seamless integration of e-business.

### 3. Related Researches

Many works for workflow modeling are based on the input-process-output(IPO) approach [13]. It provides the task-oriented view on the workflow, that is, a workflow is considered as a set of interrelated tasks which processes inputs and produces outputs. This approach is good for modeling structured workflow such as business trip approval process and purchasing process. On the other hand, the language/action approach is also used for workflow modeling [12]. It focuses on the conversations between workflow participants, and has merits for modeling unstructured workflow such as project planning. Some researchers employ object-oriented approach for workflow modeling and enactment [10]. Bose presented five classes of objects as key constructs: roles, organization structures, procedures, transitions, and documents. In his model, workflows are executed through message passing between participating objects of the workflow. Both of Chang and Scott and Jennings et al. suggested agent based approach for workflow management. In their architecture, autonomous and problem solving agents interact through their own protocol to achieve the workflow management goals.

The issue of flexible workflow management has been addressed in Casati et al., Reichert and Dadam, Dellen et al., and Bogia and Kaplan [5]. Casati et al. suggested a set of primitives that allow for the modifications of workflow schema, and introduced taxonomy of policies to manage the evolution of running when the corresponding workflow schema is modified. Reichert and Dadam defined a complete and minimal set of change operations that support users to modify the structure of running workflow while maintaining its structural correctness and consistency. Dellen et al. suggested the CoMo-Kit system in which it is possible to refine and extend the software process model during the process execution using the dependency management and the change notification mechanism. In these studies, managing the changes such as adding or deleting tasks

and changing predefined task sequences are the main concern without considering mechanisms to handle changes in the organizational structure and business rules.

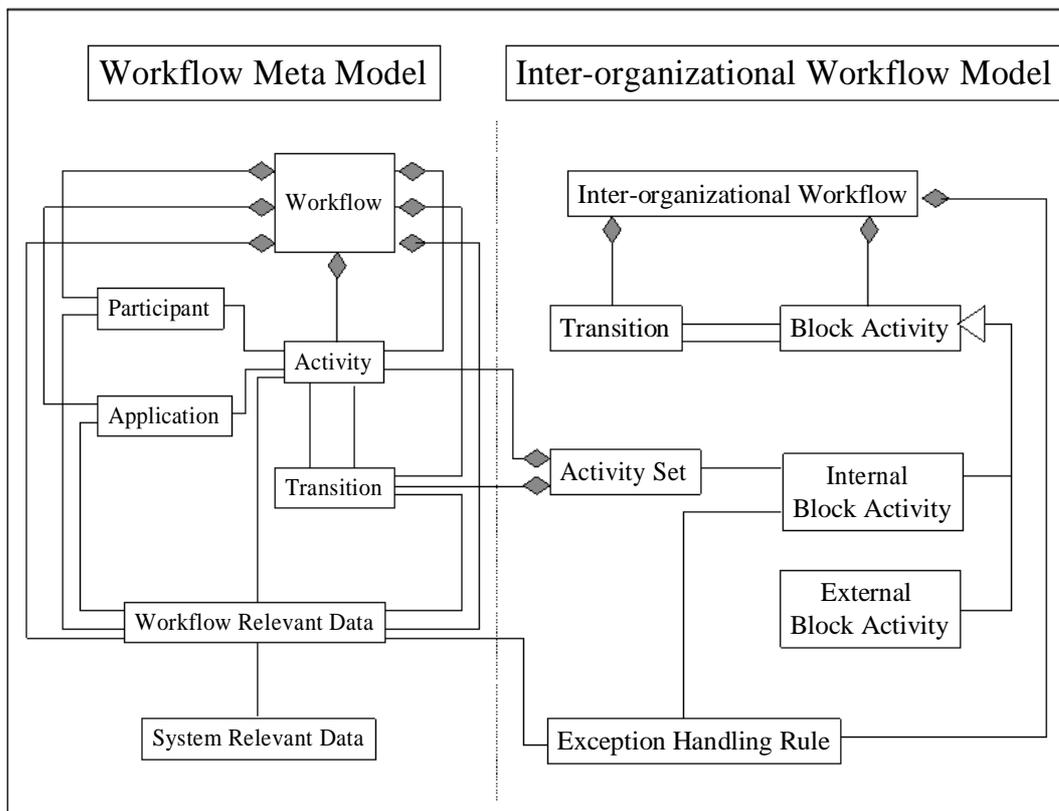

Basu suggested intelligent e-service as the future of workflow in e-business environment [1]. It contains negotiation, complex querying, and exception handling, etc. Aalst, et. al. suggested a public and private workflow for inter-organizational workflow modeling [14]. This formal modeling permits verification of soundness of inter-organizational workflow. But this model requires full information of the inter-organizational workflow before the execution, which is unrealistic in reality. Moreover, this formal model can't reflect the frequent changes or exceptions in e-business environment. Joeris used reactive task agents for flexible inter-organizational workflow [6]. But suggested multi-agent system is not compatible with existing workflow management systems. WfMC suggested the workflow reference model and 5 types of interface [18] [19] [20]. But they defined minimal standards so using only these interfaces for implementing adaptive inter-organizational workflow has limitations.

### 4. Inter-organizational Workflow Model

The proposed inter-organizational workflow model is based on the following two basic assumptions. First, there is no global and perfect view of inter-organizational workflow. Any one of participating companies doesn't have to play the central role of managing the inter-organizational process and doesn't have the right to do so. Each participating company sees the inter-organizational workflow in its own view point. One inter-organizational workflow can be defined differently depending on who defines the inter-organizational workflow. Each company performs its internal process and interacts with other companies for inputs and outputs as defined in the local viewed inter-organizational workflow. The global view is only attained via coordination of local views of participating companies.

Second, the model for inter-organizational workflow not only defines the normal sequence of inter-organizational process, but also manages the rules for handling exceptional situations. As explained in section 2, the inter-organizational process in e-business is exposed to many exceptions and changes and the inflexibility of inter-organizational process is the main obstacle of customer's satisfaction. The change or exception in the inter-organizational workflow effects not only on one participating company's process, but also on several companies' processes. Each participating company has its internal policies for exception handling on its internal process and makes decisions depending on the status of internal process at that moment. The exception handling of full inter-organizational workflow is achieved by coordinating the partial exception handling of participating companies.

The proposed inter-organizational workflow model is summarized as in [Figure 2].

[Figure 2] The inter-organizational workflow model

In this model, an inter-organizational workflow is defined as an ordered sequence of 'block activities' in contrast to that the existing intra-organizational workflow is defined as a ordered sequence of activities. The 'transition' represents the precedence relationship between block activities. The 'resource' captures the information, documents, artifacts, etc, which are exchanged between block activities as inputs or outputs.

#### 4.1 Internal and External Block Activities

The concept of 'block activity' is used as the basic unit for modeling inter-organizational workflow. Block activity is classified into two types by their control authority; internal and external. Because internal and external are relative concepts, inter-organizational workflow model of each participating company is different with one another. This local view of inter-organizational workflow is the appropriate modeling mechanism for autonomous workflows. Participating companies don't have to open their detailed process definitions nor permit access control to their confidential processes. They only abstract their process into a number of block activities and inform the information about them to other participating companies.

The internal block activity refers a separately defined set of internal activities, which have high coherence and share common inputs and outputs. The activities of the referring activity set are already defined in the internal process definition, such as organizational workflow model. The internal block activity is the

boundary of independent and autonomous execution of internal process. The control of inter-organizational workflow is transferred to the pertinent company while its internal block activity is executed. Each internal block activity has inputs and outputs for their execution, which are defined in the resource part of inter-organizational workflow model. Participating companies define and manage exception handling rules for each internal block activity. Exception handling rules are defined

The external block activity refers an external process and is perceived as a black box with pre-defined inputs and outputs. But this black box is not a fixed environmental variable, but a negotiable entity. If the effects of some exception handling rules come over to this type of block activity, the appropriate request for exception handling should be passed to the pertinent company and the result should be checked before the actual exception handling.

#### 4.2 Exception Handling Rules

An exception handling rule is composed of three parts; request type, condition, and result. There are six generic 'request types'; cancel, suspend, resume, roll-back, expedite, and change. The first five is for the process control and the last one is for the information control. Every complicated exception can be interpreted into the combination of these six generic request types. Detailed description for each request type is summarized in the [Table 1].

[Table 1] 6 generic request types for the exception handling

Control	Request type	Description
Process	Cancel	Cancel the currently executing process
	Suspend	Suspend the currently executing process temporarily
	Resume	Resume the currently suspending process
	Roll-back	Roll-back the currently executing process to a certain point
	Expedite	Expedite the currently executing process until a certain time
Information	Change	Change the value of inputs of currently executing process

```

<ExceptionHandlingRule Id="1" name="cancellation for publishing">
  <RequestType>Cancel</RequestType>
  <Conditions>
    <ActivityConditions>
      <ActivityCondition Id="activity23" state="unstarted"/>
    </ActivityConditions>
    <ArtifactConditions>
      <ArtifactCondition Id="publishing schedule" state="generated"/>
    </ArtifactConditions>
  </Conditions>
  <Results>
    <ActivityResults>
      <ActivityResult Id="activity22" state="unstarted"/>
    <ActivityResult Id="activity21" state="unstarted"/>
    <ArtifactResults>
      <ArtifactResult Id="publishing schedule" state="not_exist"/>
    </ArtifactResults>
    <Costs>
      <Cost name="scheduleing cost" value="$4.5"/>
    </Costs>
  </Results>
</ExceptionHandlingRule>

```

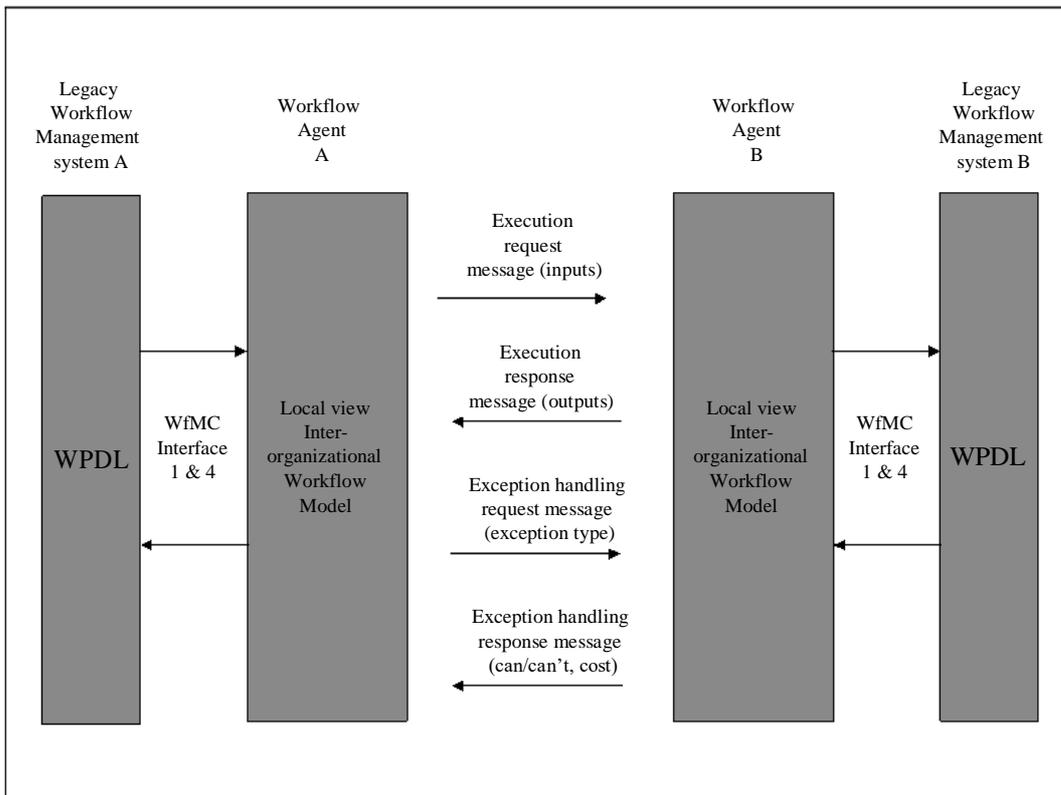

[Figure 3] Example representation of an exception handling rule

The ‘condition’ specifies the required status of inputs, outputs, and activities of referring activity set. The ‘result’ specifies the resulted status of inputs, outputs, and activities. The status for inputs and outputs is defined one of followings; not\_exist, generated, and a specific value. The status for activities is defined one of followings; unstarted, running, suspended, completed, and aborted. And the incurred cost is also specified in the result part. The incurred cost can be used in the negotiation process as the criteria for a decision making about exception handling. [Figure 3] is the example representation of an exception handling rule.

### 5. Multi-agent System for Adaptive Inter-organizational Workflow

In order to be adaptive, the inter-organizational workflow should handle exceptions accordingly, even though the effects of the exceptions go over other

participating companies’ processes. Each participating workflows are autonomous, so the exception handling of inter-organizational workflow is only achieved by the coordination between participating workflows. Software agent has communication and reasoning capabilities for problem solving, so multi-agent system is a suitable mechanism for implementing this coordination. Each software agent represents its belonging company and interacts with legacy process management systems, such as organizational workflow management systems. So this multi-agent system is an additional layer on top of the legacy systems. The multi-agent system for inter-organizational workflow is depicted in [Figure 4]. Each workflow agent defines its own inter-organizational workflow model based on the model defined previous section. It also manages exception handling rules for each internal block activity.

[Figure 4] Multi-agent system for adaptive inter-organizational workflow

Each workflow agent separately defines local viewed inter-organizational workflow model and controls the normal execution of it. When the turn comes round, the workflow agent receives pre-defined inputs for its internal block activity from external block activities and conveys them to the legacy process management system. After finishing the execution of block activity, the workflow agent collects outputs and delivers them to the

appropriate workflow agent of next block activity. The workflow agent also actively monitors exceptional situations and coordinates the exception handling. The workflow agent follows the coordination algorithm for exception handling as described in the [Figure 5]. The more detailed coordination process is presented in section 6 with example case that is explained in the next section.

1. Depending where the exception is occurred
  - A. If the exception is occurred in the internal block activity, detect the exception and decompose it with 6 generic type exception handling request
  - B. If the exception is occurred in the external block activity, receive the exception handling request
2. Query the status of its workflow and update the fact base for reasoning the exception handling rules
3. Choose the currently executing block activity
  - A. If the currently executing block activity is internal, fire the exception handling rules for that request type and adds results into the fact base
  - B. If the currently executing block activity is external, request the exception handling to the workflow agent and wait for the response
  - C. Find the next influenced block activity and repeat stage 3
4. If there is no more influenced block activity or the response is impossible, then response back the requester whether the exception handling can be successful or not

[Figure 5] Coordination algorithm for exception handling

## 6. Example Inter-organizational Workflow

In this section, the Internet bookstore example is revisited. As described in section 2, there are 4 participating companies in this example; bookstore, publisher, shipper, and paper manufacturer.

The bookstore's view for this example inter-organizational workflow is as follows. The customer's order is received and processed. Then orders for some out-of-stock books are issued to the appropriate publishers. While the publishers supply ordered books, the bookstore finds its own warehouse for stocked books. When all ordered books are prepared, books are checked and packaged for shipping. The shipper delivers ordered books to the customer. After shipping, bookstore's billing process is started.

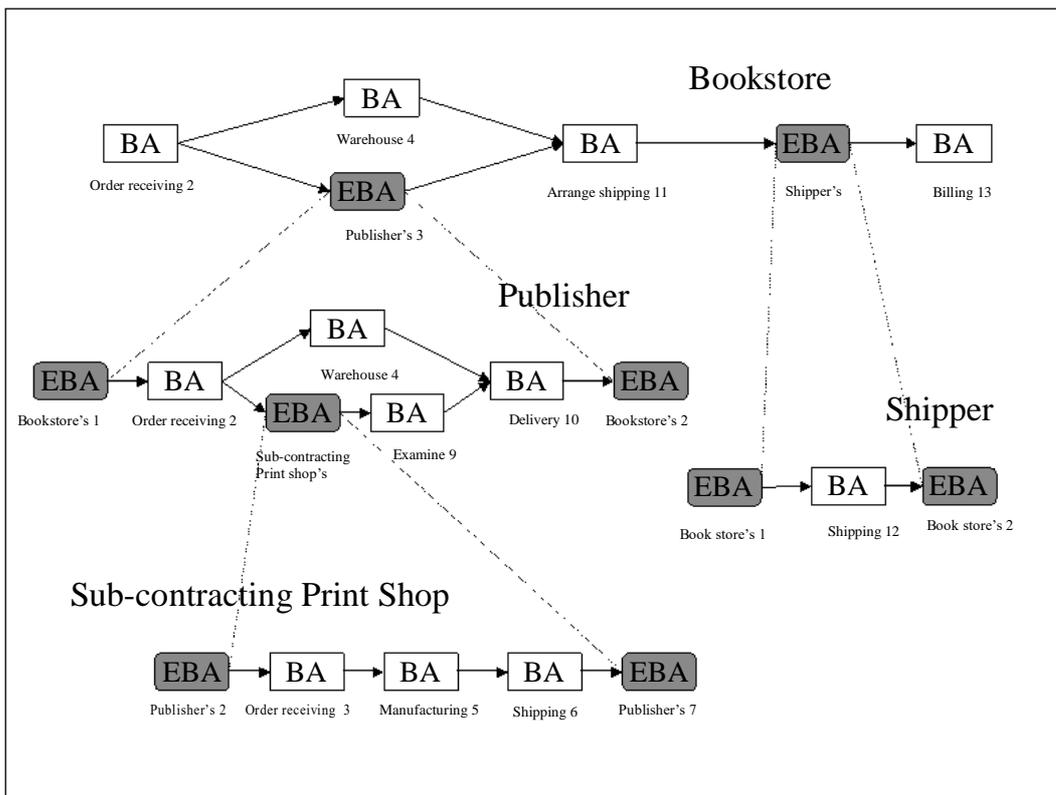

The publisher's view for the same process is fairly different. Publishers don't care who ordered their books or to where their books are delivered finally. They only fulfill the order from the bookstore. The publisher checks its warehouse stocks and re-schedules out-of-stock books. In tern, the subcontracting print shop prints and delivers books as the publisher's schedule. Then the publisher examines the delivered books. Finally, the publisher delivers ordered books to the bookstore and its

role is over in this inter-organizational workflow.

In the shipper's view, the process is simple. The bookstore requests the delivery of some books to the customer. The shipment schedule is made and shipping is accomplished. Then the result is notified to the bookstore.

In the subcontracting print shop's local view, the publisher initiates the inter-organizational workflow. The publisher requests to deliver books to it as their schedule. The print shop follows some internal activities and finally delivers requested books. Then the publisher executes its remaining tasks.

[Figure 6] represents four local views of participating companies. There is no global view, which covers all participating processes. Four companies participate in the same inter-organizational workflow, but each company only sees a certain portion of the full process. Even though the bookstore's view is the widest, it can't see the hidden process of subcontracting print shop. The suggested model reflects this substantial characteristic of inter-organizational workflow. The each local viewed inter-organizational workflow model abstracts the full process using internal and external block activities.

[Figure 6] Modeling of example inter-organizational workflow using block activities

	<p>book store agent</p> <ol style="list-style-type: none"> <li>1A. Detect the cancellation exception from the customer and decompose it as the cancel type exception handling request</li> <li>2. Query the status of bookstore's workflow and update the fact base</li> <li>3B. Current executing block activity, 'publisher's 3' is external, so request the exception handling to the workflow agent of block activity 'publisher's 3' and wait for the response</li> </ol>
	<p>publisher agent</p> <ol style="list-style-type: none"> <li>1B. Receive the cancellation exception</li> <li>2. Query the status of publisher's workflow and update the fact base</li> <li>3A. Current executing block activity, 'print 10' is internal, so fire the exception handling rules for that request type and adds results into the fact base</li> <li>3B. Current executing block activity, 'paper manufacturer's 9' is external, so request the exception handling to the workflow agent of block activity 'paper manufacturer's 3' and wait for the response</li> </ol>
	<p>paper manufacturer agent</p> <ol style="list-style-type: none"> <li>1B. Receive the cancellation exception</li> <li>2. Query the status of paper manufacturer's workflow and update the fact base</li> <li>3A. Current executing block activity, 'order receiving 3' is internal, so fire the exception handling rules for that request type and adds results into the fact base</li> <li>4. There is no more influenced block activity, so response back the publisher agent that the exception handling can be successful</li> </ol>
	<p>publisher agent</p> <ol style="list-style-type: none"> <li>3A. Current executing block activity, 'print 5' is internal, so fire the exception handling rules for that request type and adds results into the fact base</li> <li>4. There is no more influenced block activity, so response back the bookstore agent that the exception handling can be successful.</li> </ol>
	<p>book store agent</p> <ol style="list-style-type: none"> <li>3A. Current executing block activity, 'order receiving 2' is internal, so fire the exception handling rules for that request type and adds results into the fact base</li> <li>4. There is no more influenced block activity, so response back the user that the exception handling can be successful</li> </ol>

[Figure 7] Coordination process between agents of example inter-organizational workflow

The exception handling of inter-organizational workflow is a practical problem especially in the e-business environment. Each participating company can't have the control over other's autonomous process. Each company only has the right to control its own internal process. So in reality, most of Internet bookstores permit users to cancel their orders only before the process is handed over to other company's control.

For example, assume that customer wants to cancel his/her order when the bookstore already handed over the order for the out-of-stocked books. In this case, the control is on the publisher, so the bookstore can't permit customer's cancellation request. The customer has no option, but returning the delivered package after the delivery. This inflexibility raises the customer's inconvenience and lowers the customer's satisfaction. Of course it brings high returning rate to the bookstore.

Using the multi-agent system as described in section 5, this kind of exception handling can be resolved. If each participating company models its internal policy for exception handling, the exception handling process can be checked by coordination between workflow agents. The coordination process of this example case is summarized in [Figure 7]. This posterior verification for

exception handling is different from the prior verification of other formal inter-organizational workflow modeling. The assumption that the information of all participating companies' processes is fully known before the execution is too strict. The decision according to the exception handling rules is dependent on the situations of the company, so the inter-organizational workflow can be more adaptive. This coordination can defer the deadline for cancellation and it must have a good effect on customer satisfaction and returning rate.

## 7. Conclusions

In this paper, a local viewed inter-organizational workflow model was suggested to achieve adaptive inter-organizational workflow. Especially in e-business environment, this model can play the role of intermediate stage. Each participating company has its own autonomous process. The coordination of this autonomous process is important for the inter-organizational workflow to be adaptive. The suggested model uses the concept of block activity. The inter-organizational workflow is abstracted into internal and external block activities. Internal block activity refers an activity set and also contains related exception

handling rules for that activity set. The external block activity refers the owner of that part of process. This modeling is relative and only reflects its local view point. The exception handling rule is defined using 3 slots; exception handling request, conditions, and results. There are six types of exception requests.

A multi-agent system based on the suggested inter-organizational workflow model is suggested and an example case of inter-organizational process is explained. Each workflow agent interacts with legacy workflow management system for querying the current internal status and communicates with each other workflow agents for normal execution and exception handling of inter-organizational workflow. The book order process example illustrates how the autonomous processes can be coordinated in the multi-agent system and how the adaptiveness is achieved.

Further research issues includes revising the suggest model to compatible with existing workflow models including WfMC's reference model. And experiment of the suggested multi-agent system with some commercial workflow management systems is under way.

## Abstract

This paper deals with new work concepts, especially the so-called alternating telework. A close relationship between the introduction of E-Business and telework is assumed. This type of working can be interpreted as a technology push factor. A research project at the University of Trier (Trier Telework Study) investigated living and working conditions of 277 alternating teleworkers. The findings focus on the following research topics: reasons for participating in telework, working-time arrangements and flexibility, organization of family obligations, ways of balancing work and leisure. Moreover, integration of telework into a traditional office environment (e.g. flow of information, tasks performed) is analyzed too. This includes reflections on the current e-transformation processes. The analysis consider first results of an ongoing research project as well as evidences from further (empirical) studies in the field of E-Business. Consequences, requirements and conditions for implementing electronically supported work arrangements are discussed. It seems important to combine the new situation with the traditional settings and processes in an effective and social way. Furthermore the findings suggest a management of integration.

## 1. E-Business and telework: Definitions, types of telework and penetration

The increasing availability of modern information and communication technologies enables organizations to change their styles of operation, procedures of communication and the ways of cooperation. In this context E-Business concepts are becoming more and more incident. The term is still vague and covers several dimensions (e.g. dot-com companies, e-commerce). Within the scope of our research studies “E-Business” is defined as the sum of all processes in a firm that are supported by information technologies leading to a close integration of business, communication and transaction processes on a company and market level (see figure 1) [15] [11]. According to this frame of reference the organization and coordination of internal business processes is an important module. This includes different forms of electronically based work concepts (e.g. computer supported cooperative work, virtual teams),

particularly several kinds of telework. In this context a close relationship between the introduction of E-Business and telework can be seen. For example, introducing this type of working is a suitable test for virtual structures.

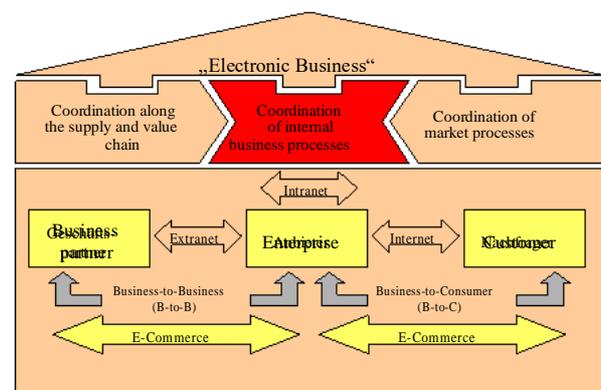

Figure 1 Dimensions of E-Business

Moreover telework can be interpreted as a technology push factor. Attained experiences offer valuable clues to current changes in companies (e.g. leadership, business reorganization). Nevertheless, within the recent years a growing number of people chose their home as a workplace while using modern communication networks to transfer work results. These work arrangements imply partly a shift of gainful employment into the domestic sphere. This ongoing process in working life as well implies that “The Joy of Flex” [3] is no longer a theoretical idea, it’s rather an expectation that is proved more often in practice. According to results of a pan-European survey conducted between March and May 2002 13% of the EU workforce are practicing currently some form of telework [5]. In 1999 this share accounted for 6%. In contrast, about 25% of the U.S. labor force practice some form of telework in 2002. This suggests a considerably lack between the U.S. and the EU. But there are marked differences among the European countries as figure 2 illustrates. A north-south decline can be noticed. Scandinavian countries show leading positions in terms of highest telework diffusion rates. The Netherlands are still an exception. Here, political and public support programs as well as a great openness towards technological and organizational innovations among the population may have positive influence on the spread of

telework. In addition, a sufficient technological infrastructure can be assumed in the leading areas. For example, in 1999 the Swedish government initiated regional growth agreements supporting the network ability within 15 areas (e.g. local/urban area networks) [9].

Telework solutions generally need a technological infrastructure (e.g. internet). This includes as well the use of modern communication technologies like e-mail, corporate databases and/or videoconferencing [7]. The introduction of telework takes (remote) access for granted. In regard to the acceptance of E-Business the use of modern technologies plays an important role too.

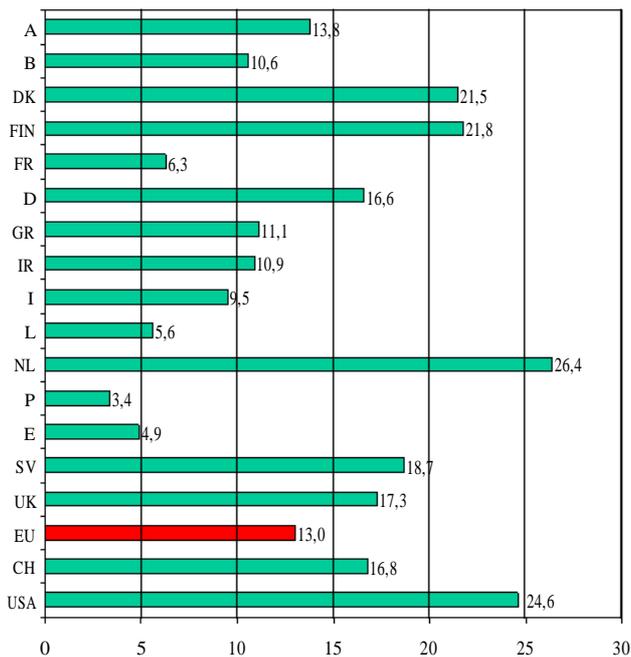

Figure 2 Spread of telework in the EU and the U.S. (in % of labor force 2002)

However, about 17% of the workforce in Germany (=6 million employees) are currently referred to as teleworkers. Figure 3 illustrates the 1999 and 2002 German diffusion rates according to different forms of organization. The results show a fast growing segment of supplementary home-based telework. Majority of occasionally teleworkers is male. However, this mode of working implies a mobilization of ideas off the job as well as employees' need for time flexibility. Obviously, the availability of modern technologies did not replace the traditional office workplace, but more and more employees want to benefit from spending a fraction of the working time at home. In other words: the organization of work in modern societies is still based on a clear distinction between residential and working area.

Alternating telework suggests blurring lines between living and working sphere, additionally organizational and personal challenges (e.g. leadership, culture, time-management) might be limiting factors for this form of work. This can be a reason for less acceptance of models with relative high amount of working days at home.

Currently only about two percent (1,6%) of the German workforce spends at least one full working day per week at home. Since 1999 the number of these teleworkers has not grown much at all (+0,1%). In contrast about 58% of German labor force is interested in alternating telework. With regard to the introduction or extension of telework there are obviously various barriers. Some of them will be discussed in this paper. Nevertheless, home-based working is normally perceived as an unusual change as Maitland (with reference to a report in UK magazine Flexible Working) states: “[...] they began to feel their work identity was being challenged. Some went into the office when not required. Some found it difficult to cope with the blurring of boundaries between work and home. One felt it necessary to recreate his office at home, complete with flip-chart stand, photographs of his colleagues, and a name badge on his study door” [13].

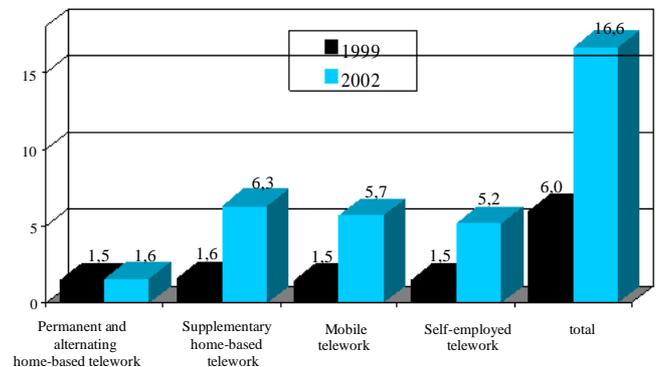

Figure 3 Types of telework and penetration in % of German labor force (1999 and 2002)

## 2. Experiences with E-Business and alternating telework

Our outline of research results considers different variables determining the acceptance of E-Business. Figure 4 presents several dimensions that are discussed below.

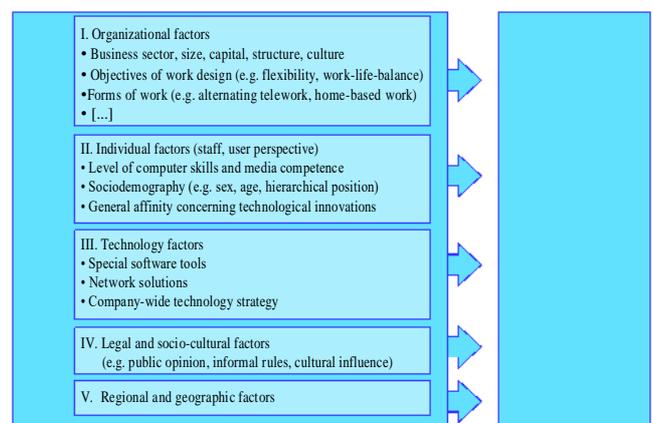

Figure 4 Frame of research

Hence our research concentrates on employees who stay about two full working days a week at home. Furthermore

these teleworkers are in salaried employment (only one employer) and use an online connection to company wide computer networks. Our definition excludes self-employed workers, occasional business travelers as well as mobile field staff (mobile telework). Details on participants of the Trier Telework Study are presented in table 1.

Table 1 Demographic composition (Trier Telework Study)

- sample size: n=277
- sex: women 68 %, men 32 %
- family status: 82 % married
- children: 76 % have at least 1 child at home
- age: 38 years (average)
- level of education: 37 % apprenticeship, 30 % university degree, 21% college of higher education, 9 % technician, 3 % other
- 48% official in charge, 32% expert, 14% staff function, 6% business management
- days per week at home: 3,1 (average)
- hours of work: 48 % full-time workers (approximately 20 hours per week at home), 52 % part-time workers (approximately 15 hours per week at home)
- telework experience: approximately 1 year
- job tenure: approximately 12 years

### 2.1 Setting up a project: Employers' objectives in E-Business and employees' motives for telework

Within the framework of an ongoing research study (so-called SPIRIT-project) we are currently investigating the E-Business introduction processes in 6 German and 3 U.S. American companies. The studies will likely be finished in the year 2004 [4]. First results indicate that market orientated objectives seem to be the most important reasons for implementing projects (e.g. speed-up business processes, customers demand, lower costs, competitiveness). Companies make use of internal project teams or special task forces. In this context "high-level"-champions (e.g. chief executive officers, management board) play an important role. They are responsible for developing a corporate E-Business strategy and the coordination of various projects. This might be a success factor while assigning priorities needs authority. Furthermore employees, business management, ICT-and/or special business units are involved in the implementation process. Interestingly enough customers and suppliers seem to play more and more the role of driving forces. In our study we can observe an integration of "outsiders" in several activities within E-Business projects (e.g. participation in project teams). Networking often is still at the beginning but external forces can exert pressure on internal changes. Speeding-up rather seems to be a mega trend in companies as well as in modern

societies. Changes in market are an important push factor for internal reorganization processes. Electronically based co-operations between companies, customers and suppliers become more and more reality. In this regard it is quite unsurprising that procurement, customer relationship management and supply chain management applications are of top priority in many companies. The adoption of online procurement still varies significantly with establishments' size (e.g. in number of employees) or the turnover [8]. According to results of a study in four European countries and the U.S. (n=2321 companies) conducted in 2001 about the half of German establishments practiced online ordering of goods or similar business transactions (e.g. maintenance, repair and organization goods). Especially small companies (e.g. < 9 employees) have less experiences than bigger ones (e.g. 200-499 employees) (for further details see table 2).

Table 2 Online procurement according to companies' size in 1999 and 2001 (in % of respondents)

		Employees									
		< 9		10-49		50-199		200-499		> 500	
Year	State	'99	'01	'99	'01	'99	'01	'99	'01	'99	'01
	D	14,0	34,6	16,8	48,5	34,4	50,8	37,1	64,0	38,0	55,2
	Fin	26,6	24,9	38,6	52,1	64,4	40,1	55,2	48,4	50,8	58,0
	UK	23,0	26,7	27,5	30,7	38,4	41,6	42,0	47,8	42,6	28,2
	I	6,4	22,5	14,6	19,9	21,9	27,3	22,2	33,7	47,0	34,0
	U.S.	29,3	34,9	22,8	44,0	19,4	47,6	45,6	61,1	41,9	64,7

Results of this study suggest as well a varying intensity of online procurement. In the U.S. 58% of those companies who practice e-procurement at least ordered about 5% of the goods online. In Germany 43% reached this share. More generally, lacks of diffusion and use of modern technologies (e.g. internet, intranet, extranet) occur in the professional context. These phenomena are already known in terms of various "digital divides" (e.g. less well-educated, older people) [12]. In the context of E-Business unused or refused media opportunities might closely be related to these groups. There seem to be further, specific obstacles [1]: doubts of profitability, insufficient customization, lacking applicability of products, deficient usability and/or less acceptance by employees. Often supposed benefits are still not attained (see chapter 3 for further obstacles to corporate E-Business).

However, market as well as customer demands are in the focus of E-Business efforts. This can be proved by the results of a recently conducted study: in 2001 about 81%

of German CIO's (=Chief Information Officer, n=310) pursue the speeding-up of business processes as the most important target of E-Business projects [2]. Besides 63% reported to increase their flexibility (e.g. adaption to market changes). Figure 5 illustrates most important E-Business targets of German companies in 2001. Financial budgets will likely not be reduced in 2002. Quite the contrary might be done: majority of the interviewed companies (56%) stated to expand their investments. This is remarkable while about 30%-50% are current not satisfied with the results of ongoing projects. However, 68% attempt to increase their attraction for employees while restructuring their business processes.

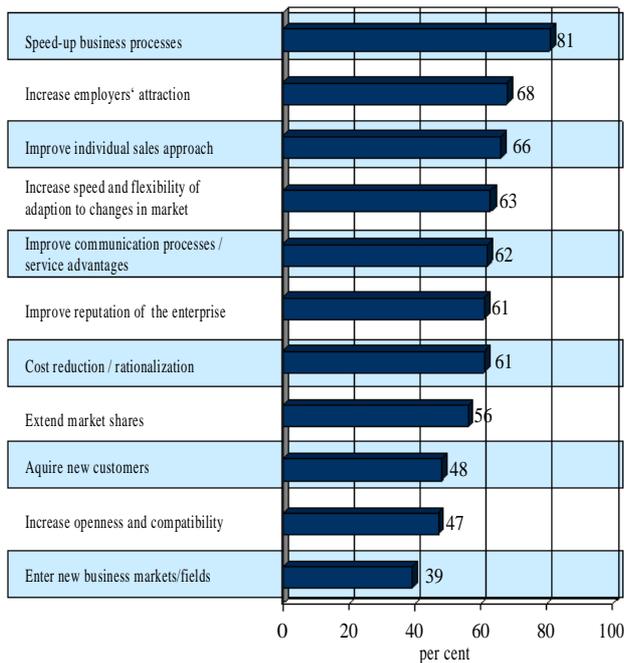

Figure 5 Most important E-Business targets 2001 (in % of respondents, n=310 German Chief Information Officers)

Humanizing the workplace is a factor of increasing importance. Telework can be one step in this direction. Thus company programs are not only introduced on the basis of strategically expectations alone. The Trier Telework Study suggests a wide range of motives. Setting up a telework pilot is often initiated by employees themselves. Demand for telework can trigger a “bottom-up”-process. Figure 6 illustrates motives for engaging in alternating telework for men and women. Decisions can differ significantly between men and women (e.g. parental leave, offer from employer). Considerations may be affected by individual preferences, private circumstances (e.g. children) and/or work-related aspects (e.g. career, coordination). For example, majority of female teleworkers (76%) use telework for balancing private and working life and are between 30 and 39 years old. In these cases parental leave is the main reason for working at home.

Correspondingly, employment switches to part-time. Here, the participation in alternating telework may be characterized as a “career break with time limit” (e.g. taking care of (preschool) children).

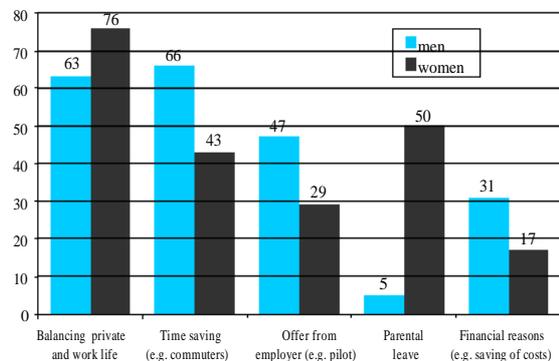

Figure 6 Reasons for telework in % of respondents (Trier Telework Study)

Legal regulations in Germany (until January 2001) did not allow to work more than 19 hours per week during parental leave. However, telework has the quality of a bridge to the labor market. After a certain period of time female employees might give up working at home and return to office-based work. This probably can be a factor for relative low diffusion rates of alternating telework in Germany and the EU in the last three years.

Nevertheless, majority of male workers (66%) chooses alternating telework to avoid commuting. This factor has been an origin in discussion of telework. Nilles together with co-editors Carlson, Gray and Hanneman [14] already examined in 1976 human as well as economic costs and benefits of reduced traveling while using communication links with the employer. Consequently, the dominating term in the U.S. has been “telecommuting”. To avoid commuting problems is still an important reason.

However, our male teleworkers are usually full-time employees and only switch the work location for about two days per week. Executive staff (e.g. employees in managerial position) work usually about 15 hours at home. In contrast, officials in charge stay the longest time outside the office (average: 3 days; 19 hours) (see figure 7). In some of these cases jobs and/or operations are made suitable for home-based working (e.g. less complex work routine). Particularly, younger men and/or male executives could anticipate disadvantages in getting ahead. Working largely outside the office might be perceived as an “out of sight, out of promotion”-situation. Just 30% of male teleworkers is between 30 and 39 years old. Here, professional career is at its beginning. That’s why average age of male workers might be higher than of female teleworkers (men: 43 years vs. women: 36 years). Furthermore demands of work (e.g. tasks performed, consultations) certainly affect time arrangements.

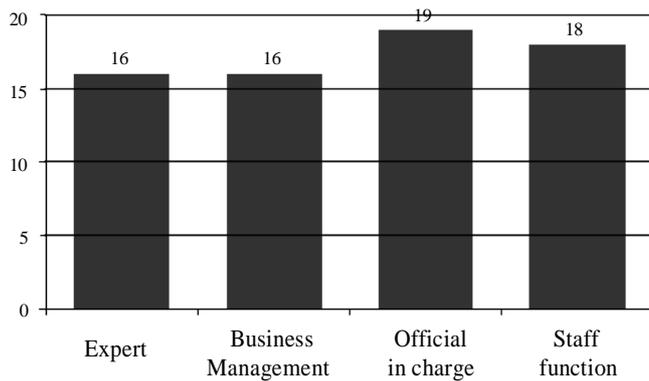

Figure 7 Average hours of work time at home (Trier Telework Study)

For example, it is more difficult to coordinate work with colleagues if tasks entail a high level of communication and a high extent of spontaneous conversation (e.g. involvement in networks). However, private-familiar circumstances (e.g. children, age, attitude to telework) and supposed benefits for work life balance are important factors concerning time-arrangements.

## 2.2 Temporal flexibility, coordination and communication

The benefit of temporal flexibility cannot be granted. Self-organization and self-discipline favor a good work arrangement. Regulations and social factors (e.g. company demands, acceptance) may constrain temporal flexibility. For example, about 25% of the teleworkers have to work core hours at home, nearly 32% are obliged to regard contractual obligations and nearly 41% have to follow defined deadlines (“milestones”). Moreover teleworkers coordinate their activities with office staff and must be attainable at certain times. The necessity and the amount of coordination are influenced by several factors (e.g. position, job characteristics, full-/part-time, organizational skills). However, domestic life has its own rules and rhythms. Non-work and work has to be organized, teleworkers have to integrate different “time schedules” (e.g. kindergarten hours, business hours of spouse, family obligations, child care). The organization of working time varies with the availability of human resources. Especially in cases where children are present this often means working at unusual times (e.g. in the evening, at the weekend). For example, some female respondents work when their partners can look after the children, otherwise the assistance of a (paid) day mother is necessary. Therefore temporal flexibility is a matter of frames and situations. Additionally the telework experience is an important factor. There are significant differences in the working time arrangements between beginners and experienced teleworkers (for further details see figure 8).

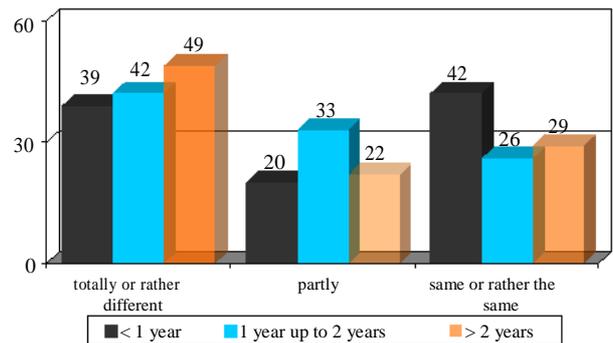

Figure 8 Organization of working time at home (Trier Telework Study)

About the half (49%) of those who already work more than two years from home organize their working time totally or rather different. In contrast the majority (42%) of the beginners (<1 year telework experience) practice traditional labor rhythms. In other words: Teleworkers can profit from learning processes in the way how work is organized. Nonetheless, the majority of our participants report a growing potential of flexibility (e.g. shopping, authority matters). Especially, those who can organize home-based working time totally or rather different (compared to hours of work in the office) seem to gain from the new circumstances (see figure 9).

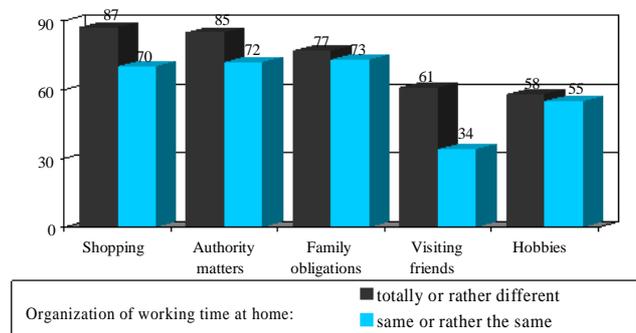

Figure 9 Flexibility of obligations and leisure time (in % of respondents) (Trier Telework Study)

In this context perception of traditional time and leisure arrangements have an impact on how work is organized. Many leisure activities are conducted in groups (e.g. sport club) and still take place in the evening or on the weekend. To work unsocial hours implies an exclusion from social events. In addition, societal landmarks and industrial organisation of labor are constraints of equal importance.

Modern technologies play a key role in the context of new forms of working. Therefore one might state: “To speak of organization is to speak of communication”. There are marked changes in communication patterns while working at home (see figure 10). Electronically supported communication (e.g. telephone) increases significantly, face-to-face meetings, especially informal

conversation with colleagues, decrease. E-Mail use is taken for granted: about 77% of teleworkers report a more frequent use in case of staying at home. In contrast typical opportunities (e.g. lunch, coffee break) occur less because of reduced presence at office. For example, majority of teleworkers (60%) perceive a decrease of informal conversation. Consequently, working outside the central office requires one's own initiative to be informed.

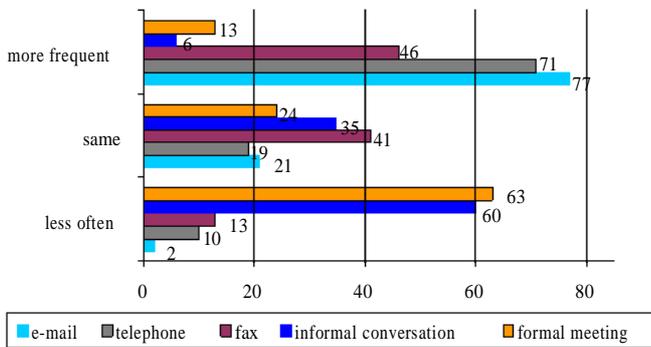

Figure 10 Media use and communication (in % of respondents) (Trier Telework Study)

It is important to keep efficient communication links. Furthermore a lack of media competence or “computer skills” leads to unexpected frustrations.

### 3. Organizational change: Perspectives for E-Business and alternating telework

Alternating telework is still an unusual mode of work. This applies to management, family as well as employees. Furthermore, know-how and new competencies (e.g. computer literacy, time-management, self-discipline) are critical factors (for further details see figure 11). Generally spoken: the acquisition of skills might be an important “bottleneck” within the scope of current organizational changes. New requirements for skills are arising continuously in the course of technological progress. Current problems (e.g. technology refuses (“refuseniks”), skills gap, diffusion lack) may intensify in the future. Therefore staff and management developments as well as further trainings are particularly suitable. To avoid mismatches between offered and demanded qualifications private-public partnerships should be improved (e.g. schools and industry).

Difficulties in managing teleworkers, insufficient knowledge of management and problems in organizing communication are still dominant barriers to the introduction of telework. Management may as well has to learn new skills. Leadership implies electronically based relationship. This includes adaptations of methods for controlling or ensuring a good flow of information. Reduced visibility in case of remote-work environments requires trust. In this context personal relationships as well as technological solutions are applied. For example, in 1999 data security problems ranked top as a

constraining factor for telework. This has been a predominant barrier to telework for about 53% of German decision makers [6]. To ensure IT-security, data security and to raise confidence among users is an important condition in the course of E-Business (e.g. commercial transactions, payments systems) too. Nonetheless, extension of telework is driven by acceptance of the social and work environment (e.g. managerial attitude, employee attitude, family).

Figure 11 Competencies and skills

The implementation of telework arrangements pushes the integration of technologies of interaction (see figure 12).

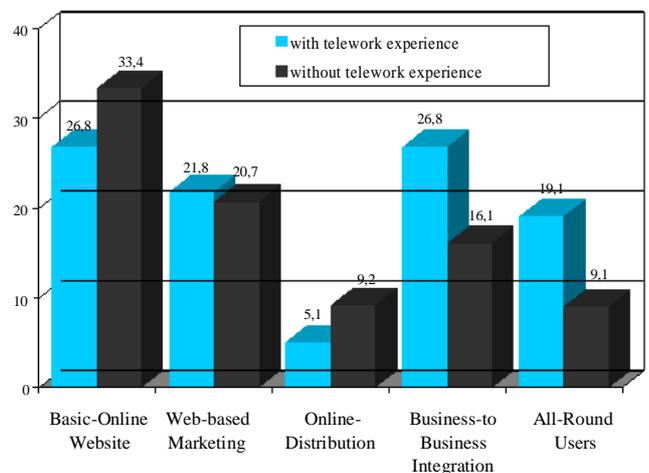

Figure 12 Telework experience and E-Business

For example, 26% of companies with telework experience have integrated Business-to-Business applications. The share for establishments without telework experience is accounted for 16%. This implies experiences with non-territorial offices (e.g. desk-sharing), flexi-time schedules or changes on corporate culture too. However, the speed of organizational transformation is accelerating with the influence of different groups (e.g. management, works council, employees, customers, suppliers) (see figure 13). The

power of driving or restraining forces pushes or slow down the changes. Time can take up the role of a success factor.

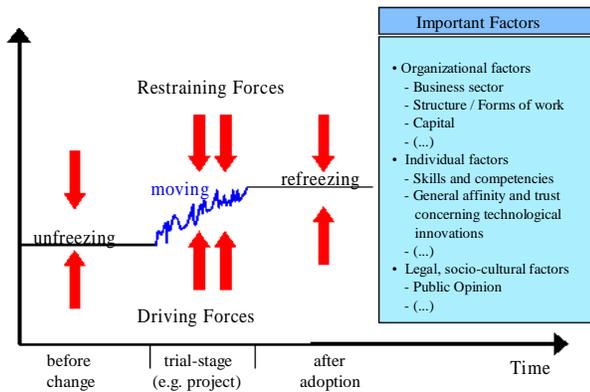

Figure 13 Organizational change

For example, 47% of German CIO mentioned long periods of amortization (e.g. quantitative improvement) as a main barrier to implementation of E-Business [2]. Previous experiences indicate that the majority of companies (about 80%) is still at the beginning in the process of transformation [2]. Germany will probably not pass through an “electronic revolution”. What is more likely to happen is an “evolutionary change” of traditional working practices: “Nothing changes overnight”.

# Foundation for a Successful Web Site

Aren Vartanian

California Polytechnic University, Pomona  
Pomona, CA United States  
vartanian@csupomona.edu

## Abstract

There are many factors that come into play when designing the architecture for a successful web site. The web site must be up and running 99.99% of the time. Redundancy is the key to achieve this.

## 1. Introduction

There are many ways to design the architecture of a web site. The two options are to either host the site using an outside vendor, or purchase the necessary hardware and software to host and maintain the site yourself. A 4-tier architecture is by far the best method of design for hosting your own site. The goal of a 4-tier architecture is to manage each specific function separately while still working together. The client would be the 1<sup>st</sup> tier. The application servers would be the 2<sup>nd</sup> tier. The payment servers would be the 3<sup>rd</sup> tier, followed by the database as the 4<sup>th</sup> tier.

## 2. Hardware

There are a number of key hardware and software that make up the 4-tier architecture. Some of the hardware discussed will include the routers, load balancers, and servers along with a description of the software and providers that operate each of these machines.

### 2.1 Routers

Routers are used to direct traffic to the appropriate machines. By definition they are computers that determine the best way to direct data packets to their specified destination.[1] The dominant supplier of routers today is Cisco Systems (CSCO). Another vendor is Nortel Networks (NT). Price for routers in the market today range from \$10,000 to \$55,000. Cisco routers range slightly higher than it's competitors but they attract a list of loyal consumers who pay the extra time and time again.[2]

### 2.2 Firewall

Firewalls are a key component in guarding the traffic flow in and out of your site. Their key purpose is to prevent unauthorized access into the site. In other words they are a defense mechanism between the network inside the firewall and the network outside of the firewall. They

also track the users accessing the site and keep a record of what they do and where they originate from and report any problems to the system administrator.[3] Cisco Systems, Check Point (CHKP), and NetScreen are some providers of firewalls in the market today. Prices for firewalls range from \$11,000 to \$18,000 with Check Point and Cisco dominating the market.

### 2.3 Load Balancer

Load balancers are either hardware, for large websites, or software that are used to direct traffic to servers that can respond and return the content to the user quickly.[4] By balancing the workload of the servers, the overall performance of the website is improved. Cisco Systems, F5 Networks (FFIV), and Nortel Networks are some major providers of load balancers. The price ranges of load balancers are from \$4,500 to \$30,000 and F5 Networks leads the market with new features.

### 2.4 Web Server

Web servers are dedicated computers that contain information, clients can access. They contain all the files needed to make up the webpage. The software required to operate the web server is usually free of charge bundled with the purchase of an application server. The most common vendors are Apache, Microsoft (MSFT), and Sun Microsystems (SUNW).[2]

### 2.5 Application Server

The application server runs on its own hardware and acts as the brains behind the application. It is a machine that services requests of other hardware and software on the network to satisfy a client's request. Some common vendors are BEA Systems (BEA), Borland (BORL), and IBM (IBM) with price ranges from \$8,000 to \$35,000 per CPU.[2]

### 2.6 Payment Server

The payment server processes all the credit card payment transactions that a user submits. In most cases it is best to outsource payment transactions to outside vendors. An example of a payment processing company is iAuthorizer and Authorize.Net. This company for example provides order forms, shopping carts, CGI scripts,

and transaction processing. They use a protocol called SET (Secure Electronic Transaction), which provides security for credit card payments.[1]

### 2.7 Database Server

A database server can be used to store text, graphics, sound, personal information about customers, and track inventory as well as various other tasks. Their key purpose is to store structured information, become self-describing, support transactions, and permit rapid information retrieval. Key players in database management are IBM, Microsoft, and Oracle with price ranges from \$11,000 to \$40,000 per CPU. [2][5]

### 3. Design Layout

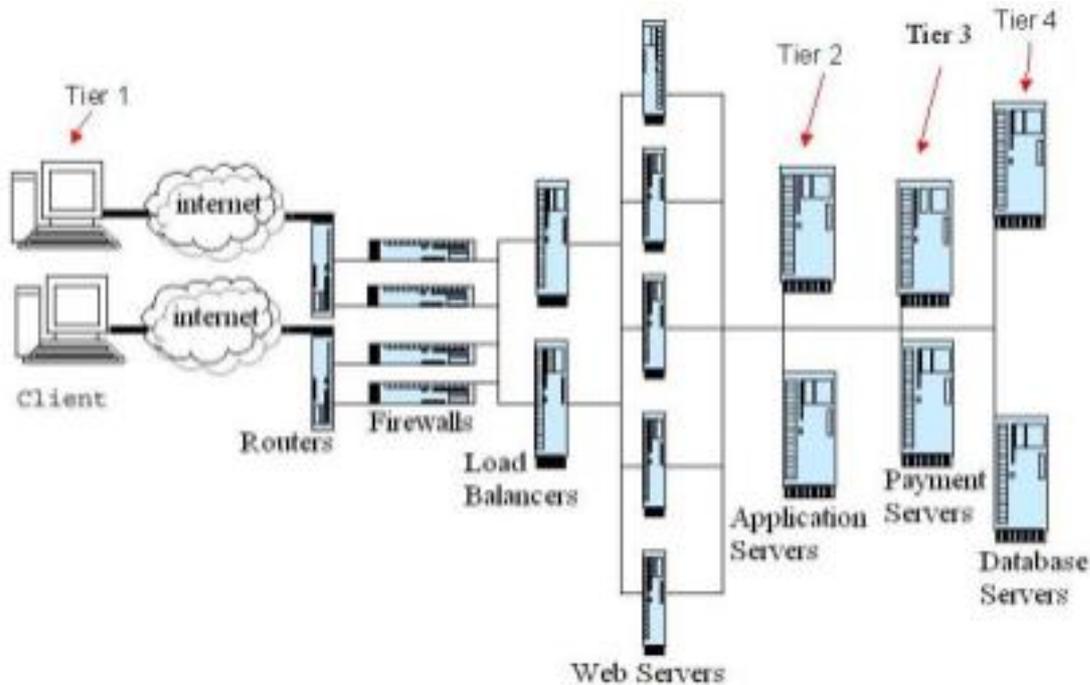

The important part of all this is how everything is connected together. As I mentioned before redundancy is the key to the success of the website. In some cases it might be justified to spend the extra money and have backup machines in the case that one fails to operate correctly. If at any time a router, firewall, or server fails to operate correctly, the entire site and business will shut down until that machine is fixed. If there is a backup then business will continue operating while the first machine becomes operational.

Using two Internet connections from different ISP's will also enhance the flow of traffic into the site. Again if one network line goes down, clients can continue to access the site through the second connection.[6]

The combinations of these hardware, software, and layout will produce a foundation for a successful web site. This architecture design combined with a good business plan and the right resources becomes the start of the next successful business.

# Missions for Executives in Developing an E-Management Platform

Yen Zen Wang \*, Sheng Chung Chen \*\*

clkchen@cc.fec.edu.tw

## Abstract

Under the impact of internet, many promises of e-management are provided. However, so far, executives are still skeptical in developing e-management platform, the anxieties come from the fact that too many IT developing projects failed. In practice, IT is a specialty which is quite heterogeneous to business management, to achieve e-management makes the issue of integration of these two domains can not be neglected any more.

A failed project is by no means the duty of IT team only; it would be the reason that the interaction between IT team and executives is too weak. To reduce the gaps in platform developing, executives have some missions are offered, they are: a. Let IT group understand executives' business affairs; b. Review architecture of platform; c. Involve to system test. It deserves to assert that, in developing an e-management platform, executives are not just the users, but also a part of developing members.

## 1. Introduction

Under the impact of internet, prefixing "e-" to nouns has become a token of this era, for example, e-business, e-commerce, e-learning, e-management ... and what you like. However, rigorously surveying, "e-something" is not just a slogan, it still indicates that two different specialties – IT and the field after "e-" should be integrated seamlessly. For example, e-management implies that executives can make decisions in aid of a platform which is built by IT, however, whether this platform can be satisfied by executives is always skeptical, since IT is a specialty which is quite heterogeneous to business management. In other words, promises of this platform would not be fulfilled thoroughly once there are some gaps between these two specialties. Unfortunately, too many failed projects reveal that gaps are almost inevitable. This anxiety just likes a black cloud on internet sky, how to diminish or even ruin such gaps is the incentive of this paper.

No doubt, many executives are skeptical. They've heard outsized promises, and they've spent a lot of time and money on information system developing, but the gain is poor [1]. It would be believed that the critical causes of failure of system come from software architecture. Though, software and hardware are two main components in an information system, however, the

problems of hardware are much fewer in comparison with software. In software developing, one of important keys to success is team work [2]. The members of the team are not just software developers, but also executives. A successful project developing, both program developers and executives should communicate and cooperate with each other seamlessly.

In this paper, e-management is the subject to be studied. The causes why gaps between IT and management existed will be discussed, and then solutions to avoid such gaps happened are tried to offer.

## 2. Causes of Failure

A project of an e-management platform developing, in essence, is a project of software systems developing, therefore, the reasons why software products failed in marketing are more or less accommodated to this research. It is well known that software developers' and executives' disdain for rigid procedures lead to failure, in most of projects, instead of conflicts happened, executives always choose to keep away from software team in period of system developing, and make themselves just as users of the e-management platform.

During developing an e-management platform, usually, the time executives involved compared to the one whole system built is very short. Project always commences in necessities collected, in most cases, executives list all necessities to IT team, then they never involved the developing process until system finished. After the system on line, instead of being praised, IT group always receives endless criticisms. Under such weak interaction between IT team and executives, it is difficult to make these two parts cooperate coincidentally.

It is unfair for IT group to bear the burden of proof; a failed information system is by no means the duty of IT team only. To make project success, the causes of failure should be tried to remove. To sum up, the solution to enhance the interaction between IT group and executives should be revealed. If executives could be more aggressive to involve the project developing, the gaps between IT and executives would be reduced significantly. Therefore, in order to make e-management platform being developed successfully, missions for executives should be specified clearly, and this is the main purpose of this paper.

### 3. Missions For Executives

Usually, IT developers are apt to communicate with machines well. In order to improve the relation to engineers, it would better for executives to be active to discuss with IT team. In other words, there are some missions for executives in developing e-management, they are offered as follows:

a. Let IT group understand executives' business affairs: It is not enough for IT team to construct the platform for executives if only a function list is given. It is necessary for executives to hold a meeting for IT group before project is begun, let IT group know how business run day by day, and what kind of data is important in making decision. Such communication can not be neglected absolutely, or the direction of project will deviate from executives' visions unconsciously.

b. Review architecture of e-management platform: Before programming, architecture of platform should be designed completely, the elements should be reviewed by executives are: user interfaces, data flow and functions. However, almost executives have no IT background, the architecture should be presented by a visual model which can be communicated without any impediment, UML (Unified Modeling Language)[3] would be a very convenient tool in presenting software architecture. Executives have not to hesitate to challenge the architecture, it is very critical, a right architecture is half the success of a project.

c. Involve to system test: System test is a routine step before functions finished, but bias will be inevitable if this step only done by IT group, once something insufficient or inexact found too late, unexpected cost will happen possibly. Executives involve to test system, not only bias

can be reduced, but also schedule of project can be checked.

The gaps between IT team and executives would be diminished, if above obligations could be carried out.

### 4. Conclusions

Most of time, there are no any overlap between IT group and executives in business, but the impact of e-management creates breakthroughs in these two domains. To develop an e-management platform successfully, the interaction and communication between executives and IT group should be very frequent. To improve the interaction between IT and executives, three missions for executives are offered as: a. Let IT group understand executives' business affairs; b. Review architecture of e-management platform; c. Involve to system test. To specify the missions for executives is to assert that executives are also a part of developing members; they are not just the users of system only.

# Global Geo-Demographic Data and GIS for E-Business

Mark R. Leipnik, Sanjay S. Mehta & Rose Seidel  
Department of Geography & Department of Marketing  
Sam Houston State University  
Huntsville, Texas  
geo\_mrl@shsu.edu

## Abstract

The results of a comprehensive survey of the availability and characteristics of digital geo-demographic data in 40 countries around the world are presented.

Geographic information systems (GIS) often used in conjunction with the Internet are being used by technologically savvy companies to perform marketing studies and provide location specific data such as maps to clients and customers. However, the national level Availability and characteristics of the required digital geo-spatial data vary considerably from nation to nation. Every country's data differs in terms of existence, cost, accuracy, precision, format, content, and availability over the Internet. Some countries (such as Switzerland and the United Kingdom) have current data on every hectare and house along with demographics for every group of 100 residents available for interactive web-based mapping and analysis. Other nations have such data in only non-digital forms and then only internally. Most nations are intermediate in terms of the use of characteristics and availability of geospatial data relevant for E-business.

Presented here are the results, especially those pertaining to E-business, of an e-mail survey of the national census and national mapping authorities of 40 selected countries. These the G7, Russia, China (PRC, Taiwan and Hong Kong), India, Australia, many European countries, along with 4 other Asian, 4 Latin American, 2 Middle Eastern and 2 African nations. Also presented is statistical analysis of the responses and information from follow-up questions.

## 1. Background

A survey of the National Census authorities and National Cartographic Authorities of 40 developed and developing countries was conducted starting in January 2002. The purpose of the survey was to gauge the character and availability of geodemographic data and infrastructure data (principally streets and building locations and footprints) in a GIS format for use in marketing, location studies and similar applications. The surveys consisted of 23 and 24 questions respectively questions initially emailed to the national census authority and national mapping, cartographic cadastral or land planning authority of the country the authorities were

identified using a web page maintained by the U.S. Census Bureau and a web page maintained by the U.S. Geological Survey and containing contact information for 120 census bureaus and mapping authorities. Follow-up by email, fax and in several cases phone call elicited further information. As of Mid June 2002, 19 of the 40 countries had responded, to one or the other survey instrument or replied to the email with the results presented and analyzed below.

## 2. Choice of Countries

The criteria for selection of the countries were primarily the likelihood based on prior knowledge or development level that GIS. Thus the USA, Canada, Australia, Great New Zealand, Britain, the Netherlands, Sweden, Finland, Switzerland, Singapore were selected. Also economic importance in the global economy was a factor thus Japan, France, Italy, Spain, Germany, India, Russia, China were selected although the level of technological development was significant for most of these countries as well. In an attempt to get a good geographic distribution of countries, Israel (middle east), South Africa (Africa) Chile, Argentina, Brazil, and Mexico (Latin America), Eastern Europe (Czech Republic, Poland, Hungary) Asia (Taiwan, South Korea) were selected. Australia and New Zealand also helped to represent every populated continent. Review of web sites led to the inclusion of Malaysia and Egypt to the list. In addition Belgium, Luxembourg, Denmark, Austria, Ireland and Portugal. The decision to only survey 40 countries was arbitrary and exclusion of such countries as Greece is probably more of an oversight than a deliberated decision. Exclusion of Sierra Leone (last on the U.N. Development Index) and a host of "fourth world" countries reflects the low likelihood that these nations use GIS in their census or mapping activities.

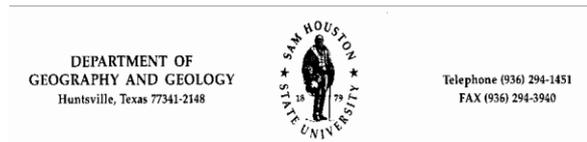

## 3. Contacting the Respondents

Most census bureaus had web sites which were visited. Most national mapping authorities likewise had web sites. Using either contact information on the web or information obtained via enquiries to the sites web master emails were sent to representatives of each authority. As of June 2002, 19 of the forty census authorities had responded. Also responses from 12 Mapping authorities were obtained. Follow up faxes were sent to the

authorities. This elicited several additional responses. In addition to those countries that responded by completing and returning the survey three countries responded but did not complete the survey. The Czech Republic stated they would respond but did not, the French stated (in French) they would only respond to a survey in French and the Mexicans indicated in Spanish that they had information on a web site about their use of GIS. Singapore responded to the email by stating they do not use GIS in their census activities and to the fax by faxing back a polite refusal to respond to the questionnaire. The countries that responded before June 2002 included. Australia, Belgium, Brazil, Canada, Finland, Hong Kong, Iceland, Israel, Italy, Germany, New Zealand, Norway, Singapore, South Africa, Sweden, Switzerland, Taiwan, the USA and the United Kingdom. Japan, Denmark, Holland and Portugal were all contacted indirectly and their use of GIS was determined, but no official response was made prior to mid-June 2002. Thus 19 countries responded completely, three additional countries responded by stating they would reply soon, but did not follow through nor respond to faxed enquiries. Thus an initial 50 % response rate was achieved. A Spanish, French and Chinese language version of the survey was prepared but no responses to these versions of the survey dispatch in May of 2002 were received prior to the preparation of this paper.

The surveys of mapping authorities involved more difficulties than the survey of Census authorities. This is largely because although all developed nations use GIS for national mapping, the mapping function resides in many agencies with many names in different countries. Thus in England one has an Ordnance Survey in the U.S. one has a Geologic Survey with a cartographic division, in Canada mapping is in the department of natural resources, in Norway a national Cartverk (Cartographic Workshop), in Switzerland a National Cadastral agency, in Holland a spatial planning agency, in Portugal a National GIS, in Spain an Institute for Geography, in Japan a national geographic Survey, etc, etc. In Chile and Italy mapping is a function of the military but in Chile it is an institute of military geography while in Italy the navy maps the coastal areas, the army the interior and the air force aerial navigation charts are a responsibility. Therefore just identifying which agency has responsibility. In fact they can be overlapping responsibilities. Thus the topographic maps in Germany are prepared by one agency at the national level while the cadastral maps are state by state as is aerial photography and land-use mapping. Since in all the agencies GIS is widely used figuring out exactly who to have responded has been a problem. Nevertheless as of mid-June 2002, 12 agencies have responded.

A sample of the cover letter is presented in figure I below.

*Dear National Census Authority representative...the following are instructions for completion and return of the accompanying survey of GIS use in your organization.*

**INSTRUCTIONS:**

This is a survey of GIS use in Census Authorities around the world. Agencies in your country and in 39 other advanced countries are being contacted. The following page contains a survey of geographic information system (GIS) use in developing products such as maps used by your agency. It is being used to gather information that potential customers and other users of your agencies data would appreciate having. The results of this survey will be presented at the world's foremost international GIS conference. They will not be used for commercial purposes. Please answer every question to the best of your ability. Place a check mark in the appropriate box for the (YES X, NO\_\_\_) format questions. If you are unsure about the nature of the question or need clarification about what is an appropriate response, do not hesitate to contact me. Your personal information name phone number etc. will not be divulged and are request solely so I can contact you to clarify any questions I have about your response to this survey. Please respond within one month of receiving this instrument. I will make an effort to follow up with the recipient of each and every survey instrument sent out within two weeks of the time this survey is dispatched.

- ◆Can you provide examples of Businesses, consulting firms or research institutes in your country using GIS? If so please send that information to Dr. Leipnik at the address below.
  - ◆Can you provide a sample of the GIS products your agency generates? If you can provide samples of such data please send them via airmail or email to Dr. Leipnik at the address below.
  - ◆Can you provide publications or references to publications describing your available cartographic products (maps and/or GIS data)? If so please send the title of such publications and information on how it can be obtained to me at the address below.
- You have my special thanks for participating in this survey, which will help users of GIS around the world!

Sincerely

Dr. Mark R. Leipnik, Associate Professor.  
Department of Geography & Geology,  
Sam Houston State University  
P.O. Box 2148.  
Huntsville, Texas 77341.

(that is geo underscore mrl)

#### 4. Questions on the Census Survey

The questions on the survey include queries intended to obtain contact information (items 1 and 2). A question about how often the national census is conducted (item # 3) which is designed to gauge the currency of data. A question about the smallest geographic units data is collected for (#4) which is designed to gauge the spatial precession of data. A question about privacy restrictions (#5) designed to determine to what extent individual responses are masked by aggregation. A question (#6) about use of postal addressing systems to track respondents which gives insights into integration of census enumeration with postal addressing something useful to marketers who have address lists of customers. A question (#7) about collection of income data and at what level of geographic subdivision this data is collected. This question provides perhaps the most important demographic information to marketers besides the actual presence of respondents. A question (#8) about occupational employment and at what geographic subdivision this data is collected which is useful to marketers and is not asked by all censuses of population. A question (#9) about educational attainment. This is a key determinant of future income and development and thus of great interest to marketers. A question (#10) about residential living arrangements and at what level this data is collected and aggregated. This is a key determinant of wealth and demand for a wide range of consumer products. A question (#11) about business location and activity this is an item frequently missing from census of population but is of great interest to companies doing location studies since it helps identify competitor's locations. A question (#12) about the level of interest expressed in obtaining census data for use in geodemographic studies. This question gauges the level of use of this data in geodemographic marketing and location studies. If little use is being made of the data a low number on a scale of 1 to 10 would be reported. A question (#13) about whether the agency uses GIS, this is a key question since if GIS is not used then by the agency then GIS data sets for the country will require a major effort by outside parties to develop. If the answer to this question is no then the respondents skip to number 23, a question (#14) about the number of years the agency has used GIS. A question (#15) on how useful on a scale of 1-10 GOS has been for the agency. A question (#16) about what features are portrayed on the base maps used in the GIS. This is designed to determine if building footprints are present, if only enumeration district boundaries are present, if roads are present etc. This is key to many other uses of the data. Question (#17) concerns the public availability of GIS data related to census activities. Since GIS may be used in an organization but the data may not be publicly available. Question (#18) concerns how long data has been publicly available. Question (#19) concerns what language the data is available in. Question #20 concerns the cost of the data. The question specified cost for nationwide coverage but most agencies specified cost for a smaller area. Question

#21 concerned available over the internet and the URL of the website where the data resided. Question #22 concerned use of GPS technology by the agency. This was to see if the base maps are being built by this approach. Question #23 concerned plans for future use of GIS at the agency as was relevant for those not yet using the technology.

*A sample of the survey instrument is reproduced in figure II below.*

#### Survey of GIS use and availability of national demographic data for inclusion in a GIS.

1) Country Name: \_\_\_\_\_

Date: \_\_\_\_\_

2) Official Title of Agency: \_\_\_\_\_

\_\_\_\_\_

Mailing Address

\_\_\_\_\_

Name and Title of person completing survey:

\_\_\_\_\_

Email: \_\_\_\_\_

Phone: \_\_\_\_\_

Fax: \_\_\_\_\_

3) At what time interval is a national census of population conducted? \_\_\_\_\_.

4) What is the smallest geographic subdivision for which data is collected? \_\_\_\_\_.

5) What privacy restrictions exist? \_\_\_\_\_.

6) Is census information collected using a postal addressing system to track respondents locations? **YES** \_\_\_ **NO** \_\_\_.

7) Is income data available for individuals in your country? **YES** \_\_\_ **NO** \_\_\_. At what level of geographic subdivision is the data available? \_\_\_\_\_.

8) Is employment data available? **YES** \_\_\_ **NO** \_\_\_. At what level of geographic subdivision is the data available? \_\_\_\_\_.

9) Is educational attainment data available? **YES** \_\_\_ **NO** \_\_\_. At what level of geographic subdivision is the data available? \_\_\_\_\_.

10) Is residential living information data available? **YES** \_\_\_ **NO** \_\_\_. At what level of geographic subdivision is the data available? \_\_\_\_\_.

11) Is business location and characteristics data available? **YES** \_\_\_ **NO** \_\_\_. At what level of geographic subdivision is the data available? \_\_\_\_\_.

12) On a **scale of 1-10** where **1** represents “**no interest**”, **5** represents “**moderate interest**”, and **10** represents “**very active interest**”, how much interest has been expressed by businesses in your country for using and obtaining geo-demographic data? \_\_\_\_\_.

- 13) Does your agency use GIS?  
**YES** \_\_\_ **NO** \_\_\_. (If **NO**... go to # 23).
- 14) For how many years has your agency employed GIS in the census process? \_\_\_\_\_ **Years**.
- 15) On a scale of 1-10; where 1 represents “counter-productive”, 5 represents “moderately useful” and 10 represents “extremely useful”. How useful has GIS been in the process of enumerating and characterizing the population of your country?  
 \_\_\_\_\_.
- 16) What features (streets, building locations, etc) are present on the base-map you also use to portray census results on? \_\_\_\_\_.
- 17) Is the census data publicly available in a GIS?  
**YES** \_\_\_ **NO** \_\_\_. (If **NO**... go to # 22).
- 18) For how many years has census data in a GIS format been public ally available? \_\_\_\_\_.
- 19) What language(s) are the data available in?  
 \_\_\_\_\_.
- 20) What is the cost (in local currency) of nationwide GIS format census data? \_\_\_\_\_.
- 21) Is the data available over the Internet?  
**YES** \_\_\_ **NO** \_\_\_, **URL**: \_\_\_\_\_.
- 22) Does your agency use global positioning systems for systematic mapping?  
**YES** \_\_\_ **NO** \_\_\_.  
 23) Does your agency plan to use GIS in the future?  
**YES** \_\_\_ **NO** \_\_\_. At what date? \_\_\_\_\_.

Thank you for your assistance... You may return this survey via fax to (01) 936-294-3940, via email to [geo\\_mrl@shsu.edu](mailto:geo_mrl@shsu.edu) that is geo “underscore” mrl @ shsu.edu or by mail to Dr. Mark Leipnik, Department of Geography SHSU, P.O. Box 2148, Huntsville, Texas 77341.

## 5. Questions on the Survey of Mapping Authorities

The initial three questions on each survey were contact information related questions and were the same as on the census survey. Question #4 related to the scale of topographic maps and was designed to determine the precision of available data for inclusion in a GIS. #5 concerned the features portrayed. If buildings are portrayed this is significant for business applications. Question #6 regarded the intervals that maps are prepared. In the U.S. for example remapping in non-systematic with the average age of topographic maps being 28 years and the oldest map that is still the official “current” topographic being 67 years old. Question #7 dealt with the system of geographic subdivision in use. Question #8 regarded tracking residences, it is important since to geo-code customer information one needs this data or street address ranges. Question #9 concerns if business locations are mapped. Question #10 regards a postal addressing system. Question #11 asks if GIS is used.

Question #12 asks for how many years has it been in use. Question #13 asked how useful the system is internally. Question # 14 regards tracking street addresses. Without such street address ranges or building footprints geo-coding customer locations can only be done to a region. Question #15 regards the public availability of GIS data. Question number #16 formats the GIS data is available in. Question # 17 involves the cost of the national level data. Question #18 regards the languages the data is available in. Question #19 involves availability of data on the Internet. Question #20 involves level of interest expressed by external users in obtaining data on a scale of 1-10. Question number 21 involves use of remotely sensed imagery, question #22 involves use of digital aerial photography. Question #22 involves availability of this digital aerial photography data. Question # 24 involves future likelihood of using GIS.

## 6. Follow-up Questions

For all agencies responding to the survey a follow up message was sent in every case where GIS was used it enquired as to what GIS software was being employed. Also various clarifications were sought. For example if the agency such as New Zealand indicated that the smallest geographic subdivision that data was available for was a “meshblock” but did not define what this constituted a request to clarify what this was made. Also those agencies not responding to the initial email were emailed again within two weeks, and then a fax was sent to all non-responding countries. Another approach was then adopted for non-respondents with emails sent to GIS specialists in academic institutions in each country. Thus Japan, Denmark, Holland, Austria and Portugal were contacted. The Universities were University of Tokyo, Copenhagen University, University of Utrecht, Technical University of Vienna and New University of Lisbon. This produced some useful information. Specifically that GIS was not in use by the Dutch who had their last census in 1971 and use registers and for Japan were GIS is in use in the national census but at the very beginning stages and application.

With respect to choice of software ESRI products were used by all respondents with the exception of the Australian census authority which uses Map/Info products primarily.

## 7. Response Rate

The response rate and the time it took to respond were a very useful if indirect measure of the efficiency of the organizations and their responsiveness at least to queries made in English. The most rapid response was from Norway which Responded within 1 day. Singapore and Sweden also responded within 2 days and Germany responded within 1 week. Many countries failed to

respond within 1 month and a follow up email was sent, after two months a follow up fax was dispatched. The table below shows the response status as of mid June 2002. As an objective measure of the development level of the country the UN development program human development index rank is also displayed. The table lists responders in order of response.

**Table 1.**

Norway	Yes 4/16	Yes	2	1	1
New Zealand	Yes 4/16	Yes	2	1	19
Sweden	Yes 4/17	Yes	3	2	4
Australia	Yes 4/22	Yes	8	3	2
Germany	Yes 4/25	No	11	4	17
Switzerland	Yes 4/30	Yes	15	5	11
U.K.	Yes 1/5	Yes	16	6	14
Spain	Yes 5/8	Yes	19	7	21
South Africa	Yes 5/15	Yes	31	8	94
Hong Kong	Yes 5/19	Yes	35	9	24
Israel	Yes 5/20	Yes	36	10	22
Taiwan	Yes 5/21	Yes	37	11	Not rated
USA	Yes 5/22	Yes	38	12	6
Italy	Yes 5/27	Yes	43	13	20
Belgium	Yes 5/27	Yes	43	13	5
Finland	Yes 5/28	Yes	44	14	10
Brazil	Yes 5/30	Yes	46	15	69
Singapore	Yes 5/30	No	46	15	26
Iceland	Yes 5/31	No	47	16	7
Canada	Yes 6/5	Yes	52	17	3
France	4/30	?			13
	French				
Czech Rep.	receipt 5/2	?			33
Mexico	5/10	Yes			51
	Spanish				
Netherlands	Academic	No			8
	Response				
Japan	Academic	Yes			9
	Response				
Luxembourg	No	?			12
Denmark	Academic	yes			15
Austria	No	?			16
Korea	No	No			27
Portugal	Academic	Yes			28
	Res				
Argentina	No	?			34
Hungary	No	?			36
Poland	No	?			38
Chile	No	?			39
Russian	No	?			55
Federation					
Malaysia	No	?			56

China	No	?	87
Egypt	No	?	105
India	No	No	115

The table indicates some relationship between response time and United Nations Development Index rank although there are outliers like Canada. In all fairness, Canada responded within 10 days with a question about how many respondents were required and the system eventually produced a very thorough response. France also responded promptly, but indicated only a questionnaire in French would be acknowledged, A French translation was prepared and sent a month later but no response was received as of mid June 2002. It is also clear that except for the Germans which do not use GIS in their census efforts that those countries not using GIS are more likely not to respond or respond later. The usually efficient Dutch did not respond contact with the leading GIS center in Holland (University of Utrecht) elicited the information that the Dutch do not use GIS in the census efforts and last conducted a census in 1971. They have however accurate postal code GIS. Also those countries low on UNDI are less likely to use GIS. Non-responses from Denmark, Japan and Portugal were also surprising. Follow up with academic institutions in these countries resulted in forwarding of the survey to GIS experts in census authorities and the information that GIS is used in census efforts in all three countries, the completed surveys were not available by mid-June however.

## 8. Salient Points

### 8.1 Census Authority Survey

Several salient points can be learned from study of the responses to the questions. One is that GIS use is becoming common place among census authorities in developed countries. Another is that a few countries that have systems of registers and require registration when citizens move from one locality to another have not adopted GIS in site of technological advanced status. These nations include Singapore, Germany, Holland and Iceland. In the case of Iceland most of the population is concentrated in one City.

With respect to the census frequency, most countries have copied the U.S. method set down in the constitution of a decennial census. However, Finland conducts a census every year while New Zealand uses 5 year intervals and Sweden uses 5 years and 15 year intervals. Holland last conducted a census in 1971 and Germany last conducted a census in 1983.

As to the collection of various types of data most countries collect educational attainment and residential living data, fewer collect income data and very few collect information about business establishments. Finland asks

the most complete set of questions.

As to the geographic subdivisions that data is collected for, most countries have something equivalent to census tracts and blocks used in the U.S. typically 100 people approximately reside in these enumeration areas the use municipalities while several countries have data for individual residences such as Switzerland, Finland, Norway, U.K. and Sweden. Few countries have postal addressing links, England and Holland being exceptions.

Privacy is protected by all countries to some extent, some like aggregating the data to municipalities, mostly aggregating it to groups of 100 or more (so % data cannot be ascribed to a single individual) a few such as Sweden have 5 or more respondents. Duration of use of GIS varies greatly from a high 27 for Sweden, 25 years for the U.S. and 15 years for Canada to only 2 years for Brazil and in the developmental stages in Taiwan and Japan..

Most countries found GIS very useful and most had had significant interest in use of GIS expressed. The mode for utility was a 10, while the mode for interest was a 9.

All countries that responded released data publicly in some form, some on CD, some over the Internet. Many will sell digital data commercially.

The languages the data was available in varied. In France it is exclusively in French, In the Latin American Countries it is exclusively Spanish, except for Brazil which has data in Portuguese and English. Data in English is also available in Norway, and Germany. And Canada (French also for Canada).

Use of the Internet to disperse data was less common with the U.S., New Zealand, and Norway being leaders. Most agencies preferred to sell data with costs ranging from a low for the U.S. of approximately \$300. Switzerland was notable in setting a rate of .0002 Swiss franc per hectare a unique approach made possible by the use of a 50 meter grid as to track data. The U.K. estimated that it's nationwide GIS (including both census and topography) would be sold for a modest 40 million pounds!

GPS use was very rare with only Brazil and Australia really using GPS in census activities, probably because of their sprawling size.

## 9. Mapping Authority Survey Responses

Scales of Maps prepared ranged from Switzerland which had GIS data for a 50 meter grid to Australia which only had data at scales of 1:100,000. The U.S. uses a scale of 1:24,000 while England uses a 1:500 scale.

Typical features portrayed on the topographic maps include political boundaries, Roads and rail lines,

hydrographic, counters. Some maps portray land-use such as U.S. and German, some portray building footprints such as German, U.K. and Swiss. Some have unique features portrayed such as the fence lines on Australian maps or the individual fruit trees on Swiss maps.

Maps were updated every 1-5 years in the United Kingdom, every 5 years in New Zealand every 5-20 years in Australia and on average every 28 years in the USA.

Some countries mapped residences such as Great Britain, Norway, Germany and Switzerland

Few countries mapped business locations specifically only Britain and Switzerland.

Most countries had a national system of postal addressing in Spain, Germany, Holland, and Great Britain that system is in the GIS, It is not in a GIS in the USA.

Most countries contacted used GIS with the possible exceptions of Egypt and India (non-respondents who are largely relying on colonial era mapping).

The number of years that GIS was in use varied from more than 30 in the USA and Canada to 30 in the U.K. to 18 in Spain to 15 in Germany.

Cost of the data ranged from \$1,500 for New Zealand to 40 million pounds for the U.K.

The USA, Canada and Switzerland were among the few countries with GIS data available over the Internet.

Use of remotely Sensed imagery was common although less common than use of aerial photography. However most nations did not have available digital aerial photography, Switzerland and Germany were exceptions however.

## 10. Respondent information

Information used to contact the National Census Authorities is summarized below.

## 11. Conclusions

GIS use is becoming widespread in the Census authorities of the World. It is even more common in the national mapping authorities, although the specific organization responsible for national mapping varies. The countries surveyed as to use of the technology by the census authority can be divided into those which are integrating geodemographic data into national multi-purpose cadastres these include the Swiss, Swedes, Norwegians and British, Those that follow the U.S. model of a separate census based GIS with street centerlines and census enumeration districts but not features like building foot-prints or actual residential locations geo-coded these include Canada, Australia, New Zealand, Israel, Belgium, Finland, Brazil. Then there are the countries with detailed registers of population that enable them to track their residents on an essentially continuous basis and where maps are not in use these include Germany and Holland and Singapore. Lastly there are countries that are not at the level of technological sophistication to use GIS in governmental activities like census taking. Since most countries surveyed were in the top 20% of nations in terms of development this was not a common problem however

for Egypt, India and China it is.6.Also this may explain lack of response from eastern Europe and Russia and Latin America except for Brazil. Missing data from France and Latin America reflect communication difficulties or national chauvinism and possibly developmental lags in Mexico and recent poverty in Argentina. Over all, the results show a growing body of geodemographic data and spatial infrastructure data that can be used in marketing studies and locational applications as well as by social scientists and urban planners. As countries increasingly adopt the technology and standardize the content, this source of data will become a mainstay of GIS analysis throughout the world in the coming century.

# Utilize E-Commerce to Further Open the Door of China

Shan He  
Lingnan College  
Zhongshan University  
China

## Abstract

In the end of 2001, China re-entered the World Trade Organization, which means a pivotal step to further open. On the other hand, the advent of Internet makes it easier, cheaper, faster to find and communicate with potential customers and partners across the globe. The e-commerce, combined with the WTO entry, seems to become a powerful wagon for those foreign companies that have long salivated over China's huge market.

In the beginning of this paper, we briefly point out the huge potential of e-commerce in the country. Then we proceed to provide you with a picture of the e-commerce circumstances in China. At last, we give some suggestions to foreign companies on how to make a go of e-business in China.

## 1. Introduction

More than 2,000 years ago, invading tribes from the north were repulsed by the 1,500-mile Great Wall, built by vassal states of the Qin Dynasty to protect the fertile lands of China.

At the beginning of the 21st century, the walls that separate the Chinese economy from the rest of the world are poised to fall a notch with China's re-entry into the World Trade Organization. With that opening, tariffs will be lifted and trade barriers are about to fall. Certainly, the WTO will open China's market in a way they've never been open before. Besides the entry, Internet, one of whose promises is to make it easier, cheaper, and faster to find and communicate with potential customers and partners across the globe, seems to become another powerful wagon for the foreign companies to open the door of the waken-up dragon.

With the combination of Internet and China's entry to WTO, foreign companies will now have an historic opportunity to get into the largest potential market of the world and reap tremendous rewards----many foreign e-businesses hope to utilize the Internet to tap into vast new markets and to link to new business partners.

China and its massive market, have long been the envy of the business community, ranging from huge international consumer goods companies to feisty entrepreneurs with an idea to sell or a niche to exploit. Nowhere is the potential for gain more evident than the lucrative Internet business.

Although China currently comprised only 4.2 percent of all Internet users, while trading through e-commerce in China came to less than 0.6 percent of the worldwide

volume, with one-fifth of the world's population, China is viewed as one of the greatest untapped Internet commerce territories —its Internet users could grow from an estimated 17 million now to 60 million by 2005, and its strong manufacturing base combined with WTO accession will make it a major e-commerce market. According to the WTO EMarketer. Inc., in New York, estimates of B2B e-commerce revenues in China will grow from \$1.5 billion this year to \$21.8 billion by 2004. International Data Corp predicts that China's Internet commerce revenues will get 70.1 billion by 2004.

The development of e-commerce gets strong support from the government, too. On August, 2000, at the World Computer Congress -- a gathering in Beijing of Internet entrepreneurs and regulators from 70 countries -- President Jiang Zemin said that "virtual reality is changing the way people produce, learn and live," and the "melding of the traditional economy and the information technology will provide the engine for the development of the economy and society in the 21st century."

Given the huge potential e-commerce market in China, it makes great sense for foreign companies with a desire to do business in China to use e-commerce to roll out their e-globalization strategies in that large country. But have patience! They should have a clear and specific understanding of the e-commerce circumstances in China to determine correct strategies of launching a successful e-commerce operation. Only in that way, can the foreign companies roll out their e-globalization strategies in China and can they further open the door of China's market.

We will discuss these problems one by one in the following of the paper

## 2. Is China ready for e-commerce?

To launch a successful e-commerce operation in China, foreign companies should first have a clear picture of the circumstances of e-commerce in China. Let's discuss them at length.

### 2.1 The Culture of the Market

First and foremost, there is no one Chinese market. Management gurus stress that it is key to realize that companies are working in cultures, not markets. China is one culture and many cultures at once. It is beyond the scope of this paper to provide a cultural map of China, but part of any preparatory work for e-business investment in China should include a series of briefings

on the complexities of China's many cultures and on the "rules of the game" in the Chinese market.

## 2.2 Growth of the Internet

The exponential growth that has occurred in the number of Internet users in China makes it a prime target for foreign investment in e-commerce. In 1995, there were fewer than 50,000 Internet users in China. At the beginning of 1998, there were some 2.1 million users. By the end of 2003, the China Internet Information Center projects there will be 20 million users.

## 2.3 The Legal Framework

The fact is, there is no legal framework. However, work on an overall legal framework is underway. Some rules are expected to be published on a gradual basis, following China's entry into the WTO. In addition, center of computer and microelectronics industry and development (CCID) is collaborating with the taxation authorities to draft tax regulations.

Some regulations that foreign companies should keep in mind include a licensing requirement for all dotcoms, strict limits on direct foreign investment and a mandate to keep user records that are surrenderable to the government upon request. Another problem is the regulations now in place regarding encryption. Initially foreign businesses were required to register the encryption products they used in China. This would have given the state the ability to decode traffic passing through the Internet between branches of the same business. The state has since backed down on this requirement. But Chinese firms are still forbidden to use any foreign-made standalone encryption products. They may only use Chinese-made products registered with the new State Encryption Management Commission. This gives the state a means of monitoring computer traffic.

## 2.4 Payment method

Government restrictions aside, China's e-commerce is also handicapped by a lack of convenient payment methods. In a survey "Greater e-China Insights," conducted by Cheskin Research and Chinadotcom Corporation, only 30 percent of mainland Chinese respondents said that they have a credit card. The most common payment method for online purchases in mainland China is cash-on-delivery (COD).

## 2.5 Trust Issues

Respondents to the survey were also distrustful of companies that exist only in cyberspace without a brick-and-mortar counterpart. According to the study, few Chinese would make a purchase from an e-tailer that they had never heard of before.

Since the Greater Chinese online market is just in its infancy, it's even more critical to pay attention to online trust. As technology penetrates global markets, access to e-commerce won't be the issue, creating loyal

relationships through service, authenticity, and trust will be key. There is still a long way for China to build a certificate of authentication system and construct a healthy credit system.

## 2.6 Delivery services

E-commerce is not all about the technology. You have to be able to move things around speedily and in a flexible way to meet the customers' needs. The transportation infrastructure is not established. Even in the prosperous coastal provinces in the East, transportation can be very problematic. While packages in the United States can be shipped cross-country in a matter of days, for example, in China the roads--or lack thereof--mean that, even if B2B e-commerce were to take off, there is no efficient way to deliver products.

## 3. How to make a go of e-business in China?

Despite many barriers, potential of China's e-commerce market is huge and growing. But a growing market is irrelevant unless you develop a strategy to make it work for you. Markets do not wait. Your success all depends on your strategy and your understanding of the power of e-commerce. Besides translating your web site to Chinese and providing contents that appeals local culture, here are some other suggestions for foreign companies to launch a successful e-commerce in China.

### 3.1 Have a good understanding of China's e-commerce circumstances

A foreign e-commerce company should have a good understanding of China's e-commerce circumstances: the telecom infrastructure, the number of people who often surf the net and the growth of this population, the on-line payment methods, people's perspectives about e-commerce, to what extent the people accept e-commerce, the legal framework, the trust issues of on-line business, the commercial culture, the transportation infrastructure, the delivery services, etc. All of these are important for a foreign e-commerce company to make a correct strategy.

### 3.2 Strategic Planning: The Initial Stage

Most e-commerce companies can no longer afford to sacrifice capital on ill-planned experiments.

The path to a successful e-business strategy for Mainland China starts with the basic tenet of all good strategies—planning. This means that 12 months prior to your launch date, you should identify a China team to set goals, draft a strategy and map out the enterprise architecture to attain your business objectives. Who should be involved in this initiative? We recommend that they be key representatives of the marketplace (such as customers), those with execution capability (such as IT), and finance people. We've seen a maximum of four team leaders with 15 managers focused on project management,

and a minimum of eight managers from IT and customer service involved at any one time.

### 3.3 Establish an appropriate company website

Firstly, the content of the company website should be expressed in Chinese. Although translating the website into Chinese is a demanding task—besides the translating machine, language experts probably have to stand by to assist the machine. Attracting customers is the first step of success. Compared with foreign language websites, websites in Chinese have an obvious advantage. It's hard to imagine customers or potential business partners would be willing to spend more time on an foreign language website (even he knows or master that language). It will be costly if company translates itself. There are many professional companies offering the solution for website translation. So e-commerce company can outsource the task of translation. But the company still need to supervise the results of translation.

Besides the local language content, what is more important is to provide localized products and services. That is, the products and services should adapt to Chinese culture, which means a lot of effort "below the web".

### 3.4 Consult law specialists

Equally important will be your choice of an international law firm with proven China expertise. We also advise employing an outside consultant to serve as an overall facilitator and troubleshooter in China. They should be responsible for briefing the head office on the complexities of the Chinese market.

### 3.5 Find the Right Ally

Leverage local relationships. The multicultural nature of global business creates a degree of complexity that cannot be easily satisfied just by establishing a Web presence.

Businesses cannot underestimate the value of a local presence and the insight that having an on-site window into the culture represents. Local partners can help provide the answer to problems of trade regulation, and tariffs, and legal and regulatory complexities. Foreign e-commerce companies can use network of local offices and distributors to fulfill orders, to figure out the pricing in local currency, and to arrange payment by the preferred method.

Partnering with Chinese companies is smart because:

(1) It offers benefits that go well beyond easing compliance with Chinese regulations. Business in China, as in many Asian countries, is built on trust and enormous amounts of personal contact. As a result, B2B e-commerce can be a tough sell. Finding a partner in China can help resolve some of those cultural issues.

(2) If you anticipate substantial technology costs or substantial operational expenses like brand recognition (such as advertising), then it would make sense to

consider a partnership or alliance with a Chinese counterpart who already has a related business vehicle up and running. For example, consumer-oriented offerings require heavy investment in branding because of the fight for eyeballs in a crowded market. By choosing the partnering route, you avoid spreading your resources thin, and you're building expertise for the future.

Since a joint venture partner will have knowledge of the market, commercial network and political savvy that you, both as a newcomer and outsider, lack, you can expand your business opportunities network and better position yourself for the anticipated e-commerce growth in China. Make sure that your partner is selected with all due diligence.

### 3.6 Others

Besides what we have illustrated above, foreign e-commerce company should be cautious about the followings:

(1) Provide as many payment methods as possible. Since the payment system is not so advanced that foreign e-commerce companies should provide payment methods at different levels.

(2) Pay attention to trust issues.

(3) Outsource the delivery services to international cargo companies, such as DHL, UPS, etc.

## 4. Conclusions

China is viewed as one of the prosperous e-commerce market, and companies first investing in such market will undoubtedly take first-mover advantage. Empowered by the convenience and cost benefits that the web is designed for, and with correct understanding of e-commerce, foreign e-commerce companies who are patient and willing to play by China's complex rules can find a bright future.

## Abstract

The e-business application can be considered as a new generation of computer information systems in the Internet era that needs the support from a solid information technology infrastructure including strategic objectives, physical components, and operational management. A survey was conducted to investigate some current practices and its implications of the information technology infrastructure existed in thirty organizations from ten different industries located in California. These organizations reported that they have implemented two or more e-business applications using the different types of the network operating systems and network security protections. The most used e-business development method is still the traditional in-house development method that offers the best management planning and controlling strategy to align the overall business and information technology objectives together. The system integration, e-mail system management, and customer relation management have gained their importance in the routine operating functions at the information technology department.

## 1. Introduction

The constant improvement of the powerful and inexpensive microcomputers and the advancement of the distance networking communication technologies have pushed the birth of the Internet. On the other hand, the invention and usage of Hypertext Markup Language (HTML), Hypertext Transfer Protocol (HTTP), Transmission Control Protocol and Internet Protocol (TCP/IP) have produced the World Wide Web (WWW) [1] [2]. Consequently, the combination of the Internet and WWW has established a special environment for a new communication system that enables the individuals and organizations to create, transfer, locate, and view multimedia documentation between locations without any time and distance limitation [3] [4].

The individual and organization have quickly recognized the potentials and captured the benefits that could be offered by that new Internet and World Wide Web

communication system. Those individual and organization have then developed the Internet economy or electronic economy (e-economy) that utilizes the enormous capability and power of the Internet and World Wide Web communication system to conduct different types of business named electronic business (e-business).

An e-business not only can offer the individual and organization a brand new channel of conducting business through the electronic network, but also can increase the efficiency and effectiveness of the routine operations to gain competitive edge in this information era. Meanwhile, like any traditional computer information system, a winning e-business application definitely requires the support from a solid information technology infrastructure that includes strategic objectives, physical components, and operational management [5] [6] [7] [8].

The major objective of this research paper is to present some preliminary survey results of the information technology infrastructure that have been utilized by a sample of the thirty organizations located in California. The sample has ten different types of the organizations including consulting, education, government, manufacturing, health, pharmaceutical, real estate, retail, service, and utility.

## 2. The Survey

An appropriate questionnaire was developed in an attempt to determine some answers related to the current information technology infrastructure for the organizational e-business applications. Specifically, the present practices of the following questions were to be sought:

1. How many and what types of organizations are utilizing the e-business applications?
2. What types of the e-business applications are being implemented in the organizations?
3. What types of the network operating systems are being installed for the e-business applications in the organizations?

4. What types of the e-business security implementations are being employed by the organizations?
5. What types of the development methods are being adopted for the e-business applications in the organizations?
6. What types of the functions related to the e-business are being supported by the information technology department in the organizations?

A three-page questionnaire was mailed to a sample of randomly selected organizations that are located in the three areas including Los Angeles, Silicon Valley, and Sacramento of California. Thirty properly completed questionnaires have been returned by the responding organizations that provide the data source for the analysis and discussion presented in this paper.

### Users of The E-business Applications

On the questionnaire, the organizations were asked to indicate their total annual revenue, total number of employee, and the number of years using a network. The summarized results are presented in Table 1. It is interesting to note that the total annual revenue of the responding organizations ranges from eight million dollars to twenty six billion dollars, and the total number of employee ranges from thirty five individuals to one hundred and thirty thousands. These two statistics imply that the e-business applications are used in the big business organizations as well as in the small ones.

**Table 1: Characteristics of the Responding Organizations (n=30)**

Characteristics	Low Value	Median Value	Average Value	High Value
Total Revenue (millions)	\$8	\$1,000	\$5,765	\$26,000
Total Employee (thousands)	0.035	4	20.89	130
Year of Network Use	2	12	12.92	35

The only usage difference of these two types of organizations is indicated by the number of years using a network. The big business organizations have started the network communication as long as thirty-five years ago that is way before the creation of the Internet. On the contrarily, the small business organizations could enjoy the inexpensive network communication is solely due to the birth of the Internet. It is not surprising that the average number of years using a network is around thirteen years that is closely equal to the number of years for commercial usage of the Internet. The Internet does

level the playing ground in terms of telecommunication for the business organizations regardless of their size.

**Table 2: Types of Organizations Using the E-business (n=30)**

Industry	Number of Using E-business
Consulting	6
Education	2
Government	5
Manufacturing	6
Health	1
Pharmaceutical	1
Real Estate	1
Retail	1
Service	3
Utility	4

The survey asked the responding organizations to specify their primary business activity. Table 2 presents the industry background of the organizations that have implemented the e-business applications. The sample has ten different types of the organizations including consulting, education, government, manufacturing, health, pharmaceutical, real estate, retail, service, and utility.

### E-business Applications

The responding organizations were asked to indicate every type of their e-business application. Table 3 summarizes the current practices of the various e-business applications implemented by the responding organizations.

**Table 3: E-business Applications (n=30)**

Application	Number Responding	Percentage Responding
Intranet	30	100%
Portal	16	53%
Business -to- Business	15	50%
Business -to- Customer	23	77%
Customer-to- Customer	5	17%
E-mail	28	93%
Electronic Data Exchange	17	57%
Others	3	10%

It appears that the e-business applications being most widely used are Intranet, e-mail, and business-to-customer. The e-business applications such as electronic data exchange, portal, and business-to-business are also used by more than fifty percent of the responding organizations. Whereas, the only e-business application named customer-to-customer appears to be not as widely used by the responding organizations.

Apparently, every responding organization has installed more than one e-business application. The three most important intensions of the e-business applications are to increase the organizational productivity, to facilitate the organizational communication, and to create a sales channel. The less popular intensions of the e-business applications are to exchange information between business partners and to establish a online gateway for the Internet users. The least usage of the e-business application is building a public auction market on the Internet.

### Network Operating Systems Used for the E-business Applications

The questionnaire, also, asked the responding organizations to identify the names of the network operating systems installed to run their e-business applications. Table 4 illustrates the statistics of network operating systems used for the e-business applications in the responding organizations.

It is not surprising that the Windows NT developed by Microsoft is the most popular network operating systems used by ninety seven percent of the responding organizations. The Unix created by AT&T is the second popular network operating systems that have been used by seventy seven percent of the responding organizations. The less popular network operating systems include Linux, Sun Solaris, and HP-UX.

**Table 4: Network Operating Systems Used for E-business Applications (n=30)**

Network Operating Systems	Number Responding	Percentage Responding
Window NT	29	97%
Unix	23	77%
Linux	11	37%
Sun Solaris	14	47%
HP-UX	8	27%
Others	6	20%

There are two interesting facts related to the two popular network operating systems that dominate the market. First, the criteria used by responding organizations to purchase the network operating systems might include the factors such as the software performance records, the amount of support, and the availability of skillful experts.

Second, the responding organizations might have separated networks for their different e-business applications since they install more than one network operating systems to fulfill the special requirements.

### Security Implementations for the E-business Application

In the questionnaire, the responding organizations were asked to indicate the types of the security implementation that have been installed for protecting their e-business applications. Table 5 provides a summary of the types of the security implementation for which the responding organizations have used.

The responding organizations do emphasize their network security, data integrity, and information privacy since they have installed more than one security scheme. It appears that the firewall is the most commonly used security method to block the intruders and unauthorized users from accessing the extranet and/or intranet applications. More than fifty percent of the responding organizations utilize the private key and public key as a safeguard measurement to scramble the data and information during the message transmission between the sender and the receiver.

**Table 5: Security Implementations for the E-business Application (n=30)**

Security Implementation	Number Responding	Percentage Responding
Firewall	27	90%
Electronic Signature	10	33%
Private Key and Public Key	16	53%
Secure Electronic Transaction	11	37%
Digital Certification	8	27%
Other	4	13%

The security methods such as electronic signature, digital certification, and secure electronic transaction are less used by the responding organizations. This result may imply that the nature of these three methods is not for the purpose of safeguard the network. The electronic signature and digital certification that involves a payment to the third party are especially for the safe transmission of an important documentation and/or sensitive information. Whereas, the secure electronic transaction is mainly for the financial transactions between the business organizations and customers using a secured private network.

## Development Methods for E-business Application

The responding organizations were asked to identify the e-business application development method used in their organizations. Table 6 provides a summary of the development methods that have been utilized in implementing some of the e-business applications in the responding organizations.

The responding organizations overwhelmingly favor in-house development method over the other two development methods named outsourcing and off-the-shelf package in every types of the e-business applications. Apparently, the responding organizations consider every one of their e-business applications as a vital and strategic computer information system. Therefore, the organizations need to have an internal team with profound business knowledge and information technology skills to plan, create and control their e-business applications in order to achieve its predetermined objectives for competitive advantages.

**Table 6: Development Methods for E-business application (n=30)**

Type	In-house	Outsourcing	Off-the-shelf Package
Web Page	26 (87%)	6 (20%)	4 (13%)
Electronic Data Interchange	14 (47%)	5 (17%)	2 (7%)
Intranet	27 (90%)	4 (13%)	4 (13%)
Business-to-Customer	18 (60%)	5 (17%)	2 (7%)
Business-to-Business	13 (43%)	3 (10%)	2 (7%)
Customer-to-Customer	4 (13%)	1 (3%)	1 (3%)
Call Center	11 (37%)	3 (10%)	8 (27%)

The outsourcing development method is slight over the off-the-shelf packages that have been used by the responding organizations in every category except the call center. This result indicates that most of the responding organizations have their own special requirements in the e-business applications. These special requirements cannot be fulfilled by a generalized off-the-shelf package. On the other hand, the e-business application in a call center is related to the call distribution system that can be provided by a prepackaged private branch exchange telephone system for more efficient operation and less investment risk.

## Functions Supported by Information Technology Department

The responding organizations that have an information technology department or division were asked to indicate the functions performed by their information technology department in the current information era. Table 7 presents a summary of the types of the tasks executed by the information technology department in the responding organizations.

**Table 7: Functions Supported by Information Technology Department (n=30)**

Functions	Number Responding	Percentage Responding
Technical System Development	28	93%
Technical System Maintenance	28	93%
Off-the-shelf Package Evaluation	25	83%
System Integration	27	90%
Outsource Contract Management	21	70%
Customer Relationship Management	22	73%
E-business Development	20	67%
E-business Maintenance	20	67%
E-mail system Management	27	90%
Database Management	28	93%
Data Warehousing/Data Mining	22	73%
Network Management	25	83%
Internal User Support	25	83%
Other	3	10%

The five functions including technical system development, technical system maintenance, system integration, e-mail system management, and database management have been selected as the most commonly performed tasks in the responding organizations. This result indicates some interesting points. First, the traditional functions such as system development, system maintenance, and database management are considered by ninety three percent of the responding organization as their routine duties. Second, the only function related to the e-business application is e-mail system management. Where the information technology department takes the responsibilities of managing the operations of e-mail server, controlling the storage area, and preventing the virus, etc. Third, the responding organizations do not adopt the new development policy to replace the old information systems. On the contrary, the responding

organizations emphasize the system integration approach to merge the old and new computer information systems by using open standard and middleware.

The off-the-shelf package evaluation, network management, and internal user support are ranked by eight three percent of the responding organizations as the next group of most commonly performed tasks in their information technology department. It is interesting to note that the majority of the responding organizations are not likely to use the off-the-shelf package for their e-business applications as illustrated in the previous Table 6. On the other hand, the information technology department of the responding organizations does often perform the off-the-shelf package evaluations for other types of computer information systems as indicated in the current Table 7.

Seventy three percent of the responding organizations have reported that the customer relationship management, data warehousing, data mining, and outsource contractor management have become part of the routing operations performed by their information technology department. This is not a surprising result since the major purpose of data warehouse and data mining is to accomplish the personalization or mass customization for the e-business applications. In addition, the online customers of any e-business application do periodically encounter technical difficulty and requires the assistance from the skillful staff member of the information technology department. The outsourcing contractor management also has gained its important status since it is a quick alternative method to obtain knowledgeable individuals by the information technology department for instant problem solving in this fast changing environment.

### 3. Conclusion

The advance information technology has created a new type of economy named electronic-economy or e-economy that has pushed the business society to a new frontier in the last decade of twenty century. This e-economy has leveled the playing ground for every types of organization to conduct its business functions regardless its size, resource, location, and time.

It is important for any organization to properly obtain this incredible power by developing the e-business applications on time for the purpose of increasing its internal productivity, reducing its operating costs, or enhancing its customers and suppliers relationship in this e-economy environment. On the other hand, it is also essential for the organization to establish a well-structured information technology infrastructure in order to backing its business applications.

A survey was conducted to investigate some current practices and its implications of the information technology infrastructure existed in the organizations. Thirty responding organizations from ten different types

of industries reported that they have implemented two or more e-business applications using the different types of the network operating systems and network security protections. The most used e-business development method is still the traditional in-house development method that offers the best management planning and controlling strategy to align the overall business and information technology objectives together. The system integration, e-mail system management, and customer relation management have gained their importance in the routine operating functions at the information technology department.

## Abstract

Business firms are increasingly taking part in online business activities through internet as the size of the e-commerce market is rapidly growing in the recent years. Electronic commerce (EC) activities now become an essential part of the business strategy for survival as well as growth for both large enterprises and small- to medium-sized enterprises (SMEs).

Previous studies on e-commerce mostly focused on the adoption of EC by business firms, and also have been carried out with the data from big enterprises. More often than not, the results obtained from the large business firms are used to provide the guidelines for small to medium-sized enterprises (SMEs). SMEs are, however, different from large business firms in many aspects, and need to be studied on their own.

This paper extends the previous research on EC in two aspects. Firstly, we study the e-commerce issues in the area of implementation in relation to the business firm's performance, beyond the adoption and diffusion of IT technology which has been the research issues in many previous research. Secondly, we focus on small and medium enterprises which comprise a large portion of national economy with significant influence.

## 1. Introduction

Business firms are increasingly taking part in online business activities through internet as the size of the e-commerce market is rapidly growing in the recent years. Electronic commerce (EC) activities now become an essential part of the business strategy for survival as well as growth for both large enterprises and small- to medium-sized enterprises (SMEs). [1][4][7][8][9][11][12]

There has been a lack of empirical research on e-commerce, and those few previous studies on e-commerce mostly focused on the adoption of EC by business firms [3][5][6][10] such as identifying the factors for adopting e-commerce. Nowadays, it is inevitable to use EC in one way or another and the adoption of information technology is accepted as given for most business firms. It is then a time to decide which type of EC system to adopt and how effectively to use them.

Another drawback of previous research on EC is that they have been carried out with the data from big enterprises. More often than not, the results obtained from the large

business firms are used to provide the guidelines for small to medium-sized enterprises (SMEs) as if they are miniature big enterprises. SMEs are, however, different from large business firms in many aspects, and need to be studied on their own.

This paper extends the previous research on EC in two aspects. Firstly, we study the e-commerce issues in the area of implementation in relation to the business firm's performance, beyond the adoption and diffusion of IT technology which has been the main research issues in many previous research. For this purpose, we construct a theoretical model incorporating environmental factors, implementation variables, moderating variables, and the firm performance. Secondly, we focus on small and medium enterprises which comprise a large portion of national economy with significant influence.

## 2. Research Methodology

### 2.1 Research Model and Hypotheses

While previous studies focused on the adoption issues (Figure 1), this paper is to investigate the relationship between the factors and the variables that affect the adoption and implementation of the E-commerce by small and medium enterprises as shown in the research model (Figure 2). Table 1 contains the explanations for the variables, and the hypotheses that will be tested are as follows:

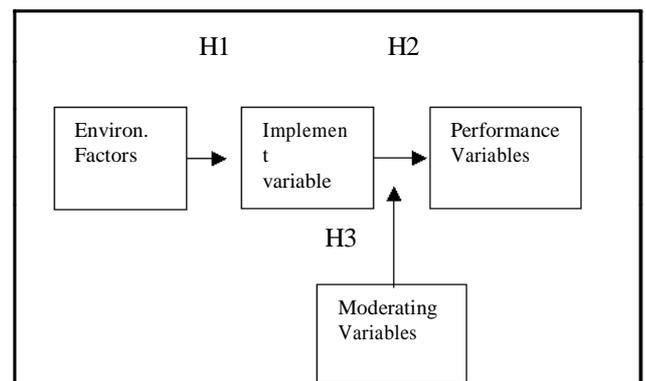

Figure 2. Research model for E-Commerce implementation.

**Hypothesis 1:** The firm's decision on which type of EC to implement is affected by the environment in which the firm operates.

The industry situation would affect a firm's decision when selecting the type of EC to adopt and implement. For example, those firms in such industries as logistics and

banking industry are more likely to use a Business-to-Consumer (B2C) type of E-Commerce system while manufacturing firms are more likely to adopt a Business-to-Business (B2B) type of EC system.

**Hypothesis 2:** The performance of a firm is affected by the type of EC which the firm implement.

A firm's performance is generally improved by adoption and implementation of electronic commerce. The magnitude of improvement, however, would be different by the type of EC system implemented by a firm.

**Hypothesis 3:** The impact of the EC type on the firm's performance would be affected by the moderating variables that show the general condition of the firm's information system such as IS intensity and maturity.

It is suggested that there is a time-lag before any IT system may produce substantial benefits for a firm. [2] Likewise, an EC system would need a lead time before it becomes an effective tool for improving the firm's performance.

**Table 1.** Explanation of the variables.

Variables	Contents
Environmental Factors	These are the environmental factors that affects a firm's adoption and implementation of the E-commerce such as the size of the and age of the firm, type of industry, competitive pressure, vertical relationship with other firms, environmental uncertainty.
Implementation Variables	These are the possible types of E-commerce that can be implemented by a firm such as: - B2B vs. B2C - Value chain vs. Industry type - Transactional, Strategic, or Informational types
Moderating Variables	These are the general condition of a firm's information system (IS) such as : - IS maturity - IS intensity
Performance Variables	These are the firm's performance in E-commerce area such as: - E-commerce (EC) utilization - EC satisfaction - EC usefulness

## 2.2 Data Collection and Analysis

For a preliminary test, we circulated questionnaires to 100 small and medium enterprises in Korea and 41 firms have returned the questionnaires. The data collected from the sample of 41 firms are used for analyses. Descriptive statistics are used for this conference paper and we will further use statistical methods such as analysis of variance (ANOVA) and regression to analyze the data for a final

version of the paper.

## 3. Preliminary Results

### 3.1 Business Environment and EC Implementation

The effect of the business environment on the firm's decision on EC implementation is measured. Two variables are selected to define the firm's business environment: the degree of competition facing the firm and the degree of information sharing with the suppliers and customers. Two dimensions of the firm's decisions are analyzed: the types of EC and the purpose of EC implementation. The types of EC for firm's selection include Business-to-Business (B2B), Business-to-Customer (B2C), and Business-to-Government (B2G). By the purpose, EC systems are classified into Transaction EC, Information EC, and Strategic EC.

The results from regression analysis show that a firm's decision on EC type selection is affected neither by the degree of competition nor by the degree of information sharing with the suppliers and customers, which are the partners in the firm's supply chain. Regardless of the degree of competition or information sharing, firms adopted fairly equally among the 3 types of EC. Also, the firm's purpose for implementing an EC does not seem to be affected by the business environment.

### 3.2 EC Implementation and EC Performance

We tested the relationship between the two implementation variables discussed above, EC type and EC purpose, and the EC performance experienced by the firm, utilization, satisfaction and usefulness. The average performance is compared between the groups of firms implementing the same type of EC and with the same purpose.

Among the EC types, those firms adopting B2C expressed the highest level of performance experience in all three measures of utilization, satisfaction and usefulness. The firms' experiences, however, are different between the implementation purposes. Information EC produced the best utilization and satisfaction for the firms, while Strategic EC provided the best usefulness for the firms.

### 3.3 IS Maturity and EC Performance

The impact of IS maturity, measured by the firm's knowledge and attention for the EC system, on the EC performance is examined. As portrayed in Figure 2, IS maturity is a moderating variable that plays an important role in understanding the relationship between the EC implementation and the firm's performance.

IS maturity is found to have a positive impact on the EC performance. As the level of firm's knowledge and attention for the EC system became higher, all three performance measures of utilization, satisfaction and usefulness increased. A higher level of knowledge and attention for the EC system can be achieved by a sustained investment in information technology by the firm over a long period of time. Therefore, a firm can improve its EC performance by

continued investment in IT system and resource.

# The Comparison in Cognition on Outsourcing Decision for Accounting and Taxation between Cross Straits

Chiung Feng Ko

Department of Accounting  
Soochow University  
Taipei, Taiwan  
joanko@mail2.scu.edu.tw

## Abstract

By inquiring both companies between the Taiwan and Mainland China, the purposes of this study are (1) to specify the contents of accounting and taxation activities will be outsourced, (2) to identify which segment is suit for outsourcing and what are the odds, (3) to compare the attitude toward the taxation agent systems, and (4) to know whom will be eligible for serve in the accounting and tax service.

Following main findings are reached through this study. First, the companies in Taiwan do not conceive such kinds of activities, which on cash flow and budget matters could be outsourcing from outside while those of Mainland China do. However, such activities like tax closing entries and tax calculation are considerable to be outsourced in Taiwan. Second, both companies concur that parts of the organization functions should be outsourced. Furthermore, there exists significant difference on information disclosure and independence of outsourcee (external service providers) among the merits and demerits of outsourcing. The Mainland Chinese companies think that outsourcee may loss its independence on account of outsourcing. Third, both companies have consistently cognition on the system of professional accounting and taxation agent. Finally, the one who is a CPA, a tax expertise, or a tax practitioner will be qualified to take on such responsibilities.

Keywords : Outsourcing, CPA, Tax Practitioner, Tax Expertise , Disintermediation

## 1. Introduction

The practice of outsourcing has been a logical alternative for non-strategic areas such as payroll processing, public relations, building maintenance, and human resources. Recently, outsourcing has become a more visible perception as companies turn to it in operational areas, such as engineering, logistics, design, and tax. Firms are regularly outsourcing their accounting and tax function to CPA (Certified Public Accountant) firms or tax accountant firms (Tax practitioner), as well as to niche firms that specialize in the service. According to research compiled by G-2 Research Inc. [31], the percentage of U.S. corporation's tax compliance costs spent with outsourcers has quintupled from about 3 percent in 1992 to 15 percent in 1996. In the vertical integration and transaction cost economics respects, Alexander and Young [1] conducted that outsourcing is worthy of special

attention only of changes in current attitudes and practices could unlock significant latent or unrealized value.

On the other hand, a survey of the Ministry of Economic Affairs [50] reported that near 80% of companies in Taiwan are outsourcing their accounting or tax related matters from professional agents, including CPA firms and tax declaration agents, to save costs for the past few decades. Meanwhile, since 1994, Value-Added Tax (VAT) was reformed in Mainland China and contributed more than 40% of the government revenue [51]. Not only are they saving more costs, but also they are facilitating the focus of their tax and accounting practices to be more proactive.

The systems of accounting and tax between Taiwan and Mainland China are different, however, the cognition on outsourcing decision is homologous. For example, the purpose of tax declaration agent system in Taiwan is to help taxpayers to file tax return properly, and, the main function of VAT in Mainland China is to help government to moderate tax evasion problem. On the other hand, both the agents of accounting firm and tax firm in Mainland China must pass professional examination before they serve such kind of services. In Taiwan, however, only the CPA does. Because the system of tax accountant is not legislating yet, tax firms offer such kind of services through lore and experience. Thus, the services of Tax practitioner are subject to booking and a wide variety of tax services, but no auditing work.

To learn more about the perception of the accounting and tax function, the compatibility of outsourcing, the merits and demerits of outsourcing, the role of tax accountant, and the precedence of intermediary, this paper conducts a survey of senior officers both at small and medium-sized companies of cross strait.

There is a minimum level of business required for outsourcing. Factors such as minimum processing costs, current active business, and projected growth are considered in the outsourcing equation. Along with the extension of IT, would such kind of services be negligent under the e-business environment? Does e-business in taxation service system may replace the traditional role of Tax practitioner? This paper is the second of two articles reporting the results of that survey. The first article was presented at The 2002 Cross-Strait Conference on Finance, Economics and Business, Taipei in April 2002 and focused on views of companies and professional

firms in Taiwan. This article addresses the comparison in cognition on outsourcing decision between the cross straits.

## 2. Views of Accounting and Tax Outsourcing

In the past, a company hired outside expertise such as legal services for a specialized purpose, but did not shift wholesale responsibility for its accounting needs to another entity.

There is wider recognition of outsourcing as a tool for day-to-day management. Outsource services CPA firms provide most often are accounting and finance functions, payroll, accounts receivable/payable, financial statement preparation and analysis, budgeting, cash management, internal audit and tax.

Since the mid-1980s, Taiwan has launched two important tax reforms: one was the change of sales tax from the multiple-stage gross business receipts tax (GBRT) to the value-added tax (VAT) in 1986; the other was the establishment of the integrated system since 1998. The VAT has served as an effective remedy for resolving the problem of double taxation in sales tax. Similarly, the integrated system is the only way to mitigate double taxation on dividend income. Both systems discard multiple or double taxation and both are consisted with different stages of economic development.

Hereupon, the purpose of tax declaration agent system is to help taxpayers to file tax return properly. However, the existence of this system and its function has been debated for the last few decades. People argue the quality of financial statement the Tax practitioner made, doubt the ability of tax declaration agent, and require tax declaration agents to get license before they are qualified for this job.

In recent years, companies have looked primarily to technological improvements to cut expenses. While companies continuously seek creative methods to improve efficiency, handling both tax and accounting bills and payments can be a costly headache for companies. Thus, outsourcing these functions may offer many benefits. Johnson [21] stated that tax service is at the forefront of outsourcing because of the market is competitive and fees have continued to stay low over the years.

Most companies have traditionally outsourced a variety of tax functions, including international and expatriate tax administration, executive tax preparation services, relocation tax administration, acquisition and merger tax, investment tax credits, reverse sales audits, and property tax billing.

Before the emergence of the Internet and the Web, practitioners generally found the most reliable and most easily accessible source of tax information in tax services or in tax journals published by reputable organizations.

For most large companies the primary reason to outsource may reduce costs<sup>1</sup> and for some companies the main motivation may be to gain access to greater expertise or to be able to focus on core activities. For companies, five principal reasons to outsource are to: (1) reduce and control operating costs, (2) improve company focus, (3) gain access to world-class capabilities, (4) free internal resources for other purposes, and (5) obtain resources that are not available internally [5]. On the other hand, companies that outsource often experience one or more of the following drawbacks. There are: inflexibility, loss of control, reduced competitive advantage, locked-in system, unfulfilled goals, and poor service [29].

In early 1990s, Levine and Lerner [22] described how the tax executive might better approach the issue of outsourcing to do a more effective job of managing the tax function of the company. After having digested the accounting firm's responses to an outsourcing survey, Moore [23] concluded that accounting firms are becoming more aggressive in pursuing outsourcing until proven otherwise. Tax professionals in private industry are willing to change, adept, streamline, and automate.

The 1990s were the decade of integrated software, with software suites playing a prominent role. Crampton and Graig [10] compared Microsoft's Office Professional with the competing products from Lotus and Borland in terms of included applications, system requirements, and retail prices. Gellis [18] and Bradbury [6], as well as Yakal [34], also introduced computer software for Windows and for Macintosh respectively for tax accountants. Furthermore, Hawaleshka [19] reported on two Canadian companies offering services for doing income taxes online. It seems that a tax practitioner or an accountant may attempt to access pertinent information quickly from the Web as a free source. However, after trying hundreds of hours, Sumutka and Chang [32] concluded that it is not that easy and in many cases the information is not that useful either. They asserted that the Web does not change the fact because none of these sources are available on the Web free of charge. The problems encountered by tax accountants in accessing information from the Web are its accuracy, degree of sophistication, and accessibility (i.e., its usefulness).

Determining if clients are the right cultural match for each other and establishing a clear understanding of the engagement specifications at the outset are the key to making outsourcing work [5].

Based on strategic outsourcing theory, the transaction-cost motivations have been studied in a variety of settings. For examples, Dunbar and Phillips [15] indicate that transaction costs relating to human-asset specificity, proprietary technology, and economies of

---

<sup>1</sup> For example, Berson (2001) stated that most large, for-profit organizations outsource their accounting, and it can cut them by 25% to 50%.

scale, along with the status of firm's top tax professionals and recent growth, are factors that affect the tax function outsourcing decision. This paper extends this investigation to a knowledge-based professional services setting in which external tax professionals have opportunities to serve tax and accounting knowledge that increase firm value.

A general economic trend in corporate tax function outsourcing has been viewed with concern. In a study more closely related to mine, Dunbar and Phillips [15] provides the first evidence of the standpoints associated with tax and accounting function outsourcing between the cross straits. Dunbar and Phillips [15] investigated the factors associated with firms' decisions to outsource corporate tax-planning and –compliance activities.

### 3. Methodology

This study employs survey research to investigate small and medium-sized enterprises in Mainland China and Taiwan. The outsourcing questionnaire consisted of 80 questions covering many areas of concern common to the private industry tax community. Information for this study was obtained through a questionnaire mailed in November 2000 to 317 senior tax administrators of companies. There were 171 responses to the request. The overall response rate was 53.94 Percent. A broad cross-section of companies responded to the survey.

The survey includes general instructions and questions relevant to constructing the survey-related variables. Questionnaires were sent to corporate executives at random. Survey instruments were sent to 317 firms totally. Of which 217 copies were sent to Taiwan and the others were sent to Mainland China. In Taiwan, three or Four weeks after the initial mailing, non-respondents were sent Fax or call reminders. Thereafter, non-respondents were sent second reminders along with the questionnaire. After removing unavailable or blank data from the sample, this process yielded 160 survey responses, resulting in a response rate of 73 percent. Neither however, suffer for economy, neither Fax nor second reminders were sent for non-respondents in Mainland China. Many responders felt the questions were "hard," "tough," "copious," etc. This process yielded only 14 survey responses, resulting in a response rate of 11 percent after filtering out 3 percent of nullity.

### 4. The Main Findings

The findings of the preliminary and principal studies comprise many different facets.

Table 1 presents descriptive statistics that compare Taiwanese firms to Mainland China firms at fundamental items. The comparative statistics presented indicate that Taiwanese firms are longer, larger, more variety at industry and human resource. The survey do not targeted

larger firms with a tax executive to ensure a response rate adequate to produce a sample large enough to test any hypotheses. Accordingly, it is not clear whether the results generalize to larger publicly traded firms.

Insert Table 1 here.

Insert Table 2 here.

The comparative statistics presented in Table 2 reveal the ways of declaration, bookkeeping, tax-announcement between Taiwanese firms and Mainland China firms. Most of the firms respond that firms do bookkeeping and tax-announcement by themselves or their accountant. Many of the companies do tax related works via the assistance of accounting professional service firms.

Insert Table 3 here.

Table 3 presents the descriptive statistics and t-Test of difference in means on the contents of accounting and taxation activities will be outsourced. At the "cash budget" item, the means for Taiwanese firms and Mainland China firms are 2.238 and 2.9, respectively; indicate that the perceptions of cash budget made to external service providers differ rather. Moreover, at the "budget management" item, the Taiwanese firms are reluctant to outsource while the Mainland China firms are neutral. In addition, the means for "tax calculation" item are 3.453 and 2.6 respectively, indicate that Mainland China firms are quite object to let this matter be outsourced. Both at the "tax closing entries" and "preparing annual income tax return" items, the Mainland China firms relict at budgets providing by outsiders. Taken altogether, the Mainland China firms do not conceive such kinds of activities, which on "tax calculation," "tax closing entries," and "preparing annual income tax return" could be staffed from outsider while those of Taiwanese do. However, such activities like "budget matters" are not considerable to be outsourced in Taiwan.

Insert Table 4 here.

Companies typically maintain those things that differentiate them from their competitors and provide a true competitive advantage. How do the firms determine what to outsource? Table 4 presents the result about what segments of organization to outsource. Outsourcing part of corporate departments is probably the solution for most of the companies that currently have accounting/tax departments. For most sample companies, core functions include internal auditing and payroll, of which functions choose to outsource eventually. The first segments for Mainland China Firms to outsource are part of operating functions and Administrative functions. Similarly, the first two choices for Taiwanese firms are Tax and part of operating functions. That is to say, with the growing trend toward focusing on core business capabilities, both the companies are outsourcing selected business functions to outside expert partners who can perform them more efficiently and cost-effectively.

Insert Table 5 here.

The results of the conception among merits and demerits of outsourcing are reported in Table 5.

There exists significant difference on information disclosure and independence of outsourcee among the merits and demerits of outsourcing. The Mainland Chinese companies think that outsourcee may lose its independence on account of outsourcing. However, the Taiwanese companies admit outsourcing of solution and of transparency. But, the Taiwanese companies do not assume that external service providers may lose its independence.

About the potential for loss of control of outsourced processes, both the companies do not think that they will be lost of costs management, nor shrinking organization or worse communication. In fact, many of the companies take the matter that there are a number of controls to maintain and enhance the management of the accounting and tax functions through outsourcing.

Taken altogether, both Mainland China and Taiwan companies seem agree at the merits but demerits. The first two advantages management seeks from outsourcing are: reduce and control operating costs and improve company focus. In a tight market, expense control is more important than ever. But today, as clients demand increased value and security requirements escalate, cost saving seems unachievable. Most will uncover the obvious - reengineer antiquated systems, automate manual processes, consolidate systems, launch a new methodology, and the list goes on.

Insert Table 6 here.

The t-Test results of difference on comparing the attitude toward the taxation agent systems are presented on Table 6. Both companies have consistently cognition on the system of professional accounting and taxation agent. Moreover, the Taiwanese companies show more positive attitude than Mainland China companies. Particularly, at the items of "Insuring firm's processing criteria" and "Reducing operating expense," the Taiwanese companies are significantly assenting.

Insert Table 7 here.

Though accounting and tax outsourcing start as an outgrowth of cost-cutting initiatives, today, the industry is looking into strategic alliance. Accounting and tax outsourcing is a decision a lender should approach with definable objectives and measurable results. From the result of Table 7, it indicates that a CPA, a tax expertise, or a tax practitioner will be qualified to take on such responsibilities. The company who can complement its accounting and tax capabilities in consulting, systems integration and outsourcing will be eligible to form business alliance with company.

## 5. Conclusion

This research provides the first evidence of the

standpoints associated with tax and accounting functions outsourcing between the cross straits. Regardless of the company being downsized, reengineered, or overcapacity, the most common reason cited for outsourcing a portion or all of the accounting and tax functions was financial savings. Besides, there are technological changes being made in the industry that have significantly streamlined processes and reduced manual efforts commonly associated with the business. In this study, both of the companies do not fear for losing competitive advantage.

On the other hand, tax service companies are facing new challenges and creating new ways to perform traditional services. With regard to the continuous outsourcing accounting and taxation, when international accounting and taxation are complex, task difficult, and change of requirements frequent, facilities and human resources can be substituted by contractors to reduce risk and to increase flexibility. The practice of tax or accounting outsourcing is not new and is reviewed as an outgrowth of cost-cutting initiatives; today companies are looking beyond cost cutting and into strategic alliances.

# Adaptive Strategies of Firms in High-Velocity Environments: The Case of B2B Electronic Marketplaces

Jai Ganesh                      T R Madanmohan                      P D Jose  
jganesh@iimb.ernet.in      madan@iimb.ernet.in              jose@iimb.ernet.in  
Indian Institute of Management Bangalore, India

## Abstract

Electronic marketplaces operate in highly dynamic environments. B2B (Business-to-business) e-Commerce (Electronic Commerce) is expanding rapidly, but Independent Internet based Electronic Marketplaces (IBEM) have passed through periods of boom and bust. In start-up entrepreneurial ventures such as IBEMs, adaptation is critical than at any other stage in the life cycle and hence the ability to learn and adapt becomes a key competency. The research uses the resource-based theory as a means of analyzing the evolution and adaptation of the resources and capabilities of IBEMs and the sustainability of competitive advantage. We use four case studies to trace the pattern of adaptation as well as identify the variables. Based on the inputs from this, we use a comprehensive sample of 135 IBEMs across various geographic regions covering 15 industry segments. The findings of this study provide key managerial insights into various issues that are important to IBEMs in particular and start-up entrepreneurial firms operating in highly dynamic environments in general. These include the stages of evolution and the sources or the lack of competitive advantage at each stage, the type of resources and capabilities, which need to be built, the type of complementary assets, which needs to be leveraged and the degrees of adaptation at various stages.

## 1. Introduction

The Internet is transforming the nature of interorganizational commerce by enabling various types of business-to-business (B2B) transactions. Internet is also having a major impact on the roles of markets [39] [40]. By reducing the search costs of buyers it is facilitating price competition among sellers Bakos [41] [42]. Independent Business to business Internet based Electronic Marketplaces (IBEMs) leverage Internet technologies and standards to distribute product data and to facilitate online-transactions. IBEMs have undergone rapid changes in terms of their market valuations, customers, lines of businesses, mode of service/product delivery, distribution channels as well as their alliances. In high-velocity environments, changes in demand, competition and technology are rapid and information is inaccurate, unavailable or obsolete. IBEMs operate in an industry characterized by all the above factors. From 1998 to 2000, B2B eCommerce grew more than 1000%, and by the second quarter of 2000, however, there were a few hundred marketplaces remaining. An increasing number of independent IBEMs have either expanded their

business models beyond market making, merged with other IBEMs, been acquired, or failed outright. They have also adapted and evolved into new forms. Thus we can see that the IBEMs operate in a highly competitive, dynamic, entrepreneurial and innovative environment and hence their adaptation capabilities will determine which organization will survive. Organisations operating in stable environments can adapt gradually through continuous incremental change whereas those operating in highly dynamics environments such as IBEMs, need to adapt and evolve very fast to create and sustain competitive advantage. Studying the adaptation and evolution of industries, which operate in such environments would give us valuable inputs on current/future industries operating on similar environments. The adaptive behavior of IBEMs is important due to their vulnerability to competition as they have limited cash reserves and debt capacity, over-dependence on a limited product/service line, relatively limited market presence, significant demand fluctuations and aggressive competition.

Adaptation is likely to occur in different degrees and different ways depending on where an organization is in its life cycle. In start-up entrepreneurial ventures (most IBEMs fall in this category), adaptation is critical than at any other stage in the life cycle. In such firms the products/services, customers, and marketing approaches not well established and there is also a high degree of environmental changes. Hence it would be useful to understand the adaptation and evolution of IBEMs. In this paper, we attempt to answer the following questions:

- How do IBEMs evolve and what are the stages in the adaptation of IBEMs?
- What are the key resources, capabilities and complementary assets of IBEMs at each stage of their evolution?
- What are the adaptive strategies pursued by IBEMs to leverage resources and capabilities
- Can IBEMs develop long-term competitive advantage using their internal resources and capabilities?

## 2. IBEMs: Taxonomy and organizational perspectives

The IBEMs offer services such as buyer/supplier and product/services searching, transactions such as procurement, asset disposal etc. IBEM act as Market Makers whose primary roles are to match buyers and sellers, broker deals, and facilitate transactions. Market

makers perform four basic functions such as price setting, coordinating exchange, market clearing and allocating goods and services [38]. IBEMs differ from the traditional marketplaces as they offer increased personalization and customization of product offerings, and aggregation and disaggregation of information-based product components to match customer needs.

There are various ways of classifying business-to-business marketplaces. For this research we are classifying them into public, private and consortia marketplaces. Our research focuses on public marketplaces.

*Public Marketplace:* A public marketplace, also known as neutral marketplace or third-party marketplace brings together buyers and sellers within a particular industry for the purpose of commerce. It provides content, value-added services and transaction capabilities e.g. Freemarkets. *Private Marketplace:* Private marketplaces are owned and operated by a one company to transact with a select group of suppliers. They have the potential to provide high performance and tight integration with current suppliers. Examples of enterprises that have private marketplaces include: Wal-Mart, Dell, Sun Microsystems, Amtrak, and Cisco.

*Consortia Marketplace:* Consortia marketplaces are jointly owned by several large enterprises that deploy applications and infrastructure to facilitate collaboration and conduct business among trading partners. They are highly customized and integrated with the process of its founders. They also require a large investment and have long implementation schedules.

### 3. Theoretical Framework

Research on the evolution of firms has been carried out within theoretical streams such as industrial economics, strategic management and organization theory. Some of the studies have identified multiple stages or phases of firm evolution [1] [2] [3] [4] [5] [6]. Other studies have analyzed the impact of internal factors such as resources and capabilities, organizational structure, strategy, top management team characteristics and external factors such as market structure, competition and government regulations on firm growth and survival [7] [8]. There are also studies, which draw parallels to the neo-Darwinian theory of evolution in Biology [9] [10] [11]. Adaptation strategy concerns specific ways in which the firm makes adjustments, as it seeks to survive and capitalize on external circumstances. Such adjustments can be made in a variety of product, market and resource management areas [15] such as a broader product mix, new product development, exploration of new markets and market segments, speed of response, outsourcing and resource leveraging, formation of strategic alliances etc. Organizations operating in highly competitive environments rely on strategies that are more adaptive [12] [13] as the success of a concept and a business is a function of appropriate and timely adaptation of the concept over time. However, the degrees of adaptation

that occur, and the outcomes of this adaptation, are likely to vary considerably as a function of a variety of factors [21].

The catalysts of adaptation may be internal or external. The internal catalysts could be short or long term goals. The external catalysts could be structural factors of resource dependence, or industry-based factors. Organizational punctuated equilibrium model can be used to analyse resources changes in growing ventures. We can also integrate this model with the Resource-Based Theory of the firm, by suggesting that each stage of organizational growth can be represented as a distinct configuration of resources being built by the firm to achieve competitive advantage. See *Figure 1* for a diagrammatic representation of the process of resource configurations.

A key aspect of evolution is adaptive capability to the changing environment and adaptation is an important aspect in organizational evolution. Evolution is driven by the process of interactions between organization and the environment, learning behavior, and the survival/growth strategies in different environments. Product Life Cycle models have been used to trace the product as well as organizational evolution [16] [17] [18] [19] [20]. Industries have witnessed an initial large number of competitors and later experienced a shakeout decreasing the producers. This phenomenon is common in manufacturing industries such as automobiles where many often the number of producers reduced by 50% or more during the formative times [16] [21].

The resource-based view of the firm [22] [23] [24] [25] [26] [27] [28] suggests that differences in firm performance are primarily the result of resource heterogeneity across firms. Firms that are able to accumulate resources and capabilities that are rare, valuable, nonsubstitutable, and imperfectly imitable will achieve an advantage over competitors [22] [24] [26]. Resources can be divided into physical, human, and organizational assets [23]. Capabilities are capacities to deploy resources, usually in combination, to effect a desired end [29]. Dynamic capabilities [30] is an extension of RBV approach. It explores how valuable resource positions are built and acquired over time. Dynamic capabilities are rooted in a firm's managerial and organizational processes, such as those aimed at coordination, integration, reconfiguration, or transformation [43] [44], or learning [45]. Applying the RBV facilitates a better understanding of the nature of competitive threats as it would help to identifying resources critical to gaining and sustaining a competitive advantage.

In many cases a firm's ability to commercialize an innovation may require that its internal resources be utilized in conjunction with the complementary resources of another firm. Complementary resource endowments have been noted as a key factor driving returns from alliances [46] [47] [48] [49] [50]. In the context of IBEMs complementary assets can be defined as assets that are required to gain competitive advantage from the

implementation of best marketplace practices. A new entrant wishing to duplicate them would be facing significant entry barriers including high capital costs, scale economics and learning. New businesses such as IBEMs may not be able to develop all their resources and capabilities internally and therefore it is critical to address the issue of the influence of complementary assets on the adaptation of IBEMs.

## 4. Research Design and Methodology

The study adopted two methodologies across two phases. First phase involves the usage of the case study method and the second phase adopts the case survey methodology.

### 4.1 Case Study

Adaptation is a dynamic activity that unfolds over time and hence we have adopted a case research methodology, aimed to more accurately capture the nature and degree of specific changes as they are made. Moreover the factors influencing organizational processes often include path dependencies that are cumulative and historically conditioned. Hence the research design was longitudinal in nature and was designed to enable the multiplicity of factors that may have shaped the processes. The case study strategy is particularly helpful in situations of a “phenomenon in the making” to gain novel and rich insights [73]. These are situations where there are few theoretical foundations and exact measures for the key variables. In-depth interviews were conducted and the study adopted a multi case design to allow for replication logic. To overcome the weaknesses of this approach such as the difficulty of generalizing individual case studies, multiple case studies were used.

A non-probabilistic sampling method was favoured as generalization in a statistical sense was not one of the objectives. We chose a sample from which the maximum can be learned. The following criteria were used to choose firms for case study:

- Firm is a business-to-business market maker
- Derive at least 30% of their revenues through transactions facilitated through the Internet
- Use the Internet as a key mode of delivery of their services

We chose four Indian IBEMs, which met the above criteria. (See *Table 1* for a brief description of the firms).

#### 4.1.1 Data and Analysis

Data was collected through semi-structured interviews with the CEOs, CIOs, CFOs, Vice Presidents, as well as the Managers of the IBEMs. Interviews lasted from one to four hours and an interview guide was used to avoid losing focus and to ensure that all relevant questions were asked. Questions were both closed and open-ended. Respondents were thus given the opportunity to express their thoughts on the topic of interest as freely as possible. Based on the responses, the resources and capabilities

were classified under various categories and their adaptation measures were identified (See *Table 2*).

## 4.2 Case Survey

Based on the variables captured through the above method, we conducted a Case Survey [74] [75] [76] [77] of firms based in the US, Europe, South America, Canada and Asia Pacific. Case surveys bridge the gap between surveys and case studies to combine their respective benefits of generalizable, cross-sectional analysis and in-depth, processual analysis [77].

The criteria used to choose firms for the case survey was the same as that used for the case study. For our case survey, we had a list of 135 IBEMs from across the world and data coding was carried out based on information from sources such as information from company annual reports, SEC filings, research reports, published cases, academic papers and various other sources. In addition we extensively used the WayBack Machine of The Internet Archive ([www.archive.org](http://www.archive.org)). Questions were closed ended to facilitate statistical analysis. Diverse sources of data were used as they offer multiple points of analysis into the phenomenon of interest. In addition to this, the questionnaires were emailed all the IBEMs used for the case survey. We received 37 responses and they were used to test the validity of the methodology.

### 4.2.1 Data and Analysis

The closed-ended questionnaire had 32 questions across sections such as Business Model, Customers, Environmental Characteristics, Resources and Capabilities, Alliances & Complementary Assets and Products and Services. Two raters were used to fill the questionnaire for two random samples of 25 firms across the years. Both the raters were trained in management (MBA and above). The correlation of the scores between the author's ratings and the first rater was found to be .9 and the second rater was found to be .93. Since the inter-rater correlations were high, the reliability of the author's ratings was judged to be good. Ratings were identical for 1035 out of 1150 responses between the author's and the first rater and 1070 out of 1150 between the author's and the second rater. The correlation between the author's ratings and the responses from the firm responses was found to be .94 and was also judged good. In this case the ratings were identical for 1600 out of 1702 between the author's and the firms. Based on all the responses and the ratings of the raters, the adaptation scores were calculated for all the factors (See *Figure 2*).

From the figure we can see that for almost all the factors, the adaptation scores are increasing over the years. Adaptation scores for factors such as Strategy and Vision seems to be decreasing for the year 2002, which can be attributed to the reduction in competition.

## 5. Proposed Framework

The three-stage framework proposes that firms rely on continuous adaptation to regenerate competitive advantage under conditions of rapid change. This is achieved by adapting their existing resources and capabilities, acquiring new resources and capabilities and accessing complementary resources and capabilities through alliances. Firms change what they are and what they offer through the continuous adaptation process and hence they need to regenerate competitive advantage relative to the new competitors they encounter in these domains. The adaptation and evolution of IBEMs could be described in terms of the following 3 stages: *Aggregation, Dynamic Transactions & VAS and Integration & Collaboration* (See Figure 3 for the proposed framework).

### 5.1 Stage 1: Aggregation

In this stage, the main purpose of IBEMs is to reduce transaction costs, bring together buyers and sellers as well as facilitate price discovery. They brought together buyers and sellers over a static transaction platform and there were no dynamic transactions. They had limited financial resources and limited organizational, technological as well as managerial capabilities. The key resources identified in this stage are technological resources, information based resources and financial resources. The key capabilities during this stage were technological and managerial (Sales and marketing, Strategic relationships with Venture Capitalists). Technological capabilities were difficult to obtain as there was a mismatch between the supply of capable people with the required technological capabilities and their demand. Hence all the firms had an ongoing recruitment program. Technological development activities for the web site and the new version of the technology were also considered important by all the firms. Sales and marketing abilities were considered important as this was a new business opportunity and the awareness levels of the customers was very low. Development and maintenance of critical strategic relationships with Venture Capitalists was a key capability and they considered the degree of interest of the Venture Capitalists could make or break their firms. All the firms considered the competition at this stage to be extremely high. (See Table 3 for the Resource Changes across the stages). Propositions one to six can be arrived from the above discussion.

*P<sub>1</sub> In the aggregation stage, IBEMs are at a competitive disadvantage as there are no factors, which differentiate them from the competition*

*P<sub>2</sub> The technological resources and capabilities of IBEMs built in the aggregation stage offers only short-term competitive advantage and are prone to imitation and substitution*

*P<sub>3</sub> In the aggregation stage, first mover IBEMs have marginal competitive advantage*

*P<sub>4</sub> In IBEMs, technological resources alone do not explain the significant performance variation among firms*

*P<sub>5</sub> For IBEMs, managerial, technological and organizational capabilities satisfy the resource-based criteria for being valuable, rare, inimitable and non-substitutable as they are strongly firm specific and path-dependent*

*P<sub>6</sub> In IBEMs, managerial, technological and organizational capabilities complementary to technological resources explain the significant performance variation between them*

### 5.2 Stage 2: Dynamic Transactions and Value Added Services (VAS)

Between Stage 1 and 2, there was a high degree of adaptation (D=4). A new way of delivering the services was being explored and strategic initiatives were started to access complementary assets. The IBEMs were in the process of delivering dynamic transactions and value added services. Most important characteristic of Stage 2 was the low transaction volume and the inability to achieve the critical mass of transactions (the number transactions required to achieve break-even). "We were a long way from the number of transactions required to achieve critical mass and we were running out of cash", acknowledged the CFO of Company 3. The companies were also increasing Organizational capabilities around their core technology. For example, the dynamic transactions required an entirely new set of capabilities. The IBEMs started facilitating dynamic transactions through mechanisms such as auctions and reverse auctions. They entered into alliances with partner firms to access complementary assets. Value added services (VAS) are defined as services, which supplement the actual transaction, cataloguing and search capability. The main VAS includes financial services, logistics services, analytics services, inspection, and settlement of disputes. Among these, the two most important services are credit & payment and logistics services. The IBEMs also considered order fulfillment and financial settlement as two key areas of differentiation. The importance of having financial services arises from the fact that B2B marketplaces must offer a trusted environment, because the parties do not necessarily have previous relationships and have therefore not built up any trust between them. This brings us to propositions seven and eight.

*P<sub>7</sub> In the dynamic transaction & value added services stages, first movers IBEMs have marginal competitive advantage*

*P<sub>8</sub> IBEMs access complementary assets, as the time window during which they need to succeed in commercializing their products and services is very short*

### 5.3 Stage 3: Integration & Collaboration

A major punctuated shift (the dot com bust) occurred between Stage 2 and 3. In this stage, the degree of adaptation was very high ( $D=5$ ). Most of the firms at this stage were putting on hold their expansion plans and were restructuring, downsizing and retrenching. In all the companies a number of people were laid off and the basic orientation of the company was redesigned. After that, the resources that emerge remained constant through the following three data collection phases. In Stages 2 and 3, long term contracting and service delivery became salient, in contrast to the previous focus on sales and marketing. The companies were also shifting towards services, which assured more returns such as Consulting. The knowledge base in the companies went through a lot of changes due to the lay offs as most of the firms lost about a quarter of their employees. Also as the new consulting contracts expanded, the planning and strategy formation functions became more formal. Development and maintenance of critical strategic relationships with key partners and customers was a key capability as most of the IBEMs had still not achieved the critical mass of transactions.

The IBEMs started integrating their products/services with those of their customers and thereby build switching costs. This is the stage wherein managerial, organizational or technological capabilities give the firm scope to create competitive advantage. To facilitate integration and collaboration, the IBEMs were developing competencies such as data mapping repositories including XML document exchange formats and trading partner agreements which will allow the customers to switch from one market to the other at any time. Integration also involves modeling, automating, and integrating business processes and trading relationships between partners. Integration of information refers to the sharing of information among participants of the IBEM such as buyers and suppliers. This includes data such as inventory data, demand data, capacity plans, production schedules, promotion plans, and shipment schedules. What characterizes this stage is their ability to achieve sustained competitive advantage by exploiting stage 1 and stage 2 activities. Whereas stage 2 activities involve the ability to invent and enter into alliances and exploit the same, stage 3 activities involves the ability to create interorganizational processes. This brings us to proposition nine.

*P<sub>9</sub>In the integration and collaboration stage, IBEMs have scope to create sustainable competitive advantage as they are able generate lock-in effects by integrating with the processes of its partners*

## 6. Conclusion & Future Research Directions

Figures and tables should be placed as close as possible to where they are cited. Captions should be Times 10-point boldface. Figures and tables must be numbered separately. Figure's captions should be centered below the

figures, and Table captions should be centered above the table body. Initially capitalize only the first word of each caption.

The framework aims to capture the types of resources and capabilities as well as complementary assets, which were leveraged by IBEMs at various stages and their adaptation. The framework has the advantage that its sequential mode of analysis allows to identify precisely where and at what stage the firm has built its resources and capabilities and what is their adaptation process. It is not necessary that all IBEMs must pass through all stages or must pass through the stages one at a time. Many firms do not reach stage 3 or even stage 2, and most firms contain activities that are at more than one stage. The activities at the three different stages of development of the firm are supported by different types of internal and external resources and capabilities. Thus, resources that support the stage 3 activities may be different from the type of resources that support stage 1 or 2 activities. Whereas important stage 2 resources may be complementary assets, the important stage 3 resources are managerial, organizational or technological capabilities. Moreover managerial and organizational capabilities may better satisfy the basic resource-based criteria for being rare, valuable, costly to imitate, etc. This is so because they are more likely to be strongly firm specific and hence difficult to imitate. This is due to them being internally accumulated through path-dependent processes of change. Thus, in this way the analysis of firm adaptation, the analysis of resources and capabilities as well as the analysis of sustainability of competitive advantage are merged. In order to survive and maximize economic gains, an IBEM has to reach the Integration stage. Although the IBEMs in the value added services stage have marginal competitive advantage, they can rarely demand premium for their services. On the other hand, IBEMs in the Integration stage maximize economic gains by creating stable interorganisational processes. This research contributes to a growing body of research seeking to understand the determinants of organizational ability to adapt and gain competitive advantage in new competitive and high-velocity environments by leveraging the right resources and capabilities and complementary assets. One of the important implications of our framework is that competitive advantage is associated with a process of ongoing renewal and access to resources and capabilities rather than with a favorable position in an attractive industry. Future research could be in terms of the context in which these IBEMs are operating and whether IBEMs operating in different countries or IBEMs targeting different industries show a distinct pattern of adaptation and evolution.

**Figure 1: Process of Resource Configurations**

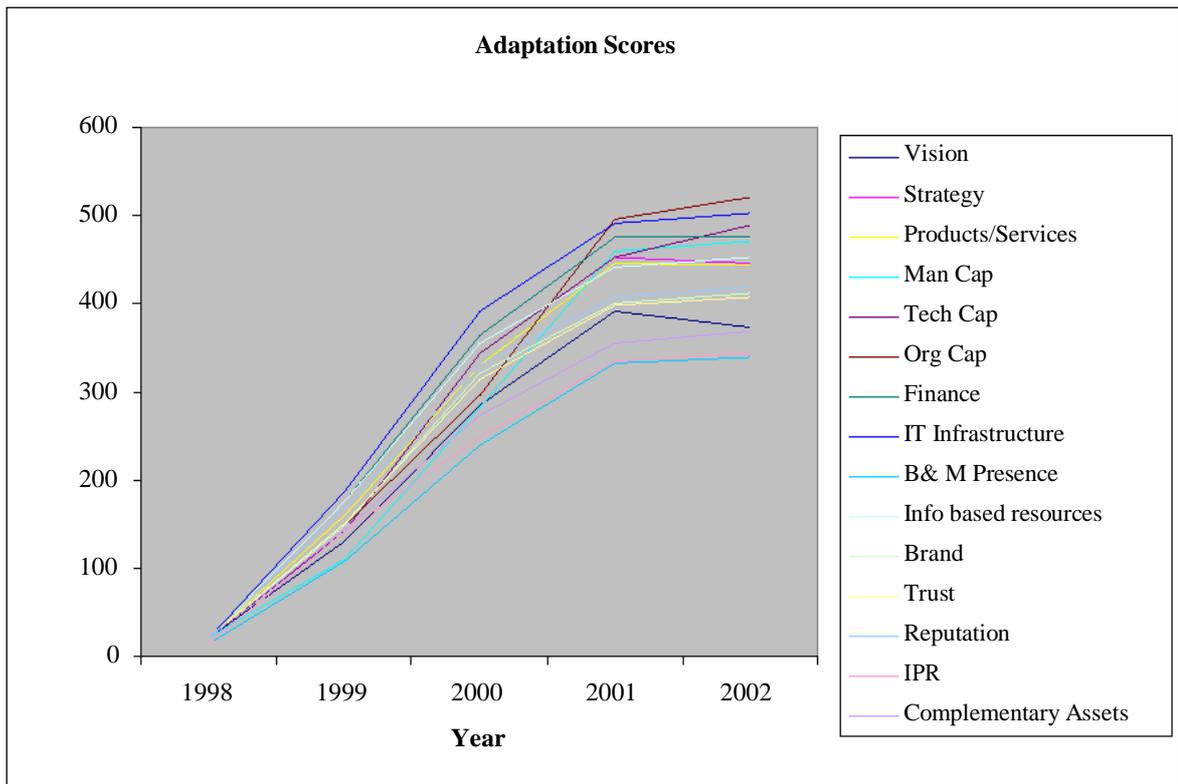

**Table 1: Brief Description of the firms used for case study**

Company description	State of adaptation	Degree of adaptation (D)
<b>Company 1</b> Business-to-business auction site targeted at industrial assets. Service launched in August 1999 No. Of employees: 40	Aggregation & static transactions (Mid to late 1999) Dynamic Transactions & VAS (2000) Integration & Collaboration (2001)	High (D=4) Between #1 & #2 Very High (D = 5) Between #2 & #3 Medium (D = 4) Current Stage
<b>Company 2</b> e-Procurement Services provider, also offers market-making services. Service launched in September 2000 No. Of employees: 63	Aggregation & static transactions (End 2000 to mid 2001) Dynamic Transactions & VAS (II half of 2001 to present) Integration & Collaboration (2001 to present)	High (D = 4) Between #1 & #2 Very High (D=5) Between #2 & #3 High (D=4) Current Stage
<b>Company 3</b> Business-to-business marketplace offering company specific Private Marketplaces The service was launched in 2000 No. Of employees: 25	Aggregation & static transactions (End of 1999 onwards) Dynamic Transactions & VAS (End of 1999 onwards)	High (D = 4) Between #1 & #2 Medium (D = 3)
<b>Company 4</b> Procurement and Asset Disposal Exchange The service was launched in 1998 No. Of employees: 70	Aggregation (End of 1999 onwards) Dynamic Transactions & VAS (2000 Onwards) Integration & Collaboration (2001 onwards)	High (D = 4) Between #1 & #2 Very High (D=5) Between #2 & #3 High (D=4)

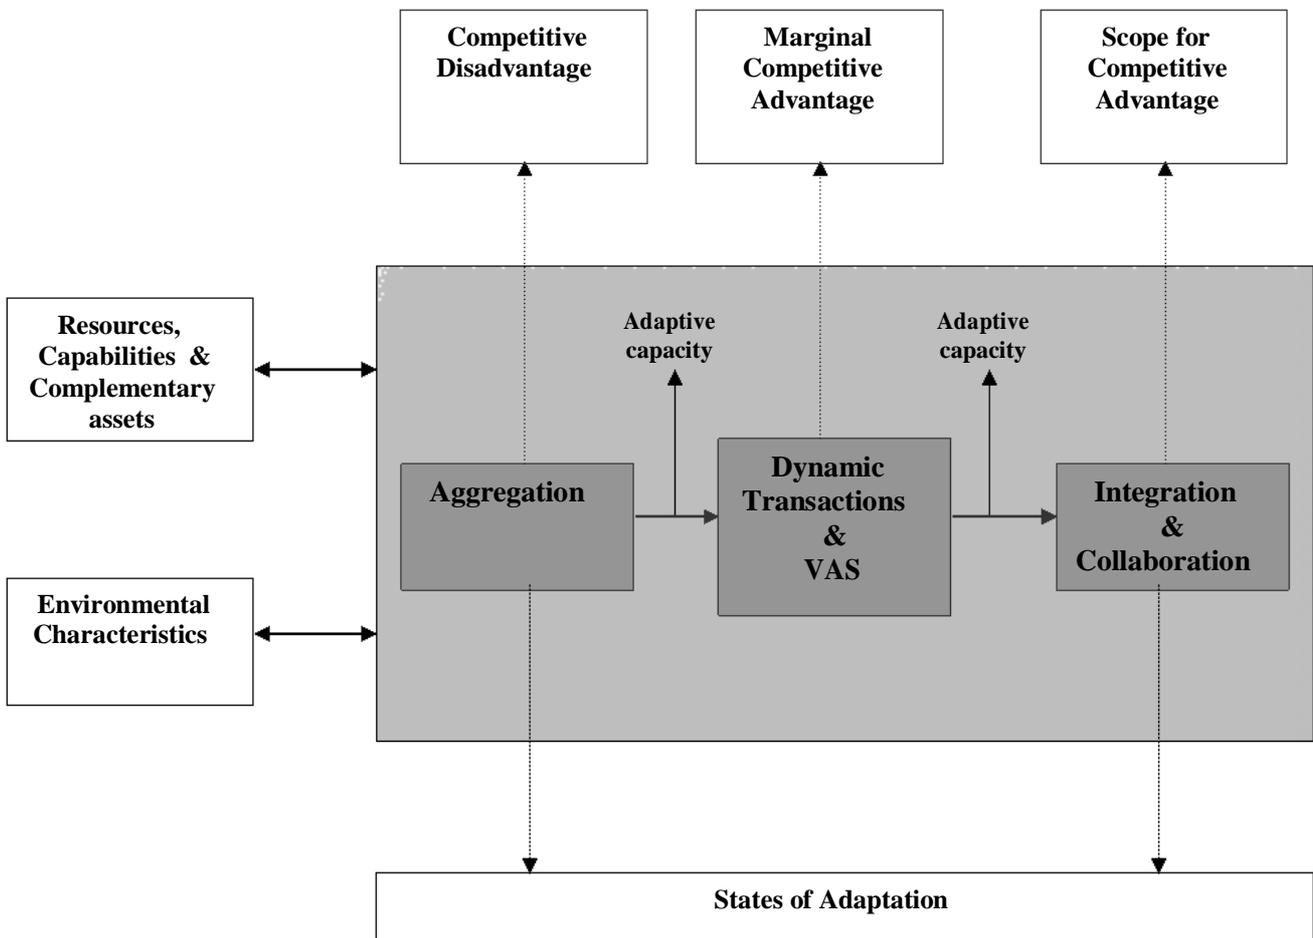

**Table 2: Type of Resources and Capabilities and their Adaptation measures**

<b>Resource &amp; Capabilities</b>	<b>Example</b>	<b>Adaptation measures</b>
<b>IT Infrastructure</b>	Web servers, PCs, System software, Databases, Data Mining, Data Warehousing, Routers etc.	◦ Has the firm developed or added to the existing IT Infrastructure?
<b>Information based resources</b>	Buyer and seller databases, catalogs etc.	◦ Has the firm developed or added to the existing Information based resources?
<b>Financial Resources</b>	Firm's ability to generate internal funds, borrowing capacity and its market value	◦ Has the firm accessed new sources of capital?
<b>Brick &amp; Mortar Assets</b>	Land, buildings and location	◦ Has the firm developed or added to the existing B&M assets?
<b>Intellectual Property Rights</b>	Patents, trademarks, copyrights etc.	◦ Has the firm developed or added to the existing IPR?
<b>Reputation</b>	Reputation with customers, suppliers, government agencies, competitors and partners	◦ Has the firm made investments to improve its reputation?
<b>Trust</b>	Confidence in the firm's quality of service, privacy and security policies	◦ Has the firm made initiatives to improve trust?
<b>Brand</b>	Distinctive product, service, or concept	◦ Has the firm made investments to promote its brand?
<b>Complementary Assets</b>	Logistics, insurance, credit, payment, rating etc.	◦ Has the firm developed or added to the existing Complementary Assets?
<b>Managerial Capabilities</b>	Knowledge, experience, account and transaction management, end user training, domain knowledge, marketing capabilities	◦ Has the firm recruited/retrained personnel, made changes to its key personnel etc.?
<b>Technological capabilities</b>	Software design, development, testing, working across multiple platforms, integration, customisation, and database management	◦ Has the firm introduced a new product /service or a new version of the existing product/service, developed new technological capabilities etc. ?
<b>Organisational capabilities</b>	Reporting structures, organization culture, innovation, responsiveness, management of alliances, training programs, R&D, knowledge creation, innovation and organizational learning	◦ Has the firm made changes to its organizational structure, entered into alliances, invested in new R&D projects etc?

# Using Association Rule Techniques to Improve Document Retrieval

Timon C. Du, Jacqueline Wong, and Honglei Li  
Department of Decision Sciences and Managerial Economics  
The Chinese University of Hong Kong

## Abstract

Document management is one of the fastest growing areas of information management. Most conventional approaches assign keywords to documents so that documents can also be retrieved through keywords. The management of data and documents are different. For example, documents have to be appeared in the full contents unlike the selected attributes are retrieved in the data queries. Also, the documents may not relevant even the values of specified attributes are identical. Moreover, documents may be related even they do not have the same keyword value. This study uses an associated knowledge rule algorithm, revised from Apriori algorithm, and classification scheme to discover the relationship between keywords of documents. The proposed algorithm can retrieve related documents without matching specified keywords in users' queries.

## 1. Introduction

Document management is one of the fastest growing areas of knowledge management. The end-user today is involved in saving, searching, scanning, routing, and revising documents, as well as choosing a system. According to O'Mears, a dynamic and intelligent document system is needed in order to resolve the challenging business environment and support decision making of good quality [1].

Document management merges with knowledge management at the level of the enterprise. Generally speaking, organizational knowledge system delivers the right knowledge to the right person at the right time in the right format to enable the right action [2]. Therefore, the role of conventional database administrators has been changed into knowledge administrators. The knowledge administrators manage not only the data but also the knowledge. The management of data and documents are not exactly the same, although both of them can be managed by relational database. To manage documents, several keywords are chosen for each document beforehand. The keywords are maintained by relational database. When users query document by specifying keywords. The system maps the specified keywords with documents, and the documents with matching keywords will be retrieved. Like database, knowledge management has its own terminology, ontologies, which define the shared vocabulary used in the knowledge management system to facilitate communication, search, storage, and

representation [6]. However, the management of data and documents are different. For example, the document has to be appeared in the full contents unlike the selected attributes in the data queries. Also, the documents may not relevant even the values of specified attributes are identical. Moreover, documents may be related even they do not have the same keyword value. This study will propose an algorithm, called associated knowledge rule algorithm, to discover the association of keywords. So that when documents are extracted from database, some related documents would also be retrieved according to the association rule even the related documents do not contain the specified keywords. This can improve the retrieving process for transactions.

## 2. Data Mining And Document Classification

### 2.1 Data Mining

Data mining, also called knowledge discovery, is a technology of finding information from data. With the universal usage of computers more data and documents are accumulated in the database. And then, data mining techniques become a useful tool to discover the knowledge from database. There are three types of data mining problems: classification problems, association problems, and sequences problems. The classification problems group the data into clusters while association problems discover the relationship between data. The sequence problems focus on the apparent sequence of data [3]. For solving these problems, there are several well-known data mining techniques, such as classification rules, discriminant rules, clustering analysis, characteristic rules, association rules, sequences search, and mining path traversal [4]. Other than that, machine-learning approaches are also being adopted. The examples include neural network, genetic algorithm, simulated annealing [5].

This research will use the association rule approach to demonstrate the characteristics of managing documents. Several famous algorithms of the association rule approach are: Apriori [3], DHP (Dynamic Hash Pruning) [4], AIS (Agrawal, Imielinski and Swami) [7], Parallel Algorithms [8], DMA (Distributed Mining of Association Rules) [9], SETM (Set-Oriented Mining) [10], and PARTITION [11]. Since the Apriori is the most illustrious, it will be used in this study. Basically, the Apriori algorithm generates higher-level of strong related entities (documents in this study) from lower-level strong related entities. It first scans database and produces single

entities from the very primal data (transaction database in this study) and select candidate entities according to the requirement of predefined support in the first round. The support is a constant to indicate the frequencies of the occurring patterns in the data set [4]. Only the entities have larger frequencies than the support value can be considered as strong related entities. And then it will produce a table of 2-entity sets in the second round based on the strong related entities of the first round. The process is repeated until different levels strong related entities are completed obtained. The association rules are acquired from different levels of strong related entities. There are several researches dedicated to improve the efficiency of the algorithm. For example, DHP [12] use a hashed table to filter the candidate entities in each round and reduce the time of counting the support of each round.

## 2.2 Classification Scheme

Due to advances in storage technology, large-scale full-text retrieval systems are available at a reasonable price. The database therefore maintains not only pure data but also full-text documents. The system accepts user search queries toward both data and documents. One way to organize a document database for a full-text retrieval system is to classify a document under one or more *classes* according to the topical domains that the document discusses. This is commonly referred to as *classification*. Traditionally, classification is done by human classifiers and therefore is slow to update and operate. Also, the classification results are highly dependent on the subjective opinions and experience of a human classifier. Fortunately, automatic classification attempts to replace human classifiers by having computers to analyze the content of a document and to assign the document to the appropriate class or classes. Automatic classification has two major components: classification scheme and classification algorithm. The classification scheme defines the available classes under which a document can be classified and their inter-relationships can be specified. On the other hand the classification algorithm defines the rules and procedures for assigning a document to one or more classes defined in the classification scheme.

Most of time the classification is based on keyword subjects of documents or system vocabulary. The keywords are normally the key terms of documents while the system vocabulary consists of subject thesaurus. Most computer systems adopt both the controlled vocabulary and keywords as the subject terms to represent the documents. Moreover, information such as author's name, date of publication, and language can also be used for searching. The indexed documents are kept in the document storage while the document representations—that is, surrogates such as keywords, vocabulary, and so forth—are used for matching. Both the documents and surrogates are stored in the database for future searches. Using this approach, the retrieval process

will be very efficient.

## 3. Using Association Rules to Discover Knowledge

This study argues that discovering knowledge from documents is different from data in the following ways:

1. The document has to be appeared in the full contents unlike the selected attributes in the data queries.
2. The documents may not relevant even the values of specified attributes are identical. For example, two documents having value of *virus* in a keyword attribute do not mean that they are in the same category. In fact, one document may belong to computer science and the other can be an article published by Department of Health.
3. Both SQL keywords search and full-text browsing can be used to search documents.
4. The Boolean operation can be used to filter the queried documents in exact match, but is not appropriate for mapping to related terms.
5. The association rule can be used to discover the documents even without specified keywords. Referring the classification scheme as described in session 2 can do this.
6. The classification scheme can be updated by association rules.

Section 3.1 describes the framework of this study while using Apriori algorithm is presented in session 3.2. An algorithm for applying association rule is discussed in session 3.3.

### 3.1 The Framework of Document Knowledge Discovery

Most of current system maintains documents in the relational database. The documents are allowed to assign numeric keywords and the keywords are used to retrieve documents. The keywords of documents are constructed into relations of relational database in the keyword database. The users type-in segmented words as anchored to query documents. During query processing, Boolean operation can be further used to limit the query results queried by the segmented words. However, the conventional approach cannot retrieve a document without specified keywords. This is why association rule technique can improve the knowledge discovery of documents. The association rule identifies the occurrences of entities and discovers the relationship between entities. The Apriori algorithm of association rule techniques analyzes the transactions and determines the strong related entities. However, as will be shown in the example of session 4, some irrelevant documents may be erroneously identified. For example, the virus can infect both human and computers. But, it will be considered as two different subjects if we are discussing about virus infection. In this case, the classification scheme is used to recognize the

subjects of keywords. The keywords are classified into different subjects classes in the classification scheme. The entities belonged to different subjects should not be retrieved as the related document. That is, the classification scheme can distinguish the difference between computer virus and virus disease. Then, the association rule is memorized as associated knowledge rules. Therefore, combining both associated knowledge rules and classification scheme, the documents having matched keywords and related words will be returned to users.

### 3.2 Mining Association rules and Apriori algorithm

Given a knowledge database, the association rules search for the relations between ontologies (keywords of documents) such that the presence of some ontologies will imply the presence of other ontologies when the same knowledge (document) are retrieved. Let  $K = \{k_{11}, k_{12}, \dots, k_{1n}, k_{21}, k_{22}, \dots, k_{nm}\}$  as the set of ontologies. Let  $D_i$  of  $D$  be a set of retrieved objects where  $K_{ij} \subseteq D_i$ . Each transaction  $t_i$  in  $T$  is represented as a set of ontologies such that  $T \subseteq D$ . Let  $A$  be a set of objects and a transaction  $t_i$  is said to contain  $A$  if and only if  $A \subseteq T$ . Also, let  $X$  be a set of ontologies and a transaction  $t_i$  is said to contain  $X$  if and only if  $X \subseteq T$ . An association rule is an implication of the form  $X \Rightarrow Y$ , where  $X \subseteq T$ ,  $Y \subseteq T$ , and  $X \cap Y = \emptyset$ . The rule  $X \Rightarrow Y$  holds in the transaction set  $T$  with confidence  $c$  if  $c\%$  of retrieves in  $T$  that contain  $X$  also contain  $Y$ . The rule  $X \Rightarrow Y$  has support  $s$  in the transaction set  $T$  if  $s\%$  of transactions in  $T$  contain  $X \cup Y$ . Note that the confidence denotes the strength of implication and the support indicate the occurring patterns in the rule [4]. Apriori algorithm scans the transaction database and counts the occurrences each entity and generates a 1-level document relationship. Then the occurrences are filtered by the predefined support. Then it generates 2-level documents according to the Cartesian product  $L_k * L_k \subseteq I_i \cup I_j \mid I_i, I_j \subseteq L_k, \mid I_i \cup I_j \mid \subseteq k \subseteq I$ , where  $k$  is the entities level,  $L_k$  is the strong entities of the  $k$  level and  $I_i, I_j$  are the entities of  $L_k$ . Then it filters 2-level entities according to the predefined support.

### 3.3 Associated Knowledge Rules

The associated knowledge rules are obtained from applying the association rule technique toward both the document database and transaction database. The Apriori algorithm of the association rule techniques is adopted in this study. This algorithm evaluates the occurrences of entities (documents) and only the occurrences over the predetermined support value will be adopted. The support value specifies the minimum strongly level of entity relationship. The Apriori algorithm begins with finding the

occurrence of one entity and then reaches occurrence of higher levels entity. To simplify the problem illustration, the algorithm of associated knowledge rules only adopts 2-entity generation. The higher degree can be implemented in the similar manner.

## 5. Conclusion

This study revised the Apriori algorithm of association rules into an associated knowledge rule algorithm. The algorithm can discover the relationship between keywords of documents. By using both the associated knowledge rules and classification scheme, the related documents without specified keywords can also be retrieved.

# Peer-to-Peer Knowledge Management: Overcoming Bottlenecks and Improving Information Quality

Andreas Neus   Philipp Scherf

IBM Unternehmensberatung GmbH

Hamburg, Germany

{andreas.neus, philipp.scherf}@de.ibm.com

## Abstract

Access to current, complete and relevant knowledge is a key competitive differentiator in the present economic market space. But most knowledge management today only shifts the traditional, expert-based KM processes onto electronic media. This paper discusses a paradigm shift from an expert-centric to a peer-to-peer approach to knowledge creation and management. Leveraging the lowered transaction costs provided by Internet technology, methods and tools of collaboration that have been invented and refined by the Open Source and Free Software community over the last two decades are now being adopted by early movers in the Knowledge Management space. This new approach, based on a peer-to-peer approach and open collaboration, has shown the potential to revolutionize the way knowledge is created, developed and managed. We outline the characteristics of the two opposing paradigms and present ways in which the peer-to-peer knowledge management approach is already being successfully used in practice today. We address how the quality of information is kept high without a traditional review/quality-check role by using a revision control system and distributing the task to all interested practitioners. Finally, we discuss four key challenges for introducing the new paradigm within companies.

## 1. Introduction

“Science is the belief in the ignorance of experts.”  
(Richard P. Feynman, Nobel Laureate, Physics [4])

Several upheavals in the competitive landscapes in recent years have demonstrated that a defining characteristic of electronic business is the disruption of both current market equilibriums and current economic models by technology radically lowering transaction costs.[2] Phenomena like peer-to-peer file-sharing, networks such as Napster and Gnutella [12], or the success of Open Source software such as Linux (an “impossible public good” according to traditional economic theory) [16] [10] prove that the Internet radically changes the way we communicate and collaborate by reducing the cost associated with communication and collaboration

This paper discusses how a paradigm shift from an expert-centric to a peer-to-peer approach to knowledge creation and management has been enabled by using concepts, tools and methods developed in the open source and free software community over the last two decades.

Information today is mostly created, quality-controlled and disseminated in a closed, centralized fashion with a clear distinction between producers and consumers – just like software used to be.

Yet several high-profile initiatives using a peer-based, open source approach to collaboratively create and develop knowledge have already been launched, mainly in academic, educational and research environments (i.e. MIT OpenCourseWare, Harvard OpenLaw, Wikipedia [9] [5] [17]).

While these environments are obviously conducive to such an open model (with the scientific principle based on openly publishing results to enable replication and peer-review) this new approach can also be used inside a commercial organization that is challenged with a need to rapidly develop, update and share information. It is especially applicable when the knowledge about an issue is not (yet) a solid, coherent, structured body of information that can be easily taught, but rather still an evolving system of bits and pieces of knowledge, that has yet to reach maturity. Some people would argue that with the world around us growing more complex and changing ever faster, most of the knowledge fits the latter description.

Knowledge with these still “imperfect” characteristics is created, developed and managed in essentially open systems. We will discuss the four key obstacles for the realization of a Peer-to-Peer Knowledge Management system in companies with regard to:

- Information quality
- Issues concerning confidentiality
- The need for transparency and accountability
- The necessity to implement organizational and cultural changes

## 2. Peer-To-Peer Knowledge Management

Presently, the idea of Peer-to-Peer Knowledge Management is mostly a grass-roots movement, much the way the idea of open source software first entered corporations below the radar screen, based purely on its practical utility in solving certain problems.

One problem that has been known for some time is the aging of information both between the creation and initial publication and the “aging” of published information that becomes outdated because the world it describes relates to has changed.

The first challenge, which is especially felt in the rapidly developing fields of knowledge such as

biotechnology or particle physics, has been met by researchers publishing their papers first on pre-print servers, in order to get the information out in time to be relevant. The traditional publication, months later, is more pro-forma, as the active researchers have already read the electronic version. While this process speeds up the time to publication, it does not address the problem of information becoming outdated quickly. A method that has been developed to address this latter problem exists in so-called “Wiki Webs”s [8] for supporting collaborative, peer-to-peer knowledge creation and management, which have been increasingly appearing in research, but also corporate environments over the last few years. (Fig. 1)

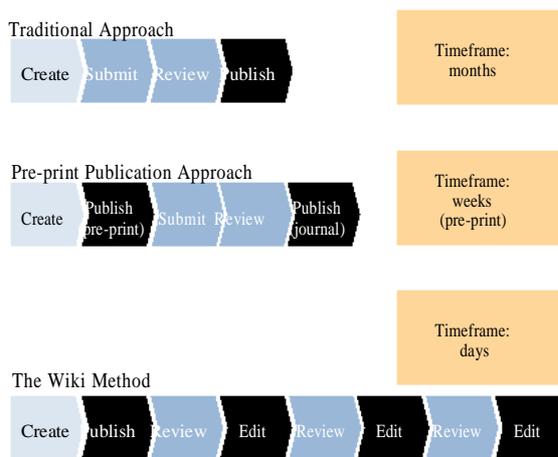

Figure 1: Three approaches to publishing knowledge.

A “Wiki” (Hawaiian for “quick”) is a collaborative knowledge management environment that eliminates the distinction between expert writers and lay readers, producer and consumer of information by making all users information “prosumers”.

In such an open, peer-to-peer context, every user can create and edit information without the bottleneck of a moderator or web-master having to approve or effect the changes. Quality is managed by keeping all changes in a detailed revision control system so that any unappreciated change can be undone by subsequent readers/editors. As an additional disincentive to low-quality contributions, the identity of the author of every change is stored and available to all users.

While such an open approach is certainly not a solution for legally binding or official information, it can be a good, evolving breeding ground for quickly documenting and formulating ideas together.

### 3. Paradigms: Brooks’ Law vs. Linus’ Law

In order to understand the issues connected with implementing such an open, peer-to-peer approach to knowledge management inside a company – and the related tricky organizational challenges – we compare and discuss several aspects of the two competing paradigms. These are exemplified by a number of opposing concepts. (Fig. 2)

Our traditional paradigm of collaborative development, such as Brooks’ Law (named after Frederick P. Brooks, author of “The Mythical Man Month” [1]) can be paraphrased as “Many cooks spoil the broth”. In accordance with this belief, only a small and select circle of designated “experts” should be allowed to create and improve high quality information, relegating the vast majority of practitioners to pure consumers of the information produced by the experts. On the other hand, Linus’ Law, named after Linus Torvalds, a term coined in the context of Open Source development [16], can be paraphrased as “The more, the merrier” and predicts that the more people are involved with (and spend their attention on) an information product, the higher the quality will be.

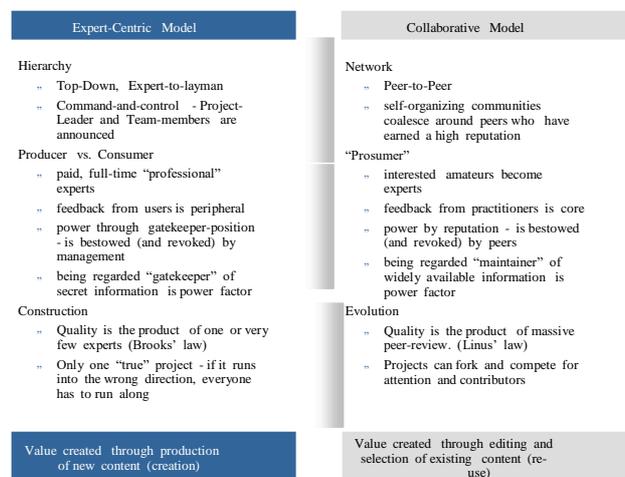

Figure 2: Expert-centric vs. collaborative model

In essence, the traditional, expert-based approach to Knowledge Management is a “construction” or “perfection” approach. Consistent with the high transaction costs for information in previous years, a static, “perfect” document was to be created before the expensive reproduction process and effective publication commenced. However, given the negligible cost of electronic publication, the open, peer-to-peer approach relies on “evolution” or “improvement” over continuing releases rather than initial perfection [11]. Eric Raymond calls this policy “release early, release often” in his famous essay The Cathedral and the Bazaar [14].

In the context of knowledge, Ives & Jarvenpaa predict a “revolution in knowledge creation”, as the review process becomes more open and the documents less static. “In the past, journals were archived in research libraries where they remain unchanged. But living web documents are considerably more volatile. Simple errors, typographic and otherwise, can be quickly repaired before they are inaccurately cited.” [7]

Other opposing concepts in this context are:

Traditional approach vs. Open, Peer-to-Peer approach

Brooks' Law	vs.	Linus' Law
Hierarchy	vs.	Network
Experts	vs.	Peers
Teams	vs.	Communities
Cathedral	vs.	Bazaar
Construction	vs.	Evolution
Perfection	vs.	Improvement
Information scarcity	vs.	Attention scarcity

### 3.1 Hierarchies vs. Networks

Let us examine some of these concepts in greater detail. Hierarchical structures are very good at getting well-defined tasks done in a “divide and conquer” paradigm. But the key challenge of knowledge management today is not dividing the work, but rather sharing the knowledge. Yet for facilitating the free exchange of knowledge, a network structure (such as peer-to-peer) is inherently better equipped than a hierarchy. From an information sharing standpoint, a hierarchical, tree-like organization is a worst-case scenario because it is a collection of bottlenecks: There is only one “official” path between any two nodes in the graph and the likelihood of people sharing information can drop as a function of their distance in the corporate org chart if alternative venues (physical or virtual) are not provided to support knowledge sharing.

Because the bottlenecks can be overworked, on vacation, or simply disinclined to pass on information and instead decide to keep it for themselves as a strategic advantage.

This does not mean that we would advise to attempt to run a company in a peer-to-peer fashion, but for the special tasks of sharing and improving the collective knowledge, a peer-to-peer network poses far fewer problems in terms of bottlenecks and re-inventing the wheel.

### 3.2 Experts vs. Peers

In a world of readily available information, the traditional distinction between “expert” and “laymen” blurs and in many respects, we become “peers” with people even on “their” home turf. For example, with the amount of medical information available online, many sufferers of chronic diseases have joined together in virtual communities to exchange information on their common ailment. Medical doctors have been faced with increasingly well-informed patients over the last few years – which is not surprising: If you have the time and obvious motivation to dissect and digest all available new information on your particular disease with a community of like sufferers, spending hundreds of hours educating yourself on all aspects – who is going to be the expert on your disease when you go to your general practitioner? Is it sensible to label the MD “expert” and you “layman” with respect to this niche of knowledge?

This is something we are seeing in many areas. Another interesting clash between “expert” and “layman” is the famous public debate between Tanenbaum and Torvalds over whether Linux had any future held on Usenet in 1992.

Professor Tannenbaum, the prominent and recognized expert on operating systems, predicted that Linux would never be portable, i.e. run on another processor than the x386. Linus Torvalds, the computer science student, defended his idea against the expert. Today, Linux is known as the most portable operating system of all times – running on everything from embedded systems, PDAs, PCs, up to supercomputers and mainframes [3].

In this case again, the traditional distinction between expert and layman is not helpful to decide who had the more worthy input. Note that in the traditional, pre-Internet world, the layman would never have had the chance to publicly debate with the expert in a way that gives both an equal footing in the debate.

### 3.3 Teams vs. Communities

Some people have taken to calling teams “communities” because this term has become a focus of attention in the knowledge management space, especially in the context of Communities of Practice. But the two terms are not interchangeable. A team is simply a group of people who have been assigned a certain task together. A team usually has a formal, appointed leader who can wield authority over the others. A team is given goals by which it is measured. It is clear at any time who is a member of the team and who is not – the boundaries are clear. And, most importantly, team members are selected by management.

A community, as in a Community of Practice, however, is a different story. Communities usually do not have a formal leader with authority over the community members. That does not mean that all members are equal – far from it: A community usually has very different roles. A coordinator may exist, and leaders who are valued as advisors by their colleagues will usually either emerge, or may have been the community’s attractor in the first place. But any authority they wield is usually not formally bestowed by management. This is because of another important attribute: Members of communities are volunteers. They choose to interact, to share information on a common set of problems or interests. They decide their level of activity or inaction. Members are not primarily measured by their activities in the community. And communities do not have clear boundaries. There will be different roles with different levels of involvement, such as community elders, “newbies”, “lurkers” (those who read but rarely contribute), FAQ maintainers, etc. Also, the level of members’ activity changes over time to accommodate their knowledge sharing needs.

### 3.4 Information vs. attention scarcity

Information used to be expensive and difficult to access. Those who had access to privileged information, through professional associations, a corporate library or at university, were at a clear advantage.

But today, using internet technology, being denied access to information is no longer a problem in most areas. You can get the most current, cutting edge research articles in physics from pre-print servers on the internet half a year

before they are ever printed and put into a library. Today the problem is the huge information overflow.

Thus the scarce resource is no longer the available information, but the available limited attention we can spend on the information glut. This has been likened to trying to drink from a fire-hose. Therefore, the focus of knowledge management is no longer on storing and indexing the few “holy scriptures” for a given subject, but rather on helping us to sift through the millions of pieces of information and putting them together in a way that makes sense. It is less the creation of new knowledge from scratch, but rather the combination and smart re-use of existing information. This is also why Communities of Practice play such an important role: Every member serves as eyes and ears for the thematic community and helps filter out the relevant pieces from the information flood. These pieces can then be assembled by the community of peers to gain and document new knowledge. The Usenet FAQs are a good example of this. They direct our limited attention and allow us to optimize our time.

### 3.5 Key benefits

The key benefits associated with an open, peer-to-peer knowledge management approach are

- f* much higher speed of content creation, capture and development
- f* broader collaboration and use of skills
- f* getting know-how out of people’s minds and desktop computers and into the open
- f* increased transparency and accountability
- f* more efficient re-use of existing assets (less “re-inventing the wheel”, more “standing on the shoulders of giants”) and
- f* dramatically reduced bottlenecks for the flow of information.

## 4. Overcoming obstacles to P2P KM

But reaping the benefits of the peer-to-peer paradigm on a larger scale inside a company requires overcoming a number of concerns and obstacles.

### 4.1 Information Quality

Electronic business relies on quick, easy and cheap exchange of information. It is an often raised argument that by empowering regular employees to be not just a consumer, but also a producer of information, the quality of information is diluted. Only the experts, the argument goes, should be allowed to create, review and update information on a corporate intranet, in order to assure high quality. But quite on the contrary, it has been demonstrated numerous times that massive peer review and participation in reviewing and editing information can actually lead to higher information quality than traditional approaches based on the review of only a few designated experts. This has not only been shown in the area of Open Source development and documentation, but also regarding traditional journal publication (i.e.

PublicLibraryOfScience.org [6]).

Indeed, there has been a recent case of large-scale scientific fraud, where a prominent researcher was able to publish 16 different papers in traditional, respected science journals, without the fraud ever being noticed during the 16 review processes. Only a tip-off by a peer brought the house of lies tumbling down [15].

### 4.2 Confidentiality

Confidentiality and intellectual property issues are part and parcel of corporate life. I.e. a consulting client may require strict non-disclosure agreements to protect his assets. Of course, this makes a peer-to-peer approach to knowledge management more challenging. However, corporations have dealt with confidentiality issues for a long time and have developed proven methods for coping with them, e.g. judicial, administrative and technical solutions. The real task at hand is questioning the basic notion that knowledge created in one team or department should be kept secret from another at all, as this creates corporate fiefdoms, silo thinking and leads to re-inventing of wheels.

Of course, in day-to-day reality, “keeping information secret” is not usually the result of a conspiracy or stubbornly denying access, but a brew of lack of transparency, lack of (default) access rights and non-publication of pointers to the information. You can theoretically track down the information if you know it exists – but the chances of finding it serendipitously are very slim.

### 4.3 Transparency

It appears that many of the concerns and fears regarding quality and confidentiality are in fact a reaction to the greater transparency associated with an open, peer-to-peer approach to knowledge management. This may be disconcerting to some people. With an open, peer-to-peer approach to knowledge management, people outside the designated “expert” team get to review, comment on and improve the available information. To quote Linus Torvalds [16]:

“In that regard, open source – or open anything, for that matter – is unforgiving. It shows who can get the job done, who is better. You can’t hide behind managers.”

This new degree of accountability can understandably appear threatening to some who are relying on traditional, non-transparent approaches to sustain their expert status.

But it is precisely this transparency that creates an incentive to share rather than hoard information. The decision for knowledge workers to share or not share their information in a situation where their decision is not transparent to a large number of their colleagues, can be modeled as a simple prisoner’s dilemma. Defecting (using information provided by colleagues but not providing any information yourself) is the rational strategy, as it maximizes your gains. The adverse effect to your reputation is negligible, if your behavior is only apparent to one colleague at a time. This is typically the case when

there is no “shared space” with easy write-access for exchanging information, but rather an official knowledge database that is filled with information through a standard process and used mostly in “read-only” fashion by the knowledge workers.

The picture changes dramatically when we introduce true shared spaces, such as newsgroups, discussion boards, team-rooms or Wikis. Non-compliance with a request for sharing information will result in significant damage to ones reputation, if both the request for help and the non-cooperation can be witnessed by many colleagues. This will lead them to one of two conclusions: A) the self-proclaimed “expert” refuses to cooperate or B) the self-proclaimed “expert” has no valuable knowledge to share.

The first conclusion lowers the expert’s social standing, the second lowers his professional standing with his peers. In such a “shared space” setting, it is likely that the role of experts as valued advisors will quickly pass from those who hold an “official” title to those who are actually willing and able to help you in your day-to-day work. This creates an internal marketplace for information, where an expert reputation has to be earned, rather than bestowed.

Our prisoner’s dilemma is also transformed: From the simple prisoner’s dilemma to the iterated prisoner’s dilemma, which is played with the same partners over extended periods of time and where the history of previous actions of all partners are visible and available to all players. In this setting, cooperation becomes the rational choice, as the reputation based on previous defection or cooperation behavior becomes a significant asset. Nobody is going to play cooperation with a known defector, whereas the known cooperators can optimize their mutual gain in the long run.

#### 4.4 Organizational and Cultural Change

Therefore, the concerns of the employees have to be mitigated by a culture that encourages experimentation and failure over inertness and perfection. Only in such a “forgiving” environment will employees feel confident to experiment with and vent new and “half-baked” ideas, which can then be developed and brought to perfection in a collaborative approach. A culture will need to be established in which the incentive for sharing information is greater than the benefit of hiding it.

This is possibly the hardest part of implementing a peer-to-peer approach. An organization is a very complex system of human actors, with their different needs, motivations and expectations set within org charts, processes and both written and unwritten laws governing behavior. Any change is likely to be rejected unless introduced, motivated and managed properly. And the transparency awarded by an open approach to knowledge management is very different indeed from the way most organizations organize knowledge management today – as a form of electronic library, focusing on storage and retrieval rather than creation and development.

## 5. Conclusion

The application of peer-to-peer concepts to knowledge management has the potential to improve the quality, currency and comprehensiveness of a company’s readily available internal knowledge by an order of magnitude.

With Internet technology at our disposal, we have the necessary tools in various different flavors. But the key challenge for the success of a peer-to-peer knowledge management is the creation of a cultural foundation which encourages and rewards transparency over information hiding. It requires the sponsorship and political will to “rock the boat” and to threaten the positions of information gatekeepers where they are more of a burden than a boon. Only an environment where every practitioner of information can also easily internally publish without going to a gatekeeper, only when the child (intern) can publicly call the emperor (expert) naked is the necessary feedback in place to keep improving the internal knowledge at a pace that keeps up with the needs of knowledge workers.

Tools can make this transition easier, but the key component of modern knowledge management is the support of the practitioners themselves. You cannot force a knowledge worker to share his knowledge. Today, we see the focus of Knowledge Management moving beyond IT into organizational and cultural change issues. The solution of which, while very challenging, also hold yield the rich rewards for an organization in terms of speed, adaptability and competitiveness.

E-mail: [swc@cyut.edu.tw](mailto:swc@cyut.edu.tw), [Kevin\\_Lee@mail.adi.com.tw](mailto:Kevin_Lee@mail.adi.com.tw)

## Abstract

Knowledge discovery from large databases has become an emerging research topic and application area in recent years primarily because of the successful introduction of large business information systems to enterprises in the electronic business era. However, transferring subjects/problems from managerial perspective to data mining tasks from information technology perspective requires multidisciplinary domain knowledge. This paper proposes a practical framework for enterprise knowledge discovery in a systematical manner. The six-step framework employs the cause-and-effect diagram to model enterprise processes, tasks and attributes corresponding diagram to define data mining tasks, and multi-criteria method to assess the mined results in the form of association rules. This research also applied the proposed framework to a real case study of knowledge discovery from service records. The mining results have been proven useful in product design and quality improvement and the framework has demonstrated its applicability of guiding an enterprise to discover knowledge from historical data to tackle existing problems.

**Keywords:** *knowledge discovery, data mining, association rules, cause-and-effect diagram, MCDM*

## 1. Background and Motivation

With the maturity of technology in business information systems, enterprises successively introduced large systems such as ERP, EC, SCM, CRM, etc. [1]. As information technology advances, it is a major issue an enterprise has to face to enhance competitiveness by acquiring useful analyzed information or knowledge to develop a more effective competition pattern or improvement strategy. But while enterprises obsess large bunches of data, they need a practical framework to analyze the data and discover knowledge using data mining methods [2].

In the process of enterprise decision-making, it is common to rely on decision-makers' experiences. But it may lead decision-makers to misjudgments not only because of the shortage of information in objective environment but also because of personal subjective preferences. Solving problems with traditional expert systems requires the establishment of enormous data and traditional discussions to locate problems and suitable solutions. The process of collecting data and searching feasible solutions, however, is very complicated. And

the knowledge base is often incomplete and soon to become outdated.

This research presented a framework to help enterprises analyze interesting subjects, either operational or managerial, locate subjects to be explored, and discover knowledge from existing databases through systematical steps with data mining and other problem analysis technologies.

## 2. Literature Review

Processes that consist of tasks are building blocks of an enterprise from the perspective of operations management, both for manufacturing and service industries. The competitiveness of an enterprise is therefore heavily dependent on the efficient operations and management of the processes. Over the decades, various technologies and researches have been devoted to improve it, such as total quality management (TQM), just in time (JIT), business process reengineering (BPR), and enterprise resource planning (ERP). Many of them are operations research and quantitative approaches, while some are managerial or philosophical approaches. And these approaches all attempt to make the processes fulfilled efficiently and correctly at lowest costs and highest quality. Along with the introduction of ERP systems, all the data about the historical, ongoing, or future processes are all stored in the databases. However, there are more than a thousand tables in the database for a large ERP system, and the significant amount of transactions in the database make it impossible to analyze efficiently solely with traditional statistical methods. Data mining is such a new emerging technique that has gained the significant attentions and applications of practitioners.

The purpose of data mining is to apply different data analysis methods to enormous data to discover significant rules or knowledge. By doing so, we can help enterprises get a better understanding of subjects interested and offer enterprises related knowledge when they face problems [3].

This research aims to utilize association rules analysis to discover related knowledge on subjects/problems that an enterprise greatly concerns. First of all, we have to understand the definition of association. Take an example of maintenance data, if the replacement of material B is 90% co-existed with the replacement of material A in maintenance records, the relation between them is an association[4].

We further make a more specific definition on the association rules [5]: Suppose that  $I = \{i_1, i_2, \dots, i_m\}$  is a

set of items. Let  $D$  be a set of database transactions where each transaction  $T$  contains a set of items such that  $T \subseteq I$ . Each transaction is associated with an identifier, called TID. Let  $X$  be a set of items. A transaction  $T$  is said to contain  $X$  if and only if  $X \subseteq T$ . An association rule, represented as  $X \subseteq Y$ , where  $A \subseteq I$ ,  $Y \subseteq I$ , and  $X \cap Y = \emptyset$ . The rule  $X \subseteq Y$  holds in the transaction set  $D$  with support  $s$ , where  $s$  is the percentage of transactions in  $D$  that contain  $X \subseteq Y$ . The rule  $X \subseteq Y$  has confidence  $c$  in the transaction set  $D$  if  $c$  is the percentage of transactions in  $D$ , containing  $X$ , that also contain  $Y$ .

Association rules mining algorithms such as Apriori [5] generally begin with single items and then join frequent single items to obtain multiple item sets. The method of Apriori requires a lot of times of scanning on the database, thus a great amount of time and space are required. This research adopts CIT algorithm [6], which only requires a scan on database at the beginning of the mining process, and thereafter association rules can be generated based on the constructed index tree.

Though we could thoroughly unearth numbers of association rules by data mining methods, it's uneasy to determine which are constructive association rules by algorithms. Therefore, the key technology lies on how to produce association rules and determine constructive and meaningful rules to avoid worthless effort on meaningless association rules [7]. Determining whether an association rule is constructive may reply on more than a single criterion, and the criteria vary with domain areas too. To consider multiple criteria simultaneously, a multi-criteria decision making (MCDM) method [8] is needed, of which utility theory is an effective method when the decision makers' preferences are under consideration [9].

### 3. Proposed Framework for Enterprise Knowledge Discovery from Databases Using Data Mining

This research proposes a framework for enterprise knowledge discovery, which features on practical and systematical data mining procedure and extracting important and meaningful knowledge from the numerous mined association rules. The framework contains two stages. The first stage is to look into an enterprise's processes where the subject areas the decision makers feel interested or the problems had occurred. By mapping the tasks of the selected processes to the corresponding attributes of the database tables, data mining tasks can be defined and conducted. The second stage is the multi-criteria assessment on the results analyzed and mined at the first stage in order to assure the meaningful and important knowledge is discovered. The framework of this research is displayed in Figure1, which will be further introduced in the following sections.

#### 3.1. Search for subjects/problems

The processes of an enterprise can be searched and examined to define the interested subjects or problems. Cause-and-effect diagram (or fishbone diagram) can be used to depict the overview of an enterprise's main processes [10][11]. Figure 2 shows a cause-and-effect diagram for the main management processes of a manufacture enterprise.

In constructing the diagram, main management processes have to be identified first, and the corresponding sub-processes for each main management process are listed next.

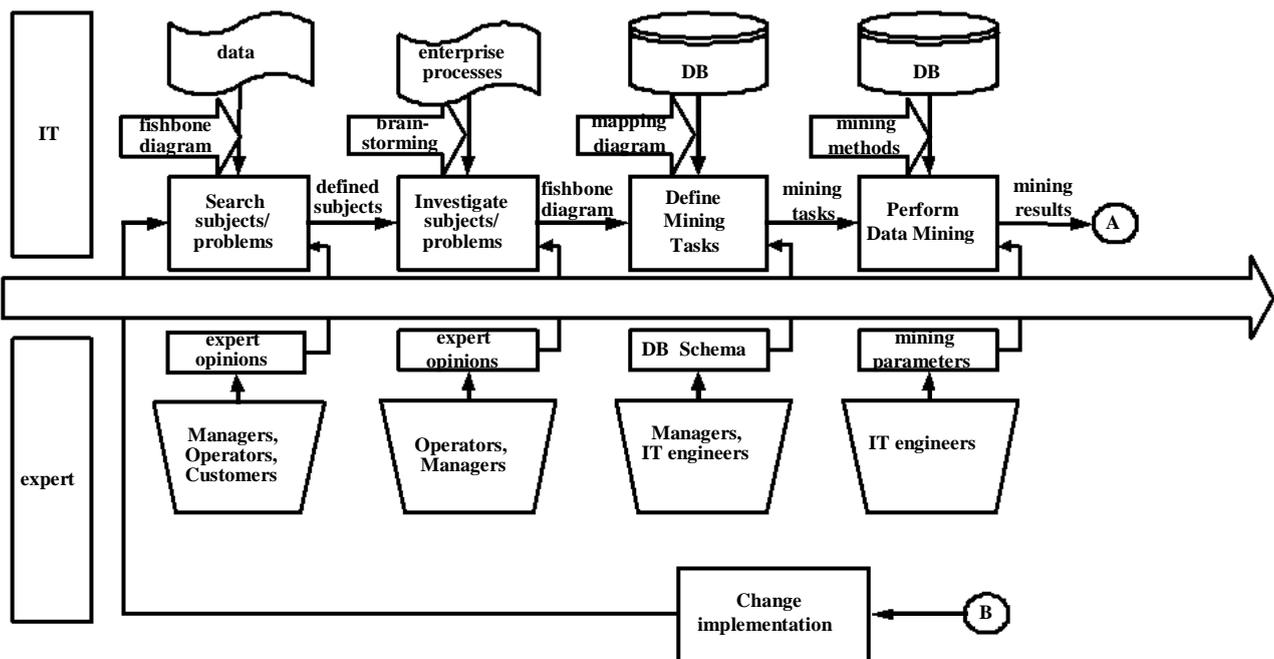

Figure1. A proposed framework for enterprise knowledge discovery from databases using data mining

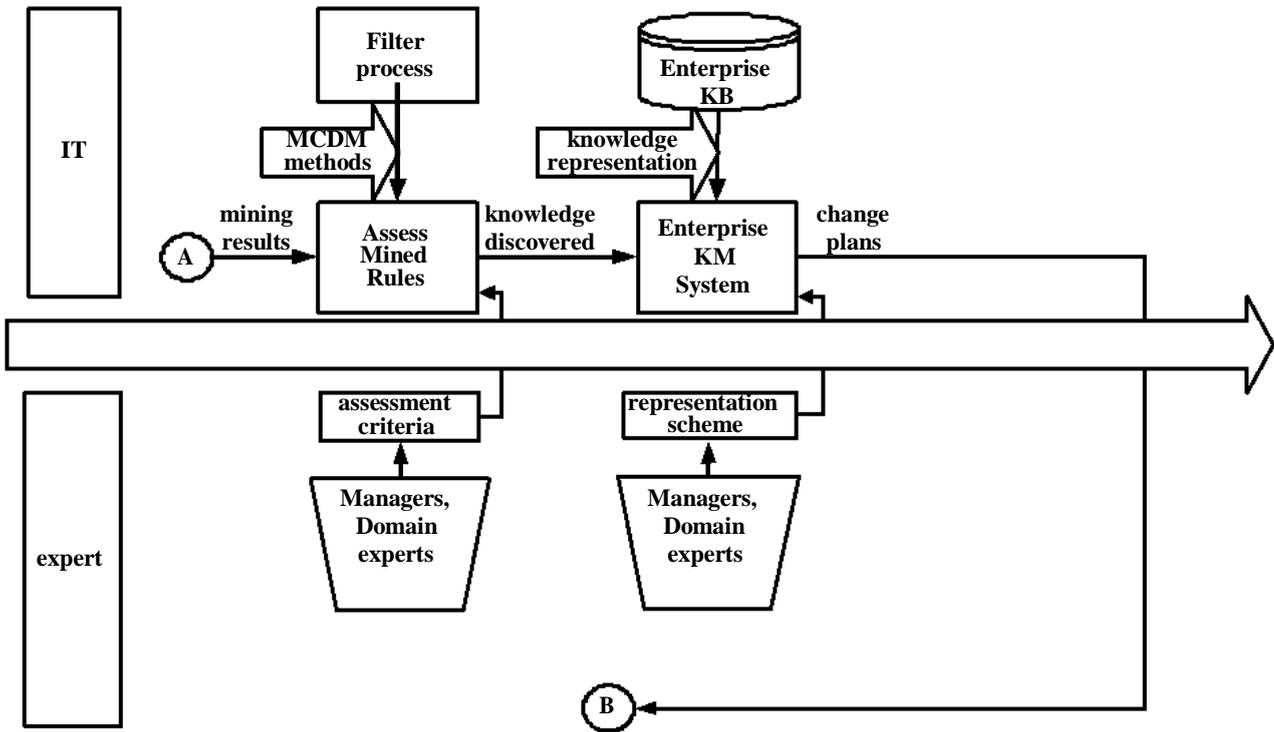

Figure1. A proposed framework for enterprise knowledge discovery from databases using data mining (Cont.)

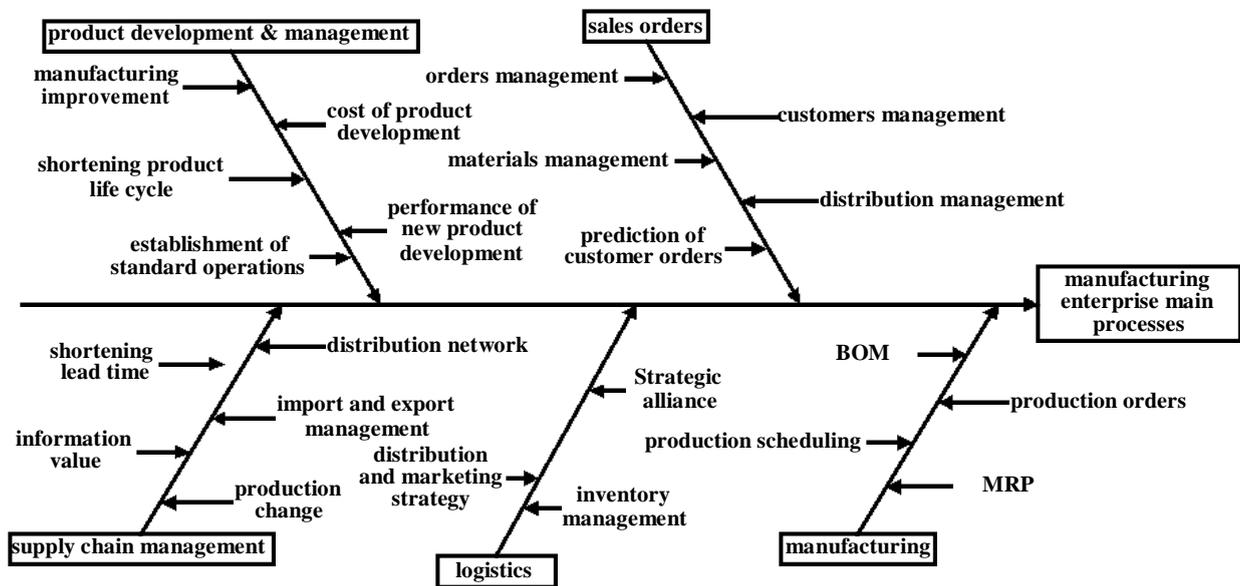

Figure 2. A cause-and-effect diagram for enterprise main functions

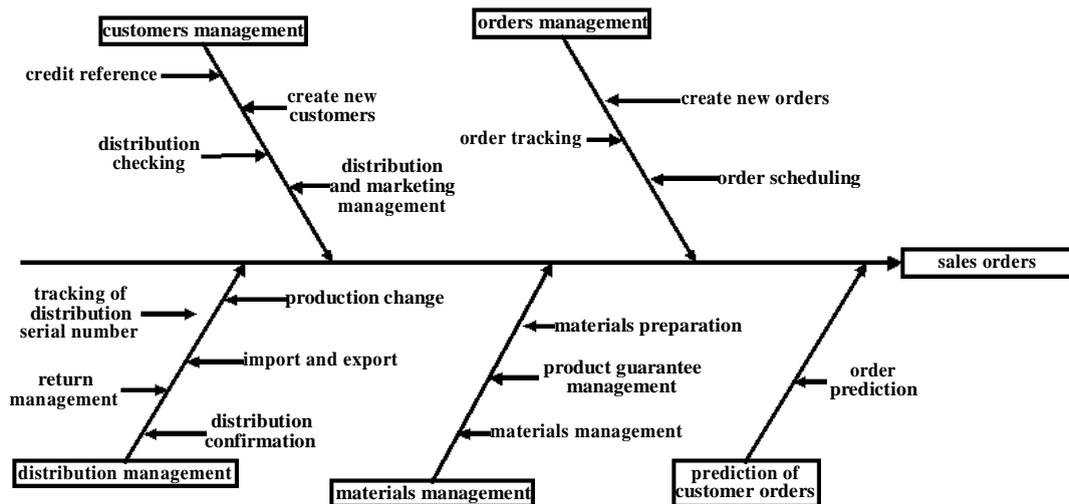

Figure 3. A cause-and-effect diagram for customer orders

The sub-processes can be further decomposed into sub-processes at a more detailed level. The cause-and-effect diagram of sales orders in Figure 2 is shown in Figure 3. Similarly other main processes can be decomposed and depicted as separate cause-and-effect diagrams at a more detailed level. With the processes of an enterprise depicted using cause-and-effect diagrams in detail at different levels, the interested subject areas or existing problems can be easily identified [12].

### 3.2. Investigate subjects/problems

After we locate the interested subjects/problems, the next step is to separate the associated processes into two parts: one that can be analyzed by data mining or the other that cannot [13]. Those processes to be mined are further investigated. Operators, managers, and domain experts all need to join the brainstorming team and opinions can be exchanged to better understand the subjects/problems, and finally the directions of data mining tasks can begin to take shape.

### 3.3. Define mining tasks

The function of Data Mining is to discover all kinds of hidden patterns from the data set. The purpose of this step is to search for the data for mining that are related to the target enterprise subjects/problems. Therefore, as defined in prior sections, the selected enterprise processes are compared with the attributes in the database. Finally compose a *tasks and attributes correspondence diagram* for Data Mining [14]. Figure 4 is an example of tasks and attributes correspondence diagrams. The diagram corresponds the enterprise processes interested, from managerial perspective, to the attributes in the databases, from data mining perspective. According to the tasks and attributes correspondence diagram, data mining tasks can be defined to discovery knowledge related to the selected enterprise processes from the databases. Before data mining is performed, data has to be preprocessed. Data preprocessing generally includes the following steps:

1. Conceive the data source and commence data collection
2. Acquire related knowledge and technology
3. Integrate and check data
4. Remove false or inconsistent data

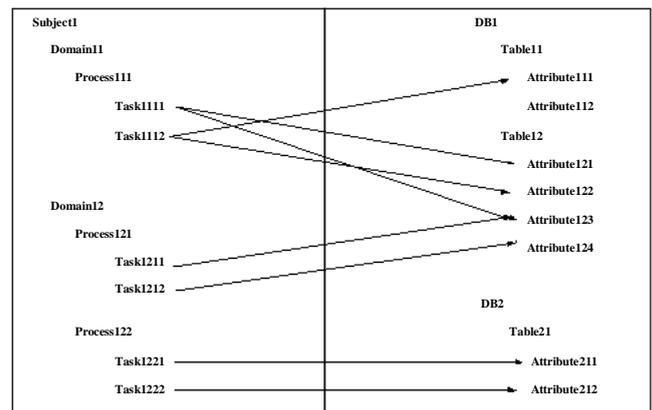

Figure 4. A tasks and attributes correspondence diagram

### 3.4. Data mining

By the progress of information technology and the entering of electronic business era, enterprises have already focused on making the best use of databases to acquire useful information or knowledge rather than only collecting and storing data. It becomes increasingly important nowadays for enterprises to effectively acquire data mining tools for database data mining when competing with competitors. Figure 5 displays the data mining project for enterprise knowledge discovery.

The feature of data mining is to search for meaningful patterns from giant databases. It acquires meaningful patterns from databases and transforms them into information or knowledge for supporting enterprise decision making. Different kinds of technologies, such as Genetic Algorithms, Neural Networks, Fuzzy Logic, Case-Based Reasoning, etc., could be used for data

mining. This research adopts an association rules mining algorithm, CIT Algorithm [6] to look for possible results. The advantage of it is that CIT algorithm allows for mining with causality. Take the problem of quality control for example: we could have the materials replaced for cause attribute and the malfunctioning conditions for effects to search for specific associations between replacement materials and malfunctioning types. Mined association rules may provide valuable reference information or knowledge for product research and development.

### 3.5. Assess mined rules

This step assesses patterns from the mined results according to the predefined criteria and unimportant or minor association rules will be ignored. To effectively determine the assessment criteria, this research proposes a concept which lays emphasis both on objective and subjective factors in the process of filtering. There are two basic elements in the process of assessment: feasible alternatives and decision-making criteria. Criteria either objective or subjective, taking quality issue for example, such as the cost of processing, the effect on goodwill, the improvement on productivity, the violation on policies, and the decrease in the number of service can be applied based on the criteria importance and decision maker's judgment.

Since multiple criteria are being considered in assessing the mined association rules, weighted sum model (WSM) is used to formulate the assessment equation:

$$Rule\_imp(j) = \sum_{i=1}^m w_i * x_i, \text{ for } i = 1, 2, \dots, m.$$

where

$Rule\_imp(j)$  is the importance value for rule  $j$ ,

$x_i$  is performance value for criterion  $i$ ,

$w_i$  is the weight for criterion  $i$ , and

$m$  is the total number of criteria considered.

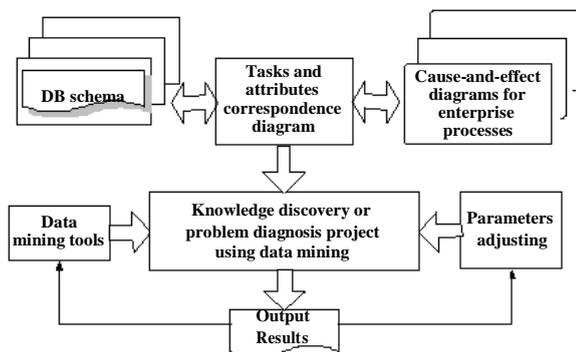

Figure 5. Data mining project

### 3.6. Enterprise knowledge base

Personal know-how through knowledge acquisition process and knowledge discovery using information technology both contribute to the creation of enterprise

knowledge base. When decision makers are dealing with semi-structured or unstructured problems, enterprise knowledge base can be referenced to improve the quality of enterprise decision making. To make the knowledge acquired accessed and shared, an enterprise knowledge management system is needed. Besides, knowledge representation scheme is necessary for systematically storing the acquired knowledge. The associated managers and operators to improve the current performance or to solve the problem can reference the discovered knowledge related to the selected subjects/problems. If the mining results cannot satisfy the associated personnel, the whole knowledge discovery process needs to be initiated all over again. If the knowledge discovered provides insight in solving the problem or improving performance, the resulting change plan then can be implemented, and it ends the knowledge discovery process.

## 4. A Case Study on the Quality Improvement in a Manufacturing Company

The proposed knowledge discovery framework and the associated methodology were applied to quality improvement on product design in a manufacturing company. In product development, it will be, however, a Herculean task for the R&D center to reassemble parts and test to find all the defective items provided by the manufacturing bases located world wide. Usually the purpose of these tests is only to locate the incompatibility among some electronic items to reduce the occurrence of uncertain operational breakdowns after the goods left the factory.

Owing to the numerous combinations in product items, how to prevent this kind of problems from happening again and again has always been a tough task for industries in analyzing the maintenance data. The burden of analyzing the incompatibility among electronic items is always untaken by experienced experts. This kind of approach is however time-consuming yet ineffective. In fact, the industry already has established a database and a complete collection of all detailed maintenance data from service centers world wide. We should be able to make good use of the database, accumulated for years, for analysis and data mining.

The proposed methodology was applied to the R&D problem. A cause-and-effect diagram was generated as shown in Figure 6.

Next we constructed the tasks and attributes correspondence diagrams and defined the association rules mining tasks. CIT algorithm was applied to more than twenty thousand real maintenance records of products being returned for service due to malfunctioning with six attributes from two database tables. We employed different values of *minimum confidence* and *minimum support* and obtained different number of association rules as shown in Table 1.

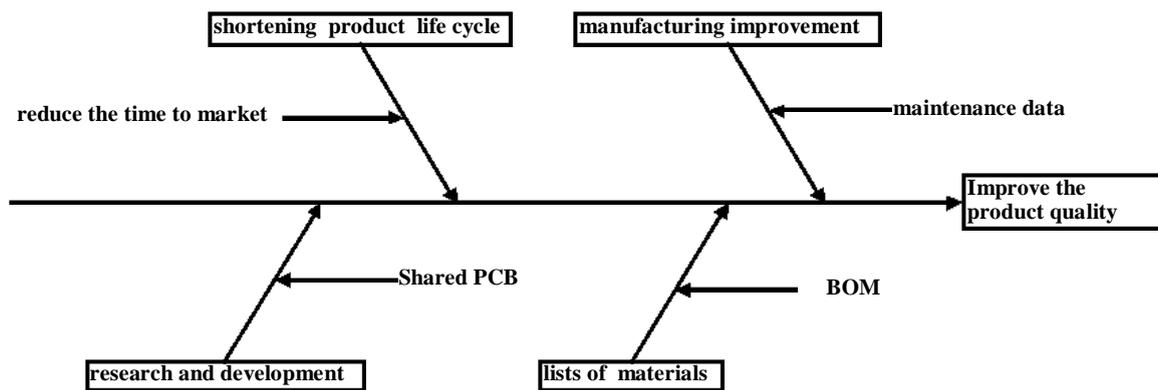

Figure 6. A cause-and-effect diagram for improvement of product quality

Table 1. Numbers of association rules extracted using CIT algorithm for different values of support and confidence

Support \ Confidence	5	10	20	50
99%	376531	40566	2288	58
80%	505550	43767	2878	58
50%	515960	48907	2878	93

The association rules generated from maintenance records as in Table 1 contain a great deal of meaningless association rules. After eliminating these meaningless ones, we can better understand the quality problems due to defective parts or incompatibility in the assemblies. Defining the rules of eliminating meaningless association rules requires domain knowledge about maintenance and design processes and three rules are shown below:

- Rule 1 For an association rule “items A and B together cause the failure of item C,” if the confidence of the rule is not 100%, it will be eliminated. This is to make sure defective items A and B simultaneously do relate to the failure of item C.
- Rule 2 Only defective electronic parts are considered in discovering knowledge about incompatibility problems. If the defective parts contain non-electronic items, the rules are eliminated.
- Rule 3 By checking with the BOM structures, if different electronic items from different products are found in an association rule, it will be eliminated. This is because the incompatibility problem only considers items on the same product.

In the data mining process, for the circumstance of the *minimum confidence* set to be 99.9% and the *minimum support* set to be 10, 40566 association rules were acquired. 2788 association rules were left after elimination based on rules 1 and 2. Finally, 82 crucial association rules were obtained when the third elimination rule was performed. Some of the final

association rules are listed in Table 2.

The 82 eventually gained association rules were assessed in terms of five criteria and assigned with separate weights. Five criteria cost, goodwill, productivity, policy, and service are assigned with weights of 30%, 30%, 20%, 10%, and 10%, respectively. Cost criterion refers to direct and indirect costs spent related to the service; reputation refers to the level of enterprise’s reputation was affected due to malfunctioning types; productivity refers the level of enterprise’s productivity can be improved by redesign; policy means importance from the perspective of enterprise’s policies from decision makers (e.g. the phased out models will not be processed); and service indicates the times of services required can be reduced after redesign.

Table 2. Examples of association found by data mining on incompatibility problem

Part ID	Part ID	Part ID	=>	Related Part ID
BA015J1	BP022A4	BY400B0	=>	BA015J1
BC176G0	BL003W0	BN012A5	=>	BC176G0
...				

In terms of these 5 criteria, we used weighted sum model (WSM) to calculate the rule importance for each association rule. The importance can be regarded as the priority for each association rule. Some of the results are shown in Table 3.

After testing and verifying the proposed framework on enterprise knowledge discovery on quality problem, it is found that the mined association rules provide frequent associations of multiple electronic items occurring on the same products being serviced. These rules may provide interesting and valuable information in product research and development, they can also be provided for inspection of a new model design to reduce the possibility of the same failure to happen again.

**Table 3. Rules importances calculated for mined association rules**

Part ID	Part ID	Part ID	=>	Related Part ID	Rule importance
BA015J1	BY400B0		=>	BP022A4	2
BA015J1	BY400B0	BY809B0	=>	BP022A4	1
BP022A4	BY400B0	BY809B0	=>	BA015J1	3
BU002S5	BN012A5		=>	BR008B5	5
BR008B5	BU002S5		=>	BN012A5	7
BR008B5	CR107C0		=>	BN012A5	6
RR229F	TP156Z0	RR229F1	=>	BN012A5	4
...					

## 5. Conclusions

This research has proposed a practical framework for enterprise knowledge discovery using data mining. The six steps of the framework are described in detail along with associated techniques or methods. By cause-and-effect diagrams, the processes of an enterprise can be modeled and analyzed. With tasks and attributes correspondence diagram, data mining tasks can be defined. Collect the right data from the enterprise database, then proceed data mining to discover the association rules relevant to the subjects/problems selected. In the case study, we extracted relevant association rules to incompatibility issue out of more than 20,000 maintenance records. After filtering process, fewer significant and more meaningful association rules are left. With multi-criteria decision making method, the rule importance can be calculated for each association rule. The association rules then can be referenced based on the rule importance. The association rules discovered have been found very useful in improving the product design and to reduce the failure in products due to incompatibility. This proposed framework that integrates multiple techniques provides a very practical approach and guidance for practitioners in knowledge discovery and problem solving. The case study also demonstrated the applicability of the framework in the industry.

## Abstract

Mass Customization (MC) is a new production mode developed from the combination of Mass Production (MP) and single customization. News businesses putting the News Mass Customization (NMC) in force has its inherent advantages and NMC is a new way to get competence. The paper firstly analyzes two problems—notation of MC and NewsML which have strong relation with NMC. Secondly, Compared with the MC rules in manufacturing industry, we draw the feasibility of NMC in News Businesses. Finally, according to the usage of Petri nets, we describe the NMC process and provide a detailed implement method.

Keywords: News Mass Customization (NMC); NewsML; Personalized News

## 1. Introduction

With the rapid development of society and civilization, the post-industrial era characterized by information technology (IT) and cybernation [4] is coming. While the traditional industrial economics has been replaced by knowledge economics, the useful information has been noted as a new and rare resource. At the same time, with the development of Internet, the emergence of all kinds of Websites like the bamboo shoots in the spring rain, and the electric commerce is gradually recognized as a new model of transaction. Any coin has two sides, we are now locating at a situation that we can not get the rapid and exact information even if the total number is enormous, as the saying goes “Rich data, Poor information”. How to provide the exact information for special customers is always to make the researches confused [1][2].

The word of Mass Customization (MC) stems from

the manufacturing industry, its core is to provide the personalized and customized products or/and services for customers with low cost and high efficiency of Mass Production (MP)[3][4]. On one hand, in the fields of news, the number of documents in database of news media is becoming more and more enormous, and the volume of the data is increasing exponentially. The news issuing and transmitting format is complex, the incompatibility is exist between them as well. On the other hand, while it is becoming more critical for customers to the news quality, the traditional standard has been replaced by a new mode which has open, interfacing, free and equal properties. The news with normalized, varied and personalized attributes is the tendency, and a new technology criteria as the basic platform is needed which can organize and issue colossal news information.

## 2. The notation of MC and the criteria of news—NewsML

Changing market, global competition and customized demand are severely challenging the traditional production modes. There are two elementary modes—Mass Production and single customization in recent years. The MP can provide the monotony product with low costing and high efficiency while single customization provides variable handmade products with high costing and low efficiency. Both of them have their merits and defects. Getting an efficient production mode is a seeking object for businesses to combine their merits and discard their defects. In the past decades, with the development of network and computers and the emergency of management modes such as Concurrent Engineering (CE), Supply Chain Management (SCM) and Customer Relationship Management (CRM), it is possible

that business produce customized production with the costing and efficiency of Mass Production (MP). In 1992, the master piece *Mass Customization: the New Frontier in Business Competition* [3] by an American scholar B. Joseph Pine II symbolizes the birthday of MC theory.

MC is that businesses use advanced technology such as Computer Aided Technology (CAD/ CAM/ CAPP), Flexible Manufacturing System(FMS), Group technique(GT) and advanced management modes such as CE,SCM,Business Process Reengineering (BPR) and CRM. to provide customized products and/or services for customers and put all or partial product process reengineering in force to produce products which costing and efficiency is the same or similar to that of MP[3][4][5]

Generally, Mass Customization has the following attributes:

(1) MC is a push/pull mixed production mode oriented to customers' demand.

(2) MC is a kind of Agile manufacturing mode to improve the adaptive ability of environment.

(3) MC emphasizes the customization in different levels. The similarity to the variety strategy is to satisfy the personalized demands.

(4) On the base of the standard, reasonable and generalized parts, MC tries to design modularized product so as to provide cheap and customized product in rapid speed.

(5) MC design is divided into new product development and distorted design. They have the sequent relation. The first part is to satisfy the low costing and the second is to satisfy the customized demands.

(6) MC emphasizes the support of IT and flexible manufacturing technology.

From the point of notation of MC, if a news business wants to provide NMC for customers, it must have a new technology criteria to organize and issue colossal news information. International Press Telecommunications Council (IPTC) issued a news logo language (NewsML version 1.0) in October, 2000. It gives a new lease to news sharing and issuing, and it is important for news businesses to satisfy customized demands.

NewsML is not only a terse, extensible and flexible standard as a news treatment framework, but also a

format standard for the uniform description, package, storage and transmission of media news [1]. It is convenient for computer to handle. The news with different contents supplier can be shared and exchanged on the base of it.

In sum [2], NewsML document always has three parts, DTD or Schema for defining the NewsML document logic structure, XSL for defining NewsML document display format and News document file which is written according to the DTD or schema .In addition, DTD(Document Type Definition) is a new series of syntax rules for news information marker sign. It defines the element contained, element attributes and relationship among these elements .XSL(extensible Stylesheet Language) is responsible for the display format of document in user's look through terminals. Different format of the same news are displayed with different stylesheet . NewsML document file is the main of NewsML document which refers to the file contents on the base of DTD or schema [7][8].

### 3.The feasibility of NMC

In the fields of news businesses, news is its products .The concerning and valuable customized news maybe regarded as a type of MC. From the analyzed attributes of MC, NMC also has these related attributes.

News occurs at all the time and the number is enormous. When a reader prints concerned keywords, network may arrange the related news from enormous databases to meet the reader's requirement.

A good Websites and corresponding news institution must focus on the social situations and issue the messages and policies to readers in time, so we must issue news with agile model.

While news contents are varied and can be classified, readers may look through interested news, at the same time, almost all the news agencies issue concerned news corresponding special events, thus embody the variety of news.

In order to get exact and valuable information and ensure the issued channel straightaway, we must get the rapid transmitted measure by using the standard, reasonable and generalized issue format.

In manufacturing fields, the design process of MC

has two stages. And maybe there are two stages in NMC. For example, a news group may have several kinds of newspaper, the core content concerned with domestic and foreign may be similar, but in order to reflect respective characteristic of different newspaper, the exact content is different.

The news issuing is supported by computer and IT in itself, the intention of flexible manufacturing is to manufacture customized products and/or services in rapid speed. While news itself needs to record the occurred and occurring matters, the flexibility totally depends on the reporters and the editors' ability

Although there are several successful cases with MC in foreign such as DELL computer corporation, Motorola corporation and Anderson door and window corporation. Seldom businesses take the MC in our country. The essential reason is that our business can not implement the three steps as a seamless whole from product specification to product logistics [6].

(1)Elicitation: a mechanism for interacting with the customer and obtaining specific information

(2)Process: flexibility: production technology that manufacture the product according to the information.

(3)logistics: subsequent processing stages and distribution that are able to maintain the identity of each item and to deliver the right one to the right customer

Generally speaking, the customers are often amazed at deciding what they want. They are easily overwhelmed by too many selections on a store shelf or a Web page. Business may make use of identification, customers' selections from menus of alternative, physical measurements and reactions to prototypes to complete, but all these measures are expensive in China. In news fields, business may list a questionnaire through network, customer may leave names and preference, and then use the special database to store them, and either customer or business itself may accept the method.

As for the flexible manufacturing, businesses must put into much of human, material and financial resources for the advanced equipment characterized computer and network communication. The situation is not prevailing even abroad. Because of the peculiarity of product in news fields, news business may not invest these expensive equipments and only depends on the human and network

intelligence to provide news for customers.

After the product is manufactured with customers' specific information, here may be several additional processing and transportation tasks. It is not easy to transport the special products to special customer, it depends on the developed logistic system. But for the news business, it is easy to achieve, It may use network to fulfill them without any waste of human, material and financial resource. Customer may open his own mailbox to get the special products.

According the analysis mentioned above, we may conclude that it is feasible to accomplish NMC in news business.

#### **4.NMC process description based on Petri nets[9][10]**

. As mentioned above, we emphasize that NewsML is a general platform for news issuing and sharing, NMC process is the application of the NewsML.

In the full description, we take Petri nets as a tool. Place means information status represented by circle. Transition means the handling of concerned data represented by box.

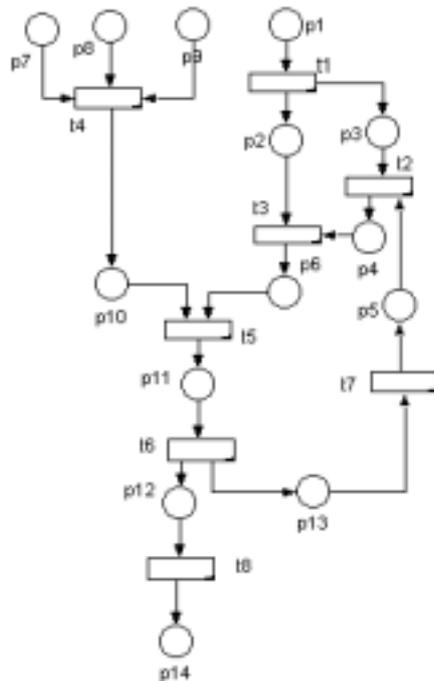

As Fig.1 shows, the NMC process mainly contains three components, requirement interface process, information integrated process and data mining and issuing process. Place p5 is the customers' database recording customers' characteristic, when customer print keywords, we may analyze customers' characteristic according to the keywords and the special database. After getting the required information, we renew and store new records. Places p7, p8, p9 are the representatives of all kinds of databases, news business integrate these databases by an agent mechanism and get the integrated information which provides operation objects for data mining. According the mined data, we divide them into two parts and store in places p12 and place p13.

#### **5.Conclusions**

NMC is a new way for news businesses to provide top-quality and customized news for readers. It can win competency and customers' appeal. Based on the market situation and news issuing and sharing faults, we firstly analyzed notation of MC and NewsML, which are

strongly related to NMC, and explained the attributes of MC in manufacturing industry and the attributes and components of NewsML as well. Secondly, the feasibility of NMC is analyzed by the comparison of news businesses and manufacturing ones. At last, we use Petri nets as a tool to describe the NMC process based on the NewsML, as figure 1 shows that the combined measure is

taken of requirement characteristic and data mining. And agent mechanism is used to integrate all kinds of database and then provide customized news for customers. As we know the concept of NMC is proposed as a new thing, there is still a long way to go. In this paper we just explored the feasibility and method in theory, the full application is to be studied in the future.

## Abstract

In today's business environment, competitive advantage increasingly requires the open sharing of knowledge by organizational members [22]. Although the practitioners place emphasis on the importance of knowledge sharing, empirical researches on knowledge sharing are still limited, and little research has been done to understand the factors that influence knowledge sharing in organizations. This study investigates cultural and interpersonal factors that influence an individual's propensity to share information and knowledge that he or she has created. Three different situations of sharing (information product, self-developed knowledge and organization-developed knowledge) were considered. The study found that organization culture influenced individual's beliefs of organization trust and psychological safety, and those who perceived higher trust and psychological safety seemed more likely to share information and knowledge with others.

Keyword: knowledge management, knowledge sharing, organizational culture, trust, psychological safety

## 1. Introduction

In today's business environment, competitive advantage increasingly requires the open sharing of knowledge by organizational members [17]. Drucker et al. [10] have identified harnessing "the intelligence and spirit of people at all levels of an organization to continually build and share knowledge" as a top priority for firms wishing to succeed in today's competitive environment. However, the efforts of many companies to manage knowledge have not achieved their objectives.

David and Liam [9] revealed that organizational culture is widely held to be the major barrier to creating and leveraging knowledge assets. Organizational culture creates the context for social interaction and forms individuals' beliefs about interpersonal relationships. Organizational research has emphasized cognitive and interpersonal factors to explain effectiveness, showing that individuals' tacit beliefs about interpersonal interaction inhibit learning behavior and give rise to ineffectiveness in organizations [1]. However, the role of beliefs about the interpersonal context in individuals' willingness to share information and knowledge under threatening or trusting psychological state has been largely unexamined.

Although the practitioners place emphasis on the importance of knowledge sharing, empirical researches on

knowledge sharing are still limited, and little research has been done to understand the factors that influence knowledge sharing in organizations. Many researches have relied on qualitative studies that provide rich detail about cognitive and interpersonal processes, but do not allow explicit hypotheses testing. This paper presents a model of knowledge sharing and tests it with a survey method. This objective of study was to investigate whether culture and beliefs about the interpersonal context influence the propensity of employee to share information and knowledge.

## 2. Theoretical Background

Constant et al. [5] advanced a theory of information sharing to understand the factors that support or constrain information sharing in technologically advanced organizations. The theory goes beyond communication and information exchanges among friends and personal contacts to include "organizationally-remote strangers they will never meet in person". Their theory consists both organizational contextual factors and psychological factors including feelings, values, and self-identities. They use this model to explain why people are or are not sharing their best information and knowledge, regardless of the financial incentive, organizational mandate, and amount of technology.

The Constant et al. [5] theory of information sharing roots in social exchange theory. Social exchange theory provides a complementary perspective to the economic exchange perspectives. Sharing Information and knowledge as social exchanges are similar to economic exchanges in the concept that there is an expectation of what will return exactly. Kim and Mauborgne [15] and Culnan and Armstrong [6] argue that rules of social exchange govern knowledge sharing. Individuals participate in social exchanges to maintain future relationships, the balance of power, and image. Organizational culture creates the context for social interaction and forms individuals' beliefs about interpersonal relationships [9]. When people embedded in the same culture examine values and norms in that system, the result can affect individuals' beliefs of interpersonal relationships and psychological safety and may in turn influence information and knowledge sharing behavior.

### 3. Construct definition and Hypotheses

#### 3.1 Propensity to share information and knowledge

Propensity to share information and knowledge is part of attitudes toward pro-social organizational behaviors (Jarvenpaa and Staples, 2001). The pro-social attitudes capture the general tendency of people wishing for good outcomes not only for themselves, but also for other employees or the organization [3]. Acts like helping, sharing, and volunteering are aimed at maintaining the well-being and integrity of others and the self, and are not directly or explicitly rewarded, but contribute positively to the organization's performance.

Barnes [2] notes "An individual possesses power by being a referent in a distribution of knowledge." When people share what they know with other people, they have lost ownership of knowledge they alone had previously controlled. So individual have good reasons not to share what they know. Knowledge is used at the individual level for both control and defense.

#### 3.2 Organizational Culture

Organizational culture refers to the shared values and attitudes of the members of an organization. Organizational culture has long been argued to affect the consequences of knowledge sharing. Dialogue between individuals or groups are often the basis for the creation new ideas and can therefore be viewed as having the potential for creating knowledge. Culture may encourage/discourage knowledge sharing behavior in organization. For example, Orlikowski [18] found that "in competitive and individualistic organizational cultures-where there were few incentives or norms for cooperating or sharing expertise- groupware did not engender collaboration."

When people embedded in the same culture examine values and norms that shape behavior in that system, the result can increase (or decrease) trust. Good inter-personal relationships, and open communications are continually identified by case studies to be critical in maintaining trust, thus we hypothesize:

H1: Organizational culture is positively associated with an individual's trust

Psychological safety is defined as belief that an individual is safe for interpersonal risk taking. Mutual face saving thus makes normal social relations possible. But in that very process we operate by cultural rules that undermine valid communication and create what Argyris[1] calls "defensive routines." To be polite, to protect everyone's face, especially our own, we tend to say what we feel is most appropriate and least hurtful. It becomes cultural rule to "say something nice if you say anything at all, and if you can't say something nice, don't say anything." Thus we hypothesize:

H2: Organizational culture is positively associated with an individual's psychological safety.

#### 3.3 Trust

Trust, defined as reciprocal faith in others' intentions and behavior, has been identified as integral not only to the performance of small teams, but also to many current organizational arrangement. Trust is an expectation that alleviates the fear that one's exchange partner will act opportunistically. The attainment of trust leads to knowledge sharing behavior. A study of the relationship between marketing research providers and users, shows that trust is a facilitating factor of other relationship processes such as quality of interactions and involvement levels. By alleviating the fear of the unexpected and facilitating interactions and involvement, trust encourages a climate conducive to the sharing of knowledge.

March and Olsen(1990) suggest that trust facilitates learning between partners and that decisions to exchange in knowledge under certain conditions are based on trust. Without trust people assume self-protective, defensive postures that inhibit learning [19]. An atmosphere lacking in trust leads to the withholding of information and can be harmful to the processes of knowledge articulation, internalization, and reflection.

We expect the individual's organizational trust to affect their propensity to share information and knowledge with other colleagues in organization. Thus we hypothesize:

H3: Trust is positively associated with an individual's propensity to share information and knowledge.

#### 3.4 Psychological Safety

Psychological safety is defined as belief that an individual is safe for interpersonal risk taking. Lipshitz, Popper and Friedman (1999) defined psychological safety as "a state in which people feel safe in honestly discussing their mistakes and what they think, and how they feel." For the most part, the belief tends to be tacit- taken for granted and not given direct attention by the other individuals. The construct has roots in early research on organizational change, in which Schein and Bennis (1965) discussed the need to create psychological safety for individuals if they are to feel secure and capable of changing. Schein (1993) noted that learning new habits and skills sometimes involves unlearning, which is emotionally difficult, and making mistakes, which raises anxiety owing to feelings of incompetence. Thus, people are more likely to act transparently, and to investigate their own mistakes with integrity when they are psychologically safe than under threat. The term is meant to suggest neither a careless sense of permissiveness, nor an unrelentingly positive affect but, rather, a sense of confidence that the other members in the organization will not embarrass, reject, or punish someone for speaking up.

The importance of trust in organizations has long

been noted by researchers. Trust is defined as the expectation that others' future actions will be favorable to one's interest, such that one is willing to be vulnerable to those actions. Team psychological safety goes beyond interpersonal trust; it describes a climate that "people are comfortable being themselves." [11]

Employee tend not to share the unique knowledge they hold, such that discussion in organization consist primarily of jointly held information, posing a dilemma for sharing in organizations. Those who actively share what they have may place themselves at risk; for example, by admitting an error or asking for help, an individual may appear incompetent and damage his or her image. In addition, such individuals may incur more tangible costs if their actions create unfavorable impressions on people who influence decisions about promotions, raises [11]. Image costs have been explored in research on face saving, which has established that people value image and tacitly abide by expectations to save their own and others' face. Asking for help, admitting errors, and seeking feedback exemplify the kinds of behaviors hat pose a threat to face, and thus people in organizations are often reluctant to disclose their errors or are unwilling to ask for help. Even when doing so would provide benefits the organizations. Similarly, research has shown that the sense of threat evoked in organizations by discussing problems limits individuals willingness to engage in problem-solving activities. In sum, people tend to act in ways that inhibit sharing when they face the potential for threat for embarrassment [1].

Nonetheless, in some environments, people perceive the career and interpersonal threat as sufficiently low that they do ask for help, admit errors, and discuss problems. In hospital patient-care teams, Edmondson [11] observed that significant differences in members' beliefs about the social consequences of reporting medication errors; in some teams, members openly acknowledged them and discussed ways to avoid their recurrence; in others, members kept their knowledge of a drug error to themselves. Team members' belief about the interpersonal context in these teams could be characterized as tacit; they were automatic, taken-for-granted assessments of the "way things are around here." For example, a nurse in one team explained matter-of-factly, "Mistakes are serious, because of the

toxicity of the drugs -so you're never afraid to tell the nurse manger"; in contrast, a nurse in another team in the same hospital reported, "You get put on trial! People get blamed for mistakes... you don't want to have made one." These quotes illustrate markedly different beliefs about the interpersonal context; in the first team, members saw it as self-evident that speaking up is natural and necessary, and in the other, speaking up was viewed as a last resort. Thus, we hypothesize:

H4: Psychological safety is positively associated with an individual's propensity to share information and knowledge.

In sum we combine four hypotheses and construct the conceptual model as Figure 1.

#### 4. Method

A questionnaire-based study was conducted to test the research model. This section describes the sampling method, construct measures, and analysis methods.

##### 4.1 Sample

The college students who are on the job were selected. Every student serves in different organization with different culture and work climate. In our study, the unit of analysis was an employee in an organization.

Questionnaires were sent to 480 students in classroom. 208 students voluntarily complete the questionnaires. overall response rates of 43.3 percent were achieved. Table 1 summarizes the demographic characteristics of the respondents.

##### 4.2 Construct Measurement

To test the hypotheses, we operationalized the conceptual model as Figure 2.

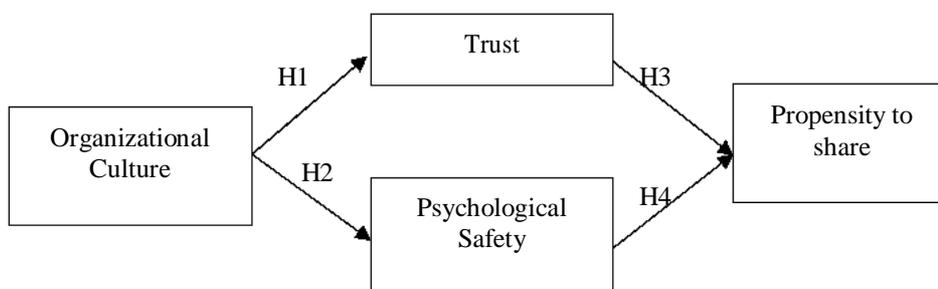

Figure 1. Conceptual Model

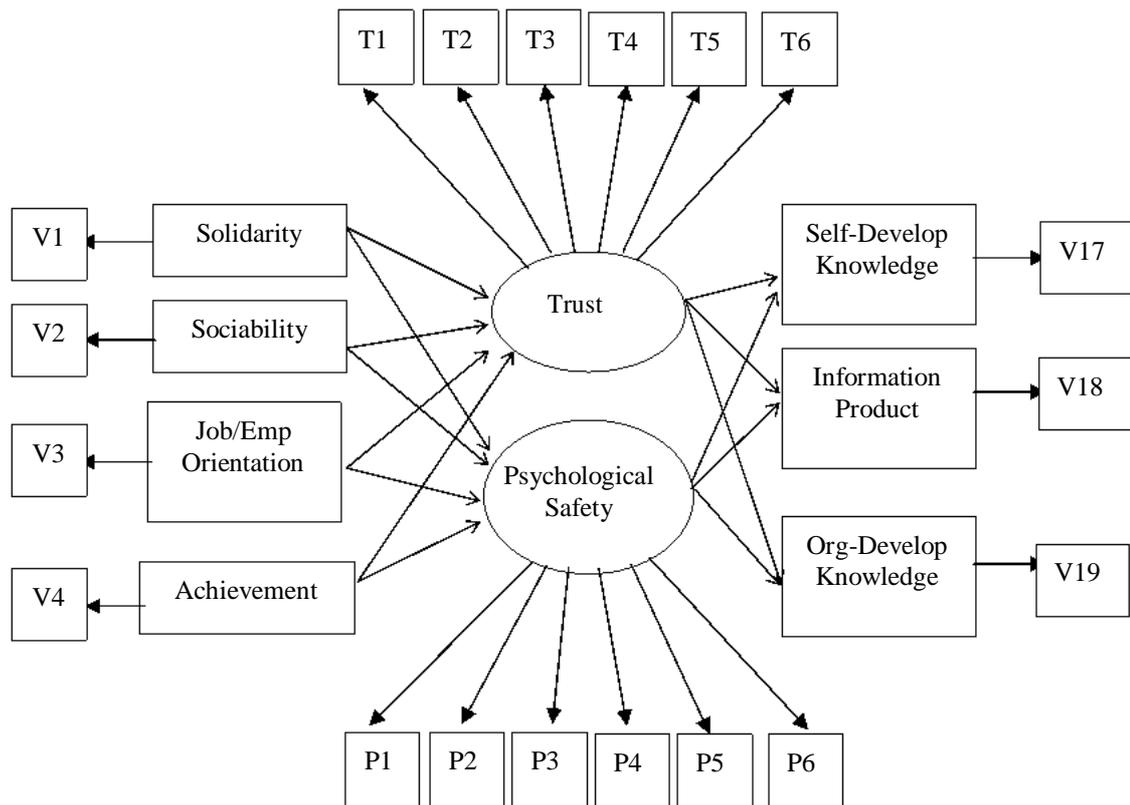

Figure 2. Research Model

The questionnaire contained multiple measurement items relating to each of the constructs in the research model. A pretest of 30 on-the-job students was carried out. Scales that had demonstrate good psychometric properties in previous studies were employed if it was possible.

Goffee and Jones [12] defined and developed measures for two dimensions of corporate culture that relate to producing and maintaining the well-being and the integrity of other coworkers as well as the organization at large- sociability and solidarity. Sociability is a measure of sincere friendliness among members of a community. Solidarity is a measure of a community's ability to pursue shared objectives quickly and effectively, regardless of social ties. Hofstede et al. [14] proposed a related dimension of employee-oriented (concern for people) versus job-oriented (concern for getting the job done). Scholz [20] identified a dimension of need for achievement. Need for achievement focuses on the importance placed in the organization on advancement and prestige.

Solidarity is associated with unarticulated and unquestioned reciprocity [12]. Sociability fosters teamwork and an environment in which individuals go beyond the requirements of their jobs to help their community succeed, Sociability is also associated with openness, which should mean fewer tendencies for individuals to want to control information and use it to build their personal power bases.

The mediators, trust was measured use Robert et al. [19] organizational trust scale. Besides the scales developed by Edmondson [11] for psychological safety, We added additional items such as "It is embarrassing to provide immature thought or advice to fellow worker."

The dependent variable, views of the propensity to share information and knowledge, was measured in 3 scenarios: sharing information products, sharing self-developed knowledge, and sharing organization-developed knowledge. The three scenarios were modified from Jarvenpaa and Staples [21]. In each of the three scenarios, a contrastive vignette technique (CVT) was used to measure the propensity to share in each of these situations. CVT is an indirect-structured methodology developed by Burstin et al. [4] to measure social attitudes. Directly to assess attitude is difficult because of the confounding effect of social desirability perceptions. Specific context are presented to respondents in short vignettes or stories. Constant et al. [5] also used this technique in their study to assess the propensity to share.

Since propensity to share is an attitude about pro-social behavior (Constant et al. 1994), this research tries to assess a pro-social attitude and not simply reciprocity and self-interest. We use Jarvenpaa's [21] vignettes describing that the individual was asked for something from a person whom had previous refused to help. In this way, we were able to capture information about the pro-social attitude.

Table 1. Sample Demographics

		Count	Percentage %
Age	20 to 29	148	71.2
	30 to 39	59	28.4
	40 to 49	1	0.5
Gender	Male	124	59.6

## 5. Analysis

The research depicted in Figure 2 was test using structural equation model. EQS statistical packages was used to simultaneously (a) create the theoretical latent variables from observed variables using confirmatory factor analysis and (b) generate estimates of the relationships among the constructs using path analysis. Testing a multivariate model using analysis of structural

The test of the hypothesized model indicated an moderate fit of the model to the data:  $\chi^2(141, N=208)=230.965, p<0.001$ . Non-significant chi-square indicates no significant difference between a hypothesized model and observed data. However, because the chi-square statistic is affected by sample size and some assumptions regarding the statistic may be invalid (Bentley, 1990), other indexes

relationships offers a number of advantages. The researcher is able to estimate direct and indirect effects simultaneously. Also, each path coefficient is estimated after the effects of all other paths have been taken into account. Table 2 reports the number of items used to measurement each construct, the reliability of the items, and the correlation matrix among the constructs.

## 5. Result

Goodness of fit were examined in this study. CFI=0.933; IFI=0.935; GFI=0.899; AGFI=0.864; Standardized RMSR=0.057; RMSEA=0.056. The standardized solution is depicted in Figure 3. Overall, the predictor variables accounted for 16.83%, 9.94%, and 11.08% of the variance in dependant variables respectively.

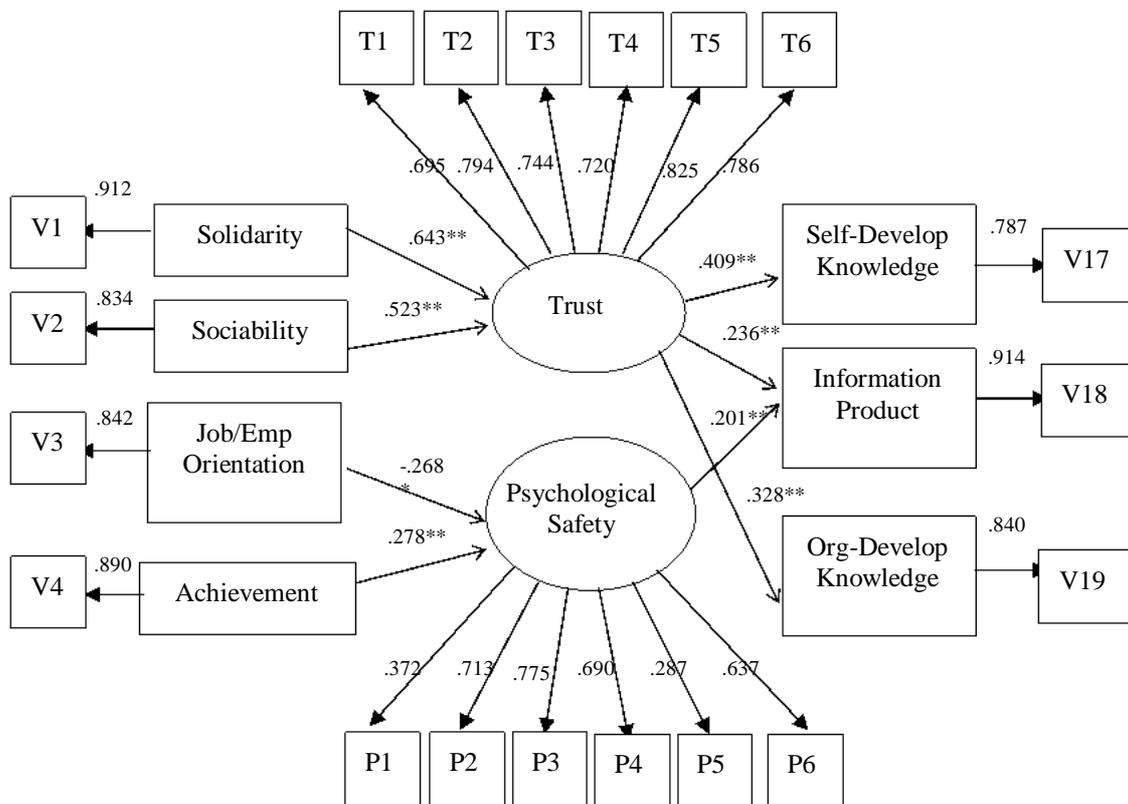

Figure 3. Standardized solution for propensity to knowledge sharing

Table 3. Variance explained in research model

Endogenous variable	Trust	Psychological Safety	Self-Develop Knowledge	Information Product	Org-Develop Knowledge
Variance explained ( $R^2$ )	69.20%	14.99%	16.83%	9.94%	11.08%

## 6. Discussion and Conclusion

Many scholars in knowledge management emphasize the employee control of information and knowledge and the importance of creating a situation that renders the employee willing to share voluntarily. Davenport [7] distinguished information sharing from involuntary information reporting. Information sharing is a “voluntary act of making information available to others...sharer could pass information on, but doesn't have to” [8]. Kim and Mauborgne [15] similarly argued that the firm is dependent on individuals' voluntary will to cooperate and share their expertise.

However, Greater sharing is not always reached. Even in work groups, individuals do not always volunteer information that would allow the group to work efficiently and effectively [13]. Concerns of psychological safety and trust lead people to hide or hoard information and knowledge. In the knowledge economy, knowledge is seen to be the source of power [8]. Information can be seen as an asset that is to be owned and controlled by individuals in order to elevate their own power and status relationships in organization [16]. An atmosphere lacking in trust leads to the withholding of information and can be harmful to knowledge sharing. Davenport [7] concluded “As people's jobs and roles become defined by the unique information they hold, they may be less likely to share that information- viewing it as a source of power and indispensability- rather than more so.”

Organizational cultures have effect on individuals' beliefs of trust and psychological safety. Individuals that rated their organizations high on solidarity- relationships based on common tasks, mutual interests, and shared goals, and sociability- relationships based on friendliness, rated high on trust. A culture characterized by solidarity and sociability perhaps gives them a sense of confidence that their behavior would be fairly reciprocated with appropriate benefits or rewards by the organization.

On the other hand, psychological safety was significantly affected by employee-oriented (concern for people) versus job-oriented (concern for getting the job done) and need for achievement (importance placed in the organization on advancement and prestige). Those that characterized their organizations with higher need for achievement and more employee-oriented felt psychological safer than those did not.

Propensity to share information and knowledge are positively associated with trust. Support was found for all three scenarios. As predicted, Employees who perceived higher trust in their organization were more likely to share information and knowledge with others.

Partial support was found for the psychological safety hypothesis. We had hypothesized that psychological safety would be positively associated with the propensity to share information and knowledge, but the result suggests only significant association in information sharing scenario.

This study tried to show how cultural and interpersonal factors-trust and psychological safety-

influence information and knowledge sharing propensity. With the more uncertainty, more change, and less job security in future organizations, organization have to endeavor to build trust climate and provide more psychological safety for individual at work.

The samples of this study were gathered from college on-the-job students and the sampling method was convenient rather than randomized, the generalizability may be questioned. It is important to note that we used a cross-sectional design. Thus the result show in Figure 3 can only be considered suggestive of possible causal relationships until more appropriate longitudinal studies with random samples are conducted. Although we found several of the relationships in our study to be statistically significant, several were not. The lack of significance might be due to the methodological defects.

## Abstract

This study examines the benefits and problems arising from the electronic brokerage services and the electronic investment banking processes. Some important benefits of the electronic financial services include greater transparency, more unprecedented opportunities for innovation and competition increase in trading volume, and creative methods for risk reduction. Problems about online broker-dealers and electronic investment banking include lack of direct contact between investor and broker, and glitches in the technology that inconvenient the end users. In the equity market, the channel of distribution through online IPO is limited when compared to traditional public offering through underwriters.

One important problem with financial e-commerce is the security and privacy problem. The security issue of online trading business can be divided into two parts: hardware security and software security. Hardware security problems involve network corruption, system crash, communication problem between networking servers and execution servers. Software security problems involve hacking, insider fraud, and account information theft. Brokerage firms use multiple security mechanisms to deal with these problems. These security mechanisms include: (1) Account and password control. This is the basic security control. (2) Encryption of transaction data. Transmission of data online always involves security flows.

Government as well as online financial service providers needs to take responsibilities to educate and communicate with investors to help them understand the benefits and risks of electronic financial services. To create a healthy investment environment is also vital to the future development of an electronic equity market.

## 1. Introduction

Today, the Information Technologies have achieved wide spread acceptance as one of the means to allow an organization to improve efficiency and productivity, to

become more responsive to the changing market in which it operates by developing, producing, and selling new products and to provide better levels of service to its customers. The Internet and the electronic data processing have also made a considerable impact on the financial industry. These technological advances change the ways of doing business in the financial markets.

One of the most successful examples of electronic commerce in financial markets is the electronic brokerage service. In particular, the electronic on-line ordering system (e-trading) has increased the efficiency of information flows and the trading process. The official trading hours can no longer limit security traders; investors are able to trade in global equity markets across different time zones, which may enhance their liquidity position. The electronic investment banking process is another example of electronic commerce that affects the traditional underwriting business. When raising capital, issuing companies can avoid underwriting spread and directly access capital markets through on-line initial public offering.

The purpose of this study is to examine major issues that are related to the e-commerce in the financial markets. We will examine the benefits and problems arising from the electronic brokerage services and the electronic investment banking processes. This study will also address the security and privacy problem, which is an important limitation to the development of financial e-commerce.

## 2. Advantages and Disadvantages of Electronic-trading and Investment Banking

### 2.1. Advantages of the Electronic-Trading System

The electronic trading of securities on the web has dramatically increased. Over the past few years, on-line securities sales went from zero, to more than a third of all retail trades [1]. Mutual funds have also taken a prominent position on the Internet, moreover, web-based

advisory services are provided. The benefits of the electronic trading include:

*(a) Operational Capability and Efficiency are Increase*

In the 1960s, many broker-dealers choked on the vast streams of paper flooding their back offices. It violates the SEC anti-fraud provisions to accept or execute any order for the purchase or sale of a security, if the broker-dealer do not have the personnel or facilities to enable it to promptly execute and consummate all of its securities transactions<sup>1</sup>. This is no longer a problem with the new information technologies; however, the network and server's capability are of concern. The good news is servers and networking bandwidth are less costly and their prices could only go lower in the future.

Most broker-dealers use powerful microcomputers to support their market making and brokerage functions. These workstations allow individuals to simultaneously perform multiple trade support functions, such as order management, monitoring net long or short positions in specific securities, calculating profit or loss real-time, analyzing risk and receiving market data [2]. Other trade support functions include trade reporting, records of completed transactions, links to back-office systems and order routing to various execution points. In addition, some broker-dealers provide order transmission capabilities to their registered representatives, correspondent broker-dealers or customers to permit them to electronically transmit all relevant information concerning an order to the broker-dealer's trading desk.

*(b) Cost Efficiency*

Since the whole trading process mainly concerns with the information flow, the difference between traditional trading and electronic-trading is the change of intermediary. Electronic trading technology is cost efficient, the start-up costs as well as the operating costs are lower than the traditional trading system. Electronic trading technology changes the dynamics of the marketplace. It removes at least three physical constraints imposed on markets. First, the physical space constraint no longer exists. The floor members on the tradition stock exchange have time and place advantages over those off the exchange floor in the past. With the electronic trading system, investors trade in the cyberspace, time and place advantages of the floor member become less significant.

With Internet and the e-trade system, investors can (1) place their orders anytime anywhere with Internet connection, (2) get instant information of their investing objects and also get the full information service from the online brokerages, and (3) lower their trading cost [1]. The lowering trading cost is evident from Graph 1.<sup>2</sup> The commission on a per share basis decreased from 8.1 cents in 1991 to 6.2 cents in 1998 for exchange-listed stocks, and from 7.4 cents in 1995 to 6.3 cents in 1998 for over the counter stocks. The electronic trading process plays

an important role in the reduction of trading commissions. For investment companies and brokerage firms, they could (1) increase their appearances though Internet, (2) attract the Internet age customers to broaden their customer base, and (3) decrease the management and human resource cost would be decreased [1]. In addition, Electronic trading reduces the transaction cost, especially in high volatility stocks. This is evident from Graph 2.<sup>3</sup>

*(c) Better Information Dissemination*

In 1996, an estimated 30 million households owned a personal computer (or about 25% of all households in the country)[3]. A 1995 survey showed that ownership of personal computers among mutual fund shareholders exceeded the national average<sup>4</sup>. The growing use of personal computers and the Internet by the public has not been lost on the financial services community. A recent list of investment management firm web sites includes over 200 entries [4].

Through Internet, investors can easily obtain information from the market listed companies, on-line brokerage firms, on-line financial advising service companies and etc. Any information disseminated through Internet is instant. Investors may subscribe to a variety of services offering access to real-time market data, company profiles and earnings reports, mutual fund data, and news services over the Internet. In addition, most of the leading commercial on-line services receive data feeds from information vendors and provide such information to their clients.

The exchange-listed companies have aggressively used new technologies to communicate with their shareholders, as well as to deliver prospectuses and other required information to shareholders. Investment companies use new technologies to provide their shareholders with the opportunity to communicate with them electronically. The on-line brokerage firms provide financial advices, trading reports, market status and some other information services to their customers easily through electronic medias. With enhanced information dissemination technology, markets become more efficient.

*(d) Better Customer appeal and focused marketing*

With information technologies, financial institutions can analyze their clients' trading behavior, understand and better satisfied their needs. The electronic trading system will improve customer appeal. Market participants can be geographically dispersed since they don't have to be located on the premises. Electronic trading technology allows foreign investors to access the U.S. equity markets.

Many companies believe that Internet technology offers a valuable forum for communicating with current and potential shareholders [5]. According to a National Investor Relations Institute ("NIRI") survey, over 95% of companies with over \$1.5 billion in market capitalization,

<sup>4</sup> Gavis, "Investment Company Institute, Fundamentals, Mutual Fund Research in Brief, 1995

and over 75% of companies with under \$1.5 billion in market capitalization, either already have or soon plan to establish a web site.

*(e) Market Without Boundary*

The electronic trading made possible a more efficient global equity market. Investors can hedge their investments in different stock markets worldwide. For instance, small investors can buy British Telecom's ADR in NYSE and hedge this investment by selling British Telecom in LSE. Cross-border equity flows have increased dramatically. Gross cross-border equity transactions, including all foreign purchases and sales of corporate securities in the United States, increased from under \$93 billion in 1980 to over \$1.5 trillion in 1994<sup>5</sup>.

## **2.2 Disadvantages of the Electronic-Trading System**

Although electronic trading system provides many benefits to the capital markets, relative to the traditional trading system, it is not without shortcomings. A major disadvantage of the electronic trading is the service quality is not as good as traditional trading. The e-trade system lacks interpersonal communications. Security advising is one of the responsibilities of a broker-dealer. For the unskilled investors, they may need assistance from brokerage firms' professional advices; the e-trade system is not able to provide face-to-face consultation. In addition, because on-line brokerage firms use e-trade system to lower their costs, they may not hire enough employees to deal with emergent difficulties.

Today, complaints against online broker-dealers include (1) brokers fail to process orders or delay their execution and investors experience difficulty in accessing their accounts or contacting their brokers; (2) brokers making errors in processing orders, in account records, or investors experiencing execution problems. Most of these complaints against online brokers involved glitches in the technology.<sup>6</sup>

## **2.3. Advantages of Electronic-Investment Banking**

Raising capital on-line has clear benefits, for example, it is quick and broad in dissemination of information. The Internet provides companies direct access to a huge pool of investors and prospective investors. The Internet enables a company to distribute its offering materials to the broadest possible audience and to solicit interest in its securities without regard to location. This has proved a boon for new businesses without an established investor base as well as for established corporations seeking to leverage their name recognition on a global basis.

---

<sup>5</sup> U.S Treasury Department.

<sup>6</sup> Laura Unger, "Investing in the Internet Age: What You Should Know and What Your Computer May Not Tell You", <http://www.sec.gov/news/speech/spch342.htm>

The use of electronic media to disseminate offering materials has some obvious economic advantages. It can reduce costs associated with the capital formation process, printing and distribution costs as well as advertising and promotion expenses. Electronic offering materials can also be supplemented and updated more efficiently and economically. These savings have significantly reduced the cost of capital, particularly for smaller businesses where such costs take a significant part out of the total offering proceeds.

One of the common complaints about underwritten offerings is the imprecision of the pricing process. In order to ensure the complete sale of securities, the lead underwriter and the investment bankers may under-price the offering securities to attract investors. One way to eliminate the under-pricing in the initial public offering process is to use the online "auction" pricing approach. In theory, this auction process should result in the maximum amount of offering proceeds for the company, while ensuring a more equitable distribution of offering shares.

## **2.4. Disadvantages of Electronic Investment Banking**

Most concerns involved in online initial public offering (IPO) are around three subjects: channel of distribution, liquidity issue, and education of participant investors. Underwriters normally acted as a "gatekeeper" in the security offering process. They conduct due diligence about the issuer and the offering, participate in preparing the registration statement, make pricing decisions, and provide research and aftermarket support. Without an underwriter, investors must rely on the issuer to carry out these responsibilities. Issuers would also retain sole liability for material omissions and misrepresentations. Compare to traditional public offering, online public offering can't provide as the same quality financial services and disclosures as traditional ones.

The channel of distribution through online IPO is limited. The purpose of public offering is to distribute securities to the public investors. However, it is difficult for online public offering to do the "massive" distribution. Currently, the online underwriting accounts for two percent of all initial public offering capital. According to the survey of Credit Suisse First Boston Technology Group, until year 1999, there were only five online underwriting players in the online underwriting business.

For the online public offering market, because of the small percentage of whole underwriting market and distribution problems, the issuing shares in the market are scares. Moreover, because participant investors are relative fewer than the traditional public offering, liquidity is reasonable lower than traditional ones. Until Internet-based services develop established customer bases and access to a liquid market for secondary trading, they pose little threat to traditional investment banks.

### 3. Security and Privacy Issues

There are limits and challenges of new web-based information technology to equity market. Among them, the most important one is the security issue. Investors would only invest their money in a secured environment, and this privacy concern applies to the entire e-commerce. In this section, we will discuss the current security mechanisms for the online investment, the tools and applications that online brokerage firms use to protect their customers, and we will also discuss the privacy issue.

#### 3.1 Privacy and Security Issues

Approximately thirty broker-dealers currently offer online trading. Most of these are discount brokers, and they offer a substantial discount on commissions for their clients [6].<sup>7</sup> The number of firms offering on-line trading will continue to grow, as compliance and security problems being resolved. Most broker-dealers require their customers to use an Internet browser that supports encryption, assuming this level of encryption to be sufficient to protect their information flows. Therefore, how to ensure the security in the online trading environment is important for the online brokerage firms to attract the perspective customers.

The security issue online trading business can be divided into two parts: hardware security and software security. First, hardware security problems involve network corruption, system crash, communication problem between networking servers and execution servers [1]. Among them, network corruption and system crash are mainly relates with online brokerage firms' systems capacity. The communication problem between networking servers and execution servers is mainly related to how brokerage firms manage their information systems. Today, with the advanced network technology, cost of bandwidth and processing devices is low and they are no longer serious concerns.

Software security problems involve hacking, insider fraud, and account information theft [1]. Brokerage firms use multiple security mechanisms to deal with these problems. These security mechanisms include: (1) Account and password control. This is the basic security control. (2) Encryption of transaction data. Transmission of data online always involves security flows. In order to ensure the integrity and confidentiality of data, the following mechanisms are used:

(a) *Secured Socket Layer (SSL) & Transport Layer Security (TLS)*

SSL/TLS providers a range of security services for client-server session. This security mechanism can provide server authentication, confidentiality, integrity, and client authentication [6]. By implementing SSL/TSL, brokerage firms can ensure that third party will not manipulate orders made from their customers. In

addition, with client authentication feature implemented, brokerage firms can ensure the source of orders.

(b) *Data Encryption Standard (DES)*

DES was adopted by United States federal standard in 1977.<sup>8</sup> DES is a block cipher operates on 64-bit blocks of data and employs a 56-bit key. DES can also ensure the integrity of transmitted data [6]. The demise of DES as a cryptosystem suitable for commercial use resulted primarily from its comparatively small key space.

(c) *Firewall*

Firewall is the most powerful and commonly used mechanism for online security. It is a system that enforces access control policy between two networks. The firewall determines which inside services can be accessed from the outside and vice versa. The firewall can be thought as a pair of mechanisms: one to block traffic and one to permit traffic. The firewall system performs like a guard watching the network traffic.<sup>9</sup> Firewall can provide can effectively prevent network intrusions and hacking.

### 4. Conclusion

While the full effect of recent technological developments remains to be seen, these developments have significantly changed the ways in which many investors obtain information about their investments and conduct financial transactions. Overall, recent advances in technology have brought greater transparency, provided unprecedented opportunities for innovation and competition, facilitated tremendous increases in trading volume, and made possible the development of methods to reduce risk. There are many benefits the information technology brings to the equity market, both for trading and investment banking.

The effective use of technology is the key to maintain active and competitive equity market. Technology has infused our equity market and its participants with a new and greater drive to compete. Equity market is being challenged every day to reexamine their business models, to reevaluate their services, and, in some cases, to reinvent itself. The pace of change and the strength of the securities markets generally have enabled investors to more directly participate in the securities markets.

Online brokerage has significantly changed the dynamics of the marketplace, causing one of the biggest shifts in individual investors' relationships with their brokers. It provides investors with tools to analyze information, and to act quickly on this information. Investors who use the online investing tools need to be more educated. Government as well as online financial service providers needs to take responsibilities to educate and communicate with investors to help them understand

# The Impact of ECN on the Trading Structure of Taiwan's Securities Market

Chichang Jou, Ming-Hung Chen  
Department of Information Management

Tamkang University  
Tamsui, Taipei, Taiwan

cjou@mail.im.tku.edu.tw, minghong@mail.im.tku.edu.tw

## Abstract

Along with the booming of internet, many enterprises have modified their business models accordingly, which then has influenced the trend and direction of many industries. In the securities market, investors could utilize internet to obtain order information more easily and completely. Especially, with the easy access of foreign securities information through internet, investments transactions are becoming globalized too. Traditional trading support no longer satisfies investors' requirements. That has contributed to the global rise of electronic communications networks (ECNs). These new trading platforms make the competition among exchanges more severe. With the gradual opening of Taiwan's financial market, the approaching of these new players becomes inevitable. We study the impact of ECN on the trading structure of Taiwan's securities market, based on the trading contents, trading methods, and trading support requirements. We first analyze the impact of ECN on the trading structure of United States securities market. Current trading structure of Taiwan's securities market is then analyzed for stocks, bonds, and futures separately. We also develop an experimental ECN with the negotiation mechanism. The system is then tested by several trading experts. Their answers to our survey are summarized as our conclusion.

## 1. Introduction

The trading functions of traditional securities exchanges are order matching, clearing, and settlement. Electronic Communications Networks (ECNs) accomplish order matching electronically, and provide an open platform for individual and institutional investors. Although most brokerages in Taiwan are already engaged in providing electronic order entry through internet, the current electronic trading services provided by Taiwan's securities exchanges are insufficient, which limited the whole effects of internet. For example, although investors could enter orders through internet anytime, matching for after-hours orders will be delayed to the official trading time next day. Furthermore, real-time price information is incomplete, and the trading cost for investors is still high.

Before joining WTO, Taiwan government had modified law so that Taiwan's stocks, bonds, and futures exchanges will no longer enjoy current monopoly by opening securities

market to foreign competitors [5]. Since the setup of ECN is relatively easy and inexpensive, the first competition they would encounter would be from ECN. ECNs in the United States have created new forms of derivative portfolios and attracted individual investors. We would like to have a systematic study on the impact of ECN on the trading structure of Taiwan's securities market.

Because most institutional and individual investors in Taiwan do not have any experience of ECN, we implement an experimental ECN system to help them understand ECN's functions and characteristics. Besides normal trading operations like order inquiry, price inquiry, and matching, the system also provides risk management and negotiation mechanisms. We then interview several trading experts after they test the system. Their answers to our survey are then systematically analyzed to investigate the impact of ECN on the trading structure of Taiwan's securities market based on trading contents, trading methods, and trading support requirements. In trading contents, we will emphasize on the demographic change of trading investors and the migration of trading goods. In trading methods, will focus on the percentages of order entry and matching choices. In trading support requirements, we will focus on the demand of the trading support tools and of trading information. This analysis architecture is applied both to Taiwan's and U.S. securities markets.

## 2. Related Work

In this section, we introduce ECN. Its origin, functionalities, characteristics, and current status are discussed first. The impact of ECN on the trading structure of U.S. securities market is then analyzed.

ECN is defined as any electronic system that widely disseminates to third parties orders entered into it by an exchange market maker or over-the-counter market maker, and permits such orders to be executed in whole or in part [16]. It originally appeared as Alternative Trading System (ATS) by providing a proprietary communication channel and information display for private trading of institutional investors and broker-dealers. It added order matching functions like traditional exchanges, and provided real-time price information through internet. Although Meridien Research predicted ECN will be a short lived phenomenon under electronic automation of traditional exchanges[11],

with the low cost in establishing and maintaining ECN, trade share volumes through ECN in Nasdaq has already reached 33.1% in May, 2002 [12], rising from 25.8% in September, 2000 [13].

The functionalities of ECN could be classified as follows: (1) Real-time matching: Order matching is the most important function of ECN. Once orders are entered into ECN, the matching mechanism will immediately process them. (2) Anonymous trading: Current ECN matching does not reveal the identities of order holders. This improves the willingness of investors to participate in the market, and reduces the impact of individual orders on the market. (3) Real-time price information: In U.S. traditional exchanges, the trading process is unfair to most investors since they do not have the channel to obtain complete real-time price information. ECN attracts investors by providing real-time complete price information like "which identity number issued what orders at what time". (4) Order transfer: ECN match orders inside its own system first. For orders unable to match inside, it could search other connected ECNs for orders matched with the best price, and then transfer the orders to that ECN.

The characteristics of ECN are as follows: (1) Fast trading: The order entering and matching in ECN could be completed without human participation, which improves the trading speed dramatically. According to McAndrews and Stefanadis [6], the average processing time for each order in an ECN in the United States was 2 to 3 seconds in 1999, compared to 22 seconds in the traditional exchanges. (2) Low cost: According to McAndrews and Stefanadis [10], in 2000, the personnel costs incurred from operators and dealers in NYSE and Nasdaq were about 55% and 25% respectively. Without much of the human participation, the operation cost of ECN is greatly reduced. Many ECNs have thus lowered the service charges to participating investors. (3) Long tradable time: Not only the order entry and matching are uninterrupted by weekends and holidays, but also are services improved by after-hours trading. Investors could make prompt trading decisions based on up-to-minute events. (4) Huge trade volume: The easy connection to the order entry system of brokers and other ECNs increases matching opportunities for orders. The low cost of ECNs also reduces the service charges imposed on the investors. The above two factors contribute to the increased ECN trade volume in Nasdaq. (5) Open structure: Traditional exchanges only allow their member brokers to connect to their system. The procedures of joining traditional exchanges and the establishment of their system take a long time. Non-member brokers need to enter orders to member brokers of a traditional exchange to trade their orders in that exchange. ECNs provide a standard application program interface for brokers and investors to easily establish connection.

## 2.1 Current Status of ECN

Current ECNs have two trading modes: open and closed. After receiving an order, ECNs will try to match it with other orders inside immediately. If the matching does not succeed, in ECNs with open trading mode, they will try other connected exchanges or ECNs, while in ECNs with closed trading mode, they will not.

The most developed and sophisticated ECNs are in the United States for stocks listed in Nasdaq. There are three cross-border ECNs in Europe. Singaporean and Australian stock exchanges have formed an alliance to trade their listed stocks. Many Japan's and Taiwan's internet brokerages have worked together with U.S. ECNs for international market information. These could be perceived as a trend in the acceptance of the idea of ECN. The percentage of trade dollar volume through ECN in Nasdaq in May 2002 is 36.2% [12], increased from 32.2% in September 2000 [13]. In 2001, besides stocks, four ECN's in the United States provide bonds trading, and two provide capabilities to trade European stocks. Jupiter predicted that the online trade dollar volume will reach 5.4 trillion U.S. dollars in 2005 [14]. ECN will enjoy the most significant increase in this trend.

## 2.2 The Impact of ECN on the Trading Structure of U.S. Securities Market

Before ECN, most trade volumes in traditional exchanges mostly came from human negotiations by market makers. After the establishment of ECN, the following changes in trading structure have been observed:

### 1. Trading contents:

- A. Growth of the percentage of individual investors: In the United States, the order information was unfair to individual investors in traditional exchanges. The service charges for them based on number of transactions were high for individual investors. Most individual investors needed to delegate professional dealers to handle their investments. In ECN, the information is fairly shared among individual and institutional dealers. ECN's service charges are relatively low compared to those of traditional exchanges. These contribute to the increased percentage of individual investors.
- B. Growth of new forms of derivatives: Derivatives were inconveniently traded through telephones before ECN, which made their trade volumes low. ECNs provide an easy to access environment both for information inquiry and for transaction completion for derivatives. It makes new forms of derivatives, like exchange of baskets of stocks, possible.

## 2. Trading methods:

Growth of the percentage of electronic trading: Traditional matching was through negotiation by market makers, which is inefficient and error prone. ECNs provide an easy to access electronic platform for order entering and matching. The percentage of trade share volumes through ECN in Nasdaq has increased from 25.8% in September 2000 [13] to 33.1% in May 2002 [12]. This statistics does not count orders matched inside each ECN or between ECNs. Therefore, the actual percentage of stock volume traded through ECN in Nasdaq is even higher.

## 3. Trading support requirements:

- A. Increased demand for professional trading tools: Many new trading tools emerge after the appearance of ECN. For example, global market maker HullTrading [8] linked all exchanges and ECNs to provide a complete market linkage trading system. It helped the investors to search the best price in the market, and to enter orders in the appropriate ECNs or exchanges to obtain the best price margin.
- B. The emergence of the requirement of consistent price information: ECNs caused the fragmentation of the securities market. The investors could enter their orders in both traditional exchanges and ECNs freely, which caused different prices for the same stock. The problem is especially severe when the market is hot.

## 3. Current Trading Structure of Taiwan's Securities Market

We will survey the current trading structure of Taiwan's stocks, bonds, and futures market separately in terms of trading contents and trading methods. Due to slow financial reform, the trading support requirement in Taiwan's securities market is mainly on the opening and linking of foreign and domestic markets. We will not survey this aspect in the following.

### 3.1 The Trading Structure of Taiwan's Stocks Market

#### 1. Trading contents:

The percentage of individual investors in Taiwan is relatively high. For example, the percentage of individual investors was 87% in February 2001 [17]. According to Taiwan Stock Exchange Corporation (TSEC), the number of individual investors involving internet issuing is about 317,000 in August 1999 [3], and the number has increased to 2.16 million in March 2002 [2], about 10% of Taiwan's population. It is easy to see that the acceptance of internet among Taiwanese investors is very high. In terms of trading

goods, due to the relative closeness of financial laws, the number of derivatives regarding stocks and other securities is low.

## 2. Trading methods:

Current trading methods could be classified as follows:

- i. On spot orders: investors could enter delegation orders in person in the brokers' counters.
- ii. Telephone orders: Investors could call the brokers to relay their order information, which will be filled in to the delegation orders by the operators.
- iii. Internet orders: Investors could fill in order information in their broker's web sites.
- iv. Programmed telephone orders: Investors could call a special telephone number to issue orders by answering programmed instructions.
- v. Mobile orders: This is similar to internet orders, except the media is now through WAP or GPRS of cellular phones.

Note that after the orders are entered, order matching is then performed in TSEC electronically in the official working hours. Chang [1] argued that TSEC is already like a big ECN in terms of order matching. However, with the definition in Section 2, we do not treat TSEC as an ECN. Currently, most order entries are through telephone. According to TSEC, the percentage of electronic order entering was 8.66% in the first quarter of 2002 [2], rising from 7.29% in October 2000 [9].

## 3.2 The Trading Structure of Taiwan's Bonds Market

#### 1. Trading contents:

Current trading unit for bonds in Taiwan is NT 50 million dollars. Since the minimal trading value is huge, most investors are institutional dealers. The trading goods include government bonds, corporation bonds, monetary bonds, and cross-country monetary bonds. Trading modes are classified into outright purchases (OP) and repurchase and reverse repurchase (Repo, Reverse Repo). In OP, the ownership of traded bonds is transmitted to the purchaser on the date of the transaction. In Repo, the seller agrees to purchase back the bonds in a fixed date with an agreed interest rate. In Reverse Repo, the buyer agrees to sell the bonds back to the seller in a fixed date with an agreed interest rate.

#### 2. Trading methods:

Most bonds in Taiwan are traded over the counter in brokers' offices through individual negotiations. This makes the whole trading process and pricing information neither transparent nor real-time. The trading is either through telephone conversation or through the bond trading system

operated by GreTai Securities Market (GTSM, formerly Over-the-Counter Securities Exchange). However, the bond trading system in GTSM is mainly for batch trading among professional bond dealers, and it is not open to investment companies and individual investors. Although this system could generate matching information during trading sessions, it does not proactively notify the dealers their trading results. With slow response and insufficient functionalities, the system does not receive good market reaction.

### 3.3 The Trading Structure of Taiwan's Futures Market

#### 1. Trading contents:

Taiwan only opens index-based futures markets. Taiwan's domestic futures market started trading in July 1998, with the product Taiwan weighted stock index futures. Taiwan electronic and banking & insurance sector stock indexes were listed in July 1999. Taiwan stock index options was then listed in December 2001. The percentage of individual investors in Taiwan's futures in terms of trade volumes in lots is about 95.92% for the first half year of 2002 [15]. Initial margins in Taiwan's futures market are much higher than those in the United States. In addition, since there is a 7% fluctuation bound in Taiwan's stock market, the daily gain or loss in Taiwan's futures is also limited.

#### 2. Trading methods:

Taiwan's futures are already traded electronically. However, information of foreign futures, like commodities or SIMEX MSCI Taiwan Stock Index Futures, is hard to obtain, and trading channels for them are inconvenient.

## 4. The Design and Implementation of an Experimental ECN

### 4.1 System Requirement

Besides the aforementioned ECN functionalities of real-time price information, immediate matching, order transfer, and standard API, we believe a negotiation mechanism with an ICQ-like interface with log capability is very important. The log could provide negotiation history, evidence when there is an argument, and confirmation after the negotiation is complete.

### 4.2 System Architecture

Fig. 1 demonstrates the system architecture for our proposed ECN. The investors in the left of the dash line represent the client side of the system to enter orders through internet. The main modules are as follows:

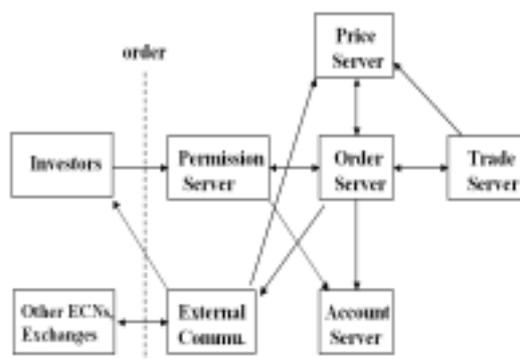

Fig. 1: System Architecture of Our ECN

1. Permission server: It is responsible for registration, security and authentication control. Negotiation and usage logs are recorded here.
2. Order server: It is responsible for coordinating all order related operations. It will dispatch orders to corresponding modules based on their status. Other modules will report their processing results to it too. It will also proactively transmit order information through External Communication to interested investors and brokers in other ECNs. Chen [4] provided details about its operation.
3. Trade server: It is responsible for order matching. After it receives the order information from order server, it will try to match the order immediately. The result will then be sent back to order server.
4. Price server: It stores the price information from trade server, order information from order server, and the external price information from other ECNs. External orders will be sent to order server for matching.
5. Account server: It is responsible for storing account related information, like current balance and detailed securities holdings, so that the user could inquire their financial data to perform risk management.
6. External communication: It is to handle communication with end users and other ECNs or exchanges. External orders will be sent to price server to store related information before matching. Orders unable to be matched in the system will be sent to other ECNs or exchanges through this module. For system extensibility, the format for the communication is FIX 4.2 [7], the format for standard financial transactions.

### 4.3 System Application

Brokers could handle the received order information based on their own needs. To verify the usability of our system, we also implement a testing client system for brokers to query information and enter orders. For example, a user could query price information for a bond by simply typing in the bond's number.

In addition to normal functionalities of ECN, we also provide the following extra functions:

1. Control of dealer's handling amount: We provide this mechanism for the broker to control the maximal daily handling amount for their dealers. It will prevent the broker from huge loss caused by adventurous dealers.
2. Negotiation: The negotiation mechanism could allow the investors to negotiate with several dealers simultaneous to obtain the best price.

### 5. The Impact of ECN on the trading structure of Taiwan's Securities Market

In this section, we first explain the background of the inevitability of the approaching of ECN. Questions for several trading specialists are then presented. Their answers to these questions are then summarized according to the analysis structure in Section 2.

There are two main reasons why the approaching of ECN is inevitable:

1. The trend of cross-country trading: Currently when an Taiwanese investor plans to participate in foreign securities market, the usual channel is through purchasing mutual funds for foreign securities. If he wants to handle the investment in person, then he needs to enter orders in various foreign exchanges, which is very inconvenient. The capability of order transfer in ECN is an off-the-shelf solution to alleviate this issue. Most corporations also are willing to have their stocks or bonds traded cross-border to collect capital. Global cross-country exchanges have been booming recently. Euronext comprises stock exchanges of New York, Paris, Amsterdam, and Brussels. Nasdaq, London, and Frankfurt stock exchanges are already linked. Singapore and Australian stock exchanges have formed an alliance. The easy connection of ECNs also makes their entrance into other countries easy.
2. The openness of financial market after WTO: Before joining WTO, Taiwan government has removed the monopoly protection to domestic

exchanges. Foreign exchanges, ECNs, investment banks, etc., are entering into Taiwan's financial market with their professional knowledge and huge capital. For example, Taiwanese web sites, like Cnyes [6], have already linked with U.S. ECNs to provide real-time stock information. It is inevitable that Taiwan's financial market will link with global markets. Taiwanese brokers have started the process of merge and acquisition since 1999 to react to the emerging global competition.

We demonstrated our experimental ECN system to several trading specialists and asked them to test it. We then interviewed them with questions based on the analysis structure we mentioned in Section 2. Table 1 demonstrates the questions we proposed:

**Table 1: Questions to Taiwan's Trading Specialists**

Interview questions	Reasons for asking
What will be the advantage of ECN in Taiwan's current securities trading environment?	Since the securities trading environments are quite different in Taiwan and the United States when ECN is booming, some advantages of ECN in the United States may not hold in Taiwan.
What kind of ECNs will prosper in Taiwan?	Since order matching in Taiwan is already completed electronically, and order entry through internet has been booming in Taiwan, we believe the ECNs that will prosper in Taiwan will be different from those in the United States.
What will be the impact of ECN on the trading structure of Taiwan's securities market?	This is our research thesis.
What will be the influence of the negotiation mechanism on the trading methods?	We would like to investigate the effect of our ECN's ICQ-like negotiation mechanism on the trading methods of Taiwan's securities market.
What will be the impediments of ECN in Taiwan? Are there other missing functionalities?	We would like to understand the problems ECN will face in Taiwan.

Since the interview should be conducted to people with some background knowledge of ECN, it is difficult to find proper trading specialists for the interview. We only interviewed three specialists before December 2001. The following is the conclusion of our interview:

1. The impact of ECN on trading contents of Taiwan's securities market

a. Increased percentage of institutional investors: The percentage of individual investors in Taiwan is already very high. With the introduction of many new financial goods to Taiwan, ECNs will increase the flexibility of investment combinations of securities, and also increase the difficulty of investment management. Thus, individual investors will seek the help of trading specialists, which will increase the percentage of institutional investors in Taiwan's securities markets. On the other hand, in the United States, before ECN, since individual investors had difficulties in obtaining complete trading information, and the service charges were high, the percentage of individual investors was relatively low. ECN changed the above trading environment in the United States, and increased the percentage of individual investors.

b. Emergence of diversified securities goods: Taiwan's current tradable securities goods are limited. Besides easy combination of securities goods, ECN is suitable for cross-country trading. That will make the securities goods more diversified. Part of the investment capital will be moved to these new financial goods. Thus the percentage of stock investment in total investment will then be reduced. On the other hand, because the financial goods in the United States have been relatively complete before ECN, ECN has little impact on the percentage of securities goods, and it just increased the flow of current financial goods.

2. The impact of ECN on trading methods of Taiwan's securities market

a. Trading volume will be shifted to ECN: Although order matching in Taiwan is already completed electronically, it is performed in a black box. With the advantages of ECN, investors will be attracted to complete their orders in ECN, especially for after-hours market. On the other hand, in the United States, the reduce of percentage of trade volumes through non-ECNs in Nasdaq has been mainly due to the speed up of ECN compared to slow human negotiations by market makers.

3. The impact of ECN on trading support requirements of Taiwan's securities market

a. The growth of the demand of supporting investment tools: With the expected booming of new diversified investment goods, the demand for investment tools to analyze and to support trading of these diversified goods will also increase.

b. The emergence of the requirement of transparent

trading information: Current price information in Taiwan is not transparent in real-time for both institutional and individual investors. With the provision of complete ordering information in ECN, investors in the traditional exchanges will ask for the same support. On the other hand, in the United States, since individual investors did not have sufficient order information of orders from market makers, the demand of transparent trading information has been existent before ECN.

c. The emergence of the demand of negotiation mechanisms: Although order matching in Taiwan is completed electronically, the human negotiation process still exists in bond trading and after-hours market. They currently are completed mostly through telephone conversations. The demand for the negotiation mechanism will increase. On the other hand, the trading market in the United States before ECN had been mainly by human negotiation. The demand to add negotiation mechanisms in ECN was not so obvious in the beginning.

## 6. Conclusion

With the gradually opened Taiwanese financial market, most people have noticed the booming trend of internet brokerages. This trend has been extended to the traditional exchanges in other countries, and ECNs have already occupied noticeable market share already. However, the trend seems not noticed by most investors in Taiwan. We surveyed and accumulated related data about ECN in the United States. We designed and implemented an experimental ECN with the negotiation mechanism. The system was tested by Taiwan's trading specialists. Their interview answers were then summarized for the impact of ECN on the trading structure of Taiwan's securities market based on an analysis structure of trading contents, trading methods, and trading support requirements. The conclusion of our interview is as follows:

1. Securities goods will be more diversified.
2. The percentage of trade volumes from institutional investors will increase.
3. Part of the trade volumes will be shifted to ECN.
4. The demand for supporting investment tools will increase.
5. The requirement of transparent price information will arise.
6. The requirement of negotiation mechanisms will arise.

Future research topics include:

1. Investigation of required modification of regulating laws: Since the regulation about

securities trading is different for each country, it has become an obstacle in establishing a global trading market. Most financial reforms will need to adjust the current law in each country. A consistent and systematic investigation is needed to compare the differences in each country.

2. The enforcement of security: Since the trading dollar amounts are normally huge, it will become an obvious target for security intruders when order information is communicated electronically. Therefore, a proper design and implementation of network security mechanisms is very important.
3. The impact of ECN on the trading structure of securities market in other countries: It has been difficult for us to find related academic works about this research. We hope our research will be helpful for later investigation for other countries.

# Using Hidden Markov Model for Stock Day Trade Forecasting

Wen-Chih Tsai    An-Pin Chen  
Institute of Information Management  
National Chiao Tung University  
Hsinchu, Taiwan  
ibm@iim.nctu.edu.tw

## Abstract

Around the world, the Hidden Markov Models (HMM) are the most popular methods in the machine learning and statistics for modeling sequences, especially in speech recognition domain. According to the number of patent applications for speech recognition technology from 1988 to 1998, the trend shows that this method has become very mature. In this thesis, we will make a new use of the HMM and apply it on day trading stock forecast.

However, the HMM is based on probability and statistics theory. In a statistics framework, the HMM is a composition of two stochastic processes, a Hidden Markov chain, which accounts for temporal variability, and an observable process, which accounts for spectral variability. The combination contains uncertainly status just likes the stock walk trace. Therefore, the HMM and the stock walk trace have the same idea by coincidence. In this thesis, we will try to learn the stock syntax; just like how the HMM model was used in speech recognition in different languages, and the take the next step ahead in price prediction.

Additionally, the stock market is the reflection of the economy. The stock trace is impacted by many factors such as policy, psychology, microeconomics, economics, and capital, etc. There, in this thesis, the TAIFEX Taiwan index futures (TX) and day trade are used to avoid all the uncertainty factors. After the all experiments, it is proven that the HMM is better than the benchmark method-Random Walk method and the Investment Trust & Consulting Association method- Modified Trading method. Moreover, the result is very conspicuous by the statistics testing of significance.

Key words : Day trade、Hidden Markov Model、Modified Trading method、Time series forecasting

## 1. Introduction

A typical problem faced by stock managers is to take invest that various stocks, or stocks classes, in an optimal way. To do this the stock manager must first develop a model for the evolution, or prediction, of the rates of return on investment in each of these stock classes. A common procedure is to stock of return are drive by rates of return on some observable factors. In this research we propose a model for the rates of return in terms of observable and non-observable factors; we present algorithms for the identification for this model, (using filtering and prediction techniques) and indicate how to apply this methodology to

the (strategic) stock prediction problem using a mean-variance type utility criterion.

Earlier work in filtering is presented in the classical work of Liptser and hirayayev. Previous work on parameter identification for linear, Gaussian models includes the paper by Anderson et al. [1]. However, this reference discusses only continuous state systems for which the dimension of the observations is the same as the dimension of the unobserved state. Parameter estimation for noisily observed discrete state Markov chains is fully treated in [2]. The present paper includes an extension of techniques from [2] to hybrid systems, that is, those with both continuous and discrete state spaces.

In recently, the Hidden Markov Model (HMM) is a popular technology in speech recognition domain. Especially in the telephone weather query, telephone timetable query, banking telephone services, telephone stock query, ... etc. Investigating into the G06 and G10 of the international patent classification (IPC) can find out that the speech recognition patents are growth from 1988 until 1998. Those patents are researched in Hidden Markov Models in the mostly. So it's implied the conclusion that the speech recognition technology is very ripe after 1998. This is illustrated in Fig. 1.1.

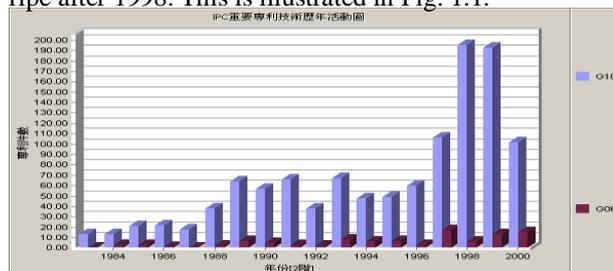

Fig1.1 IPC G10 and G06 analysis graph

As far as we know, the traditional speech recognition system shows the some major components. This is illustrated in Fig. 1.2. The digitized speech signal is first transformed into a set of useful measurements or features at a fixed rate. These measurements are then used to search for the most likely word candidate, making use of constraints imposed by the acoustic, lexical, and language models. Throughout this process, training data are used to determine the values of the model parameters. In this work, the input signal will be transfer into stock day trade wave signal.

In order to facilitate identification of objects from patterns, this work will assume that the set of patterns that can be produced by a component is finite. So this work will make some experiment for try to find out the pattern from

the day trade history records of the Taiwan Stock Exchange Capitalization Weighted Stock Index (TAIFEX future, TX) from 1998 to 2002. In additionally, according to the law source of the Securities and Futures Commission (SFC) day trade rule in May 1994. The law provides a lawful transaction rule to investor. This work will base on the law for approve the architecture feasibility.

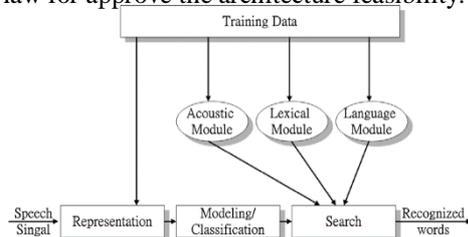

Fig1.2 The speech recognition system architecture

## 1.2 Research scope of this work

In this work, the research source data is the day trade history records of the TAIFEX futures (TX) from 1998 to 2002. As result of the records are day trades. So it will not be impacted form any factors. No matter policy, psychology, microeconomics, economics, capital, last night USA stock market etc. It's included the opening price, opening quotation, and closing price, closing quotation, volume, transaction price, high price and low price. It's total 866 days trade history records from 21, July, 1998 to 20, February, 2002. The training time is from 21, July, 1998 to 21, July, 2001. The simulation time is from 24, July 2001 to 20, February 2002. Additionally, this work will try to apply the HMM into the recognition model to be the forecasting strategy and compare two traditional invest strategy models. One is the Random walk[9] strategy model that is the benchmark model, and the other is the Investment Trust & Consulting Association Modified Trading model[18].

## 2. Background

### 2.1 Overview stock market theory

The trade credit is the generic term for a stock investor's purchase of supplies. In the traditionally, the vendors and suppliers are often willing to sell on credit and this source of working capital financing is very common for both startup and growing businesses. Suppliers know that most small business rely primarily upon a limited number of suppliers and that small businesses typically represent relatively small order risks; as long as the supplier keeps a tight rein on credit terms and receivables, most small businesses are a worthwhile gamble for future business. But the stock trade credit is be provided rule form SFC for those vender's want to buy stock but they have not enough money, or those supplier want to sell stock but they have not hold any stock. The rule has three systems include Purchase on margin, short on sell and day trade.( Purchase on margin ,Short on sell and Day trade)

The day trade is the generic term for a stock investor's to loan stocks or money from Stock Exchange Company and

sell or buy stocks in the same day. That is due to one of the lowest risk transaction process. In the other words, it's the lowest return transaction process. In fact the process have a very good operation in the same day. So it can evade the risk of the last night USA stock risk[19]. No matter what's happen, the investor just loss the 7% of capital even which the decision is wrong. So the day trade of the SFC provides a very stability trade system. But the day trade system has three previous conditions as below.[19]

- . The volume must over some quotation. That is because the investor can buy and sell into stock exchange market any times.

- . The price undulation must over some degree. That is because the investor can buy and sell into stock exchange market any times. So the investor can have at least returns.

- . The transaction cost must low or the returns of the investor will be reduce comparative.

Summing up the previous various reasons, the stock market cannot find out the stock to fit the each condition. But in fact, it is not adapting to the stock market day trade conditions. The conditions are more adapting to futures market. As well as, the Taiwan government trend to encourage investor to make uptrend. Just as the margin of finance margin trade is lower than the margin of stock margin trade. Such as the other rules limits to the buy and sell order. So the strategy of the operation is very important. The thesis will experiment in the TAIFEX futures (TX) .

### 2.2 TAIFEX futures (TX)

The TAIFEX futures (TX) contract is based on the SFC security and future laws. The TAIFEX futures (TX) is the generic term for each stock's volume of circulation, which enter the market, be weighted to calculate the index value. In other words, the big capital stock will impact over the small capital stock. It is mean that TAIFEX futures (TX) contract is based on the volume of circulation-weighted index to be the target. So the relation is very interdependence between the TAIFEX futures (TX) and the volume of circulation. Even the weighted index pulsating will bring the TAIFEX futures (TX) pulsating in the same time. So the investor does not need to study each stock changing. The investor just need to study the TAIFEX futures (TX).

### 2.3 Overview forecast time series theory

In the section, the thesis wills introduction two major basic time series stock forecast models, Linear forecast model and Non- Linear. forecast model. The section will introduction from basic model. So the section will introduce four linear forecast models and five non-linear forecast modules. The introduction will not only introduce the module theory and also introduce the application.

### 2.4 Overview Modified Trading method theory

In the current method of the Investment Trust and Consulting Association, the trader uses the population method of modified trading on day trade. About the method is follow as the experiment of the Investment Trust

and Consulting Association. So this work will to implementation the theory in an algorithm. The method can transfer to the below table. The method catches three statuses from three-time point. One is 9:05 and the other is 9:10, and other is 9:15. The three statuses can combine to a status series.

The Modified Trading method applies to all eight Full and Partial Gap scenarios above. The only difference is instead of waiting until the price breaks above the high; you enter the trade in the middle of the rebound. The other requirement for this method is that the stock should be trading on at least twice the average volume for the last five days. This method is only recommended for those individuals who are proficient with the eight strategies above, and have fast trade execution systems. Since heavy volume trading can experience quick reversals, mental stops are usually used instead of hard stops.

### 3. Hidden Markov Model

#### 3.1 Overview Hidden Markov Model

The Hidden Markov Model has been published form 1960s[5]. This model is based on the probability and statistics theory. The Hidden Markov Model is a finite set of states, each of which is associated with a (generally multidimensional) probability distribution. The model is the population method on the speech recognition domain. Transitions among the states are governed by a set of probabilities called transition probabilities. In a particular state an outcome or observation can be generated, according to the associated probability distribution. It is only the outcome, not the state visible to an external observer and therefore states are "hidden" to the outside; hence the name Hidden Markov Model. This work hope to applied the model in the stock day trade forecast.

As well the HMM has two major basic model which one is Continuous HMM(CHMM) and the other is Discrete HMM(DHMM) by the observation probability. As a result of the stock daily record is coming from matched pricing between buy and sell. So the day trade records are one of the discrete observation probabilities. The thesis is picking up the discrete HMM to experiment.

An HMM is a Markov chain and a double-layer random probability system, where each state generates an observation. Only see the observations, and the goal is to infer the hidden state sequence. HMMs are very useful for time-series modeling, since the discrete state-space can be used to approximate many non-linear, non-Gaussian systems. The hidden layer cannot be observation directly. But the hidden layer can be observed from the past random process output series sets. It is mean that the Markov chain includes the hidden layer and observation output layer.

In the thesis, the HMM is assumed that the day trade signal was produced status series (hidden layer) by a random process. Then produce an observation sequence by the status series and the other random process. The generally HMM is a Left-Right Hidden Markov Model. The HMM's architecture is a double stochastic process. This is illustrated in Fig. 3.1.

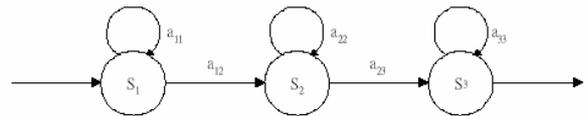

Fig 3.1 the three status Left-Right HMM

However the un-observed layer is a finite set markov chain. Its state probability distribution and states transaction are decided on between the state initial probability vector and state transition probability matrix. But the observed layer is the output of the output layer, which based on each probability distribution.

In theory, the HMM can be a multi layer. Although the result of the multi layer Markov chain is better then the single layer Markov chain. But in opposition, the model is more complex and operation.

However, the work apply the HMM into stock forecast recognition domain. It have to resolve some problem first as the below. (1)How to split each signal? (2)How to like the state sequence? (3)How much is the each status probability?(4)How to detect the next status?

About the problem, the first three problems are belonging to tanning problem. The (4) problem is the recognition process. The (1) belongs to the HMM pre-process problem. The (2) (3) belong to the building the HMM problem. The (4) is the short path problem. In the speech recognition domain, the popular problem is the Vitergbi algorithm.

#### 3.2 HMM Parameter

The HMM consisted of a triple observed probability parameters(A,B, $\pi$ ). So the mathematical model of HMM can be represented to $\lambda=(A, B,\pi)$ .

Each probability in the state transition matrix and in the confusion matrix is time independent - that is, the matrices do not change in time as the system evolves. In practice, this is one of the most unrealistic assumptions of Markov models about real processes. So the  $\lambda$  is the Markov Model. In order to define an HMM completely, following elements are needed.

In order to define an HMM completely, following elements are needed.

- . The number of states of the model, N.
- . The number of observation symbols in the alphabet, M. If the observations are continuous then M is infinite.
- . A set of state transition probabilities  $A = \{a_{ij}\}$ .

$$a_{ij} = p\{q_{t+1} = j | q_t = i\}, 1 \leq i, j \leq N \quad \text{where } q_t \text{ denotes the current state.}$$

Transition probabilities should satisfy the normal stochastic constraints,

$$a_{ij} \geq 0, \quad 1 \leq i, j \leq N \quad (3-2-1)$$

$$\text{and } \sum_{j=1}^N a_{ij} \geq 0, \quad 1 \leq i, j \leq N \quad (3-2-2)$$

- . A probability distribution in each of the states  $B = \{b_j(k)\}$

$$b_j(k) = p\{a_t = v_k | q_t = j\}, 1 \leq j \leq N, 1 \leq k \leq N \quad (3-2-3)$$

Where  $V_k$  denotes the  $k_{th}$  observation symbol in the alphabet and  $O_k$  the current parameter vector.

. Following stochastic constraints must be satisfied.

$$b_j(k) \geq 0, \quad 1 \leq j \leq N, 1 \leq k \leq M \quad (3-2-4)$$

$$\text{and } \sum_{j=1}^N b_j(k) = 1, \quad 1 \leq k \leq N \quad (3-2-5)$$

. The initial state distribution,  $\pi = \{\pi_i\}$

Where,  $\pi_i = p\{q_t = i\}, 1 \leq i \leq N$

Therefore function can use the compact notation

$$\lambda = \{A, B, \pi\} \quad (3-2-6)$$

to denote an HMM with discrete probability distributions.

### 3.3 Vector quantification

In this paper, the recognition system must to do a characteristic value first. [29] Otherwise the system will have a very complex calculate and data. So the vector quantification will calculates the classification by the similar classes. But the general quantification will level down the recognition rate. So this work will apply the vector quantification to do the pre-process.

The code book is been produced by the vector quantification of all stock day trade training data.. The vector quantification will been selected from the stock day trade traing data by the geometric distance clustering. The clustering will group by the closing group. Then it will find out the must representative vector ( A mean of the culster) to do the code word. Ex: Assuming that the two vector quantification are

$$X = [x_1, x_2, \dots, x_n]^T \quad (3-3-1)$$

and

$$Y = [y_1, y_2, \dots, y_n]^T \quad (3-3-2)$$

so the distance define is as below

$$d(X, Y) = \sqrt{\sum_{i=1}^n [x_i - y_i]^2} \quad (3-3-3)$$

This work will need N vector quantification to produce M code word. The population is the K-mean Clustering algorithm. The algorithm lists as below steps.

Step 1: Select an initial partition with K clusters

¢ An initial partition can be formed by first specifying a set of K seed points which can be the first K patterns or K patterns chosen randomly from the pattern matrix

¢ Different initial partitions can lead to different final clustering because algorithms based on square-error can converge to local minima. This is especially true if the clusters are not separated well.

Step 2: Generate a new partition by assigning each pattern to its closest cluster center.

Step 3: Computer new cluster centers as the centroid of clusters

¢ A set of K patterns that are well separated form each other can be obtained by taking the Centerior of the data as the first seed point and selection successive seed points which are at least a certain distance away from the seed points already chosen.

¢ Square-Error

Step 4: Repeat steps 2 and 3 until an optimum value of the criterion function is found

¢ Partitions are updated by reassigning patterns to clusters in an attempt to reduce the square-error.

¢ The Euclidean metric is the most common metric for computing the distance between pattern and a cluster centers

Step 5: Adjusts the number of clusters by merging and splitting existing clusters or by removing small, or outlier, clusters.

¢ Some clustering algorithms can create new clusters or merge existing clusters if certain conditions are met.

### 3.4 Building Hidden Markov Model

In this research, the stock day trade records will be representated vector. pre-process. So the each day will be transfed to the vector series. It represents the each day vector quantification code book. Then the system can forecast the closing pric by the code book seraching.

But the system must been trained the history day trade data before forecast. The training process can get the each model prameter  $\lambda_1, \lambda_2, \dots, \lambda_v$ . Assuming that the  $\lambda$  is known number and the  $O = \{o_1, o_2, \dots, o_T\}$  is the output vector quantification series ( $T = \text{length}$ ). The system will generate the  $q = \{q_1, q_2, \dots, q_T\}$  which is the input vector quantification series. So the probability is as below.

$$P\left(\frac{O}{\lambda}\right) = \sum_q p(O, \lambda) = \sum_{q_1, q_2, \dots, q_T} 1 \cdot b_{q_1}(o_1) a_{q_1 q_2} b_{q_2}(o_2) \dots a_{q_{T-1} q_T} b_{q_T}(o_T)$$

To assume that the HMM have N status, and the HMM can transfer from any one state to anothers. So the status transfer series have  $N^T$ . If the T is very big, the system will have very heavy Big-O. So the probability of the HMM vector quantification series can calcuate form the Forward procedure and Backward procedure.

#### 3.4.1 Forward procedure

Definition: In t time points, there are status in the i status.

And the observed probability is the  $O_1, O_2, \dots, O_t$ , and

the probability of the series is  $\alpha_t(i)$ .

$$\alpha_t(i) = P(O_1 O_2 \dots O_t, q_t = i | \lambda)$$

$$P(O_1 O_2 \dots O_t, q_t = i | \lambda) = \sum_{i=1}^N P(O_1 O_2 \dots O_t, q_t = i | \lambda) = \sum_{i=1}^N \alpha_t(i)$$

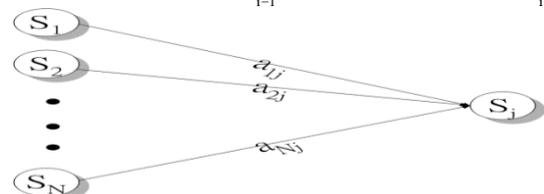

Fig 3.2 The Forward procedure

Algorithm step:

Step 1: Initial setup

$$\alpha_t(i) = \pi_i b_i(O_t), 1 \leq i \leq N$$

Step 2: Recursive

$$\alpha_{t+1}(j) = \sum_{i=1}^N \alpha_t(i) a_{ij} b_j(O_{t+1}), \quad 1 \leq j \leq N, \quad t = 1, \dots, T-1$$

Step 3: Final

$$P\left(\frac{O}{\lambda}\right) = \sum_{i=1}^N \alpha_T(i)$$

### 3.4.2 Backward procedure

Definition: In  $t$  time points, there are  $\lambda$  in the  $i$  status.

And the observed probability is the  $O_{t+1}, O_{t+2}, \dots, O_T$

from  $t+1$  to  $T$ , and the probability of the series is  $\beta_t(i)$ .

$$\beta_t(i) = P(O_{t+1}, O_{t+2}, \dots, O_T, q_t = i | \lambda)$$

$$P(O_{t+1}, O_{t+2}, \dots, O_T, q_t = i | \lambda) = \sum_{k=1}^N P(O_{t+1}, O_{t+2}, \dots, O_T, q_t = i | k) = \sum_{k=1}^N \alpha_T(k)$$

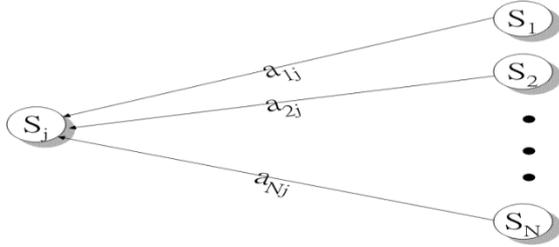

Fig 3.3 The Backward procedure

Algorithm step:

Step 1: Initial setup

$$\beta_T(i) = 1, 1 \leq i \leq N$$

Step 2: Recursive

$$\beta_t(i) = \sum_{j=1}^N a_{ij} b_j(O_{t+1}) \beta_{t+1}(j), \quad t = T-1, T-2, \dots, 1, \quad 1 \leq i \leq N$$

Step 3: Final

$$P\left(\frac{O}{\lambda}\right) = \sum_{i=1}^N \beta_1(i)$$

### 3.5 Estimate the HMM

One great advantage of HMMs is that they can be estimated from sequences, without having to align the sequences first. The sequences used to estimate or train the model are called the training sequences, and any reserved sequences used to evaluate the model are called the test sequences. The model estimation is done with the forward-backward algorithm, also known as the Baum-Welch algorithm, which is described in [4]. It is an iterative algorithm that maximizes the likelihood of the training sequences. So assuming that two vector

quantifications  $P(O/\lambda), P(O/\bar{\lambda})$  to represent the likelihood of  $O$ . Then have the  $P(O/\bar{\lambda}) \geq P(O/\lambda)$  relation between the two vector quantifications. Then use the substitution methods to find out the new parameter  $\bar{\lambda}$ .

Step 1: In  $t$  time points, there  $\lambda$  transfer from the  $i$  status to  $j$  status. The  $\lambda$  probability is  $\zeta_t(i, j)$ .

$$\begin{aligned} \zeta_t(i, j) &= P(q_t = i, q_{t+1} = j | O, \lambda) \\ &= \frac{P(q_t = i, q_{t+1} = j, O | \lambda)}{P(O/\lambda)} \\ &= \frac{\alpha_t(i) a_{ij} b_j(O_{t+1}) \beta_{t+1}(j)}{P(O/\lambda)} \\ &= \frac{\alpha_t(i) a_{ij} b_j(O_{t+1}) \beta_{t+1}(j)}{\sum_{i=1}^N \sum_{j=1}^N \alpha_t(i) a_{ij} b_j(O_{t+1}) \beta_{t+1}(j)} \end{aligned}$$

Step 2: In  $t$  time points, there  $\lambda$  transfer from the  $i$  status to  $i$  status. The  $\lambda$  probability is  $\gamma_t(i)$ .

$$\begin{aligned} \gamma_t(i) &= \sum_{j=1}^N \zeta_t(i, j) \\ &= \frac{\sum_{j=1}^N \alpha_t(i) a_{ij} b_j(O_{t+1}) \beta_{t+1}(j)}{p(o/\lambda)} \end{aligned}$$

Step 3: The new transfer function will be changed to  $\bar{a}_{ij}$

$$\begin{aligned} \bar{a}_{ij} &= \frac{\sum_{t=1}^{T-1} \zeta_t(i, j)}{\sum_{t=1}^{T-1} \gamma_t(i)} \\ &= \frac{\sum_{t=1}^{T-1} \alpha_t(i) a_{ij} b_j(O_{t+1}) \beta_{t+1}(j)}{\sum_{t=1}^{T-1} \sum_{j=1}^N \alpha_t(i) a_{ij} b_j(O_{t+1}) \beta_{t+1}(j)} \\ &= \frac{\sum_{t=1}^T \gamma_t(i)}{\sum_{t=1}^T \gamma_t(j)} \\ \bar{b}_{ij} &= \frac{\sum_{t=1}^{s.t. O_t = v_k} \zeta_t(i, j)}{\sum_{t=1}^T \gamma_t(j)} \\ &= \frac{\sum_{t=1}^T \sum_{j=1}^N \alpha_t(i) a_{ij} b_j(O_{t+1}) \beta_{t+1}(j)}{\sum_{t=1}^T \sum_{j=1}^N \alpha_t(i) a_{ij} b_j(O_{t+1}) \beta_{t+1}(j)} \end{aligned}$$

Step 4:  $\alpha \beta$  scaling

$$\alpha_t(i) a_{ij} b_j(O_{t+1}) = \frac{\alpha_t(i)}{\prod_{r=1}^T c_r} a_{ij} b_j(O_{t+1}) \frac{\tilde{\beta}_{t+1}(j)}{\prod_{r=t+1}^T c_r}$$

$$= \frac{\alpha_t(i) a_{ij} b_j(O_{t+1}) \tilde{\beta}_{t+1}(j)}{\prod_{r=t+1}^T c_r}$$

Step 5: So the  $\alpha_{ij}, \beta_j(k)$  changed to.

$$\alpha_{ij} = \frac{\sum_{t=1}^{T-1} \alpha_t(i) a_{ij} b_j(O_{t+1}) \tilde{\beta}_{t+1}(j)}{\sum_{t=1}^{T-1} \sum_{j=1}^N \alpha_t(i) a_{ij} b_j(O_{t+1}) \tilde{\beta}_{t+1}(j)}$$

$$\beta_j(k) = \frac{\sum_{t=1}^T \sum_{j=1}^N \alpha_t(i) a_{ij} b_j(O_{t+1}) \tilde{\beta}_{t+1}(j)}{\sum_{t=1}^T \sum_{j=1}^N \alpha_t(i) a_{ij} b_j(O_{t+1}) \tilde{\beta}_{t+1}(j)}$$

### 3.6 Viterbi algorithm

Summary pervious process, this work will have a very complex algorithm to find out the correct  $P(O_1 O_2 \dots O_T | M)$ . So the Viterbi algorithm is been used to find out status transfer series by the stock day trade vector quantification. So the algorithm can closing the  $P(O_1 O_2 \dots O_T | M)$  in the optomation algorithm.[12]

Assuming that the vector quantification is as below.

$$\text{Vector quantification: } O = (O_1 O_2 \dots O_T) \quad (3-6-1)$$

This initializes the probability calculations by taking the product of the initial hidden state probabilities with the associated observation probabilities. The max probability is as below.

$$\delta_t(i) = \max_{q_1, q_2, \dots, q_t} P(q_1, q_2, \dots, q_{t-1}, q_t = i, O | \lambda) \quad (3-6-2)$$

According to the recusrive algorithm, So the max probability is as below during the status j at the time point t+1.

$$\delta_{t+1}(j) = [\max_i \delta_t(i) a_{ij}] \cdot b_j(O_{t+1}) \quad (3-6-3)$$

Step 1: Formal definition of algorithm

The algorithm may be summarized formally as:

$$\delta_1(i) = \pi_i b_i(O_1), 1 \leq i \leq N \quad (3-6-4)$$

$$\varphi_1(i) = 0 \quad (3-6-5)$$

Step 2: Recursive

$$\delta_t(i) = \max_{1 \leq j \leq N} \delta_{t-1}(j) a_{ji} b_i(O_t), 2 \leq t \leq T, 1 \leq j \leq N \quad (3-6-6)$$

$$\Psi_t(j) = \arg \max_{1 \leq i \leq N} [\delta_{t-1}(i) a_{ij}], 2 \leq t \leq T, 1 \leq j \leq N \quad (3-6-7)$$

Step 3: End criteria

$$P^* = \max_{1 \leq i \leq N} [\delta_T(i)] \quad (3-6-8)$$

$$q_T^* = \arg \max_{1 \leq i \leq N} [\delta_T(i)] \quad (3-6-9)$$

Step 4: Path look back

$$q_t^* = \Psi_{t+1}(q_{t+1}^*), t = T-1, T-2, \dots, 1 \quad (3-6-10)$$

Symbol define:

$\delta_t(i)$  : The path have the max probability at time point t.

$\Psi_t(i)$  : The satus is that before current status.

$P^*$  : The result is that be calculated by Viterbi algorithm.

$q^*$  : It is the optimal status time series.

$(q_1^*, q_2^*, \dots, q_T^*)$

Summarized pervious, the Viterbi algorithm is follow the initial probability  $\delta_t(i)$ . Then it can obtain a max probability series by rescursive algorithm.(3-6-8) The Viterbi algorithm can obtain the max probability status time series. (3-6-10). So the algorithm can reduce the algorithm search time. This is illustrated in Fig. 3.4.

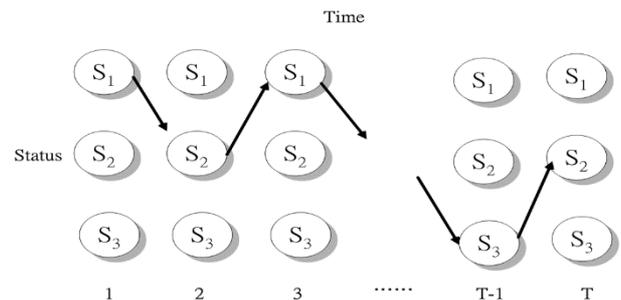

Fig. 3.4 The optimal algorithm of the Viterbi algorithm

## 4. Implementation

### 4.1 Research scope

This paper will build a HMM architecture to forecast the TAIFEX futures (TX) closing price by the previous training. The data source is come from the TEJ database. This paper is forecasting the TAIFEX futures (TX) closing price. So this paper will to build an each five minutes day trade records first. This paper will to forecast the TAIFEX futures (TX) behavior in one day.

The source data of this work is as below list.

- (1)The records of the each five minutes TAIFEX futures
- (2)The volume of the each five minutes
- (3)The high price of the each five minutes
- (4)The low price of the each five minutes
- (5)The opening price
- (6)The closing price

The source data has 41439 records of the each five minutes TAIFX futures (TX). The source data can transfer to total 866 days trade history records from 21, July, 1998

to 20, February, 2002. The training time is from 21, July, 1998 to 21, July, 2000. So the training data has 20946 records. (Table 4.1) The simulation time is from 24, July 2001 to 20, February 2002. So the simulation data has 20493 records.

#### 4.2 Simulation architecture

In this section, this work will to introduce the HMM method in detail that is because the model is more complex than the other two methods. The simulation architecture is illustrated in Fig. 4.1.

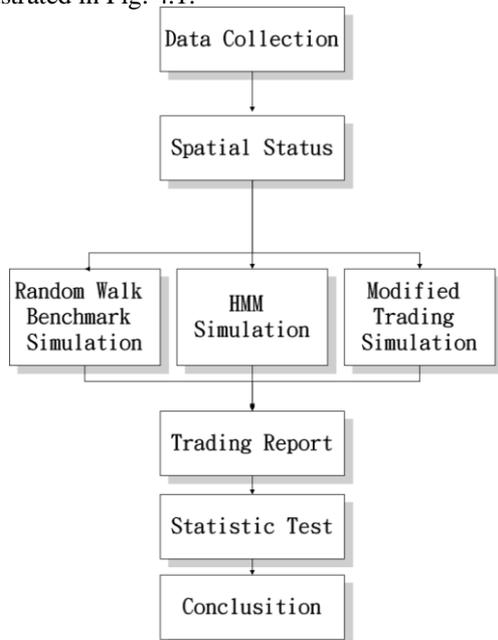

Fig. 4.1. Simulation Architecture

#### 4.3 Simulation model

In this section, this paper will to introduce the two simulation methods in the next two small sections. The first section is the benchmark method - Random Walk method. The second section is the method - Modified Trading method. The next section is the HMM. This work will to introduce the HMM method in detail that is because the model is more complex than the other two methods.

##### 4.3.1 Random Walk model

Robbers publish this Random Walk model is in 1967. The model has not intercept item. So the revenue of the forecasting mean( $\mu$ ) should be zero. The mean is that the random variable is the zero expected value. The Random Walk model is sampling form the simplex with probability density proportional to

$$Z = \frac{x - \mu}{\sigma}$$

$$f(Z) = \frac{1}{\sqrt{2\pi}} e^{-\frac{z^2}{2}}; -\infty < Z < \infty$$

$$E(z) = E\left(\frac{x - \mu}{\sigma}\right) = \frac{1}{\sigma} E(x - \mu) = 0$$

The model is the weak-form efficient market hypothesis in the financial forecast domain. This work will compare HMM model to this financial benchmark model.

##### 4.3.2 Modified Trading model

The Modified Trading Method applies to all eight Full and Partial Gap scenarios above. The only difference is instead of waiting until the price above the high or below the low for a short. The method has fast trade execution systems. Since heavy volume trading can experience quick reversals, mental stops are usually used instead of hard stops. In simple terms, the Gap Trading Strategies are a rigorously defined trading system that uses specific criteria to enter and exit. Trailing stops are defined to limit loss and protect profits. The simplest method is also being applied into Taiwan. All eight of the Gap Trading Strategies can be applied to day trade.

About the method is consists of 3 time points. That is the 10:30, 10:35, and 10:45 respectively. But it is applied in the Taiwan stock market. The method should be mapping into the 9:00, 9:05, and 9:10. That the intrados chart is graphed slightly differently, showing a composite of the trades occurring every 5 minutes. The figure is illustrated in Fig. 4.2. The figure is that Akamai Technologies stock each 5 minutes char. Although a trade-by-trade charting tool would show the exact bid and ask spread, this tutorial will refer to the left-side horizontal line of each bar as the open, and the right side horizontal bar as the close of each trade.

#### 4.4 HMM model

##### 4.4.1 HMM template training model

This work stock day trade training architecture has two major units. One is the parameter analysis unit and the other is the HMM template unit. The architecture is illustrated in Fig. 4.3

###### (1) Parameter Analysis unit

This work will sample the stock day trade time series. This work will to record the all day trade time series signal. Then scattered about each 5 minutes. So separated the each 5 minutes. So the original forecasting architecture has two major units. One is the parameter analysis unit and the other is the HMM database unit.

###### (2) HMM template database unit

This unit will store the stock day trade time series. The database purpose is storing the each day trade time series for HMM template model. The architecture is illustrated in Fig. 4.3

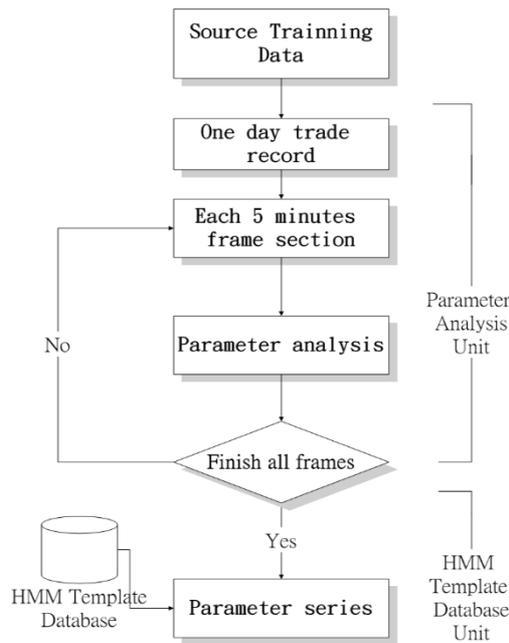

Fig. 4.3. The HMM training architecture

## 5. Experiment

### 5.1 Research scope boldface

The source data has 41439 records of the each 5 minutes TAIFX futures (TX). The source data can transfer to total 866 days trade history records from 21, July, 1998 to 20, February, 2002. The training time is from 21, July, 1998 to 21, July, 2000. So the training data has 20946 records and 538 days. The simulation time is from 22, July 2001 to 20, February 2002. So the simulation data has 20493 records and 326 days. So the experiment result will have 326 days trade record. This work will follow each experiment simulation report to do a comprehensive survey.

### 5.2 Random Walk experiment

The Random Walk method simulation follows previous data scope to simulation. Then the method result is the below table 5.1. The result is for statistic test. So the result will follow the below three functions 5-2-1, 5-2-2, and 5-2-3 to calculate result. The simulation time is from 22, July 2001 to 20, February 2002.

$$\text{Sum} = \sum_{\text{Day}=1}^n \text{Re sult} \quad (5-2-1)$$

$$\mu = \frac{\sum_{\text{Day}=1}^n \text{Re sult}}{n} \quad (5-2-2)$$

$$\text{Variance} = \sigma^2 = \frac{\sum_{\text{Day}=1}^n (\text{Result} - \mu)^2}{n} \quad (5-2-3)$$

Simulation Result

### 5.4 HMM experiment

This work obtained a TAIFEX futures (TX) status transfer probability matrix as the Table 5.3. In the table, the two status (HH and LL) are the maximum of the night status probability matrix. So if the relative high status is occurring in the second time points, then the 3<sup>rd</sup> time point will be relative high status which is 50.1034% of probability.

### 5.5 Statistic tests

This work obtained a result of the TAIEX futures (TX) each simulation methods. The result is been ordered into the table 5.5. So this section will to do some statistic test to verify the result. This work will use the difference variance tests and the difference of means tests.

Simulation Result			
Method	RW	MT	HMM
Sum	-3435	3611	8488
No deal	0	125	112
Success	142	107	126
Fail	184	94	88

N	326	326	326
Max	412	456	411
Min	-456	-363	-412

Table 5.5 The each method Result

#### (1) Difference variance tests:

For match pair, the output generated includes the value of the F statistic for the null hypothesis that the variance of the differences is equal to zero. In the other words, that the variance of the one simulation result will beater then the other. This work will use the Right-tailed test to verify. So the test calculates as below.

$$H_0 : \sigma^2_{MT} \geq \sigma^2_{RW} \quad (5-4-1)$$

$$H_1 : \sigma^2_{MT} < \sigma^2_{RW} \quad (5-4-2)$$

$$F^0 = \frac{\hat{S}^2_{MT}}{\hat{S}^2_{RW}} = \frac{12873.59841}{19638.98484} = 0.65561 < F_{0.05}(\infty, \infty) \approx 1 \quad (5-4-3)$$

So according to the staistic difference of means tests,

this work must to reject  $H_0$ . In other words, the tests obtained the significance result of this, which the Modified Trading method is beater then the Random Walk method.

#### (2) Difference of means tests

For match pair, the output generated includes the value of the T statistic for the null hypothesis that the mean of the differences is equal to zero. In the other words, that the mean of the one simulation result will beater then the other. This work will use the Left-tailed test to verify. So the test calculates as below.

$$H_0 : \mu_{RW} \geq \mu_{MT} \quad (5-4-4)$$

$$H_1 : \mu_{RW} < \mu_{MT} \quad (5-4-5)$$

$$t^0 = \frac{\bar{d} - 0}{\frac{\hat{S}_d}{\sqrt{n}}} = \frac{-21.635}{\frac{113.636}{18.055}} = -3.43 < t_{(0.05; 326)} = -1.645 \quad (5-4-6)$$

So according to the staistic difference of means tests, this work must to reject  $H_0$ . In other words, the tests obtained the significance result of this, which the Modified Trading method is beater then the Random Walk method.

$$H_0 : \mu_{MT} \geq \mu_{HMM} \quad (5-4-7)$$

$$H_1 : \mu_{HMM} < \mu_{MT} \quad (5-4-8)$$

$$t^0 = \frac{\bar{d} - 0}{\frac{\hat{S}_d}{\sqrt{n}}} = \frac{-14.96}{\frac{114.028}{18.055}} = -2.368 < t_{(0.05; 326)} = -1.645 \quad (5-4-9)$$

So according to the staistic difference of means tests, this work must to reject  $H_0$ . In other words, the tests obtained the significance result of this, which the HMM method is bater then the Modified Trading method.

### 5.6 Time series analysis of regression

The Time Series Forecast is determined by calculating a linear regression trend line using the Least Squares method. The least squares fit technique fits a trend line to the data in the chart by minimizing the distance between the data points and the linear regression trend line. The HMM method have the best revenue. But the result can't be sure the revenue will very good in future. So the analysis of regression can make sure the result. So the Least Squares method calculate as below.

Unit : day

Origin : 2000/7/20

$$Y_T = a + bX \quad (5-5-10)$$

$$a = \frac{\left| \begin{matrix} \sum Y & \sum X \\ \sum XY & \sum X^2 \end{matrix} \right|}{\left| \begin{matrix} n & \sum X \\ \sum X & \sum X^2 \end{matrix} \right|} = \frac{\sum Y \sum X - \sum X \sum XY}{n \sum X^2 - (\sum X)^2} = 44.01153 \quad (5-5-12)$$

$$b = \frac{\left| \begin{matrix} n & \sum Y \\ \sum X & \sum XY \end{matrix} \right|}{\left| \begin{matrix} n & \sum X \\ \sum X & \sum X^2 \end{matrix} \right|} = \frac{n \sum XY - \sum X \sum Y}{n \sum X^2 - (\sum X)^2} = 0.019704 \quad (5-5-11)$$

So from the slope of the HMM method will have a plus revenue in the long-term trend.

### 5.7 Statistic Test conclusions

Summarized the previous section, this work have some conclusion. That HMM have the best revenue. Because the HMM method is bater then the Modified Trading method and the Modified Trading method is bater then the Random Walk method.

The HMM method have the best revenue. But in the risk view, the HMM just only have the same risk with the Modified Trading method. So this work will arrange the relation in the below table 5.7 and table 5.8.

	RW	MT	HMM
RW		No	No
MT	Yes		No
HMM	Yes	Yes	

Table 5.7 The each method revenue compare

	RW	MT	HMM
RW		No	No
MT	Yes		Equal
HMM	Yes	Equal	

Table 5.8 The each method risk compare

## 6. Conclusion

### 6.1 Thesis Conclusion

The HMM model is a very population model in the speech recognition domain. This work approve the HMM model have a very well forecasting in the stock recognition domain. Especially, the TAIFEX futures from the opening price recognized the closing price.

However, this work has a very conspicuous by the statistics testing of significance. The HMM model is beater then Random Walk model and the Modified Trading model. But this work only has a blemish in an otherwise perfect thing, which the risk is same with the Modified Trading model. Additionally, this work approve that long-term trend of the HMM model will be a positive slope line. In other words, the revenue will be increasing.

In clusion, the HMM model is a feasible and stable model in the TAIFEX futures day trading. The HMM model will have positive revenue in the long-term time series.

### 6.2 Discussion

This work has a very conspicuous result by the statistics testing of significance and the approving of the time series method. But this section will draw a conclusion to collect

factors of back. This work has some conclusions as below list.

- (1)The HMM model is based on the traditional Bayes' theorem. So the model can calculate the probability of the each status delivery.
- (2) The HMM model can recognize the complex speech domain. So this method can easy to recognize three status of the stock market even to forecast the future.
- (3) The TAIFEX futures have similar characters with the speech frequency.
- (4) The pass papers just apply the HMM model in American stock market and those papers just apply into the next day trading.
- (5) The TAIFEX futures have some special characters just in Taiwan.

### 6.3 Future directions

Even if, this work has very conspicuous result. But the HMM model have a risk just like the Modified Trading method. So in the future, this feet of clay can be fixed by the invest strategy just like some speech recognition system be fixed some defect s form the system architecture. So this work has some suggestions as below list.

- (1) This work just applies the model in the TAIFEX future. In the future, the experiment can apply into the other stocks.
- (2) The HMM model has a risk. In the future, the experiment can try to find out the optimal invest strategy to evade the risk.
- (3) The HMM model is been applied into the neural network in the pass patents. In the future, the experiment can try to lead in the neural network.
- (4) This works just splitter three statuses. In the future, the experiment can try to use the really K-means algorithm. In the other words, the experiment can try to use the binary splitter status.
- (5) This work just used one Lot to order the TAIFEX future. In the future, the experiment can try to find out the optimal number of Lot.
- (6)This work just applied the method in the front process. In the future, the experiment can try into the rear process. Just like search algorithm or strategy decision.

## Abstract

There are been many claims that the Internet could represent a “frictionless” and almost perfect market [1]. This belief was particularly evident in that banking industry, where Internet was considered as a source of sustainable competitive advantage for a new generation of banks focused on this sale channel.

E-banking in Italy, ever if it was started later then U.S.A. and other european countries as now reached a fast expersion stage. Most of the banks though whit different timing and structures have developped web-sites to growt customers banking and trading access through Internet. At the same time new competitors not in the banking business have recently entered in the market.

Our research empirically analysed the e-banking services offered by a sample of 54 Italian banks.

We considered as e-banking services all banking services that can be accessed through the Internet.

Data on offered services and their prices were collected on a quarterly base. We analysed the following aspects:

- Trend in services offered on-line to customers;
- Trend in market segmentation and in banks strategies;
- The economics emerging from the competition in on-line banking.

We used these data for testing the hypothesis of “frictionless market”. The obtained results seem to show that the market of e-banking services is very different from early expectations, and that economies of scale and brand remain as important sources of competitive advantage.

## 1 Introduction

One of the most important and innovative aspects of the new set-up of the banking distribution system is the use of virtual channels for distributing financial services, which will certainly represent key factor in the future structing of banking. The new distribution channel have a strong potential impact all aspects the relationship between the customer and the financial broker, which cover from the choice of the broker up to the identification of a specific financial service to the delivery. In spite of the fact that at present stage of the cultural environment, the human contact is not easily replaceable as the foundation of the financial brockering, the virtual channel is likely

appearing as radically innovative instruments for most of the current transactions, in terms of efficiency and convenience [3].

The present paper purpose is to analyse the delivery of financial services and retail banking through Internet.

E-banking in Italy, ever if it was started later then U.S.A. and other european countries as now reached a fast expersion stage. Most of the banks though whit different timing and structures have developped web-sites to growt customers banking and trading access through Internet. At the same time new competitors not in the banking business have recently entered in the market, these new commerce taking advantage of the substantial reduction of the obstacles to the entry in the sector, have developed offers of on-line banking services with the objectives of gaining market shares taking advantage of the synergies they have with their own core business ( i.g. the network of promoters working for on line banks originated from insurance business).

Our analysis has covered a simple of banks and SIM wich offer on-line financial services taking into a count types, completeness and pricing of the services. We have tried to draw a model of this new virtual market including the strategies used and being used by the brokers in order to obtain an entry and describing the new types of banks which are succesfull. The research is focused on the analysis of the offer of retail services for private customers (BtoC) and was aimed at verifying the consistency of the theoretical viewpoint that claimed that the Internet could represent a “frictionless” and almost perfect market. This belief was particularly evident in the banking industry, where Internet was considered as a source of sustainable competitive advantage for a new generation of banks focused on this sale channel, due to the fact that “location” was irrelevant and customers were fully informed of prices and product offerings. Such hypothesis was based on the following (and often untested) facts:

- on-line banks would have had lower operating costs and a wide product portfolio; fully informed customers will recognize these advantages and will switch to these banks;
- it would have been very difficult for incumbent banks to imitate newcomers strategy, loosing profitable customers attracted by newcomers’ services;
- Internet would have divided banking services into

<sup>1</sup>Marco Brugiati and Giuseppe Vironda are gratefully acknowledge for their work in data collection and analysis. The research was funded by the Istituto Superiore Mario Boella.

new segments, with different customers and profit margins;

Competition among newcomers will lead to lower and more homogeneous prices. Our research empirically analysed for a period of 18 months (from December 2000 to June 2002) the e-banking services offered by a sample of 54 Italian banks (they account for about the 80% of Italian banking industry).

The research was limited to the main Italian banking groups as well as to all virtual banks thus covering 60% approx of the total all Italian banking system, using as a ranking criteria the total business value. The term virtual bank describes both the new virtual banks and the spin-off of traditional banks who have chosen a new brand name for the Internet services distribution.

The scenario of the banks considered relevant in the business includes the first 29 Italian banks plus other six banks which are located between the thirty-sixth and the fifty-sixth rank in the ranking by business value and which offer Internet banking services of remarkable innovative type. On the other all virtual banks and SIM operating on-line have been taken into consideration since their number is relatively small.

We considered as e-banking services all banking services that can be accessed through the Internet.

Data on offered services and their prices were collected on a quarterly base. We analysed the following aspects:

- Trend in services offered on-line to customers;
- Trend in market segmentation and in banks strategies;
- The economics emerging from the competition in on-line banking.

## 2 Characterizing Competition in Electronic Markets

A basement computer room at Buy.com [2] headquarters in Aliso Viejo, California holds what some believe is the heart of the new digital economy. Banks of modems dial out over separate ISP accounts, gathering millions of prices for consumers products: books, CDs, videos, computer hardware and software. Specially programmed computers then sift through these prices, identifying the best prices online and helping Buy.com deliver on its promise of having "the lowest price on earth". Buy.com's model seems to represent the economic ideal for frictionless markets: low search costs, strong price competition, low margins, low deadweight loss.

This paper approaches this expectation by exploring aspects of business to consumer electronic commerce markets. Expectations in terms of "frictionless markets" that we tried to test in banking on-line were the following:

- By using the Internet, buyers have perfect information of sellers offering and of higher price elasticity. Price elasticity measures how sensitive consumer demand is to change in price. For commodities, price elasticity may be an important

signal of market efficiency. In efficient markets, consumers are more sensitive to small changes in prices, at least as long as substitute vendors or products exist. Higher price elasticity may result from lower search costs or lower switching costs for Internet consumers. Low buyers switching and search costs will promote price competition among sellers and reduce price dispersion;

- Operating and menu costs are lower for banks that offers only on-line services. Menu costs are the costs retailers incur when making price changes. In a conventional setting, menu costs result primarily from the costs to physically re-label products on shelves. In an electronic market we hypothesize that menu costs should be lower, comprised primarily of the cost to make a single price in a central database
- There will be a new segmentation of the retail banking industry, with the newcomers serving the most profitable part of the market.

Data collection was therefore focused on the evolution of services characteristics, prices level and dispersion, menu costs, market segmentation.

## 3 The Results of the Analysis

We have found that the offer of e-banking is far from what theory expected. More in detail our findings were the following.

### 3.1 Market Segmentation

After a very short period, banks clearly divided their on-line services into three segments, each oriented to a different type of customer:

- on-line upgrade of existing accounts, that allowed customers to access both via the Internet or existing branches the "traditional" accounts. In this case banks' strategy was to allow existing customers to on-line access "traditional" banking services, including trading. In 2001-2002 this segment was the one with the highest growth rate in Italy, and is also gaining market shares in stock trading. The offer of this type of product is in line with the "multi-channel strategy" presently followed by most of the traditional banking institutions. The promotion campaign for this product is generally carried on the branches and marginally on media specifically at the time of the introduction on the market;
- pure on-line accounts, offered mainly by newcomer "virtual" banks, are cash deposits with high interest rates and low prices. These once "virtual" products are now becoming more "physical" by offering the possibility to operate through bank branches. This type of

product is offer by the on-line banks, which are new financial instiution, generally spin-off of traditional banks or insurance company which have elected Internet as their main distribution channel and as a core business. This financial institution considered e-banking channel as an opportunity for obtaining a substantial competitive advantage on the traditional institutions, thanks to the reduction of the huge costs of structure and personal due to the operation of the branches

- pure trading accounts are cash deposits with advanced trading services. This product is obviously the only one offered by all SIM and is addressed to a type of customers whose only interest is to operate on stocks market through Internet. Such product is also offered by some traditional banks that have the objective of specializing their offer for the on-line traders, thus aiming to get reach new customers.

In each segment medium banks developed versioning strategies, by offering a basic (and usually low cost) and an advanced (with more services and high annual fees) version of their accounts. Initially, accounts belonging to the basic version were devoted to customers oriented, firstly, towards banking services. Those belonging to the advanced version were devoted to customers with trading needs.. Nevertheless after 18 months we observed how the distinction between basic and advanced versions is rapidly reducing. On the contrary, large incumbents immediately gave up to versioning by offering standard, low cost and all-included accounts [Fig.1 and 2]

### 3.2 Price Level

We founds that prices of banking services are always lower on-line than in branches. Such saving is mainly due to the lower commissions on share trading, which is three times cheaper on Internet. Transfer cost is also lower, since in most cases money transfer by the Internet are free of charge. Sometimes few trading transactions can generate enough savings on commissions to offset tha yearly cost of internet banking services. Sometimes no charge are applied for a given number of yearly transactions.

Bank size seems to be an important driver in determining prices and number of offered services, since large banks are offering more services and have the lowest prices. This fact contradicts the claim of cost advantages for newcomers and shift focus on the importance of economies of scale and existing customer relationships [Fig.3].

On line banking services show a different perspective. The most renown players are those who offer the overall best terms.

However success depends strictly on a well-know and high reputation brand name. This is evidenced by the market scenarious:

- The higher shares of market belong to the new

players (on line banks and financial services); “the first mover” advantage depends onbeing perceived by the customer as a market leader in the supply of innovative services since the very onset.

- In the case of traditional players, being backed by a well know and established brand name enhances credibility and customer confidence; this is evidence by the substantial market shares obtained in a few months by the quantity of customers acquired over a short period of time by traditional large bank Sanpaolo, as compared with other players already established on the market.

### 3.3 Economics and Strategy

Menu costs are the costs retailers incur when making price change. In a conventional setting menu costs result primarily from the costs to phisically re-label products on shelves.Menu costs are close to zero from a theoretical viewpoint; nevertheless banks found very difficult and costly to include in advertising information about price change different from fees for stock trading and interest rate on deposits;

Although customers have a perfect information from a theoretical viewpoint, they have to deal with information overload caused by banks strategies. On line accounts cost is not generated by early charges only.

- As opposed to other possible instances, the cost of these type of products consists of two elements: the cost of the account or the upgrade package; the fee whose total yearly amount depends on the number of client’s transactions. Such strategies have made the cost structure of accounts (in terms of mix of fixed and variable costs) very complex and difficult to be compared. This aspect strongly affects the ability of customers to find the best account and to move to a new bank, explaining the problems that both newcomers and incumbents are experiencing in attracting new customers.
- Branding and trust remain sources of heterogeneity and competitive advantage;
- Competition is not on prices. Prices did not significantly change in18 months and, more significant, their dispersion slightly increased [Fig.4]

In the same period each type of offered accounts increased the number of additional services [Fig.5].

In terms of competition, what we have observed is that Internet is transforming the retail banking industry in way that is very different from the one expected.

On-line account is becoming a commodity, causing e-banking services to evolve “down-market” to a low margin – high volume business. Initially, competition was based on “price” and “differentiation”. The service was particularly standardised, banks tried to acquire new

customers by reducing more and more the trading commissions for negotiation approaching to zero the costs for the use of the basic banking services. Then, banks reacted, trying to differentiate their products, enriching them with new functions and new services: all players chose an improvement of the trading services and of all the services which supported the trading. These went from the platforms of technical analysis to the tools which operated on derivatives. But, they soon realized that any innovation could be easily imitated by competitors, making products more and more homogeneous. Now, banks are looking for the wholeness of the offer, for an improvement and a development of services also through the enlargement of channels from the call centres integrated with web to wireless systems. The offer of the service is not enough. The future will probably see a further change aimed at the elimination of the “dematerialization” of the relationship with the consumer.

As an effect of product increased homogeneity, after their initial success newcomers lost their momentum and now are serving some sorts of up-market niches (on-line and trading accounts for a small number of sophisticated customers). Incumbents rapidly imitated the behaviour of newcomers and focused on low cost – all included upgrade of existing accounts, including in some cases services that are close to the ones of the trading accounts. According to this strategy, at the moment the largest incumbents are the more competitive in terms of breadth of offered services and have the lowest prices [FIG.6].

The resulting market competition does not seem to be close to what was figured out a couple of years ago. On-line pure player have been pushed to niche segments, and there will be probably no more room for them. Since technology can be easily imitated and requires large investments, it is the ability to effectively manage the relationship with the customer that makes the difference. Large incumbents developed a strategy based on offering on-line services at a very reduced cost in order to progressively convince customers to move to the Internet, in order to reduce cost of the network of branches.

#### 4 Concluding Remarks

In conclusion Internet hasn't full filled the expectations. Even though on one hand the price level obtainable on the virtual market is lower than the true market's (however the difference is small) also on the e-market the spread of prices is extremely wide.

In essence it can be said that the offer of the banks is in line only on the costs factors which are very “visible” such as commissions which have been the focus of the marketing campaign of all institutions. The price spread is due to several factors such as:

- the variety of products. This is in fact main the factor of the spread. Many services can be combined to the accounts or to the “package”, and each bank has its own policies and strategies, It's very hard to find two different accounts that

allow to perform exactly “the same functions in the same manner”;

- the diversified information. It is sensible to assume that the players are not all equally know and that most of the potential customers know only some out of them. The result of such situation is that banks are located in a scarcely competitive scenario, and this fact may justify the spread of prices;
- branding and trust;
- “lock-in effects”. The lock-in effects represents the last exploration to the price spread. Several banks are trying to develop the fidelity of their customers. It is too expensive for a customer in terms of the time required to change the bank.

In addition it was a common thinking that Internet would have been a diminishing factor for the banking system but at the end we can say that even though the strategies adopted by the “incumbent” appear as conservative, they have anyway succeeded in obtaining competitive positions against the new commerce on the e-banking market. Furthermore the fact that all banks have set up a virtual counter and that the virtual banks have not multiplied as expected indicates that the incumbents have been successful in reacting by offering products capable of attracting new customers.

# Simulating the Investor's Behavior in Stock Market with an Intelligent Agent

FengYu Chang; DenYiv Chiu

Institute of Information Management

Chung Hua University

Hsinchu, Taiwan

[phungyu@mi.chu.edu.tw](mailto:phungyu@mi.chu.edu.tw); [Chiuden@mi.chu.edu.tw](mailto:Chiuden@mi.chu.edu.tw)

## Abstract

In this paper, from the investor's perspective, we will use intelligent agents to simulate the investor's behaviors. The intelligent agent will learn the investor's behavior according to investor's historical data. It will learn from the decisions making for the investment. And we will build a virtual stock market in which intelligent agents can invest according to their decisions. Intelligent agents' investment decisions are different due to different consideration and conclusion for the same message. Then, every intelligent agent will deal with these messages. We will train intelligent agent with data mining technology and artificial neural network to make the intelligent agent's behaviors similar to investor's behaviors in the real world. The intelligent agent makes decisions and invests in the virtual stock market.

## 1. Introduction

The investors will expect satisfactory benefit from the investment by applying best planning. There are many financial management tools about the investment to serve the investors. Some investors may trust the tools and some may doubt of these tools. They may believe in their own judgments or investment consultants. They may have their habits to invest stocks in the stock market. This research is from another point of view to propose a new architecture in which prediction can be performed from investor's perspectives.

An investor is a member in the stock market. Investors make their investment decisions in stock market. Stock price is influenced by their buying or selling stocks, so we can say that investor's supply and demand decide stock price. Because the investor's supply and demand decide the stock price, we can think about stock price from the investor's perspectives.

From the investor perspective of prediction, because investor's supply and demand will form stock price and they decide the TWSP (Taiwan weighted stock price index). The investors sell and buy stocks to decide the stock price. The investor is an entity of the stock market. We can simulate the investor's investment decision or portfolio and put the decision to the virtual stock market. It can decide the trend of the TWSP or the stock price.

So, in this project, we will use intelligent agents to simulate the investor's behaviors. We will use intelligent agents to learn the investors' behaviors according to investor's historical data. Then, agents will find the rules about the investors' behaviors. These rules help agents to

make decisions. And we will construct a virtual stock market that is a virtual place for agent to commit its transactions. If we can learn investor's decision-makings, we can predict the result of weighted stock prices. I hope that the research can provide valuable reference for real investors.

We will discuss background, problem definition and motivation about this research in the following sections.

### 1.1 Background

Some of researches [16,10] use artificial intelligent technologies to predict the tendency of stock market. Others are studies about interest rates [8], and financial data [11, 12]. The others are studies about behaviors [14, 15, 9]. But the price fluctuations of the stocks are the result of individual operations of many individual investors in the financial markets [21]. Most investors believe that messages about stock affect stock prices, and also they have significantly influence on investor's behaviors. Investors invest in the stock market to behave in various manners depending on their individual preference, expectations, decision environment, strategy, and individual difference [6]. So, this paper explores how the investor's behaviors are influenced by the messages about the stock, and also uses investor's historical data to simulate the decision process. We use those approaches to predict investor's behaviors and decisions.

#### 1.1.1 Messages and Information Affecting Investors

The stock price is decided by the supply and demand, and it is also formed by the behaviors of the investors mutually. So, the messages rather affect the stock price than affect the investors. Then, investors' behavior affects the stock price. An investor will anticipate the trend of all investors' trading in the stock market, and the investor may follow the tendency to invest. This tendency is the foundation of stock price [6].

The messages and information that affect the stock market actually affect individual investors or institutional investors. We simulate the investors' decision-makings and predict it according to how investors are influenced by financial messages.

The factors affecting the investors can be classified into following:

- (1) Politics: this includes the war, Cross-Strait relationship and situation of politics. In October of 1998, sent the TAIEX plummeting, where the weighted index had taken a free-fall from its high 10,200 points straight

down to bottom at an all-time low of 5,421 points, this can be the immediate cause of the missile threats by mainland Chinese authorities or the ripple effects of the Asian financial crisis, or a long-time effect of over-specified stock valuations [6]. And some crash situations about politics will also influence the stock market [19].

- (2) Economics: this includes the exchange rate, interest rate, inflation, money supply, international economics, and internal economics. The fluctuation of exchange rate had obvious influence [5]. In the 1997, the Thailand's currency went straight down to 80% in one day. It started the Asia financial crisis. The stock price fell or the foreign money flew out. Those factors triggered the starting time of the financial crisis [3]. The government diminished the interest rate to make increment of money supply. And investors were encouraged to invest their money in the stock market. The international and the internal economics influence investor's behaviors.
- (3) The risk of company: this includes the technical analysis, economic condition, financial structure, cash flow, debt paying ability, buying on margin, short sales, and so on. The market to book ratio has a positive relationship with prior 1,2,3 and 4 period's return rate. Book to market ratio and size effect exists constantly in Taiwan's electronic stocks. This is a positive relationship between return rate and systematic risk [4].
- (4) Others: this includes earthquake and others. The earthquake influences the stock because it will cause much danger for the electronic industry.

### 1.1.2 Investor's Behaviors

Investor's behaviors may change because of the relative messages, technology analysis, base analysis and so on. We can explore the investor's behaviors to analysis his possible investment path. In the common theory proposed by Kenyes, he had done the research about the mentality of the herding people. He pointed out that investors might not make decisions from the information he collected, but investors would follow the herding.

Herding and feedback trade can be used to explain potential finance situations, including excess volatility, momentum and reversals in stock prices.

Herding means that a group of investors follow mutually to trade in the same way in the some period. Feedback trade is a relation between the herding and lag return.

Feedback trade has two types as below.

- (1) Positive feedback trade strategy: The decision threshold is the average performance in the pass. If the stock's performance is higher than the threshold, it can be highly recommended to purchase. If the stock's performance is lower than the threshold, it should be sold.
- (2) Negative feedback trade strategy: It is a negative strategy to the positive feedback trade strategy. Buy the stock if the performance of the stock is lower than the threshold performance, and sell the stock if the

performance of the stock is higher than the standard performance.

The investors follow the same messages to form the herding. The individual investor sells the stock that he earned a few profits, but a loser holds the stock for a long time [18]. The individual investing stocks may follow his own behavior patterns.

The intelligent agent is simulating investor's behaviors in the research. The individual investor may be influenced by messages, individual preferences and wealthy structure. The intelligent agents receive messages about stock to decide buy or sell the stock. These messages include the noise of stock market, the operating situations of companies, and other relative information. The intelligent agent makes different decisions because of the individual preferences. It has also the different influence to stock market because of individual wealthy structure. Every intelligent agent may make different investment decisions. Major Institutional Investors have the huge capital that can be used to buy a lot of stock, and they have strong influence on the stock market. But most of individual investors may have similar tendency about buying or selling, this situation also can make strong influence on the stock market. So, each of investors can play an important role in the market.

## 1.2 Motivation

As discussed above, we can know that an investor is the most important role in the stock market. Because stock price is influenced by investors' buying or selling stocks from economic view according to some researcher's proposition. And then, if we can simulate the investors' behaviors and predict them, we can predict the tendency of Taiwan stock market. So, we will use intelligent agents to simulate the investor's behaviors.

## 1.3 Purpose

Our purpose is to simulate the investor's behaviors with intelligent agent. Intelligent agents will have themselves rules, and we will let the agents to make their decisions according to the rules in the virtual stock market. So we would construct the virtual stock market according to real working operations in the Taiwan stock market. The intelligent agents can buy stock on margin, cash, or short sales in the virtual stock market. Then, we will compare the real trade investors' situations with agents' decisions and evaluate the performance.

## 1.4 Assumption

We use the concept of classification technique of Chinese news proposed by Kun-Po Chuang's thesis, and he had made several assumptions. Therefore, we also have to observe these assumptions as followings.

- (1) We focus on processing Chinese document which contains a caption and a content. (This type of documents includes newspapers, magazines and some reports.)

- (2) Each classification keyword contains at least two characters and the main keywords of a document appear frequently in the document.
- (3) All Chinese news that happens each day can be obtained by every investor.
- (4) Chinese news is affecting the Taiwan Stock Market Weighted Price Index (TSWPI).

And we also have one assumptions in our framework:

- (1) Every investor would obtain all macroeconomic variables and technological analysis variables that happen each day.

The construction in this paper is described as following. In the section two, we will review related literatures and related technologies. Next, we will give a complete description of our model in the section three. In the section four, we will describe the experimental results of our model and analysis the performance of our model. The last is the conclusion and the future works.

## 2. Literature Review

We would introduce technologies that be used in this research.

### 2.1 Artificial Stock Market Technology Review

Shu-Heng Chen and Chia-Hsuan Yeh proposed an architecture to study artificial stock markets. This architecture rests on mechanism called “school” which is a procedure to map the phenotype to the genotype [20]. It’s an agent-based model of “school”, and considers “school” as an evolving population driven by single-population GP [20]. An agent is a trader who is an investor. Traders would learn the investment’s strategies in the business school and trade with these strategies in artificial stock market. This model gives us an ideal about simulating individual investors. In this project, we propose a framework in which we use agents to simulate individual investor’s behaviors. And, we will build the virtual stock market as the ‘school’ in which an agent acts as a trader to make decisions and to invest.

### 2.2 Data Mining Technology Review

Data mining is the process of extracting potentially useful information from raw data [7]. Data mining can mine large amounts of data. This makes data mining a fast and inexpensive way of summarizing, exploring, understanding, and analyzing data [7].

We will find rules from historical data. We will use data mining to find rules. Data mining often mentions finding patterns, rules, and facts in raw data. And we introduce two mining n-dimensional inter-transaction algorithm:

#### 2.2.1 EH-Apriori

EH-Apriori is a method to mine N-dimensional inter-transaction rules. EH-Apriori is the extension of Apriori based algorithm. EH-Apriori adopts a similar technology of hashing to filter out unnecessary candidate

2-itemsets. When the support of candidate  $C_1$  is counted by scanning the database, EH-Apriori accumulates information about candidate 2-itemsets in advance. Such resulting hash table can be used to greatly reduce the number of 2-itemsets in  $C_2$  [10].

#### 2.2.2 OP-Apriori

OP-Apriori is used to reduce the total mining times [5]. OP-Apriori scans the database to find out the  $L_1$  and  $L_2$  in the first time. It doesn’t use  $C_2$  to produce  $L_2$ . It used to need  $C_2$  to produce  $L_2$  before the OP-Apriori method. OP-Apriori modified this way to perform better than EH-Apriori.

Mining n-dimensional inter-transaction association rules is more complex than mining classical association rules. Investor’s behaviors are also complex. We try to use n-dimensional inter-transaction to mine investor’s investment data, and try to find rules about investor’s behaviors.

### 2.3 ANN and Document Classification Used to Deal with News

In the Chunag’s research [13], he combines neural network with document classification techniques to deal with news. Chinese historical news are classified into several fixed categories. And he uses document classification and keywords table to classify these Chinese historical news. He also collects the Taiwan Weighted Stock Price Index (TWSPI) and computes the raising or falling rate every day. And he maps this result to map the Chinese history news. He quantities the information of Chinese historical news by transformation process. Finally, he feeds the quantitative data and qualitative data into artificial neural network and use artificial neural network to train the weights as the degree of influence.

First, he uses these keywords to classify the Chinese history news collected from WWW, as shown in figure 1. After classifying, this component of classification mechanism saves and output some keywords. Secondly, he uses clustering methods to deal with each category. This method would group the similar Chinese history news into the same type for each category. In this framework, he used hierarchical clustering to group the similar news into the same type.

Then, he can use raising or falling rate of each historical news to compute average raising or falling rate for each type. We also compute how many times raising or falling occurs for each type. We use ANN-document classification to deal with news and try to find the news that has influence on investors.

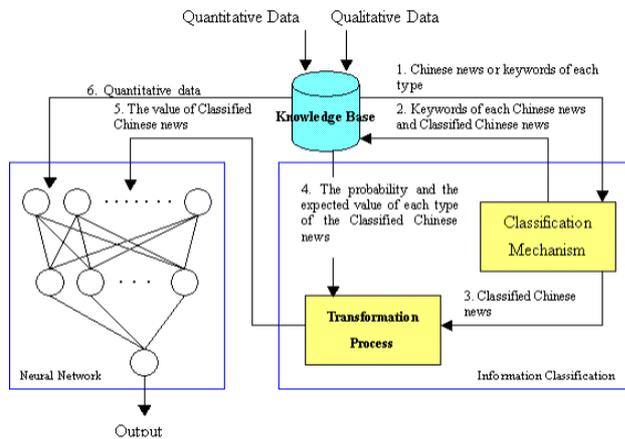

Figure 1. Main Process of ANN and Document Classification Method

### 3. Methodology

We would introduce our methodology in this chapter. We divide this chapter into two parts. The first part is our architecture. The second part is agent's decision framework.

#### 3.1 Architecture

We use agents to simulate real investors' behaviors, and each agent represents an individual investor. Then, each agent has his own decisions and it can make decisions in the virtual stock market. These decisions can affect every stock's price in the virtual stock market. And weighted stock price index is composed of stocks' prices in the virtual stock market, as shown in figure 2.

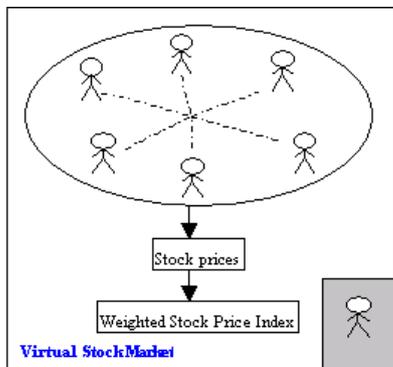

Figure 2. Agent's Decision Making

The agent's simulating architecture would learn from individual investor's historical data. We divide the simulating architecture into two parts. The first part is the agent's learning cycle. The second part is the learning framework for the agent.

##### 3.1.1 Agent's Learning Cycle

Agent's learning model has following elements.

- (1) Historical Data: Investor's investment transactions will be saved to historical data every day. The historical data consists of stock name, stock shares, times, and

other investor's investment information in the past. And historical data also concludes the difference between agent's decision and real investor's decision. Then the difference will be used to modify the agent's learning model.

- (2) Analytic Information: We use historical data to analyze investor's behaviors. The analytic information includes the frequency of investor's trade, individual investors' preference, day interval and rules about investor's behavior.
- (3) Investment Portfolio: This is an investment list that agent may want to invest. Many events influence investor's behaviors. So we will use analytic information and events to find out agent's portfolio.
- (4) Decisions: An agent makes decisions by his portfolio obtained from the step three in virtual stock market.
- (5) Events: Events are the news or qualitative data happening every day. News and messages may affect the investor's behaviors. So we will use ANN-Document Classification to deal with the events.

The agent's learning cycle is shown in figure 3. First, this model will save the investor's historical investment data and use historical data to analyze investor's behaviors. But events also may affect investor's behaviors. So, we use analytic information and events to decide agent's portfolio.

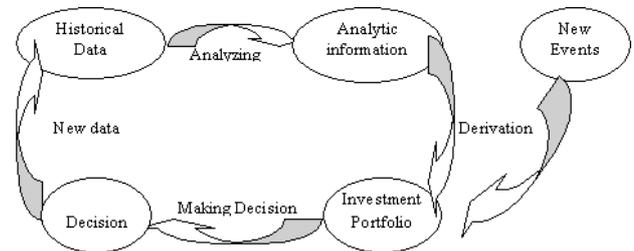

Figure 3. Intelligent Agent's Decision Learning Cycle

Then, agents can make their decisions in the virtual stock market by his portfolio. Finally, there may be difference between the agent's decisions and the real investor's decision. The difference and the real investor's decision become the new data for next learning cycle. Then, the agent will learn the historical data and the new data in the next learning cycle.

##### 3.1.2 Learning Framework for an Agent

The research would construct the framework to simulate the investors. The framework consists of the following components shown in the figure 4.

- (1) Individual Wealth Structure: Individual wealth structure means how much money an investor can invest in the stock market. Individual investor has himself individual wealth structure. Individual wealth structure would record the wealthy distribution about bonds, common fund, stocks and so on. In the record, we can find how much money investor can invest in the stock market. If an agent

has ability to buy more stocks, he has more influence to the stock market. An agent's wealthy structure would change while an agent gains or loses from investments, and he will leave from the virtual stock market if he loses all of his money. An agent also can enter the market again if he has money. Wealthy structure decides whether an agent is active or not in the virtual stock market.

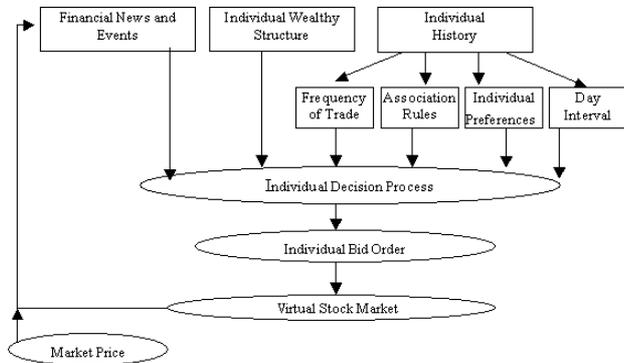

Figure 4. The Framework of Simulation

- (2) Individual Investor Historical Data: This component stores data that investors invest every day. The data of this component includes: 1. stock names, stock prices, and stock shares that investors buy or sell. 2. information about investor's buying stocks on margin sales or short sales.
- (3) Individual Decision Process: Individual decision process uses the frequency of trade, individual preference, association rules, and day interval form the component two. And individual decision process will produce individual bid order of an agent.
- (4) Individual Bid Order: Individual bid order is the trading list that an agent will trade next week. The intelligent agent will make decisions by his bid order next trading week in the virtual stock market.
- (5) Virtual Stock Market: We will construct the virtual stock market to simulate the real stock market in Taiwan. The virtual stock market includes three parts.
  - (a) An Intelligent Agent: An intelligent agent represents an investor. An agent can trade according to his bid order in the virtual stock market.
  - (b) Model of Price Determination: The mechanism is to decide the stock price at which agents buy or sell. And the mechanism is similar to the real Taiwan stock market. The agents can buy the stocks by cash, margin sales, and short sales. Virtual stock market may decide the stock price according to the agents' investment decisions, buying or selling the stock.
  - (c) Taiwan Weighted Stock Price Index (TWSP):

The virtual stock can decide the TWSP according to all stocks' prices. So we can find that the supply and demand from the intelligent agents in the virtual stock market can predict the Taiwan weighted stock price index.

### 3.2 Agent's Decision Framework

This part will introduce the technologies used in the agent's decision framework and we will explain how to construct our framework step by step. Our framework is shown in the figure 5 and it has several elements as followings:

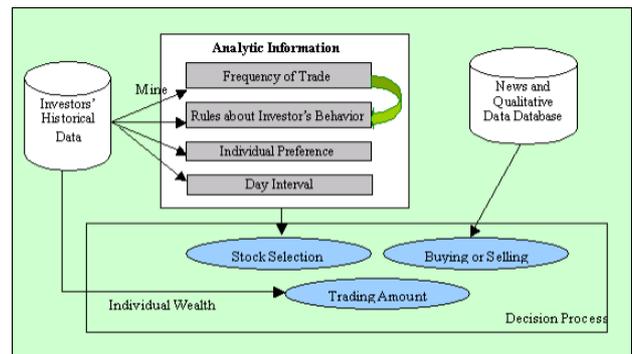

Figure 5. Agent's Decision Framework

- (1) Buying or Selling Stocks: We will collect all kinds of events including news or qualitative data, and use the events to decide whether investor would buy or sell stocks or not. We will also construct database to save news and qualitative data, and use ANN-document classification methods to deal with news and qualitative data. Then, we can obtain the result and use the result to decide whether investor would buy or sell stocks or not.
- (2) Trading Amount: Trading amount means how much money an individual investor can invest in stock market. We can compute investor's wealth from the transactions of investor's investment in the stock market and infer individual investor's trading amount that may investe in the stock.
- (3) Stocks Selection: We will use analytic information to select stocks that an individual investor may invest in the stock market. We can find analytic information from investor's historical data. Analytic information includes rules about investor's behaviors, individual preferences, and frequency of trades. We use n-dimensional inter-transaction (OP-Apriori) and Apriori to mine associate rules. The frequency of trades will be used as scale of sliding windows' dimensions. If an investor has higher investment frequency in the same stock, we can get the higher value of individual preference. Then the higher value of individual preference means that the investor has better opportunity to invest in the stock. Day interval is the duration of two successive transactions for the same stock committed by an investor. So we can use the analytic information to select stocks that investor may

invest next week.

### 3.2.1 Buying or Selling Stocks

We can use events to decide whether investor would buy or sell stocks or not. The events include news, technology analysis data, economic variable, and EPS etc. We will use ANN-document classification to deal with events that may influence investor's decisions. Every investor has different decision about the same events. We use ANN-document classification to deal with events and try to find degree of influence for each agent. Every agent has his own ANN-document classification to deal with news that may influence the investor and trains his ANN-document classification according to his buying or selling stocks every day. We describe the process in the followings.

(1) Inputs: ANN's input includes following elements. And following element would be save in news and qualitative data database in figure 5.

- (a) Qualitative Data: this part is responsible to search daily Chinese news, including internal politics, political situations, internal economic situations, international political situations, international economic situations, company situations, cross-Strait relationships, general investment environments, and so on.
- (b) Macroeconomic Variables: this part is responsible to search several economic indicators consisting of daily change in exchange rate, daily change in interest rate, monthly change in unemployment rate, annual change in economic growth rate, annual change in consumer price index, annual change in Gross Domestic Product (GDP), monthly change in inflation rate, and monthly change in money supply rate. These data can be collected from several major countries, including American, Japan, Hong Kong, Singapore, Korea, England, France, and Germany.
- (c) Technological Analysis Variables: this part is responsible to search Taiwan Weighted Stock Price Index (TWSPI) and compute several technological indicators, including Twenty-Four Days Moving Average (MV), Relative Strength Index (RSI), Bias, Moving Average Convergence/Divergence (MACD), Volume Moving Average, and Twenty-Four Days On Balance Volume (OBV).

(2) Outputs: Individual investors may buy or sell their stocks. Events influenced whether the investors would buy or sell stock or not. We assign one to buying stock and assign -1 to selling stock.to train the ANN-document classification model.

(3) Prediction: We will predict whether the investors would buy or sell stock or not next week.

### 3.2.2 Trading Amount

We may not have individual wealthy structure. But we can compute individual wealthy through an investor investment in stock market. We will find how much money an investor can invest in the stock market. This can influence how many stocks that an investor can invest. We will use following equation to compute trade size, as shown in figure 6

An investor may own following stocks, and we can compute his wealthy.

Asset	Shares	Prices
Stock <sub>1</sub>	Share <sub>1</sub>	P <sub>1</sub>
Stock <sub>n</sub>	Share <sub>n</sub>	P <sub>n</sub>

$$\text{Trading Amount} = \text{Share}_1 * P_1 + \dots + \text{Share}_n * P_n$$

Figure 6. Trading Amount

### 3.2.3 Stocks Selection

Analytic information includes frequency of trade, rules about an investor's behaviors, individual preferences, and day interval as shown in figure 5. We use analytic information to select stocks.

#### (1) Frequency of Trade

This part will compute the frequency of trade that an investor may trade daily, weekly, monthly, or a long time from his historical data. An investor has his own habits to trade stocks. We will use following equation to compute average frequency of trade, as shown in figure 7. We can use frequency of trade to be the size of each dimension for the sliding window.

T<sub>1</sub> : Trade date that an investor invest the first time

T<sub>2</sub> : Trade date that an investor invests the next time

T<sub>n</sub> : Trade date that an investor invests Nth time

$$\text{Frequency of Trade} = \frac{\langle T_2 - T_1 \rangle + \langle T_3 - T_2 \rangle + \dots + \langle T_n - T_{n-1} \rangle}{N-1}$$

One scale of Sliding Window's "Time" Dimension = Frequency of Trade

Figure 7. Frequency of Trade

#### (2) Mining Rules about Investor's Behaviors

We use OP-Apriori and Apriori algorithm to find out rules about investor's behaviors from individual historical data. When algorithm scans the database, it will produce C<sub>1</sub> and C<sub>2</sub> directly the first time. And we will record the support of C<sub>1</sub> and C<sub>2</sub> in an array after scanning the database. We will mine association rules for investors' behaviors with following steps.

- (a) Transforming to Star Schema: We will transform our individual historical data into star schema and we will transform all

transactions to star schema in the next step. Table 1 shows the original data and the table 3 shows its star schema. And table 1 shows the meaning of the sliding window's dimension.

Table1 Original Data in Database

Investor	Stock-Number	Buy-or-Sell	Price-Difference	Time
A	2806	sell	2	4/22
A	2409	sell	3	4/23
A	2409	buy	-2	4/24
A	2325	buy	-3	4/25
A	2806	buy	-1	4/26

Dimension one: dimension one is the field of buying-or-selling and its value can be sell or buy. Then we transform "buy" to "1" and "sell" to "2".

Dimension two: dimension two is the field of price-difference and its value can be -3, -2, -1, 2, or 3. Then we transform "-3" to "1", "-2" to "2", "-1" to "3", "2" to "4" and "3" to "5".

Dimension three: dimension three is the field of time and its value can be 4/22, 4/23, 4/24, 4/25, or 4/26.

$$\text{Frequency of trade} = \frac{(4/23 - 4/22) + (4/24 - 4/23) + (4/25 - 4/24) + (4/26 - 4/25)}{5 - 1} = 1$$

The scale of dimension three is one.

Then we transform "4/22" to "1", "4/23" to "2", "4/24" to "3", "4/25" to "4" and "4/26" to "5".

Table 2. Meaning of Sliding Window's Dimension

		Value	Meaning of Value
Events		a, b, c	a is {2806}, b is {2409}, c is {2325},
Dimension One	Buy-or-Sell	1, 2	1 is {buy}, 2 is {sell}
Dimension Two	Price-Difference	1,2,3,4,5,6	1 is {-3}, 2 is {-2}, 3 is {-1}, 4 is {2}, 5 is {3}
Dimension Three	Time	1, 2, 3, 4, 5	1 is {4/22}, 2 is {4/23}, 3 is {4/24}, 4 is {4/25}, 5 is {4/26}

Table 3. Comparison of Sliding Window's Dimension

Investor	Stock Number	Event	Buy or Sell	Dimension One	Price Difference	Dimension Two	Time	Dimension Three
A	2806	a	Sell	2	2	4	4/22	1
A	2409	b	Sell	2	3	5	4/23	2
A	2409	b	Buy	1	-2	2	4/24	3
A	2325	c	Buy	1	-3	1	4/25	4
A	2806	a	Buy	1	-1	3	4/26	5

(b) Scanning the Database: OP-Apriori will scan the investor's star schema. There are two steps as followings. First, it scans each point in the N-dimensional database with sliding windows to find base address. Secondly, it will infer the relative address according to base address and it will move the sliding window to scan the n-dimension database.

By using the data in table 3, we can draw a 2-dimensional sliding window as shown in figure 8.

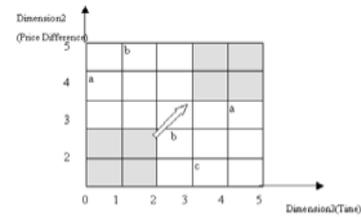

Figure 3-8: A Sliding Window Example

Figure 8. A Sliding Window Example

(c) Saving the Association Rules: We will record these association rules, and an agent will use these rules to select stocks.

(d) Saving the Association Rules: We will record these association rules, and an agent will use these rules to select stocks.

### (3) Individual Preferences

An investor may interest in some kind of stocks. If someone likes to invest in stocks of electronics industry, he may be familiar with Taiwan Semiconductor Manufacturing Company and United Microelectronic Corporation. If he invests in Taiwan Semiconductor Manufacturing Company and United Microelectronic Corporation, he may interest in investing in other stocks of electronics industry. An investor may interest in several kinds of stock. So, we can find the stocks that he prefers to invest.

### (4) Day Interval and Density Rate

Day interval is N's trading date minus N-1's trading date of the same stock for the same investor. Density rate is how many times that an investor invests in the same stock the same week.

There is an example in the following table 4. First, we would compute the day interval that investors invest in the same stock. Investor A invests in stock A on 2001/3/18, 2001/3/19, 2001/3/26 and 2001/3/28. We can compute the day interval which are 0, (2001/3/19 - 2001/3/18), (2001/26 - 2001/3/19), and (2001/3/28 - 2001/3/26). And we can get the day interval, 0, 1, 7, and 2. The one represents that investor A may trade stock A next day. The two represents that he may trade stock A next two days. We use following rules to compute density rate as shown in figure 9.

Table 4. Investor's Data

Auto_Number	Investor's Name	Stock Name	Date
1	Investor A	Stock A	2001/3/18
2	Investor A	Stock A	2001/3/19
3	Investor A	Stock A	2001/3/26
4	Investor A	Stock A	2001/3/28

---

```

Day Interval= Daten - Daten-1
If 0 < Day Interval < 7 then
  Count=Count + 1
endif

Density Rate= Count /Sum of Trading Times

```

---

Figure 9. Day Interval

We will compute the sum of trading times of the investor A. Because we have four data for investor A, its sum of trading times is four. There are two data with day interval between 0 and 7. So, the density rate is fifty percent, two of four.

Fifty percent is high rate of density and it has high correlation this week. But it may not have any correlation between two weeks. If the density rate is higher than fifty percent, it has higher correlation on one week. And we can use the stocks transacted in the preceding half of the week to predict the stocks that investors will trade in the next half of the week.

#### (5) Main Algorithm to Select Stocks

We have following steps to select stocks according to the result obtained from previous steps:

Step 1: Searching the association rule database

In this step, we will use the following algorithm to search the association rule as shown in figure 10.

---

```

IF support value > threshold, then
  association rules will be selected
  IF the number of appropriate stocks > 2, then
    compare the stock of association rules, and find the popular stock
    then output the stock name
  else output the stock name
else
  Search the preference database and day interval database.

```

---

Figure 10. Selecting Rules

Step 2: Searching preference database and day interval database

We use ANN-document classification to decide whether an investor would buy or sell stocks or not. If we know an investor who will buy the stock next week, we find the preference of his buying stock in the past. And we select the most popular stocks in the buying preference data. If we know an investor who will sell the stock, we find the preference of his selling stock in the past. We also would use the final n trading data to find day interval of these

stocks. Finally, we select the most popular stock in the selling preference data and select the most popular stocks in the day interval database.

### 3.2.4 Individual Decision Process

Agents will use analytic information to select stocks which an individual investor may invest in the stock market. An agent will select the stock that an agent will invest according to the step of stocks selection. An agent computes the average trading amount of each trading, and he gets the stock quantity that an agent will invest in the virtual stock market. An agent uses ANN-document classification to decide whether an investor would buy or sell stocks or not. And the agent will take the action, buy or sell. Therefore, an agent issues a bid order showing his investment data. An agent will use his bid order to trade in the virtual stock market.

## 4. Experiment

In this section, we will introduce data preparation, experimental design, and experimental results.

### 4.1 Data Preparation

We would simulate an investor's behaviors, and we need to collect individual investors' investment data. But, it is not easy to obtain individual investor's investment data due to personal privacy. There is an opportunity to get simulated data. In a class, the instructor teaches students how to operate stock's relative softwares and let students simulate investing in stocks. These students work for semiconductor manufactures located at the Hsinchu Science-Base Industrial Park and they are familiar with stock market. They usually trade in the stock market. The instructor assists us to achieve students' investment data. So, we use these data as our experimental data.

### 4.2 Experimental Design

We will perform the experiment in the three sections. In first section, we use an investor's preference stocks to predict stocks' name that an investor will trade next week for each agent. In second section, we combine the individual preference stocks and the day interval to predict stocks' name that an investor will trade next week for each agent. In third section, we use individual preference stocks, the day interval, and association rules to predict stocks' name that an investor will trade next week for each agent. The result of first section and second section will be compared with the result of third section.

### 4.3 Experimental Result

We trained our agents with the simulated data. The result of experiment is shown in table 5. Prediction of 54.3 percent of investors is better than other predictions. Prediction of 14.3 percents of investors is not better than other prediction. Prediction of 11 percents of investors is

the same percentages as other predictions. There is a better result than other predictions in the whole.

We would integrate the result in the table 6. We have prediction rate of 37.3 percent in total average. There are some investors that almost never trade in the same stocks and we cannot predict their behaviors. If we drop these investors, we can get the prediction of 42.19 percent. It would have 40 percent of investors that has high prediction rate, 58.57%, and standard deviation is 0.0875. So, the accuracy rate of each investor is approximate. Therefore, our result has high representation. This is the best result for the experiments. There would be 11.4 percent investors of investors that we cannot predict and their prediction rate is zero. It is not the best prediction, but it also can be accepted.

Table 5. Integrated Prediction of Experiment

Investor	Preference Average	Day Interval Average	Density Average	Average in proposed Model
A001	20%	20%	20%	25%
A002	60%	80%	80%	60%
A005	35%	47.5%	47.5%	50%
A009	60%	60%	60%	60%
A011	20%	20%	20%	30%
A015	22.5%	22.5%	22.5%	20%
A017	50%	50%	50%	50%
A027	0	0	50%	50%
A035	45%	70%	70%	65%
A039	25%	22.5%	22.5%	25%
A043	42.5%	70%	70%	80%
A049	20%	20%	20%	25%
A051	31.4%	38.5%	38.5%	40%
A053	0	35%	35%	35%
A057	0	0	0	0
A061	45%	45%	45%	50%
A063	20%	10%	10%	20%
A069	0	0	20%	20%
A071	35%	35%	35%	40%
A073	20%	20%	20%	20%
A077	60%	60%	60%	65%
A081	12.5%	12.5%	12.5%	15%

## 5. Conclusion

In this research, an agent would simulate an investor's behaviors according to his historical data. An agent can find the analytic information including association rules, preference stocks of an investor, and so on. The agent would use the analytic information to predict the stock that agent would trade next week. In experiment, we would have a satisfactory prediction rate.

This research would provide another perspective for investors to think how to predict the trend of stock. The stock price is decided by the supply and demand. Every investor plays an important role in the stock market. If we can predict the investors' behavior more accurately, we can predict the trend of weight stock price in Taiwan stock market better.

The following work can be continued in the future: The following work can be continued in the future:

- (1) Classifying the Investors according to Investors' Intentions: Because there are so many investors in stock market, we can't simulate every investor. So we can classify the investors according to investors' intention. For example, some of investors will invest the other financial market including bonds, mutual funds and treasury bills etc for avoiding risk. Another investors will accept high risk because high-risk assets may offer higher expected returns than low-risk assets may offer. The others may not care risk of stocks at all, and they have their investment principles like herding, positive feedback trade strategy, negative feedback trade strategy and etc. So, we can classify investors to several classifications in the future work.
- (2) Getting Real Investors' Investment Data: Our data is simulated data, not real investors' investment data. There may be differences between simulated data and real investors' investment data. If we can collect the real investors' investment data, we can predict better. The followings can be considered in the future.
  - (a) Hundreds or Thousands of Investor's Data: If we can get these data, the model will perform better. If we can get hundreds of investors' data or thousands of investors' data, use our agents to simulate. It can produce plenty of trading data in the virtual stock market and agents can trade with the other agents. This architecture can

perform better than results that have done in our experiments.

(b) Long Data Period: Experimental data should be collected for a period longer than six months, a year or a cycle period to train our agents. Enough data can train our agent that can be similar to real investors.

(3) Getting Data from Three Major Institutional Investors (TMII): Major Institutional Investors have the huge capital that can be used to buy plenty of stock, and they have strong influence on the stock market. So, we can collect the investment data of TMII and use our agents to simulate the behaviors of TMII. We can modify our agents' architecture to fit with the behaviors of TMII. It can be a right direction for the future works.

# Mobile Business: Characteristics, Advantages and Strategies

Chang-Sung Yu

Department and Graduate Institute of Business Administration

National Taiwan University

Taipei, Taiwan

yucs@ccms.ntu.edu.tw

## Abstract

The introduction of Internet technology has led to the business revolution, the so-called e-business. As a consequence, the e-business led the surprising economy booming for certain years. However, in the last few years, e-business also led to a global economy recession. The rises and falls of e-business raise curiosity to researchers for further investigation on the impacts of Internet technology on the business operations. What goes wrong with e-business becomes an interesting question, and deserves in-depth investigation.

In this paper, we give the definition of mobile business and construct its advantages. We analyze why e-business did not perform well in the last few years by showing how traditional Internet users were blocked by corporate firewalls from interactions with e-business.

Based upon transaction cost theory, we decompose transaction cost into analytical components: transportation cost, information cost, telecommunications cost and management cost, and therefore, derive the profit realization equation. We then use this profit realization equation to analyze how mobile technology impacts business operations.

As a result, this paper provides an analytical framework for enterprises implement mobile business and reengineer business operations. The enterprises can therefore set up corporate strategy to restructure the enterprise resources to build superior core competence and enhance corporate competitive advantages.

## 1. The Rises and Falls of Internet Economy

The introduction of Internet technology has led to a brand new way that business communicates. As a consequence, business operations changed accordingly, and led to the new way of business operations and strategies, namely, e-commerce, and furthermore, e-business.

The evolution of Internet and e-business has not only greatly innovated the way we operate business, but also dramatically revised the way we evaluate the stock values in global market. Due to the revolutionary value changes, the Internet technology and e-business has gained global attentions, and has been studied by researchers on how they impact the existing and future businesses.

Recently, after the global economy recession and the so-called DOTCOM bubble, the e-business has been

severely reviewed. Since then, people are trying to find out what goes wrong with Internet and e-business. Nevertheless, e-business has always been a critical factor reshaping the way business operates.

## 2. The Synergy of Mobile and Internet Technology

Due to the Internet revolution, each business can globally reach all the supply resources and global market demands with fingertips. Enterprises began to compete in global bases, and therefore, intensified global competitions. As a consequence, enterprises must find more efficient ways for business operations.

The usages of mobile phones (Stallings, 2001; Fitzgerald and Dennis, 2002) freed enterprises from having employees working in offices and waiting for clients to call in. Therefore, enterprise may send employees out to meet the potential suppliers and to really on site qualify the services or product quality; and to take care of the customers face-to-face for better customer satisfactions. Even if face-to-face is not possible, the mobile phones give employees mobility to move from one place to another to concurrently schedule, handle and process simultaneous business events.

While the employees are away from office, how about the support information for business execution and decision-making? Calling back to the office for information could do it, of course. However, the enterprise can do better by retrieving information and work instructions over Internet via mobile devices. In other words, mobile employees do not need to travel back and forth between offices and the meeting locations, and hence dramatically save traveling times, and reduce the setup times between activities. The number of accomplished activities, such as sales, purchases or customer cares, can be greatly increased. Therefore, the synergy of mobile and Internet technology innovates a new form of business operation — the mobile business.

## 3. The Characteristics and Advantages of Mobile Business

To better describe mobile business, we call the old style e-business the traditional e-business, or fixed-business. In fixed-business, enterprises started to

build web sites that store business related information and business operation processes. These web-based information and business processes are the keys to the evolution of e-commerce.

Given the technology advances (Stallings, 2001; Fitzgerald and Dennis, 2002), Internet mobile phone is available in the market. With the integration of Internet and mobile phone into business operations, for example, I-mod (Takeshi, 2000), the mobile business is created. Mobile business is then an extension over fixed-business with mobile Internet communications technology. In other words, the fundamental differences between mobile business and fixed-business are the mobility and always-online capabilities. (For convenience, we use mobile phone to mean Internet mobile phone for the rest of this article.)

To be specific, we define mobile business as follows:

Mobile Business: a business that utilizes the mobile and Internet technologies, and empowers the employees with mobility and always online to access business intelligence and mission processes.

Therefore, the mobile business enterprise must be on Internet, and has a databases to store business intelligence and mission processes. Also, the employees are mobile, and maybe the offices are mobile, too. The employees are free to travel without losing the connectivity with the enterprise. In other words, mobile business can be characterized by the following three characteristics:

- (1) Mobility: Mobile employees, and the offices too, are the trend of contemporary enterprises.
- (2) Always Online: employees, offices and enterprise body are always online, connected together, and ready to communicate with each other.
- (3) Online Business Intelligence and Process: The business intelligence and processes are electronically stored in the business system, and can be retrieved via Internet by mobile phones.

The mobility characteristic of mobile business comes with the innovation of global mobile phone systems. It is known that mobile phones are lightweight and small enough to be carried around anywhere at anytime (May, 2001). It is also known that the mobile phones are much easier to use than PCs, and could be described as a device for anybody. The always online and Internet enhancement allow the owner to retrieve information and business processes over Internet. Therefore, the add-on of mobile phones gives the following advantages to business operations.

- (1) Anybody: The mobile phone is easy to use for anybody, not just young kids but also easy to use for old ones or even busy business executives;
- (2) Anytime: The mobile phone is always accompanying with the owner at anytime;
- (3) Anywhere: The mobile phone is always accompanying with the owner in anywhere;
- (4) Any information: With business Internet enhancement, the mobile phone is able to communicate with Internet devices, client PC,

server and others, through certain format or protocol translation, to retrieve any information;

- (5) Any process: With built-in enterprises' mission processes on line, mobile phone can assist employees to follow the procedure to accomplish given mission;
- (6) Mission-trigger operation: to be described in the following section.

#### 4. Mission Sequence and Mission-Trigger Operation

A mission is an attempt to accomplish a goal. And each mission can be successfully accomplished if each of the following steps is realized:

- (1) Right person carries out this mission,
- (2) At right time,
- (3) In the right place,
- (4) With sufficient information on hand, and
- (5) With process assistance for decision-making or taking actions to execute the mission process.

For convenience, we call the above Mission Sequence.

An execution of business mission (or activity, task, assignment...) is called mission-trigger if the mission can be automatically triggered to execute by an associated mission sequence. A mission-trigger operation can be stated as an automated execution of mission operation, and can be depicted by the following figure:

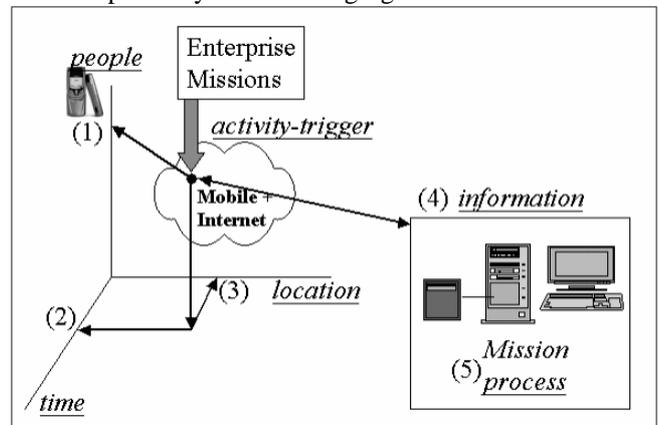

Figure 1: The Mission Sequence and mission-trigger operation

With mobile business technology, the business operation systems can automatically help (1) identify available qualified responsible persons (2) at anytime (3) in anywhere, and can trigger the designated persons to (4) retrieve sufficient information, and (5) furthermore assist the person with predefined mission process to accomplish the mission. We therefore claim that mobile business can be of mission-trigger characteristics.

There are lots of examples for mission trigger operations in the mobile business environment. For example, in parcel pickup and delivery service industry, we may have each service truck equipped with a GPS

system and mobile connection device. Then, once receiving a service request to pick and deliver a package, the dispatching center can identify the most appropriate vehicle near by the pickup location at that time, pass to it customer service information, and assist to perform the service with predefined procedures.

Corporate with better competitiveness, of course, may have better capability to realize the mission. Let  $r$  be the possibility of accomplishing a given business mission. Furthermore, let  $r_b, r_t, r_w, r_i, r_e$  be the probability of the right person, right timing, right place, right information and right procedure assistance to execute the mission, respectively. Then, we have the following competitive factor equation:

$$r = r_b r_t r_w r_i r_e$$

It is worthwhile to point out that if the possibility of each of the 5 factors is increased by a factor of 2, then the total possibility is improved by a factor of  $2^5=32$ , which is a significant improvement to corporate profit generation.

The advantages of mobile business imply that each of  $r_b, r_t, r_w, r_i, r_e$  may approach to 1 and hence increase the possibility of successfully accomplishment of business missions. The mission trigger operation can be effectively implemented especially if mobile technology is deployed, and is very important for contemporary enterprises competing in the intensifying competitive global market. The mission-trigger operation is an automated execution of business mission, and therefore is an ultimate advantage of mobile business that is never available before.

## 5. What Goes Wrong with Traditional e-Business?

For a long time, the introduction of Internet really empowered the business and the employees. It is expected that e-business is a friction-free economy. That is, with very little marginal cost, there will be immense volume of products or services out there in Internet market waiting for consumers to acquire, or for providers to supply. Therefore, industrial analysts believed that the e-business will revolute the business operations and dramatically promote business productivity. Therefore, e-business led to a booming global economy.

However, investors gradually realized that the promising DOTCOM enterprises do not overturn the traditional business. The e-business does not have enough momentum to generate profit, and finally, led to a global economy slum. Why does not the immense friction-free equilibrium quantity get realized in practice? To answer what the traditional e-business goes wrong, our analysis of mobile business advantages provides fundamental insights.

Traditional e-business has PC (or notebook PC) as the only Internet connection device. First of all, PC is complicated to use to most users, and therefore, not suitable for everybody. PC is not convenient to carry while traveling. So, PC is not anytime accompanying with the user. Even if the PC is with the user, it is not everywhere

turned on ready for use. PC allows user to access any information over Internet, of course, but not always online for access. Furthermore, PC is usually blocked out from business process by enterprise firewalls in order to prevent from non-business activities usages. Therefore PC is of less possibility of the mission-trigger advantage as well.

From commerce viewpoint, sales or services delivery are the basic transactions for enterprises to make profit. Consider a given e-commerce transaction to be accomplished. At the first glance, it seems that PC can help the buyer to access the information, and the automated e-process can assist the buyer to step through and complete the order placement. But, PC limits itself to comprehensive users, and is not easy to configure for Internet access. Even in the office, the only official available access tool is the office PC that certainly should be blocked out by corporate firewalls to prevent from unauthorized usages. Therefore, the most B2C activities have been blocked out and could not be realized. As a consequence, B2C e-commerce did not do well in the past.

However, B2B has always been very successful, and help enterprises reengineer the corporate. Although with only fixed-Internet connections, the introduction of Internet technology effectively coordinates the needs between the supplier and the business purchaser through fixed-location authorized business operations.

## 6. The Realization of Business Transactions

We have demonstrated how traditional e-business being blocked from timely matching the supply and demand for successful transactions in the B2C marketplace. However, how does mobile business overcome these obstacles? We will answer this question based upon transaction theory (Coase, 1937) and mobile business advantages.

Based upon transaction theory, a business operation can be viewed as a collection of business transactions, each of which is aimed to generate profits for the enterprise. Each business transaction can be decomposed into sub-activities, and be described by the following transaction model and transaction costs:

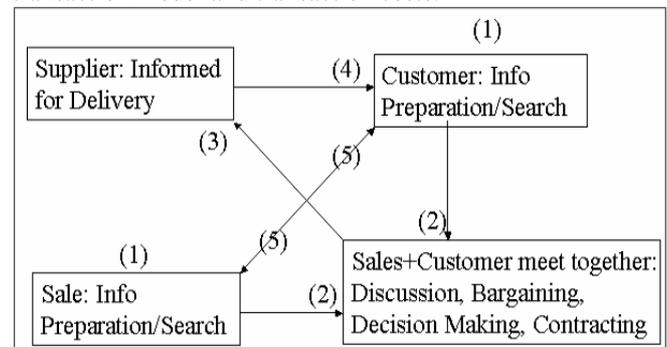

Figure: The transaction model with sub-activities and transaction costs

- (1) Information searching: Each customer searches for in-depth information about desired products/services and each sales agent searches for potential customers. During the process, we call this transaction cost the information cost,  $c_i$ , which includes both search cost and document preparation cost in a transaction.
- (2) Negotiation and decision making: With some information on hand, the customer and the sales agent communicate with each other either via telecommunications or via traveling to face-to-face meet-together for further discussion. In this phase, the sales agent and the customer discuss the case, negotiate for the prices, make decisions on appropriate choices, and finally settled with a contract. Besides the time spent in the process, the transaction costs involved are transportation cost,  $c_t$ , and telecommunication cost,  $c_v$ .
- (3) Informing the supplier: When the transaction reaches an agreement, the supplier, if needed, will be informed via transportation contact, telecommunication informing or digital document/data exchanges. The transaction costs involved are transportation cost ( $c_t$ ), telecommunication cost ( $c_v$ ), and information cost ( $c_i$ ).
- (4) Services/products delivery: The supplier delivers the services/products to the customer to fulfill the purchase transaction. The transaction costs involved are transportation cost ( $c_t$ ), telecommunication cost ( $c_v$ ), and information cost ( $c_i$ ).
- (5) Transaction management: During all process phases, it is enterprise's responsibility to monitor and administrate all activities in order to follow the transaction requirements. When the transaction service is fulfilled, it is enterprise's responsibility to maintain the customer's satisfaction. These transaction costs are the policing cost and enforcement cost, and will be denoted by management cost,  $c_m$ . The management cost covers the sales labor costs in our analysis for convenience.

Based on the above analysis, the total transaction cost,  $c_T$ , consists of the following components:

$$c_T = c_t n_t + c_v n_v + c_i n_i + c_m (t_a + t_1)$$

where,  $n_t$ ,  $n_v$ , and  $n_i$  are the frequencies of transportation, telecommunications and information retrieval/preparation costs, respectively, and  $t_a$  is the active processing time and  $t_1$  is the time lost during the transaction process.

According to the transaction model, the total realized profit can be described by the following equation:

$$\pi = (p - c_p - c_T) r q$$

where,

- $\pi$ : the total profit of all e-business transactions
- $p$ : the sales price

$c_p$ : the product cost

$r$ : the probability to realize a transaction and close the deal

$q$ : the potential quantity of transactions to the enterprise

In other words, the total realized profit equation could be restated as follows:

$$\pi = \{p - [c_p + c_t n_t + c_v n_v + c_i n_i + c_m (t_a + t_1)]\} (r_b r_t r_w r_e) q$$

## 7. How Mobile Technology Impacts Business Operations

Recall that mobile technology provides us with anybody, anytime, anywhere, any information, any process and mission-trigger advantages. These advantages empower both suppliers and customers to reach each other without been blocked-out. Given the above stated profit realization equation as well as the mobile advantages, therefore, we may analyze how mobile technology impacts business operations.

**Mobile Business Strategy 1: Reducing transportation activities by utilizing mobile communications, mobile Internet information retrievals and process assistances.**

First of all, we have analyzed the transaction costs and classify them into four categories, namely, the costs of transportation, telecommunications, information and management. Among these costs, traditionally, the information cost is the most expensive one, and transportation cost is the least, i.e.,  $c_i \gg c_v \gg c_t$ . Therefore people tend not to use technology.

However, with given Internet and mobile phone infrastructures development, the transportation cost becomes the most expensive one, and is significantly higher than those of telecommunications cost and information cost. For instance, transportation cost of each round trip tour to see a customer in Taipei City, besides about forty minutes or more time lost, is about 300 dollars. However, each 20-minute mobile call costs about 150 dollars, and the information retrieval cost is significantly less. In other words,  $c_t \gg c_v \gg c_i$  if mobile business is adopted. Therefore, it is not only clever to reduce the frequencies of each cost, but also clever to further replace transportation frequencies by telecommunications or mobile Internet information retrievals.

**Mobile Business Strategy 2: Reducing active processing time and eliminating time lost by meeting customers at effective location, closing the deal in an efficient manner and greater customer satisfaction, and utilizing unavoidable traveling time for other transactions scheduling or coordination by mobile communications.**

The time required to accomplish a transaction is another important factor to reduce the transaction cost. One can reduce the active processing time,  $t_a$  and the time

lost  $t_1$  with mobile technology. Anybody (either sales agent or the customer) can prepare sufficient information back and forth over Internet, anytime, anywhere, and settle the deal much more effectively. This will greatly reduce active processing  $t_a$ . As to the time lost, choosing an appropriate location with the customer with mobile technology for better communications and sufficient information, then one can concurrently coordinate simultaneous transactions to reduce the time lost dramatically, and furthermore gives much better customer satisfaction.

**Mobile Business Strategy 3:** Mobile technology gives much better possibility of getting the right persons, at right timing, in an appropriate location with right information to assist and settle down business contracts.

As described earlier, the probability of having a transaction to be successfully accomplished is  $r = r_b r_t r_w r_i r_e$ , where  $r_b, r_t, r_w, r_i, r_e$  are the probability of the right persons, right timing, right place, right information and assistance to execute, respectively. The third area to improve the business operation is to increase each of the probabilities by utilizing mobile technology.

It is worthwhile to point out that if the possibility of each of the 5 factors is increased by a factor of 2, then the total possibility is improved by a factor of  $2^5=32$ , which is a significant improvement to corporate profit realization.

**Mobile Business Strategy 4:** To increase realized transaction quantity and to lower unit cost can be achieved by adoption of mobile technology.

The last part in the profit realization equation is the realized transaction quantity. Note that the maximum quantity that a corporate can serve is the total working hours divided by the total processing time for each transaction. Denoted by  $T$  the working hours per month, then the maximum quantity that the corporate can serve per month is given by

$$r q = T / (t_a + t_1).$$

In other words, the shortened processing time significantly increase the capability of product selling. Furthermore, note that the product cost  $c_p$  is a function of realized transaction quantity  $rq$ , due to quantity discount:

$$c_p = f(rq),$$

where  $c_p$  decreases when  $rq$  increases.

With mobile business advantages, it is much easier to realize transaction quantity. An enterprise hence may expand the transaction volume easily, especially if the others have not yet done so. For newly startup mobile business, it is easier to reach critical amount of business transactions, and hence help entrepreneur. Given increased realized transaction quantity, therefore, it is easier to accumulate bargaining powers for discounted volume cost  $c_p$ .

**Mobile Business Strategy 5:** Mobile business is a must to competitive corporate. Because mobile phones are easy to use to anybody, the assigned mission can trigger the

responsible persons to execute accordingly. As a consequence, every competitive corporate will adopt mobile technology into operations, due to intensifying global competition.

Another fundamental question is: what are the prerequisites or sufficient conditions for an enterprise to adopt mobile technology to turn into a mobile business?

In traditional e-business environment, the implementation of e-business requires a lot of obstacles, such as highly educated computer employees and customers, only office or certain restricted places are equipped with internetworking infrastructure, etc. In mobile business, the capable persons are expanded those who use mobile phones, which is about 10 more time of PC users. Because of this anybody advantage, it is 10 times easier to hire qualified employees. Furthermore, it is easier to have a qualified CEO for such mobile business strategy planning and implementation as well.

Finally, substituting of above equations,  $r q = T / (t_a + t_1)$ , into the profit realization equation, we have

$$\pi = \{ p - [c_p(q) + c_t n_t + c_v n_v + c_i n_i + c_m (t_a + t_1)] \} (r_b r_t r_w r_i r_e) [T / (t_a + t_1)].$$

This equation states the relevant components that may be used to improve business operations by adopting mobile technology.

## 8. Concluding remarks

In the last decay, the e-commerce just got started, and gave traditional business great competition pressure. However, the Internet customers are usually blocked away from freely accessing and placing purchase orders at wills. On the other hand, the traditional business had already controlled most product supplies, and had tried hard to compete with Internet e-business. As a consequence, the first wave Internet e-business were difficult to realize business transactions, and did not survive to make enough profit. Therefore, most of DOTCOM enterprises were shaken out, and caused global economy recession.

In this paper, we analyze and propose the advantages of mobile business, namely, anybody, anytime, anywhere, any information, any process and mission-trigger. These fortes are available only in the newly developed mobile business environment, and can bypass the problems of being blocked out from realization over the Internet marketplace that traditional e-business had suffered.

The mobile technology significantly impacts business operations, and we can have the following strategies to improve business efficiency. We can utilize mobile technology to help corporate (1) lower all kinds of transaction costs, (2) shorten transaction processing time or time lost, (3) increase the probability for reaching agreement and getting settled with better customer satisfactions, and therefore (4) can handle more customer requests and lower the unit product cost. Furthermore, due to the easy to use/implement nature, mobile technology

can be easily adopted by most corporate, and hence (5) the mobile business adoption is a must to modern business operations.

This paper provides a framework for enterprises to utilize mobile technology and reengineer business process. Top management can therefore set up corporate strategies to restructure the enterprise resources, build superior core competence, and enhance compete in the global market.

## Abstract

This research has developed an analytical framework, which incorporates four measurement variables for a competitive marketing channel, they are channel structure, channel power, channel climate, and channel performance. Based on the questionnaire and personal interview, an empirical survey on mobile phone marketing channel located both in Taipei and Beijing was applied for system survey. SPSS statistical software tool was applied for survey data analysis with the functions of factor analysis, T test analysis, Pearson correlation coefficient analysis, and regression analysis. The major conclusions are summarized as followings: 1. Channel structure has significant influence on channel performance. 2. Channel power has significant influence on channel performance. 3. Channel climate has significant influence on channel performance. 4. Channel structure has significant influence on channel power. 5. Channel power has significant influence on channel climate. 6. Channel structure has significant influence on channel climate. Through the data surveyed, it is sufficient for us to make the characteristics comparison of marketing channel located in Taipei and Beijing. Channel management, information, protectionism and customer response speed etc. are the major problems occurred in China now.

Key words: Marketing channel, Channel structure, Channel power, Channel climate, Channel performance

## 1. Introduction

In the era of new economy, the life cycle of most products became shorter and shorter due to the continuous developing of information technology. In recent decades, the progress of industry developing in Taiwan is marching on the direction of high technology and high value-added precision industry, information communication is the most outstanding one especially. On situations of mature technology applied to the products of relative competitors, as well as the variety of customer demand, marketing channel has become the new policy for success. In adapting to this fluctuating marketing environments, to create a competitive marketing channel is the major business strategy, also it is the core capability and the critical successful factor for corporations in this new coming era.

China has borne the most attractive economic power

all over the world since 1979, the year of open, for her marvelous population and high economic growth rate. China has been the member of WTO (World Trade Organization) in 2002, that should lead China to adjust her economic developing style from production-oriented to customer-oriented, reduce and release the barrier of government regulation. Free trading, global marketing and global information flow should be the future trend for China. In the coming future for the corporations to win in China, it is the first consideration to build a strong marketing channel, then, they can grasp the keys to success.

Government regulations on telecommunication have been released step by step both in China and Taiwan. The opening on this new application area induces many new profitable business, business on internet, mobile phone, fixed network and broadband network are some typical applications. Due to the huge marketing capacity and high developing potentials in China, it's of no doubt for many competitors to share this "big pie" from both local and foreign corporations.

Taiwan and China are separated by Taiwan Strait, the distance is short geographically across the strait, but it's long in economic environments. Due to the difference in political and civil situations, the trading and marketing circumstance are quite different. This research has developed an analytical framework based on the questionnaire and personal interview, SPSS statistical software tool is applied for survey data analysis. The three major goals for this research are: (1) Survey on the relationship between marketing channel structure and marketing performance for retails of mobile phone in Taipei (Taiwan). (2) Survey on the relationship between marketing channel structure and marketing performance for retails of mobile phone in Beijing (China). (3) Compare and tell the difference in marketing channel structure and marketing performance between Taipei and Beijing.

## 2. Literature Review

This section will describe the definitions of marketing channel, channel structure, channel climate, channel power and measurement of channel performance. The corresponding literature reviews are summarized as Table 1.

Table 1 Characteristics of marketing channel

Topic	Brief Concept	Authors
Channel Structure	Divide into three major types based on processing functionalities: marketing trading, intermediate trading, hierarchical trading.	Owyer et al. (1981)
	Describe channel structure based on the level of intermediate trading: 0-level channel, 1-level channel, 2-level channel ...	Kotler (1997)
Channel Climate	Encourage the members of marketing channel to bear the feeling of mutual support based on the arrangement of partnership.	Rosenbloom (1987)
	The relationship among all members of marketing channel.	Reve & Stern (1986)
	Maintain a permanent partnership based on strategic consideration for the purpose of close and stable relationship.	Sheth (1994)
Channel Power	The control power of marketing channel strategies that one member of marketing channel overrides the others. This power can influence the decisions of total channel.	Stern et al. (1996)
	The source of channel power comes from the power perception of channel members. The common value and self-regulated rules generated through indirect and non-economic factors can influence the channel members with less disputable.	Lusch (1998) Rosenbloom (1987)
Channel Performance	Channel performance measurement should be built with multiple attributes and multiple levels' structure.	Stern et al. (1996)
	Review on the performance of retails based on the viewpoint of suppliers, there are four review modules: rationality system, behavior system, inner process system, open system.	Kumar et al. (1992)
	Review on the performance of wholesales based on the viewpoint of manufacturers, the quantitative index on profit rate and growth rate are the majors.	Kotler (1997)

A. Marketing Channel: The construction of all members who process the trading activities of goods or services from original providers to end consumers (Kotler, 1997). Trading process includes physical distribution, property transferring, payments, information exchange, risk management. The channel emphasize on the transferring process from providers to customers.

B. Characteristics of Marketing Channel

There are three major factors which compose the characteristics of marketing channel, they are channel structure, channel climate and channel power, all of these factors may have the critical influence to channel performances.

B-1. Channel Structure: The channel types that express how the marketing channel works.

B-2. Channel Climate: The perception of interrelationship among members of marketing channel.

B-3. Channel Power: The member who bears the control power over the others to influence the strategic activities of total marketing channel.

C. Measurement of Channel Performance: The outcome structure of total marketing channel as well as the performance measurement of their corresponding performance index.

3. Research Methodology

3.1 Survey Structure and Hypothesis Test

The three major characteristics in marketing channel has been discussed in the previous section. Figure 1 demonstrates the interrelationship among the three factors in marketing channel as well as channel performance. Based on the questionnaire and personal interview, we provide six hypothesis tests for system survey.

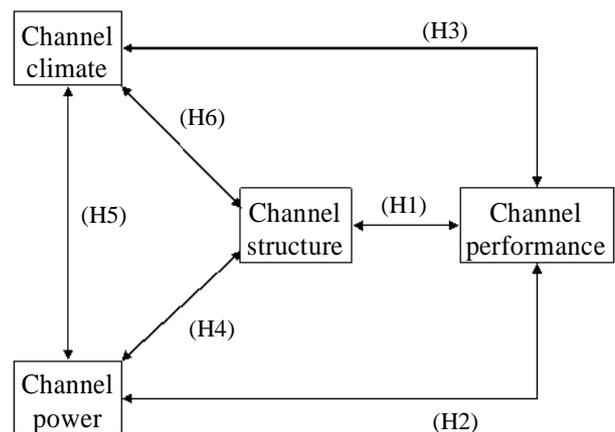

Figure 1 Survey structure

H1: Channel structure has significant influence on channel performance.

Channel structure has the sufficient influence on the characteristics of marketing channel and channel performance, communication styles are varied from one marketing channel to another (Rosenbloom 1987). On

the relational channel structure, the closer the channel relationship, the more the constructive communication is achieved (Etgar, 1997).

H2: Channel power is positively related to channel performance.

Channel power is defined as the decision variable that one member of the marketing channel has the power to control or influence on confidence, attitudes and activities of the others (Anderson et al., 2000; Stern et al., 1996). Channel power is positively related to the non-forced strategies of marketing channel (Brown et al., 2001). The higher the channel power appears, the more the non-forced strategies are applied on marketing channel (Mayo et al., 1998; Lusch, 2001).

H3: Channel climate bears the influence to channel performance.

Good channel climate will infer to good channel performance, that is strongly supported for all related literature survey on organization theory of marketing channel (Stern et al., 1996; Schul et al., 2001).

H4: Channel structure is significantly dependent on channel power.

There are mutual interrelationships between channel structure and channel power (Stern & Reve 1980). It is suitable to build up a marketing channel system based on centralized consideration in views of both channel structure and channel power, Under the marketing trading structure, the communication style will be collaborated if the channel power is symmetric, otherwise, it will be self-determined (Williamson 1981).

H5: The more effective of the channel power has the will to set a good channel climate.

“Trust” (Anderson, Lodish & Weitz, 2000) and “Permanent Relationship” (Hammond, Brown & Harmon 1996) are two critical variables affect the channel climate most. Trust is defined as the mutual self-regulated engagements or contracts, it is stable and reliable for all members of marketing channel, also, it is the commitment for every trading partner within a marketing channel. Permanent relationship refers to the perceptions of all trading partners in a marketing channel, they all have the will to maintain continuous and forever interrelationship (Hammond et al. 1996).

H6: Channel structure is significantly dependent on channel climate.

Members of marketing channel can process the relational exchange under the base of mutual support and full trust. Thus, the interrelation between channel climate and channel structure can catch its best effects. The more mutual confidence the members have, the more sufficient communication they do under the relational structure with climate of mutual support (Dwyer, Schurr & Oh 1981).

### 3.2 Data Collection

The survey population comes from mobile-phone retails located in Taipei and Beijing, the major retail

categories include IT (Information Technology) shopping malls, 3C (Computer, Communication, & Consumer Electronics) shops, chain stores and individual retailers. Survey data is randomly sampled proportional to its population and density of business activities, data is collected through personal interview. We issued 125 samples in Taipei and 116 samples in Beijing, 113 and 101 effective data is successfully collected, respectively.

The content of survey questionnaire data is focused on channel relation between mobile-phone manufacturer and retail, one unique manufacturer (brand) and one retail are set to be a survey “entity”, with which we can catch the relationship among channel characteristics and channel performance. The statistical software tool SPSS for Windows with version 10.0 is used for corresponding data analysis, it is also applied for variables validity and reliability assured.

### 4. Data Analysis

There are four characteristics considered in questionnaire design, they are channel structure, channel power, channel climate and channel performance. There are four, thirteen, eighteen and eight attributes contained in each characteristic respectively (see Table 3 - Table 6). Survey data is measured in Ordinal Scale (1, 2, 3 ...) for channel structure, the others are measured according to Likert's 7 grading scales (e.g. 1 represents extremely satisfaction, 7 represents extremely dissatisfaction). We issued 125 samples in Taipei and 116 samples in Beijing, 113 and 101 effective data is successfully collected, respectively.

The basic types of channel structure are similar on mobile phone marketing located in Taipei and Beijing, the upper lever (1-level) includes manufacturers and agents owned by local or foreign corporations, the middle level (2-level) is distributors, and the lower level (3-level) is retails. Retails can be owned by various categories, they are individual retails, voluntary chain stores (VC), franchise chain stores (FC), regular chain stores (RC) owned by manufacturers, agents, and mobile service company. The communication type is direct and fluent between members of level-1 and level-2, level2 and level-3, also, members of level-1 can contact with members of level-3 and catch sufficient information through telephone, facsimile, meeting, and personal contacts. Distributors play the roles of intermediate linking functions for both material flow and information flow, the major objective for distributors is to increase distribution efficiency, reduce total inventory, and reduce business risk.

SPSS statistical software tool is applied for survey data analysis: 1. Factor analysis is used for channel structure declarative data analysis. 2. T test analysis is used to review whether channel characteristics and their relative attributes have significant difference. 3. Pearson correlation coefficient analysis is applied to review whether the data among all characteristics of marketing channel is significantly dependent. 4. Regression analysis answers the questions about “What's the relationship between each pairs of marketing

channel's characteristics?" and "How about the degree of correlation?".

#### 4.1 Declarative Data Analysis of Channel Structure

Declarative data analysis is based on the types of retail (5categories) located in Taipei and Beijing, Table 2 summarizes the survey data of channel structure between Taipei and Beijing. The major difference occurred is that VC and FC stores take the brief portions (37.17%) in Taipei, while individual retails in Beijing win the top (42.57%). Due to the progressing of standardization on mobile phone industries, specialization, scale enlargement, and centralized control should become the new tendency, thus, IT shopping mall, 3C shops, VC and FC stores, and RC owned by telecommunication service company, will take major portion of channel structure in the near future. The channel structure developed in Taipei is earlier than which in Beijing, it tells the reason why the difference occurred.

Table 2 Channel structure summary (Taipei vs. Beijing)

Type of retails	Number		Ratio (%)	
	Taipei	Beijing	Taipei	Beijing
Individual retails	29	43	25.66	42.57
VC or FC stores	42	24	37.17	23.76
RC owned by agent	31	21	27.43	20.79
RC Owned by mfg.	4	3	3.54	2.97
Others	7	10	6.19	9.90
Total	113	101	100	100

#### 4.2 T-test on Channel Characteristics and Their Relative Attributes

T-test is used to review whether the data of two areas (Taipei and Beijing) has significant difference according to attributes within each characteristic of marketing channel (see Table 3 - Table 6).

##### 4.2.1 Attributes of Channel Structure

Survey data is measured in Ordinal Scale. Table 3 shows the summarized analysis results, the content of each attribute is described as follows:

- Retails Types: 5 categories are divided and refer to: 1. individual retailers, 2. VC and FC stores, 3. RC owned by agents, 4. RC owned by manufacturers, 5. others.
- Retails Location: the place where mobile phone products are sold. 1. IT shopping malls, 2. VC and FC stores, 3. 3C shops, 4. RC owned by telecommunication service company, 5. individual retails, 6. others.
- Ordering Types: set up a replenishment order, 1. to manufacturer directly, 2. not to manufacturer directly.
- Ordering Methods: the way setting up an order from retailer to manufacturers, 1. by telephone, 2. by facsimile, 3. by post mail, 4. by EOS (Electronic Ordering System), 5. through internet, 6. others.

Table 3 T-test on attributes of channel structure

Attributes	Average		S.D.		Avg.	S.D	T Value
	Taipei	Beijing	Taipei	Beijing			
Retails type	2.78	2.26	1.61	1.02	2.52	1.32	2.79*
Retails location	2.84	3.03	1.41	1.63	2.94	1.52	-0.90
Order to mfg.	1.00	1.01	0	0.10	1.01	0.05	-1
Ordering method	3.77	1.93	1.06	1.16	2.85	1.11	11.96**

Remark: \*\* Means  $P < 0.01$  \* Means  $P < 0.05$

##### 4.2.2 Attributes of Channel Power

Survey data is measured according to Likert's 7 grading scales. Likert's 7 grading scales refer to 1. extremely satisfied, 2. very satisfied, 3. satisfied, 4. fair, 5. unsatisfied, 6. very unsatisfied, 7. extremely unsatisfied. Table 4 shows the summarized analysis results for significant items only.

Table 4 T-test on attributes of channel power

Attributes	Average		S.D.		Avg.	S.D	T Value
	Taipei	Beijing	Taipei	Beijing			
Technical support	5.82	4.14	1.44	1.08	4.98	1.26	1.84*
Policy and procedure of order-return	4.50	4.23	1.40	1.18	4.37	1.29	-1.51
Fair price negotiation	4.04	4.66	1.30	1.16	4.35	1.23	3.66**
Strict punishment on counter-regulation	5.54	5.86	0.98	1.20	5.70	1.09	2.13*
Support on marketing strategies and competition information	5.44	5.78	1.04	1.10	5.61	1.07	2.30*
Mutual discussion on business strategies	5.38	4.02	1.30	1.30	4.70	1.30	3.55**
Show expectation only, no incentive, no punishment	5.42	4.12	1.59	1.44	4.77	1.52	3.37**
Hint on "accept my suggestions, comes more profit"	5.46	4.14	1.33	1.32	4.80	1.33	3.74**
Feedback business information periodically	5.41	4.46	1.57	1.29	4.94	1.40	5.36**

#### 4.2.3 Attributes of channel climate

Survey data is measured according to Likert's 7 grading scales referring to 1. extremely satisfied, 2. very satisfied, 3. satisfied, 4. fair, 5. unsatisfied, 6. very unsatisfied, 7. extremely unsatisfied. Table 5 shows the summarized analysis results for significant items.

Table 5 T-test on attributes of channel climate

Attributes	Average		S.D.		Avg.	S.D.	T Value
	Taipei	Beijing	Taipei	Beijing			
Commit to business strategies	5.71	4.06	1.37	1.07	4.89	1.22	2.06*
Manufacturer is royal	5.53	4.33	1.36	1.20	4.83	1.28	4.58**
Adaptable to environments	3.66	4.12	1.29	1.07	3.89	1.18	-2.83**
Take care on retail's business troubles	5.35	4.23	1.20	1.20	4.79	1.20	5.34**
Provide resource support	6.88	5.92	1.01	1.08	6.40	1.05	7.14**
CIS of mfg. is good to benefits	5.15	4.57	1.46	5.54	4.86	3.50	2.47*
Desire to maintain permanent relationship	5.06	5.68	1.19	1.32	5.37	1.26	3.53**
Keep mutual cooperation with mfg.	5.25	4.00	1.14	1.07	4.63	1.11	4.92**
Acknowledge to keep permanent relationship	5.08	5.87	1.27	1.28	5.48	1.28	4.47**
Willing of permanent contracts	6.84	4.09	1.32	1.28	5.47	1.30	6.99**
High degree of team-work	5.05	4.34	1.26	1.22	4.70	1.24	7.55**
Share the common benefits	6.74	4.38	1.37	1.28	5.56	1.33	8.98**
Keep good partnership atmosphere	5.01	4.02	1.14	1.36	4.52	1.25	5.82**

#### 4.2.4 Attributes of Channel Performance

Survey data is measured according to Likert's 7 grading scales referring to 1. extremely satisfied, 2. very satisfied, 3. satisfied, 4. fair, 5. unsatisfied, 6. very unsatisfied, 7. extremely unsatisfied. Table 6 shows the summarized analysis results for significant items of channel performance.

Table 6 T-test on attributes of channel performance

Attributes	Average		S.D.		Avg	S.D	T Value
	Taipei	Beijing	Taipei	Beijing			
Satisfy on current ROI	6.77	5.30	1.11	1.17	6.04	1.14	3.39**
Satisfy on current marketing shares	5.21	5.52	1.20	1.03	5.37	1.12	2.01*
Sales is grown up stably	5.71	4.05	1.14	1.24	4.88	1.19	2.10*
Achieve average inv. requested by manufacturer	5.70	4.32	1.41	1.25	5.01	1.33	3.42**
Achieve sales performance requested by mfg.	5.52	4.33	1.39	1.29	4.92	1.34	4.42**
Wills to keep continuous cooperation with mfg.	5.29	5.85	1.66	1.41	5.57	3.07	2.62**

T-test is also used to review whether the data of two areas (Taipei and Beijing) has significant difference according to each characteristic of marketing channel, Table 7 lists the summarized results on four characteristics of marketing channel. Based on the analysis results listed at Table 7, it is clear to find out that there exists significant difference ( $P < 0.01$ ) between Taipei and Beijing in every characteristic of marketing channel. The difference in channel structure may be caused by the business revolution on channel structure, business tendency to chain store system and large-scale shopping malls, difference in economic policies and consumption attitudes.

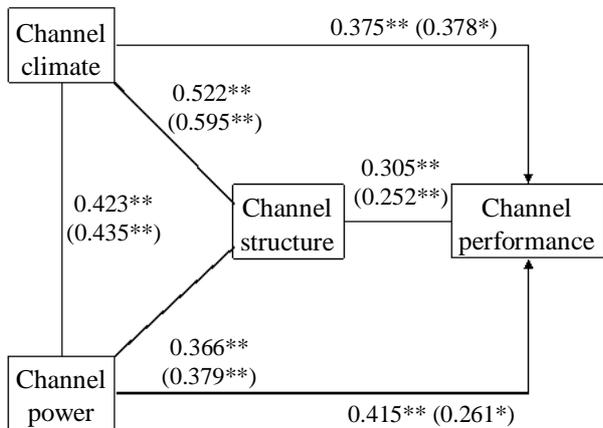

Table 7 T-test on characteristics of marketing channel

Characteristic	Avg.	Taipei	Beijing	Difference	T Value
Channel structure	6.33	6.60	6.06	0.54	6.30**
Channel power	4.83	5.65	4.01	1.64	3.67**
Channel climate	4.67	5.30	4.04	1.26	9.43**
Channel performance	6.20	6.48	5.92	0.56	4.72**

#### 4.3 Pearson Correlation Coefficient Analysis

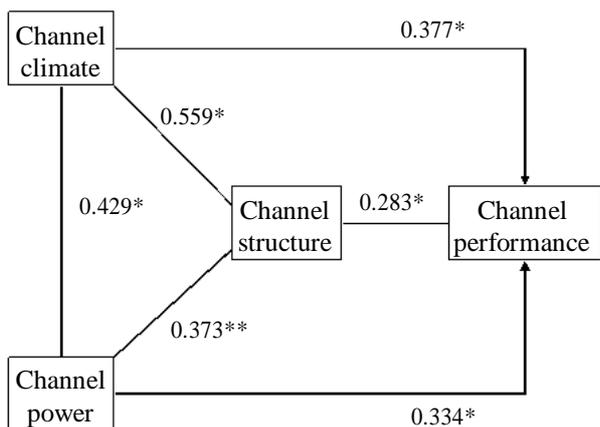

Pearson analysis is used to review whether the data among all characteristics of marketing channel is significantly dependent according to data of two areas (Taipei and Beijing) in individual and in summary. Figure 2 and 3 demonstrate the Pearson correlation coefficient in Taipei, Beijing, and summary, respectively.

The higher the value of correlation coefficient, the more correlated of the pairs. Based on Pearson correlation coefficient analysis, almost all the characteristics of marketing channel are mutually significant correlated.

Remark: \* P < 0.05, \*\* P < 0.01 ; the value in parentheses means Beijing.

Figure 2 Correlation coefficient for Taipei and (Beijing)

Remark: \* P < 0.05, \*\* P < 0.01

Figure 3 Pearson correlation coefficient (summary)

#### 4.4 Regression Analysis

Based on the results of Pearson correlation coefficient analysis, we find out that all the characteristics of marketing channel are mutually significant correlated, the advanced question is, What's the relationship between each pairs? How about the degree of correlation? Regression analysis is used to review, whether "yes or no" and how about, the assigned dependent variable (abb. Dep. V.) is varied proportional to the assigned independent variable (abb. Indep. V.).

All regression analysis on pairs of characteristics of marketing channel are listed at Table 8 – 10, they demonstrate the analysis results on channel structure, channel power and channel climate vs. channel performance (Table 8), channel structure vs. channel power (Table 9), channel structure and channel power vs. channel climate (Table 10), respectively. Based on the analysis data, we get a general conclusion as that, there is significant correlation between assigned independent

variables vs. dependent variables except "channel climate vs. channel performance".

Table 8 Regression analysis on channel variable vs. channel performance

Indep. V.	Dep. V.	Performance		
		(Taipei)	(Beijing)	(Total)
Channel structure	*Coefficient	0.312**	0.257**	0.285**
	R <sup>2</sup>	0.202	0.189	0.196
	Adjusted R <sup>2</sup>	0.196	0.173	0.185
	F Value	11.298*	7.044*	9.171*
Channel power	*Coefficient	0.412**	0.370**	0.391**
	R <sup>2</sup>	0.283	0.280	0.282
	Adjusted R <sup>2</sup>	0.253	0.241	0.247
	F Value	5.658*	5.653*	5.656*
Channel climate	*Coefficient	0.202	0.262	0.232
	R <sup>2</sup>	0.141	0.190	0.331

	Adjusted R <sup>2</sup>	0.158	0.141	0.150
	F Value	6.534*	5.453**	5.994*

#### 5. Conclusions

This research has developed an analytical framework, which incorporates four measurement variables for a competitive marketing channel on mobile phone located both in Taipei and Beijing. According to 6 hypothesis tests listed at Figure 1, we get the conclusions that all characteristics (channel structure, channel power, channel climate) of marketing channel have significant influence on channel performance, and there are inter-relationship among channel characteristics.

The conclusions of data analysis in details are summarized as follows:

1. Channel structure has significant influence on channel performance.

On the relational channel structure, the closer the members of marketing channel are, the more effective

and cooperative communication they have (Brown 1981; Bharadwaj, Varadarajan & Fahy 1993; Colin 2000). We get the same conclusion as the result of literature review. There exists some basic difference between marketing orientation structure and relational channel structure, the closer the relational channel structure is, the more fluent communication, better negotiation, closer cooperative relationship they have, thus, will achieve better channel performance.

2. Channel power has significant influence on channel performance.

Based on the results of literature review, the dominating member exists in a marketing channel, will have the capability to build up a smoothing communication procedure and set up a good channel climate. It is not to abuse the rights one override another, but increase the power to influence the others, thus, it forms a good channel climate and improve the channel relationship. The strategies of dominating member can influence the total strategies of marketing channel through channel communication (Frazier 1983; Summers 1984). The higher degree of dominating power that one member has, the more probable that non-forced policy can be used (Lusch & Brown 1996). If the dominating member can use the power properly, then, they can march on the common goals and catch better channel performance under the situations of cooperative communication and close relationship.

3. Channel climate has significant influence on channel performance.

The members of marketing channel can achieve better team-work cooperation on the channel climate with higher mutual confidence and longer permanent relationship, which is similar to the conclusion surveyed (Anderson & Weitz 1989). If the better channel climate is built, the more smooth mutual communication will be, thus, increase the strength of team-work cooperation and channel performance.

4. Channel structure has significant influence on channel power.

Marketing channel of mobile phone is now progressing on the situations of continuous innovation, new incomer of channel structure impacts much on the current marketing channel, it cause the rearrangement of current channel structure, thus, it impacts the relationship of current channel power also.

5. Channel power has significant influence on channel climate.

Under the interrelationship between channel power and channel climate, members of marketing channel can choose either "go one's own way" or "mutual cooperation" while facing on issues of power conflict. If they choose mutual cooperation, then, it can reduce the negative effects caused which is similar to the conclusion surveyed (Kotler, 1997).

6. Channel structure has significant influence on channel climate.

On the interrelationship of channel structure and

channel climate, members of marketing channel bear the perception of common benefits, they are eager to create an atmosphere of mutual confidence, build up a relational channel structure, and set up a smooth communication channel. They all search for the goals of long-term channel performance, thus, can reduce the overall channel cost.

Marketing channel is a true business resource, to control the marketing channel means to handle the gate to customers, will hold the key to success. Communication industry is a great growth, giant changeable and quick customer response industry. In China, there are many shortcomings appeared, less efficiency transportation system, bureaucracy, protectionism and less operational efficiency are the majors, which should be improved much more.

The characteristics of marketing channel can be extended to a wide scope, the economic and social factor can be introduced in the future study, the more factors considered, the more complicated situation may be occurred, thus we can catch more in details. In the same way, this model can also be applied to various industries for advanced survey.

## Abstract

As mobile sites (m-sites) are introduced a very relevant question to ask is “How should these sites be different from the typical websites developed for desktop PCs?” This paper presents an initial, exploratory attempt to address some issues related to m-sites. This evaluation of sites was conducted using wireless PDAs in a WLAN environment. The results indicated that regular sites and m-sites differed significantly in perceived search engine functionality. The evaluated m-sites showed little differences across various industries. A discussion of these results as well as recommendations for managers and academic researchers are provided.

## 1. Introduction

According to the forecast of PriceWaterHouse Cooper [17], more users are expected to access the Internet in the future on mobile devices rather than on desktop computers. The report went on to predict that by 2005 the penetration of mobile data services in Western Europe will still lead the world (91% of its total population), followed by Japan (90%) [17]. United States, coming in third, will have increased its mobile data consumption up to about 83% while the worldwide penetration rate will be 20% [17].

As of September 2001, according to the National Telecommunications and Information administration [18], the vast majority of Internet users in the United States accessed the Internet through a desktop or laptop computer. Only 1.8 percent of households had an Internet accessible personal digital assistant (PDA) or

other handheld device. The other devices capable of accessing the Internet such as cell phones and pagers were only owned by 4.8 percent of households. Virtually, all of these households with mobile devices also had computers [18].

Mobile communication, since the 90s, has been evolving from voice only transmission to simple data transmission, followed by Enhanced Message Service (EMS) and then Multimedia Messaging Service (MMS) (See Table 1). MMS is classified as third generation (3G) cellular technology. Nippon Telephone and Telegram (NTT) DoCoMo system in Japan has successfully employed 3G technologies. The success of DoCoMo not only relied on its rollout of the infrastructure layers but its quality of service (QoS) in handhelds and content services – i-Mode which offers mobile websites and i-Appli offers more interactive applications [11]. Nationwide deployment of 3G in the U.S. was conducted by Sprint during the summer of 2002 tied with the release of Men in Black II, in which the company’s service was featured.

When discussing wireless research, the technical issues, such as the interoperability, have been the primary topics. However, there have been few known scholarly studies examining how website contents appear on the mobile devices. As m-sites are introduced a very relevant question to ask is how should these sites be different from the typical websites developed for desktop PCs? As shown in Table 2, accessing the Internet with m-devices is likely to be a very different experience for users compared to the experience with desktop computers.

Table 1 : Evolution from Text to Multimedia

	1990s	2001	2002
Characteristics	100-200 characters	Text messages, sound Picture, text formatting	Multiple rich media formats
Content reformatting for mobile necessary	Yes	Yes	No
Application	Simple person-to- person messaging	Person-to-person messaging	Person-to-person messaging with visual feel
Multimedia Messaging	All phones	EMS standard expected to be Widely adopted	MMS standard expected to be Widely adopted

Table content extracted from Lewis [15].

Further, although use of an m-device has one big advantage over PCs (mobility), it also has several disadvantages. Compared to desktop modem access, data transfer via mobile devices is more expensive. Compared to the rest of world, the majority of U.S. population still prefers the desktops over mobile devices to access information via Internet. Theoretically, regular Web and the mobile Web have distinct audiences, purposes and characteristics that supposedly warrant different features and content. In reality, how do sites compare at this point?

This paper presents an initial, exploratory attempt to address some issues related to mobile sites. How successfully are these changes from regular to “mobile” sites currently being made? How are users reacting to these mobile sites? What improvements appear to be needed? This paper will report on the analysis of over seventy sites and discuss managerial implications as well as recommendations for future studies.

Table 2: Contrast of Alternative Means of Accessing Internet

Attribute	Desktop Computer	Handheld devices
Connection speed	fast	Slow/moderate
Connection expense	cheap	expensive
Monitor size	large	small
Visual quality	great	poor
Sound quality	great	poor
Navigation ease	good	poor
Mobility	poor	good

## 2. Literature Review

Mobile websites (referred to here as the Mobile Internet) involve the use of wireless communications technologies to access network-based information and applications from mobile devices [17]. Customers engaged in m-commerce use wireless communication technologies to access network-based information and applications from mobile devices. Excluding laptops, there are currently two principal classes of mobile devices: mobile phone handsets and handheld computing devices (e.g., Personal Digital Assistants, PDAs). As shown in Table 2, analysts cited a number of obstacles to the development of the mobile Internet in the United States, such as minimal screens, low data rates (less than 20 Kbps), and cumbersome text input mechanisms [14][15].

In transition from regular web sites to presenting the content on the wireless platforms, such as Time Division Multiple Access (TDMA), Code Division Multiple Access (CDMA), and Global System Mobile Communications (GSM), the service providers have developed different ways to modify the presentation. Typically, regular web sites provide the same information

to the mobile sites. Sometimes, you may click through the mobile site via regular Web sites, for example, CNN, The Wall Street Journal (which is hard to navigate through). Some regular sites have distinctly different mobile sites to show their unique presentations on the wireless platforms.

There are several ways to develop wireless e-business applications (See Table 3), such as:

1. Create regular Web pages that users view from the small displays on mobile devices.
2. Using the Wireless Application Protocol (WAP) to connect to the Internet.
3. Build applications optimized for handheld devices using Web clipping.
4. Build a Native application that can incorporate on-line and off-line components and are available when network connections are not.

Table 3 : Wireless Development Option Comparison

Capabilities / application	Web pages	WAP	Web clipping	Native
<b>Data transfer</b>				
Multiple modes	No	No	Limited	Yes
Intelligent selection	No	No	No	Yes
<b>Data access</b>				
Local databases	No	No	No	Yes
Local processing	No	No	No	Yes
<b>Data interactivity</b>				
Rich display	No	No	Yes	Yes
Flexible input	No	No	Yes	Yes
Mobile computing	No	Yes	Yes	Yes
Intl coverage	Yes	Yes	Yes	Yes

Table content extracted from [16].

No matter what type the application is, there are different characteristics to define QoS. In terms of technology, QoS parameters may include timeliness, bandwidth, and reliability [5]. From the user’s point of view, QoS requirements may become a perceived QoS. Depending on the type of data transmission application, the priority can be defined among different flows in multimedia stream by picture resolution, color accuracy, video rate, video smoothness, audio quality, video/audio synchronization, cost and security [12].

Buchanan et al. [3], in their usability research of WAP phones, identified design guidelines which: 1) provide direct, simple access to focused valuable content, 2) use simple hierarchies, 3) reduce the amount of vertical scrolling, and 4) reduce the number of keystrokes. The study resembled issues identified during the early stage of website development for desktop computers.

Followed by Chan et al. [6] using cognitive walkthrough and heuristic evaluation methods, they evaluated the usability of ten wireless sites in three platforms: WAP-enabled mobile phones, Palm OS based wireless PDAs, and Pocket PCs running Windows CE operating systems. Their usability findings pertained to user tasks, content presentation, search, navigation

systems, and the design constraints imposed by form factors impacted on usability [6].

The research objective of Chan et al. [6] was to assess the usability of wireless sites of the most popular e-commerce companies as well as to provide the examination of wireless interface design. In defining wireless sites, their definition of tasks focused on transactional, and information retrieval. They found that all ten sites accessed using mobile devices were designed with steps similar to their counterparts designed for PC-based access [6]. However, in mobile environment, there was neither enough time nor content for users to perform such tasks. As insightful as this study was, only ten sites were evaluated. The very small number of sites could have greatly biased their evaluations. Further, it precluded their ability to make comparisons across industries.

Cellmania.com launched a free directory of 10,000 of the most “effective” WAP sites [2]. As a third party from the Web industry and consumers, Cellmania reviewed mobile sites with four criteria: overall usefulness to the mobile consumer, content, ease of use and navigation, interactivity and robustness of site. Thirteen categories were evaluated by the experts and users. Those categories are communications, travel, reference, news, games, financial/business, directory services, weather/traffic, sports, portals/search, m-commerce, food and entertainment [10]. Unfortunately, very little information about the analysis made by Cellmania.com was publicly released. Thus, we still do not know how sites optimized for mobile devices compare to those optimized for desktop PCs or what differences may exist across industries.

Given the previous work that has been conducted, two research questions were addressed in this research. First, what differences are there between the typical

websites constructed for the desktop experience and those sites designed with mobile devices in mind? The second question has to do with the possibility that some industries may be more innovative than others in preparing for this new form of Internet access. Thus, what differences are there between industries in terms of the ways their sites appear on a mobile device?

### 3. Methodology

The study was conducted with students in a MBA course at a large university in the Midwestern United States. The students were put into groups and provided some instruction on using the m-devices. They were each assigned seventy-four sites to evaluate and they were not told specifically whether the sites were regular or mobile sites. Reports in the popular press as well as the researchers’ experiences with the devices provided insight into the key problems that users could encounter at websites.

Thirty-four (See Table 4) out of over 600 mobile sites were filtered from Palm.net Web clipping services [9]. Forty regular websites in addition to the mobile sites were evaluated in this research (a total of 74). Five industries were chosen from Palm.net, whose sites were presented with average users’ ratings. Evidently, there were more regular websites than the mobile sites. Originally, the researchers selected more than 74 sites; however, some mobile sites were deleted because of their loading difficulty and/or unavailability when this research was conducted. Those sites may have been temporarily out of service or simply out of business because of economic downturn.

Table 4: The Evaluations of Websites and Mobile Sites in Five Industries

Industries	Entertainment	Finance	News	Shopping	Travel
Regular Websites	Dodgeball	Ameritrade	CNN	GapCo	eLocal
	Dorcino	BigCharts	ESPN	Amazon	Fodors
	Egolfscore	CBSMarketWatch	LATimes	InternetGroceries	Freightgate
	Fandango	NewYorkFed	AllLotto	BarnesNobles	HotelDiscounts

	Dorcino	Quicken	InfoBrand	GoAmerica	OAG
	Egolfscore	WellsFargo	Chronical	Oreilly	
	Moviefone		CBS		
	InterBUG		VegasInsider		
	Airguitar				

The evaluations made by the judges addressed several issues. First, how well did the page fit within the screen when the respondents looked for a particular function like a “search engine?” Did the respondents need to scroll around on the minimized PDA to find the function? While meeting the task of “looking for a search function” on the sites, the respondents were asked to evaluate if the text was readable, and if the graphics were presented right. Finally, the respondents assessed how easily they found a search function. The rationale behind this procedure was that by completing a task - find a search engine, the respondents gave their quick responses to what was presented in a particular Web site, regular or mobile.

The m-devices used in the study were PDAs. Specifically, they were a top-of-the-line color version running Pocket PC with Microsoft CE including Internet Explorer. The devices connected to the web via “Wi-Fi” (802.11b) network. The screen size was approximately 3” x 2”. Although it would have been valuable to use 3G cell phones, at the time the study was conducted cell phones with Internet services were still rare in the U.S., not to mention the difficulty and expense of obtaining enough handsets and service to use in the exercise.

The URLs for the sites were put in the Favorites folder of each device ahead of time by the researchers. The procedure was for each site to be accessed using Internet Explorer and then for the questions to be answered. To make the job as simple as possible yet remain in the mobile domain, students used an Excel form created by the researchers running simultaneously on the PDA. By using programmable function buttons on the front of the devices, students could easily switch between a view of a website and the spreadsheet upon which they entered their assessments.

Once a group had finished judging all of the sites they e-mailed their Excel file to an address provided. The researchers then merged the data from each of the groups into one file and analyzed the data. T-tests were utilized to analyze the differences between the mobile sites and the regular sites. ANOVA was used to analyze the differences among the various industries. This study was not concerned about potential differences in group or individual evaluations but instead focused on differences between sites as judged by the groups.

#### 4. Results

The assessments of the five groups of judges of the seventy-four sites were analyzed to address the research questions. The findings with respect to each question are presented below.

#### Research Question 1: Mobile vs. Regular Websites

Surprisingly, there were few significant differences found between mobile and regular Websites. Among the site characteristics tested, we found that only the presence of a search engine showed a significant difference ( $t = 2.117, P < .05$ ). In other words, the regular websites (mean = 3.35) provided easier access to search engines than m-sites (mean = 2.96). The other criteria, adequacy of fit to the screen, degree of graphic distortion, and readability of text, did not show a significant level of difference between regular websites and mobile sites (See Table 5).

Table 5: The Differences between Regular & Mobile

	*Web/ Mobile	Mean	Std. Dev	t	df	Sig. (2- tailed)
Fit	Web	2.61	1.265	.065	365	.948
	Mobile	2.60	1.202			
Readable	Web	3.88	1.109	-.502	365	.616
	Mobile	3.94	1.056			
Distorted Graphics	Web	2.77	1.423	-.249	365	.803
	Mobile	2.81	1.488			
Search Engine	Web	3.35	1.782	2.117	365	.035
	Mobile	2.96	1.781			

Web N = 198; Mobile N = 169

#### Research Question 2: Differences among Industries

The sites were grouped into five industries: entertainment, finance, news, shopping, and travel. In Fit, Readable, Distorted Graphic, and Search Engine criteria, there were no differences among five industries using ANOVA (See Table 6). The researchers further ran the t-test on 14 paired industries to see if there were any differences. It turned out that, only two industries, finance (mean = 3.14) and shopping (mean = 2.40), showed significant differences ( $t = 2.184, P < .05$ ). Specifically, typical websites were viewed as different from m-sites in their degree of distorted graphics (See Table 7). Therefore, among those sites we evaluated, the sites in finance industry were more likely to present distorted pictures than those in shopping industry.

Table 6: The Differences between Industries

		Sum of Squares	df	Mean Square	F	Sig.
Fit	Between Groups	2.900	4	.725	.496	.739
	Within Groups	239.739	164	1.462		
	Total	242.639	168			
Readable	Between Groups	1.558	4	.390	.344	.848
	Within Groups	185.850	164	1.133		
	Total	187.408	168			
Distorted Graphic	Between Groups	12.080	4	3.020	1.376	.244
	Within Groups	359.861	164	2.194		
	Total	371.941	168			
Search Engine	Between Groups	10.277	4	2.569	.807	.523
	Within Groups	522.433	164	3.186		
	Total	532.710	168			

Table 7: The Differences between Finance and Shopping Industries

	Industry	Mean	Std. Dev	t	df	Sig. (2-tailed)
Fit	Finance	2.72	1.162			
	Shopping	2.37	1.159	1.183	57	.242
Readable	Finance	3.97	.981			
	Shopping	3.77	1.278	.669	57	.506
Distorted Graphic	Finance	3.14	1.529			
	Shopping	2.30	1.418	2.184	57	.033
Search Engine	Finance	3.31	1.775			
	Shopping	3.17	1.840	.305	57	.761

Finance N = 29; Shopping N = 30

## 5. Discussion

As more people begin to connect to the web using mobile devices than PCs the sites themselves will have to change. Chief among the changes noted in this study was ease of finding a search engine. It appears that right now it is much more likely to find a search engine at a normal site than at an m-site. Having an easy to find search engine is important even for those who access the web with desktop computers. But, for those using m-devices they are likely to be critical. That is because navigating around a site to locate something of interest is so difficult when the screen is small and the keyboard is limited or non-existent. When a search engine is not prominent upon reaching the front page of a site visitors could quickly become frustrated and go elsewhere.

Because of its distinct characteristics compared to regular websites, mobile sites will need to define further on QoS when the research related to content analysis, usability and websites development. The constantly changing mobile industries have several ways to create their m-sites. However, while Web clipping service providers offer a unique setting for the handheld optimization which utilizes synchronization function of PDAs, there are more disappointments on mobile devices than satisfaction. At least, our study made less dramatic evaluations. Different protocols and mobile applications appear to have made great differences in results.

No matter what type of application is used, there are different characteristics to define QoS. For example, in transferring an image file, the picture quality and the response time could be considered as appropriate factors [12]. In terms of technology, QoS parameters may include timeliness, bandwidth, and reliability [5]. From the user's point of view, QoS requirements may become a perceived QoS. Depending on which type of data transmission application is used, the priority can be defined among different flows in multimedia stream, e.g., picture resolution, color accuracy, video rate, video smoothness, audio quality, video/audio synchronization, cost and security [12]. For content delivery, a new breed of Mobile Internet Providers (MIPs) is filling the gaps over the airways until the new data networks are in place.

It has to do with the fact that users are unfamiliar with using the devices for data purposes and the devices are inferior to the desktop experience in many ways (as shown in Table 2). For those consumers who have alternatives, they may just continue surfing the Web using desktops until mobile devices overcome the barriers of human usability and technical difficulty. In addition, most websites are not constructed with m-devices in mind. Thus, this study examines some ways in which "good" and "bad" sites differ.

In general, most users expect a wireless website to be somewhere between the level of sophistication of an interactive voice response (IVR) system and a Web site [1]. Mobile devices, PDA, cell phone or pagers, have their limitations to the screen size and their cumbersome text input mechanisms. Despite the convenience, most U.S. consumers will probably continue using the easier and faster interface on their home computer until mobile devices overcome the current problems. Gillick et al. [7] suggested a speech recognition technology for text input on a very small mobile device. Cellmania [4], however, just introduced WebNum to the market that consumers can simply use numeric shortcuts associate with the Internet site's domain name to overcome cumbersome Web surfing by keying different sites.

Businesses servicing websites should develop their mobile Internet sites in both WML (wireless mark-up language) and HDML (handheld device mark-up language) to ensure their customers can access them despite the sort of mobile device they have. Moreover, marrying the company's website to the mobile one may

be useful in some cases so that some interactions can start on the desktop and finish on the phone and vice versa [1]. Meanwhile, the voice interface may be used to enhance the Internet access experience for speaking with a customer service representative but not losing their data processing. VoIP (Voice over IP) should be anticipated to provide data and voice messaging via mobile devices in the near future.

# A SCADA Management Strategy for Mobile Industry

Jung-Chin Chen

International Graduate School of Management  
University of South Australia  
cyc168@ms6.hinet.net

## Abstract

Taiwanese mobile telecom industry encounters the difficult of operation and management due to the dispersing of mobile stations and telecommunication system in different areas. Therefore it is the important policy for mobile telecom that how to draft an effective operation method and to drop the cost of management and human resource.

The aim of this research is to study the operation and management cost reduction of the telecom industry through the supervisor control and data acquisition (SCADA) system application during globalization, privatization and liberalization competition. Yet this management system can be proposed functions: prevent faults, eliminating faults fast, operating monitor and to drop the cost of management.

Through literature and empirical analysis, the author found that the SCADA system is applied in telecom industry and mobile stations in Taiwan, the operation and management characteristics can be proposed as follows: (1) Macro Mobile Stations (2) Multi-Task and Multi-User (3) Line/ Modem, OA- LAN stability (4) Real time control program (5) System redundant.

Results indicated that the SCADA system has been highly willing to mobile and telecom industry in the development of power supply quality and to drop the operation and management cost. Also this research aims at measuring the benefit on SCADA system applications in mobile stations and to provide decision-makers and managers with useful operation and management strategies as reference.

Finally, the author suggests that the further research shall focus on the processing equipment characteristics and the management characteristics of other industry with large power demand. It is also desired that a feasible useful management strategy is developed to assist the other industry customer to reduce operation and management cost and to increase the competitive capability.

## 1. Introduction

### 1.1 Motivation

Before 1985, the reserved capacity of Taiwan Power Company (TPC) could stably and sufficiently supply the power consumption; our government didn't lay much emphasis on the development of load management policy

in power energy. It is therefore that the industries didn't pay much attention on their own power energy management procedures.

From 1985 to 1995, the rapid growth of economy as well as the prosperity of industry and commerce, which result in the increase of power consumption year by year. Besides the construction of nuclear power station and power transmission and distribution was conflict with the doubts of their safety and environmental pollution from the general public. Therefore the projects for power development were hampered by these difficulties and the power supply of on-peak hours was gradually insufficient. Thus our government emphasis on the load management of those industries with large power consumption in this duration. There are therefore many papers and relevant reports related to load management of power energy ready for reference [1][2][3].

Recently, Taiwan government has been putting lots of effort on joining WTO and developing the operation center of Asia Pacific area. With these regards, how to open Taiwanese telecom market to be freely and internationally accessed by other communities is an important issue. However, the government owned companies deliberate our steps for performing on the international stage, since they have been criticized with low operating performance. Therefore, how to privatize the government owned telecom industry efficiently and efficiently is of major interest for the government and public.

Taiwan telecom industry encounters the difficult of operation and management due to the dispersing of mobile stations and communication system. Therefore it is the important policy that how to draft an effective management method and to drop the cost of management.

The aim of this paper is to study the operation and management cost reduction of the telecom industry and through the SCADA system application during globalization and liberalization. Yet the system can be proposed functions: prevent faults, eliminating faults fast, operating monitor and to drop the cost of management.

Now SCADA system applies in telecom stations and mobile stations in Taiwan, the characteristics of management and operation can be proposed as follows: (1) Macro Mobile Stations (2) Multi-Task and Multi-User (3) Line/ Modem, OA- LAN stability (4) Real time control program (5) System redundant [4].

## 1.2 Trends and Drivers of the Telecom Industry

Trends of deregulation, technological advancement and privatization are causing turmoil in a once stable and highly profitable industry. The advent of competition is exerting continuous pressure on prices with margins falling as a result, and necessitates the introduction of value-added services to sustain volume and profitability. Asia has not been spared these trends, which are global and sweeping in nature. Technology is advancing, with new services such as Internet telephony threatening to gain substantial market share in domestic and international voice traffic at the expense of established telecommunication companies. The pressure will most be felt in international traffic which produces only an estimated 12-15 percent of the revenues of the big operators but 30-40 per cent of profits [5]. Internet telephony is forecast to account for as much as 15-30 per cent of the market for voice and fax calls within five years. Internet telephony is inexpensive, and allows segmentation of the market, where consumers can choose the level of service they require and be charged accordingly. It also enables the provision of several value-added services to consumers, for example real-time billing, cheaper video-conferencing and shortly unified messaging.

In Asia, Internet telephony is said to be a "regulatory minefield", with some countries banning it, others embracing it and some unsure as to how to handle it [6]. Such technological improvements are a huge threat, but also an opportunity for the companies which can be entrepreneurial and innovative enough to invest in and develop further this technology, in an industry shifting from proprietary to open standards, as happened to the computer industry in the 1980s. To become effective competitors in such conditions would require a cultural change for most telecommunication companies, historically operating in a slow-moving, monopolistic and protectionist world. The idea is to create a company run by people who think in terms of a world where the ratio of performance to price doubles every 18 months, and where deals have to be snapped up at once" [7]. Such a cultural change is difficult to achieve; British Telecom, for example, has not made a serious effort at such change, until its dominance in international phone traffic in the UK has been seriously threatened during the last two years [8][9].

The huge overcapacity in telecom, intensifying competition, as well as the Asian financial crisis, are increasing the pressure for consolidation in the Asian telecom industry, where stronger companies may acquire weaker ones, especially newer competitors recently awarded telecom licenses. One interesting outcome of the crisis is that it gives some breathing space to the established players, since challengers find it much harder to realize their expansion plans [5].

The above trends in the telecommunications industry are expected to continue in the future, with even more substantial effects on the telecom companies. The Asian

competitive climate in this industry differs in some respects, such as the vast infrastructure investments that have to be carried out in order to improve teledensity rates and service availability and quality. Future trends in Asian telecommunications include those listed in Table 1.1 [10].

Table 1.1 Trends in Asian Telecommunications

1. Strong growth of fixed line and mobile telecommunications networks due to low teledensity rates (Taiwanese mobile telecom networks are higher)
2. Acceleration of deregulation and privatization and the resulting increased competition
3. Concession/licensing periods of 15-25 years utilizing the Build-Transfer-Operate model or a variation thereof
4. Strong demand for debt and equity capital to finance expansion
5. Industry rationalization through mergers and acquisitions
6. Technology trends and their pricing impact

## 1.3 Characteristics and Environment of the Telecom Industry

The trends of business globalization in the late twentieth century enhance the centralization among industries and therefore form business conglomerate. In the latest survey of top-fifty business conglomerate by Common-Wealth Magazine, those industries such as consumer electronics, computer, and communication which are also known as 3C industries were all except communication on the survey lists; however, the communication manufacturing industry which is the most protective industry in Taiwan was excluded from the survey lists.

Since the revenue of their products ranked top 10 around the world in 1985, the information electronic industries have become the benchmarking industries in Taiwan. Besides, the potential markets arising from telecommunication liberalization and privatization have brought the number of information electronic industries into the R&D and manufacture of telecommunication products. And moreover, the widespread applications of Internet help integrate information and communication technologies. Under the trends of the above development, this research considers the managerial strategies of information electronic industry as the basis of investigating strategies of communication manufacturing industry.

In Taiwan, government policies play an important role in the development of communication manufacturing industry. And those impacts can be summarized as six dimensions there are:

(1) The monopoly of telecommunication service business;

- (2) Dual roles of Directorate General of Telecommunication as operator and supervisor;
  - (3) Business managerial model determined by procuring policies of government's telecommunication equipment;
  - (4) Deeply politic- economic involved digital switching industry;
  - (5) Transmission equipment industry which is regulated by government procurement policies;
  - (6) The first liberalized telephone set industry.
- Taiwanese telecom operates under very different conditions from the telecommunications providers in the rest of Asia.

## 2. A SCADA Management Framework Application in Mobile Industry

### 2.1 The Management Strategy of the SCADA System

In recent years telecom industry has experienced an unprecedented degree of change in management, process technology, customer expectations, supplier attitudes, competitive behavior and many more aspects. Indeed all the evidence suggests that change is now a permanent feature of business environment and that companies which can adapt to this new environment are likely to gain significant competitive advantage.

Thus, using the Porter (1980) generic strategies as a simple illustration, a firm operating an unfocused, differentiated strategy might also be capable of operating a focused differentiated strategy, but not for example an unfocused, least cost strategy [11]. Some transitions between strategies will be relatively easy, others will be more difficult. Abell (1979) suggests that strategy space can be represented as comprising a number of dimensions which might be market, product or technology groups. Within each dimension a number of levels will be open to the organization depending on its strategic competences [12].

Competitive advantage is commonly defined as a position attained by a business unit and perceived by its customers when it is compared with its competitors. They may be characterized as lower cost or differentiation [11]. Focus, which selects one or more segments of the company's advantage and tries to develop competitive advantages, such as A SCADA system.

Now SCADA system applies in telecom stations and mobile stations in Taiwan, the management and operation method can be proposed as follows: (1) Centralize management (2) Disperse management (3) Hierarchical management.

A SCADA system hierarchical management framework include: Central Processor (CP), Terminal Processor (TP), Monitor And Controller (MAC), Sensors and Transducer, such as: figure 2.1 and figure 2.2.

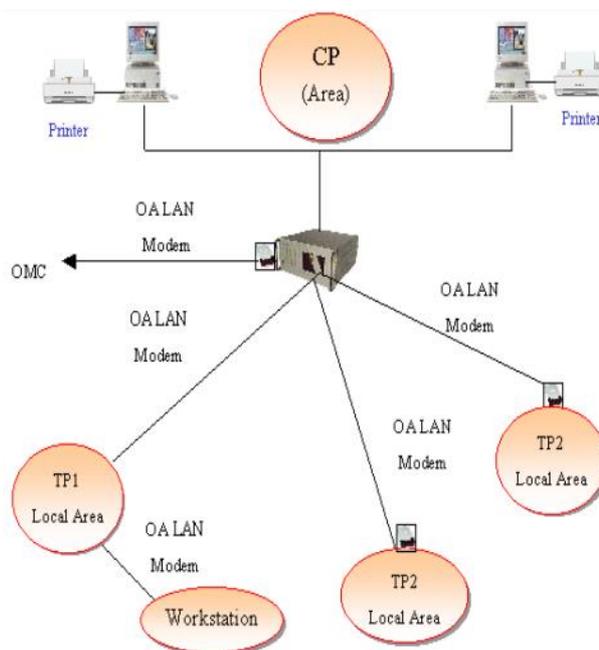

Figure 2.1 The CP Management Framework in SCADA System

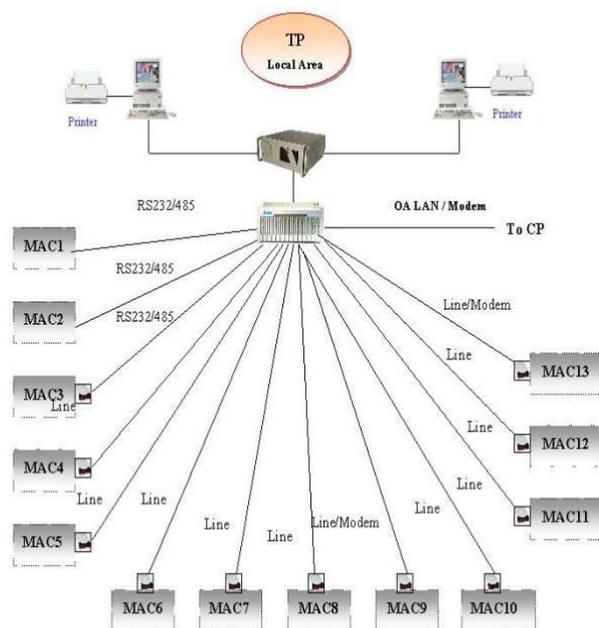

Figure 2.2 The TP Management Framework in SCADA System

### 2.2 The Equipment of Monitor and Control in Telecom Station

Monitor And Controller (MAC) provides the interface of monitor and control in mobile station (see figure 2.3) [13][14].

Alarm items include as follows:

- (a) AC source -- AC current / AC voltage detect
- (b) DC equipment -- DC equipment alarm / DC voltage output

- (c) Air condition -- Air condition operating status and Temperature
  - (d) Control Entrance -- Control Entrance detect / Alarm detect
- Control item include as follows:
- (a) Air condition control -- Air condition operation / Fan / ON-OFF.
  - (b) DC equipment -- DC equipment alarm / DC voltage output.
  - (c) BTS Remote Reset / HDLC Modem Loop-Back Test

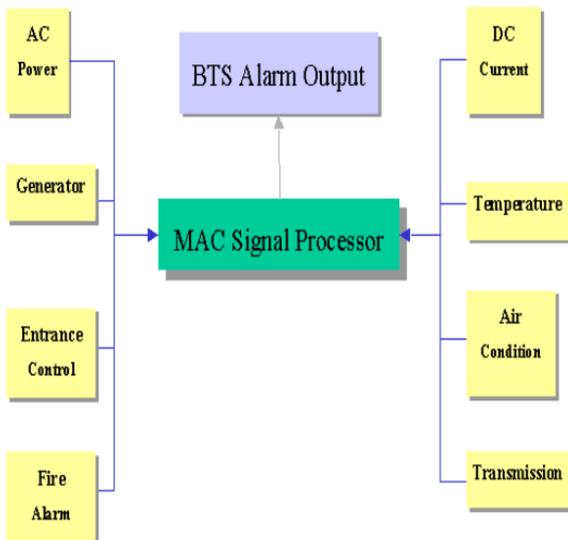

Figure 2.3 The MAC on Monitor and control equipment in SCADA System

### 2.3 Dialup Modem Application in BS Transmission Network Frame

Dialup Modem application in Basic Station (BS) transmission network. The function include as follows: [13][15][16]

- (1) The messages of equipment alarm upload to Base Transceiver Station (BTS) and MAC
- (2) Alarm messages through BTS to operator management center (OMC)
- (3) OMC through Alarm message to TP
- (4) TP use Dial-up method to control MAC and BS
- (5) TP use Dial-up method to collect history data period time.

### 2.4 GPRS Application in BS Transmission Network

General Packet Radio Service (GPRS) application in Basic Station (BS) transmission network. The function include as follows: [13][15][16]

- (1) The equipment's alarm upload to BTS and MAC
- (2) Alarm message through BTS to operator

- management center (OMC)
- (3) MAC received alarm message through GPRS to TP
- (4) TP use GPRS method to control MAC and BS
- (5) TP use GPRS method to collect history data during period time.

## 3. The Affecting Factors on Management Effective in SCADA System

### 3.1 Foreword

The basic function of SCADA in telecom station and mobile station as follows:

- (1) Alarm Real-Time upload -- (a) As alarm take place information OMC immediately (b) System with Real-Time monitor function.
- (2) Operating condition inquire -- (a) Operator can inquire equipment condition any time (b) OMC can monitor and control remote telecom station / mobile station operating condition any time.
- (3) Auxiliary function -- (a) Run basic control instructions (such as remote control) (b) According special demand to run control instructions, such as Reset (c) Remote fault remove and reduce maintenance cost
- (4) History Database -- (a) equipment and management optimization (b) equipment operating record (c) Faults and alarms statistics analysis.

### 3.2 The Analysis on Factors of Management SCADA System

After evaluating the above-mentioned information related to the SCADA system. Using Delphi method, the author has taken the items of table 3.1 to interview experts, workers and managers of telecom industry and recheck it. The content of the scale is based on a three-round Delphi survey of 10 experts. Finally, the author had concluded the effective measures that are divided into four management dimensions. There are equipment, training, personal and maintenance as bellows:

Table 3.1 The Analysis on Factors of Management SCADA System

Management Dimensions	Factors
Equipments	Network stability and Dual route
	Micro computer Base redundant The stability of MAC, Sensors and Transducer
Training	Ignore cultivation plan of worker's skills Accumulation of working experiences cannot really cultivate worker's skills

	Lack of cultivation organization of skill
Personal	Manager's concept neglect worker's skill
	Education and training is ignore
	Worker's concept with effective ideal
Maintenance	Understand software parameter and function
	Operating procedure standardization
	Use software with familiarity
	The speed on alarm of responds and inquire

### 3.3 To Draft Management Strategy in SCADA System

This section describes the information collection and system management options for the telecom industry and then the decision of management strategy in SCADA system (see table 3.2).

Table 3.2 The Analysis of Management Strategy in SCADA System

Problems	Method/Strategy
Monitor and control system stability	Draft to keep the system stability methods
Technical personnel education and training in SCADA maintenance	Technical personnel education and training
	Training on Training Institute
	Training on work
Lack of full authority by occupation, coordination and integration	There is a consensus of reducing human costs and attaching importance to worker's skills
Software parameter and function operation	Parameter setup by technical and set standard value as reference
Management and operating procedure standardization	Alarm processing procedure standardization and statistics data reports standardization

## 4. Measure the Effective on Management and Maintenance Network

### 4.1 The Analysis of Management and Maintenance Network

The section 3 has several factors analysis of management SCADA system. This paper will study and analyze the rate policy of mobile industry and also this section will discuss the effective on management and maintenance framework in SCADA system (see table 4.1). The competitive priority of cost is frequently considered either as a cost reduction or operational excellence strategy. The cost reduction or operational excellence

strategy implies a systematic improvement of company operations without the accomplishment of radical innovations.

Table 4.1 The Effective Comparison of Three Framework of Transmission in SCADA System

Framework Item	Modem / Line	E1 Time Slot Sharing	BTS Node Input Modem Dial-up	BTS Node Input GPRS
Network stability	Medium	High	Medium	Medium
Modem (quantity)	N*2	N*2	N+1	N+1
Transmission equipment cost	Medium	High	Low	High
Line/ Network Maintenance cost	High	Low	Low	Low
Response time of alarm	About 5 sec	About 5 sec	About 5 sec	About 7 sec
Speed of inquire and remote control	About 5 sec	About 5 sec	30-60秒	About 7 sec
Real-Time monitor capability	Yes	Yes	No	No
System development difficulty	Medium	Medium	Low	High
Overall investment cost	High	High	Medium	High

### 4.2 Measure the Benefit on Operation and Management in SCADA System

A SCADA system, which would provide telecom industry with guidance on:

1. The suitability of using specific competitive strategies in business environments exhibiting particular environmental characteristics;
2. The competencies required to support specific competitive strategies effectively;

3. The ability of the company to compete effectively in a number of future business environments.

Adam and Swamidass (1989) assert that “the core content of a manufacturing strategy include cost, quality, flexibility, and technology” [17,p.182].

•Costs

Costs, which means seeking a lower manufacturing cost. The customer expressed willingness in the SCADA system, but the installation of automatic monitor and controller need extra operation cost which therefore reduce the participation willingness from the customer. From the long-term viewpoint, this load management strategy will save electricity cost for the customer. After the explanation, the customer can accept the concept and will proceed to implement this alternative.

With the rapid growth of air conditioner load, the peak loading of customer in summer daytime period increases dramatically and the condition of peak loading in 15-minute leading demand contract becomes more serious. According to the electric price system in TPC, customers are asked to pay extra cost with respect to the portion of basic fee in the case that the peak loading is higher than the demand contract. On the other hand the inappropriate higher demand contract setting can avoid the occurrence of previous stated problem but will results another problem of higher basic electric fee payment. The basic idea of optimal demand contract strategy is to derive a better demand contract such that the annual electric basic cost can be minimized.

•Quality

Quality, which means implies offering high quality products and services to the customers.

1. Real-time analysis & reporting
2. Providing comprehensive reports
3. Software are easily operated and well documented.
4. Options of network connection to other systems requiring our data are provided.

•Flexibility

Flexibility, mainly related to the innovation of products and services, product mix and production volume. A SCADA system need include: operational flexibility, control flexibility, function flexibility and information system flexibility, etc.,

1. Operator can inquire equipment condition any time.
2. Operator can monitor and control remote telecom station / mobile station operating condition any time.
3. For power monitoring, electroplating process, air conditioning equipments, burn-in room monitoring etc;
4. The Windows-based system can be used to monitor equipment performance and productivity, to diagnose system problems, and to assist maintenance personnel in monitoring alarms.

•Technology

The control method of load consumption is another

way to reduce electric cost. The load consumption in automatic control can prevent the customer from penalty of exceeding contract capacity. It means when the power consumption climbs up to the climax, this method can get rid of unimportant load or the interruptible electricity equipment.

The rate, which Taiwan Power Company charges to the industrial customer, is the total power consumption in each month, i.e. how much is one kilowatt-hour? In addition, the added rate is defined as “how much is the power consumption climax in one month.” The load control device of power consumption aims to prevent the occurrence of new climax with the hope of reducing the added rate.

Owing to the deviation factor, all electricity equipment doesn’t operate at the same time. Besides the power consumption is in the status of dynamic variation due to the reasons of the boom-and-bust, season or production and sale plan. The customer has to carry out the control management of load consumption, if the purpose of the economical use on the electricity equipment is required. The monthly power consumption can be reviewed at any time to decrease the electricity cost.

## 5. Conclusions and Suggestions

### 5.1 Conclusions

1. Results indicated that the SCADA system has been highly willing to mobile and telecom industry in the development of power supply quality and to drop the operation and management cost. Also this research aims at exploring the benefit on SCADA system applications in mobile stations and to provide decision-makers and leaders with useful operation and management strategies as reference.
2. It is hoped that the conclusion of this research will be adopted by the telecom industry to implement SCADA system decrease rate expenditure and to reduce human cost.
3. The mobile industry is also willing to install the automatic SCADA system, although initial investment need extra cost.

### 5.2 Suggestions

1. The author suggests that the further research shall focus on the equipment characteristics and the management characteristics of other industry with mass and disperse power equipment. It is also desired that a feasible useful management strategy is developed to assist the other industry customer to reduce operation and management cost and to increase the competitive capability.
2. The final suggestion is that the future research shall

focus on the analysis of power consumption characteristics for the various industries with large power consumption.

## Abstract

Mobile e-commerce is immersed rapid familiar to other high-flying Internet markets. With the fast developing of wireless connections and Internet, electronic commerce more and more moves to mobile environment. Streaming, as a rapid growing application in Internet, will be more used in mobile e-commerce. In this paper, we'll review the network protocol used in mobile e-commerce and streaming technology. An optimized architecture is given based on MPEG-4 and Mobile IPv6. The core streaming protocol used in this architecture is RTSP/RTP proposed by IETF. This system gives one possible implementation of streaming over wireless network. Two key bottlenecks we found in this project are wireless bandwidth and mobile client power. To avoid the two problems, self-adaptive methodology is used. Let streaming application be adaptive to the wireless network environment to improve streaming performance.

## 1. Introduction

With the fast growing of wireless connections and Internet, mobile e-commerce is immersed as other high-flying applications. Enterprises are incorporating mobile commerce into their operation as a way to cut costs, generate revenue and gain efficiencies. Consumers are also like to accept multimedia content while not static ones. Applications will be developed for the mobile e-commerce and enable enterprises and consumers communicate efficiently. Of course, these applications and new mobile e-commerce solutions will drive the growth of mobile e-commerce.

Streaming as another fast growing application in Internet catch more and more users' attention. With the emergence of webcasting, users enter into a new world of digital content. Wireless communication gains the huge success and will be integrated into Internet. While wireless network is different from wired network, streaming over wireless network is challenging. In wireless network, bandwidth is low, latency is large and mobile handset is not powerful. All these characters are critical to move streaming over wireless network. To solve these problems, we use self-adaptive methodology to let the upper layer applications to be adaptive to the lower network environment. Wireless network is not stable. Bandwidth and latency is always changing. To make streaming be adaptive to the wireless network is a possible solution. When wireless network performance decreases, change

the streaming bit rate to a lower value that the wireless network can provide. Then users can receive smooth stream in mobile environment. It's critical to mobile e-commerce.

This paper is organized as following. Section II will review the protocols used in mobile network. In section III, streaming technology is discussed. Streaming over mobile network architecture is defined in section IV. Future work is discussed in section V. Section VI gives our conclusion.

## 2. Protocols in Mobile Network

IP (Internet Protocol) is designed for wired network. How to use it over wireless network is challenging. Mobile IP [1] and Mobile IPv6 is the network layer protocol standard proposed by IETF to supporting roaming between different networks.

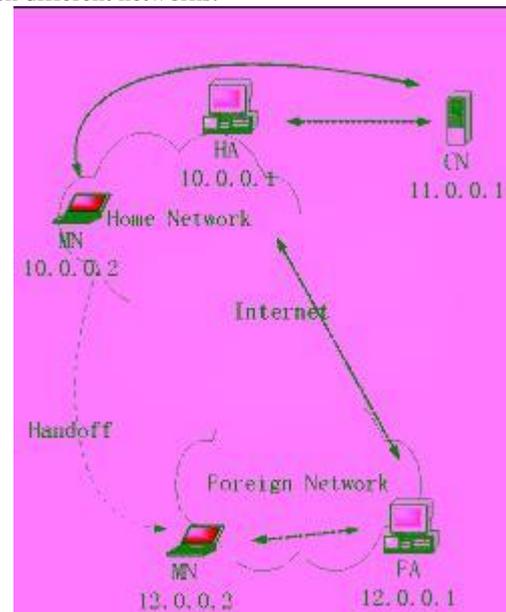

Figure 1. Mobile IPv4

In wired network, when node is connected to an IP network, it has a static IP address that identifies itself and one default router to communicate with foreign network. However, mobile device will connect to different network and will use different IP address and router. For example, a laptop computer may be connected via an Ethernet card at home. At office, it's connected via wireless LAN. When on bus, it goes online through a GSM connection. Different connection media supports different service. Also only one IP address without Mobile IP is not possible. User

needs to change the IP address when changing connection. But changing IP address will make upper layer application not work. Mobile IP and Mobile IPv6 are Internet standard to provide mobility in network layer. To upper layer, IP address is not changing with Mobile IP/IPv6. So they provide transparency to upper layer.

In Mobile IP and Mobile IPv6 protocol, the main problem is how to maintain one IP address while in different network. They use HA(Home Agent) to provide transparency for upper layer. When MN(Mobile Node) is at home network, it uses its own home address as normal IP. While MN moves to foreign network, all the packets between MN and CN(correspondent Node) are relayed by HA. So CN will not be care about where MN is, since it only needs to know MN's home address. MN at foreign network will use its COA(Care-Of Address) to communicate with home agent. The main idea in Mobile IP is using agent to provide transparency. One problem here is that triangle routing exists. It will decrease transmission performance. So in Mobile IPv6, Binding Cache is used to avoid it. There is a binding cache in CN and HA, which is maintain a map between MN's home address and care-of address. Then, when MN moves to foreign network, it will send binding update to CN and HA. CN will communicate with MN using this care-of address while not through HA. Triangle routing problem is avoided.

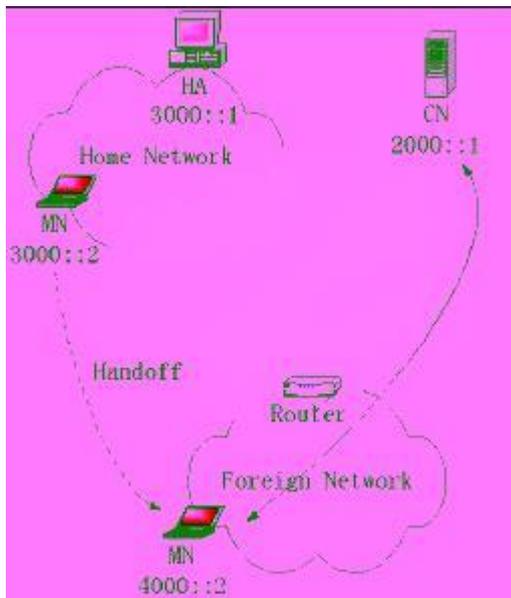

Figure 2. Mobile IPv6

Handoff time interval is important to users, since real-time applications cannot be tolerant to large delay time. There're two handoff mechanisms, Network Initiated Handover and Mobile Initiated Handover. In network initiated handover, the router has predictive information about the new point of attachment to which the MN will move prior to the actual movement of the Layer 2 connection. The router initiates signaling to the MN and HA to start the Layer 3 handover. In mobile initiated handover, the MN has predictive information about the

new point of attachment to which it will move, or it chooses to force movement to a new point of attachment. The MN initiates signaling to the router to start the handover.

### 3. Streaming Technology

Streaming is the ability to distribute "continuous" digital content over networks in real time. Digital content can be streamed to any network device. Different network has different performance. That performance will determine the streaming quality. Below, some figures are listed.

Streaming Media Capabilities by Bandwidth

Connection	Bandwidth
Modem	28.8-56Kbit
ISDN/Frame Relay	64-128Kbit
Cable Modem/DSL	100Kbit-1Mbit
WLAN	1Mbit-10Mbit
Corporate Networks	1Mbit+

Table 1. Connections and Bandwidth

Streaming Transfer Rates

Medium	Transfer Rate
Audio	Under 22Kbps
Typical 2001 Internet streaming	56Kbps to 300Kbps
VCR/TV quality	1-2 Mbps
HDTV quality	6-9 Mbps and eventually higher for MPEG-4

Table 2. Streaming Transfer Rates

Some market trends will influence the streaming technique and its application according to [6] [7].

- 1 Advances in encoder and production techniques
- 1 Proliferation of broadband access to consumer and enterprise users
- 1 Increased number of powerful PCs capable of playing rich streaming media
- 1 Web site differentiation for broadband users

#### 3.1 MPEG-4

MPEG-4 is the most recent multimedia standard developed by Joint Technical Committee ISO/IEC JTC 1, Information Technology. MPEG-4 standard implies that motion video can be manipulated to a form of computer data and can be stored on various storage media transmitted and received over existing and future networks and distributed on existing and future broadcast channels. MPEG-4 provides features that include Scalability, Shape coding, Error resilience, Face animation, etc.

Below is some key features of MPEG-4 System:

- 1) MPEG-4 Systems provides a consistent and complete architecture for the coded representation of the desired combination of streamed elementary audio-visual information. This framework has a broad range of applications, functionality and bit rates. Through profile and level definitions, MPEG-4 Systems establishes a framework that allows consistent progression from simple applications (e.g., an audio broadcast application with graphics) to more complex ones (e.g., a virtual reality home theater).
- 1) MPEG-4 Systems augments this architecture with a set of tools for the representation of the multimedia content, viz., a framework for object description (the OD framework), a binary language for the representation of multimedia interactive 2D and 3D scene description (BIFS), a framework for monitoring and synchronizing elementary data stream (the SDM and the SyncLayer), and programmable extensions to access and monitor MPEG-4 content (MPEG-J).
- 1) MPEG-4 Systems completes this set of tools by defining an efficient mapping of the MPEG-4 content on existing delivery infrastructures. This mapping is supported by the following additional tools: an efficient and simple multiplexing tool to optimize the carriage of MPEG-4 data (FlexMux), extensions allowing the carriage of MPEG-4 content on MPEG-2 and IP systems, and a flexible file format for authoring, streaming and exchanging MPEG-4 data.

## 4. Optimized Streaming over Mobile IPv6

### 4.1 Features of Mobile IPv6

Handoff time

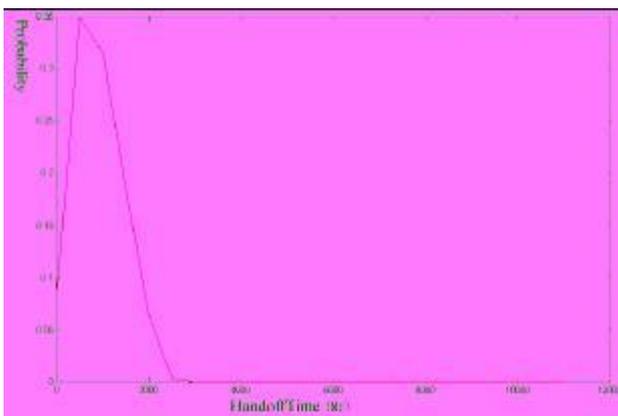

Figure 3. Mobile IPv6 Handoff Time

Below, a typical handoff time is given in Figure 3. We can see that the average handoff time in mobile ipv6 is 1.5m. The handoff time will directly influence the streaming performance. In the handoff interval, the streaming packets

will be dropped. So the faster the handoff, the better the performance when handoff.

### 4.2 Objectives

This implementation is to enhance streaming transmission in mobile network. Wireless or mobile network is challenging to multimedia applications. It's different from wired network. Some characters of wireless network: 1) Error prone network; 2) Slow handoff; 3) Packet transmission are critical to upper layer applications. While multimedia applications require more bandwidth and even rate, some challenges stay here. This project is to enhance streaming quality when handoff in mobile network.

### 4.2 Methodology

To enhance streaming quality when handoff, more function should be added in network layer and upper layer. In network layer, we modify mipv6 to add an interface. This interface is to provide previous and current network performance to upper layer. Latency and bandwidth are concerned. In the upper layer, we modify RTSP protocol to adapt streaming transmission to the current environment.

Assume one Mobile Node was playing movie from Correspondent Node source. The Mobile Node switched from one network to another network and handoff occurred. The environment changed including bandwidth and latency. Assume the previous network bandwidth is 100k and the current is 60k. If the streaming rate is 90kbps, the current bandwidth clearly can not afford the streaming. Then packet dropping will be serious. So we need a mechanism to deal with it. In our implementation, when handoff, the network layer (mipv6) told upper layer the round bandwidth. The upper layer (RTSP) will decide how to deal with it. Of one condition, RTSP will request low rate steam to be adapted to the low bandwidth. Of other condition, RTSP will request high rate stream to improve the media quality since the bandwidth is enough after handoff.

In this project, Mobile IPv6 support in linux ([www.mipl.mediapoli.com](http://www.mipl.mediapoli.com)) is used to provide mobility in network layer. Streaming server uses Darwin Streaming Server ([www.apple.com](http://www.apple.com)) and client uses MPEG4IP ([www.sourceforge.net/project/mpeg4ip](http://www.sourceforge.net/project/mpeg4ip)). MPEG4 stream is used to test streaming.

Other relative projects and methods such as [2] [3] [4] [5] focus on improvement in network layer. They provide mobility and are transparent to upper layer, which is different from our method. Since the network performance is critical to streaming, we provide network feature to upper layer.

### 4.3 Challenge

- 1) We choose Darwin Streaming Server (DSS4) as it's open source and supporting mpeg4. Port DSS4 to ipv6.
- 2) Add a function in Mobile IPv6 protocol stack to

provide network bandwidth and latency to upper layer. It's difficult to test bandwidth. Round bandwidth is given here.

3) Support more SDES items used to change streaming rate.

4) Application console to let the user decide what to do when handoff.

#### 4.4 Implementation

In the network layer, we add an module to detect network performance. Its function is to detect the current network bandwidth and latency and provide them to upper layer. In application layer, we use User Control Panel to get user's decision. The decision will directly influence the transport layer and represent layer.

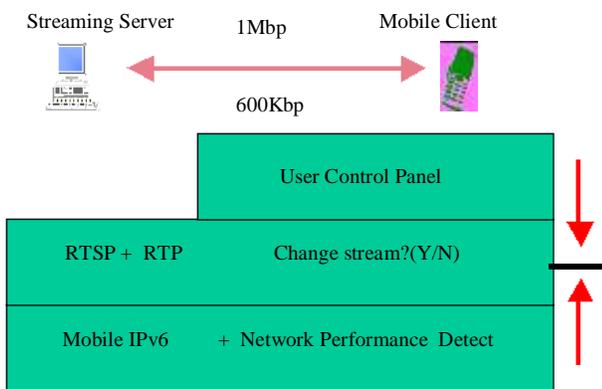

Figure 4. Architecture

Let's see the process in mobile network. When MN is in home network, the bandwidth it could use is 1Mbps, which is provided by the NPD (Network Performance Detect module). When MN is switched to foreign network, NPD module will detect the handoff and provide the new network performance to the upper layer. Assume the bandwidth in foreign network is 600kbps. Sure, if MN is playing video in 800kbps, the handoff will cause so much packet dropping. The video quality will remain poor in the foreign network. In our architecture, the User Control Panel will capture the handoff event and get the network performance from the NPD module. There're two strategies here. Let user decide or let MN auto configure. Each strategy is an decision to be adaptive to the current network performance. In this example, just let user decide how to do with the handoff. It could be using low bit rate streaming to get fluent video or just going back to the older network.

## 5. Future Work

About future work, we'll focus on the module of Network Performance Detection. How to detect the network performance while consuming little network resource is important to the architecture. If possible, prediction of the new network will improve the system performance very much. Another important task is to research the strategy. It's more close to user. We should make a tradeoff about it.

## 6. Conclusion

This paper provides a possible solution to how to improve streaming quality in mobility environment. we use self-adaptive methodology to let the upper layer applications to be adaptive to the lower network environment. In the network layer, we add an module to detect network performance. Its function is to detect the current network bandwidth and latency and provide them to upper layer. In application layer, we use User Control Panel to get user's decision, which will influence the transport layer and represent layer. An implementation is given.

# Building an End-To-End Security Infrastructure for Web-Based Aerospace Components E-Trading

Stephen C. Shih

Department of Information Management Systems  
College of Applied Sciences and Arts  
Southern Illinois University  
Carbondale, IL 62901-6614, USA  
shihcs@siu.edu

## Abstract

The research paper focuses on the development of a generic framework and architecture for building an integrated end-to-end security infrastructure and closed-loop solution to secure e-commerce and m-commerce. As an integral component, an intelligent decision support mechanism is developed in helping systems designers and managers make architectural, design, implementation, and deployment decisions on employing particular security solutions to issues and requirements arising in various e-commerce and m-commerce scenarios. In addition, this research identifies the key features, options and benefits of several security technologies as well as provide guidelines in managing the costs and complexities involved in the deployment of those security solutions. As an important groundwork for building a prototype based on the proposed research work, a study has been conducted to investigate the current B2B e-commerce operations between Pratt & Whitney (P&W) [15] (a division of United Technologies Corporation (UTC) [17]) and its partnering e-business and supply chain players in the aviation industry.

## 1. Research Objectives

Addressing the essential security issues and needs in e-commerce and m-commerce, an integrated and scalable security infrastructure is crucial to enable a company to reap substantial business values and financial benefits by safeguarding online transactions according to the policies, processes and procedures unique to its business.

As a significant research result, the proposed common framework will help a company achieve its security objectives in different dimensions as follows:

- 1) Construct an integrated, flexible and scalable security infrastructure that tightly fits in with other corporate e-business, supply chain management, customer relationship management, and enterprise resource planning

(ERP) applications as well as with those of its customer and business partners.

- 2) Develop a security architecture with segmental entities (computers, local networks, private networks, public networks, etc.) to help isolate and identify the security issues, possible attacks, data vulnerability, and associated security requirements and in turn find attainable solutions to address specific requirements (specified assurance levels, security services, etc.) for each entity in various B2B interaction scenarios.
- 3) Reduce the chance of a security breakage by removing security issues from the application level and raising them to an architectural level.
- 4) Provide proactive and reactive security strategies, policies and guidelines.
- 5) Provide decision support capability [16] for selecting security tools and technologies as well as managing the costs and complexities involved in the technology deployment.

## 2. Background of E-Commerce Security in Aerospace Industry

B2B e-commerce for online trading of aerospace and aviation components is still in its infancy [9]. The potential of using the Web as a B2B commercial medium has been widely explored. However, a critical assessment of its B2B e-commerce challenges and issues has just started to receive attention. The new economy of ubiquitous B2B e-commerce usually introduces new risks [7], [8].

Based on the initial study, P&W's customers and suppliers can process online transactions through either private corporation e-business channels or via semi-private web-enabled exchanges (e.g., Cordiem [12] and Exostar [13]). E-business transactions in a B2B environment can happen in the context of a bilateral or multilateral exchange. Such a virtual marketing environment gives unprecedented open participation of business trading and information sharing. As submerging

under the uncharted waters, each type of exchange may raise significant issues and concerns threatening the objective of establishing a secure trading environment between P&W and its e-business counterparts (customers, suppliers, and other business partners). Without proper security measures and strategies, it will make e-marketplaces susceptible to such incidents as denial of service (DoS) attacks (which will halt on-line operations [10]), 'bid snatching' (wherein a set of malicious colluding agents halt another agent by using attractive bids to fraudulently 'snatch' and non-perform on all the targets' subcontracts), 'bid collision loops' (where a pair of agents halt online B2B transactions by establishing an infinite loop of colliding bids), and so on. This project effort specifically tackles one of the threads to this resource availability, the denial of service (DoS) attack [7], and suggests a viable solution to preventing possible loss of business due to the fact that P&W's data are made impossible to access by the legitimate customers or suppliers.

Electronic markets (e-markets) also give unprecedented scope to the deployment of relatively untested marketing and bidding mechanisms whose vulnerabilities have not been fully explored [18]. The consequences may thus bring forth the potential for serious disruptions in B2B operations of targeted business trading participants and/or the e-markets themselves.

### 3. E-Business Security Requirements

Addressing the potential risks and pressing issues of on-line B2B trading, this research project tackles a number of challenges in various e-commerce scenarios, such as client authentication, server authentication, authorization, etc. Proper access control is important. In other words, the company needs to know that the customers or suppliers who involve in a B2B dialogue are in fact who they claim they are, which can be referred to as "client authentication." On the other hand, when the customers or suppliers access a web site in the B2B e-marketplace, they want to make sure that they are indeed interacting with that site and not with an impostor. This is referred to as "server authentication." It is also necessary to control what information which business partners are allowed to access and/or modify. In addition, a reliable access for external players to gain access to a company's e-business ballpark and interact with the specified data is one of the critical requirements – all the legitimate B2B players should be able to access the required resources at any time under optimal performance.

Electronic data traveling on a complete supply chain and B2B environment requires more than access control. Authorization is recognized as another important

security criteria and recognized as a problem with greater complexity than authentication and access control. The user privileges of the corporate customers and suppliers should be manageable and interchangeable across enterprise applications as well as other B2B communities of security domains. Furthermore, it is required that pertinent business rules and constraints should be dynamically weighed up coupling with fine-grained role privileges for initiating and committing required business transactions and processes.

"Integration" is a key to the proposed common framework for ensuring that all the security decisions (on authorization, authentication, auditing, etc.) that implement on each enterprise application and exchange point are consistent with those made across the entire B2B arena. The security infrastructure should be pervasive across the entire enterprise to establish greater communities of trust. As more and more business partners exchange trading information via various network connections (a private network, Internet, etc.), different security control services and standards are indispensable. The proposed security infrastructure is open in nature to ensure sound security interoperability – the capability of supporting heterogeneous security standards and platforms as well as different e-business interaction models and security services.

### 4. Research Methods

An engineering and scientific approach [11] is adopted to the research tasks undertaken in this project.

Primarily, the following methods [1], [2], [3], [5] are used to validate the proposed framework:

- 1) Conceptual Design. To construct a conceptual security framework and an integrated, flexible and scalable security architecture that tightly fits in with P&W's enterprise resource planning applications as well as with those of its customer and business partners.
- 2) Security Solutions Evaluation. To evaluate a number of state-of-the-art security solutions and technologies (such as Entrust's Privilege Management Infrastructure integrated with XMI, ebXML, and Security Assertions Markup Language) and elaborate how the solutions fit into the entire security framework.
- 3) Cases and Best Practices Study [4], [6].
- 4) Scenario-Building. To develop a series of scenarios to test the security requirements of different segmental entities (computers, local networks, private networks, public networks, etc.) to help isolate and identify the security issues, possible attacks, data vulnerability, and associated security requirements and, in turn,

find attainable solutions to address specific requirements (specified assurance levels, security services, etc.) for each entity in various B2B interaction scenarios (Figures 1 and 2).

- 5) Laboratory Experimentation [14] and Simulation. To create an artificial environment, in order to isolate and control for potentially confounding variables; to conduct the study of a simplified, formal model of a complex e-commerce environment, in order to perform experimentation not possible in a real-world setting.

## 5. Research Results

Key outcomes of this research effort as well as major benefits from deploying the proposed framework are summarized in the following paragraphs:

### 5.1 An Integrated Security Framework

The developed framework is used to examine the explosion in B2B e-commercial activity on the Web especially for a company and its business trading partners. The framework provides a viable decision support mechanism in making architectural, design, implementation, and deployment decisions on employing particular security and connectivity solutions to issues and requirements arising in various B2B e-commerce scenarios.

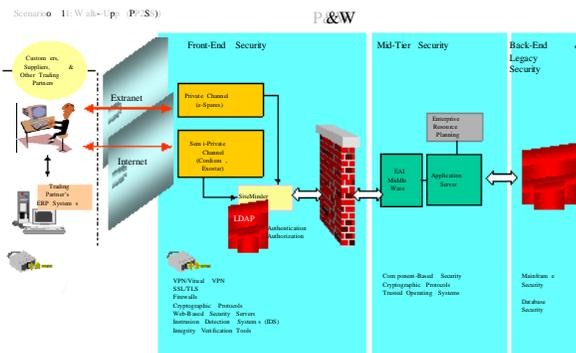

Figure 1. Aviation B2B E-Commerce Security Architecture: Transactional Scenario 1: Person/Human-to-Systems (P2S) Interaction.

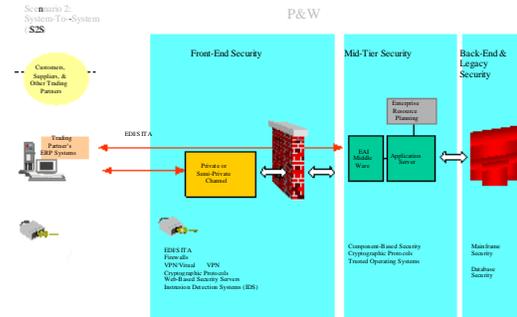

Figure 2. Aviation B2B E-Commerce Security Architecture: Transactional Scenario 2: Systems-to-Systems (S2S) Interaction.

### 5.2 A Decision Support System for Web Security Analysis

Security involves a total set of exposures in B2B e-commerce. Besides storing on computers, transactional data need to travel from within the perimeter of company's network (Intranet) to the space of its suppliers' and business partners' enterprise applications through Extranet or Internet as well as to voyage to the terrain of its customers via Internet. As a result, it is unattainable to maintain a robust security control by simply implementing an "one-size-fits-all" solution. Data traveling between diverse communication dimensions need to be secured differently. For instance, each of the communication points may have its own authentication and authorization policies and schemes. Accordingly, a decision support Expert System (ES) is to be developed to aid the corporate security analysts in finding a fitting security solution and configuring proper settings at each of the network points throughout the entire B2B chain. In the research, the security requirements are identified and categorized based on different needs on the two sides of an e-marketplace:

**The Seller Side.** The selling parties in the B2B e-marketplace are mostly interested in the identification and authentication of users (buyers). The sellers are concerned with acquiring adequate buyers' data and installing robust security measures for billing and other business transactional purposes, such as preventing the sender of a message from denying having sent it and mitigating the risks of so called Denial-of-Service attacks.

**The Buyer Side.** The participants on the buyer side in the e-Marketplace share a common interest in the

integrity and confidentiality of the information transmitted. Usually, buyers are more interested in reliable services and expect their privacy to be soundly protected. In most of the cases, they may prefer to use services without being identified and being monitored of their every single movement on the Web by the unrelated business parties.

Consequently, the first phase in the decision support ES construction focuses on the six essential security requirements shown as in Table 1.

Table 1. Security Requirements on Buyer’s and Seller’s Sides

	Security Category Code	Requirement	Description
Seller Side	A1	Authentication	Verifying that the trading partners are really who they claim they are. A process is necessary to proof the two parties involved in a B2B interaction are given a guarantee that they are indeed interacting with whom they think they are interacting.
	A2	Authorization	Ensuring that each business party is performing what it is authorized to do.
	A3	Availability	Tacking the Denial of Service (DoS) attacks .
	NR	Non-Repudiation	Preventing the sender of a message from denying having sent it.

Buyer Side	C	Confidentiality	Protecting the contents of messages or data transmitted over the Internet from unauthorized people.
	DI	Data Integrity	Shielding sensitive trading information from being modified or tampered by an attacker.

Based on specific security needs and scenarios, the decision support ES (with the code name, AirB2B SecurityGuru) will be assisting in finding corresponding security solutions. For instance, a viable authentication technology will be recommended to tackle A1 requirement while a proper authorization solution and an encryption solution is suggested to address the access control and the tampering issues, respectively. Furthermore, the user is allowed to enter English-like questions on any specific security problems via natural language processing.

As a powerful tool, the ES can give consultations in the following areas:

- Identify assets and vulnerabilities to known threats
- Identify likely attack methods, tools, and techniques
- Establish proactive and reactive strategies
- Develop an incident response plan
  - Developing incident handling guidelines.
  - Identifying software tools for responding to incidents/events.

### 5.3 Security Solution Matrices

One of important deliverables of this research effort is to construct a pertinent security solution matrix for providing information and assessment on various feasible solutions to security needs (at both the company side and trading partner’s side) based on a given scenario.

### 5.4 A Security and Performance Analysis Model

Security is an important element in B2B interactions but performance is the price to be paid to meet the desired security criteria. Therefore, it is

important to determine the adequate level of security for special e-business exchange scenarios without incurring unnecessary costs and sacrificing too much system performance. In this research, the decision of the degree of security is modeled as an optimal function of resource protection, system performance and the security-related costs (infrastructure, implementation, maintenance and processing costs, etc.)

### 5.5 A Laboratory Experimentation and Simulation Environment

A laboratory environment is built to simulate various B2B interaction scenarios (system-to-system or person-to-system). Based on the existing security countermeasures and infrastructure, the lab environment helps identify vulnerabilities in various spots in the entire e-business chain (such as Internet connections, remote access points, connections to other business partners, physical access to network hardware, and user access points) and the type of threats. Performing such simulations and experiments will assist in determining the risk levels (system-level, network-level, or organization-level) and, in turn, seeking for a set of viable solutions (including technologies and processes) to address specific security attacks and needs.

In the developed simulation environment, a number of essential B2B Actors are created to simulate how those key business trading actors interact with each other in various B2B transactions. Some of the key B2B actors identified in the first phase of this research effort are: CUSTOMERS, PARTNERS, SUPPLIERS, REGULATORS, MEDIATORS, and INTERNAL EMPLOYEES.

### 6. Conclusions

Besides the technical aspect of the B2B e-commerce discussed in this paper, an equally important organizational issue is to be dealt with to ensure a truly secured and safe e-marketplace for doing business on the Web -- trusts among business partners. To fully utilize the advantages of the open and ubiquitous technology of the Internet, trust makes it possible for extensively cooperative and collaborative endeavors among various players in the B2B e-marketplace. Trust is a key to positive interpersonal and inter-organizational relationships in various settings. Trust becomes even more central and critical to sustain everlasting business relationships, especially, when a great deal of sensitive business data are required to be shared among business partners over an Internet-based network. As a result, one of the future research efforts will be focusing on conceptualization of business trust model which should be cross-organizational in nature. Research work in other

disciplines (e.g., social science and organizational behavior) on trust will be studied and compared. Ultimately, the development of new e-business models for innovative business processes reengineering is perceived as one vital research activity for achieving to truly trusted and trusting B2B e-commerce environment.

## Abstract

With consideration of the increasing importance of auditing system and the present auditing systems' incapability of performing packet reassembling analysis, this research attempts to develop a "network-based auditing system with session tracking and monitoring" to assist network administrators to analyze and rearrange the packets into separate session groups. This developed system is able to reveal every single step of the unauthorized activities. As a result, the administrators can investigate each network session and its transferred data more efficiently, and reduced greatly the time for auditing data analysis. In addition, the event reconstruction simulates the actual event occurred at that time; this feature provides network administrators with more detailed and realistic insight concerning vulnerabilities in network security that need to be fixed. Also, this system keeps track of all network events, and collects related information in a set of auditing files (log files). Moreover, the collected records and reassembled files can serve as evidences in tracing cyber-crimes and as references for recovery process.

Keywords: network-based auditing system, session tracking, session reassembling, cyber-crime

## 1. Introduction

Ever since computer's birth, its popularity grows with its increasing importance. In fact, it has become an indispensable tool in today's modern society. Internet's advent creates a new medium that allows messages and data to be transmitted globally. As Internet progresses, more and more crimes are gradually extending its domain from human communities to this virtual dimension. And, network security has become a critical issue for users around the world. Nowadays, hackers vandalizing servers, violating privacy and stealing confidential information have become the new type of criminal act, which often causes victims to suffer from great damages. Hence, effective management and sound defensive facilities are crucial in ensuring network security. Techniques such as implementation of IDS and firewall have being widely applied to fortify and protect network system from intrusion. However, despite of putting in great effort in enforcing the defense measures, there is still no guaranteed security. Nevertheless, an auditing system can be installed to keep track of all system events

and collect related information in a set of auditing files. These records served as evidences and references that can be utilized later in tracing cyber-crimes. Very often, the notion of getting caught can prevent hackers from actually carrying out the illegal act. Also, by analyzing auditing files, system managers are able to discern unusual activities. Presently, many types of intrusion detection system (IDS) have been proposed; however, those auditing files are kept in binary form [1] [2] [10] [12] and requires manual work to "read out", hence it requires complicated expertise and significant amount of time. In consideration of the increasing importance of auditing system and the need of improving efficiency of analysis on auditing files, this research attempts to develop a network-based auditing system, that has the ability of session tracking and monitoring. This developed system will rearrange those auditing data recorded by network-based IDS to reconstruct and simulate the real events occurred to overcome analysis difficulties. In addition, records and reassembled files can serve as evidences in tracing cyber-crimes and as references for recovery process.

## 2. Literature Research

### 2.1 Definition of Auditing System in Information Technology

"Auditing System" is a system that keeps track of system events and examines the audit files and audit trail actively, periodically or randomly to detect any trespasses and suspicious activities. All the information system on firewall, computer and server will records detailed information about each services provided. And, the collection of all these records, storing the information concerning system events, is called an audit file or log file. By studying the information extracted from audit files, system administrators are able to discern both implicit and explicit problems. Also, solutions can be devised in accords to the given analysis result in order to prevent similar problems form affecting system operation again.

Network auditing, simply, is a mechanism that targets on tracking network-specific events. Generally speaking, these detected activities are, likewise, stored into log files for reference in the future. Through network auditing, network administrator can investigate the data traveling between servers and clients, or monitor a specific connection and event. Such mechanism is

capable of detecting and tracing any unauthorized activities, as well as potential hackers.

Therefore, administrators should examine these log files periodically. However, the analysis process is complicated and the audit files' content is difficult to understand; hence, the task is preferably to be completed with the assistance from analyzing tools.

## 2.2 Categories of Auditing System

Auditing systems can be categorized into "Host-Based" and "Network-Based", according to the source which they collect information from. Host-Based auditing system's main mission is to monitor the intrusion events from the host itself. For instance, user priority, file access and system manipulation are all monitored locally. Network-based auditing system treats each incoming and outgoing packet with different storing processes. The packet recording process and historical audit files often provide helpful information, such as debug process, system performance evaluation and evidence for illegal acts, in times of anomalies' occurrence. Network-Based auditing system captures packets stealthily; it gives no hint to the suspect in realizing the existence of this system. On the other hand, the audit files kept by Host-Based auditing system are likely to be modified by intruders intending to erase the crime evidence.

## 2.3 Present Auditing System

### 2.3.1 Host-Based Auditing System

- tripwire: tripwire is a "System File Integrity Inspection System", which finds out what are the files that have been modified. The system performance is satisfactory, and it occupies minimal space. Also, tripwire inspect the forged sessions coming from intruders. In addition, tripwire can re-adjust itself to accommodate various system configurations and provide flexible control in managing system file locations.
- Swatch: swatch is "Simple WATCHer" for short. It is the most popular host-based auditing system under Unix operating system. Swatch verifies the new-recorded events in the historical audit files to check whether they satisfy the requirements of predetermined configuration. Once the system event matches, Swatch will report to the user immediately. Moreover, it can even monitor log file of syslogd (a unix daemon), and respond with suitable solutions when problem arises.

### 2.3.2 Network-Based Auditing System

The mostly utilized Network-based Auditing Systems are as follows:

- TCPdump: It is currently most popular network-based auditing system. TCPdump is an "OSI Certified Open Source Software" [6]. Therefore, any user can download this tool without charge. TCPdump captures the packets traveling on network for analysis. It is able to monitor network users'

(especially the potential hackers) every single activity. However, despite of its convenience and fame, understanding the generated auditing data may rather be difficult.

- Snort: Likewise, snort another free IDS software supported by Open Source. This system has the capability of monitoring the computers of a same domain. It searches through the captured packet data, and perform analysis on the contained information. Snort compares attach pattern with deterministic rules to detect various kinds of attacks. Its core source code is an altered version of tcpdump; hence, the audit files generated also troubled many users.

All in all, analyzing the audit files generated by the present auditing system, especially the network-based, requires the knowledge of network specialist. Due to the fact that packets are directly stored as in raw format, analysis process becomes inconvenient and time-consuming. Also, analysts have to one by one investigate each packet in the audit file. In attempting to solve this problem, this research proposed to introduce the concept of session into the analysis procedure.

## 3. The Proposed System

The present network-based auditing systems are often incapable of performing session analysis. Moreover, records accumulated for a long period of time usually lack in organization and have no meaningful structure. Therefore, it posts a considerable difficulty for the analysts. If these records can be rearranged prior to the analysis process, the complication of the work will be greatly reduced. As a result, analysts would, then, be able to find out unauthorized activities more efficiently. In consideration of the problem and needs, this research proposed "Network-Based Auditing System with session tracking and monitoring".

### 3.1 System Framework

The proposed system followed the traditional network-based IDS framework. In order to capture the transmitting packets, the system must be located between intranet and gateway. As soon as the system is activated, Ethernet interface card will immediately be placed into promiscuous mode, starting to collect the packets. First, the captured packets are automatically processed by network card driver and system kernel. Then, they are sent to the proposed auditing system for further analysis. The system framework is shown in below:

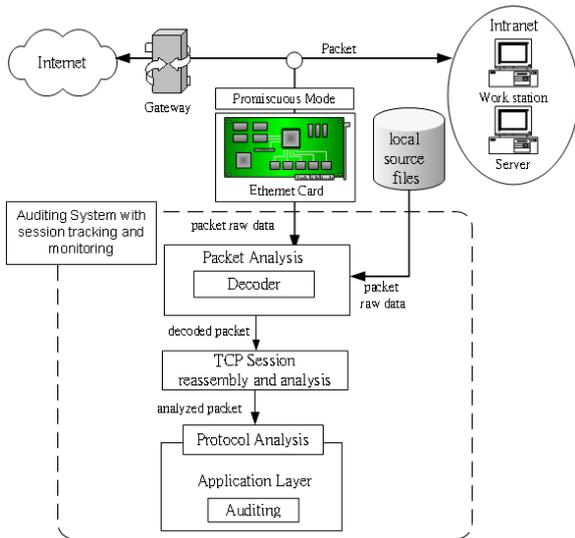

Figure 1. System framework

According to figure 1, the input raw packet data can either be obtained from local source files or packets captured on network. While system is operating on on-line capturing mode, it will keep collecting the packets traveling.

After the packets have been captured they are analyzed and categorized immediately. Meanwhile, the captured raw packets will also be stored in libpcap format (section 4.1) locally for reference in the future. Afterwards, these raw packets will be reassembled, preparing for restoring actual network events and activities.

First of all, raw packet data are sent to packet analyzer module for structure analysis in order to determine individual headers. In addition, the decoder contained within is responsible for converting raw data into understandable textual or numerical format.

The early stage of the analysis focuses only on packets' structure and characteristics. Consequently, the result is simply a collection of raw packets ordered by precedence; therefore, no distinct relationship is established between them. In fact, this is the major problem that creates the complication on analyst's work. In order to overcome this obstacle, it's necessary to design a calculation to rearrange the packets into individual session groups. TCP session analysis module is specifically designed to serve that purpose.

Finally, the analyzed packets will arrive at protocol analysis module. This module is the last module prior to packets' entry into application layer. It determines the packets' protocol type and decides how they will be treated for the later process. At this stage, analysis process will vary in accords to the protocol. This is where the TCP session groups from the previous module are combined into files if applicable. In the end, the analysts will be able to see the actual event be restored. After analytical processes have completed their task, each packet will then be summarized in textual form and stored into an audit file.

### 3.2 TCP Session Analysis and Reassembling

Usually, data will be chopped locally into several pieces prior to its transmission when its length is considered too long. Then, they will be reassembled into its original form after arriving the destination. Hence, packet reassembling is the process of reconstruction and rearrangement of packets base on their individual protocol, characteristics and sequence.

According to figure 2, in TCP layer, the communicating sides must synchronize with each other before any connection is established. This synchronization process is also known as "Three-Way handshaking". Thus, this special interaction procedure signifies each beginning of a new session. Likewise, prior to the end of a session, both sides will inform each other that they are about to close the transmission by sending FIN signal. In other words, every TCP session can be determined by "Three-Way handshaking" and FIN signal. After the beginning and the end of each session are defined, the rest of the packets will be grouped in accords to their IP, port, acknowledge and sequence number.

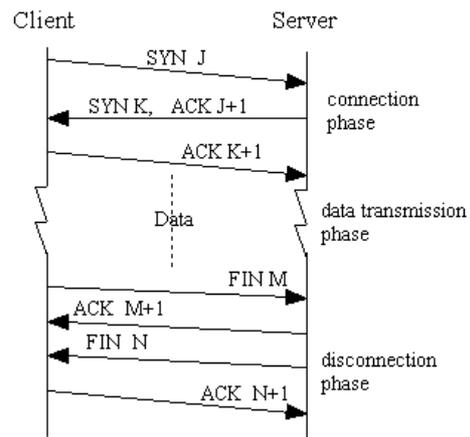

Figure 2. TCP session [13]

Once the session groups have been completely analyzed, reassembly takes place. In this research, attempts are made to simulate the reconstruction process at application level. For HTTP, the restoring process focuses on the commands and files transmitted. For example, a client sent a "GET" request to a web server for an index page file. Then, the server responds with a HTTP message followed by series of packets containing the requested file data. The request and respond packets provide crucial information in the reassembly process. For instance, the name of the requested file can be referenced from the "GET" command line in the request message, and content length can be found in HTTP message. Finally, with the given information and sequence number, the requested file will be generated using the data contained in the packets.

## 4. System Design and Demonstration

The proposed system, “Network-Based Auditing System with session tracking and monitoring”, is developed under Windows and Linux operating system, using interface library WinPcap and Libpcap respectively. Libpcap is a network capture library developed by Network Research Group (NRG) of the Information and Computing Sciences Division (ICSD) at Lawrence Berkeley National Laboratory (LBNL) in Berkeley, California. Libpcap and several other packet analyzing tools are often included as part of the operating system as auxiliaries.

### 4.1 System Design

As what has been mentioned, Libpcap is an interface library, which provides packet capturing function for other applications. It has defined a file format, which the implementing application should apply to. Libpcap

file consists of several sections including “File Header”, “Record Header” and raw packet data; and no paddings in between. Each section header provides information pertaining to its content.

In a libpcap file, the section of the first 24 bytes is called “File Header”, which is followed by many packet records. And, each record consists of 16 bytes “Record-Header” and the contained packet raw data. In other words, a libpcap file has only one “File-Header” but many packet records. A conceptual libpcap log file structure diagram is shown below.

In a libpcap file, the start of each packet record can be determined by record headers. Likewise, this header provides several important information, such as packet length, capture data and time. Applications must recognize the headers in order to access the raw packet data the follows.

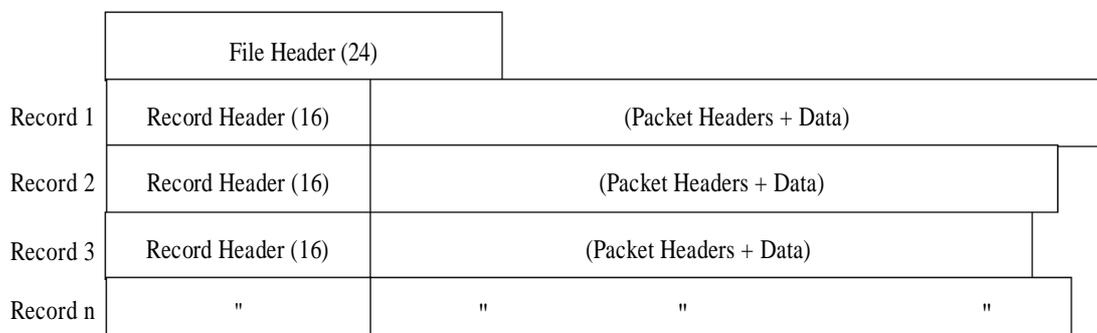

Figure 3. Libpcap file structure

Table 1. File-header format

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
MN				MajV		MinV		TZO				TSA			
LLT				SNP											

Table 2. File-header fields detail

Field	Length (byte)	Meaning
MN	4	Magic Number is a 4 bytes long hex: “0x1a2b3c4d”. The main purpose is for the application, that is reading this file, to determine whether the writing pattern is big-endian or little-endian.
MajV	2	Major Version Number
MinV	2	Minor Version Number
TZO	4	Time Zone Offset
TSA	4	Time Stamp Accuracy
LLT	4	Link Layer Type
SNAP	4	Snap Length: The maximum length of the captured packet data.

Table 3. Record-header format

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
TS								CPL				ACL			

Table 4. Record-header fields detail

Field	Length (byte)	Meaning
TS	8	Time Stamp: The first 4 bytes represents the total seconds from the date of 1970/1/1 00:00:00 up to the time of packet being captured. The next 4 bytes are microsecond.
CPL	4	Captured Length: The length of the packet captured (can be configured).
ACL	4	Actual Length: The actual length of the packet captured.

### 4.2 System Requirements

This system is written in Python; hence, it also supports cross platform. Presently, this system has been tested to operate both on Linux and NT environment. There are a few software requirements. First of all, needs to install Python interpreter version 2.2, and libpcap library for Linux and Winpcap library for NT. There is no required for extra hardware requirement besides Ethernet card. However, a machine that is set up for IDS is, of course, the faster the better, and preferably equipped with larger storage space. That is, high performance hardware is likely to carry out its mission more efficiently.

### 4.3 Scenario: Monitor HTTP As An Example

In order to provide convenient and efficient control, this system has a graphical user interface. Once the system is activated, the user enters the main executing window immediately. In figure 4, sections marked A, B, C, D and E are parameter section, session tracking, packet summary, detailed packet structure tree and raw packet data view. Every system function can be started from this window, which is the core of the whole system. This system works in two different modes: real-time capturing and analyzing mode. Users can directly switch between modes with a mouse click.

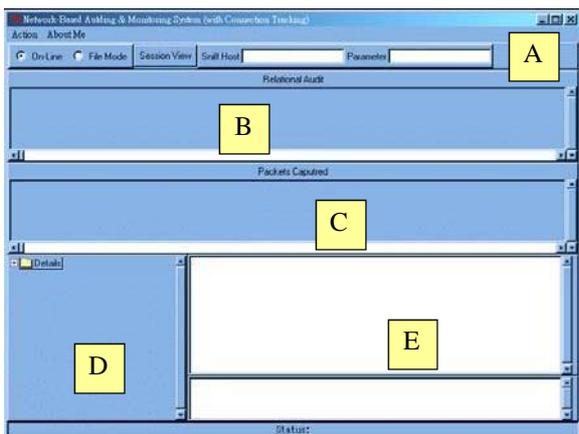

Figure 4. Main executing window

When it is placed into real-time capturing mode, the system will start to capture every incoming and outgoing packet. Of course, network administrator can also enter specific parameters and focus on a particular IP or protocol.

As shown in figure 5, packets that satisfied the defined requirements, will be captured. Filtering out the uninterested packets, the overall analysis accuracy and efficiency will be improved.

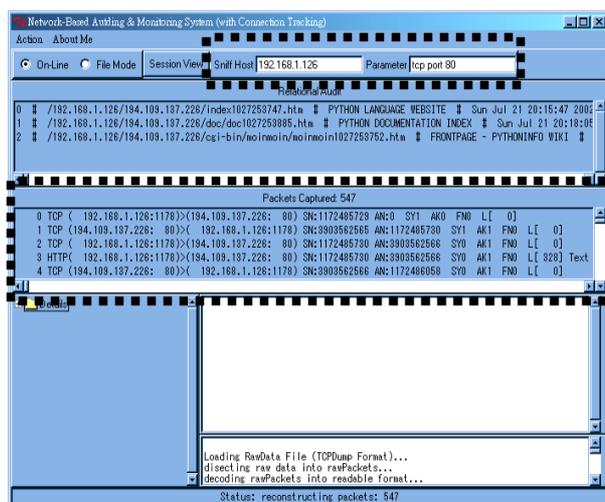

Figure 5. Capturing packets that satisfied the requirements

After packets have been captured, the system immediately takes the responsibility to analyze their structure. The result will be shown in the packet summary section. To see more detailed information about a specific packet, users can simply click on a packet listed in summary section. Then, the complete packet structure (with consisted headers) and raw packet data (in hex format) will be shown (figure 6).

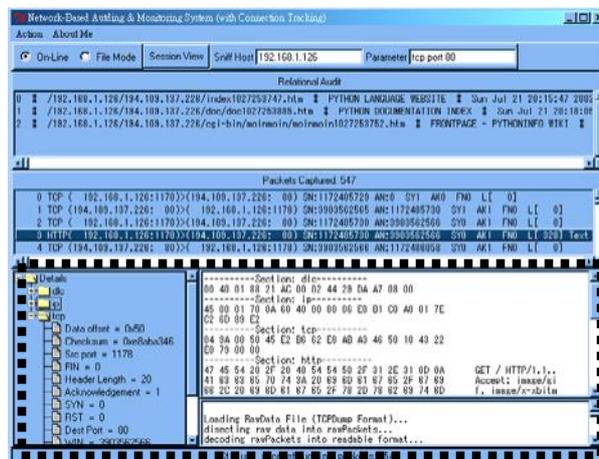

Figure 6. Packet's full detail

This system is also capable of performing session tracking and packet reassembling. That is, the collected packets are processed and reassembled by the system to generate files; for example, a web page. These files will be listed in chronological order in the session tracking section. Users can directly view the file by selecting the listed item. As in HTTP, the files are most likely to be the web pages or graphics. In fact, with this mechanism, the administrators can see the restoration of the actual event occurred and what exactly the monitored users have done. Indeed, this feature can allow administrators to manage the network much more effectively. As shown in figure 7, 8 and 9, the pages browsed by the monitored user are all captured and listed.

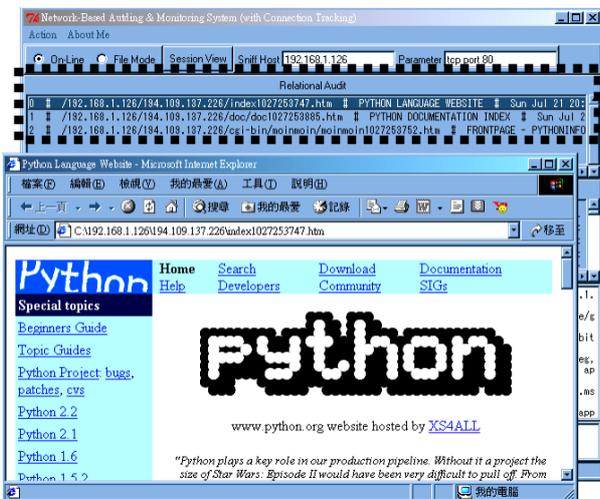

Figure 7. The result of the reassembled packets: web pages browsed by the monitored user

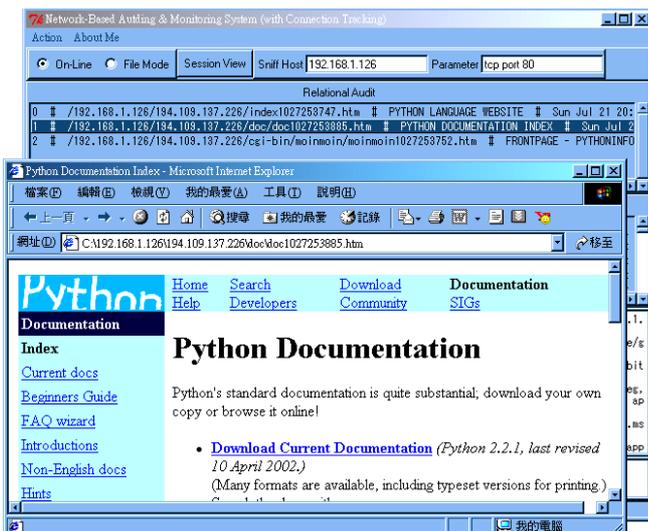

Figure 8. Web pages browsed by the monitored user (continuation)

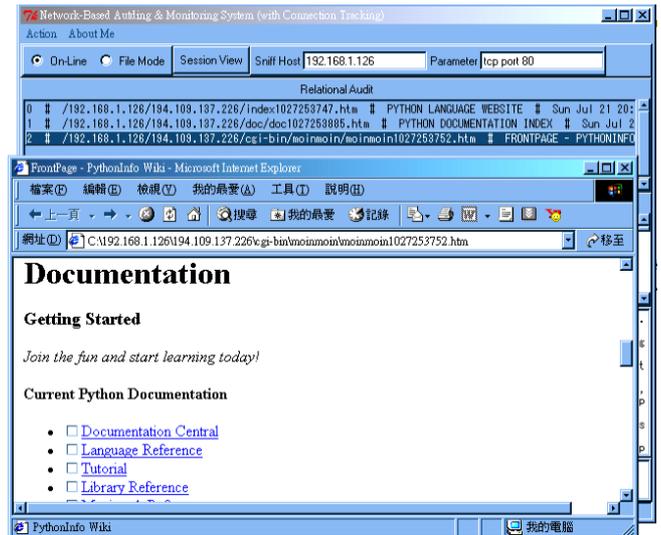

Figure 9. Web pages browsed by the monitored user (continuation)

Other than regular analysis, network administrators can also utilize this system to determine individual session. In figure 10, each session in the session tracking window is grouped by its IP and port (both source and destination). Both total number of consisting packets and the sum of data length are noted behind each session group. After selected a session group from the list, the files that are generated in this session will be listed in the window shown below. Then, by clicking on a specific file, the users are able to see the packets that constitute it (figure 10, 11).

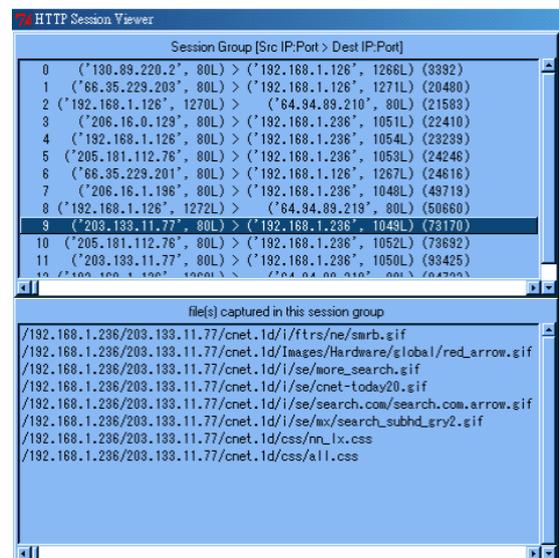

Figure 10. Selecting a desired session group

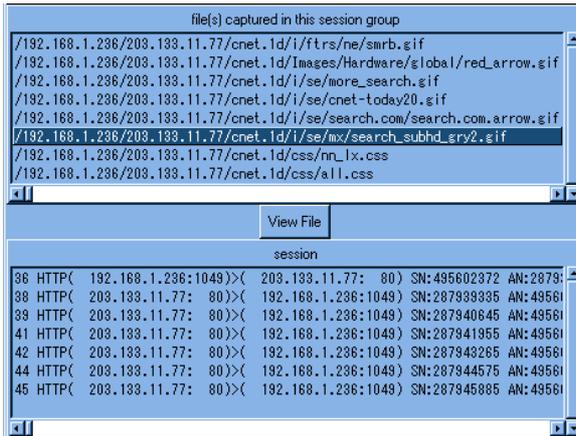

Figure 11. The selected file's consisting packets

Each analyzed packet will be recorded in textual audit files, and these records will become important references for future verification (figure 12).

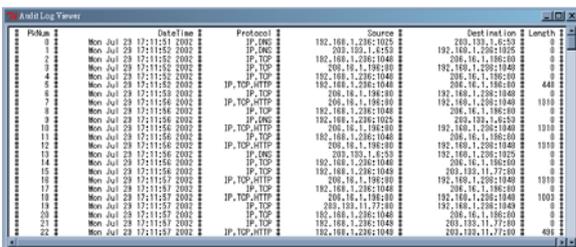

Figure 12. Textual audit file

## 5. Conclusion and Future Improvements

Network security is becoming increasingly important. Besides firewall and intrusion detection measures, enforcing an efficient and effective security mechanism is the key to secure working environment. The importance of IDS should not be ignored. Auditing system will be the crucial monitoring technique towards cyber-crime. In this research, a "Network-Based Auditing System with session tracking and monitoring" is developed. Despite the packets are captured or retrieved from a raw packet source file, the actual monitored network events can be reassembled and replayed.

This system solves the problem of network administrators in overcoming the difficulty in analyzing the audit files. When network attacks occur, the administrator can specify the query time and event to reveal the suspected network activities. These reassembled records will serve as references that can provide great help in tracing the intruders.

In the future research, the system is expected to support more protocols, such as dns, ftp, smtp, pop3 and etc. Also, a through evaluation should be done on the system operating under various network traffic stress in measuring its stability. If necessary, further improvements will be made on this auditing system's efficiency by transforming this centralized system to distributed system.

## Abstract

Electronic business is rapidly popularized and extended through Internet. Internet has many security weaknesses, so we need the security solution such as Intrusion Detection System that minimizes the damage of hacking and responds the intrusion dynamically. It is difficult for legacy management system to process the security environments and electronic business, because legacy system lacks of security policies and integrated security methods. In order to resolve these problems, we need security management system that has standard security policy, consulting, diagnosis, maintenance, and repair function. In this paper, we design and implement Web-based security management for intrusion detection. Our security system consists of network nodes, general hosts and a management node. A management node manages a network node, that is a secure router, and general hosts by security policies. We design the channel between the management node and the network node using IPsec (IP Security). We have applied java and Web to implementing user interface of security system. As the proposed system makes use of Web, security management system is easily accessed through the Web.

## 1. Introduction

Nowadays the business markets of Electronic Commerce (EC) [1] have rapidly extended through Internet. Internet has many security vulnerabilities such as sniffing, spoofing and computer virus. It is necessary to provide the security of Internet services for electronic business. In order to overcome the weakness of Internet, we make good use of security services such as firewall, Virtual Private Network (VPN), Enterprise Security Management (ESM) and Intrusion Detection System (IDS) [2].

IDS is a next generation security solution that minimizes the damage of hacking, in case a firewall fails in the isolation of intrusions, and responds the intrusion dynamically. IDS has three types that are Network based IDS (N-IDS), Host based IDS (H-IDS) and Hybrid IDS. N-IDS is installed in network nodes and analyzes the packet from network nodes. N-IDS has some advantages which are OS independence and the low cost of operations and installation, compared with H-IDS. H-IDS is installed in the server which wants to monitor the network. It monitors the system log files stored by an audit and

system call in the operation level. But H-IDS is difficult to implement and has the high cost of setup, compared with N-IDS. The limits of IDS are the false positive rates of misuses, the process of encryption packets and the hacking by a roundabout way. New advanced filtering technology and rules, updated by well known patterns, are needed to reduce the rates of misuses.

Today's standard of IDS is in progress by consortium and IETF. Internet Security System (ISS), Tripwire software, IBM, and Network Associates joint Intrusion Detection System Consortium (IDSC). IETF Intrusion Detection Working Group (IDWG) [3] defines a data format that exchanges the information of various IDS products.

It is difficult for legacy management system to process the security environments and electronic business, because legacy security management hasn't any security policy [4, 5] or integrated management method. In order to resolve these problems, we need security management system that has standard security policy, consulting, diagnosis, maintenance, and repair function. It is necessary to develop security management technologies that are integrated and can be reconfigured in real-time whenever the network administrator wants.

In this paper, we design and implement Web-based security management for intrusion detection. Our system consists of network nodes, general hosts and a management node through networks. A network node is a security router that provides packet filtering, intrusion detection, intrusion analysis, intrusion response, and policy enforcement. A management node manages network nodes and general hosts by security policies. We design the channel between the management node and the network node using IP Security (IPsec) [6].

This paper is organized as follows. Section 2 describes related works which are Java Server Page (JSP) and IPsec. Section 3 designs the architecture of our system. Section 4 describes the implementation of Web-based security management. Finally, section 5 summarizes this paper.

## 2. Related Work

### 2.1 Java Server Page (JSP)

Java Server Page (JSP) is a technology for controlling the content or appearance of Web pages using servlets. JSP allows Web developers and designers to rapidly develop and easily maintain Web pages that support

existing business systems. JSP enables rapid development of web-based applications that are platform independent. JSP uses XML-like tags and scriptlets written in the Java programming language to encapsulate the logic that generates the content for the page.

Java Server Page is an extension of the Java Servlet technology. Servlet is a small program that runs on a server and platform-independent module. Servlet provides Web developers with a simple, consistent mechanism for extending the functionality of a Web server and for accessing existing business systems. Servlets have made many Web applications possible. JSP is comparable to Microsoft's Active Server Page (ASP) technology. While a Java Server Page calls a Java program that is executed by the Web server, an Active Server Page contains a script that is interpreted by a script interpreter such as VBScript or JScript before the page is sent to the user. An HTML page that contains a link to a Java servlet is sometimes given the file name suffix of .JSP.

## 2.2 IP Security (IPsec)

The research on the next generation Internet is already in progress worldwide. IPsec (IP security), which is a common security service, is proper for characteristics of the Internet as a mandatory technology in next generation Internet IPv6. IPsec provides various security services at the IP layer. It is mandatory to implement IPsec in IPv6 and IPsec provides scalability and interoperability that are required to the Internet security protocol. It is not required to modify the software to use the security services of the IPsec and users don't care about the existence of the IPsec. IPsec is an extension of IP, it has Authentication Header (AH) [7] and Encapsulating Security Payload (ESP) [8]. IPsec can provide Internet security services that are access control, connectionless integrity, rejection of replayed packets, data origin authentication, confidentiality, and limited traffic flow confidentiality.

AH is security protocol that provides security services using message checksum (ICV). ESP is security protocol that offers security services using data encapsulation. AH is used to protect an entire IP payload and ESP is used to protect upper-layer protocols of an IP payload. ESP gives security services to only encapsulated field, but AH provides security service for IP packet. AH and ESP support two modes, transport mode and tunnel mode. Transport mode is used to protect upper-layer protocols and tunnel mode is used to protect entire IP datagram.

IPsec SA is that how to protect the traffic, what traffic to protect, and with whom the protection is performed between host and gateway or end hosts. It is consisted of Security Parameter Index (SPI), destination address and security protocol, AH or ESP. SA decides IPsec protocol as simplex connection entity and IKE negotiates about SAs. Since SA is simplex connection, there exist SA tables according to outbound or inbound processing. SAs are indexed by SPI that exists in IPsec protocol headers, the IPsec protocol value, and the destination address.

## 3. System Design

### 3.1 System Framework

Our system consists of network nodes, general hosts and a management node through networks. The network node is a security router that provides packet filtering, intrusion detection, intrusion analysis, intrusion response, and policy enforcement. The management node manages the network node and general host by security policies. Figure 1 shows the system framework of Web-based security management for intrusion detection. The management node and the network node communicate using IPsec.

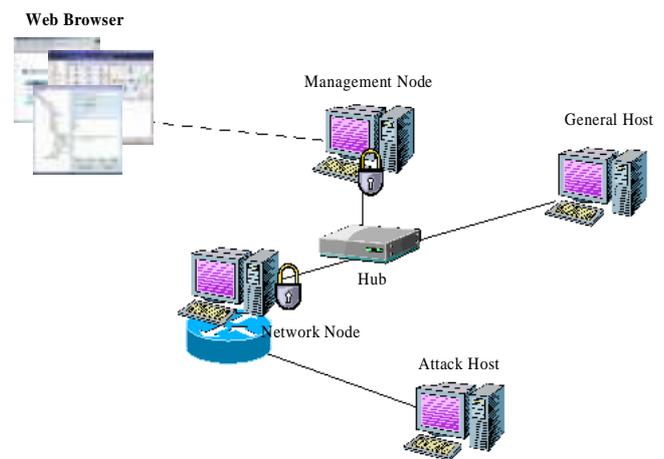

Figure 1. System Framework

### 3.2 Architecture of Management Node

The management node manages the network node and general host by security policies. Management node has management servlets, network sensor, policy decider, policy parser, audit manager, audit handler and databases. Policy DB stores the policy for intrusion detection such as the access rule, filtering rule, and detection rule. The policy parser writes, configures and deletes policies from policy DB. After the policy parser reads the policy DB, the policy decider selects a suitable policy for the network node.

Tomcat 4.0 provides the servlet engine for management servlets. Management servlets, which are executed by tomcat program, communicate with the Web interface. Web interface is Web browser, e.g. Netscape or Internet Explorer. We run Web browser and put the URL of the management node. Then login servlet sends the logon page to Web browser and we can access logon page. After putting ID and password on logon, login servlet checks ID and password from the user DB. If user is authorized, security management program is downloading form Web server. If user is not authorized, Web reloads the logon page.

Figure 2 shows the architecture of the management node. The network sensor collects network information

such as host data, routing data and packet data from networks, and stores at network DB. The audit handler and audit manager deals with the alarm of illegal access, bad packet and intrusion. The network node is a security router that provides packet filtering, intrusion detection, intrusion analysis, intrusion response, audit handle, access control, and policy enforcement. The network node operates intrusion detection by policy and communicates with the management node using IPsec.

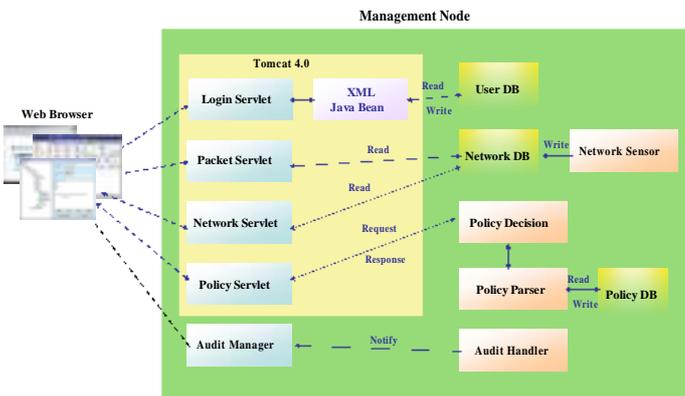

Figure 2. Architecture of Management Node

#### 4. Implementation

We have implemented our system in Linux 7.1 using JDK 1.3.1 [9], JSP server (tomcat) 4.0.3 [10], pcap library 0.4 and gcc 2.96. We can access to security system using Web such as Netscape or Internet Explorer in Windows 2000, Linux or Solaris. A management node configures and deletes policies, and monitors the network. The policy is sent to a network node, then the network node enforces policy, collects packet and analyzes the intrusion detection of networks.

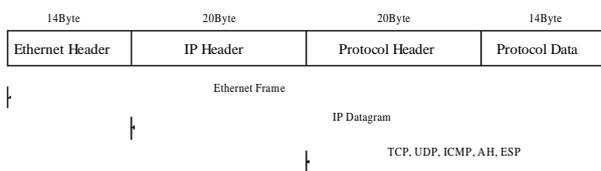

Figure 3. The format of Ethernet Frame

Figure 3 shows the format of Ethernet frame. We define that “default length of snap” is 68bytes of the macro used with the network sensor using pcap library. Length of frame is variable and the minimum length is 68bytes. The minimum length is sum of Ethernet header length, IP header length, TCP header length and protocol data length. Ethernet header is 14bytes, IP header is 20bytes, TCP or UDP header is 20bytes, and the length of protocol data is 14bytes.

```

#define DEFAULT_SNAP_LEN          68
#define DEFAULT_NET_DEV          "eth0"
#define FILTER_RULE_LEN          256
#define ETHER_TRAILER            4
#define LOG_FILE                  "packet_info.log"

static void analyze_packet (unsigned char *user, const struct
pcap_pkthdr *pkthdr, const u_char *p) {
    const struct ip *p_ip;
    const struct ether_header *p_ehdr;
    uint16_t ether_type;

    snap_start = p;
    snap_end = p + pkthdr->caplen - 1;
    set_cur_pkt_timestamp (pkthdr->ts);
    frame_time = pkthdr->ts;
    p_ehdr = (const struct ether_header *)p;
    ether_type = ntohs(p_ehdr->ether_type);
    p_ip = (const struct ip *) (p + sizeof(struct ether_header));
    set_cur_pkt_ether_type (ether_type);
    set_cur_pkt_etheraddr (p_ehdr);

    if (ether_type == ETHERTYPE_IP) {
        set_cur_pkt_ipproto (p_ip->ip_p);
        set_cur_pkt_ipaddr (p_ip->ip_src, p_ip->ip_dst);
        if (is_normal_ip (p_ip)) {
            analyze_ip_datagram ((const u_char *)p_ip +
                sizeof(struct iphdr), p_ip->ip_p);
        }
    }
    next_pkt_entry();
}

static void analyze_ip_datagram (const u_char *p, u_char ip_proto)
{
    switch (ip_proto) {
        case IPPROTO_TCP:
            analyze_tcp (p);
            break;
        case IPPROTO_UDP:
            analyze_udp (p);
            break;
        case IPPROTO_ICMP:
            analyze_icmp (p);
            break;
    }
}

```

The packet is captured from networks, “analyze\_packet()” function classifies the header of the packet. “analyze\_packet()” function finds out source address, destination address, source port, destination port and protocol. “analyze\_ip\_datagram()” function classifies protocol using the protocol field of ip header. If the protocol field of ip header is “IPPROTO\_TCP”, “analyze\_tcp()” function is called. If the protocol field of ip header is “IPPROTO\_UDP”, “analyze\_udp()” function is called. If the protocol field of ip header is “IPPROTO\_ICMP”, “analyze\_icmp()” function is called. The analyzed packet is useful about knowing the intrusion detection, packet traffic, and packet statistics.

#### 5. Conclusion

In this paper, we design Web-based Security Management for Intrusion Detection. Our system consists of network nodes, general hosts, management node through networks. The network node is a security router

that provides packet filtering, intrusion detection, intrusion analysis, intrusion response, and policy enforcement. The management node manages the network node and general hosts by security policies. We have applied java and Web to implementing system. Java is used to program the user interface. As the proposed system makes use of Web, security system is easily accessed through the Web in real time.

## Abstract

E-system, a new commerce model, is a new era for business direction. When a principal is absent (goes on an errand or on leave), a well-designed deputy system keeps the business operations working. In the network world, identity verification and any substitute for traditional signature can be done by digital signature [1]. Deputy signature guarantees the existence of deputy system in e-system. Current deputy mechanism addresses the verification of deputy signature. No research has been done on the prevention of the illegal use of deputy system when the principal returns and the deputy system is not in use. We propose a mechanism to solve the problem of illegal use of deputy system when the power of deputy system is not legally "ON."

Key words: information security, digital signature, deputy signature.

## 1. Introduction

In the information era, information technology is an important tool to support all work. The popularity of network changes the methods of information transfer and speeds up the development of e-commerce. As a new model of commerce, e-commercialization is a competitive goal for all business users. A well-designed deputy system is helpful to business operations in non-network system and is imperative in network system.

In a network environment, in addition to verifying the identity, digital signature can also be used to substitute for the traditional handwritten signature. During the principal's absence, deputy signature keeps the system running and the security of private key as well. The characteristics of deputy signature are as follows: private, identifiable, secure, and undeniable. Current deputy mechanism addresses the verification of deputy signature. No research has been done on the prevention of the illegal use of deputy system when deputy system is not in use. We propose a mechanism to solve the problem of illegal use of deputy system when the power of deputy system is not legally "ON." Our scheme provides a delegation time schedule for the receiver to solve the associated problem of deputy signature. Unauthorized deputy will be ruled out once

the principal returns and the deputy's authority has lapsed.

The layout of this paper is as follows. Literature review is in Section 2. Section 3 introduces our scheme. In Section 4, we analyze the security of our scheme. Section 5 concludes the paper.

## 2. Literature Review

Digital signature fulfills the requirement of signature in network environment and enhances the feasibility of e-commerce. In the E-era, the un-deniability of digital signature enables e-documents to be widely and legally accepted. The principal uses his/her private key to sign and send documents. The receivers verify the documents by public key. When one cannot sign documents personally, deputy signature enables the deputy to keep the system working without using the original private key. Mambo et al [2,3] propose deputy signature in 1996. Deputy signature allows deputy to sign documents with equal efficacy. In general, deputy signature has properties as follows [11]:

- A. Distinguish-ability: The difference between deputy signature and original signature is distinguishable.
- B. Unforgeability: No one else can forge deputy signature other than the real deputy.
- C. Verifiability: The receiver(s) can believe that the principal agrees to deputy signature for the documents.
- D. Un-deniability: deputy cannot deny deputy signature. Unfortunately, the Mambo deputy signature is deniable. Zhang [4], Lee et al [5], Sun and Hsieh [6] solve this problem in their schemes.

## 3. Our Scheme

### 3.1 Registration

First, firm should set up a system center. The manager of system center chooses a big prime  $p$  [7,8,9] to satisfy the following equations:

$$p = 4p_1q_1 + 1$$

where  $p_1, q_1$  are big primes.

Let  $n = p_1q_1$

Then, select a number  $g$  modulo  $p$  with order  $n$ , i.e.,  $g^n \equiv 1 \pmod{p}$ ,  $g^{p_1} \not\equiv 1 \pmod{p}$ ,  $g^{q_1} \not\equiv 1 \pmod{p}$ .

$\{p,n,g\}$  is the public key of the system center.  $\{p_1,q_1\}$  is private key.  
 The principal (hereafter A) selects a number  $x_A \in Z_n^*$  calculates:

$$y_A \equiv g^{x_A} \pmod{p} \dots\dots\dots(1)$$

and registers to system center.  $\{y_A\} \{x_A\}$  are the public key of A and private key, respectively.

If A is to assign B as his/her deputy to sign documents during  $T_A = [t_1, t_2]$ . B selects a number  $x_B \in Z_n^*$ ,

calculates:

$$y_B \equiv g^{x_B} \pmod{p} \dots\dots\dots(2)$$

and registers to system center, where  $\{y_B\} \{x_B\}$  are the public key of B and private key, respectively.

### 3.2 Delegation

**Step 1:** A selects a number  $d_1 \in Z_n^*$  and calculates:

$$D_1 \equiv g^{d_1} \pmod{p} \dots\dots\dots(3)$$

**Step 2:** Calculate:

$$y_B + T_A \equiv x_A D_1 + d_1 E_1 \pmod{n} \dots\dots\dots(4)$$

**Step 3:** Send deputy certificate  $\{T_A, D_1, E_1\}$  to B as shown in Diagram 1.

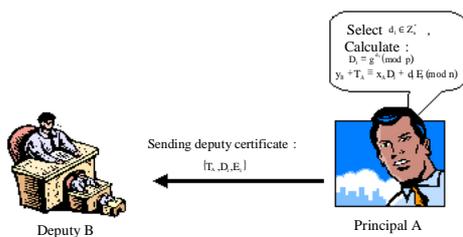

Diagram 1: Delegating deputy and sending deputy certificate

### 3.3 Generation of deputy signature

If B is going to sign on the message m during deputy time,

**Step 1:** Select a number  $d_2 \in Z_n^*$  and calculate:

$$D_2 \equiv g^{d_2} \pmod{p} \dots\dots\dots(5)$$

**Step 2:** Calculate:

$$E_2 \equiv mx_B + d_2 D_2 \pmod{p} \dots\dots\dots(6)$$

**Step 3:** Sending deputy certificate  $\{T_A, D_1, E_1\}$  and the digital signature  $\{m, D_2, E_2\}$  with message m to a receiver C as shown in Diagram 2.

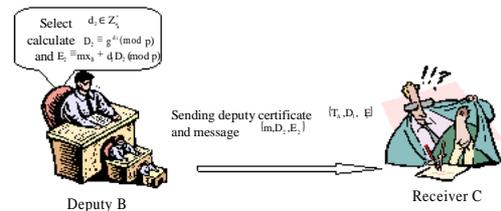

Diagram 2: Running of Deputy signature

### 3.4 Verification of deputy signature

The receiver C verifies:

$$g^{y_B + T_A} \equiv y_0^{D_1} D_1^{E_1} \pmod{p} \dots\dots\dots(7)$$

$$g^{E_2} \equiv y_B^m D_2^{D_2} \pmod{p} \dots\dots\dots(8)$$

If the equations above are valid, accept deputy B. If not, reject.

## 4. Security Analyses

**Theorem 1:** If A is honest, Eqs.(7)(8) are valid.

**Proof:**

To have base g for the both sides of Eq.(4) and obtain:

$$g^{y_B + T_A} \equiv g^{x_A D_1} g^{d_1 E_1} \pmod{p} \\ \equiv y_A^{D_1} D_1^{E_1} \pmod{p}$$

According to Eqs.(1)(3)

For the same reason, having base g for both sides of Eq.(6) and obtaining:

$$g^{E_2} \equiv g^{mx_B} g^{d_2 D_2} \pmod{p} \\ \equiv y_B^m D_2^{D_2} \pmod{p}$$

According to Eqs.(2)(5), the theorem 1 is proven.

**Theorem 2:** The difficulty of forging Eq.(1) is the complexity of discrete logarithm

**Proof:**

ElGamal [10] has proven that following equations to be discrete logarithm:

$$g^m \equiv y^r s \pmod{p} \dots\dots\dots(9)$$

Comparing Eq.(7) and Eq.(9), we find that if

$$y_B + T_A \equiv m \pmod{n} \dots\dots\dots(10)$$

then Eq.(7) is similar to Eq.(9). Namely, the complexity of Eq.(9) is discrete logarithm. So is Eq.(10). On the contrary, if Eq.(10) is the problem of discrete logarithm, So is Eq.(9). In addition, the complexity of forging Eq.(8) is at least equal to the complexity of Eq.(7). The proof is similar and omitted. Thus, theorem 2 is proven.

From the two theorems above, we know that if an attacker (A or B) is going to invade our system, he/she has to solve the complexity of discrete logarithm.

## 5. Conclusion

In recent years, along with the development of network, e-commerce is expanding rapidly. In addition to overturning the traditional model of transactions, this new business activity also provides ample business opportunity. Network is used for business activities and generates e-business. For e-business, information security is an important topic. In a non-e environment, deputy system can be done by written delegation certificate. In an e-environment, a trustable deputy signature is needed. Our deputy signature has the advantage of timing for the verification of deputy signature. No illegal deputy can be accepted once the principal returns and the deputy's authority has lapsed.

## Abstract

Extranet has received growing popularity among business-to-business trading partners today. It has been used to reduce delivery lead-time and improve customer service. The inter-organization nature of Extranet, coupled with the omnipresence of Internet, create competitive advantages for a company over those who do not have Extranet linkage. This study investigates the factors affecting the adoption of Extranet in rubbers and plastics industry. The results reveal that "characteristics of end user" is the most importance factor affecting the adoption. The other significant factors include the characteristics of business itself, degree of understanding new technology, the characteristics of business network, and the support of top management.

## 1. Introduction

Electronic network linkages in the value chain have fundamentally changed the nature of inter-organizational relationships (McIvor et al., 2000). Many companies today are sharing their information resources through a competent network infrastructure, known as the Extranet. Internet has been commonly known as the first revolution of network, followed by Intranet and Extranet. More and more businesses are redesigning their internal structure and their external relationships, creating value chain networks to facilitate improvement of information quality, communication of data, and knowledge, while improving coordination, planning, and decision making (Warkentin et al., 2001). Under today's dynamic business environment, competitive pressures are forcing companies to take necessary actions on compressing time between each stage of the value chain and achieving costs down (McIvor et al., 2000). Many companies have utilized information technology to create competitive advantages (Bakos and Treacy, 1986; Cash, et al., 1992. Ives and Learmonth, 1984). They have been upgrading their enterprise information systems to improve the efficiency and the effectiveness of supply chain networks. The inter-organization nature of Extranet has made it a vital vehicle for maintaining these networks. In this study, we first identify the potential factors affecting the adoption of Extranet. Through factor analysis and discriminant

analysis, these factors are tested for their significant effects. Finally, conclusion and recommendation for managers are presented.

## 2. The Research Methodology

### 2.1 Research Model

Through the review of related literature, we have developed a research model as indicated in Figure 1.

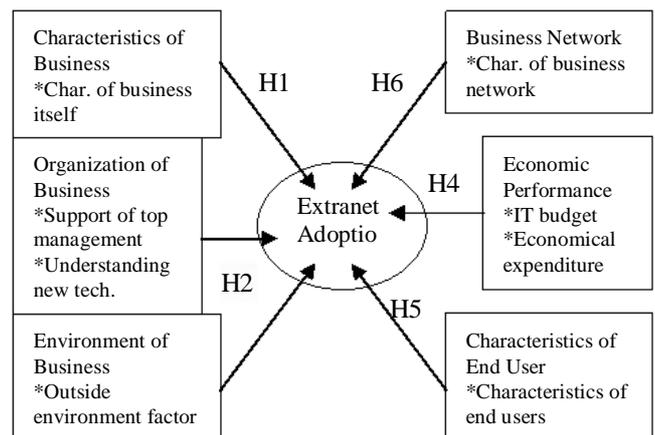

Figure 1. Research Model

### 2.2 Research hypothesis

Following the research model in Figure 1, we have formulated six hypothesis.

H1: The characteristics of business affect the adoption of Extranet in an enterprise.

H2: The organization of business affects the adoption of Extranet in an enterprise.

H2a: The support of top management affects the adoption of Extranet in an enterprise.

H2b: Understanding new technology affects the adoption of Extranet in an enterprise.

H3: The environment of business affects the adoption of Extranet in an enterprise

H3a: Outside environment factor affects the adoption of Extranet in an enterprise.

H3b: Outside environment threat affects the adoption

of Extranet in an enterprise.

H4: The economic performance of business affects the adoption of Extranet in an enterprise.

H4a: IT budget affects the adoption of Extranet in an enterprise.

H4b: Economical expenditure affects the adoption of Extranet in an enterprise.

H5: Characteristics of end user affect the adoption of Extranet in an enterprise.

H6: Business network affects the adoption of Extranet in an enterprise.

### 3.3 Data Analyses and Hypothesis Tests

This section utilizes difference analyses to test the hypotheses and reports the results.

#### 3.3.1 Different Discriminant functions

In addition to the discriminant loading, we further utilize profile group difference, discriminate weight, and individual discriminate weight to contrast the findings and identify the most significant factor determining the adoption of Extranet. Table 4 shows that “Characteristics of end user” is the most significant factor.

Table 4. Summary of methods used in this study

Method	Criterion	Results
Profile group difference	The difference of variable mean	Understanding new technology
Loading	The weight of loading values	Characteristics of end user
Discriminate Weight	The amount of Weight values	Characteristics of end user
Individual Discriminate Weight	The difference of variable mean	Characteristics of end user

#### 3.3.2 The Accuracy of Discriminant Function

In order to examine the accuracy of the discriminant function, 50 (33.3%) respondents were held out as for validation purpose. The remaining 100 respondents are use as the training sample to derive the discriminant function. Table 5 indicates that the resulting discriminant function is able to classify correctly 80% of the held-out sample. This value (0.80) is larger than the threshold ( $C_{pro} * 1.25 = 0.545$ ) recommended by Hair et al. (1995). Therefore, the discriminant function we derived in this study has significant discriminant power.

Table 5. The accuracy of discriminant function

Training sample			Held-out sample				
Not adopt	Adopted		Not adopt	Adopted	Summary		
Not adopt	36	22	58	Not adopt	28	6	34
Adopted	11	31	42	Adopted	4	12	16
Overall accuracy = 67%			Overall accuracy = 80%				

## 4. Discussion

This study focuses on rubbers and plastics

relationship industries that there are a lots of factors of itself and influence to adopt Extranet. Following these influence factors to do discussion.

### 4.1 Character of business

The result was displayed on adopt extranet, characteristic of business, understanding new technology and characteristic of end user that these functions enable to keep heavy discrimination power. But the characteristic of business network and support of top management that two items functions to adopt extranet also to keep significations discrimination effect (see figure 2). The enterprise dependents IT more heavy than technology efficiency was powerful. Opposite, the others efficiency is weak (Applegate et al., 1996). Following in analysis data have got characteristic of business to adopt extranet discriminate effectiveness p-values is 0.0032 that less standard values 0.05, the result is supported H1 hypothesis.

### 4.2 Business organization

Asano (1989) at his research have argued many enterprise executive e-business technology there are signification difference of development. In this data also examine literature view point, the support of top management affects the adoption of Extranet in an enterprise. It's p-values is 0.0223. Pinto and Mantel (1990) have expressed administrator and end-user low ideals and acknowledges to IT, it should be influence enterprise adopting IT. This analysis data have developed that understanding new technology affects the adoption of Extranet in an enterprise. The p-values is 0.0016 to keep more discriminate power. This result is supported H2 hypothesis (see table 6).

Table 6. Results of Hypothesis Testing

Hypothesis	p-Value	Test Result
H1: The characteristics of business affect the adoption of Extranet in an enterprise.	0.0032	Supported
H2: The organization of business affects the adoption of Extranet in an enterprise.	N/A	Supported
H2a: The support of top management affects the adoption of Extranet in an enterprise.	0.0223	Supported
H2b: Understanding new technology affects the adoption of Extranet in an enterprise.	0.0016	Supported
H3: The environment of business affects the adoption of Extranet in an enterprise	N/A	Not supported
H3a: Outside environment factor affects the adoption of Extranet in an enterprise.	0.0868	Not supported
H3b: Outside environment threat affects the adoption of Extranet in an enterprise.	0.0709	Not supported

H4: The economic performance of business affects the adoption of Extranet in an enterprise.	N/A	Not supported
H4a: IT budget affects the adoption of Extranet in an enterprise.	0.3441	Not supported
H4b: Economical expenditure affects the adoption of Extranet in an enterprise.	0.6658	Not supported
H5: Characteristics of end user affect the adoption of Extranet in an enterprise.	0.0007	Supported
H6: Business network affects the adoption of Extranet in an enterprise.	0.0257	Supported

### 4.3 Business environment

How to succeed in today's rapidly changing competitive environment is a question weighing heavily on many a manager's mind. The business competitive environment more multiples than IT roles more key issues of business environment (Hannan, McDowell, 1984; Levinet, et al., 1987). In the data showed as outside environment factor and outside environment threat that affects the adoption of Extranet in an enterprise. The p-values is 0.0867 and 0.0709 (see table 6). Also this research not support H3 hypothesis.

### 4.4 Economic performance

Competitive pressures are forcing enterprises to take available actions to compress time between each stage of the supply chain and costs down (McIvor et al., 2000). Ives and Jarvenpaa (1991) have argued when the enterprise beginning adopt computerize. IT equipment cost is adopt information systems one of successful issue factors. This data showed as IT budget and economical expenditure affects the adoption of Extranet in an enterprise. The p-values is 0.3441 and 0.6588 (see table 6). Also this research not support H4 hypothesis.

### 4.5 Character of end user

Pinto and mantel (1990) appealed to the research, the experience, profession technology and understand IT knowledge of end user, these factors enable influence business successful adopt IT equipments. Morris and Trotter (1990) research end user and IT adopt have argued accept new IT degree, learning new technology interest of end user, these factors become business adopt IT successful key issue. Hendry (1989) also have argued enterprise focus staff growth, training education degree, enable influence end user operation IT interest. The result was showed the characteristics of end user affect the adoption of Extranet in an enterprise. The p-values is 0.0007 more less than standard 0.05, so this result supported H5 hypothesis.

### 4.6 Character of business network

Erenguc, Simpson, and Vakharia (1999) review the effective management of operations using SCM. They suggest that a firm's competitive position and the nature of

the relationship among SCM participants play a significant role. They also explain why the determination of contractual agreements between the channel members and the incentive structures for information sharing should be further researched. Johnson and Mattson (1987) have argued that business network is one group firm was depended by each other, and rely on long-turn benefit for each relationship. In business network not only keeps competitive and compensation but also has exchange and adaptive interaction relationship.

This data showed as business network affects the adoption of Extranet in an enterprise. The p-values is 0.0257 (see table 6). Because this research support H6 hypothesis that business network affect the adoption of Extranet.

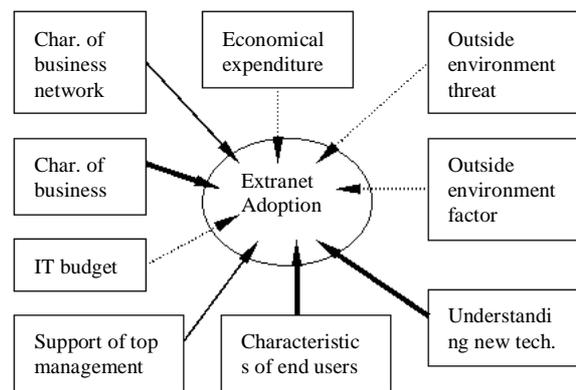

Figure 2. Discrimination

Heavy power: **→** General: **→** Weak: **→**

## 5. Conclusion and Recommendation

Under today's ever-increasing competitive pressure, the quest for competitive advantages has been the vital action of every business. Many success stories have been told in the literature regarding the use of information technologies by businesses to improve the competitive edge. In particular, the Extranet has been an outstanding tool for a business to exchange and share information among inter-organizational partners within a business network. Our study has revealed the critical factors that influence Extranet adoption of a business. Both the characteristics of end user and the characteristics of business itself are the two factors most significantly affect Extranet adoption.

Another two factors of significant importance are the support of top management and understanding of new technology. It is apparent that the degree of understanding new technology would directly affect the support of top management toward adoption of new technology. Therefore, we strongly recommend top management to tirelessly capture new knowledge and establish a culture of learning organization. This in turn would increase the users' interest in learning and using new technology and increase the chance of success in introducing a new technology into the company.

# Business-to-Business Solutions for a Changing Scenario in Brazilian Economy

## Abstract

This paper has the purpose of describing the development of Business-to-Business in Brazil and its adoption by companies and the government to reduce costs and reach new markets. It also shows the support provided by the Brazilian Government to this development, by means of the creation of the Electronic Commerce Executive Committee, in a joint effort with the private sector, and the implantation of a financing instrument for small and medium companies destined to electronic commerce, among other measures. Examples of creative solutions adapted to the conditions of the Brazilian economy, such as the Energy Marketplaces, established during the electric-energy rationing in Brazil, between May 2001 and February 2002, where thousands of companies were able to commercialize their energy quotas by means of electronic auctions, as well as tools directed to the governmental acquisition of goods and services, show the great potential of Business-to-Business.

## 1. Introduction

The promise that Internet enterprises would change the face of the economy in the early years of the new century seems to have fallen apart. The disastrous performance of stocks of technology companies at Nasdaq, the slow increase in electronic-commerce sales of virtual stores and the difficulties of portals to generate revenues have produced a general bad feeling about everything related to the Web.

A study carried out by Forrester Research, a company focused on identifying and analyzing new tendencies in technology and their impact on business, has shown that the American economic crisis of 2001 and the problems presented above have not discouraged senior executives in the USA from joining electronic business between companies, also known as Business-to-Business, or B2B. While 85% of executives state that one of their top priorities is to find a way to work closer to their business co-partners and clients, 38% classify such integration strategy as vital to the health of their business.[9]

Business-to-Business is the electronic-commerce segment with the highest potential growth in the world, according to the analysis of research institutes specialized in the Information Technology segment. Such tendency is

being confirmed by all studies published by leading research institutes. International Data Corporation, IDC, has revealed that the amount of transactions made by corporations by means of e-commerce solutions should increase from US\$ 282 billion in 2000 to around US\$ 4.3 trillion in 2005, which represents an average yearly increase of 73% in this period.[10] As stated by the Gartner Group, an American research institute, Business-to-Business will represent, in the next three years, 7% of the global economy, or something around US\$ 7.3 trillion.[14] Although growth estimations for B2B vary significantly among the several research institutes, depending on the assumptions adopted, all of them confirm such increase tendency.

According to Jupiter Media Metrix, the automotive industry will have an essential role in the growth of e-business. The institute says that, by 2005, almost 50% of Business-to-Business transactions in the automotive sector will take place online.[11] The institute also states that other segments that should present significant growth are Computer Science, Telecommunications, Chemistry and Defense.

This same tendency has been noticed among Brazilian companies. According to a poll conducted by IDC in 2001, from the total number of companies questioned that still did not have a site in the Internet, 57% of them intended to create one within the next twelve months.[8] In large companies from different segments, although their total Internet-generated revenues were not greater than 2%, they expected to double such number in the year 2001. To 27.5% of the poll's participants, the integration of their business with the Internet is among their top three priorities, since this process represents a means of supporting sales and communications with clients. The financial sector has placed such integration as its first priority.[8]

According to a study carried out by Fundação Getulio Vargas, a Brazilian research institution focused on economy, and by the Giga Information Group, an international consultancy firm devoted to the Information Technology field, Brazil is ahead of other Latin-American nations in the development of electronic commerce. They have noticed, however, that the participation of companies in e-commerce is still low: 1.18% in Business-to-Business transactions and 0.35% in Business-to-Consumer transactions. In some specific segments, such as online banking and the automotive industry, Brazil is among the best in the world. The above

institutes highlight bank Bradesco and Volkswagen as prominent examples. The latter is currently performing 90% of its transactions with suppliers and dealers online.[2]

## **2. The Government Encouraging B2B in Brazil**

Aware of the importance of Business-to-Business, the Brazilian government has created, in 2000, the Electronic Commerce Executive Committee, which works primarily as an interface between public and private sectors. The public sector is represented by the Ministries of Finance, Foreign Affairs and Communications, as well as Anatel – National Telecommunications Agency, responsible for implementing the national policies in the telecommunications field and for regulating corporate activities in the segment. The private sector is represented by the Brazilian Federations of Industry, Commerce, Transports, Agriculture and Exports, the Brazilian Federation of Bank Associations, Software Associations, and a representative of the scientific community, among others. The Committee's main goal is to understand and speed up the development of electronic commerce in Brazil.

The Electronic Commerce Executive Committee is constituted by six thematic subcommittees, which, directed by the private sector, are responsible for elaborating and open to discussion the contributions of entities represented in the Committee. Such discussions yield projects and recommendations, which are taken to the competent organisms and result in the revision of norms and regulations, in the adoption of technical standards, etc., apart from the examination of propositions made by the general public. The subcommittees are the following:

- I- Subcommittee on Forms of Payment for Electronic Commerce: infrastructure for communications, forms of payment and security of electronic transactions;
- II- Subcommittee on Logistics and Regional Integration for Electronic Commerce: logistics, distribution, regional access, costs, investments, legislation and statistics relative to transportation for electronic commerce;
- III- Subcommittee on Economy and International Aspects of Electronic Commerce: investments, financing, costs, legislation, statistics, international agreements and intellectual property;
- IV- Subcommittee on Technologies and Products for Electronic Commerce: technologies, products and services for electronic commerce;
- V- Subcommittee on Electronic Commerce for Small- and Medium-Sized Companies.

## **3. The Development of B2B in Brazil**

The consultancy company KPMG estimates that Business-to-Business will represent US\$ 60 billion in the next three years in Latin America only,[14] and a study

made by Serasa, one of the largest companies specialized in economic, financial and registration analyses and information in the world, assures that virtual deals among Brazilian companies will also increase to rates above 50%.

According to the e-commerce manager of Microsoft in Brazil, the B2B market in Brazil in the next four years will be of over US\$ 50 billion. Around 70% of the companies assure they intend to invest in this segment. An example that this segment is undergoing a good moment was the recent creation of the Springer marketplace. Springer is the largest manufacturer of air conditioners in Brazil. Even with the Brazilian energy crisis, at the end of the year 2001, combined with the global situation, the company has decided to invest in the online segment, creating a marketplace and trusting on increasing sales of its products during the Summer.[14]

The development of Business-to-Business is being pushed forward by the need to reduce costs, increase efficiency and establish a closer contact with suppliers and sales channels. It is also a consequence of the establishment of a new business culture based on trust in the electronic media. However, vital questions such as the existing technology, the integration of Web environments with current systems, the means of communication, the effective transactions among different groups of suppliers, distributors, clients and the government, as well as long-established corporate policies tend to restrain the progress of electronic commerce. According to the poll by Jupiter Media Metrix, leading companies are convinced that B2B portals are useful, but they do not make deals through the Web because their providers still do not take part in large corporate marketplaces. 60% of purchase agents claim that the main obstacle to online shopping is that their preferred providers do not work via the Internet, and 55% of them say that lack of knowledge about online markets prevents them from entering such markets. To 45% of them, lack of trust is the second most common reason to explain the slow increase of Business-to-Business transactions. Favoring the development of B2B, 71% of the participants mention cost reduction as the main benefit of online commerce, while 56% mention fast search for products.[13]

The strong competition in Business-to-Business and the high costs of the technology involved have jeopardized the survival of many companies in this market. By means of partnerships with firms specialized in the different types of technology that integrate electronic commerce, it is possible to obtain high-quality technology and services, assuring system integration and commercial quality in the procedures of acquisition and distribution of goods and services. Examples of such partnerships include: full e-procurement services, purchase management, development and maintenance of supply agreements, technological platforms for electronic commerce via the Internet, management of means of payment, logistical managing, delivery tracking, consultancy in corporate credit and financing operations, and services of authentication, validation and payments through the Internet. To Jonathan Gibs, researcher at

Jupiter Media Metrix, independent online industrial marketplaces must seek to be acquired or to join greater companies in the regional B2B scenario to avoid the risk of being left behind in the competition. Gibs highlights three potential partners for an independent online marketplace:[1]

- Large offline agents in their respective industrial sectors, to which the independent companies may act as an online channel;

- Large B2B portals supported by several companies in a particular industrial sector – the so-called ISM, Industry-Sponsored Marketplaces;

- Subsidiaries of large corporations.

A successful example of Gibs' suggestion is Webb Negócios Online ([www.webb.com](http://www.webb.com)), a Brazilian initiative taken by an enterprising group with great ability to attract partners. In order to offer high-quality technology and services, assuring system integration and commercial quality in acquisition and distribution procedures, it has established partnerships with leading market companies in different segments.

Another example worth mentioning is Agrega, a portal jointly developed by AmBev, a large Brazilian beer producer, and Souza Cruz, the greatest cigarette manufacturer in Brazil. The high costs of implementation, maintenance and update of B2B solutions have taken these companies to share one same sector of acquisition of indirect goods and services.[6] Agrega works in the provider end, integrating the value chain of the companies involved only with the purchase of MRO (Maintenance, Repairs and Operations).

Traditionally, purchases of services and indirect materials were left to a second plan in most companies. This treatment can be explained by the low strategic importance involved in such purchases due to the diversity of items involved and the lack of technological tools that allowed dealing, at a relatively low cost, with such complexity. With the advent of the Internet and the development of e-procurement tools, this whole process can now be implemented at a relatively low cost, by means of introducing e-procurement solutions connected to marketplaces in the Internet. On the other hand, despite the rationalization and elimination of paperwork, and of the increase in the base of suppliers allowed by this technology, it does not replace the purchaser's task of identifying and characterizing the demand and, from it, establishing the best acquisition strategy. Concerning strategic business such the supply of raw materials for beer, or tobacco to manufacture cigarettes, it is the responsibility of the companies and cannot be the purpose of the portal.[5]

Agrega's whole operation is performed through an outsourcing system with Tradecom, a developer of solutions for electronic commerce in the Business-to-Business segment focused on developing, managing and operating horizontal and vertical, open and close marketplaces, providing Agrega a secure operation, access to state-of-the-art technology and know-how on the business. The alliance with Tradecom allowed Agrega

to reduce the time to become operative and to focus its attentions on its purchase systems.

#### 4. Financing B2B in Brazil

The need for sites in the Web that offer financing for working capital, projects, purchase of machinery, accounts receivables or any other type of enterprise that require credit, has led to the creation of portals that concentrate banks and financial institutions. The purpose of such portals is to offer, through the Internet, an easy and secure system for the several financial institutions to analyze credit requests and offer financing rates to companies by means of a single register file.

One of such portals is Multivalor ([www.multivalor.com.br](http://www.multivalor.com.br)). It offers companies free consultancy in credit operations to finance working capital, projects, purchase of machinery, accounts receivables, etc. to help them find the financing best suited for their reality.

Through Multivalor, a company can access 16 financial institutions with a single registration, receive credit proposals and choose the one which offers more advantages. As partners, the portal concentrates in a single site 14 banks and five small-credit institutions that provide the company their financing options and rates. The banks include BBV, BVA, Cacique, Citibank, Santander, and Emblema, among other. Among the institutions and companies that are clients of Multivalor, we can mention Unisys, João Fortes and Ipiranga.

The products offered include:

- Transfer of accounts receivable, where the Provider (Transferer) can transfer discounted receivables of large companies;

- Financing to clients in which any provider of equipments in general that wish to obtain financing to its clients can register such requests in Multivalor and access several financing products (CDC, Leasing, FINAME – Industrial Financing Program – and Working Capital), rating the operation with several banks at the same time.

The National Bank for Economic and Social Development (BNDES), a public company associated to the Ministry of Development, Industry and International Commerce, has recently made R\$ 300 million (around US\$ 100 million) available to an initiative for the creation of a credit card and online operations for small- and medium-sized companies. Bradesco, the second largest Brazilian bank; Visanet, company in charge of the relationship with commercial institutions affiliated to the Visa System; ABRAS, Brazilian Supermarket Association; and Visa do Brasil are its partners in this enterprise.[4]

The portal, which is being technically supported by Scopus, a company owned by Bradesco, and by Visanet for issues concerning the capture of credit data, was launched in late September of the current year. According to BNDES' Director of New Products, the initiative of creating a credit card financed by the entity to serve small

and medium companies was under study for at least 18 months. The consolidation of the Internet and electronic commerce have accelerated their decision to provide online credit.

The credit limit to the companies will be of R\$ 50 thousand per client. The BNDES card will be similar to any other credit card. Suppliers will receive the value of the sale 30 days after the operation and will be discounted a tax of 3%. The buying companies will have their limit studied – BNDES believes that the average limit will be around R\$ 20 thousand, not necessarily spent on a single purchase – and will pay the financing agent that issues the BNDES card in 12 fixed installments with monthly interests of around 2%.

Although trusting the electronic commerce initiative, BNDES estimates that over 90% of the transactions will be made by telephone. “The culture of online business still does not exist in this category of small- and medium-sized companies.”

In the first stage of the project, the beneficiaries will be supermarkets. The President of ABRAS, says there are potentially 16 thousand companies in this sector that might benefit from the BNDES card. They have difficulties obtaining credit and may now, by means of their suppliers or by Bradesco, have access to this credit line through the portal, which provides a simpler and less bureaucratic model.

BNDES expects, by October, to expand the portal and the credit card to sectors such as the shoe industry and especially that of components for production, health and education.

## 5. E-Government Solutions in Brazil

In May, 2000, the Brazilian government passed the Fiscal Responsibility Act.[7] It sets sanctions to Public Administrations that spend more than they collect, forcing them to manage their cash more efficiently and to show more transparency in their purchase procedures.

The use of the Internet will help the national, state and municipal governments to do so, making it easier to observe the restrictions set by the new Act.[15] The Internet also increases the competition among suppliers that take part in public biddings, apart from eliminating intermediates. With these gains in efficiency, an economy of up to 35% in the costs is expected, an amount that can be employed in benefits for the population.

Several public agencies are also already using the Web to make acquisitions, publish information on biddings, provide services and communicate with the population. Since, in some situations, the time needed to offer these services is limited, some of these sites are employing an ASP (Application Service Provider), which provides the development, customization, implementation and operation of the system, without requiring the agencies to invest in hardware, software or human resources.

An example of an e-Government solution is the one provided by Webb Negócios Online ([www.webb.com.br](http://www.webb.com.br)). This company provides a complete solution to public agencies that wish to relate with their commercial

partners and the society in general. This relationship is built by means of a special portal that allows publishing information and performing purchases quickly and efficiently.

The solution presented by Webb was named Governo@Webb. This solution is formatted according to the legislation on biddings and is hosted in a data-processing center with the highest security resources, assuring a fast implementation of the electronic-commerce project in public administration. By hiring the solution Governo@Webb, public agencies are free from the high investments for the construction and acquisition of an electronic-commerce platform.

The resources presented by the solution Governo@Webb include:

- Electronic catalogue: a tool that allows the public agency to, among other functionalities, register buyers and manage suppliers, add and approve purchase requests, control user access and register all of its acquisitions.

- Electronic auction market: a tool that allows the public agency to create and manage electronic auction markets, apart from obtaining minutes and registers of all acquisitions made.

- Message board: a tool that allows the public agency to publish news and information relative to public biddings, including calls, minutes and norms, as well as providing downloads and customized news via e-mail to assistant suppliers. The message board also includes an e-mail tool that allows suppliers to contact the Purchase Department of the public agency.

- Cataloguing and catalogue upload: the cataloguing service consists in creating a hierarchical navigation tree that better responds to the needs of the public agency. After the structure's design, the products are inserted in their respective categories.

- Registration of the approval workflow: a workflow is the purchase-approval flux within the public agency, built as a sequence of requests and approvals of the electronic catalogue. The use of the approval workflow assures total control over the acquisitions and the purchase limits of each user in the agency.

- Broad and detailed training offered by Webb to the main user in the public agency. The training seeks to present the main user his/her role in managing the purchase portal, making him/her able to carry out all management functions, such as registrations, user permissions, maintenance, etc.

- Technical support: this service offers the public agency support to clarify user doubts. For such, Webb provides a support center to solve technical doubts and deal with operational problems of the portal, offering attendants specialized in each solution. The support center can be accessed at any time by the main user of the public agency

Several Brazilian cities have already subscribed to this initiative, such as Campina Grande, in the state of Paraíba; Juiz de Fora, in Minas Gerais; Florianópolis, in Santa Catarina; and Jundiá, in São Paulo. In the case of

Campina Grande, the government has obtained, among other results, a reduction in the costs of internal procedures, due to the automation of administrative activities; a reduction in the time spent in purchases, such as using telephone, fax, and processing the requests; and uniform purchase guarantees within the established regulations.

## 6. Solutions of Private Companies in Brazil

Some of the largest corporations in the field of consumer goods, such as Pão de Açúcar, Procter & Gamble and Santista Alimentos, and means of production, such as Aventis CropScience (agribusiness) and GE Polymerland (plastics), are investing in their own sites while waiting for the consolidation of market portals (e-marketplaces) and the standardization of electronic data transmission technology, which should congregate several suppliers and buyers from specific segments, obtaining cost reduction and an increase in supply-chain efficacy.

Grupo Pão de Açúcar is a Brazilian retail market leader, with 443 stores in 11 Brazilian states. In February 2000, it launched pd@net, a Business-to-Business portal for suppliers of the group. Their strategy to attract users focused on small and medium suppliers in the state of São Paulo, which represent 80% of Pão de Açúcar's purchases. Today, 97.4% of the group's purchases to its 2,500 suppliers in São Paulo are made through the portal. The most significant results include a reduction in the time spent by the purchaser to make the order: it took an average of 30 minutes by telephone, but only 10 minutes through the Internet. This represents a monthly economy of over 6,000 working hours. Time was also saved in the verification of receipts: before, it was done in 5 minutes; now, in 1 minute. Apart from electronically exchanging all information relative to the purchase procedures, pd@net has brought other functionalities, such as access to information on the performance of each supplier's products in each of the group's stores. Thus, if the sales of a given product are not fulfilling the expectations, the supplier can know this in real time and change its strategy for that store. By the end of 2001, Pão de Açúcar had finished the implementation of the pd@net system, allowing 6,000 suppliers to converge into it.[3]

Since September 2001, the Pão de Açúcar group is coordinating, together with the French group Casino and the Dutch group Royal Ahold, the Latin-American implementation of Worldwide Retail Exchange (WWRE), the largest electronic marketplace devoted to the development of collaborative commerce and supplier relationship.

Another example is the sales portal launched by Procter & Gamble, owner of popular brands in several segments (Ariel, Pampers, Hipoglós, among others) supplied by means of around 20 distributors to almost 300 thousand small- and medium-sized points of sale, and 300 large direct clients. The portal employs technology already globally adopted by the group and represents an investment, in the Brazilian division, of

US\$ 250 thousand, being directed to scattered clients. All clients of the company will be able to access the portal's contents, but the sales policies by means of distributors will be maintained, as well as the EDI (Electronic Data Interchange) for the large clients who do not wish to migrate to the new solution. According to the Logistics and IT Director of Procter & Gamble do Brasil, the portal is a channel for relationship and communication, as well as a low-cost, good-performance option for small and medium retailers to integrate in electronic commerce, reducing supply-chain costs.[16]

The company expects to obtain an economy in the sales procedures of R\$ 1 million per year as of 2002, having commercialized around 35% of the total volume via the Internet by the end of the year 2001.

A third example of a successful solution is the portal of Santista Alimentos, one of the largest food companies in Brazil. Santista Alimentos is market leader in margarines and cake mixtures, wheat importing and milling, and the production of flours for domestic, industrial and bakery purposes. It also has leading positions in pastas, mayonnaises, beverages and desserts. Its portal was developed to replace EDI in its communication with the approximately 90 transporters employed by the company. The first idea was to use the Web EDI through the same VAN (Virtual Area Network) that provided the management. Due to the high cost of the VAN and the need to provide support to the applications used by the transporters, the company opted for developing its own solution. All the actions were reproduced in the portal without any additional cost, allowing the integration of even the smallest transporters. Today, all transporters are using the portal.[16]

The good results with the transporters made the company move to the second step: integrating, through the portal, the 28 distributors that used to make their orders by fax. This was the only section that required integration, since the company's sales force was already automated by means of palm tops connected to the internal system. The distributors, on the other hand, had to undergo troublesome procedures to insert their orders in the system, which represented high costs and errors. Soon, the company will join the automation and integration system of the Bunge group, which congregates, apart from Santista, other large companies in the food sector, such as Ceval and Seara.

## 7. E-Marketplaces in Brazil

The marketplace offer is divided into environments based on product cataloguing tools and auction markets. While the electronic cataloguing environment provides a standardized list of supplier products and commercial conditions so that buyers can perform quotations and make orders, the auction markets are based on an electronic sales negotiation tool which allows total dynamism between sellers and buyers in the negotiation of a single type of product or service. These auction markets are developed according to a market opportunity or demand. An important example are the Energy

Marketplaces, developed during the electric-energy rationing, occurred between May 2001 and February 2002. These marketplaces consisted of a compensation system for electric-energy consumption goals created to support small, middle and large companies during the energy crisis period. By means of the Energy Marketplaces, thousands of companies were able to commercialize their energy quotas through electronic auctions.

The most expressive examples of Brazilian e-marketplaces include Mercado Eletrônico, the second largest Brazilian B2B portal in volume of transactions; Genexis, a portal that integrates all companies and service providers related to the health sector; and Webb Negócios Online.[12]

Mercado Eletrônico ([www.me.com.br](http://www.me.com.br)), created in 1994, was the first Business-to-Business portal that offered purchase solutions through electronic media to medium- and large-sized companies. A pioneer and leader in e-procurement via EDI (Electronic Data Interchange) in Brazil, Mercado Eletrônico has recently received capital to take its operations and contents to the Internet, provided by the GP Investimentos group, an investment corporation founded in 1993 by Companhia Cervejaria Brahma (now AmBev), Banco de Investimentos Garantia (now CSFB Garantia) and by the investment fund CVC/Opportunity, an association of the banks Opportunity and Citibank operating since 1997, one of the largest private funds in Brazil.

Mercado Eletrônico is one of the leading companies in business volume in Latin America. The portal promotes 17 thousand daily transactions, connecting around 300 buyers to 30 thousand registered suppliers. It now operates also in Latin America, by means of a partnership with the portal Senegocia.com, one of the leader B2B companies in Latin America. Senegocia started operating in April 2000, and today counts with over 10 thousand companies, among buyers and suppliers. Senegocia is installed in Argentina, Peru, Mexico and Brazil.

Mercado Eletrônico has a complete commercial-information management system, with solutions integrated to the ERP (Enterprise Resource Planning) systems of companies that wish to maximize their purchasing efficiency. This allows the company to define system parameters, quotation format and report generation, also operating as a CSP (Commerce Service Provider), offering its transaction platform for quotations and request by its clients. Mercado Eletrônico also provides an access option by means of the Web portal, without the need for local adaptation or implementation.

The Genexis portal is the result of a fusion between SSI, a company associated to the e-procurement field, with six years of experience capturing requests by distributors and making connections with laboratories, and Healthlink, a health portal that relates health operators and registered doctors. The portal integrates all companies in the health sector, such as manufacturers, distributors, retailers and hospitals, as well as service providers, such as labs, doctors, etc. Through the portal, the professionals can execute all transactions, accessing

information, buying and selling products and materials, performing online procurement quotations, and processing documents and refunds.[17]

Genexis is divided in two segments: Health Products, which comprehends laboratories, distributors and hospitals, among others, and is the responsibility of the Genexis company, and Health Services, composed by health plans, clinics and medical assistance, responsibility of Healthlink. The company was created in 1994, offering connectivity to wholesalers by means of the EDI system. In 1997, it started the Internet operation and, in 1998, electronic commerce. Currently, Genexis acts in 124 active points of sale in Brazil.

The Energy Marketplaces, developed during the energy-rationing period consisted of a compensation system for electric-energy consumption goals. By means of the Energy Marketplaces, thousands of companies were able to commercialize their energy quotas through electronic auctions operated by Webb Negócios Online. Webb implemented and operated Energy Marketplaces in five Brazilian states, together with concessionaries Cemig, Light, Celg and Sistema Cataguazes-Leopoldina (CFLCL, Energipe, Saelpa, Celb, Cenf).[18]

The Energy Marketplaces have effectively contributed for a better distribution of electric energy consumption, providing great help to the means of production of companies of all sizes and several segments. The success of this initiative can be observed in the results obtained: 1,600 registered companies, 1,300 electronic auctions operated, and 14 million Kwh/month traded.

Although the energy rationing is over, the Energy Marketplaces will resume their operation, since the Brazilian electric-energy market is undergoing deep structural change and it has been defined that the energy of national and state public plants that will be free from initial contracts as of 2003 will have to be commercialized by means of public auctions.

## 8. Conclusion

This paper was meant to present a brief report on the development of Business-to-Business in Brazil. Similarly to what is occurring in more industrialized countries, this segment of electronic commerce is the one presenting the highest growth rate in our country. Today, Brazil is ahead of the other Latin-American nations; however, the number of companies that have adhered to electronic commerce is still low.

The support provided by the Brazilian government in the creation of the Electronic Commerce Electronic Committee, in a joint effort with the private sector, has clearly shown the importance given to this new segment of commerce. The actions of this Committee in perfecting norms and regulations, as well as technical standards, will be crucial for the expansion of Business-to-Business among Brazilian companies.

Companies that use Business-to-Business have not only managed to reduce their costs, but have also demonstrated more efficiency in their operations. Examples such as Agregã, a portal jointly formed by

AmBev and Souza Cruz, and that of the Pão de Açúcar group, clearly express the benefits that can be gathered by companies with the introduction of Business-to-Business in their activities.

This work have also shown that the governmental sector can obtain great benefits with the implementation of Business-to-Business. The use of one of its tools, the electronic catalogue, allows a better management of public accounts, providing more transparency in the purchase procedures and yielding a reduction of costs with personnel and communications.

Financing policies to Business-to-Business have also progressed significantly. Recently, the National Bank for Economic and Social Development, BNDES, has launched a credit card destined to small- and medium-sized companies supported by Bradesco, Visanet, Visa do Brasil and the Brazilian Supermarket Association.

Finally, this work has outlined the development of e-marketplaces, created as a consequence of market opportunities or demands, and their contribution to the expansion of business opportunities to suppliers and price reduction for the acquisition of goods to buyers. Examples of successful e-marketplaces, such as Mercado Eletrônico and the Energy Marketplaces, developed by Webb Negócios Online, demonstrate the benefits of e-marketplaces.

New creative solutions, adapted to the conditions of the Brazilian economy, appear every day, demonstrating the immense possibilities of Business-to-Business. Thus, we can conclude our work stating that this new form of corporate business has come to stay.

## Abstract

This study contends that the low rate of e-marketplace acceptance by Asian firms cannot be fully understood without analyzing the context within which technology is exploited. Current IOS (Inter-Organizational Systems) studies emphasize the removal of barriers to e-marketplace acceptance in relation to technological, organizational, and inter-organizational factors. However, the contextual influences of IOS are largely ignored. We highlight three levels of contextual influences – structural, national/regional, and socio-cultural – that shape the adopters' expectation of e-marketplace applications in three Asian regions (India, Taiwan, and China). Our study formulates arguments that attempt to flesh out the constraint of context as one of the most significant, but often neglected, dimensions of e-marketplace acceptance.

## 1. Introduction

There has been a rising interest in using e-marketplaces (electronic marketplaces) to enable closer B2B (Business-to-Business) collaboration. Nonetheless, the widespread e-marketplaces have not been adopted readily into companies in Asia. The study is an initial attempt to explore the reasons for the non-acceptance of e-marketplace in inter-organizational contexts situated in a different cultural setting.

An e-marketplace can be defined as a platform that uses the Internet to enable buyers and sellers to conduct inter-firm trading [3]. There are three generic forms of e-marketplace [8]: (1) industry-based (i.e. vertical) or product-oriented (i.e. horizontal) e-marketplaces backed by founding members, (2) private e-marketplaces, usually formed by a single buyer or supplier, to link up their business partners, and (3) public e-marketplaces that are set up by neutral third party, known as "Net Market Makers", to facilitate business transactions for their participants, with their revenue coming from subscriptions and transaction-based fees.

Although e-marketplaces can reduce transaction costs, improve process efficiency, and enable virtual collaboration among partners, market analysts have reported that the majority of them have either closed down or are facing difficulties in attracting buyers and suppliers [21]. Recent reports, though somewhat limited, have shown that sole reliance on the application of the US business models in Asia is a recipe for failure [4][8][19][23].

The present study seeks to highlight the limitations of

a technical-economic view of e-marketplace adoption [2][18]. It explains how contextual forces that have shaped Asian businesses play an important role in the adoption of e-marketplaces.

## 2. Barriers to the acceptance of e-Marketplaces

Three broad categories of adoption barriers have been identified in current literature: technological, organizational, and inter-organizational [11][16][25]. Technological barriers are concern with technological complexity. For example, the adoption of e-marketplaces requires effective the use of external network technologies. As security technology is still at an embryonic stage, transaction risks are endemic. Other major technological challenges include system integration, software migration, data conversion, and the compatibility of hardware and software between partners [19]. For most adopters of e-marketplace, the sheer complexity of technological problems can prevent them from accepting the new technology.

A common intra-organizational inhibitor is the lack of sufficient training and education in the technologies involved. Furthermore, the adoption of e-marketplaces often requires companies to redesign their internal business processes, if the technologies are to be used effectively [5][20]. But this is not easy, especially when operations are deeply bound by different technologies in different organizations. Lee and Clark [20], for example, explore two failed attempts to introduce electronic exchanges into the potted plants and fresh meat sectors. They explain that the ineffective integration of product and transaction flow, which caused inconsistent purchasing quality, was a major cause of such failure. Clark and Stoddard [5] also point out that a key adoption barrier is to exchange marketplace data among organizations in transaction and replenishment processes. They explain that new technologies break old routines and the keepers of the old routines often resist, usually because they have to master new socio-technical skills that are imperfectly realized and barely understood in relation to existing ways of doing things.

Inter-organizational barriers often arise from the factor of power and trust [1][11]. For example, in a case study of Ford Motors [27], the company was in a strong position to instigate the use of electronic procurement with its suppliers. However, its attempt to exercise coercive power over suppliers (e.g. through the transfer of

investment costs to them) resulted in adopters' resistance. Trust factor is another barrier. There are two aspects of trust: competence trust, which is concerned with a partner's ability to perform according to expectations, and intentional trust, which refers to a partner's intention not to defect from its collaborative party [24]. For instance, Hart and Saunders [11] analyze a retail company and show that asymmetry of product information-sharing among partners may lead to distrust of the market makers' competence, leading to adopters' abortion from the e-marketplace. Allen et al. [1] investigate an unproductive e-marketplace called TransLease (designed for automobile insurance) and explain how mutual distrust in intention arose among buyers (lease firms) and sellers (repair agents), stemming from both parties' conflicting goals. From a cognitive perspective, Barrett [4] explains why adopters (brokers and underwriters) feared the uncertainty and job security brought about by the London Insurance Market, where distrust emerged as a result of adopters' negative interpretations of the technology's intention.

One important matter overlooked in current investigations is the role of context, not only as a cause of inaction but also as a key factor involved in the production of barriers [2]. In this view, barriers to the adoption of e-marketplaces may derive from institutional contexts, including structural, national/regional, and socio-cultural aspects (categories which are not mutually exclusive).

Structural constraints are key adoption barriers in the adoption of e-marketplaces, especially in many developing countries in Asia. For example, the ineffective infrastructure in telecommunications, financial systems (e.g. electronic payment systems), legal and regulatory systems (e.g. taxation), and the logistics systems (e.g. transportation) will inhibit the adoption of e-marketplaces [21].

Barriers to e-marketplace applications cannot be fully appreciated without also understanding the challenges that stem from national and regional contexts. This point is underscored by a study that examines the adoption of e-marketplaces in Cyprus [2]. As the basis for a national agenda to transform small-sized enterprises into flexible, specialized organizations, the Cyprus government initiated a major industry restructuring. Avgerou [2] examined the introduction of three consortium-based e-marketplaces in the furniture industry. In spite of the existence of sufficient technological and financial supports, the furniture manufacturers aborted the use of these systems. As such, this failure should be seen in broader national and regional contexts.

Historically, Cypriot firms had moved from mass production to mass customization in order to pursue niche market, using the strategy of flexible specialization. However, the e-marketplace had been designed for volume transactions (mass production). Using it in the context of complex transactions (mass customization) was inconvenient. Moreover, the entrepreneurs were family owners, who understood their craft, suppliers and markets well, but were not at ease with e-marketplace. Hence, it

was not possible for them to incorporate such systems in their existing operations. The owners neither had the skills to incorporate the system nor did they have the desire to make the changes. They would have had to reconfigure their customary business models and introduce professional managers into most of the family-owned businesses. This would mean asking entrepreneurs to relinquish power and undertake radical organizational transformation. These developments were all contrary to the entrepreneurs' expectations in adopting e-marketplaces, and the project ultimately failed.

The third impact of socio-cultural constraints on adoption failures may be illustrated in the case of the failure of SPRINTEL [18]. SPRINTEL was an e-marketplace designed for the textile trading community in Prato (near Florence, Italy). In spite of the provision of sound technical and economic solutions, Prato's traders did not accept the e-marketplace. In contrary, it developed distrust among traders. The distrust, which became the basis for resistance to the system, was not rooted in technical failures of the system but from Prato merchants' socio-cultural concerns.

Historically, Prato's traders had established an industry network formed by business communities that trusted each other. Their social relations were embedded within economic activities. Traders saw little value in having exchange systems that enabled faster and more reliable transactions. Prato's traders also preferred "high-context" communications (e.g. face-to-face encounters with rich body expression), and were worried that an e-marketplace might disable these preferred social interactions. Additionally, we need to appreciate that these Prato traders did not regard maximization of profit as the only purpose of business; rather, people participated in business as one important way of socialization. Moreover, these Prato traders were concerned that an e-marketplace might reveal the existence of redundant inventories, which, in their cultural context, would mean a public confession of business incompetence. Participation in a more transparent system would mean that not only other traders would know one's affairs; so would the tax authorities. The traders were worried about the impact of disclosing information about their *sommerso* (underground economy activities), such as tax evasion, in a cultural context where tax payment is seen as fair game.

While technology is typically thought of as a thing, as an entity, it is evident that for the traders of Prato it was a social relationship. The SPRINTEL study highlights the fact that technology acceptance is not based merely on technical excellence and economic gains. People do not communicate the meaning that they attribute to a technology individually, but collectively, in a common sense making. The SPRINTEL case clearly reveals that distrust resulted from the technology being interpreted negatively as a result of the socio-cultural context into which it was introduced.

Research into contextual influences offers a useful lens when examining technology adoption that involves cross-cultural transfer. Adopters' social expectations of

technology use are shaped by the context within which they normally operate. When researchers investigate the adoption of e-marketplaces in differing social, cultural, and geographical contexts, the conception of technology as a variable whose inherent capabilities premise its adoption becomes quite limited. The constraining role of context is significant in understanding the origins of resistance to technology adoption within organizations.

### 3. Research Methods

Our research took place in Commerce One (one of the leading vendors of e-marketplaces). The company had realized that their Asia headquarters were facing a major adoption challenge that had not been foreseen in terms of the marketing strategy adopted from the US headquarters. The US strategy promoted the benefit of cost reduction and process efficiency, but it did not seem to work in Asia. In spite of the company's marketing efforts, the level of acceptance remained low. With the help of the company, our pilot study involved three of their country portals (disguised name) – IndiaMarket (in India), TaiwanMarket (in Taiwan), and ChinaMarket (in China). The first author interviewed more than 50 key participants over a 16-month period (from January 2001 to April 2002). The data were mainly based on personal interviews with technology providers and adopters. Extensive field notes were taken during and immediately after these interviews. In this paper we report our preliminary findings concerning the contextual constraints that persist in e-marketplace adoption in Asia.

The approach to data analysis that we adopted is one that relies upon the contextualist perspectives [2] and cross-cultural transfer of technology [18]. An important analytical aim is to examine how the different contexts of solution providers and potential adopter influence the adopter's expectation of e-marketplace use.

Three theoretical angles were used to guide our field interviews and investigate the non-acceptance reasons in each site. In IndiaMarket, we examined the structural context and highlighted the impact of India's complex taxation systems on e-marketplace adoption. In TaiwanMarket, we turned to the conditions shaped by the national and regional contexts. We explored how industry migration in Taiwan had gradually shifted Taiwanese adopters' expectations of e-marketplaces. In ChinaMarket, we explored the extent to which the theory of Chinese Relationalism informed a different cultural pattern of business practice, in contrast to Western (Anglo-American) models of commerce. Understanding the extent to which such a pattern constitutes a different frame offers valuable explanation of the underlying resistance to e-marketplace systems in the Chinese trading community.

The three stakeholders in the e-marketplace studied consisted of buyers, sellers, and NMMs (Net Market Makers, see Figure 1), the latter as information intermediary. NMMs provide two important services to participating members. First, they offer a technological

platform for both buyers and sellers to conduct product search, procurement, auction and transaction. Secondly, NMMs offer physical value-added services to fulfill business transactions, including product content management, business intelligence, financial payment, logistics, and shipping inspection. To sustain revenue, NMMs normally charge buyers and sellers a subscription or transaction fee for their services. Alternatively, other NMMs assist adopters in installing their own proprietary e-marketplace systems by charging consulting and software licensing fees. The common goal of NMMs is to achieve a critical mass of adopters so that they can collect enough subscription fees to sustain their services. To achieve this, a common adoption strategy is to recruit large buyers and attract the associated sellers. The value proposition for buyers, offered by these three NMMs, is to access more sellers (suppliers), gain best price advantage and streamline supply chain processes.

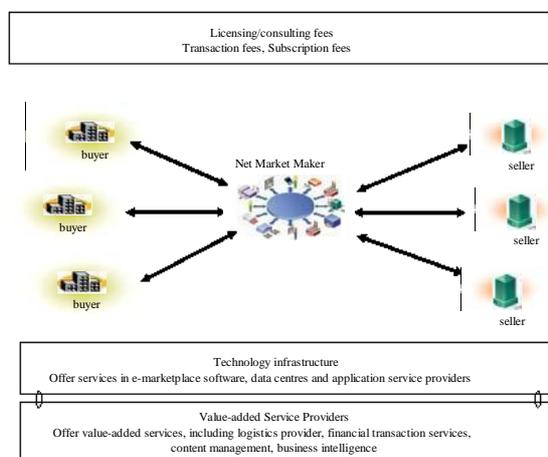

Figure 1. The Function of a Net Market Maker

NMMs had a crucial role to play as brokers, in whose interests the spread of adoption would be hastened. Yet, upon the completion of our fieldwork, most adopters had not fully adopted e-marketplace solutions, despite the actions of both Commerce One and the NMMs as providers of solutions that involved the adoption of the e-spaces on sale. The potential adopters were less concerned with technological problems, process integration, and inter-organizational trust, as emphasized in the IOS literature. Although adopters reported common constraints imposed by the public infrastructure (such as poor telecommunications and electricity provision), they seemed to worry more about the crises arising from their local contexts. We came to recognize the importance of seeing these adopters' resistance to e-marketplaces as something that required careful consideration of the influence of contextual conditions. A summary of the three cases is shown in Table 1.

Table 1. Description of Cases

	IndiaMarket	TaiwanMarket	ChinaMarket
Background	A project seeking to business opportunities in light of Indian government's IT Bill.	A quasi-government project helping Taiwanese manufacturers to integrate supply chains with MNC.	A government initiative to prepare for WTO entry.
Time of launch	May 2001	March 2001	May 2000
Technological Platform	Commerce One's e-marketplace systems: e-procurement, e-auction, and order management.		
Value added services	Change management, telecom infrastructure, logistics, Credit-rating information services, business surveillance, pre-shipment inspections, and financial payment.	Data center, hosting services, technology integration, financial transactions, business intelligence, product catalogue management.	Financial transactions, technological infrastructure, logistics, and Digital certification.
Adoption strategy	Buyer-led adoption: targeted at 50 major buyers in India.	Buyer-led adoption: leverage on a government initiated project for computer industry; aiming to recruit key buyers as shareholders.	Buyer-led adoption, government initiated: focus on state-owned exporting companies in ten key industries.
Focus of analysis: contextual constraints	Structural constraints (especially taxation issue).	National/regional contexts (Industry migration).	Socio-cultural context (Guanxi networks).

#### 4. Findings: Unearth the Contextual Influences

##### 4.1 IndiaMarket case: Taxation Dynamics

Not until the late 1980s, when the government realized the futility of shutting India off from the rest of the world and started to liberalize the economy, by opening up the Indian business community to international competition. Faced with this challenge, Indian businesses began to adopt international trade practices. The federal government also introduced an Information Technology Bill in June 2000 with the aim of integrating the fragmented markets that existed among the 30 states comprising the federation, in order to attract foreign direct investment.

By late 2000, Indian's e-commerce appeared to be promising. Large enterprises, such as TELCO, one of the flagship TATA companies, began to sell scrap machinery and manufacturing surplus to partners through e-marketplaces. Increasingly, MICO (a BOSCH subsidiary) also sold fuel injection pump inventory to its

partners over the Internet. Nonetheless, most enterprises still could not afford the cost of either setting up e-marketplaces.

In May 2001 IndiaMarket was incorporated to provide intermediary information services to Indian business communities. It commenced with an early success in the form of the introduction of an e-procurement solution for DCM Shriram Consolidated Ltd., an e-auction for Hindalco (India's largest aluminum producer), and an e-marketplace for Tata International. IndiaMarket's strategic vision was to help Indian enterprises shift their trading relationships to e-marketplaces.

In terms of structural constraints, the lack of sound infrastructure was still the primary barrier to the adoption of IndiaMarket. These explicit constraints included poor infrastructure in financial, logistic, legal and other services in India. In terms of financial infrastructure, Indian adopters reported that most areas still had no efficient inter-bank transaction systems. Issuing a letter of credit could involve as many as seven banks and government agencies. There were also no monitoring systems to evaluate suppliers' credit risks. In terms of logistics infrastructure, there were still few established third party logistics providers. It was difficult to keep track of consignments as well as to maintain reasonable control of traffic in cities. In terms of legal infrastructure, the overburdened legal system presented numerous difficulties when a legal sanction was needed against defaulting debtors. The lengthy legal processes alerted buyers to the problems of transacting with suppliers lacking credentials. Finally, because of poor telecommunications infrastructure, constant power breakdowns were a part of life. The demand for electricity outstripped supply in many industrial cities such as New Delhi and Bangalore.

These were the explicit structural constraints. However, there was one implicit structural constraint that was, perhaps the most serious threat to e-marketplace adoption: India's taxation systems. Adopters doubt whether an e-marketplace can be localized easily to accommodate the complexity of governmental taxation variation. One example of this variation is in the way in which the central and state governments levy taxes. The federal government is empowered to levy central taxes, which includes sales, custom and service taxes. The states levy sales taxes and excise duty based on the value of commodities. Another impediment is the "octroi", a tax on the entry of goods into a local area for consumption, use or sale. The federal government also allows the states to levy taxes on inter-state sales. The effect is the creation, within each state, of a tariff zone where taxes are levied on exports to other states. Even with the ceiling on the inter-state sales tax, the cascading nature of the tax system produces a situation where effective tax rates are uncertain, as tax costs vary with the process of the goods sold.

Consider the following example of an automobile parts manufacturer in New Delhi. Based in state A, when a sales forecast plan was proposed, the company had to pay pre-sales taxes to the government of state A. The company

also had to pay turnover taxes on a fiscal year basis. If the company transported products to state B, it had to pay excise taxes to the government of that state. Any components sold there would also be subjected by the local government of state B to local sales taxes, service taxes, and turnover taxes. The complexity was compounded by the constant variation of the tax structure, in terms of both the rate of tax and the range of taxable items. With components consisting of several hundred parts, putting the mathematics of taxation into a computer program would itself be a very difficult task. Moreover, one should also appreciate that Indian businessmen are always worried about exposure of their various tax-avoidance tactics (this is similar to Prato's case).

The use of e-marketplaces runs against India traders' social expectation in response to the business conventions shaped by those structural conditions. The reasons for non-acceptance of the technology can thus be understood.

#### 4.2 TaiwanMarket: Industry Migration

Before 1998, a hostile political relationship had severely handicapped formal business collaboration. The softening of those relationships encouraged Taiwanese enterprises to extend their manufacturing bases to the major cities in China. Adding to this industry migration was the strategic transfer by multi-national corporations (MNCs) of their regional headquarters to China. For most Taiwanese firms, this could involve the migration of their whole supply chain to China. In the computer industry, for example, Compaq alone procured about US\$85 billions in Taiwan in 2000. If Taiwanese firms did not move with their key buyers, they would soon put their long-established business relationship into jeopardy.

In March 2001, a Taiwanese quasi-government agent, Institute for Information Industry (III) decided to help the computer industry build an e-marketplace to link up buyers (Compaq was the first test site) and suppliers (Taiwanese firms). The purpose was to maintain close collaboration with these key buyers while assisting Taiwanese suppliers to streamline their supply chain operations.

The transformation from domestic to regional operation presented a great challenge to Taiwanese firms. The migration involved not only moving factories and people to China but also managing product designs, strategic sourcing, and supply chain activities across the different regions of China. For example, the relocation of a computer notebook manufacturer required product design engineers in Taiwan to work collaboratively with manufacturing sites in Shanghai and Xiamen. The company often had to hold co-location meetings in order to make sure that products were designed to comply with specification and manufacturability requirements. Face-to-face discussions and conference calls were perceived as trustworthy methods of communication. Moreover, the company had to extend its supplier bases to China, which meant that it had to replace some of its Taiwanese tier three suppliers and to source local suppliers in China for reasons of cost advantage.

The context of industry migration helps us to understand why these Taiwanese firms were not interested in e-marketplaces (presented in the US model) that mainly offered the functions of product search, electronic procurement, and auction. In the context of industry migration, Taiwanese firms' managerial attention was more concerned with collaborative design, strategic sourcing, supply chain management, customer retention, and regional operation. The e-marketplace did not match this expectation and was considered to be of little use.

#### 4.3 ChinaMarket: Chinese Relationalism

In 2000, China faced the challenge of entering the WTO (World Trade Organization). The government sought to transform key national enterprises (such as steel industry) in order to prepare them for the transition from the traditional planned economy to a market economy. To achieve this end, the government agent (The Development Research Center of The State Council) initially planned to construct an unprecedented industrial park, big enough to accommodate ten key business sectors. International traders could visit this industrial park, search products, identify potential business partners, and achieve one-stop shopping.

The establishment of such an industrial park required enormous investments, in terms of money, land, and other resources. Additionally, state planners envisaged that upon completion such an industrial park could result in major traffic problems, the possibility of an increase in criminality through concentrating major commerce, as well as an increased demand for enhanced public services. Thus, from the state perspective, the risks associated with such a project were high. Building a vast incubator on such a scale would also have major socio-spatial implications for the host region.

Eventually, the planners conceived the concept of a virtual business park, incorporated as ChinaMarket.com in March 2000, with the aim of enabling the idea of an e-WTO response (i.e. using electronic means to respond to the WTO challenge). An American model of commerce guided its design.

The launch was not entirely successful. Although ChinaMarket consultants emphasized the benefits of cost reduction, process efficiency, and business opportunities (especially access to more international buyers), adopters still expressed difficulties in relating the systems to their existing business practices. To appreciate this dilemma, we need to understand the socio-cultural context in which the Chinese conduct their business activity. This involves Guanxi (relationship) networks, high-context communication, and in-group favoritism [13][22][15].

In the American model of commerce [18], the purpose of business emphasizes optimal economic gains achievable under a model of rational assumptions (this generalization is only for illustration; in fact, American businessmen also emphasize relationship-based trade, see [9]). Cost and efficiency are two important criteria of this model. For example, buyers are conceived as agents wishing to invest in technology in order to reduce search

costs (by identifying suppliers more quickly), transaction costs (by increasing process efficiency), and labor costs. Buyers will readily replace suppliers should they find preferable substitutes that can offer better product quality at a lower price. If there are non-repudiation issues, buyers and suppliers can settle their disputes through legal assistance.

Chinese traders operate with a different approach to business, using a different frame of assumptions (note: again, the generalization is for explanatory purpose; it will be problematic when different regions of Chinese traders are considered). Because contemporary China has not yet established a sound market and legal infrastructure, entrepreneurship often follows a culturally conventional approach of building business from family-based networks. In this context, since most non-repudiation issues and other trade disputes cannot be settled easily within the Chinese legal framework, the selection of business partners involves high risks, especially where non-family members are involved. Thus, the tendency is to keep business, as much as possible, within the family or close kin relations. Reducing business risks becomes a prime objective of the formation of any business partnership. To evaluate the trustworthiness of their trading partners, the Chinese often employ a set of implicit, but specific, strategies.

First, Guanxi networks are used widely to extend personal (family-based) relationships to business relationships. Chinese businessmen generally consider three types of network: family, friends and strangers [7] [15]. These three types of network represent how well a person can trust their business partners. For example, Chinese traders often trace the genealogy of their potential partners to see if there is any family linkage. This does not mean that they will necessarily trust their partners as long as a kinship link is found. The purpose will be to use family relatedness as a way of tracing the partners' background, in order to learn about their credit, past record of business practice, and personal integrity. Forming business partnerships, for most Chinese traders, is like establishing life-long friendships. For Chinese traders, Guanxi is not just about forming business relationships but also about forming personal friendships, with the purpose of reducing business risks.

Second, having these networks as a method of checking personal credentials is not enough. Chinese traders also develop an implicit method for evaluating personal integrity, reducible to one ultimate question: how can I trust this person with my business? Chinese traders employ tacit communication protocols, known as high-context communication: messages are comparatively terse in words, but rich in meaning [22].

For Chinese traders, metaphors are frequently used as a means for high-context communication. This has at least three purposes: to avoid direct conflicts, to test personal integrity and intelligence, and to communicate meaning with maximum ambiguity (so no one has to promise anything and rush into partnerships). Additionally, in order to assess trustworthiness it is more important to

observe the other person's social behavior than to consider what the person says rhetorically.

Third, building business partnerships in this Guanxi-based context breeds favoritism. However, one must not be tempted to attribute negative meanings (such as bribery) to favoritism; otherwise, one may only see favoritism in terms of its face value. Favoritism is considered as an appropriate way to maintain existing Guanxi networks in Chinese business communities [14].

Understanding the socio-cultural context in Chinese business communities helps one appreciate its influence on the rate of acceptance of e-marketplaces. The introduction of e-marketplaces will inevitably threaten Chinese traders' existing ways of building and maintaining Guanxi networks. Identifying suppliers through a computer interface presumes that buyers can reasonably trust suppliers, but this assumption conflicts with the traditional Chinese Guanxi approach to assessing potential partners. Although Chinese traders could identify more promising suppliers by using an e-marketplace, they would also be hesitant to replace existing suppliers for fear of jeopardizing long-standing Guanxi networks.

Chinese adopters thus perceive the e-marketplace as an unsophisticated way to minimize business risks, especially without the fluid assistance gained by mobilizing their Guanxi networks. Additionally, for Chinese traders used to conducting businesses through human interactions, i.e. through the social processes normally used to make friends and gain recognition in business communities, the depersonalized system features were perceived as obstacles to a properly social business relation. For the Chinese, good business practice should involve assessing trusted persons through existing Guanxi networks, building business partnerships through personal relationships, and maintaining Guanxi through in-group favoritism and reciprocity. According to these assumptions, the e-marketplace based on technical-economic assumption seems to add little value, and is insensitive, to these Chinese adopters' social expectation of technology use.

## 5. Implications: The Significant Role of Context

A frequent comment suggested by adopters of these three e-marketplaces is that e-marketplaces seem to be an American management practice that does not fit easily with Asian contexts. But, why do they make such comments? Our study offers a contextualist explanation.

This research highlights three kinds of contextual influence on e-marketplace acceptance: the structural contexts, national/regional, and socio-cultural. First, the study of IndiaMarket supports Markus and Soh's [21] observations concerning the effect of structural conditions. Structural constraints, such as the lack of logistic, financial, educational, and legal infrastructures, can significantly influence the decision to accept technology. Particularly, such structural influences are often difficult to resolve within a short period of time, as they are deeply

embedded in political and economic systems within a country.

Second, our findings in the TaiwanMarket case resemble those in Avgerou's [2] study of the unsuccessful adoption of e-marketplace in Cyprus. The changing national/regional context redefines the role of information systems in business operations. Non-acceptance occurs because adopters cannot see the relevance of technology use in response to the challenge imposed by their specific national or regional context. For many such local contexts the customary business practice are of more salience than the efficient markets assumed elsewhere.

Third, ChinaMarket's case echoes SPRINTEL's failure in Italy [18]. Similar propositions are also supported by other research: for example, Martinsons and Westwood's [22] study of MIS adoption in Chinese enterprises, and Walsham and Sahay's [26] investigation of Geographical Information Systems in India.

Generally, Asian-based studies, such as Kendall et al.'s [17] survey of e-commerce adoption in Singapore, and Hempel and Kwong's [12] investigation of B2B e-commerce in China, overlook such contextual influences. Our aim in this study is to urge practitioners and researchers not to limit their evaluation to the technical-economic dimension of adoption problems, thereby failing to appreciate the more subtle aspect of contextual influence.

## 6. Conclusion

The three case studies offer an initial explanation of the adoption challenge of e-marketplace in three geographical regions in Asia. The analysis focuses on the embedded context for business activity rather than the technological features and organizational processes. We conclude that the resistance to e-marketplace was not limited to technological, organizational and inter-organizational impediments. In the three cases it is more important to understand the role of context in shaping adopters' expectation of technology use [10], which in turn led to non-acceptance. In this situation, adopters were unclear how an e-marketplace would add value to their businesses. Hence, if e-marketplace use is perceived as irrelevant to the expectation of the adopters – expectations shaped by contexts – the entire adoption effort may wither before technology has a chance to take root. Hence, effective adoption of technology depends on a consideration of how people's expectation of technology use is met in a given context. The lens of context adds a fruitful, alternative perspective in explaining and anticipating technology outcomes.

# Assessing Organizational Culture Difference between E-Commerce Companies and the Traditional Ones: A Measurement Invariance Perspective

Honglei Li

Department of Decision Sciences and Managerial Economics  
Faculty of Business Administration  
The Chinese University of Hong Kong  
[honglei@baf.msmail.cuhk.edu.hk](mailto:honglei@baf.msmail.cuhk.edu.hk)

## Abstract

Organizational culture is an important factor in organization development process. This paper explores the culture issue in the new technology age. Adopting Ruppel's new culture framework developed from traditional perspective on culture the paper tested the culture difference between organization with intranet and without intranet. Using Confirmatory Factor Analysis method with Lisrel the paper explored the research area on culture and extended the usage of Lisrel into MIS area. The result showed that organizational culture in the traditional and E-commerce Company is different in the ethical value. The research result showed that the culture is changing in the process of adopting new technology in organization, which may raise the attention of changing the management methods due to differences in culture.

## 1. Introduction

Internet and e-commerce can be claimed as the greatest changes in the 90<sup>th</sup>. "Starting from basically zero in 1995, total electronic commerce is estimated at some \$26 billion for 1997; it is predicted to reach \$330 billion in 2001-02 (near term) and \$1 trillion in 2003-05 (future)" [18]. Till now e-commerce keeps growing and penetrating in almost every perspective of social and the business area. In line with the fast growth of information technology and internet, more and more company has adopted or is exploring the feasibility of adopting the advanced information technology to enhance the enterprise knowledge management and hence the performance of the company. IT has become the major success factor of the corporations in the turbulent competitive business environment. Peter Drucker predicted in 1988 "The typical large business 20 from now, will have half the levels of management and one-third the managers of its counterpart today"; "Businesses have little choice but to become information-based" [4].

With the development of e-commerce many concerns come out either to produce the hinder the process of electronic business. Since e-commerce penetrates into many aspects of the industry many factors will be influenced by electronic commerce. On the definition of e-commerce, different party has different perspective,

"Depending on whom you ask, electronic commerce has different definitions..." [14]. According to Dow Johns definition about e-commerce, an e-commerce company is different from traditional companies mostly on how much part of its revenue comes from electronic transactions [10]. But there should be other things that are different from revenue since an e-commerce company is different from a traditional company in many ways. These differences will affect the unseen factors under a company or organization. Organization culture is one factor that gains a lot of attention in recent years [15] [3] [11][8][16]. Though many researches devoted to identify out the relationship between organization growth and organization culture, few have paid attention to the culture in the newborn e-commerce company. Some researches have discussed the role of organization culture in the process of adopting advanced technology, such as intranet [3], TQM [2], and other technologies [8]. In Ruppel's discussion, Setting up an Intranet within the organization will not only save the cost of transaction within organization but also enhance the efficiency of communication and expand the extent of communication within organization. Thus Intranet will reduce the hierarchy of the organization and influence the culture of the organization. But culture in turn will influence the adoption of Intranet. "Without a match between the culture of an organization and the cultural assumptions embedded in an IT innovation, a costly implementation failure is likely to occur" [22]. Since human's behavior in face-to-face environment is different from the virtual environment, the employee's behavior in e-commerce company environment will be different from the common company environment. For instance, evidence shows that people in non-face-to-face environment will more willingly to tell the talker truth, which mean that the communication within a virtual community will more real and effective. Thus the culture of the e-commerce organization will be different too. Due to Internet and e-commerce some aspects inner the organization must have been changed but what's been changed and what's not, and if some aspects changed how to identify such changes are also a question. Intranet changes the communication style among people and enhanced the effectiveness of communication among people too. In one aspect it must have some effect on culture. Ruppel pointed out that culture within the organization will first

affect the implementation and operation of Intranet then in turn will be affected by Intranet after successfully implementing the Intranet [9]. Such phenomenon raises the questions as what the culture difference is between e-commerce companies and traditional companies. What kind of culture is more obvious and thus helpful in e-commerce companies? How to find out the difference and what kind of difference between e-commerce organizations and traditional one? Answers to such questions are meaningful for managers in e-commerce companies. Identify out how and in what way the electronic transactions mode will affect an organization's culture structure will be very beneficial to those who want to manage their companies well and those who want to setup their business in electronic commerce area. Thus this paper try to find out the culture dimensions in the e-commerce companies and compare the culture difference between e-commerce companies and traditional companies. Gordon used CFA (Confirmatory Factor Analysis) to compare self-other disagreement between self-rating and other-rating score and give a useful and easy approach in comparing two groups or two sources. This approach can also be applied to compare any form of disagreement between two sources [6]. This paper is to identify the difference of the culture in e-commerce companies and show a new method from different aspect to do research on cross-group research. Also this method is new to MIS research. Our two sources here are e-commerce companies and traditional companies.

## 2. Literature Review

To illustrate our discussion, we first need to make clear what's our subject to be involved, that is, we first must make a clear definition on electronic company companies. They are many definitions about e-commerce since the first time it come.

"Depending on whom you ask, electronic commerce has different definition.

From a communications perspective, Electronic commerce is the delivery of information, products/services, or payment over telephone lines, computer networks, or any other electronic means.

From a business process perspective, electronic commerce is the application of technology toward the automation of business transactions and workflows.

From a service perspective, electronic is a tool that addresses the desire of firms, consumers, and management to cut service costs while improving the quality of goods and increasing the speed of service delivery.

From an online perspective, electronic commerce provides the capability of buying and selling products and information on the Internet and other online services" [14, p.3]. Turban put up with the definition

pure versus partial electronic commerce [5, p.5]. A more attractive view is from Dow Jones index, according to its definition, "It will include only companies that generate a minimum of 50 percent of their revenue from the Internet. The DJII will be made of two subindexes: "Internet Commerce" and "Internet Services." These 40 stocks represent 80 percent of the market capitalization of Internet stocks." According to this definition, only 25 companies in services section and 15 in commerce section. Though it is only restricted into the companies with initial publishing the definition could be extended to companies that didn't not have initial publishing but will have 50% or more of their annual revenue comes from Internet.

Culture concept played a key variable in the success or failure of organizational innovations and will enter its third decade of active life in the field of organizational studies [11]. On the reviewing of recent literature on organization we could find many on implementation issues of organizational culture. A lot of researchers linked the culture with the innovation in the organization. Some of them directly discussed the role of culture in the process of technology implementation or technology transfer or organizational performances. Ben and Rabi discussed the influence of the culture on the process of the technology transferring and pointed out that organizations with similar culture is easy to transfer technology inter-organizations [2]. Ruppel point out that on the process of sharing knowledge through intranet organizational culture has an important effect in the initial state of implementing intranet. [3]. James and Roger wrote a paper on the current organizational culture dimensions that occurred in recent organizational culture literature and identified out 8 dimensions [11]. Gregory and Christopher pointed out that though it doesn't have a direct effective in the implementing advanced manufacturing technology, organizational culture do act and have an effect in the long run during the process of technology implementation [8]. Ruppel [3] did some research on culture's effect on the success implementation of Intranet and pointed out that trusting and ethical culture is very important on the encouragement of sharing tacit knowledge over Intranet, which implied the success of the implementation of Intranet. Ruppel also suggested that that the people-based issues such as culture are increasingly important, and they represent a significant potential barrier to effective use despite the adoption of the technology. In his study he validates the need for the study of organizational culture as a factor in the adoption and implementation of IT innovations such as Intranets, as well as other types of innovations designed to facilitate communication. Even after implementing the Intranet successfully, mismatches in culture will still reduce the effect of the Intranet [3]. When talking about the relationship between organization design, organization culture and AMT (Advanced Manufacturing Technologies), Zammuto and

O’Connoh think the AMT failure is concerned with organization design and culture serve as a constrain. Given all these literature on organizational culture and technology aspect of organizations we can conclude that culture have relationship with the technology aspect of an organization. Turning the view to the E-commerce companies, which relies highly on Internet to conduct business, it isn’t hard to relate organizational culture with electronic companies. My concern is a) will the organizational culture in E-commerce companies be different from the traditional companies? b) if different, in what aspect or what dimension will it be different? Except above literature, in psychology and management field, there are many research on cross-culture research and cross-group research at organizational level. They provide very good methodological framework in conducting research or culture or cross-culture research [21] [6] [7]. This paper will use the cross-group research methods to compare and identify the culture difference between E-commerce companies and traditional companies.

In the definition of culture there are voices from many researchers [9][13]. “Careless utilization of the concept, for instance, refers the sharing of language, nationality, race, religion, and so on...” [9, p.110]. “Culture exists at three levels of abstraction: assumptions, values, and artifacts. The essence of culture is the set of basic assumptions that people share regarding such things as human nature, social relationships, and relationships among social institutions and their environment.” [13]. Researchers conducted analysis about culture at three levels, and values are more accessible than assumptions and more reliable than artifacts [13]. Wiener pointed out that shared values system is one of core measurable components of organizational culture [23]. Culture can be conceptualized and quantified as shared values in organization environment. Values in culture represent symbols, norms, and other culture activities around them [12]. When conducting empirical researches on organizational culture, lots of researchers analyze it at values level [15][3][11][8][17][20]. The most useful model for organizational culture at values level is the Competing Values Model (CVM) developed by Quinn, R.E and Rohrbaugh in 1983 [19]. Though there are other dimensions or frameworks for organizational culture analysis, for instance, in Chatman and Karen’s paper, 7 dimensions of organizational culture, innovation, stability, people orientation, outcome orientation, easygoingness, detail orientation, team orientation [12], based on extant literature on organizational culture, Schroeder and Mauriel synthesized 8 dimensions for organizational culture, the basis of truth and rationality in the organization, the nature of time and time horizon, motivation, stability versus change/innovation/personal

growth, orientation to task & coworkers, isolation versus collaboration/cooperation, control, coordination, and responsibility, and orientation and focus – internal and /or external [11], these dimensions are reflected that dimension in competing value model and is not so structured as CVM, which experienced content and construct validity [3]. So we will use CVM model as the basis of our analysis. Next section we will briefly introduce the competing values model.

## 2.1 Competing Values Model

Quinn’s competing values model is initially developed for the organizational effectiveness [19]. While conducting research on effective organizations Quinn found out that there are two dimensions similarly exist underlying effective organizations. The first dimension is flexibility-control and the second is internal-external. Flexibility –control axis focus on the changes in the organization and varies along the axis from flexible to controlled or structured mechanism. Internal-External dimension is related to organizational focus and is concerned with activities existing internally or externally. Internal focus emphasizes the changes in the existing organization and the external focus emphasizes the reaction to the competition, adaptation and interaction with the external environment. A quadrant organizational type is generated through crossing these two dimensions at the center (Figure 1). Each quadrant has its own means and ends. “Quinn and Kimberly subsequently argued that the competing values model could be used to ‘explore the deep structures of organizational culture, the basic assumptions that are made about such things as the means to compliance, motives, leadership, decision making, effectiveness values and organizational forms” [20, p.711].

The above quadrant will exist in organizations. An organization couldn’t have only one dimension. When the organization maintains a balance among four quadrants it will maximize its effectiveness. Though this four dimension measures the culture well but it may miss something that Internet-based culture have. For instance trust between employees “openness and honesty, sincere service attitude toward membership,” and a “high trust culture for shared learning” dimension of ethical work climate, with respect to Intranets and the organizational culture [3]. Ruppel developed a new measurement framework that includes ethics and trust measurement within organization. Hence we have a five-dimension culture construct. Figure 2 shows the dimensions of organizational culture from Ruppel’s model. In Ruppel’s model an additional dimension Ethical is added to values the culture with openness and trust.

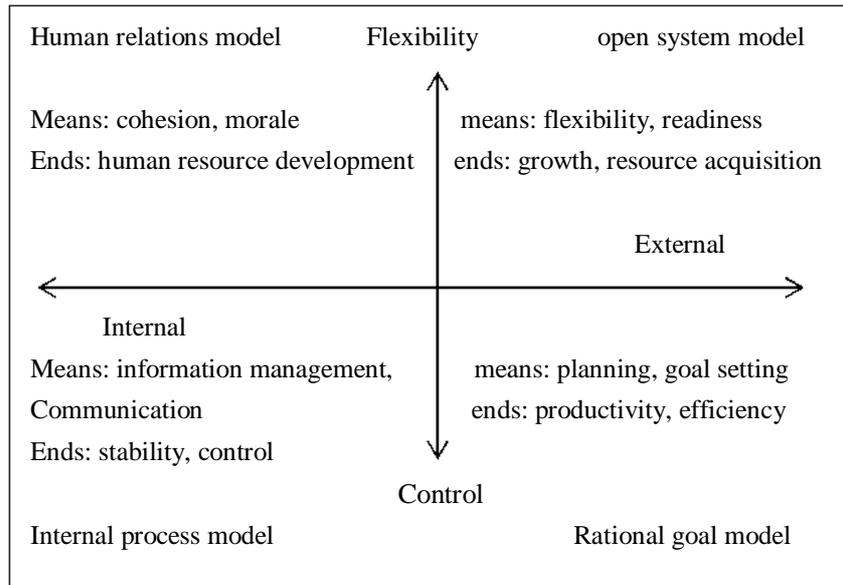

Figure 1. Competing Values Model: Organizational Effectiveness

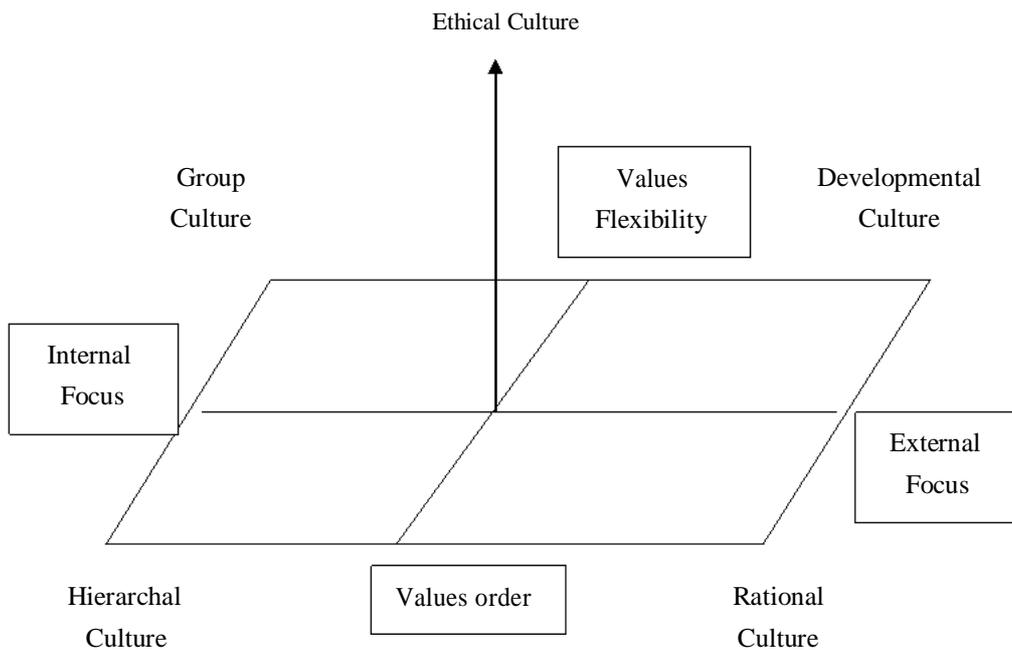

Figure 2. Ruppel's culture dimension extended from Competing Values Model

In above figure e-commerce companies have five dimensions to measure organizational culture. A development culture is a culture values flexibility and external focus [3]. An organization showing strong developmental culture will be adapted and change to external environment flexibly when face turbulent and complex external environment. A group culture values flexibility and have an internal focus. An organizational showing strong group culture will focus on the human resource development, cohesive alliance between

organizational members, organizational development. A hierarchical culture is control-based and has an internal focus. An organization showing strong hierarchical culture will values structural systems, policies and rules in organization and it will not adapted rapidly to the change in the outside environment. A rational culture is control oriented and has an internal focus. An organization showing strong rational culture values order and rightness of organization action. The managers in rational culture organization will always adopt actions

that will lead the organization to maximize the profits or productivity of organization. Though group culture reflects some kind trust between organizational members it could not replace the position of ethical culture. “While the competing values framework describes values often used for decision making, it does not include specific measures for trust and an ethical work environment” [3]. Thus our organizational culture will have five dimensions to measure E-commerce companies. Figure 3 is the measurement model of the new organizational culture.

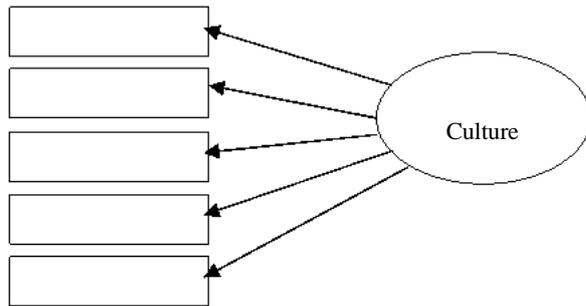

Figure 3 the culture dimensions

### 3. Hypothesis

Through the literature review we know that for an organization to maximize its effective the organization will have a balance in all the five dimensions. An organization couldn't have only one culture type. And different organization will show different degree of culture types to maximize its performance [17]. In Ruppel's empirical studies during developmental culture and ethical culture have an positive effect during the process of intranet implementation. Group culture, rational culture and hierarchical culture have no direct effect to facilitate the process of intranet implementation. According to Ruppel's explanation the group culture's effective will appear in the long run. This point is the same as the result of Stock [8], who conducted an empirical study on the role of organizational culture for external focus culture will be strong in E-commerce companies. Thus we will give our hypothesis 1 & 2.

H1: Developmental culture in E-commerce is different from those in the traditional companies. internet, an environment that is changeable, flexible and technology oriented. Also through internet it must have

H2: Group culture in E-commerce is different from those in the traditional companies. the AMT (Advanced Manufacturing Technology). E-commerce companies conduct business through rich communications with

outside world. That means an

At the same time, Internet will values trust when conducting business since people interact with each other through a virtual channel instead of face to face. Thus we give our hypothesis 3.

H3: Ethical culture in E-commerce companies is different from those in traditional companies.

For rational culture and hierarchical culture studies related with technology implementations showed that it is not very strong in organizations values innovation and technology and creation. Thus we give our Hypothesis 4 and 5.

H4: rational culture in E-commerce companies is the same as those in traditional companies.

and technology and creation. Thus we give our Hypothesis 4 and 5.

H5: Hierarchical culture in E-commerce companies is the same as those in traditional companies.

### 4. Research Methodology

In this study we first use sample survey to conduct the data collection, then use CFA-based (Confirmatory Factor Analysis) analytical procedure to compare the culture difference between E-commerce and traditional companies.

#### 4.1 Measurement & Questionnaire

The measurement framework of the five constructs extended from Ruppel [11] is as following. According to Ruppel's illustration. The measurement model is through content and validity test.

##### 4.1.1 Development Culture (item 1, 2, 3, 4)

1. The glue that holds my group together is commitment to innovation and development.
2. There's an emphasis on being first with products and services.
3. My group emphasizes on growth through developing new ideas.
4. Developing new products or services is important.

##### 4.1.2 Rational Culture (item 5-10)

5. The relationship with our customers and suppliers can best described as cooperation and trust.
6. I have found that my employees are usually dependable, especially when it comes to things important to me.
7. My department is a very product oriented place.
8. People are concerned with getting job done.
9. The glue that holds my group together is emphasis on task and goal accomplishments.
10. A production and achievement orientation is shared.

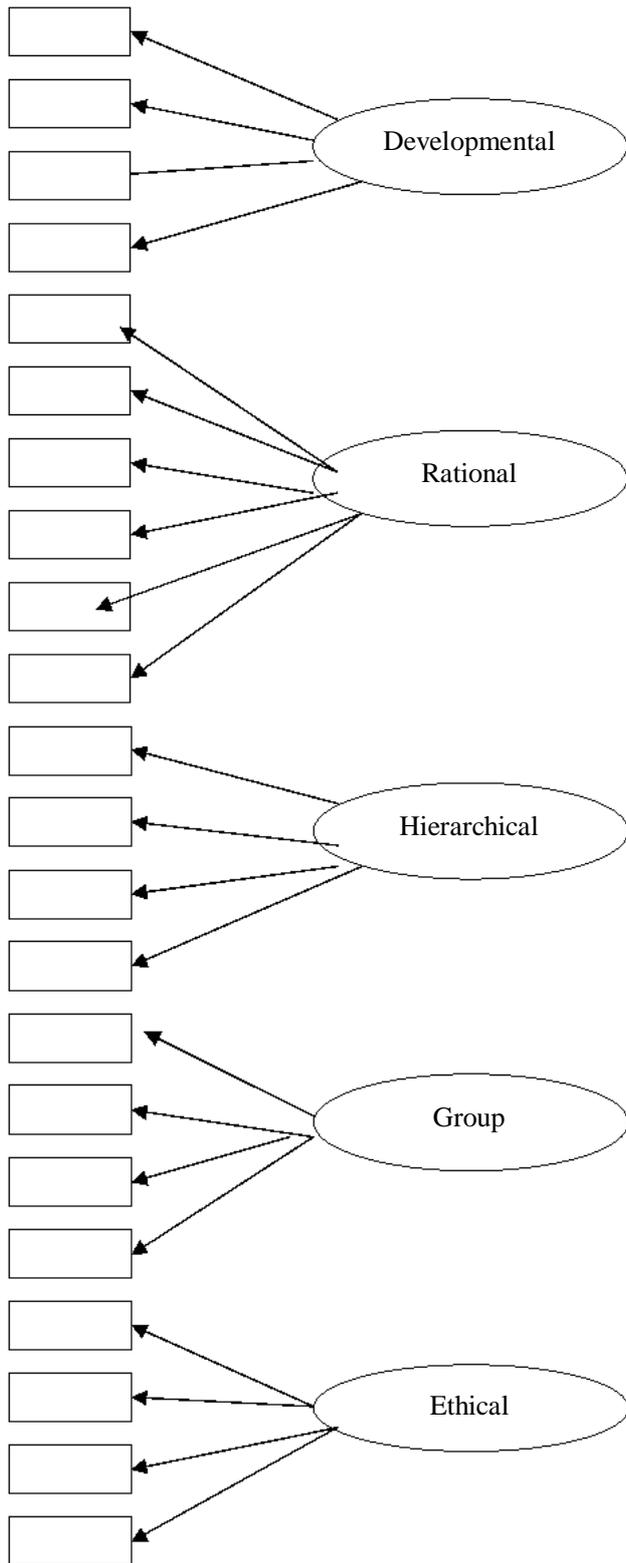

Figure 4. The CFA model

4.1.3 Hierarchical Culture (item 11-14)

11. My department is a very formal and structured place.
12. People pay attention to procedures to get things done.
13. The glue that holds my group together is formal rules and policies.

14. Following rules is important.

4.1.4 Group Culture (item 15-18)

15. My department is a very personal place like an extended family.
16. People seem to share a lot among themselves.
17. My group focuses on human resource.
18. Morale is very important.

4.1.5 Ethical Culture (item 19-22)

19. In this organization people are mostly out for themselves.
20. Our major concern in this organization is always what is the best for other person.
21. The atmosphere within this organization is best described as one of mutual confidence and trust.
22. The environment is largely ignored. With upper management interest focused on inward attempting to maintain the stability and equilibrium of the organization. In order to attain these goals managers focus on measurement, documentation and information management.

4.2 Research Method and sample frame

We use sample survey to collect data of the two groups in this paper. Confirmatory factor analysis (CFA) will be used in this paper. We identify two groups as E-commerce companies and traditional companies. For each group we focus on the culture aspect of the organization on research. Ruppel's new frame of culture with 5 dimensions will be used in this paper as the research object. For each dimension of culture we have several items to measure. In this paper we can compare the measurement model of the culture to find out the difference between organization with Intranet and without Intranet. Gordon pointed out that there are two kind of disagreement between two groups, conceptual disagreement and psychometric disagreement [6]. We will analysis this two kind of disagreement to identify the culture difference between two groups.

4.2.1 Sample frame

For the ideal situation, we can first get the directory of the enterprise in Hong Kong from Hong Kong industry Bureau and give them a phone call first to ask them whether they have Intranet How did you define "an organization with an Intranet"? . Then we identify those who have Intranet from all. The next step is to select the 500 companies each with random sample method from those who have Intranet and those who haven't. Then we send questionnaire to these 1000 companies and explain our research purpose and guarantee that we will give them the result of the result to get a high rate of feedback. The questionnaire will be sent to 2 senior managers and one IT manager or CIO How different are the views of the senior managers and the IT manager? For these two groups we get the raw data and can use these data to make a CFA analysis.

### 4.3 Analysis

After collecting data we use Lisrel to conduct a CFA analysis to compare the culture difference between E-commerce and traditional companies. In above discussion we ave our model with 5 dimensions and 22 items.

#### 4.3.1 Conceptual Disagreement

Conceptual disagreement exists when people in E-commerce and traditional companies use different conceptual form or different reference to conceptualize culture. For example people in E-commerce may conceptualize culture with 5 dimensions but people in the traditional companies may conceptualize it only with 4 dimensions. Or people in E-commerce use four items to conceptualize developmental culture while people in traditional companies culture may use 3 or 2 items. Even people in Intranet-based-organization and non-Intranet-based use the same item to measure the same dimension they may give the same item of the same dimension different loading. All of the above difference belongs to the conceptual difference.

##### 4.3.1.1 Difference in Factor form

The culture will display factor form equivalence if people use the same dimension to measure culture in E-commerce and traditional companies on condition that each dimension in both groups has the same item. In the absence of factor form equivalence the difference of culture between E-commerce and traditional companies due to the way people concept the culture. This difference can be referred to facilitate the management and enhancement of the performance of Intranet.

##### 4.3.1.2 Difference in Factor loading

Factor form equivalence exists means that people use the same dimensions and the same numbers of items to measure culture or people in the two groups conceptualize the culture with the same pattern. But factor form equivalence is only a necessary but not sufficient condition for comparing the equivalence of culture across the model. Even people conceptualize culture with the same pattern they may give the same item different weight. For example people in E-commerce may put more emphasis on the group culture and give items of group culture more weight and its countpart may not. Difference in factor form is known as factor form invariance.

#### 4.3.2 Psychometric Disagreement

Psychometric disagreement exists when people in the two groups agree conceptually on the culture but may respond to the scale in different ways. Differences may be manifested as source-specific biases. For example even though people in Intranet-based and traditional companies may conceptually agree on the culture but they be different in variability within group or random measurement errors. Five sources of psychometric disagreement will be examined here. They are (a) difference in random error, (b) difference in the

variability of latent factors (culture dimension), (c) difference in correlations among latent factors, (d) differences in latent means, and (e) difference in starting value of latent factors. For future information about these 5 disagreements please further reference [6].

##### 4.3.2.1 Difference in Random Errors

Difference in random errors is related with the reliability issue. An observed item score consists of a hypothetical true score plus random measurement error. They are two sources of errors, system error and random error. Random error may be attributable to the following people's characteristics: unfamiliarity with scale items, inexperienced with the question format, informational constraints, errors in marking responses, carelessness, and so on [6]. In culture context measurement random error may be due to people in Intranet-based and non-Intranet-based culture understand the question in different extent.

##### 4.3.2.2 Difference in Latent Factor Variability

Difference in latent factor variability exists when people in Intranet-based and traditional companies have a large within group difference. For example people in E-commerce have a large variability for group culture dimension means that some people in E-commerce give a very high score for group culture and some people may give it a very low score. If the variability difference is large it means that people in the two groups have a very high difference between in conceptualize the culture.

##### 4.3.2.3 Difference in Correlations Among Latent Factors

Correlations among latent factors measure the interaction effect between dimensions. Halo effect, which is the tendency to generalize the score of culture across dimension, can be operationalized as correlations among latent factors. Because halo inflates correlations among different dimensions the high correlation is affected by greater halo effect. When differences in correlations among latent factors exist, people in Intranet-based and traditional companies have different halo effect.

##### 4.3.2.4 Difference in Starting Value of latent factor

Though people may conceptualize the culture in the same way with equal factor loadings they may also have different perspective on the starting value of the construct. For example people in both groups may think group culture is low but one group may give low value as 3 and another group may just give it as 1. So the difference in starting value of the latent factor is required to compare latent means. If people couldn't have the same starting value of latent factor they couldn't compare at the same level and the comparison will be no sense.

##### 4.3.2.5 Difference in Latent Means

To compare latent means we have the conditions that people in the two groups conceptualize the culture in the same pattern and with equal factor loadings on the constructs. At the same time equivalence in starting value of the latent factors is required. If all these conditions are fulfilled we can compare the latent mean score of culture to see if people in Intranet-based and traditional

companies are different in culture. If the difference does exist we have conclusion that culture in E-commerce and traditional companies are different.

## 5. Analysis Result

A total of 117-finished questionnaires were collected, 71 of which have intranet and 46 of which don't have. Following seven disagreement tests and after running Lisrel we get the following test results. One thing need to be noticed is that due to small sample size we only do two steps test till the factor-loading difference. From the average score of the performance questions asked we find out that organization with intranet have better performance than those who doesn't have. In the following section we first introduced the result from Lisrel then discussed the results.

### 5.1 Factor form Invariance Test

From the result from table 1 we can see that Chi-Square of stacked model equals to the summation of the Chi-Square of both groups. So we can't reject the fact form invariance. The  $\chi^2$  of the stacked model are called as  $\chi^2_{uncon}$  and will be used in the subsequent test.

### 5.2 Factorial Invariance Test

To see if there's any other difference between two groups we need to do the factorial invariance test to check if the factor loadings are the same for both groups. The purpose of this test is to check whether people in the two groups give each item of the constructs the same importance given that they conceptualize the construct in

the same way. If there is a factorial loading difference between groups it means that the measurement models between two groups are different. For this particular test if the factorial invariance exist it is due to the people in intranet-base organization and non-intranet-based organization give the item of 5 culture dimensions different importance. If we want to do further comparison we need to find out which dimension, developmental, group, Rational, Hierarchical or Ethical, contributes to the significance of the difference. Even fourthly we can find out on which item people give different importance. This is done by test the factor ratio invariance test item by item. This test can tell us the detail information of the difference between the two groups. If the factorial invariance exists between two groups we need to do further test to see if there's any other difference such as, theta-delta test, intercept difference between groups. To check the factor loadings on the five constructs we first constrain all the parameters and see if there is any difference between the groups then make a comparison between the unconstrained baseline model to see if it is significant. Since the five constructs are independent in this model we need to constrain single construct one by one to check if the factor loadings of the five constructs are the same. Table 2 shows the results of the factorial test. For example for construct one we constrain factors of construct 1 of intranet-based organization the same as non-intranet-based organization, that is  $\lambda_{2,1}^{(1)} = \lambda_{2,1}^{(2)} \lambda_{3,1}^{(1)} = \lambda_{3,1}^{(2)} \lambda_{4,1}^{(1)} = \lambda_{4,1}^{(2)}$  and free all other parameters. The same is true for the other four constructs.

Table 1 Result of Fact form Invariance Test

	Chi-Square	df	RMSEA	CFI	NNFI	IFI
Intranet	1.85	199	0.00	0.93	0.70	0.83
Without Intranet	1.31	199	0.0	0.97	0.53	0.61
Stacked Model	3.16	398	0.0	0.95	0.91	0.94

Table 2 Results of factorial invariance test

Test	Model	$\chi^2$	df	$\Delta\chi^2$	$\Delta df$	TLI	CFI	RMSEA
1	Unconstrained baseline model	3.16	398			.91	.95	0.0
2	Fully constrained model	15.83	415	12.67	17	.91	.77	0.0
3.1	Loadings on construct1 ( $\xi_1$ ) constrained	4.22	401	1.06	3	.91	.94	0.0
3.2	Loadings on construct2 ( $\xi_2$ ) constrained	5.23	403	2.07	5	.92	.92	0.0
3.3	Loadings on construct3 ( $\xi_3$ ) constrained	4.05	401	0.89	3	.94	.94	0.0
3.4	Loadings on construct4 ( $\xi_4$ ) constrained	3.78	401	0.62	3	.96	.94	0.0
3.5	Loadings on construct5 ( $\xi_5$ ) constrained	11.72	401	8.56**	3	.91	.83	0.0

\*\*Note: P<0.05

Through the factorial invariance test construct by construct we can see that construct 5 is significant. This means that people in intranet-based organization and those in non-intranet-based organization use the same item to measure culture dimension but they give ethical culture different importance. In general perspective, people in two groups use same way to think culture. But they have different value on ethical culture. For the other four culture dimensions, they have the same values. This result reveals the culture dimension we discussed earlier in this paper. Ethical culture is special issues in new network environment which change the way people communicate.

So the model stops in this step because we find the difference between two groups. Since the further disagreement test is based on a factorial invariance test model we didn't do further test here. But through fixing the model we can either use a partial factorial invariance model or just remove the significant construct or just interpret the non-invariant items as data. How different are the two groups on the ethical culture dimension?

## 6. Contribution, Conclusion and Future Study

This paper explores the culture issue in the new technology age. Adopting Ruppel's new culture framework developed from traditional perspective on culture the paper tested the culture difference between organization with intranet and without intranet. Using Confirmatory Factor Analysis method with Lisrel the paper explored the research area on culture and extended the usage of Lisrel into MIS area.

The research result showed that the culture is changing in the process of adopting new technology in organization, which may raise the attention of changing the management methods due to differences in culture. But the paper only make the very first step in analyzing the differences between two groups. More detail study such as psychometric disagreement analysis should be studied in the future. In addition, detail research can be done to investigate to what extent intranet can affect company's performance. The study on other technologies', such as the effect of Internet on customers, effect on culture also can be done in the future.

## Abstract

After the emergence of the Internet, an interesting question arises that what is its impact on the firms' channel and pricing strategies. This paper applies game theory to study the strategic interactions between rational manufacturers, retailers, and consumers, and it generates the following results: 1. The presence of the Internet allows imperfectly competitive manufacturers to better coordinate their pricing, targeting, and channel strategies, thereby minimizing the agency costs involved in common dealing at the traditional outlets, which in turn enhances the manufacturers' profits. 2. Exclusive dealing may and may not become more prevalent in the presence of the Internet. It all depends on the ratio of the population of switchers to the entire population of consumers. 3. The presence of the Internet allows a monopolistic manufacturer to screen consumers by serving different people at different outlets. Screening is less effective, however, in the case of imperfect competition. 4. A dynamic adjustment process is obtained which describes how a manufacturer should optimally change his channel and pricing strategies when the population of the Internet purchasers grows over time.

## 1. Introduction

The prevalence of the Internet brings a great deal of business opportunities and potential markets. For one thing, manufacturers do not have to rely on retailers to sell their products to final consumers. Through the Internet, they can directly contact worldwide consumers and have better understanding about what consumers want and need. Similarly, retailers can also serve consumers that they could not have reached otherwise. However, by making searching easier for consumers, the Internet is said to intensify price competition. For example, Bakos [1] suggests that lower search cost on the Internet would lead to more severe price competition and lower profits. Brynjolfsson and Smith [2] show empirically that the price competition on the Internet is sharper than that in traditional channels for standard products like CD and books. However, some scholars have opposite views and think that a low search cost will not necessarily intensify price competition. For example, Lal and Sarvary [3] point out that for non-digital products under some conditions, consumers who search in the absence of the Internet may

shop their familiar brands on the Internet without searching. Therefore, it is possible that the presence of the Internet not only enhances the consumer loyalty but also eases the price competition between firms.

Before the emergence of the Internet, manufacturers could only sell their products to consumers in the traditional channels. If the channel is not vertically integrated, manufacturers have to contact consumers through retailers. In general, a manufacturer hopes that retailers can provide various in-store promotions for its product to increase its sales volume, including in-store advertisement, displaying its product, or even persuading consumers to switch to the manufacturer's brand on the point of purchase. However, the retailer who maximizes the profits from its assortments would promote the brand with the highest profit margin. In fact, the retailer may even use the leading brand with a lower margin to build traffic while persuade consumers to buy another high-margin brand on the point of purchase. To solve the incentive problems, the manufacturer could choose exclusive dealing [5]. Exclusive dealing is a contractual arrangement between a manufacturer and its dealers where the latter agree not to carry brands competing with the manufacturer's brand. In contrast, under common agency, manufacturers allow their dealers to carry brands competing with their own. One stream of previous literature centers on how the channel structures, in particular, exclusive dealing or common retailer, chosen by competing manufacturers affect the intensity of competition among manufacturers. Mathewson and Winter [6] argue that the retailer would not accept exclusive dealing offered by a manufacturer unless the associated wholesale price is low enough, which implies intensive potential competition between manufacturers in order to be selected as the only brand carried by the retailer. Others argue that under exclusive dealing, the perceived demands of manufacturers are more inelastic than under common dealership, thus softening the upstream competition [4] [8]. It happens because under exclusive dealing a manufacturer knows that the decrease in its wholesale price will result in not only the decrease in its own retail price but also the retail price of a competitive product set by the other exclusive dealer. In addition to the associated intensity of competition, cost is another concern when manufacturers consider whether to impose exclusive dealing or not. When manufacturers sell

products through a retailer, they would incur a setup cost. Under common agency, manufacturers could share the setup cost, thus having a positive externality compared with exclusive dealing.

The emergence of the Internet channel may give manufacturers a way to overcome a retailer's incentive problems. The Internet channel differs from traditional channels in two important ways. First, on the Internet it is consumers that decide what information to search and to retrieve. Therefore, online retailers can not influence/change consumers' brand preferences as much as traditional retailers. Second, the Internet channel can not reach consumers who do not have access to the Internet. Manufacturers when designing their optimal channel strategies must take into account the distinctive properties of the traditional channel and the Internet channel into account.

The purpose of this paper is twofold. First, we analyze how the presence of the Internet may help manufacturers alleviate a traditional retailer's incentive problems. Second, we characterize imperfectly competitive manufacturers' equilibrium channel strategies in the presence of the Internet.

To achieve the above two objectives, we consider a model with two manufacturers and two traditional retailers. For each manufacturer's brand, there are two kinds of customers, loyals and switchers. The segment of loyals have higher reservation price for the manufacturer's brand and will not be influenced by traditional retailers on the point of sales. In contrast, the segment of switchers have lower reservation price and can be persuaded by traditional retailers to buy the competing brand. Before the emergence of the Internet, a manufacturer marketing strategy crucially depends on two factors. The concern for double marginalization, which determines the segments that manufacturers want to serve and the retailer's persuasion power affects the choice of exclusive dealing or common agency. After the emergence of the Internet, the consumer market is redefined according to whether consumers have access to the Internet. Thus the proportion of consumers using Internet and the difference in cost between traditional channel and Internet channel would also affect the manufacturers' channel design and the targeting decisions in different channels. This paper applies game theory to study the strategic interactions between rational manufacturers, retailers, and consumers, and it generates the following results:

1. The presence of the Internet allows imperfectly competitive manufacturers to better coordinate their pricing, targeting, and channel strategies, thereby minimizing the agency costs involved in common dealing at the traditional outlets, which in turn enhances the manufacturers' profits.

2. Exclusive dealing may and may not become more prevalent in the presence of the Internet. It all depends on

the ratio of the population of switchers to the entire population of consumers.

3. The presence of the Internet allows a monopolistic manufacturer to screen consumers by serving different people at different outlets. Screening is less effective, however, in the case of imperfect competition, a dynamic adjustment process is obtained which describes how a manufacturer should optimally change his channel and pricing strategies when the population of the Internet purchasers grows over time.

## 2. Literature Review

One of The issues that attract many researchers' attention after the prevalence of the Internet is how the Internet affects the intensity of competition among firms. Although some scholars (eg, Lal and Sarvary, 1999) argue that the non-digital attributes of products may influence consumer behavior, which are decided by the concern of extra transaction cost, and cause the favor of existing brand. According to this argue, the firm will face better pricing condition. Nevertheless, most people agree that the development of the Internet has reduced searching cost and made consumers get information easily, which will lead price competition and sharply reduce price level. Brynjolfsson and Smith (2000) have empirically studied the price competition in two categories - CD and books - to exam whether the price competition on Internet would be more severe than the traditional channel. CD and books are both highly homogeneous products, which means that the product quality will not vary within different channels. The result shows that the product prices on web are lower than on brick, which means that pricing wars are more intensely on virtual world. Besides, the shift scale of price on web store is 1% of it on physical store, which means that the Internet trades possess lower menu cost and are more sensitive on price. Interestingly, the price dispersion among web retailer is larger than which among conventional retailer, and the leading firms in CD and books market are not the one who marked the lowest price. Firms adopt low price strategy shared few market value, which means purchasing cost is not the only concern of buying decisions even there are homogenous products. The degree of trust in website, brand, and service are important to buying decisions. Consequently, the homogenous products may not necessarily lead to competition on price on virtual channel.

Exclusive dealing is a commitment between manufacturer and retailer thatretailers agree not to carry the competing brands. That means a manufacturer requires its retailers only to sellits products. The issues of exclusive dealing in the past researches can be categorized into three types: one is the impact of exclusive dealing to social welfare; two is the equilibrium channel structure, including exclusive dealing, common dealing, and vertical integration; three is how other marketing variables, like price and promotion, change under different channel structure.

O'Brien and Shaffer (1993) correct Lin's (1990) error and argue that manufacturers eventually choose exclusive dealing as its channel structure among exclusive dealing, common dealing and vertical integration. In their setting, the competition at retail level is monopoly and duopoly under common agency and exclusive dealing respectively. For this reason, common agency gives the retailer the power to threaten manufacturers to sell only one product. Therefore, manufacturers could not extract all profits under common agency but could under exclusive dealing. In addition, manufacturers can alleviate competition through retailers, thus it is optimal for manufacturers to choose exclusive dealing. It is worthy to notice that the retailer's pricing strategy with common agency is like product line pricing, so the consumer surplus will be extracted at most. Compared to exclusive dealing, consumer surplus under common agency is even lower.

Many studies do not consider vertical integration, and they only focus on the manufacturers' choice between exclusive dealing and common agency. Bernheim and Whinston (1985) model the retail competition as perfect competition and the retail prices are set by manufacturers. It results the manufacturer would delegate some marketing decisions to common agency in order to collude with each other. That is because common agency provides an indirect mechanism through which competing manufacturers may "sell out" to a single retailer, thereby creating incentives which generate a collusive outcome. It is worth to note that the results critically depend on that the manufacturer has the power to set retail price.

Besides Bernheim and Whinston, Besanko and Perry (1993) also model perfect competition at retail level. They continue Marvel's (1982) study on free-rider problem. Marvel indicates that a manufacturer can solve the free-rider problem through exclusive dealing. For a leading brand manufacturer, it must invest much money on advertisements to let consumers aware its brand and purchase in advance. When consumers come to the retailer's outlet, they may be attracted by other competing brands because of the low prices, thus a strange phenomenon that the manufacturer invests but increases the competitor's sales arises. After the leading manufacturer chooses exclusive dealing, the incentive problem disappears and the benefits of advertisements are surely owned by the manufacturer itself.

Besanko and Perry transform the free-rider problem into interbrand externality. Interbrand externality is that when manufacturers are common agency, the benefits of their investments are shared with each other, and hence the effect is two-sided not one-sided like Marvel's. Their study explores that manufacturers would use exclusive dealing if the costs of investment were not too high. Because a manufacturer possesses whole benefits of the investment, it induces to spend more money on advertisements and the competition is thus more intensive.

The results in O'Brien and Shaffer or Bernheim and Whinston implicate that the channel structure in the market is unique, but Besanko and Perry allow different equilibrium under different conditions, and it is closer to the real world. They also prove that exclusive dealing could maximize the social welfare under and thereby it is not right to forbid exclusive dealing from the view of social welfare.

Mathewson and Winter (1987) considers a asymmetric market, where manufacturers have different marginal production cost and the retailer is a monopoly. Because the retailer is monopoly, manufacturers have to compete on wholesale price if they want to impose exclusive dealing. They argue that when the cost has big difference, the dominant manufacturer, with lower marginal cost, could guarantee itself the market by imposing exclusive dealing without its wholesale price declining too much. Thus, the equilibrium is exclusive dealing. Obviously, Mathewson and Winter also allow different channel equilibrium in different marketing environment.

Lal and Villas-Boas (1996) consider a more general model, where manufacturers and retailers are all duopoly. In their model, the situation that one retailer distributes one product and the other retailer distributes both products may arise, so the intrabrand competition is under consideration. They argue that if the retailer-loyal segment is not too large, manufacturers both choose common agency. That is because if the retailer-loyal segment is too large, it provide higher incentive to decrease wholesale price.

There are three contributions in our study. First, we introduce multiple marketing channel in discussing exclusive dealing and common agency. Because retailers have different marketing power and consumers have different ability to access the Internet in different channel, it gives manufacturers a chance to screen by channels. The idea is that manufacturers should induce different segments to shop in different channels. When the consumer structure in a channel is more homogenous, the competition between manufacturers decreases and it leads them to be more profitable. Second, given the level of externality, the equilibrium is not thus unique. In Besanko and Perry's (1993) study, they use the share of investment to express externality, and once the level of externality is given, we could know the equilibrium channel structure. In our study, we use the setup cost to express the externality, and even the level of externality is high, manufacturers may not choose common agency eventually. That is because we consider the retailer's ability of persuasion. Because a retailer could persuade consumers to purchase some brands, manufacturers would lower wholesale price to induce the retailer to persuade for him, and it leads to intensive competition under common agency. By using the characteristic that retailers have different persuasion power in different channel, we can

show that the level of externality is not enough to decide the equilibrium. Third, the discussions about the preferences of exclusive dealing or common dealing are short of consideration of the cost difference. It implies that the cost of two kinds of dealing is the same (Lin, 1990; O'Brien & Shaffer, 1993). Marvel (1982) and Besanko & Perry (1993) take the advertisement cost into account. Although the exclusive dealing will raise the manufacturers' investment on advertisement and common dealing will ease off such competition for the reason of external effect, they also assume that the advertising costs are indifferent between exclusive dealing and common dealing. Our study argues that the establishments of each retail outlet will have a fixed cost. It can be shared if manufactures choose common dealing but not for the exclusive dealings case. It means that manufactures should consider the different costs between exclusive dealing and common dealing.

### 3. Model

In the market, there are two manufactures, manufacturer 1 and manufacturer 2, producing brand 1 and brand 2, respectively. In this article, we sometimes use  $N_1$  and  $N_2$  to represent manufacturer 1 and manufacturer 2. Assume the production cost is 0 for both manufacturers without loss of generality. The population of consumers is normalized to 1, including 4 segments: (1) Segment  $G_1$ : it consists of consumers who are loyal to brand 1 and have their reservation prices for brand 1 and brand 2 equal to  $H$  and 0, respectively. The proportion of this segment is  $(1-q)/2$ . (2) Segment  $B_1$ : it consists of consumers who are the switchers of brand 1 and have their reservation prices for brand 1 and brand 2 equal to  $M$  and  $L$ , respectively. The proportion of this segment is  $q/2$ . (3) Segment  $G_2$ : it consists of consumers who are loyal to brand 2 and have their reservation prices for brand 1 and brand 2 equal to 0 and  $H$ , respectively. The proportion of this segment is  $(1-q)/2$ . (4) Segment  $B_2$ : it consists of consumers who are the switchers of brand 2 and have their reservation prices for brand 1 and brand 2 equal to  $L$  and  $M$ , respectively. The proportion of this segment is  $q/2$ . Let  $H > M > L > 0$  and  $0 \leq q \leq 1$ .

From the discussion in section 2, we know the competition among online retailers on the net is more intensive than the traditional channel in general. Thus, we assume there are two retailers  $R_1, R_2$  in the traditional channel, but there are many potential retailers on the Internet. Especially, only the retailers in the traditional channels have the ability to persuade consumers and change their preferences. A retailer can persuade consumers in  $B_1$  or  $B_2$  to buy their less preferred brand by incurring a persuasion cost  $C$  and raising their reservation price for their less preferred brand from  $L$  to  $M$ . In contrast, consumers in  $G_1$  and  $G_2$  can not be influenced by the retailer's persuasion effort. To highlight the importance of persuasion power of retailers at the traditional channels, we let  $L=0$ . After emergence of the Internet, a part of

consumers have the ability to shop on the net. Let  $\alpha_G$  and  $\alpha_B$  be the proportions of the Internet users in the segment of loyalists and in the segment of switchers, respectively.

The sequence of the game can be described as follows. First, the two manufacturers simultaneously decide which distribution channel(s) to use. Then they simultaneously choose only one retailer to sell their product for each chosen distribution channel. Then the contacted retailers accept or reject manufacturers' offers. Whenever the two manufacturers choose the same retailer to distribute their products, the common dealership occurs; otherwise, manufacturers adopt exclusive dealing. Then manufacturers set their wholesale prices and given the wholesale prices retailers set their retail prices.<sup>1</sup> As for the Internet channel, since there are many potential online retailers who will offer attractive contract in order to obtain the dealership from manufacturers. As a result, the retailer who gets the dealing right can not charge any retail price higher than its marginal price.

Denote the cost of setting up a retail outlet in the traditional channel by  $K_T$  and on the Internet by  $K_E$ .  $R_1$  and  $R_2$  set retail prices  $P_1, P_2$  given the wholesale prices  $w_1$  and  $w_2$ , and decide whether to influence a consumer's purchase decision by incurring a persuasion cost  $C$ . Besides, online retailers persuade consumers, which implies that the persuasion cost on Internet is assumed to be infinite.

Before shopping, consumers know the selling prices and their reservation prices of the two brands, and they seek to maximize their consumer surplus when choosing the product to buy. Consumers make their brand choice on the point of sales, which may be influenced by the retailer they shop at. To focus on the impact of the Internet on manufacturers' channel strategies, we deliberately abstract from the effect of consumer's differing preferences towards different distribution channels by assuming that the shopping cost of consumers at traditional channels is the same as on the Net and is equal to 0.

In what follows we use  $(X^i, Y^j)$  to denote an equilibrium where X-type consumers are served in the traditional channel and Y-type consumers are served on the Internet and  $i$  ( $j$ ) indicates the type of dealership adopted in the traditional channel (Internet channel, respectively), either exclusive dealing (denoted by E) or common dealing (denoted by C).

The game proceeds as follow:

1.  $N_1, N_2$  choose exclusive dealing or common dealing.
2. After the determination of channel structure,  $N_1, N_2$  set wholesale price  $w_1, w_2$ .
3.  $R_1, R_2$  set retail price  $P_1, P_2$ .
4. Consumers choose shopping channel

<sup>1</sup> This formulation is similar to that of Lin [4] and O'Brien & Shaffer [8.]

5. The retailer chooses whether to persuade.
6. Consumers choose brand.

### Before the emergence of Internet

Before the emergence of the Internet, the manufactures have to decide whether to distribute their product through the same retailer (i.e., common dealing) or different retailers (i.e., exclusive dealing), and which segments of consumers to target. Through exclusive dealing, manufactures are able to avoid the intensive price competition resulting from the retailer's incentive problem. Through common dealing, manufacturers can share the setup cost. Since manufactures are symmetric in every aspect, the equilibrium is also symmetric. The four possible equilibria are as follows:

1. Equilibrium ( $G^C, 0$ ): Both manufacturers only serve their respective loyals through a common retailer ( $N_1 \rightarrow (G_1, 0)$ ;  $N_2 \rightarrow (G_2, 0)$ ).

In equilibrium, the wholesale prices are set at the loyals' reservation price  $H$ , and so are the retail prices. In the equilibrium, the loyals' consumer surplus is completely extracted as in the monopoly case. The total channel profits are accrued to the manufacture and equal to  $\pi_1^M = \pi_2^M = M - (1 - q)H / 2 - K_T / 2$ .

2. Equilibrium ( $A^C, 0$ ): Both manufacturers serve all consumers in their respective markets through the common retailer ( $N_1 \rightarrow (G_1 + B_1, 0)$ ;  $N_2 \rightarrow (G_2 + B_2, 0)$ ).

First note that in order to induce the retailer to serve all consumers in manufacturers' respective market by setting the retail price at  $M$ , manufacturers would set their wholesale prices satisfying  $(M - w) / 2 \geq (1 - q)(H - w) / 2$ . The condition ensures that the retailer obtains higher profits when serving each manufacturer's switchers than otherwise. When this is the equilibrium,  $w_1 = w_2 = [M - (1 - q)H] / q$ .

Now we need identify the condition under which it is not profitable for each manufacturer to attract its rival's switchers by lowering its wholesale price and thus sustain the above equilibrium. To this end, we shall first derive the wholesale price that induces the retailer to switch consumers for the deviating manufacturer and then show that the resulting manufacturer profit is lower than staying in the equilibrium. When one manufacturer, say  $N_1$ , deviates by lowering  $w_1$ , the condition,  $(1 + q)(M - w_1) / 2 + (1 - q)[M - (M - (1 - q)H) / q] / 2 - C \geq (M - w_1) / 2 + [M - (M - (1 - q)H) / q] / 2$ , must be satisfied in order to induce the retailer to incur a cost  $C$  and persuade manufacturer 2's switchers to buy brand 1. Thus manufacturer 1 has to lower his wholesale price until  $w_1 = [M - (1 - q)H - 2C] / q$  in order to induce the retailer to switch his rival's consumers to buy brand 1. Finally, manufacturer 1 would prefer staying in the equilibrium to deviating if the condition,  $[M - (1 - q)H] / 2q \geq (1 - q)[M - (1 - q)H - 2C] / 2q$

$$(3-1)$$

holds. Simplifying the above inequality gives us:

$$C \geq [qM - q(1 - q)H] / 2(1 + q)$$

By (3-1), when the persuasion cost is high enough, both manufacturers will be content with their own customers, making it possible to sustain the equilibrium ( $A^C, 0$ ), the manufacturer's profits in this equilibrium are  $\pi_1^M = \pi_2^M = M - (1 - q)H / 2q - K_T / 2$ . When condition (3-1) does not hold, once the manufacturers choose the same retailer, they will compete with each other on the basis of the wholesale prices to obtain the retailer's support, as will be shown in the fourth possible equilibrium.

3. Equilibrium ( $A^E, 0$ ): Both manufacturers serve all consumers in their respective markets through their own exclusive retailer ( $N_1 \rightarrow (G_1 + B_1, 0)$ ;  $N_2 \rightarrow (G_2 + B_2, 0)$ ).

When each manufacturer serves consumers through their exclusive retailer, he does not need to worry about the retailer's persuasion power. Therefore, his pricing strategy is the same as in the monopoly case with the wholesale price equal to  $w_1 = w_2 = [M - (1 - q)H] / q$ .

4. Mixed strategy equilibrium: both manufacturers mixed pricing strategy through common dealing

When (3-1) does not hold, for example, when the proportion of switchers ( $q$ ) is high or/and the persuasion cost is low enough neither manufacturer will content himself with serving his own customers. Each manufacturer would like to attract his rival's switchers through the retailer's persuasion power by offering a more attractive wholesale price to the retailer, thus resulting in a severe price competition between manufacturers. On the other hand, each manufacturer can guarantee a marginal profit  $(1 - q)H / 2$  by serving his own loyals only. Thus the manufacturer will not cut his price lower than  $(1 - q)H / (1 + q)$  to attract his rival's switchers for in the latter case the resulting manufacturer profits  $[(1 - q)H / (1 + q)] * (1 + q) / 2$  are lower than in the former case. In fact, in the same spirit of Varian [9] and Narasimhan [7], there exists only the mixed strategy equilibrium where each manufacturer randomizes his wholesale price according to a distribution function. The manufacturer whose wholesale price turns out to be more attractive would succeed in obtaining the retailer's support in attracting his rival's customers for him. In this mixed strategy equilibrium, the expected profits for each manufacturer are  $\pi_1^M = \pi_2^M = (1 - q)H / 2 - K_T / 2$ , the same as the manufacturer would obtain by serving his loyals only.

Proposition 1: Let the reservation price of the loyals' be 1 and that of the switchers' be  $k$  ( $0 \leq k \leq 1$ ). Suppose that the setup cost in the traditional channel is the same as on the Internet, i.e.  $K_T = K_E = K$ .

Before the emergence of the Internet, the respective conditions for each equilibrium to occur are as follows:

Equilibrium	Equilibrium conditions
$(G^C, 0)$	$k \leq 1 - q^2$
$(A^C, 0)$	$k \geq 1 - q^2$ ; $k \leq [q(1 - q) + 2(1 + q)C] / q$
$(A^E, 0)$	$k \geq 1 - q^2 + Kq$ ; $k \geq [q(1 - q) + 2(1 + q)C] / q$
Mixed strategy equilibrium	$1 - q^2 \leq k < 1 - q^2 + Kq$ ; $k \geq [q(1 - q) + 2(1 + q)C] / q$

Table 1 The equilibrium conditions before the emergence of the Internet

The conditions above are derived from the following logic. To sustain equilibrium, the equilibrium profits have to be larger than any other profits that are derived from other possible strategies. Take equilibrium  $(A^C, 0)$  as an example. When manufacturers are in this equilibrium, they have no incentives to serve their respective loyals and to induce the retailer to persuade consumers to buy his brand. The former condition is equal to satisfy  $k \geq 1 - q^2$ , and the later condition is equal to satisfy  $k \leq [q(1 - q) + 2(1 + q)C] / q$ . As a result, the two inequalities are the conditions to sustain equilibrium  $(A^C, 0)$ . We can infer other equilibrium conditions by the same logic.

 3: Equilibrium  $(A^E, 0)$ ;      4: Mixed Equilibrium  
 $\Gamma_1$ :  $k = 1 - q^2$   
 $\Gamma_2$ :  $k = [q(1 - q) + 2(1 + q)C] / q$   
 $\Gamma_3$ :  $k = 1 - q^2 + Kq$   
 X-axis: q; Y-axis: k

By Figure 1, it is easy to show that which equilibrium happens depends on the switchers' value. When there are more switchers in the market or their reservation price is higher, we can say the switcher is more valuable. When the switcher is not so valuable, manufacturer wants to set the highest wholesale price  $H$  to serve the loyals only, it leads to equilibrium  $(G^C, 0)$ . When the switcher's value is higher but not too high, manufacturers have the incentives to serve all his own consumers but not the rival's switchers, so they can share a retail outlet peacefully and it is the equilibrium  $(A^C, 0)$ . When the switcher's value is too high, if manufacturers choose a common retailer, both of them can not satisfy with serving their own customers only, and it means they will have more intensive price competition. Thus, they are will to have more setup cost to avoid such price competition.

### After the emergence of the Internet

After the emergence of the Internet, two things are different from before. First, manufacturers can sell products through the Internet channel where retailers have much less influence on consumers' preference than in the traditional channel. Second, as mentioned in the model, not all consumers can access the Internet and thus the proportions of the Internet users in the segment of loyals (denoted by  $\alpha_G$ ) and in the segment of switchers (denoted by  $\alpha_B$ ) would determine the structure of the consumer market and hence the manufacturer's optimal channel strategy. The following lemma shows that manufacturers will choose common dealing whenever they sell products on the Net.

The problems facing each manufacturer include whether to sell his product through the traditional channel, the Internet channel or both, for each distribution channel whether to choose the common dealing or exclusive dealing, and whether to serve his loyals only or switchers as well. There are eight possible symmetric pure strategy equilibriums when manufacturers can distribute their products either through the traditional channel or the Internet channel. We describe them in the following.

1. Equilibrium  $(G^C, 0)$ : both manufacturers only serve the loyals in the traditional channel through common dealing ( $N_1 \rightarrow (G_1, 0)$ ;  $N_2 \rightarrow (G_2, 0)$ ).
  2. Equilibrium  $(A^C, 0)$ : both manufacturers serve all consumers in the traditional channel through common dealing ( $N_1 \rightarrow (G_1 + B_1, 0)$ ;  $N_2 \rightarrow (G_2 + B_2, 0)$ ).
  3. Equilibrium  $(A^E, 0)$ : both manufacturers serve all consumers in the traditional channel through exclusive dealing ( $N_1 \rightarrow (G_1 + B_1, 0)$ ;  $N_2 \rightarrow (G_2 + B_2, 0)$ ).
  4. Equilibrium  $(0, G^C)$ : both manufacturers only serve their loyals on the Internet through common dealing.
- In the above equilibrium, manufacturers set the wholesale prices at the loyals' reservation price  $H$  and so

do retailers set the retail prices. The profits of manufacturers are  $\pi_1^M \pi_2^M = (1-q) L H / 2 - K_E / 2$ .

5. Equilibrium  $(0, A^C)$ : both manufacturers serve all consumers on the Internet through common dealing. Because the retail market on the Internet is competitive, retailers can not charge any price higher than their marginal cost, i.e., the wholesale price charged by the manufacturers. As a result, the manufacturer can serve all consumers who can access the Internet in his protected market by setting his wholesale price at the switchers' reservation price  $M$ . The profits of manufacturers equal  $\pi_1^M \pi_2^M = (1-q) L q_s M / 2 - K_E / 2$ .

6. Equilibrium  $(G^C, A^C)$ : both manufacturers sell their products through the two distribution channels under common dealing. The manufacturers induce all their customers who can access the Internet to buy their products on the Net and serve their loyals who can not access the Internet in the traditional channel.

In equilibrium  $(G^C, A^C)$ , each manufacturer would like to serve his switchers on the Net and thus sets his wholesale price at  $M$ . Given this wholesale price, the online retailer would set the retail price also at  $M$  (again because of competition) while the traditional common retailer would set the retail price at  $H$ . Facing the two different retail prices, all consumers who can access the Internet would buy their preferred brand on the Net by paying a cheaper price and only the loyals who can not access the Internet buy their preferred brand from the traditional retailer. The manufacturer's profits are  $\pi_1^M \pi_2^M = (1-q) q_s M / 2 - (K_T + K_E) / 2$ .

7. Equilibrium  $(A^C, A^C)$ : both manufacturers sell their products through the two distribution channels under common dealing. The manufacturers induce all their customers who can access the Internet to buy their products on the Net and serve their remaining customers in the traditional channel.

When the consumers who can access the Internet are induced to the Net, the structure of remaining consumers in the traditional channel would change. To serve all consumers that stay in the traditional channel, the manufacturers would set their wholesale prices at  $M - (1-q)(1-\alpha_G)(H-M) / q(1-\alpha_B)$  to ensure the common retailer the same profits as those when serving the loyals only. This wholesale price is positively related to  $\alpha_G$  and negatively related to  $\alpha_B$ . With the similar reasoning used in deriving (2-1), we can derive the following lower bound for the retailer's persuading costs in order to sustain the equilibrium:

$$C \geq \frac{q^2(1-\alpha_B)^2 M - q(1-q)(1-\alpha_B)(1-\alpha_G)(H-M)}{2(1-q)(1-\alpha_G) + 4q(1-\alpha_B)} \quad (3-2)$$

8. Equilibrium  $(A^E, A^C)$ : serve all consumers with

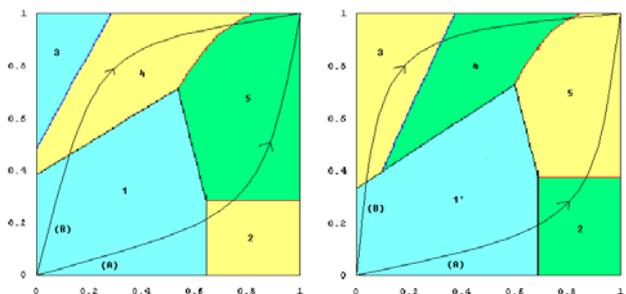

common dealing on the Internet and with exclusive dealing in the traditional channel.

If (3-2) is not satisfied, it means that when manufacturers adopt the strategy  $S(A^C, A^C)$ , they would have incentives to attract the competitor's switchers through the retailer's persuading, thus breaking the equilibrium  $(A^C, A^C)$ . When the proportion of the loyals who can access the Internet is higher than that of the switchers, inducing all Internet users to buy on the Net would lead the proportion of the switchers in the traditional channel relative to that of the loyals increases. Therefore, if manufacturers choose  $S(A^C, A^C)$ , manufacturers would compete aggressively on their wholesale prices with the hope that the common retailer can attract their rival's switchers for them. To avoid such competition, manufacturers may choose exclusive dealing in the traditional channel, resulting in the equilibrium  $(A^E, A^C)$ .

Proposition 2: Let the reservation price of the loyals be 1 and that of the switchers' be  $k$  ( $0 \leq k \leq 1$ ). Suppose that the setup cost in the traditional channel is the same as that in the Internet channel, i.e.,  $K_T = K_E = K$ . After the emergence of Internet, the conditions for equilibrium  $(G^C, 0)$  to occur are as follows:<sup>2</sup>

Follow the same logic as in proposition 1. When an equilibrium is sustained, the profits derived from other strategies are always less than the equilibrium profits. Take equilibrium  $(G^C, 0)$  as an example. A manufacturer has five possible alternative strategies. One is to serve all consumers in the traditional channel; two is to serve the loyals on the net; three is to serve all consumers on the net; four is to serve the loyals in the traditional channel and all consumers on the net; five is to serve all consumers in both channel. Compare the equilibrium profits with others derived from these strategies, and then we can get the inequalities stated in proposition 2.

$$1 - q \leq k - 1 - q^2 \quad k \geq 1 - q^2 \text{ \& } k \leq [q(1+q) + 2(1-q)q] / q$$

<sup>2</sup> Because of the page limitation, we do not list these conditions here.

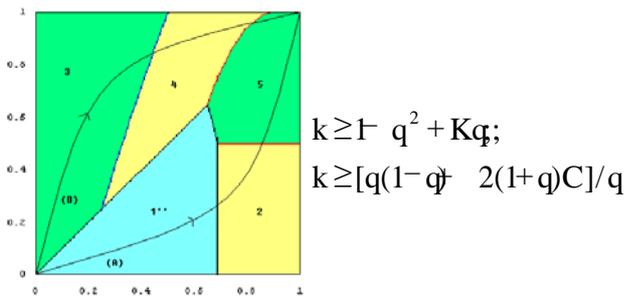

Figure 2 The equilibrium after the emergence of the Internet

Note:

1. Equilibrium: 1:  $(G^C, 0)$ ; 1':  $(A^C, 0)$ ; 1'':  $(A^E, 0)$ ; 2:  $(G^C, A^C)$ ; 3:  $(A^E, A^C)$ ; 4:  $(A^C, A^C)$ ; 5:  $(0, A^C)$
2. X-axis:  $\alpha_B$ ; Y-axis:  $\alpha_G$
3. Path A: more switchers can access the Internet than the loyals;  
Path B: more loyals can access the Internet than the switchers
4. Parameter value:  $k=0.35, 0.4, 0.8$  (from left to right);  $q=0.8$ ;  $C=0.05$ ;  $K=0.05$

Corollary 2-1: Keep the preferences and proportions of the loyals and the switchers constant. Suppose that the proportion of consumers who are able to access the Internet increases over time. Then the manufacturers' equilibrium distribution strategy will be dynamically adapted to the proportions of Internet loyals and Internet switchers.

Keeping other parameters constant, figure 2 shows that how the manufacturers' equilibrium distribution strategy varies with  $\alpha_G$  and  $\alpha_B$ . Before the emergence of the Internet (or equivalently, when both  $\alpha_G$  and  $\alpha_B$  equal zero), depending on the importance of switchers (represented by the size of  $k$ ) and the retailer's persuasion cost, the equilibrium could be  $(G^C, 0)$ ,  $(A^C, 0)$  or  $(A^E, 0)$ , which correspond to equilibrium 1, equilibrium 1' and equilibrium 1'' in the three graphs, respectively. With the increase in the proportion of Internet users, the equilibrium distribution strategy will be dynamically adjusted. The way in which the equilibrium distribution strategy adjusted crucially depends on the relative sizes of  $\alpha_G$  and  $\alpha_B$ . Two cases can be distinguished: the case where  $\alpha_G \leq \alpha_B$ , and the case where  $\alpha_G \geq \alpha_B$ .

In the case where  $\alpha_G \leq \alpha_B$ , as shown by the path A

in figure 2, with the emergence of the Internet, the distribution equilibrium may change from equilibrium  $(A^E, 0)$  into  $(G^C, A^C)$  as long as  $\alpha_B$  is high enough relative to  $\alpha_G$ . The manufacturer by expanding into the Internet channel, can induce a relatively higher proportion of switchers to buy his product on the Net, which enables him to serve only the loyal non-Internet users in the traditional channel and thus do not need worry about the traditional retailer's incentive problem of switching his customers. When  $\alpha_B$  is high enough relative to  $\alpha_G$ , the benefit from alleviating the retailer's incentive problem will outweigh the loss of the non-Internet users in the segment of switchers, thus leading to the equilibrium  $(G^C, A^C)$ . As more and more consumers can access the Internet,  $(0, A^C)$  becomes the equilibrium strategy.

In the case where  $\alpha_G \geq \alpha_B$ , as shown by the path B in figure 2, with the emergence of the Internet and the increase in the proportion of the Internet users, the distribution equilibrium may change from equilibrium  $(A^C, 0)$  first into  $(A^E, A^C)$ , and finally into  $(A^C, A^C)$  as long as  $\alpha_B$  is high enough relative to  $\alpha_G$ . The manufacturer by expanding into the Internet channel, can induce a relatively higher proportion of loyals to buy his product on the Net, which aggravates the retailer's incentive problem of stealing customers but mitigating the manufacturer's concern for double-marginalization. The latter benefit will outweigh the former cost when  $\alpha_B$  is small enough relative to  $\alpha_G$ , thus resulting in the equilibrium  $(A^E, A^C)$ . In other words, the manufacturer uses exclusive dealing to overcome the traditional retailer's incentive problem and alleviate the double-marginalization problem by mitigating loyals to the Internet channel. When the proportion of Internet users in the segment of switchers keeps increasing, it becomes less desirable for either manufacturer to induce the retailer to persuade customers and hence the equilibrium changes into  $(A^C, A^C)$ . As more and more consumers can access the Internet,  $(0, A^C)$  becomes the limiting equilibrium.

Corollary 2-2: Whether common dealing becomes more prevalent after the emergence of the Internet crucially depends on the structure of the consumer market, in particular, the importance of loyal switchers, and the proportions of Internet users in the segment of loyals and in that of switchers ( $\alpha_G$  and  $\alpha_B$ ).

1. If  $k \geq 1 - q^2 + Kq$  and  $k \geq [q(1-q) - 2(1+q)C]/q$  common dealing becomes more prevalent in the presence of the Internet channel;
2. If  $1 - q \leq k - 1 - q^2$  or  $1 - q^2 \leq k - [q(1-q) + 2(1+q)C]/q$ , exclusive becomes more prevalent only if  $\alpha_G$  is extremely high relative to  $\alpha_B$ ;
3. If  $k \leq 1 - q$ , manufacturers prefer common

dealing to exclusive dealing both in the absence and in the presence of the Internet channel.

Proof. The above corollary is derived by comparing the equilibria before the emergence of the Internet channel with those after.

## Abstract

Although auctions have been an important model for price discovery on Internet, economics does not have a precise theory of auctions. Auctions raise many problems such as what types of goods will be sold by auction on Internet, and how bidders bid on Internet auction. It is curious why some newly manufactured products that are sold on the posted-price markets are also sold by auction on Internet. This paper presents a field study on Internet to investigate the differences between the bidding behavior for secondhand and newly manufactured goods. Data is collected on an open-book auction site. The results show that there were really some bidders behaved like evaluators and whether a bidder will be an evaluator or a participator is not affected by common referenced external market price. Furthermore, the prices on posted-price market may affect bids on the auction market., averaged normalized mark up of newly manufactured items were significantly larger than that of secondhand items. Implications of the findings are also discussed in this paper.

## 1. Introduction

The Internet is shaping industries and changing business models. Internet can facilitate transactions between buyer and seller and lower the transaction cost. Some literatures suggested that Internet will cause the disintermediation effects and network services will replace traditional middlemen in the value chain [14] [16]. The issue of disintermediation has raised the debates on whether electronic marketplace can perform the functions of traditional middleman [1].

One major function of intermediaries is to gather, organize, and evaluate information, which is dispersed in society, and to set the price based on this information to clean the market [18] [20]. It is a hard work for the firms to get sufficient information to make the pricing decision. So usually either the quantity of demand is less than the quantity of supply and the product has to be sold at a discount, or the posted price is too low and there will be a rush for the product or the buyers have to pay a premium. Because it is not easy to clean the market on the posted price, traditionally, except for the transactions of some standardized commodities in retail market, most of the final dealing prices are decided by dickering or

bargaining. The price marked in the store or printed in the catalog is just the asking price of the seller. This asking price is usually higher than the price the seller can accept. Sellers and buyers will try to gather information and reveal the other's bottom line during the bargaining process.

For the posted price is usually not efficient enough, it is an interesting problem how the price is decided for products sold on Internet. Lower menu cost is one major benefit of electronic commerce [19]. Modahl [13] has suggested that the dynamic pricing model, which can change the price simultaneously according to current sales, is the most important innovative feature of electronic commerce. On the other hand, some bargaining agents, which is a software agent on the Internet and can take the place of seller or buyer in the bargaining processes, have been proposed [8]. However, although there have been so many solutions for price discovery, auction is still the seldom one which has worked in practice. Electronic auction solve the problem of getting the buyers or sellers to reveal their best price. Companies such as eBay, Ubid, Priceline, and FreeMarkets have invented various auction models in different markets and worked well. For example, eBay, which provides a platform for English auction for individual sellers and buyers, has supposed to be one of the most successful companies on Internet.

Although auctions have been an important model on Internet, economics does not have a precise theory of auctions [4]. Firms face the new type of transaction need to learning how to adopt the new mechanism in the organizations as sellers or buyers [3] [5]. Because Internet provides a different context for auction, bidding behaviors on Internet may be different from other auction markets. Internet auctions raise a variety of interesting questions for economists to investigate such as what types of goods will be sold by auction, and how bidders bid on Internet auction. It is curious why some newly manufactured products that are sold on the posted-price markets are also sold by auction on Internet. This paper will present a field study on Internet that investigated the differences between the bidding behavior for secondhand and newly manufactured goods. Results of this study may help to find out how bidders bid on the Internet and facilitate to explain the utilization of auction on Internet.

## 2. Auctions on the Internet

Auctions are processes of formalized dickering. There have been many different auction mechanisms like the English ascending-bid auctions, the Dutch descending-bid auctions, the first-price sealed-bid auctions, the Vickrey second-price sealed-bid auctions and double auctions [12]. Auction could be an effective way for price discovery if the number of participants is large enough. However, the cost of gathering enough participants at the same time is high, so in the past, auctions are seldom used in consumer markets except for some expensive collectables.

Electronic auction solve the problem of getting the players at the same time to reveal their best price. Auction evolved in a setting where people could hear and see each other. Traditionally, people participate in an English or Dutch auction have to stay and pay attention to the process during the bidding period. But Internet has provided a different context. The network can get people in different locations participate the auction easily. Besides, in order to get more participants, auctions on the Internet are usually asynchronous that the auction information is exchanged on the network and the bidding period continues for a few days. The basic challenge for Internet auction is that bidders in an auction lasting for several days have to stay on line to raise their bids. Proxy bidding solves this problem by providing a software agent. When current price is below the upper limit price specified by the bidder, the agent will bid automatically on the price mark up by the minimum increment set by the seller [4]. So people don't have to stay on line and can bid on any convenient time during the auction period. Asynchronous auctions have lowered buyers' cost to participate.

Lee [7] analyzes prices in electronic and conventional auction markets for used cars sold from 1986 to 1995. He found that prices in the electronic markets were higher than prices in the conventional markets and that this price difference seems to increase over time. This result has showed that the electronic markets have been more efficient than conventional markets for auctions.

### 2.1 Types of goods

As Internet technology lowers the cost of running an auction relative to using other pricing mechanisms, it is expected that new types of goods will be auctioned. However, the literature has not yet examined the question of what types of goods sellers would prefer to auction [11]. Wang [21] compares posted-price selling with auctions and finds that without auction costs, auctions are always optimal, and as long as there is a wide dispersion of buyer valuation, auctions will still outperform posted-price selling even if auctions were costly [6]. Similarly, Hall [4] argues auctions are favored when there is a lot of uncertainty about the market value of the objects. The value has to be high enough to make the auction process worthwhile, and the players need to have

enough time to make the auction work.

For Internet technology lowers the costs of running an auction, Lucking-Reiley [11] suggests as the market develops out of its infancy, we might well expect to see more additions to the list of auctioned. On the other hands, Liebowitz [9] emphasizes auctions are a step backward in the evolution of retailing and only make sense for odd lots, surplus, one-of-a-kind items, or items for which the audience likes the thrill of the chase. Meanwhile, Lucking-Reiley [11] suggests that auctions will be used most often for goods in limited supply where the demand is unknown to the seller, because these are the circumstances under which the benefits of a flexible, market-determined price are likely to be greatest. Lucking-Reiley [11] also notices that auctions would seem to provide relatively little social benefit in the case of newly manufactured items, because the supply of such items is not fixed, so the retailer can adjust prices or quantities in response to observed demand. By contrast, used and rare items are in relatively fixed supply, so auctions can be valuable in determining the correct price and allocation in the face of uncertain demand.

However, many auction sites do sell newly manufactured items. Lucking-Reiley [11] notes that there have been two primary business models for Internet auctions: merchant sites and listing-agent sites. A merchant site offers its own merchandise for sale, acting as a retailer who happens to conduct its transactions through auction. A listing site acts as an agent for other sellers, allowing them to register their items and running the auctions on their behalf. Some auction sites combine both types of models. Many Products sold on the merchant sites are newly manufactured ones.

### 2.2 Bidding behavior

Why these newly manufactured products are sold by auction is an interesting question because these products are sold on posted-price in the past. It seems that the cost to adjust prices or quantities on posted-price markets is higher than the cost of auctions markets on Internet. However, efficiencies of auction markets are affected by numbers and strategies of bidders. Bapna et al. [2] studies bidders' strategies in multi-item online auction and the result of the data mining shows there are three types of bidders: evaluators, participators, and opportunists. Evaluators are those who know clearly their true valuation of the good and submit high bids at the early stages of the auction. Participators are bidders who follow the bidding closely and place ascending bids. Opportunists are driven by thoughts of getting bargains – they usually place the lowest possible bids toward the end of an auction. Because there are list prices for the newly manufactured products, which are also sold on posted-price market, if the posted prices are efficient enough, these prices will be the common value of the products. There will be more bidders who know the market value of the items and may behave like evaluators.

However, Hall [4] has told another story. He argues that auction theory is based on the idea that the players all have cutoff prices in mind before the auction begins. If all bidders are eventually going to enter bids with their true maximums, it just does not matter, whether you bid at the beginning, middle, or end of the auction, or when others bid, has no effect on the outcome. The winner is always the player with the highest cutoff price, and the price is always the runner-up maximum plus the bid increment.

In fact, there is lot evidence that people learn auctions and adjust their ideas about the value of what is for sale. Bidders learn about the value of the goods by seeing the bids of others. They don't know their cutoff values before an auction begin [12]. Rather than having a good idea of the maximum they are willing to pay, they have a general idea that they want an object, and a firm desire not to pay more than it is worth. They would like to gather information from others about an object's value. Hall [4] also suggests experts who know the value of the item will not bid until the end of the auction in order not to reveal the value and raise the price. This strategy is similar to the strategy of opportunists proposed by Bapna et al. [2].

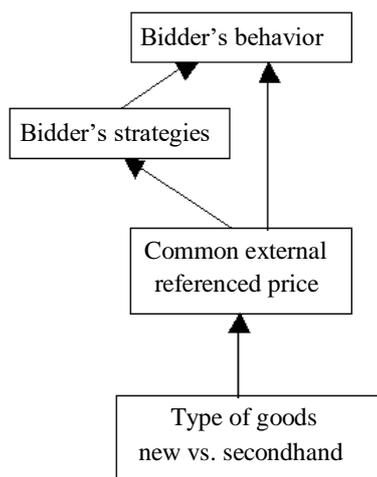

Figure 1. Theoretical model

Figure 1 illustrates the theoretical model of this study. Independent-private-value and asymmetries of information are two important assumptions of many auction theories [12]. For auctions of newly manufactured goods, Common external referenced price on the posted-price market will influence both the strategy and the behavior of bidders. Based on the classification of Bapna et al. [2], we propose that the bidding behaviors for secondhand products will be different with bidding behaviors for newly manufactured ones, and we conducted a field to verify the differences

### 3. Research Context

We got more than one hundred auction sites using two Chinese search engines. However, as mentioned by Lucking-Reiley [11], most of these auction sites were relatively small. This result reflects the network externality effects of auctions [6]. The site Go2HK (www.go2hk.com) was selected as the sample among the auction sites being searched for several reasons. First, comparing with other auction sites been searched, there were more buyers and products being sold on this site, so auctions on the site would be more likely to be efficient. Second, the site followed the rule of English auction, which is the most popular mechanism on Internet auctions. Third, both secondhand and newly manufactured items were sold on Go2HK, hence this site satisfied the requirements of our study. Fourth, auctions on this site were open-book ones, details of the auctions such as the buyer, price, and time of each bid were provided, and so behaviors of the bidders can be observed.

Lucking-Reiley [11] has surveyed types of items at auction on Internet and finds that the collectibles and the electronics and computers were the two most popular ones. Although collectibles was the largest category, transactions of electronics and computers were selected as the subjects of this study because electronics and computers were more standardized product. For the same reason, the study focused only on transactions of notebook computer and mobile phone.

Go2HK followed the rule of English auction. English ascending-bid auctions are by far the most prevalent on the Internet. On Internet English auction, bidders can search the items they are interested, view the current high bid, and decide whether to raise the bid price. In order to ensure the efficiencies, mark up of the bid must bigger than the minimum acceptable increment set in advance. The process will continue to the end of the bidding period. The last bidder, who will pay the highest price, is going to win the auction. Go2HK also provided the service of proxy bidding. A bidder with a high willingness to pay need not check back at the site repeatedly to keep raising the bid as necessary. Using proxy bidding, it will be no differences when the bidders propose their rules, the bidder with the highest upper limit price will always win the bid, and the price he pay will equal to the price of the next highest upper limit price add on the minimum acceptable increment. From the perspective of auction theory, results of proxy bidding are similar to the sealed-bid, second-price Vickrey auction [10].

Data are collected from the auction site Go2HK. Although there were many items been sold on this auction site, most of them got few responses. Because the interactions among bidders should affects bidding behavior, only the bidding records of the auctions with more than ten bids were collected. 41 auction items that terminate in the data collecting period and satisfied the criteria of bids number and were got. There were totally

1449 bids in the 41 auctions. Table 1 and table 2 show the components of the auction items and bidding records collected in the sample.

Table 1. Auction items in the sample

	Mobile phone	Notebook computer	Total
Newly manufactured items	7	6	13
Secondhand items	12	16	28
Total	19	22	41

Table 2. Bidding records in the sample

	Mobile phone	Notebook computer	Total
Newly manufactured items	223	239	462
Secondhand items	340	647	987
Total	563	886	1449

#### 4. Analysis

Bidding Strategies of evaluators are different with the strategies of participators. Evaluators know clearly their true valuation of the good and submit high bids at the early stages of the auction. On the other hand, Participators are bidders who follow the bidding closely and place ascending bids. So in English auction, participators will bid on the mark up equal to the minimum acceptable increment, and evaluators may bid on the mark up larger than the minimum increment. Comparing with the auctions of secondhand items, because there are the referenced external market prices for the newly manufactured items, bidders can more easily evaluate the true value of the item and are more likely to become evaluators. So there will be more bids which on the mark up larger than the minimum increment for the auctions of newly manufactured items.

Existence of evaluators is discussible. Even if bidders may know the value of the item been auctioned, they will avoid to reveal their valuation and try to get the item on the price as low as possible [4]. Especially by using proxy bidding, bidders can easily bid incrementally and try not to reveal their highest prices. Although there are external market prices of newly manufactured items, bidders will behave like participators and bidding behaviors of newly manufactured items will not be different with that of secondhand ones.

Table 3. Percentage of bids on mark up larger than minimum increment

	Mobile phone	Notebook computer
Newly manufactured items	19.91%	25.75%
Secondhand items	24.09%	17.12%

Table 3 presents the percentage of bids on mark up larger than minimum acceptable increment for each type of items. The table shows that, first, about one fifth to one fourth bidding bided on mark up larger than the minimum acceptable increment, there were really some bidders behaved like evaluators. And second, percentages of bids that on mark up larger than the minimum increment on secondhand items were not different with that on newly manufactured items. The results indicate that there is really someone who will behave like an evaluator on Internet auction, and whether a bidder will be an evaluator or a participator is more likely to be affected by some factors of personal characteristics, but not the factors such as common referenced external market price.

Although the external market price would not affect whether the bidders will be evaluator or participator, it is still interesting whether the external market price could make any impact on bidders' behavior. If there are not any effects at all, the reason could be that the market price is not an efficient one. Except for comparing the percentages of bids of which on the mark up larger than the minimum increment, average mark up are also compared in the study. Because for different items, the price levels were not the same, mark up is normalized by divided by the minimum acceptable increment. Formula of normalizing mark up is as follow:

$$q_i = (P_i - P_{i-1}) / P_{min} \quad (1)$$

$q_i$  : normalized mark up for the  $i$  bid,

$P_{min}$  : minimum acceptable increment,

$P_i$  : price for the  $i$  bid.

Table 4. Averaged normalized mark up for mobile phone

	New mobile phone	Secondhand mobile phone
Average	25.072	2.264
Variance	15219.156	14.969
N	223	340
t statistics	3.4081	
p (two tails)	0.0007 < $\alpha=0.1$	

Table 5. Averaged normalized mark up for notebook computer

	New notebook computer	Secondhand notebook computer
Average	50.992	2.588
Variance	53796.41	935.655
N	239	647
t statistics	5.1923	
p (two tails)	2.5786E-07 $< \alpha = 0.1$	

Averaged normalized mark up prices for new manufactured and secondhand items is compared by t test separately for mobile phone and notebook computer on table 4 and table 5. The results indicate averaged normalized mark up of newly manufactured items were significantly larger than that of secondhand items, both for mobile phone and for notebook computer. Although external referenced price may not affect whether a bidder will be an evaluator or a participator, affected by the prices on posted-price markets as common referenced value, evaluators for the newly manufactured items will bid on a higher mark up than evaluators for the secondhand items.

## 5. Conclusion

We conducted a field study on Internet to investigate the differences between the bidding behavior for secondhand and newly manufactured goods. Data is collected on an open-book auction site that lists all the bidding history on web. Results of the analyses show that, first, there were really some bidders behaved like evaluators. Second, percentages of bids that on mark up larger than the minimum increment on secondhand items were not different with that on newly manufactured items. Whether a bidder will be an evaluator or a participator is more likely to be affected by some factors of personal characteristics, but not the factors such as common referenced external market price. Third, averaged normalized mark up of newly manufactured items were significantly larger than that of secondhand items, common external referenced price may affect bidders' behaviors.

This study try to investigate what types of goods will be auctioned on the Internet by comparing bidding behaviors of newly manufactured goods and that of secondhand ones. Results of the study suggest the prices on posted-price market will not affect bidder's strategy but could still affect bids on the auction market. Because bidders do refer to the posted-price, the problem why newly manufactured products are sold by auctions remains to be further investigated. Winner's curse of the auctions may be one of the reasons [15]. Except for the bidding price, bidding time is also an important decision

variable in auctions. Experts and opportunists will not bid until the last minute of the bidding [2] [4]. The last minute effect has been well-known phenomenon on Internet auctions [17]. Bidding time should be further combined with bidding price to model and compare the bidding behaviors of various types of goods.

This study verified bidders' strategies as evaluators and participators. However, it is still curious why bidders will be an evaluator that raise the prices substantially and reveal their valuations of the items, and why bidders as a participator will bid in the early stage of the bidding. Many works needed to be done in the future.

# Managing Changes in E-Transformation

Yi-Chen Lan

School of Computing and IT  
University of Western Sydney  
Australia  
yichen@cit.uws.edu.au

## Abstract

In today's digital economy and business, firms especially the SMEs (small and medium-sized enterprises) are facing competitive challenges from anywhere around the globe. Transforming the traditional business processes and activities into electronic capable (e-capable) format has become the essential tasks for companies to not only sustain in the competitive environment but flourish in the companies' perpetual operations. During the e-transformation process, organisations normally face changes in various aspects. To success in the transformation, companies need to manage the changes effectively. The change management tasks should be developed systematically through the identification of areas where changes may occur, and the research and development of solutions that will accommodate the changes.

This study proposes a conceptual model for managing changes in e-transformation, which provide SMEs with a methodological framework in identifying and managing organisational changes.

## 1. Introduction

Many firms especially the SMEs have recognised the information technology (IT) as the key driver that could enable companies to position themselves competitively into the global marketplace. Specifically, the Internet is a prominent medium for providing SMEs with a speedy transformation process that allows companies to transit their business activities and operations from a domestic focus to the global orientation. Nevertheless, transforming SMEs into e-businesses is not just creating interactive websites and incorporating payments as part of the online functions. The real challenges for companies pursuing e-transformation is to embrace the management of changes before, during, and after the transition in all aspects.

This study aims to development a framework for managing changes in e-transformation that would assist SMEs in strategic planning and decision making for the transition. The paper starts with the revisiting of SMEs e-transformation roadmap, review the forces to organisational change, followed by the identification of organisational changes in e-transformation. Finally, it concludes with the proposed framework for change management in e-transformation and the development of a checklist for e-transformation achievement.

## 2. The E-transformation Roadmap for SMEs

There is no doubt that many SMEs are eager to engage themselves in the e-business vogue through the application of the Internet technology which incorporates eminent and fascinating functionalities such as interactive or "full-duplex" communications, online payment, and dynamic inventory et cetera. Moreover, companies are commonly impatient to develop their "corporate websites" which contain typically the same information as they put in the Yellowpages and which is rarely updated. As the result of such unplanned approach, senior executives are most likely to diminish the budget and human resources involvement and eventually suspend the e-transformation project.

In order to successfully transform small and medium-sized firms into e-capable companies, Ginige et al. [1] proposed an e-transformation roadmap which focuses on not only the website development, but also the involvement of employees as individuals, project or task teams as groups, as well as the entire company as a single entity. The roadmap (Figure 1) consists of eight phases: basic website, interactive website, e-commerce website, effective individual, effective group, effective enterprise, convergence, and new emerging business processes. The first six phases of the roadmap are formed into internal and external development approaches. The internal development approach is mainly concerned with the transition of effectiveness with a company. It is constructed as of the development of effective individuals toward the effective enterprise. On the other hand, the external development approach is related to the construction of the website and its functionalities. It is based on the development of a static, information only website towards e-commerce, online payment competent website. Each e-transformation roadmap phase is briefly outlined in the following sections.

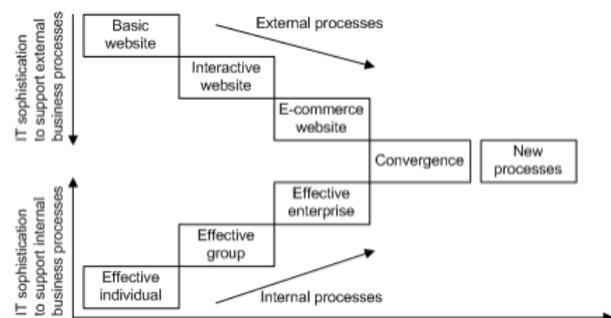

Figure 1. E-transformation roadmap for SMEs

## 2.1 Basic Website

It refers to a static, and information only website. This is a preliminary external development phase that enterprises use the Internet as the media for disseminating marketing and advertising campaigns and products information. In this phase, the Internet is employed as the same way as they have been using in the conventional promotion methods such as magazines, newspapers, and product catalogues and so on. The main task of this phase is to ensure the corporate web presence with the appropriate contents incorporated.

## 2.2 Interactive Website

In the second transformation phase, companies are suggested to construct their websites towards more advanced functions. This type of website can be seen as an interactive website which provide the browsers (eg. the clients/customers, or employees) with dynamic and up-to-date information. The key concept of the dynamic contents emphasises on the connection and interface between the front-end website and the back-end database systems. The initial task of an interactive website development is to identify what are the dynamic contents should be available on the Internet.

## 2.3 E-commerce Website

The ultimate e-transformation objective in regarding to the website evolution is to construct an e-commerce or online payment enabled website. Through an e-capable website, customers are able to place sales orders, organise accounts payables; vendors or suppliers are able to remit invoices and receive payments; and the enterprise could arrange payrolls and any other expenses. The imperative task in this phase focuses on the development of secure environment that provides all business parties confidently trading through the Internet.

## 2.4 Effective Individual

This phase refers to the initial stage for the internal approach of the e-transformation process. It is the fundamental phase that each employee should have suitable IT facilities that will support their individual needs to carry out daily business activities. The appropriate IT facilities support individuals including personal computers, laptops, word processing applications, and spreadsheets applications.

## 2.5 Effective Group

The second level of internal approach refers to the development of an effective group. Teamwork is an imperative concept in exploiting the diverse skills of individual employees and resulting efficient outcomes. Without a doubt, the IT and information systems are the keys to provide an effective team or group environment. The specific components in relation to IT and information systems comprise groupware applications (such as Lotus Notes® and Microsoft® Exchange Server), collaborative

software applications, project management applications and so forth.

## 2.6 Effective Enterprise

When moving from the effective group development towards an effect enterprise, the company needs to integrate and interconnect tasks performed by individuals and groups into a single entity. This requires supports from the adoption of network infrastructure, network operating systems, as well as the integration of information systems and the enterprise resource planning applications.

## 2.7 Convergence

Once the internal and external developments have reached the mature status – e-commerce website and effective enterprise stages, companies are competent to converge both internal and external into a single operation. That is, an enterprise's information system has the capability of obtaining information from the Internet, processing the information for specific needs, and remitting the processed information or results back to the Internet for other business parties (Figure 2). This would eventually lead to collaborative business.

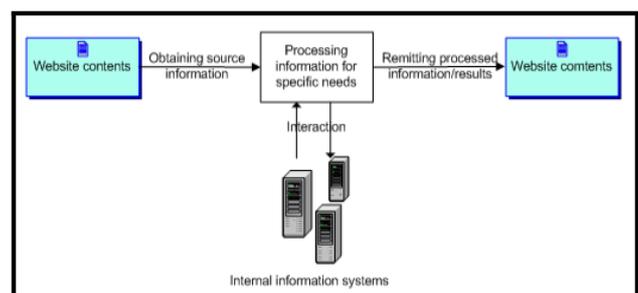

Figure 2. Internal and external convergence phase

## 2.8 New Business Processes

A number of new business processes are emerging as a result of the convergence phase. These new business processes generally relate to the activities of handling the business behaviours amongst business parties (clients, suppliers, and the enterprise itself). Such including customer relationship management (CRM), supplier relationship management (SRM), supply chain management (SCM), and knowledge management (KM).

## 3. Forces of Organisational Changes

Firms have realised that they have to make changes in order to transform themselves into e-capable enterprises. Before positioning themselves in the process e-transformation, they must clearly identify what are the driving forces for change. Because every business has different status and competencies, identification of the driving forces is essential to ensure the correct starting point of the e-transformation roadmap for each enterprise. Generally, the driving forces for change can be divided into two broad categories: external and internal.

### 3.1 External Forces

In this category, the forces for change come from outside of the company. This mainly refers to the business parties that are external to the business such as customers, suppliers, vendors, and competitors. In addition, political, economic climate [2] and certainly IT are also imperative external forces. All these external forces demand enterprises to make changes in order to sustain in the global competitive environment. Outcomes of the change generally result in reducing costs, increasing productivity and product quality, shortening distribution time, and applying IT for business operations.

### 3.2 Internal forces

The internal forces refer to the factors arise within the company. They are commonly related to changes in terms of the business development and growth. For example, in the transition of globalisation [3] enterprises are facing changes in organisational structure, reporting hierarchy, business vision and strategy.

## 4. Identification of Changes

After the investigation of each phase in the roadmap and the related driving forces, changes in e-transformation can be generally classified in five categories: business processes, applications, employee and skills, technology infrastructure, and executive management.

### 4.1 Business processes

Introduction or changes of business processes are required to

1. provide employees to perform their work effectively,
2. link or connect business functions together with an enterprise,
3. be able to share information between business parties,
4. enable website contents up-to-date,
5. allow website contents to be dynamically presented and accessed by the external users,
6. facilitate online transaction functions that are accessed and trusted by the external users, and
7. integrate the internal information systems and external website functions to handle e-commerce related business operations.

### 4.2 Applications

Introduction or changes of software applications are required to

1. carry out essential industry specific needs,
2. allow employees to communicate each other and transfer messages within an enterprise such as email applications,
3. facilitate the ability of information sharing for business purposes, for example, project

management and scheduling applications, groupwares, and intranet systems,

4. accomplish the implementation of new emerging business processes (CRM, SRM, SCM, and KM),
5. retrieve the company's website which contains static company and product information, messages for the external users, mailing lists, and frequent asked questions session (FAQs),
6. access the company's interactive website which contains dynamic product information (inventory in particular), interactive enquires and feedbacks, discussion boards, member login facility, and
7. provide online web functions for placing orders, tracking orders or delivery schedules, online payment, and distributing electronic products and services.

### 4.3 Employee and skills

Introduction of new skills for appropriate employees are essential to

1. implement basic computer applications such as word processors, spreadsheet applications, and industry specific software packages,
2. carry out work related tasks through the utilisation of computer applications for communicating within team and project environment, such as the skills of using project management software, email applications, groupwares, and accessing databases,
3. gain competency in implementing enterprise wide information systems such as enterprise resource planning (ERP), CRM, SRM, and SCM applications,
4. browse websites for searching work related information from the Internet,
5. handle interactive website functions such as responding online enquires, posting news and messages for discussion forums, updating and accessing product information dynamically, and
6. perform e-commerce website functions such as placing purchase orders, online payments, banking, order and delivery tracking through the Internet.

### 4.4 Technology infrastructure

Introduction and deployment of new information infrastructure are crucial to

1. provide adequate hardware and equipment for individual employees to carry daily business activities, such as personal computers (PCs), laptops, personal digital assistants (PDAs), printers, and many other peripherals,
2. connect the company's information systems and applications through the local area networks (LANs) or the intranet,
3. integrate the company's information systems

with business parties information systems through the extranet or virtual private networks (VPNs),

4. supply the company with the ability of accessing the Internet through a high-speed bandwidth connection and securing sensitive business information through the use of backup and restore equipment,
5. allow the company to enforce disaster recovery plans or business continuity plans for any causes of disasters, and
6. perform a secure and interactive website functions and interact with back-end information systems.

#### 4.5 Executive management

Changes of business strategy in executive management are critical to

1. support IT maintenances in hardware, software, databases, and networks,
2. incorporate policies, procedures, and processes for IT,
3. confirm that the company has agreed in the integration of enterprise wide information systems,
4. implement decision support systems for the best business practice, and
5. ensure that the company has consented to amalgamate the information systems with other business parties.

#### 5. Framework for managing changes in e-transformation

The underlying premise of managing changes in e-transformation framework (Figure 3) is that the integration of the e-transformation roadmap, five categories of changes in e-transformation processes and together with the validation process through the 7S model [4]. Both e-transformation roadmap and change categories have been described earlier in this paper; it is the final stage of constructing the framework by mounting change factors into the 7S model.

The fundamental concept of the 7-S model is that “structure” is not the only element representing an organisation; there are other six elements that form a complete organisation. These seven elements can be classified into two groups – tangible and intangible. Firstly the tangible elements, these are feasible and easy to identify. They can be found in the enterprise’s strategic plan, mission statement, organisational chart, and other corporate documentations. These tangible elements are strategy, structure, and systems. On the other hand, the intangible elements are those hardly feasible. They are difficult to describe and continuously developing and changing as the organisation evolves. These intangible factors include skills, staff, style, and shared values.

Figure 4 and the following subsections illustrate and describe these elements (both tangible and intangible) in

general as well as the context of e-transformation. The intangible ones are greyed out.

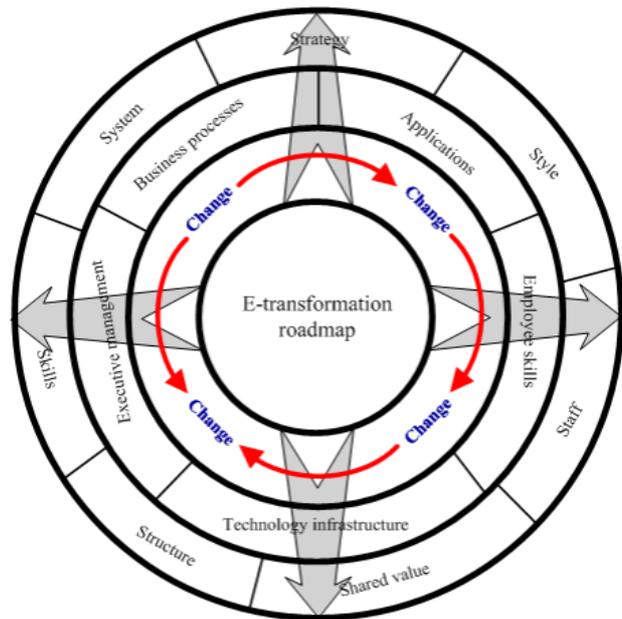

Figure 3. Framework for managing changes in transforming SMEs into E-capable companies

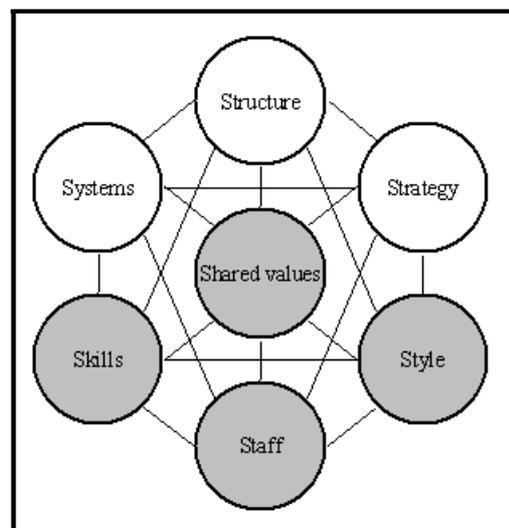

Figure 4. The 7S Model

#### 5.1 Tangible elements

##### 5.1.1 Structure

An appropriate managerial structure has to be established in order to successfully implement and support proposed changes. To achieve an effective enterprise with e-capable business functionalities, the establishment of communication channels between business functions and unambiguous definition of responsibilities for all levels of management require to be incorporated into the organisational structure. Companies need to ask themselves whether separate business functions are required to carry out e-commerce activities or incorporate the e-operations into the existing business functions. Further, the identification of people who are

responsible for any e-commerce activities, (eg. are they managers of each department?) Or whether new positions required for these e-management roles?

### 5.1.2 Strategy

It refers to actions an organisation plans in response to or anticipation of changes in its external environment. For example, the involvement of competitors in e-commerce operations may force the enterprise to shape its business plan to incorporate the e-transformation strategy.

### 5.1.3 Systems

It can be seen as formal and informal procedures and processes that support the strategy and structure. In the e-transformation context, systems comprise IT solutions and other techniques for collecting, processing, retrieving, and storing of information.

## 5.2 Intangible elements

### 5.2.1 Skills

The appropriate skills are required for implementing and maintaining e-capable business operations and an effective organisation. Such skills are mostly related to the application and utilisation of IT for advancing both the internal business operations and the external e-commerce development and implementation.

### 5.2.2 Staff

Referring to the human resource management. It includes processes used to develop managers, socialisation processes, methods of recruiting appropriate employees, and approaches of helping to manage and develop the careers of employees. As the introduction of e-commerce operations, additional staff are required to perform new emerging business and technical activities such as online customer and supplier management, administration of online transactions, maintenance of website contents, and any other IT supports.

### 5.2.3 Style

It can be seen as the culture of the organisation and management style. When implementing the fully e-commerce websites, enterprises will be facing an unprecedented challenge – sharing information with external business parties. In the e-commerce environment, inventory data, purchase orders, and sales information will intentionally be made translucent for the external business parties such as suppliers, vendors, and customers. Hence, changes of the organisational culture and management style are necessary to cope with the e-capable business operations.

### 5.2.4 Shared values

These are superordinate goals, guiding concepts, fundamental ideas around which a business is built. In the e-transformation context, the ultimate goals are to

construct and perform e-commerce operations through the amalgamation of the internal business systems.

By mapping the change factors of e-transformation with the 7S model, the following table (Table 1) intends to act as a diagnostic model for the completeness of changes required in the e-transformation processes. As the result of mapping, all change factors have been covered under the 7S model.

Table 1. Mapping of five change categories to the 7S model components

Change category	Change factor	7S model components
Business processes	individual employees working efficiently	style, staff
	connection of business functions	shared value, style
	information sharing between business parties	shared value, style
	keeping web contents up-to-date	strategy, style
	availability of dynamic web contents for external users	strategy, style
	Online transaction functions	strategy, style
Applications	integration of information systems amongst business parties	strategy, style
	industry specific software applications	system
	message transfer and email applications	system
	project management and scheduling applications, groupwares and intranet	system
	applications for implementing new emerging business processes	system
	applications for browsing static web contents	system
	applications for accessing interactive and dynamic web contents	system
applications for e-commerce functions	system	
Employee and skills	basic computer application skills	skills, staff
	communication and information sharing applications skills	skills, staff
	enterprise wide information systems skills	skills, staff
	Internet browsing and searching skills	skills, staff
	Internet interactive responding skills	skills, staff
Information infrastructure	e-commerce online transaction skills	skills, staff
	adequate hardware and equipment for individual employees	system
	intranet or local area networks (LANs)	structure, system
	extranet or virtual private networks (VPNs)	structure, system
	high-speed Internet connection and backup/restore equipment	structure, system
	facilities for implementing disaster recovery plans or business continuity plans	structure, system
Executive management	facilities for implementing a secure and interactive website functions and interact with back-end information systems	structure, system
	supporting IT maintenance	strategy
	incorporating IT policies, procedures, and processes	strategy
	agreement of the enterprise wide information systems integration	strategy
	consentience of information systems amalgamation with business parties	strategy

The proposed framework provides enterprises an overall picture of conducting the e-transformation

processes which begins with the understanding of all phases in the roadmap, recognising the changes occurred through five categories, and ensuring the entire enterprise has taken care of all change factors via the mapping of change categories to the 7S model components.

## 6. Development of a checklist for e-transformation achievement

Based on each company's current and progress status in relation to the e-transformation processes, a straightforward table-like checklist (Figure 5) is proposed to provide enterprises a quick and clear picture of the achievement in the e-transformation project. The checklist consists of the five change categories as the values of Y-axis and the first six phases of e-transformation roadmap (three externals and three internals) as the values of X-axis. Hence, it leads to the total of thirty cross-reference cells. Companies check each cross-reference cell when a change category has been accomplished for the corresponding e-transformation phase. For example, a tick should be given to the cell of employee skills and basic website when employees have the skills to access a basic website and functions. Once companies have checked all thirty cells, which means they have achieved both external and internal approaches in the e-transformation processes, and are suggested to move onto the convergence phase.

Change category	External phases			Ready for convergence process
	Basic website	Interactive website	E-commerce website	
Business processes				
Applications				
Employee skills				
Information infrastructure				
Executive management				
	Internal phases			
	Effective individual	Effective group	Effective enterprise	

Figure 5. Checklist for e-transformation achievement

## 7. Conclusion

During the process of e-transformation, companies usually face a variety of challenges. These challenges mainly associate with the changes occurred in various aspects in the organisation. Without realising and understanding the changes, the implication of e-transformation will not sustain and be part of the business strategy and operations. Hence, a framework for managing changes in an enterprise's e-transformation process is necessary. The framework development

embraces three main stages. Firstly, the e-transformation roadmap is reviewed through the investigation and identification of requirement and components of each transformation phase. The second stage deals with the classification of five e-transformation change categories. The third stage is concerned with verifying the e-transformation changes through the mapping of 7S model. Accordingly, the framework ensures changes occurred in the e-transformation process have been indicated explicitly and integrated into all aspects of the business operations.

## Abstract

A knowledge management system, Knowledge Management System for Scientific Research Group (KMSSRG) is designed to facilitate knowledge creation within a scientific research group. Implementation issues of such a system are analyzed and discussed in this paper. The main feature of the KMSSRG is the support of Internal Knowledge Evolution Network (IKEN). We developed the IKEN by (1) using Ikujiro Nonaka's SECI model to identify core sub-processes and related knowledge that are keys to knowledge creation, and (2) analyzing carefully the knowledge creation process for both individuals and teams. As a result, IKEN is a directed network that maps knowledge (both implicit and explicit knowledge) fragments created by different team members in various research activities. Context reference relationships among these knowledge fragments can also be represented.

## 1. Introduction

Nowadays universities professor often does scientific research in groups with other professors and students. They need to share information between each other through the whole knowledge creating process. Although IT tools such as FTP, BBS, mailing list and Web site provide communicating of information, and the university library systems provide sharing of publications, the functions they provide are the same for groups as for any individual researches, with no outstanding effect on the efficient management of the valuable tacit knowledge that key to group knowledge creation. Both IBM Lotus and Microsoft released Knowledge Management Systems "maintaining a central knowledge database which keeps all the information of the team project including documents, contactor, mission, discussion"[1], but pieces of knowledge and their context reference are hidden inside the files "heaped" at the database waiting for "dug". In this paper we designed a system that can support Internal Knowledge Evolution Network (IKEN) which is a directed network that maps knowledge created by different team members in various research activities. With this system both implicit and explicit knowledge could be retained and the context reference relationship among the knowledge fragments could be easily traced.

## 2. Method

To design the support system we studied the formats of and the interaction between knowledge fragments in knowledge creation process. We started by subdividing the process into four stages according to the sequence of common researching: reference searching, reference reading and studying, topic researching, summarizing and paper drafting. Although each stage may go backward and intertwined with each other, we retain this subdivision for easy of discussion.

Then by applying Nonaka's concept of tacit/explicit knowledge and SECI model[2], we discussed what characteristic is of each stage knowledge and how tacit knowledge transforms into explicit knowledge, and how one's knowledge interact with the other's.

### 2.1 Nonaka's concept of tacit/explicit knowledge and SECI model

In Ikujiro Nonaka's study, the knowledge creation process is the conversion process between tacit knowledge and explicit knowledge [George Von Krogh, Ikujiro Nonaka, Toshihiro Nishiguchi'2000]. By his definition, explicit knowledge can be expressed in words and numbers and easily shared. Tacit knowledge, such as subjective insights or emotions, is non-articulated, and embedded in contexts and actions. It is personal and hard to verbalize or communicate. Tacit knowledge, such as bodily skills or mental models, is rooted in an individual's action and experience as well as in the ideals or values he or she embraces.

In the SECI model, the knowledge creation process within an organization takes a spiral evolution form, which consists of four types of conversions (figure 1). Socialization is the process of sharing the tacit knowledge of individuals. Externalization requires the articulation of tacit knowledge and its translation into forms that can be understood by others. Combination involves the conversion of explicit knowledge into more complex sets of explicit knowledge. Internalization means the conversion of newly created explicit knowledge into the tacit knowledge of individuals.

The model can better explained using the famous 'bread machine' case as follow:

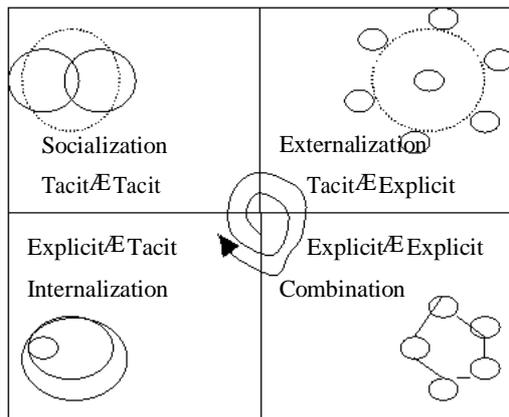

Figure 1. Nonaka's SECI Model

- ò Ms. T went to the famous bread baker to learn how to make the first-class bread by hand. The socialization conversion was implemented when the tacit knowledge of the baker was learned by Ms. T and remained tacit form in Ms. T.
- ò Ms. T shared her knowledge with her fellow workers by telling out the skill. The externalization conversion is implemented when the skill conveyed to the fellow workers in words.
- ò The group members worked together sorting out the knowledge and implemented the coding in the program of bread machine, the combination conversion is implemented when the knowledge is edited in systematic digital format.
- ò Then the machine along with its coding knowledge was accepted by other persons, the internalization conversion is implemented when the knowledge changed into tacit knowledge in the form of individual experience.

### 2.2 Basic processes for individual

To analyze the basic processes for individual, we list the content of both tacit and explicit knowledge (Figure 2), and discuss the transformation between tacit and explicit knowledge as that of SECI model.

Basic stages	Searching	Reading and Studying	Researching	Summarizing and Drafting
Explicit Knowledge	Publications such as papers, books	Comments on published works	Confirmation, Proof, Refutation	Papers, reports
Tacit Knowledge	Not remarkable	Problems, Suppositions	Advanced problems, suppositions	Not remarkable
Conversion		Explicit to Tacit	Tacit to Tacit	Tacit to Explicit

Figure 2. knowledge format and conversion

- ò In the searching process, the outside public knowledge resource are collected. The knowledge is in explicit form that stored in the published papers, books, or reports.
- ò In the studying process, both tacit and explicit knowledge are produced during the studying of outside resource. The explicit knowledge are comments or remarks on the published works, which are the externalization result of the personal internalization of published knowledge, a process of explicit to tacit to explicit. The tacit knowledge are embodied on guess and/or supposition to the solutions for project problems, which are subconscious imagination based on exist knowledge and personal experience. They are very obscure and not easy to be described concisely, and are often expressed with the aid of analogy or metaphor. They are of explicit/tacit to tacit process, and are the precursor of knowledge creation.
- ò In the researching process, both the tacit and explicit knowledge in studying process are further improved, with tacit knowledge develop into explicit knowledge, and with new tacit knowledge spring from existing explicit or/and tacit knowledge. For the tacit to explicit, the guess or supposition that can be testified are briefly proved in draft, which consist of set of knowledge fragments that will be systemized into new knowledge. For the explicit/tacit to tacit, new guess and/or supposition are continuously brought up based upon existing knowledge and personal experience.
- ò In the summarizing process, the fragments of research results are edited into systemized explicit knowledge, which is of explicit to explicit process.

### 2.3 Basic processes for team

Communication and interaction characterize team work. The exchange of opinions brings change to both the tacit and explicit knowledge. By observing the content of exchange and the transformation of knowledge, we can identify the core processes that are key to team knowledge creation. See table 1.

Table 1. the content of exchange and the transformation of knowledge in a team work

Basic processes	Types of knowledge	Content of exchange	Transformation of knowledge
Searching	Explicit	Information on the resource	
	Tacit	None	
Studying	Explicit	Comments or remarks on published works, as well as on exist comments	Accumulate: by sharing the study
	Tacit	Guess or supposition to solution of project problems, as well as comments on them	Accumulate: by sharing the insidious methods Knowledge creation: by provide new idea based on individual experience.
Researching	Explicit	Confirmation or proof to guess or suppositions, as well as comments on them	Accumulate: by sharing the proofs Knowledge creation: by jointly work on the same problems step by step.
	Tacit	More guess or suppositions, and more comments on them.	Accumulate: by sharing the insidious methods Knowledge creation: by provide new idea based on individual experience.
Summarizing	Explicit	Information on proof-reading	
	Tacit	None	

- ò In the searching and summarizing processes, the exchange focus on explicit information, such as the location of certain paper, or the proof reading of written draft.
- ò In the studying process, for the explicit knowledge, the exchange of comments or remarks on published works can speed up the accumulation of existing knowledge for each member. For the tacit knowledge, the exchange of guess or supposition diversifies the possible solutions, and arrests more attention on individual problem, which provide solid foundation for the next stage of co-work on attacking the problem.
- ò In the researching process, for the explicit knowledge, the exchange of fragments knowledge created help members to keep up with the current progress of project, and the insidious methodologies inhibit in the proof help to improve personal experience. For the tacit knowledge, more than one effort focus on individual problem. With the supplement of many efforts the power is amplified and the knowledge creation is accelerated.

## 2.4 Core sub processes

From table 1, we can see that the knowledge creation take place on studying and researching processes. Therefore, the studying and researching are core sub processes for knowledge creation. The knowledge

production can successively evolve in concord if the members can share both the tacit and explicit knowledge step by step, as seen in figure 3.

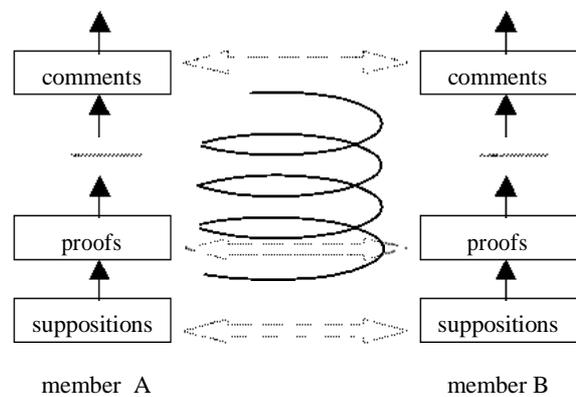

Figure 3 knowledge evolution in concord

## 3. Result

### 3.1 IKEN

And then we developed the concept Internal Knowledge Evolution Network to describe the knowledge evolution framework .

From the core processes identified in the above section, we can extract four types of knowledge.

- ò comments or remarks on published works
- ò guess or supposition to the solutions for project problems

- o proof or confirmation on the guess or supposition
- o positive or negative comments or remarks on knowledge 1-3.

These four types of knowledge increase in the process and are dependence on each other. When linking with their context relationships, the knowledge fragments created inside team construct a directed network map, as shown in the Figure 4. Along the direction of the arrows, pieces of tacit knowledge are continuously created based on previous knowledge, and converse to explicit knowledge. We define this network as 'Internal Knowledge Evolution Network'.

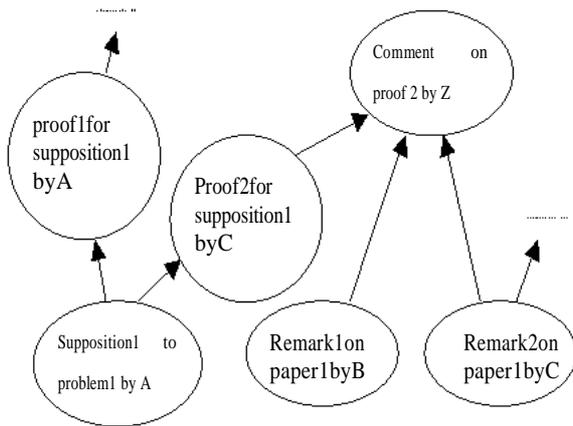

Figure4 InternalKnowledgeEvolutionNetwork

### 3.2 IKEN discussion

IKEN describes the inside team knowledge evolution map, with the similar idea as that of citation index service which provides knowledge linkage between published works. Knowledge linkages, both within and out of team, are important in creating new knowledge, but the IKEN is much important since it embody the tacit knowledge of each team member. The public knowledge is explicit and easy to locate without the risk of losing, but for tacit knowledge, it is the resource of creation which can not

afford losing. Therefore, managing IKEN is key to manage knowledge creation.

In addition, following is a list of more advantages on managing IKEN:

- o The progress of the research will not be stopped when someone leave. The personnel change used to be the most dangerous thing for project research. With the support of IKEN, the job can be easily taken over by other members, and new member can quickly keep up with the progress.
- o Virtual team can be better supported with digital IKEN which makes the members free of location.
- o Cooperation and communication obstacle caused by culture conflict or different habit can be overcome, since the digital IKEN provides more possible ways of exchange.

### 4. A Knowledge Management System for Scientific Research Group

From the previous analysis it's obvious that IKEN contains the tacit knowledge of the group. We devised a Knowledge Management System for Scientific Research Group – KMSSRG which can support IKEN..

In designing system we included other explicit knowledge resource such as books, papers, reports as the bottom layer of the knowledge (figure 5). One piece of knowledge may refers to multi-pieces of knowledge, and one piece of knowledge may be the reference of multiple pieces of knowledge.

## Abstract

Managing enterprise knowledge for decision support is crucial for enterprises to gain competitive advantages in knowledge-based economy. The valuable knowledge patterns hidden in numerous projects are important assets of enterprises. The management of such project knowledge is becoming increasingly important and challenging for organizational adaptation and survival in the face of continuous environmental change. This work proposes a project-based knowledge map framework to capture project knowledge and discover valuable knowledge patterns from previous projects. A collaborative two-phase data mining approach is applied to extract valuable project attributes, and discover their associations. Moreover, the discovered knowledge patterns are organized in a well-structured knowledge map, which facilitates effective navigation of project knowledge.

## 1. Introduction

Knowledge management is crucial to organizational adaptation and survival in the face of continuous environmental change [8]. The knowledge acquisition, storage and distribution activities in a knowledge management system enable the dynamic creation and maintenance of an enterprise's intelligence [7][8].

Knowledge management has successfully been applied in many business domains. Bolloju et al. [5] proposed an integrative model for building enterprise decision support environments using model marts and model warehouses as knowledge repositories. Massey et al. [10] proposed to reengineer the customer relationship by acquiring and disseminating knowledge to both customers and IBM's human experts. Moreover, metadata were used as a knowledge management tool for supporting user access to spatial data [13]. Rubenstein-Montano [11] surveyed knowledge-based information systems for urban planning and suggested the importance for moving towards knowledge management. The effectiveness of knowledge management has been demonstrated in these applications.

Recently, knowledge management has been considered in the field of project management. Tah et al. [12] applied knowledge management technology to identify project risk and to further improve project management. Barthès et al. [2] developed an agent-supported portal to organize knowledge in complex R&D projects. However, these applications overlook the valuable knowledge patterns and working experiences hidden in numerous projects.

Generally, a project is a 'temporary' endeavor

undertaken to create a particular product or service [14]. Unstable and temporary cooperation among a project team causes several difficulties in integrating knowledge, since the project team is usually disbanded and reorganized for another new project. This kind of volatile relationship hinders the accumulation of project knowledge. Moreover, a project can be carried out at different levels of the organization or across organizations. This complex scope results in difficulty in collecting integrated project knowledge.

Consequently, knowledge support is highly required throughout project development to solve these dilemmas. The numerous historical projects are the important knowledge source. The advance of data mining techniques has inspired applications in different problem-solving domains [4][6]. Applying data mining techniques to discover various hidden knowledge is a challenge for knowledge management [7]. Therefore, data mining approach is applied here to discover project knowledge.

This work proposes a project-based knowledge map framework to discover valuable knowledge patterns (project knowledge) hidden in projects, and to integrate these discovered patterns in a well-structured knowledge map. A collaborative two-phase data mining approach is applied to extract valuable project attributes, and discover their associations. The proposed knowledge map, clearly structured and semantically expressed, not only supports effective management of discovered knowledge patterns, but also assists users in navigating project knowledge to support further project development.

This paper is organized as follows. Section 2 describes a system model for discovering project-based knowledge maps. Section 3 illustrates meta information that pertains to a project. Section 4 discusses the mining approach to discover project knowledge. Section 5 elucidates the structure of the knowledge map. Conclusions and future work are finally made in Section 6.

## 2. System model

This section illustrates the system model for discovering project-based knowledge maps. As shown in Figure 1, three collaborative processes work together to construct the knowledge map, including extracting project meta information, mining project knowledge and finally deploying the project-based knowledge map.

First, the meta information builder is employed to extract meta information during project processing, including initialing, planning, executing, controlling and closing processes. Project meta information refers to the

important project attributes and annotations. When a project is finished to archive, the meta information is collected as well. The meta information builder appropriately annotates project attributes and converts these attributes to a consistent format for further analysis.

Second, a collaborative two-phase data mining approach is applied to extract valuable project attributes, and discover their associations. The first phase employs clustering methods to group projects into clusters according to their similarity. The second phase employs association rule mining to discover the inner knowledge patterns of the cluster of related projects, such as associations among project attributes. The discovered patterns reveal ontology-subject aspect and project domain concepts, which are very important in improving project development.

Third, the knowledge map builder integrates the discovered knowledge patterns and constructs a knowledge map to provide an information portal for accessing project knowledge.

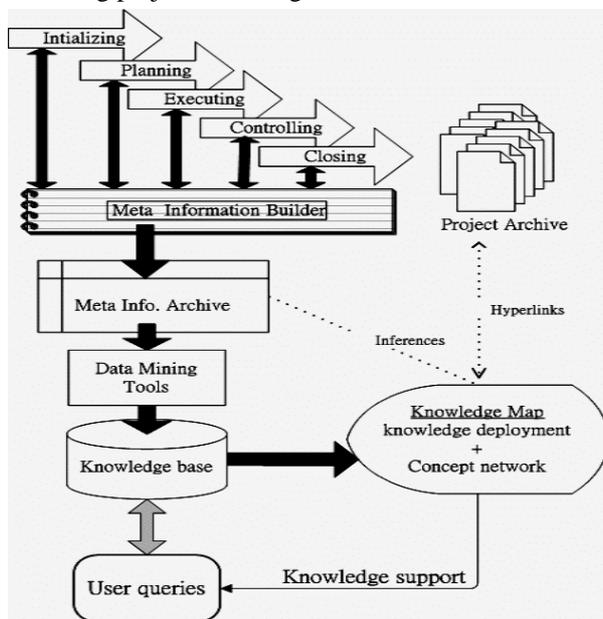

Figure 1. The system model of discovering project-based knowledge maps

### 3. Project meta information

A set of categories is used to classify project attributes. These categories may be pre-defined by human experts or generated ontology-based subjects for organizing project attributes consistently. This work considers five categories for software projects, Member, Tools, Activity, Goals and Cost, according to IEEE Standard for Software Project Management Plans (SPMP, IEEE Std. 1058-1998) [15].

- Member : a list of the key workers in a project.
- Tool : a list of major skills applied in a project.
- Activity : a list of key actions in a project.
- Goal : a list of objectives in a project.
- Cost : the financial cost and working weeks for a project.

Table 1 presents a set of example software projects. The set of project attributes, grouped by above defined

categories, constitutes the multiple project meta information. Accordingly, a vector model [3] is applied to represent these high-dimensional meta data.

Table 1. The collection of project meta information

	m1	m2	m3	m4	m5	t1	t2	t3	t4	...	g1	g2	g3	g4	g5	a1	a2	a3	...	c1	c2

Activity : a1,a2,a3,a4,a5 denote Marketing, Agency, Consultant, Alliance, Contest  
Cost : c1,c2, denote working weeks in total, total cost (Million dollars).

### Vector model

Each project is annotated as a set of key attributes, and a vector model is used to represent the attributes of a project. A vector is defined as follows. A weight value  $w_j \geq 0$  denotes the importance of project attribute  $j$  on project  $i$ . For simplicity, this work uses the values 1 and 0 for the weight value to indicate whether the attribute is important (presence) or not important (absence) to the project, respectively. A project  $P_j$  is associated an attribute vector  $P_j = (w_{j1}, w_{j2}, \dots, w_{jk})$ .

According to the meta information given in Table 1, project P001 is represented by a vector model (0,1,1,1,1,0,0,1,1,1,1,1,0,0,1,1,1,0,0,110,8), implying that project P001 includes the key team members David, John, Kim and Mary; employs the tools, Data Mining, XML, DBMS and Java; is aimed at CRM, Logistics, Data Warehouse, Re-engineering and Wireless networks; and involves the activities of Marketing, Agency, Council, Alliance and Contest. The final two items imply that this project cost 8 million dollars over 110 working weeks.

### 4. Mining project knowledge

The mining of project knowledge contains two phases. The first phase employs clustering methods to group projects into clusters according to their similarity. The second phase employs association rule mining to discover the inner knowledge patterns such as associations among project attributes.

#### 4.1 Clustering projects

This work employs an agglomerative algorithm that conducts hierarchical clustering to group projects in a

bottom-up way. The agglomerative algorithm places each object in its own cluster and gradually merges these atomic clusters into larger and larger clusters until all objects are in a single cluster [9]. The steps of the agglomerative algorithm include the following steps.

**Constructing a dissimilarity matrix:** The dissimilarity between projects depends on the distance between projects. This work uses Euclidean distance measurement to compute the proximity distance between *i*th and *k*th vectors. The pair-wise distance is useful to measure the dissimilarity and build a dissimilarity matrix for all attributes.

**Forming clusters:** The second step is to form clusters based on the dissimilarity matrix. A threshold value is an important parameter to decide how 'close' the projects will form a cluster. Projects with distance values less than a threshold value are grouped into the same cluster. For example, project P001, P100, P101 and P002 form a cluster labeled as 'Cluster#012', which is the main cluster example considered in the rest of this paper.

**Determining Cluster centroid:** A cluster of projects is a group of 'similar' projects, and a centroid is used to represent the key attributes of a cluster of projects. The centroid vector,  $C_j = (r_{j1}, r_{j2}, \dots, r_{jk})$  of a cluster *j* is determined according to the frequency (importance) of attributes. If the frequency (importance) of attribute *i* in cluster *j* is greater than a given threshold value, then  $r_{ji}$  is set to 1, otherwise it is set to zero.

The vector model is also used in the query module to find similar projects that match the partial concept or initial idea provided by users. The query includes multiple attributes from various categories, such as 'John, CRM', or a single attribute, such as ERP. Users could issue query using a partial concept or restricted conditions. A user query is represented as a vector model to indicate the query criteria of project attributes. The query result is determined according to the similarity between the query vector and the centroid vector. The similarity is quantified by the cosine of the angle between these two vectors. By ranking the similarity value, the system can find the most relevant cluster or find clusters with similarity greater than a given threshold value.

#### 4.2 Mining associations among project attributes

Association rule mining is employed to discover relationships among project attributes. This work applies Apriori algorithm [1] to discover associations among project attributes. Association rule mining extracts association rules that satisfy a user-specified minimum support and confidence. The support for an association rule,  $X \Rightarrow Y$ , is defined as the percentage of project instances in cluster *D* that contain both attribute sets *X* and *Y*, while the confidence is defined as the proportion of project instances that contain attribute set *X* that also contain attribute set *Y*.

The Apriori algorithm discovers large itemsets by means of multiple passes over the data. An itemset is a set

of project attributes. A large itemset is an itemset with support greater than minimum support. The algorithm is briefly illustrated as follows [1].

- In the first pass, Apriori counts the support of individual items and determine which of them have minimum support.
- Each subsequent pass starts with a seed set represented by the itemsets found to be large itemsets in the previous pass. From this set it generates the new potentially large itemsets, called candidate itemsets.
- At the end of the pass, it determines which of the candidate itemsets are actually large. This process continues until no large itemsets are found.

WEKA 3.0 software, an open source software issued under the GNU General Public License, is used for implementing Apriori algorithm [1]. Table 2 shows the mining result, and the support rules are explained as follows.

Table 2. The association rule of Cluster#012

WEKA 3.0.associations.Apriori	
Minimum support: 0.5

13. t2 t5 ==> m3	
14. m2 ==> m5 .....	(8)

#### Support rules

##### Support#1: Team-member dispatch

A team of workers is the most commonly employed to complete a project. Based on rule (8) in Table 2, m2 and m5 are associated team members, as follows.

- David and Mary are suitable team members.

##### Support #2: Complementary relations

The relationship between cross-category attributes is useful to understand what kind of attribute complements each other. This kind of cross-category information is helpful to select suitable tools or appropriate activities to meet certain goals.

- (i) Data Warehouse and Consultant are two associated concepts according to rule (1) in Table 2.
  - The Consultant activity works for the goal of Data Warehouse.
- (ii) CRM and Marketing are two associated concepts derived from rule (2).
  - Achieving the goal of CRM requires the Marketing activity.

- (iii) Java, DBMS and Data Warehouse are associated concepts derived from rules (3) and (5).
  - Java and DBMS tools assist in the goal of Data Warehouse.
- (iv) Data Mining, CRM and Marketing are associated concepts according to rule (4) in Table 2.
  - The Data Mining tool and Marketing activity assist in the goal of CRM.

**Support#3: Members' skills**

Knowledge of members' skills is basic knowledge for supporting work assignments and determining what trainings needed. For example, rules (6) and (7) show members' skills.

- Mary has the skill of Data Mining.
- John has the skills of Java programming and DBMS.

Assigning team members, complementary relations among project attributes, and members' skills are very important tasks in managing projects. These support rules save much effort in initial planning of projects.

**5. Deploying project-based Knowledge map**

A knowledge map is developed to integrate the fragmental knowledge patterns discovered in the mining process. Such a map provides navigation facility to assist users in locating requested project knowledge.

The knowledge map developed here is a hierarchical structure that represents relationships among a cluster, categories, features, and objects. The cluster-node, at the first-level of the knowledge map, represents a cluster derived from the clustering analysis phase. The category-nodes, at the second level, denote pre-defined categories of project attributes. The feature nodes describe

the important attributes of a cluster. The object nodes denote project resources.

Moreover, the map shows a particular object instance, which is the finance sheet, including average cost estimates and time taken. This is a notable consideration for project development, since time and cost are two important factors that require knowledge support.

A clear project-based knowledge map is shown in Figure 2 to illustrate the integrated knowledge patterns of the Cluster#012. This unique map provides the following supports for knowledge seekers.

- (i) Domain concept: employed to provide a basic overview of relevant projects.
- (ii) Information portal: used to access detailed project resources for reference.
- (iii) Budget control: used to estimate the time taken and financial cost of a new project.
- (iv) Efficient query: a clear summary of a group of related projects in response to a query.

**Conceptual network for support rules**

The support rules discovered from the association rule mining are integrated in a conceptual network as shown in Figure 3. A conceptual network contains two types of primitive element, nodes and links. Nodes are used to represent project features (attributes), while links with labels are used to describe the associations between project features.

The generated concepts may imply important project knowledge, which accumulates working experience of senior experts. The clear structure promotes the reuse of the discovered knowledge, and the conceptual network helps users to understand project knowledge.

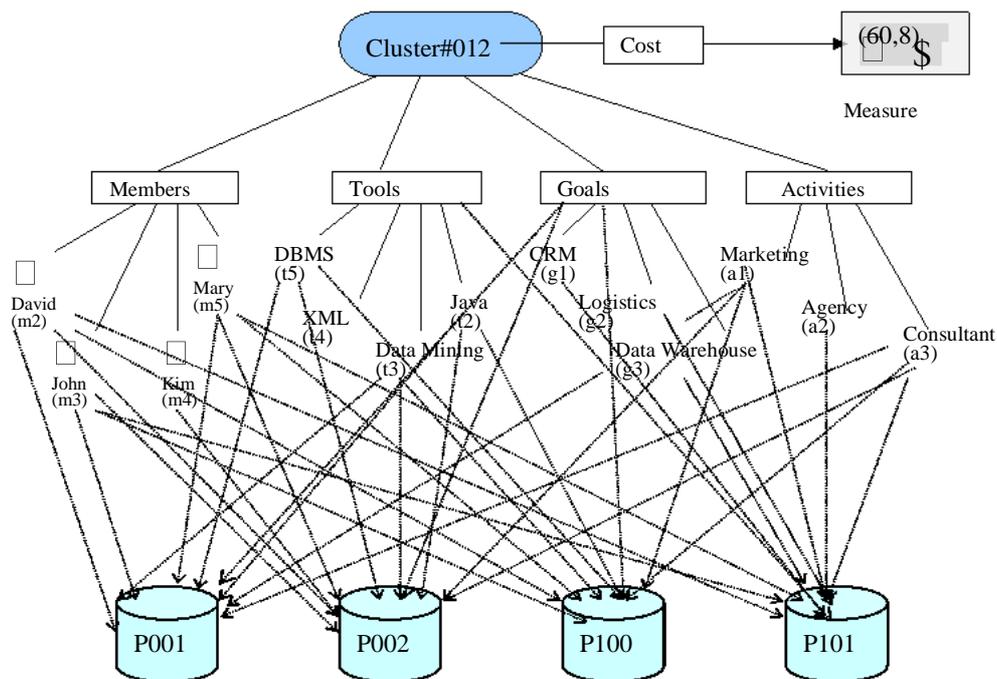

Figure 2. The knowledge map structure of Cluster#012

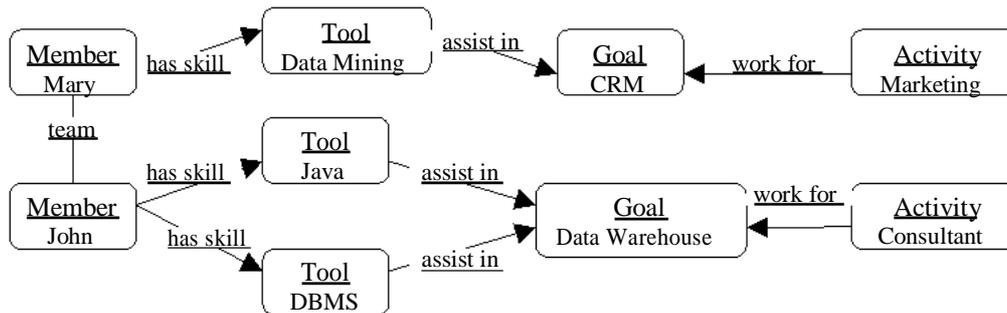

Figure 3. Conceptual network of Cluster#012

## 6. Conclusion and future work

The data mining approach is highly effective for extracting knowledge, but contributes less to knowledge sharing. The knowledge map, however, compensates for this lack. The proposed project-based knowledge map framework employs data mining approach to discover valuable project knowledge, and most importantly, integrates the discovered knowledge patterns in a knowledge map.

The approach provides effective knowledge support as follows. First, the knowledge map provides a simple but clear guide to clarify the distribution of project knowledge. Second, the extracted key attributes provide the project domain clearly. Third, each related project object is accessible by hyperlinks. Finally, the conceptual network captures important support rules discovered from the association rule mining.

The knowledge map is very helpful in supporting the management of project knowledge. Seeking innovative information technology to support other knowledge management tasks is an interesting future work. Moreover, the structure of the map must be further enhanced to increase the power of the knowledge representation. Finally, applying innovative data mining approaches in different phases to discover more valuable patterns remains a challenge.

## Abstract

This paper highlights the case study organisation of the National Science and Technology Development Agency (NSTDA) as a learning organisation. As NSTDA seeks to provide effective mechanisms for supporting small- and medium-sized enterprises (SMEs), it recognises the importance of knowledge as a mechanism for generating innovations. Thailand realises the importance of science and technology (S&T) for economic development, wealth creation and improvement in the quality of life. It is setting the direction and gaining commitment towards knowledge-based economy through the National Economic and Social Development Plans and phased programmes. In its effort to achieve this aim, the National Science and Technology Development Agency (NSTDA) plays a major role in propelling the national knowledge competence for social and economic development.

## 1. Learning organisation towards the knowledge-based economy

To support technical change at the national level and to transform technology (invention) into innovation (commercialised product), there needs to be an interaction between the public and private sector [1]. The National Economic and Social Development Plan Number 9 (2002-2006) sets out the direction that the public and private sector work together in order to support knowledge production, knowledge transmission and knowledge transfer within an economy. Learning organisation – the attempt of NSTDA to improve the

innovative capacity of the country can be shown in the Figure 1.

Currently, the manifestation of economy has been towards using information as a factor for competitiveness. For Thailand's progressing up the ladder of development, it has set up the NSTDA (a special kind of governmental organisation under the Ministry of Science, Technology and Environment) with the mission of supporting research, development, design and engineering (RDDE) in scientific and technological areas critical to the country's development. Underlying the NSTDA mission goal are three operational goals : the support of public sector RDDE projects; the support of the technological strengthening in the private sector; and the disbursement of science and technology scholarships for study abroad and locally. In effect, NSTDA's function comprises four main areas of responsibility :

### i) Research, development, design and engineering

The undertaking of RDDE includes the basic research, applied research to call for new scientific knowledge. The knowledge generation is to make effective application to the design of lab equipment and machinery.

### ii) Technology transfer

Technology transfer refers to the transfer of knowledge from innovation-oriented research projects to meet societal needs within the context of governmental policies.

### iii) Science and Technology (S&T) human resources development

The development of human capital is carried out by means of providing extensive education through schools, universities, vocational schools, distance learning approaches.

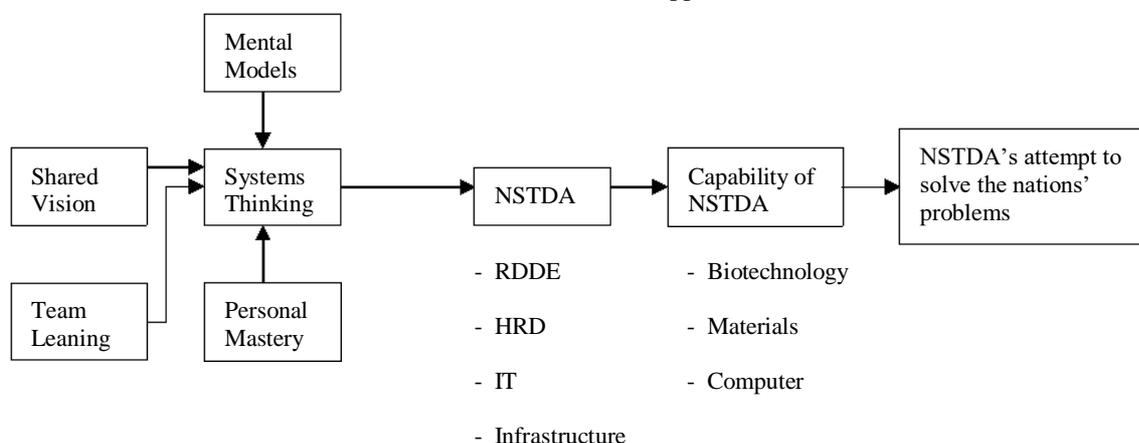

Figure 1 Learning organisation – the attempt of NSTDA to improve the innovative capacity

Table 1 R&D expenditures of Thailand

Year	R&D Expenditures (US\$ million)	R&D as % of GDP	Share of private sector
1989	113	0.17	5.5
1991	154	0.20	8.0
1997	210	0.18	15.0
1999	197	0.18	N/A

Source : The National Research council of Thailand, The National Science and Technology Development Agency

iv) Enhancement of S&T infrastructure

The principal services entail testing/QC services, certification, consultancy, training/ training co-ordination, intellectual property services to support research and development.

In the market-led economies, the private sector plays the crucial role in industrialisation. Research and development are recognised as a key factor to generate technical changes and improvements in industry. However, in Thailand, the private sector's spending in research and development is still negligible (Table 1)<sup>1</sup>. The problem is that although 80% of the firms in Thailand are SMEs, these firms generally do not engage in R&D activities. To put it another way, they tend to acquire technological capabilities from foreign sources at a superficial level – learning just to operate the systems.

Recognising the importance of private-sector technology development, NSTDA employs various policy measures. Among the policy measures to induce market-led economies are the followings.

1) R&D financing

As NSTDA's funding for R&D supports comes from fiscal budget, NSTDA becomes a major source of fund for providing supports to R&D activities in the public sector as well as private firms. At present, NSTDA has undergone the financial policies for SMEs by setting up NSTDA's Company Directed Technology Development (CD) program to provide financial support to enable private companies to invest in RDDE for commercialisation. The incentives to stimulate RDDE programmes in the form of financial assistance are grants and low-interest loans. Grants have a maximum limit of 75% of project expenses and do not exceed 3 million THB. The maximum amount given as a low-interest loan, which may cover up to a maximum of 50% of the total cost, is 20 million THB per project. The interest rate is one-half the interest rate for 1-year fixed deposits placed at banks plus 1.125% overhead charge. In granting loans, NSTDA considers that the research project of SMEs must accord to NSTDA's three priority areas, i.e. genetic

engineering and biotechnology, metal and materials technology; or electronics and computer technology.

2) R&D Tax Scheme

NSTDA undertakes the tax incentives to induce R&D investment in the private sector. In stimulating private-sector technology development, NSTDA offers tax incentives associated with setting up R&D laboratories and the related imports of machinery and equipment for use in R&D activities. The private businesses investing in R&D can deduct 200% of their R&D expenses for tax calculation<sup>2</sup>.

To encourage firm RDDE activities, other incentives include the increasing depreciation rate for laboratory equipment and machinery used in RDDE, the import duty exemption for the purchase of the equipment for RDDE, the tax exemption from sales of patents and inventions for a certain period of time.

To ensure the relevance of NSTDA's activities to the market demand of the industry, NSTDA also pursues 'demand pull' strategy by simulating the concept of 'clustering' [2] taken place at Silicon Valley in the US. In the US, public research, private (industrial) research and university research often have been intertwined closely [3]. The high technology incubators are set up to draw venture investment into the local economy. The mechanisms employed by NSTDA aim at coordinating and facilitating strategic collaborations and linkages between various research units, educational institutions and industrial sector. NSTDA is situated among the universities (Asian Institute of Technology, Sirindhorn International Institute of Technology, Thammasat University, Rangsit University, Bangkok University) which provide academic links to university research. It has established international collaboration link (e.g. Communications Research Laboratory in Japan, National Science Foundation in the USA, National Research Council in Canada) to ensure that the networks add benefit and value of generating more business for the firms. To the extent that government support policies influence a step further for private firms, NSTDA has orchestrated the R&D attack by getting firms to think through together which approaches ought to be followed and what directions pursued if commercial primacy were

<sup>1</sup> This percentage share contrasts with the situation in the advanced countries, where their private sectors accounted for 2-3% of GDP. The decreasing R&D expenditures in the year 1999 was an aftermath of the financial crisis.

<sup>2</sup> Science and Technology Development Program, Thailand Development Research Institute Foundation.

to be achieved. Clearly, the NSTDA Science Park offers resources to get the potential firms off the ground.

## 2. Conclusions

In this paper, the discussion has highlighted some interesting issues about the attempts of Thailand to develop technological capabilities and support SMEs towards the knowledge-based economy. Thailand will be able to survive in the rapidly changing economy provided the organisations and industrial sectors learn through R&D activities (not copy and development activities). This is because the method of learning, to some extent, determines the accumulation of technological capabilities. In effect, there needs to be collaboration between the public and private sectors in terms of developing the linkages and networks to push forward the governmental policy measures. This paper discusses the role of government, especially NSTDA, in producing effective mechanisms to support private enterprises. NSTDA's policy towards improving innovative capacity is in line with the National Economic and Social Development 9<sup>th</sup> plan in emphasising the development of R&D activities.

## Abstract

Collecting and analyzing training needs data using traditional survey method is extremely tedious and time consuming. Adopting a competence-based approach, this paper summarizes a conceptual model for effective training needs assessment, and presents an efficient web-based tool for assisting training specialists in conducting the needed analysis. Time saving benefit of the web-based tool was demonstrated. A sensitivity test was devised and found that the time saving benefit increases with employee size. A prototype system was implemented using MS IIS 5.0 web server, ASP web programming language and MS Access 2000 database. The complete process was demonstrated to a class of human resource managers and received favorable ratings on several measures of effectiveness and efficiencies.

## 1. Introduction

E-business is in. Company processes are being automated to increase efficiencies; business activities are linked by the newest web-technologies to add value to customers and users. In the midst of this e-frenzy, an important business process seems to be left behind. We found very few applications in support of the planning processes for the training and development of a company's most valued human capital.

The notion of a new knowledge economy reinforces the idea of employees being the most important asset. Human resource departments in many companies were compelled to look for ways to increase human capital [6]. From the perspective of long-term management, one viable way to increase a company's human capital is through carefully implemented HR practices such as training and development, performance evaluation and planned manpower changes [5]. Training, especially, is an important strategic practice in the development of internal competence.

Training activities preceded any knowledge management practices as the primary means to transfer organizational knowledge and "know-how's" to employees. However, unlike knowledge management practices, there seems to be a lack of efficient use of or coordination in modern technologies in training related processes. Though we have seen an increase in the utilization of a human resource management information system, from a humble 7% in the seventies, to 68% in the

eighties, and to a whopping 88% in the nineties, the applications are still limited to the more traditional aspects of personnel management, such as compensation and hiring [7]. Also, although e-learning is a sizzling topic for both the academia and the practitioners, the application deals primarily with the delivery of learning contents. The process of deciding who should get training on what, i.e., the planning process, is still done manually today. Blanchard and Thacker [1] highlighted the importance of structure and technology as the two internal factors which strongly affect an organization's competitive position. To improve an organization's competitive stand, we call attention to the use of the latest information technologies to support this strategic planning process called training needs analysis.

Swanson [9] proposed a technical training system model, including steps of analysis, design, development, implementation and evaluation. Needs analysis, the initial planning and analysis of a training program, is the most vigorous yet important stage in the training and development process. The accuracy of the analysis determines the legitimacy and effectiveness of training program design and subsequent deliveries in the latter stages of the training process. There are various ways to determine employees' training needs. The most commonly used method is survey questionnaires to the employees and their managers measuring the employees' skill level. However, as with any survey research, this method in its traditional manner is extremely tedious and time consuming.

This paper summarizes a conceptual model for effective training needs analysis, and presents an efficient web-based tool for assisting training specialists in conducting the needed analysis.

## 2. Competence-based Training Needs Assessment

Yeh [11] indicated that in the practical world, a training curriculum in a company is planned based on the following methods: 1) what available organizational resources are there, 2) by departmental functions, 3) what current management trends are, 4) in accordance with the labor law, 5) what corporate strategy calls for, and 6) how to fulfill corporate core competency. Since enhancing corporate core competencies has been a critical element for many companies to gain competitive advantage in their business [6], the competency-based training approach is

used to build the skeleton of the proposed conceptual model. As seen in Figure 1, the first stage of the model starts with identifying the company's vision, its mission statement, and business strategies, in order to flush out the company's core competencies. Deploying from the identified competencies, in Figure 2, a task analysis is conducted to further identify required knowledge, skills and abilities of a corresponding competency. Then needs assessment is conducted to measure the gaps of the required knowledge, skills and abilities between the "what-ought-to-be" in a company and the "what-is" in the employees. Finally, as shown in Figure 3, after ruling out non-trainable gaps, the training specialist plots the training curriculum for each employee by filling each individual gap with a learning activity.

Figure 1. Identify company core competencies

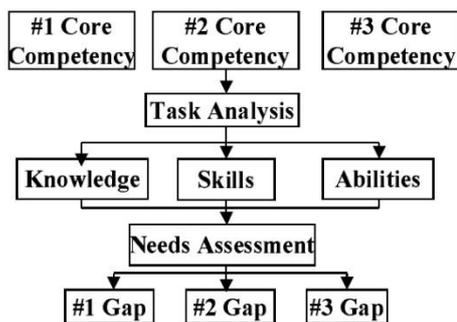

Figure 2. Perform task analysis and needs assessment

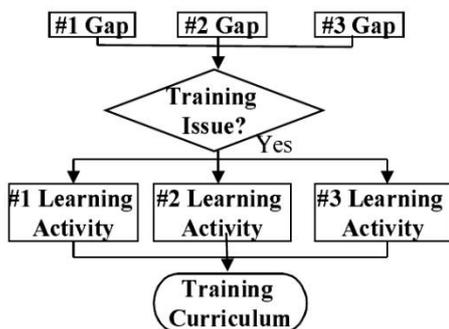

Figure 3. Design training curriculum

### 3. A Web-based Prototype System

This model provides an effective competency-based approach to planning a training program. This research converted the above conceptual model into an automated

process with necessary activities for the training specialist to accomplish the task of analyzing training needs. A supporting web-based environment is then constructed to assist the training specialist to design the training curriculum more efficiently. The functional structure chart as shown in Figure 4 illustrates the five sub-modules for training needs analysis, which includes 1) employee data management, 2) needs assessment management, 3) questionnaire design management, 4) training classes management, and 5) information. Employee data management includes basic data and training records sub-modules. Needs assessment management includes organization analysis, work analysis, and employee analysis sub-modules. Questionnaire design management includes questionnaire design, online questionnaire fill-out and questionnaire delivery sub-modules. Training classes management includes class data, scheduling data, and registration sub-modules, while information management includes BBS and message board sub-modules.

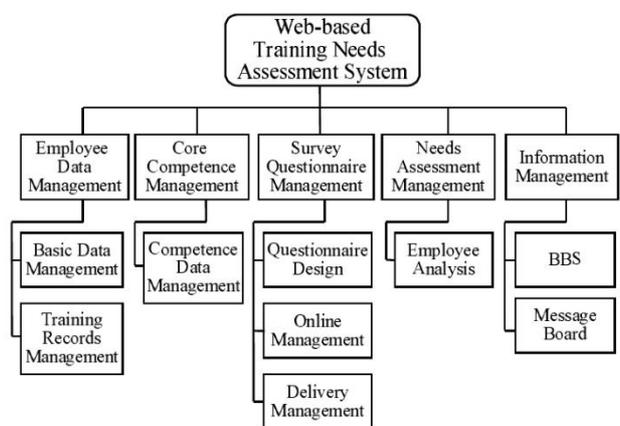

Figure 4. Functional structure chart

The web-based environment is designed to assist the training specialist to efficiently perform training needs analysis with the aid of intranet technology in the company. [10] The proposed prototype does not replace the role of a training expert. That is, the training specialist still needs to be skillful with the tasks of a training needs analysis, but the proposed web-based information system will make the execution of the process faster, easier and more automated.

### 4. Time Saving Benefit of the Prototype

Selander and Cross [8] proposed a two-stage process redesign analysis, which includes process mapping and value analysis, to evaluate the improvements and cost-savings of the new process. This research adopts the ideas of Selander and Cross by laying out the process of traditional training needs analysis, and identifying the tasks and errors which are not value added and can be deleted in the new process for cost-benefit justification. Accordingly, the claimed efficiency of our web-based prototype comes from the time saved for performing some of the tedious, time-consuming, and repeated tasks in training needs analysis processes, which include designing,

printing, and mailing the training needs questionnaires; collecting responding questionnaires, entering the data, calculating the survey results, and matching employee needs to training classes. These tasks have no value-added portions and can be converted to an automated process. The proposed system only requires the user to post the questions, setup the mailing list, schedule the survey, select the mode for calculation, and match intended training classes to needs questions; the computer will then do the

rest. Time saving increases with the employee size.

Table 1 compares the elapsed time by each process step of a traditional/manual training needs assessment with one that's done on the proposed prototype system. Time estimates for the prototype system are based on average operation, given basic employee data (e.g., name, department, e-mail address, etc.) are already entered in the system. For illustration purpose, we use very conservative, minimal time estimates for the manual process.

**Table 1: Assumptions of time spent on needs assessment process steps**

Process Steps- Manual Process		Process Steps- Prototype System	Elapsed Time - Manual	Elapsed Time - Prototype	Time Saving
Questionnaire design ( $\chi_1$ )		Questionnaire design ( $y_1$ )	3 hours	2 hours	$S_1$
Print survey ( $\chi_2$ )	In-house ( $\chi_{21}$ )	Send survey via e-mail ( $y_2$ )	1 minute	2 minutes	$S_2$
	Outsource ( $\chi_{22}$ )		24 hours		
Send survey ( $\chi_3$ )	On the spot ( $\chi_{31}$ )		1 minute		
	By mail ( $\chi_{32}$ )		24 hours		
Fill out survey ( $\chi_4$ )			24 hours	24 hours	$S_3$
Return the survey ( $\chi_5$ )	On the spot ( $\chi_{51}$ )	Fill out survey online ( $y_3$ )	1 minute		
	By mail ( $\chi_{52}$ )		24 hours		
Code the returned survey ( $\chi_6$ )		Execute data analysis to find competence gaps ( $y_4$ )	1 minute	1 minute	$S_4$
Enter survey data ( $\chi_7$ )			1 minute		
Conduct data analysis ( $\chi_8$ )	Using SPSS( $\chi_{81}$ )		1 minute		
	Using Excel( $\chi_{82}$ )		1 minute		
Calculate competence gaps ( $\chi_9$ )			1 minute		
Match competence gaps with employee training ( $\chi_{10}$ )		Match competence gaps with employee training ( $y_5$ )	1 minute	1 minute	$S_5$

Total time saving (TS) equals the sum of time saving in each process step ( $S_1, S_2, S_3, S_4, S_5$ ). Using the prototype system eliminates the editing and styling usually required when designing a survey questionnaire ( $S_1$ ). Sending the survey across the web eliminates the printing, publishing and traditional dissemination process altogether ( $S_2$ ). Similarly, other than the time required for the employee to fill out the survey, the system does not take any time to return the survey to the investigating party ( $S_3$ ). Traditionally, survey coding and data entry were the most tedious during a training needs assessment, not to mention the most error-prone. With automatic return, online database and built-in analytical tools, the system eliminates the coding and data entry steps altogether, and minimized the time and effort to calculate competency gaps ( $S_4$ ). Last but not the least, the system's automatic gap-to-training capability saves HR personnel a lot of time compared to a manual process to match training modules with each individual employee's competency gaps ( $S_5$ ).

Assuming a company of 120 employees was to conduct a competence-based training needs assessment, the total time saving (TS) realized by the company using the web-based prototype system would be: ("n" = number of employees = 120)

$$TS = S_1 + S_2 + S_3 + S_4 + S_5$$

$$= (\chi_1 - \gamma_1) + (n\chi_{21} + n\chi_{31} - \gamma_2) + (\chi_4 + n\chi_{51} - \gamma_3) +$$

$$(n\chi_6 + n\chi_7 + n\chi_{81} + n\chi_9 - \gamma_4) + (n\chi_{10} - \gamma_5)$$

$$= (180 - 120) + [(120 * 1) + (120 * 1) - 2] + [1440 + (120 * 1) - 1440] + [(120 * 1) + (120 * 1) + (120 * 1) + (120 * 1) - 1] + [(120 * 1) - 1]$$

$$= 60 + 238 + 120 + 479 + 119$$

$$= 1016 \text{ minutes} = 16.93 \text{ hours}$$

### Sensitivity test of employee size on time saving

To demonstrate that time saving increases with the employee size, a sensitivity test was conducted. Holding other variables constant, we quadrupled the number of employees twice and calculated the total time saving for both cases.

1). Time saving for a company with 480 employees:

$$TS = S_1 + S_2 + S_3 + S_4 + S_5 \text{ ("n" = number of employees = 480)}$$

$$= (\chi_1 - \gamma_1) + (n\chi_{21} + n\chi_{31} - \gamma_2) + (\chi_4 + n\chi_{51} - \gamma_3) + (n\chi_6 + n\chi_7 + n\chi_{81} + n\chi_9 - \gamma_4) + (n\chi_{10} - \gamma_5)$$

$$= (180 - 120) + [(480 * 1) + (480 * 1) - 2] + [1440 + (480 * 1) - 1440] + [(480 * 1) + (480 * 1) + (480 * 1) + (480 * 1) - 1] + [(480 * 1) - 1]$$

$$= 60 + 958 + 480 + 1919 + 479$$

$$= 3896 \text{ minutes} = 64.93 \text{ hours}$$

2). Time saving for a company with 1920 employees:

$$TS = S_1 + S_2 + S_3 + S_4 + S_5 \text{ ("n" = number of employees = 1920)}$$

$$\begin{aligned}
&= (X_1 - Y_1) + (nX_{21} + nX_{31} - Y_2) + (X_4 + nX_{51} - Y_3) + \\
&\quad (nX_6 + nX_7 + nX_{81} + nX_9 - Y_4) + (nX_{10} - Y_5) \\
&= (180 - 120) + [(1920 \times 1) + (1920 \times 1) - 2] + [1440 + \\
&\quad (1920 \times 1) - 1440] + [(1920 \times 1) + (1920 \times 1) + (1920 \times 1) + \\
&\quad (1920 \times 1) - 1] + [(1920 \times 1) - 1] \\
&= 60 + 3838 + 1920 + 7679 + 1919 \\
&= 15416 \text{ minutes} = 256.93 \text{ hours}
\end{aligned}$$

Results of the sensitivity test are tabulated in table 2. As shown, the time required when implementing a full-scale training needs assessment using the traditional/manual process multiplies quickly with increasing employee number. Whereas, the time takes to implement the same needs assessment using the web-based prototype system remains the same regardless of employee size. Consequently, the prototype system realizes tremendous time saving: 39.37% in companies with 120 employees, 71.35% in companies which employ 480, and 90.79% in companies of 1920 employees. Thus, we conclude that the time saving benefit is very sensitive to the number of employees subjected to the competence-based training needs assessment.

**Table 2: Effect of employee size on time saving**

No. of Employee	(1) Total Time-Manual	(2) Total Time-Prototype	(1)-(2) Total Time Saving	(1)-(2) / (1) % Percentage Time Saving
120	43	26.07	16.93	39.37%
480	91	26.07	64.93	71.35%
1920	283	26.07	256.93	90.79%

## 6. System Evaluation

The prototype system was implemented using MS IIS 5.0 web server, ASP web programming language and MS Access 2000 database. The prototype went through a two-phase evaluation process to establish its validity and effectiveness.

### Phase one—Quantitative measures

The purpose of the phase one evaluation was to gauge the validity of the competency-based needs assessment model and the prototype system from a practical standpoint. We looked for experienced HR practitioners as our study sample because they were most qualified to judge whether the system was valid to use in the field as a needs assessment tool. We carefully selected a class of students who were all registered in a MIS (Management of Information Systems) course offered through the HRM program in a major university. These students were studying for their master's degree in a graduate program designed specifically for experienced human resource managers and professionals. We conducted the evaluation toward the end of the MIS course to ensure that the study sample had adequate knowledge of the use of IS in human resource management. Thirty-one students participated in the study, most of whom had experience in training related jobs.

The complete process of a needs assessment using the prototype system was demonstrated in the MIS class. The demonstration took 40 minutes followed by a 20-minute Q&A. Then the class was asked to fill out a questionnaire. The questionnaire was composed of demographical questions and several measures of validity using a Likert-type scale of 1 to 5 (1 means strongly disagree and 5 means strongly agree). Descriptive statistical analysis and ANOVA were used to analyze the data.

The respondents' demographic characteristics are described below. The gender was balanced between males and females. While a majority (61%) had more than ten years of working experience, respondents were normally distributed on the six categories of the length of training-related experience. Although 68% reported working with a company that employed training and development personnel, only 50% of respondents believed that their company regularly conducts needs assessment. The profile of the respondents fit the purpose of our research nicely, and their responses on company's training function were within expectations.

Table 3 revealed the results of the validity measures. Respondents showed positive reactions toward each of the seven measures. The concept of a competency-based training needs assessment received most favorable ratings, followed by the use of gap analysis to assess these needs. Respondents were also impressed with the ability of the system to shorten operation time required of the planning process of a competency-based training.

**Table 3: Results of validity measures**

Validity Measures	Mean	S.D.
1. Agree with the concept of a competency-based training needs assessment	4.23	0.88
2. Agree with the concept of using gap analysis to assess training needs	3.84	0.90
3. The system effectively assist the planning of a competency-based training	3.32	0.94
4. The system simplifies the planning process of a competency-based training	3.48	0.93
5. The system shortens operation time required of the planning of a competency-based training	3.71	0.97
6. The system can effectively expedite the transmission of needs assessment information	3.65	0.91
7. The system makes analysis results of employees' competence gaps more accessible to training specialists	3.48	1.06

We also conducted an ANOVA analysis to find out whether the respondents' demographic background had any bearings on the validity of the prototype system. The results are presented in Table 4. Data showed, with three exceptions (marked by an \* in Table 4), differences among categories of each demographic variable were insignificant

on any of the validity measures. This served as a strong proof that the design of the prototype system was not biased toward any particular demographic group. With that

being said, a closer look at the three exceptions revealed somewhat interesting notions about the use of technology in the corporate.

**Table 4: ANOVA**

Validity Measures	Demographic Variables				
	Gender	Experience	Training related experience	Have training personnel	Conduct needs assessment
1. Agree with the concept of a competency-based training needs assessment	0.074	0.297	0.970	0.160	0.420
2. Agree with the concept of using gap analysis to assess training needs	0.155	0.156	0.878	0.018*	0.071
3. The system effectively assist the planning of a competency-based training	0.147	0.761	0.759	0.626	0.852
4. The system simplifies the planning process of a competency-based training	0.212	0.883	0.712	0.113	0.249
5. The system shortens operation time required of the planning of a competency-based training	0.086	0.257	0.283	0.042*	0.201
6. The system can effectively expedite the transmission of needs assessment information	0.023*	0.721	0.309	0.060	0.564
7. The system makes analysis results of employees' competence gaps more accessible to training specialists	0.152	0.569	0.826	0.312	0.506

\*  $\alpha=0.05$

As shown in Table5, males were stronger believers than females in the system's ability to expedite the transmission of needs assessment information. This finding seemed to reflect the stereotype of gender differences on technology, e.g., men are better at computers; men are more willing to embrace technology than women, etc.

**Table 5: Gender differences on validity of system**

Validity Measure	Mean	
	Males	Females
The system can effectively expedite the transmission of needs assessment information	4.00	3.27

Whether the company has training personnel influenced responses on two validity measures: 1) acceptance of the concept of gap analysis in training needs assessment, and 2) the system's time-saving feature in the planning of a competency-based training. (See Table 6) It's possible that companies with training and development personnel already have in place certain training needs assessment process or procedures, and believe that the gap analysis system is a better and more efficient alternative to their own practice. The disparity may also come from the fact that companies which don't employ training and development personnel don't usually conduct training needs assessment, therefore it is difficult for those respondents to grasp the ideas presented in the prototype system.

**Table 6: Whether company has training personnel on validity of system**

Validity Measure	Mean	
	Yes	No
Agree with the concept of using gap analysis to assess training needs	4.10	3.30
The system shortens operation time required of the planning of a competency-based training	3.95	3.20

**Phase two—Qualitative measures**

The purpose of the second-phase evaluation is to measure the effectiveness and the usability of the prototype system. To this end, we conducted one-on-one interviews with three training and development managers after they had experienced the operation of the prototype system hands-on.

The three T&D managers were from different industry background. Manager A was a T&D manager for a major department store and had 8 years of working experience in HR-related functions. Manager B worked as a T&D supervisor for a government agency for more than 10 years. Manager C was in charge of training for an area hospital and had 3 years of HR-related experience. Each manager received a 10-minute introduction of the competency-based training needs assessment model, then worked through each of the five modules of the prototype system to complete a hypothetical needs assessment process. The hands-on experience took 15 to 20 minutes, followed by a 30-minute semi-structured interview. Interview questions included the following: (See table 6 for a complete list of interview questions.)

1. Effectiveness, time-saving and accuracy of the questionnaire management module
2. Effectiveness and accuracy of the needs assessment module to calculate competence gaps
3. Whether the prototype system was easy to follow, straight-forward and user-friendly
4. Consistency of layout, appropriate size and amount of texts, appropriate use of graphics
5. Content accuracy, flow of information and legibility of the prototype system

Similar to the findings in the previous survey, all three managers agreed that the web-based prototype system provides a good model to assess employees' training needs, reinforces the concept of competency-based training, and simplifies the analysis stage of a planning process for training. While the training managers were positive about the effectiveness and the time saving prospects of the system, they also stressed the importance of customization to realize these benefits. The extent of customization included company organization and communication channel, a company-wise competency databank, training curriculum, process linkage to training

course registration and administration, etc. Concerns of employees mistaking a training needs analysis to performance evaluation were raised. Though not a system problem, one of the managers-Manager C-suggested adding this message to the survey: "For development purpose only, and will not be used in performance evaluation" to minimize the possibility of employees sending falsified information.

In terms of the functionality of the system, the managers suggested the following improvements:

- Provide multiple methods for data analysis or allow exporting of data to other statistical program for further data manipulation.
- Send an automatic confirmation when the survey is received by the intended employee.
- Provide better tracking mechanism, such as stats on send, reply and follow-up status.
- Provide better navigation functions, such as backtrack, system maps and on-line instructions.
- Provide options to setup the order of how respondents fill out the questions.
- Remind respondents of missing answers.

**Table 7: Interview questions and findings**

Interview Questions	Results	Improvement Suggestions
1. Do you agree with the concepts imbedded in the prototype system?	Positive	
2. Will the system facilitate the use of competence-based training needs assessment in your company?	Positive	- Customization is required prior to implementation.
3. Will the system help save time in planning employee training?	Positive	
4. Will the system simplify the planning process for employee training?	Positive	- Provide choices of analytical tools
5. Is the system effective in assisting the planning of a competency-based training?	Positive	
6. Effectiveness of questionnaire management module: Design? Dissemination? Collection?	Positive	- Automatic confirmation when message is received by the receiver. - Provide stats on send, reply and follow-up status.
7. Effectiveness of needs assessment module in quantifying employees' competence gaps?	Positive	- Stress "the survey is for developmental purpose only, and will not be used in performance evaluation"
8. Is the prototype system easy to follow and user-friendly?	Positive	- Provide system maps and on-line instructions.
9. Aesthetic appeals of the screen display: Consistency? Appropriate placement and size of text and graphic?	Positive	
10. Legibility, accuracy and flow of contents in the system?	Positive	- Provide option to setup the order of how respondents fill out the questions. - Remind respondents of missing answers.

## 7. Conclusion

We have presented a conceptual model in training needs assessment to assist organizations in their pursuit of competitive core competencies. We have also designed a web-based prototype system based on this conceptual

model to improve the efficiency and effectiveness in collecting and analyzing competence data for training and development purpose.

Neither the competence-based training approach or the needs assessment method is new to seasoned HR professionals. The method of using survey questionnaires

# An Empirical Investigation into the Impact of Electric Connectivity on the Adoption of Internet Banking

## Abstract

In recent years, Internet banking has made dramatic progress across the world. In this paper, the nature and business rationale of Internet banking are briefly reviewed and analysed. Then a multiple regression model is proposed to study the relationship between electric connectivity (PC, Internet and Mobile) and customers' adoption of Internet banking. Empirical results are obtained and analysed. The results show that the electric connectivity has important impact on the adoption rate of Internet banking. Moreover the impact of each connectivity factor on the adoption rate of Internet banking is quantified.

## 1. Introduction

Banks such as Wells Fargo in the United States and Advance Bank in Australia launched their first Internet banking and bill pay services in 1995. Initially, investments in the Internet related principally to increasing distribution channels and providing information to consumers. Based on the success of these applications, coupled with the improvement in Internet security and consumer demand, many banks around the world have made major strides by offering full account access and transactions on the Internet.

Many banks have offered sophisticated functionality to their Internet banking customers. Customers can check their account balances and transaction history going back a few months, make transfers between accounts, pay bills online using bill pay services. They can also easily download account history into variety of formats for inclusion in many popular financial software packages. All these functionalities are backed by a high-level security.

There have been many studies on issues related to Internet banking. For example, KPMG [14] investigated the status of Internet banking in

Australia in the late 1990s. Studying the adoption of Internet banking in Australia, Sathye [22] reported that security concern and lack of awareness stand out as the reasons for no-adoption of Internet banking by Australian customers. Balachandher and Balachandran [2] provided an understanding of the factors that affect the adoption of Internet banking in Malaysia. Jun and Cai [13] attempted to identify key quality attributes of the Internet banking products and services by analysing Internet banking customers' comments on their banking experiences. Howcroft et al [12] explored consumers' existing financial services behaviour and assessed their attitudes towards home-based services, i.e., telephone and Internet banking. They found that branch network is still the most popular delivery channel in the acquisition of current accounts, credit-based and investment-based services. Moreover, consumer preferences reveal that they are not generally predisposed to change their behaviour radically and adopt widespread usage of telephone and Internet banking. Changes in the use of delivery channels will occur naturally as the population matures and computer usages "seep up" into the older age groups, but this process will undoubtedly take time.

However, there has been little empirical study on how the connectivity factors impact the consumers' adoption factors of Internet banking. This paper aims to fill this gap and to shed some light on this issue by establishing a regression model on the relationship between electric connectivity and the adoption of Internet banking.

The paper is organised as follows. First, the nature of Internet banking and analyse its business rationale is addressed. Second, a regression model is proposed and conducted. Then, the empirical results are reported and analysed. Finally, the results are summarised and their implications are suggested.

## 2. The Nature of Internet Banking

Strictly speaking, Internet banking is not the same as banking via on-line services. Internet banking means that [see e.g. 7, p51]:

- Consumers do not have to purchase any additional software (the web browser is sufficient), store any data on their computers, back up any information or wait months for new versions and upgrades, because all transactions occur on a secure server over the Internet.
- Consumers can conduct banking anywhere as long as they have computers (not necessarily their own) and modems---whether it is at home, at the office or virtually anywhere in the world.
- Consumers can download their account information into their favourite programs, which means that they do not have to follow the dictates of the service provider.
- Internet banking allows banks to break out of the hegemony of software developers.

However, in recent years, Internet banking has become the dominant form of all electronic banking. Thus, in the context of this paper, "Internet banking" and "Online banking" are used interchangeably.

The world is becoming increasingly open as a result of the Internet and the World Wide Web (WWW). Internet banking has been gaining ground around the globe. For example, a recent survey by online financial services provider Egg indicating that British Internet users are becoming more likely to use financial services on-line [1]. This offers banking institutions a new frontier of opportunities and challenges further augmenting competition in the global banking market. However, the success of this new distribution channel for banking products and services depends on many factors. For example, Sullivan [24] claimed that in general banks have been neither helped nor harmed by their early commitment to the Internet as a delivery channel.

The opinion that traditional banks were "dinosaurs" that the Internet would drive to extinction is no longer widely held. A study comparing new Internet-only banks with a peer group of new branch banks by De Young [8] showed the Internet-only banks have been substantially less profitable. They generate lower business volumes and any savings generated by lower physical overheads appear to be offset by other types of non-interest expenditures, notably marketing to attract new customers. However, Internet-only banking could eventually prove to be a viable business model. De Young [8] found that

profitability improves more quickly over time for the Internet only start-ups and they may benefit more from gaining experience and be better placed to realise economies of scale than their peers.

Most researchers and practitioners believe that disintermediation is unlikely to occur and financial intermediation is still essential in the age of the Internet. Internet banking requires high initial set-up costs (both technological and marketing) with savings following later. But it appears that no major banks had achieved cost reductions through Internet banking [cf. 15].

According to the KPMG [14] survey, the rapid growth of Internet banking was due to a number of factors:

- Availability of service
- Evolving Internet technology and standards
- Customer acceptance
- Industry consolidation.

Internet banking has grown dramatically in the past decade. It is likely to continue to grow in the future [23, 6]. In a nutshell, surveys by the American Bankers Association and Grant Thornton, a leading accounting, tax and management consulting firm, say four out of five community banks in the US have websites in 2002 and nearly 20% of bankers believe the Internet will be their leading consumer banking channel by 2005 [19]. As in the past, technological developments will play an important role in the future growth of Internet banking. For example, the following developments trends are predicted:

- "Foundation" technologies such as the web, XML, OFX and IFX and upgraded middleware will improve data access and integration
- Hot applications areas will include internal data security and authentication of customers and employees and risk management across the enterprise. Customer analytics and wealth management tools will also proliferate.
- Banks will retool websites and remote channels to offer better customer service. As part of this, more intelligently designed self-service will be featured.
- Payments-oriented middleware will get more sophisticated permitting such as cash management services as real time, comprehensive positive pay. Electronically bill payment and presentment and online procurement will, after a slow start, take off.
- The banks that will win will re-engineer their tools, process, and management to permit lifecycle marketing, or programs based on detailed customer knowledge.

In sum, it appears that the Internet banking still has a great growth potential due to technology

development and the further acceptance of e-commerce by consumers. But Internet-only banks would not replace the traditional banking business completely. Instead, they would rather co-exist.

### 3. The Business Rational for Internet Banking

The Internet has emerged as a key competitive arena for the future of financial services.

The reason behind the rapid development of Internet banking lies primarily in the (potential) benefits it offers to business and customers. These benefits are reflected in the following aspects: increased revenue, reduced costs and improved customer satisfaction [cf. 13, 16].

#### 3.1 Increased revenue

On the revenue side, Internet banking does have the following impacts.

- More account sales.
- Increased customer retention, on the accepted principle of "get them now, have them forever".

- Wider market reach. The Internet does not restrict banks to areas where they have a physical presence.
- Entry into new market opportunities. The provision of Internet share trading positions banks to tap into the fast growing online market. According to widely publicised statistics, online trading accounted for 30% of all discount trades in the United States in 1997.

Online services are a must for banks that have to compete with a growing number of services from other financial institutions, investment concerns, and insurance companies.

#### 3.2 Decreased costs

Internet banking requires high initial set-up costs (both technological and marketing) with savings following later. Once marketing and set-up costs have been incurred, transaction costs (admittedly, excluding the cost of customer support) appear much lower for Internet banking, especially in high-wage economies as illustrated in Table 1.

**Table 1. Relative costs of banking transactions**

	United States	India
Physical branch	100	100
Postal	..	40
Telephone	50	18
ATM	27	18
PC dial –up	8	na
Internet	1	12
Sources: Sato et al [23]		

#### 3.3 Improved customer satisfaction

The cost reduction associated with Internet banking comes from several aspects as follows.

- Reduction in traditional branch network infrastructure.
- Reduction in customer service staff as customers service themselves.
- Reduction in cheque processing costs due to increases in electronic payments.
- Decreased mail and distribution costs as statements, disclosures and other current paper items are delivered online.
- Less data entry as customers complete forms such as loan applications, changes of address and the like online.

In sum, the more transactions that can be converted to electronic form, the more money will be saved. The cost of an electronic transaction is dramatically less when done online, and customers do most of the work themselves.

Internet banking services that are well executed do lead to satisfied customers. For example:

- Allowing customers not only to see their account data but also to analyse it and adds value that is not available from a paper statement.
- Setting up of recurring bill payments and account transfers on the Internet allows customers to save time.
- Giving customers access to transactions, account balances and information anywhere offers great convenience than waiting in line at branch during business hours.

Of course, the Internet cannot perform every function for customers. Customers will at times need or want to talk to an actual person, so that option needs to be available (although multimedia may eventually reduce still further the need for person to person contact). Defining which services

add the most value on the Internet remains possibly the greatest challenge.

In sum, Online banking has the potential to solidify and extend a bank's relationship with its customers because it brings banking services directly to a customer's home or office. The more services a customer accepts, the more likely that customer will stay loyal to the bank.

Finally, we point out that the above advantages do not come for free. Banks do incur great costs in implementing their Internet banking systems. However, such investments are mostly short term or one-off. In contrast, the benefits are always long lasting. Banks also face enormous challenges from on-line banking (for more details, see e.g. 4, 24).

#### 4. A Multiple Regression Model

The basic research question of this paper is: how important is each of the connectivity to the adoption of Internet banking? To solve this complex question, a multi-regression model need to be established under some assumptions.

The primary factor determining the level of demand for Internet banking services will the number of people connected to the Internet. Internet banking is a relative new service. Much has been written on the factors affecting adoption or usage of new products or services. The adoption or usage of any new products or services has been well studied in the literature. For example, various theoretical model of adoption can be found in Rogers' work [20]. Mantel [17] evaluates the factors associated with the usage of electronic bill payment based on a sample obtained from a large survey. Some of the major psychological and behaviour factors which affect the adoption of any new innovation such as Internet banking includes: consumer awareness, ease of use, security, accessibility, techno phobia or simply reluctance to change, preference for personalised services and cost of adopting the innovation. In this paper, we attempt to examine a number of factors that affect the adoption of Internet banking across different countries. Thus, we can categorise these factors into two groups: national factors that are different from country to country, such as the connectivity, cost of Internet banking, etc.; individual factors that are similar to all countries, such as the security, awareness, etc. We also assume that all countries use a similar technology for Internet banking.

Without any doubt, the electric connectivity is a very important factor impacting the adoption of Internet banking. The connectivity factor can be divided into three parts: PC connectivity, Internet connectivity and Mobile connectivity. PC connectivity can be measured as the percentage of

population owning PCs in a country. Internet connectivity can be measured as the number of Internet hosts for a given number of population. Finally, Mobile connectivity can be measured as a percentage of inhabitants with mobile phones.

Another important factor that explains the adoption difference across different countries is the cost factor. In Internet banking, two types of costs are involved. First, the normal costs associated with Internet access fees and connection charges and secondly the bank fees and charges. Rothwell and Gardiner [21] observed that there are two fundamental sets of factors affecting user needs, namely price factors and non-price factors. To this extent, several researchers [[9, 11, 18] have identified price as a major factor in brand switching. If the consumers are to use a new technology, it must be reasonably priced relative to alternatives. Otherwise the acceptance of the new technology may not be viable from the standpoint of the consumers.

Due to the lack of data on costs, however, we are unable to include the cost factor in our regression model. As a rough model, we are only concerned with how important are the aggregate connectivity and each component of electric connectivity. In other words, we assume the relative cost of Internet banking is similar across different countries.

Based on the above assumptions, we propose the following model:

$$IBC_i = C + \beta_1 PC_i + \beta_2 IC_i + \beta_3 MC_i + e_i \quad (1)$$

Where:

IBC = Internet banking customer as a percentage of bank customers;

C = constant;

PC = personal computer use, measured as population owning personal computers;

IC = Internet connectivity, measured as Internet hosts per 10,000 people;

MC = Mobile phone use, measured as the percentage of people who are mobile or cellular subscribers.

e = error term.

Note that the impacts of all factors that are common to all countries are reflected in the constant term C. To estimate the model, a number of issues need to be addressed. First, we may encounter the *multicollinearity problem*. For example, the independent variables, PC, IC, and MC might be highly correlated. According to our intuition, this might well be the case and Internet connectivity and Mobile connectivity may be a more appropriate ones to use. To avoid such a

problem, we may also need to consider the following simplified regressions:

$$IBC_i = C + \beta_2 IC_i + \beta_3 MC_i + e_i \quad (2)$$

Or

$$IBC_i = C + \beta_1 PC_i + \beta_3 MC_i + e_i \quad (3)$$

Another problem we may encounter might be the autocorrelation which is data specific. This will be addressed later in the empirical results.

#### 4.1 The Data

To estimate the above models, we need data for various countries, which is hard to obtain. Fortunately, a number of sources, including the data presented in Claessens et al. [5], can be used to compile such data as of the end of 1999. The relevant data for 27 countries are presented in Table 2.

**Table 2. Internet banking and connectivity data**

Country	% of banks' customers using on-line banking	Personal computer use (% of population owning PCs)	Internet connectivity (Internet hosts per 10,000 people)	% of inhabitants with mobile phones
Australia	4	47	417	34
Belgium	4	32	162	31
Denmark	6	41	72	49
Finland	20	36	1057	65
France	2	22	83	36
Germany	12	30	161	29

A few observations on the data are as follows. There is a significant variation in the Internet banking adoption figures. In some countries, industrial as well as developing, Internet banking remains in its infancy. Meanwhile, other countries have a high level of Internet banking adoption. In Sweden, nearly one third of customers use Internet banking. In some emerging markets such as Korea, India, Internet banking adoption is also at a high rate.

Around the world, consumers and countries are increasingly getting connected. Advanced countries like the United States lead in terms of the percentage of the population that owns a personal computer and has the Internet access. The density of Internet services is also the highest in the most advanced countries. Among these countries, Nordic countries stand out with high connectivity. This high connectivity is augmented by the popularity of mobile phones, which are used by almost two-

thirds of the people in Finland and Norway and three-fifths in Sweden. Connectivity generally decline with income, though there are exceptions. For example, Portugal has low computer ownership and Korea has high connectivity, including through mobile phones--yet the countries' per capita incomes are quite similar (Portugal \$11384 and Korea \$9878 in 1999).

In many countries, connectivity has been increasing sharply in recent years. Between 1995 and 1998 the percentage of people owning a personal computer in selected industrial countries rose almost 60 percent. In a sample of developing countries the rise was 150 percent, albeit from a lower base [5]. Increased connectivity is not limited to advanced emerging markets, but is also becoming important in some of the world's least developed countries. Africa Online, for example, is

growing Internet provider in Africa (outside of South Africa). Access to telecommunications is being aided by new technology, such as mobile phones with increasingly large bandwidths. Around the world, connectivity is also being further enhanced by rapid improvements in telecommunications regulation.

Hence it is of vital importance to understand how connectivity impacts Internet banking.

## 4.2 The empirical results

We first run the regression model (1). This is a natural starting point as we do not have prior knowledge such as multicollinearity regarding the data. The regression results are reported in Table 3.

**Table 3. Regression result for Model (1)**

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	1.898015	2.306937	0.822743	0.4191
PC	-0.027721	0.132247	-0.209618	0.8358
IC	0.008666	0.005725	1.513603	0.1437
MC	0.102130	0.084834	1.203886	0.2409
R-squared	0.290411	Mean dependent var		6.407407
Adjusted R-squared	0.197856	S.D. dependent var		6.962864
S.E. of regression	6.236115	Akaike info criterion		6.634545
Sum squared resid	894.4500	Schwarz criterion		6.826521
Log likelihood	-85.56636	Durbin-Watson stat		2.039168

A few observations are as follows.

- None of the coefficients is significant at 10% level (5% level for one tail, assuming the electric connectivity has a *positive* impact on the percentage of population adopting Internet banking).
- The Durbin-Watson statistic shows that no autocorrelation exists at 5% level (with  $k^*=4$ ,  $n=27$ ,  $d_L=1.084$ ,  $d_U=1.753$ )
- The  $R^2=29\%$ , which implies that all connectivity variables aggregately can explain a fair amount of Internet connectivity across different countries.
- The coefficient for the independent variable PC is negative! This is counter to our intuition.

The above evidences show clearly that the regression model (1) suffers from the Multicollinearity problem. Thus the coefficients are highly misleading [cf. 10].

Hence, we need to try regression Models (2) and (3). The results are shown in Tables 4 and 5.

**Table 4. Regression result for Model (2)**

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	1.772345	2.182852	0.811940	0.4248
IC	0.007948	0.004497	1.767529	0.0899
MC	0.091127	0.065302	1.395462	0.1757
R-squared	0.289055	Mean dependent var		6.407407
Adjusted R-squared	0.229810	S.D. dependent var		6.962864
S.E. of regression	6.110642	Akaike info criterion		6.562380
Sum squared resid	896.1588	Schwarz criterion		6.706362
Log likelihood	-85.59213	Durbin-Watson stat		2.029693

**Table 5. Regression result for Model (3)**

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	1.285922	2.331502	0.551542	0.5864
PC	0.091964	0.108817	0.845122	0.4064
MC	0.093830	0.086903	1.079708	0.2910
R-squared	0.219730	Mean dependent var		6.407407
Adjusted R-squared	0.154707	S.D. dependent var		6.962864
S.E. of regression	6.401643	Akaike info criterion		6.655426
Sum squared resid	983.5448	Schwarz criterion		6.799407
Log likelihood	-86.84825	Durbin-Watson stat		2.119692

We can immediately draw the following observations:

All estimated coefficients in both Model (2) and Model (3) have the right signs. This confirms that the Multicollinearity problem existed with Model (1).

Model (2) has a higher  $R^2$  comparing to Model (3).

Both Akaike Information criterion and Schwarz criterion confirm that Model (2) is the preferred model.

Model (2) has an  $R^2$  of 29% approximately the same as Model (1).

Our empirical results show that the most significant variable in explaining the Internet banking adoption is the Internet connectivity. This is consistent with our common sense. The electric connectivity can explain approximately 29% of the variations in the Internet customer proportion across different countries.

According to our estimate, an increase of 100 in Internet hosts per 10,000 people corresponds to about 0.8% increase in the Internet banking customer proportion; an 10% increase in the mobile phone subscribers yields about 0.9% increase in the Internet banking customer proportion.

Of course, our results are subject to the quality of the data used. The data are related to Internet banking are extremely hard to obtain, let alone to

have high precision. Thus our estimates can be treated only as a rough guide. As a first such estimate, we believe that the results presented are of high significance, both to the industry and to the policy makers.

## 5. Summary

In this paper, we have studied the adoption of Internet banking and electric connectivity. First, various issues related to Internet banking are reviewed and analysed. Then a model for the relationship between internet banking adoption and electric connectivity is set up and empirical results are obtained. It is shown that electric connectivity, particularly, Internet connectivity is important to the adoption of Internet banking. To our best knowledge, we are the first to quantify the relationship between Internet banking adoption and the electric connectivity. Our results may have important implications to the Internet banking industry as well as the policy making. For example, our result indicates that the Internet banking customer proportion will increase at various speed relative to the increase in Internet connectivity, Mobile phone connectivity etc. This may help banks to predict their base of Internet banking customers and thus allocate the appropriate marketing effort and resources towards Internet banking.

# Understanding Internet Banking Adoption and Continue-Use Behavior: A Hong Kong Perspective

Siu-Cheung Chan, Ming-Te Lu\*  
Department of Information Systems  
Lingnan University, Tuen Mun, Hong Kong  
lumt@ln.edu.hk

## Abstract

This study investigates adoption/continue-use behavior within the context of Hong Kong Internet Banking services. A research framework based on the extended Technology Acceptance Model (TAM2) and Social Cognitive Theory was developed to identify factors that would influence the adoption/continue-use of Internet Banking. Structural Equation Modeling (SEM) was employed to examine the entire pattern of inter-correlations among the eight proposed constructs, and to test related propositions empirically. The results reveal that both subjective norm and computer self-efficacy indirectly play significant roles in influencing the intention to adopt Internet Banking. Perceived ease of use has a significant indirect effect on intention to adopt/continue-use through perceived usefulness, while its direct effect on intention to adopt is not significant in this study.

## 1. Introduction

Following the approach taken by Karahanna, Straub, and Chervany [30], this study combines innovation attributes and attitude theories in a theoretical framework to examine potential and early adopters' reasons for adopting and continuing to use Internet Banking. This study also attempts to provide a better theoretical understanding of the antecedents of user acceptance and user resistance to adoption and continue-use of Internet Banking in Hong Kong. In addition, it extends TAM by adding perceived risk and computer self-efficacy as external variables for perceived usefulness and perceived ease of use.

## 2. Literature Review

This study lies at the intersection of two issues. The first is the technology adoption decision-making process. The second is the determinants of information technology acceptance and utilization among users.

### 2.1 Social Psychology

Information systems investigators have suggested intention models from social psychology as a potential theoretical foundation for research on the determinants of user behavior [42]. Fishbein and Ajzen's [22] Theory of Reasoned Action (TRA) is an especially widely validated intention model that has been proven successful in predicting and explaining behavior across a wide variety of domains.

#### 2.1.1 Theory of Reasoned Action

TRA is a widely studied model from social psychology, and is concerned with the determinants of consciously intended behaviors [3][22]. It is composed of attitudinal, social influence, and intention variables to predict behavior. TRA hypothesizes that an individual's Behavioral Intention (BI) to perform a behavior is jointly determined by the individual's Attitude Toward performing the Behavior (ATB) and Subjective Norm (SN), which is the overall perception of what relevant others think the individual should or should not do.

#### 2.1.2 Theory of Planned Behavior

Despite the predictability of TRA being strong across studies, it becomes problematic if the behavior under study is not under full volitional control. To deal with these problems, Ajzen [1][2] extended TRA by including another construct called perceived behavioral control, which predicts both behavioral intention and behavior. The extended model is called the Theory of Planned Behavior (TPB).

## 2.2 Information Technology Acceptance

### 2.2.1 Technology Acceptance Model

The Technology Acceptance Model (TAM), introduced by Davis [20], is an adaptation of TRA specifically tailored for modeling user acceptance of information systems. TAM identifies a small number of fundamental variables suggested by previous research dealing with the cognitive and affective determinants of computer acceptance, and uses TRA as a theoretical backdrop for modeling the theoretical relationships among these variables. TAM posits that two particular behavioral beliefs, Perceived Usefulness (PU) and Perceived Ease Of Use (PEOU) are of primary relevance for computer acceptance behavior.

### 2.2.2 Extended Technology Acceptance Model

Venkatesh and Davis [48] added a number of determinants of PU to TAM to develop and test an extended TAM (TAM2). It is a theoretical extension of TAM, which explains PU and usage intention in terms of social influence processes (Subjective Norm, Voluntariness, and Image) and cognitive instrumental processes (Job Relevance, Output Quality, Result Demonstrability and PEOU).

### 2.3 Risk Perception

Risk perception is also a critical factor affecting the rate of adoption. Frambach [23][24] contended that the level of Perceived Risk (PRISK) is negatively related to

the speed of adoption. Ostlund [38] introduced risk as an additional measurement in IT adoption. A common and widely recognized obstacle to electronic commerce adoption has been the lack of security and privacy over the Internet [10][16][40].

### 2.4 Social Cognitive Theory - Self-Efficacy

Social Cognitive Theory (SCT) [6][7][8][9], also called Social Learning Theory (SLT), is a widely accepted model of individual behavior. A key element in SCT is the concept of self-efficacy (SE), which refers to an individual's belief in his or her own capability to perform a specific task. Estimations of SE are formed through a gradual and dynamic weighting, integration, and evaluation of complex cognitive, linguistic, social, and/or enactive experiences.

## 3. Methodology

### 3.1 The Research Framework

The attitude literature, including social psychology and technology acceptance, provides the theoretical framework needed to define the linkages between beliefs about adopting and using Internet Banking, while TAM2 provides the underlying structure for the theoretical model of the study. The proposed conceptual model of Internet Banking adoption for this study is shown in Figure 1.

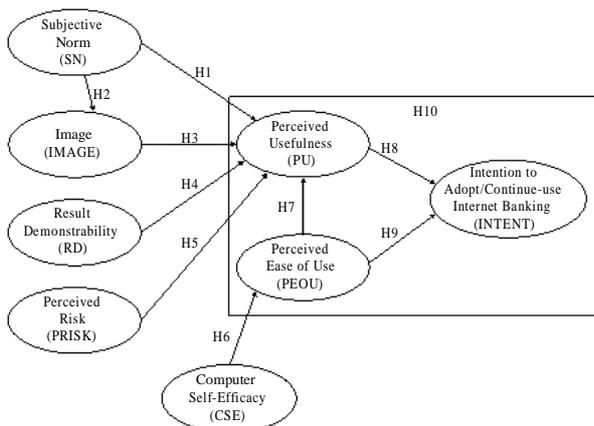

Figure 1 Proposed Internet Banking Adoption/Continue-use Model

The ten hypotheses required for the model test are shown in the first two columns of Table 1.

### 3.2 Questionnaire Design

Theoretical constructs were operationalized using validated items from prior research and the results of the elicitation study.

### 3.3 Respondents

The researcher limited the sampling frame to students under the age of 40 at the seven government-funded institutes of higher learning in Hong Kong. Eight hundred questionnaires were distributed with 634 responses (79.25% response rate). Of these, 183 were Internet Banking users and 451 were potential adopters of Internet Banking. After cases with missing data were eliminated,

the final sample consisted of 499 observations, of which 147 were users and 352 were potential adopters of Internet Banking. Males and females are approximately evenly distributed.

## 4. Data Analysis

The proposed research model was tested separately with the samples of users and potential adopters of Internet Banking via the structural path model. The partial aggregation approach was employed to reduce the level of random error. The results are as follows.

### 4.1 Users of Internet Banking

Analysis results indicate that INTENT was predicted by SN ( $\beta = 0.47, p < 0.01$ ) and PU ( $\beta = 0.53, p < 0.01$ ), which in turn was predicted by IMAGE ( $\beta = 0.11, p < 0.10$ ), RD ( $\beta = 0.40, p < 0.01$ ), and PEOU ( $\beta = 0.48, p < 0.01$ ). PEOU was predicted by CSE ( $\beta = 0.63, p < 0.01$ ). Image was predicted by both SN ( $\beta = 0.39, p < 0.01$ ) and RD ( $\beta = 0.40, p < 0.01$ ). The model explained substantial item variance: 34% of the variance in INTENT, 28% in PU, 60% in PEOU, and 52% in IMAGE.

### 4.2 Potential Adopters of Internet Banking

For potential adopters of Internet Banking, INTENT was predicted by IMAGE ( $\beta = 0.42, p < 0.01$ ), SN ( $\beta = 0.25, p < 0.01$ ), and PU ( $\beta = 0.15, p < 0.05$ ). PU was predicted by PEOU ( $\beta = 0.58, p < 0.01$ ), SN ( $\beta = 0.16, p < 0.01$ ), IMAGE ( $\beta = 0.10, p < 0.05$ ), and PR ( $\beta = -0.22, p < 0.01$ ). PEOU was predicted by CSE ( $\beta = 0.71, p < 0.01$ ). IMAGE was predicted by both SN ( $\beta = 0.19, p < 0.01$ ) and RD ( $\beta = 0.53, p < 0.01$ ). The above model also explained substantial item variance; 53% in INTENT, 34% in PU, 49% in PEOU, and 58% of variance in IMAGE.

Table 1 shows a summary of research results for both users and potential adopters of Internet Banking.

	Hypotheses	Users	Potential Adopters
H1	Subjective Norm will have a positive direct effect on Perceived Usefulness	Not Supported	Supported
H2	Subjective Norm will have a positive effect on Image	Supported	Supported
H3	Image will have a positive effect on Perceived Usefulness	Supported	Supported
H4	Result Demonstrability will have a positive effect on Perceived Usefulness	Supported	Not Supported
H5	Perceived Risk will have a negative effect on Perceived Usefulness	Not Supported	Supported
H6	Higher Computer Self-Efficacy will have a positive effect on Perceived Ease of Use	Supported	Supported
H7	Perceived Ease of Use will have a positive effect on Perceived Usefulness	Supported	Supported
H8	Perceived Usefulness will have a positive effect on Intention to Adopt/Continue-use	Supported	Supported
H9	Perceived Ease of Use will have a positive effect on Intention to Adopt/Continue-use	Not Supported	Not Supported
H10	Perceived Usefulness and Perceived Ease of Use will fully mediate the influence of selected variables on Intention to Adopt/Continue-use	Not Supported	Not Supported

Table 1 Summary of Research Results

## 5. Discussion

### 5.1 Intention to Adopt/Continue-use of Internet Banking

PU ( $\beta = 0.53$  for users and  $\beta = 0.15$  for potential adopters) is significantly positively related to INTENT, with 34% of variance of Intention to Continue-use and 53% of variance of Intention to Adopt, accounted for. This result is consistent with previous studies on TAM. It implies that if users/potential users perceive Internet Banking to be useful, they will be more likely to continue-use/adopt the innovation. Therefore, the result supports H8. The data also revealed that the effect of PU on intention was stronger for users than for potential users. On the other hand, PEOU is not significantly related to INTENT, contradicting expectations. Thus, H9 is not supported by the findings. This finding concurs with the original TAM but contradicts the results of many previous studies [33][37]. Furthermore, SN showed a significant positive relation to INTENT. This means that users feel more positive about using Internet Banking when the social environment encourages its use. This finding concurs with the extended Triandis Model by Cheung, Chang, and Lai [15], and the extension of TAM by Venkatesh and Davis [48]. However, the setting was different from studies by Venkatesh and Davis, in that the current context (Adopt/Continue-use of Internet Banking) is not mandatory. In addition, Image ( $\beta = 0.42$ ) was found to be the most significant factor affecting INTENT. Therefore, as the study has shown, IMAGE and SN were the main factors affecting INTENT for potential adopters.

### 5.2 Perceived Usefulness

Looking at the antecedents of PU, only IMAGE was significantly positively related to PU for both users and potential adopters of Internet Banking. The results support H3 that Image has a positive direct effect on Perceived Usefulness of Internet Banking. For potential users, SN and PRISK were respectively significantly positively and negatively related to PU, that is, both H1 and H5 are supported. However, H1 and H5 are not supported for users of Internet Banking. It could be argued that once users have adopted Internet Banking, their perceived usefulness is based mainly on their own personal evaluation of the technology, rather than SN. As for the different results of H5, PRISK ( $\beta = -0.22$ ) was significantly negatively related to PU for potential users. No significant relationship was found between PRISK and PU for users.

The finding of RD ( $\beta = 0.40$ ) implies that if Internet Banking produces effective/positive results desired by the users, they are more likely to understand how useful Internet Banking is. Therefore, H4 is supported for users. However, potential users may not be aware of these effective or positive results, or they may have no idea whether these results would be positive or negative. So, there is no support for H4 for potential users.

Furthermore, PEOU ( $\beta = 0.48$  for users and  $\beta = 0.58$  for potential adopters) was found to be the most significant

factor affecting PU, although it had no statistically significant influence on INTENT. The individuals' assessment of the usefulness of the innovation is influenced by the innovation's ease of use. All of which supports H7.

### 5.3 Perceived Ease of Use

CSE ( $\beta = 0.63$  for users and  $\beta = 0.71$  for potential adopters) was found to be a statistically significant factor of PEOU, and 49% and 60% of variance of PEOU was accounted for potential adopters and users respectively. The finding implies that individuals with higher CSE will perceive Internet Banking as easier to use. Therefore, H6 is supported. The data also reveal that the effect of CSE on PEOU was stronger for potential adopters than for users.

### 5.4 Image

H2 is supported. Both SN and RD were significantly positively related to IMAGE for both users and potential adopters of Internet Banking, and a large variance (52% for users and 58 % for potential adopters) in IMAGE was explained in the final model. The first part of the results conformed to prior studies of TAM2 [48], which theorize that SN positively influence image.

## 6. Conclusion

In this study, factors influencing the adoption/continue-use of Internet Banking are identified in the Hong Kong context. The results reveal that CSE plays an indirect, but significant role in influencing both intentions to adopt and continue-use of Internet Banking. Differences are found between the determinants of adopting and continuing to use Internet Banking. Risk perceptions of potential adopters hindered the adoption of Internet Banking. The majority of IS research in the belief/attitude tradition to date has focused on beliefs and attitudes related to usage of IT. Hence, our understanding of beliefs, attitudes, and norms leading to IT adoption and how these are modified over time is limited. Preliminary evidence from the current study suggests that perceptions of image enhancement induce initial adoption, while sustained usage decisions are based solely on beliefs of PU and SN. These results represent a first step toward a deeper understanding of the temporal evolution of beliefs, attitudes, norms, and behavior across different phases of the adoption process. Moreover, the degree of the mediating effect of PU is very high in continue-use intention, whereas it is not strong when explaining the adoption intention. PEOU is found to be an important antecedent of PU; however, its mediating effects on both adoption and continue-use intentions are not significant.

## Abstract

Through a qualitative research procedure, this paper intends to explore useful accounting classification relating to electronic resource and service expenditures necessarily disclosed in a library annual report. As a result, based on line item structure emerged in this paper, an appropriate direction to develop library-specific Generally Accepted Accounting Principle for reporting electronic resource and service expenditures can be evolved in the future.

## 1. Introduction

Over the past five years, the number of electronic resources has substantially increased and that tendency becomes a paramount importance to library collection management. The negligible marginal costs of reproduction for electronic resources and the rapid development of information and communication technology have created new pricing strategies for information goods vendors through bundling, site licensing, subscriptions, rentals, differential pricing, per-use fees, and other various mechanisms. The complex pricing schemes have raised several issues to existing financial reporting: assets vs. expense, cost allocation of materials bundling, value reporting of electronics resources purchased via consortia, and accounting classifications. Among university libraries in Taiwan, accounting terminology and practices on electronic resources may vary widely from school to school. Ministry of Education (MOE) has conducted a survey for library materials budgeting for two decades. Nevertheless there still have such issues that both MOE and libraries need to find solutions.

In that sense this study addresses the following research questions: 1) how much expenditure that university libraries spend on electronic resources and services including electronic serials, monographs, audiovisual clips, bibliographic utilities and research database access respectively? 2) what is the current trend of using electronic resources and services in university libraries? 3) in terms of cost budgeting, how much expenditure is that for each individual library

spending on electronic resources and services while compared with other group member libraries? 4) after research database site license expired, in financial report, is it reasonable to claim on-line access fee as operating expenditure instead of capital expenditure and to classify those full text electronic journals (published during the term) as library assets and count them as serials holdings upon paying access fee for next year usage? 5) because of different pricing scheme for electronic resources and services, how do libraries count and allocate joint expenditures for the print-based and electronic-based subscriptions? 6) in order to seek for optimum cost-efficient purchasing solution, how do libraries disclose expenditure information and value holdings in the financial report under the structure of consortia? 7) in order not to under-value the holdings of e-version serials, how do libraries define and classify such serials for preparing financial statement?

Based on aforesaid research questions, from a financial and managerial perspective, this study intends to develop concepts of consistency and uniformity of financial reporting for electronic resource and service expenditures with a focus on simplicity, accuracy and flexibility as well as to construct a framework of accepted accounting principle for identifying accounting classification of electronic resource and service expenditures in university library. Thus this paper looks at the holistic view of electronic resource financial reporting model as opposed to the traditional approach of the library collection management.

In that proposition, a qualitative research procedure will be conducted. This study utilizes the in-depth interviews [6] to explore the phenomenon of financial reporting conflicts and discuss whether existing financial report is applicable to present electronic resource and service expenditures. In order to reflect realities of participants involved in the research environment, field notes analysis [14] and interview transcripts [16] will be also employed to guide the study and uncover critical issues from observations of interaction among participants whilst there have financial reporting conflicts within the library structure. As a result, through dialectic review with findings, this study will seek to

relevance and further contribute to its theory that constructs directions for new formats of financial statements for the desires of various audiences.

## 2. Starting with Essential Concepts

This paper expects to illustrate some concepts about some basic accounting terms, “what is financial report”, “who will need it”, “what is the relationship of financial reporting to library annual report” and “How does a library define its activities and materials involved”. Hence, this paper may apply such illustrations to library management and to have an effective communication both internally and externally.

### 2.1 Glossary of Some Basic Accounting Terms

In order to provide librarians’ concepts of basic accounting terms, some terminologies are described below.

**Accrual Basis Accounting.** In accrual accounting, income is recorded when it is earned rather than when the payment is received. With the use of that concept, expense is recorded when the item is purchased rather than the bill is paid.

**Balance Sheet.** It is a summary of an organization’s financial condition at a specific time point, including assets, liabilities and equity.

**Budget.** It is a process focusing on an itemized statement and forecast of an organization’s income and expenses expected for a period in the future.

**Capital Expenditures.** It is a category for long-term expenditures of depreciated items, such as equipment or furniture.

**Cash Basis Accounting.** In cash basis accounting, revenue is recorded when collected and expense is recorded when paid regardless of when the process was completed or the item purchased

**General Accepted Accounting Principles (GAAP).** GAAP are guidelines for preparing financial statements such as the balance sheet and the income statement external to the organizations. Such guidelines govern the recognition of revenue and the determination of whether a cost should be charged to expense or capitalized.

**Income Statement.** It is a report of sales, expenses and net profits for a given period of time.

**Operating Expenses.** It is a category for costs that are budgeted and expanded on an annual basis, such as salaries, subscriptions and continuations.

### 2.2 The Objectives of Financial Report and Its Users

Financial report is defined as a tool of financial reporting covering methods and accounting principles developed within a business framework. It is important to report to users inside or outside a business framework about the financial events of that business and in relation to communication of accounting information appropriate to users’ interests. As such, various types of users can determine the different objectives of a financial report. In the private sector, for example, either existing or potential equity investors need a financial report to whether invest in a business. The lenders, another example, need to ensure their exposure to a minimum risk through financial reports of the borrowers. In the public sector, an example is where the government needs a financial report for the purpose of taxation and economic decision-making. Specifically, the fundamental objective of a financial report is to communicate economic measurements of information about resources and performance of a business [1]. However, it is noted that different users, with different purposes, may require different information about the same items [9]. Thus, to have effective communication with users, such information further revealed in a financial report is often determined by the characteristics of usefulness underlined such as relevance, reliability, completeness, objectivity, timeliness and comparability [2].

Following the concept of effective communication, the effectiveness of a financial report is concerned with its users. In that sense, in addition to comply with the characteristics of usefulness, it requires a financial report different degree of complexity and depth for different users since not all the information required is likely to be included. An example is where based on users’ ability of understanding accounting information; a financial report must be geared to the knowledge of users.

### 2.3 Financial Reporting and Library Annual Report

In practice, there has no independent library-specific financial report but annual report for libraries services, particularly for library materials, in Taiwan. Conventionally, based on different report audiences, there have three objectives for an annual report. First, it shows MOE competitive information about the status of materials and services for funding. Second, it is used as a benchmark for MOE while evaluating University library performance. Third, it is a tool for University Board of Directors and University financial controller overseeing library administration and communicating with other library directors.

However, with the continuously strained financial situation of libraries and the advent of information technology that intensifies such budget restrictions, the information of an annual report needs to be extended to,

at either a internal or external level, provide them more accurate electronic information costs for effective communication and efficient decision making in a justifiable and comprehensive manner. Accordingly, from a financial accounting perspective, with the basic features of financial reporting in mind, whether an organizational context is profits-oriented or non profits-oriented, the standard format or principle (GAAP) of financial reporting can be applied to library annual report for the purpose of effective communication.

Given that purpose, as previously highlighted, various users determine types of accounting information disclosed in a financial report. Hence, in terms of non profits-oriented, considering the uniqueness of a library and objectives aforementioned, cost containment becomes very important if a library needs to remain viable. In that sense, activity-based cost accounting [15] is the most useful tool for analyzing the cost structures of a library [3] since library services can be illustrated by many activities, particularly for those focusing on electronic resources and services. Thus, with the use of such an accounting technique and following the concept of GAAP, information can be more accurate and comparable. In consequence, internally, cost performance and higher-level administrators like library directors, department heads and other supervisors can be fairly evaluated. Externally, an easy and better communication with relevant parties such as MOE and cross-campus library directors can be achieved.

#### 2.4 The Definition of Library Activities

Obviously, to determine types of information disclosed in an annual report by using financial reporting, activities like library services and materials associated need defined. In general, in terms of practical connected sequences of work processes, library services may include enquiry, interlibrary loan, information dissemination (circulation and acquisition) and document provision. Each of those activities may consist of many sub-activities. An example is where electronic documents delivery may consist of several processes such as the original document access, the document scanning, the delivery procedure initiation, account process and order delivery system administration. In that sense, to reflect library activities, an annual report shows the status of FTE (student and faculty), collection and circulation statistics with FTE, usage and reserve, loan transaction and inventory of collection.

Fundamentally, library materials associated with services are generally divided into books, periodicals, audiovisuals, CD, microforms, vertical file, etc. In particular, for those electronic resources, based on ARL (Association of Research Libraries) definition, they are deemed as electronic indexes and reference tools, electronic full-text periodical collections and electronic journal back-files and on-line searches of remote

databases where are whether assessed remotely or installed locally from CD-ROM, magnetic tapes and magnetic disks. In contrast to electronic resources, electronic services are deemed as materials purchased jointly with other institutions if such expenditure can be separated from other charges for joint services, bibliographic utilities if the portion paid for computer files and search services can be counted, and equipments that are inseparably bundled their costs into the price of the digital products.

Given that electronic resource and service being identified, expenditures can be deemed as costs spending on such products in bibliographic utilities, networks and consortia. However, such costs do not include expenditures for those not related to end-user database access and library system software only used by library staff. Specifically, expenditures can be divided into four major categories which are computer files, electronic serials and books, bibliographic utilities / networks / consortia, and computer hardware / software.

### 3. Background

The digital and network technology have provided an excellent channel for distribution and transaction of electronic resources. Over the past five years, the number and importance of electronic resources has increased. ARL Statistics 1999-2000 reveals that ARL university libraries reported spending almost \$100 million on electronic resources, an increase of \$23 million from the previous year. Currently most of university libraries have owned more titles of electronic serial than those of print-on-paper serial. How much are university libraries spending for electronic serials, monographs, audiovisual clips, and bibliographic utilities respectively? What are the trends of electronic resources in university libraries? How does an individual library's expenditure for electronic resources compare with other libraries? It sounds very simple, but in reality these questions are quite complicated. Such questions are to be expected as university libraries move into the digital era. However, acceptable and accurate answers still remain elusive. University libraries have suffered from the information disclosure on disbursement of electronic resources and services. That is because they had not found a reconcilable way and the general agreement of reporting those library materials.

Financial reporting shows the results of the budget and account operations. In that sense the above stated three questions are all integral parts of the one problem for financial management. The library materials and operating budgets are primary financial statements for university libraries, which are used by its intended audience to evaluate and ensure the best use of resources. The records in library materials and operating budgets maintained by the accounting procedure provide a

financial picture of historical collections and activities and are used to modify and clarify the budgetary plan for future collection development and operation. Holleman [10] argued that collection development was turning into collection management. University libraries have been positioning themselves with their library material budgets in regard to the access vs. ownership debate. The disbursement of electronic resource and service has become the one of major categories in the materials budget report. Of ARL member libraries, the average percentage of library materials budget devoted to electronic resources and services has increased from 3.6% in 1992-1993 to 13.5% in 1999-2000. Electronic resources and services are characterized by large fixed costs of production and near-zero marginal cost. The negligible marginal costs of reproduction for electronic resources make many types of bundling more attractive. Information goods were previously aggregated to save on transaction or distribution costs, but new aggregations of information goods will come out to extract more consumer surplus and create new profit opportunities. Because different libraries may have drastically different values and their willingness to pay for a particular electronic resource, values-based pricing and differential pricing schemes make more feasible and popular than cost-based pricing. As noted by Chuang and Sibru [5] and Ching, Shih and Chang-Chien [4], the Internet has created new pricing strategies for information goods vendors through bundling, site licensing, subscriptions, rentals, differential pricing, per-use fees, and various other mechanisms. Knight and Hillson [11] interviewed number of publishers, vendors, and agents and identified 16 pricing models. These complex pricing models in the electronic resources have raised several issues to existing financial reporting.

### 3.1 Asset or Expense

In Taiwan, many database vendors charge libraries fixed fee or unit pricing for the usage of electronic resources and services. Since the uncertainty associated with usage-related expenditures, conventionally, some libraries classify such costs as operating expenses instead of capital expenditures while recorded in the report. And upon the license expired or terminated, they would not continuously count operating expenses recorded electronic resources and services as library assets and / or holdings like volumes, serials and numbers of databases. Nevertheless, that accounting method is only acceptable to library materials, which are primarily tangible and obviously providing contributions to the library assets and holdings.

In contrast to tangibility, however recently some vendors, Wiley InterScience, for example, define their licensed electronic journals as online editions of their journals. In that sense, the Licensee has the access to such journals including retrospective and current electronic contents. After the license expired or

terminated, vendors would provide the License with access to the full text of the Licensed Electronic Journals published during the Term of this license by continuing online access to the same materials on vendors' server. In consequence, there raises several questions such as "is it still reasonable to claim such expenditures as operating expenses" and "can libraries report such electronic journals as library assets and / or serials holdings after the termination of the License?"

### 3.2 Cost allocation of materials bundling

Many electronic subscriptions such as SDOS, Academic IDEAL, and EBSCO Online include the print publication. Electronic resources may be main and joint products of publishing production process in the digital era, and the print publications may be byproduct. In that sense products can change from byproducts to joint products while their relative sales values increase sizably or change from joint products to byproducts as their relative sales values decrease sizably. There have three kinds of pricing schemes for electronic resources: print subscription plus add-on surcharge for the e-version, the electronic subscription plus add-on surcharge for the print or free (charged for the print only). In practice, the invoices issued by vendors don't need split off such two subscriptions. How do we count and allocate the joint cost for the print and the electronic subscriptions? In the case of free charge for electronic resources, would we only count and report the print subscription because that is what we purchased?

### 3.3 Value reporting of electronics resources purchased via consortia

As vendors have aggregated large collections of full-text journals, electronic resources are sometimes quite expensive, and easily drain out a large chunk of the library acquisition budget. As Poon [13] noted that by cooperating with other libraries, resources can be pooled together and shared, so that the "whole is greater than the sum of its parts". Under the limited budgets constraints, libraries consider that it would be in their best interest to form consortia to leverage their collective purchasing power. As a group, they have worked deals for huge databases and purchased them via consortia agreements. Would libraries count only the electronic titles for which they don't have the print subscription? In the case of consortia agreements, individual library could get access to all electronic subscriptions even if it doesn't have a print subscription for a specific title. How would member libraries of the consortia report the value of their holdings with the most cost-efficient purchasing solution?

### 3.4 Accounting classifications

As the information and communication technology enabled vendors to aggregate and disaggregate information goods, university libraries are not sure how to classify them properly and are struggling with the traditional uniform blanks for a variety of electronic

resources. In Taiwan, MOE conducts the library materials budget survey annually. To count electronic resources and services, MOE has constructed a new classification "Databases" which consists of two subset categories: "Bibliography" and "Full-text Journal". In an accounting context, this development is reflected in transformations of library materials such as intangibles, hybrid, and immaterial assets. To classify something also implies defining it. In fact, "intangibles" have no generally accepted meaning. Electronic full-text journal keeps the nature of serial. As university libraries shift the serial subscriptions from the print to the e-version, the holdings of serials in the financial statements will underreport due to classify them as database. When libraries employed a wide variety of funding and budgeting strategies to purchase electronic resources, it is very difficult for university libraries to find adequate definitions to classify data and disclosure financial information in a standard and comprehensive way. In the existing MOE's library materials budget survey, there is no accounting classification for monograph or serial received and not purchased.

With these issues illustrated, this paper actually focuses on how to alleviate such problems and report electronic resource and service expenditures by adding the framework of financial reporting within a library annual report.

## 4. Methodology

Ontologically, in qualitative paradigm, the realities of things be investigated are mentally constructed and multi-subjective [7]. Following the assumption of epistemology [8], this study will report these realities relying on languages (voices) and interpretations of informants involved. Furthermore, through continuous interactions, this study will seek different perspectives of informants [6] and will observe the realities by acting as an insider that has subjective, interpersonal and value-laden view [12]. Thus, methodologically, a qualitative approach that emphasizes authenticity, relevance and contextual applicability is used.

Six library director (three public and three private schools) and their financial controllers are selected to be the informants in this paper. Structured interview and fieldnotes analysis is conducted. In order to verify trustworthiness, peer review and cross checking with CPAs external to the university libraries are also utilized.

## 5. Discussion and Suggestions

Each of informants demonstrates an overall subjective response to issues, reflecting environmental and contextual factors that eventually determine the reality informants have. Accordingly, findings and discussion will be followed with suggestions.

### 5.1 Findings and Discussions

In examining issues mentioned about reporting electronic resource and service expenditures, the following findings are discussed.

#### 5.1.1 Lack of GAAP for Categorizing Library Electronic Resource and Service Expenditures.

The finding shows that there have two accounting principles for public and private schools respectively in Taiwan, when preparing annual reports for the various purpose of budgeting funding and performance evaluation. However, that leads to an inconsistency for reporting electronic materials among university libraries since categories are not unified and not generally accepted. In consequence, the lack of GAAP, which primarily emphasizes guiding university libraries when stating electronic materials either in quantity or dollar spent within their annual reports, is noted. Hence, through the finding, it is observed that the clear definition of electronic materials category is central to responding to set out its accounting classification following GAAP in the future.

#### 5.1.2 Unclear Category Basis for Accounting Classification.

Traditionally, categories often reflect materials by type (Seer 2000). An example is where this line item structure in which categories may include books, supplementation, periodicals, looseleaves and CD-ROMs, etc. The finding shows that existing electronic materials categories for two groups of public and private schools are not meaningful enough to reflect electronic resource and service expenditures since increasingly library materials become a hybrid nature as stated previously, such as the combination of books and CD-ROMs and the combination of print and Web publication. In addition to that, an argument of "intangibles" such as digital right and "consortia purchase" such as collective resource sharing is raised. Hence, again, it is noted that clear definition of electronic materials category is essential.

### 5.2 Suggestions

As a result of findings, in fact, to alleviate issues of reporting electronic resource and service expenditures in a library annual report, as a financial reporting way, in Taiwan, the baseline work will be focusing on constructing an appropriate line item structure for the purpose of accounting classification so as to establish GAAP appropriate to library services when preparing annual report.

#### 5.2.1 Reinforcing Line Item Structure.

Line item structure typically includes several broad categories, which are further divided into many sub-categories to fit the needs of the organizations. In reviewing existing two electronic material categories model required by MOE and Department of Higher

Education, in addition to the distinction in the definition of electronic materials categories, it obviously does not reflect the hybrid nature and the complex pricing of current electronic resource and service. In that sense, for example, for Department of Higher Education, the current line item structure of categories of CD-ROM, Web-based and Database for electronic materials is not broad enough and well established, not to mention MOE merely using Database to describe all electronic resource and service. Therefore, that leads to resources allocation distorted when making budget and / or evaluating performance.

Hence, this paper suggests that the line item structure for library materials should be more specific and divided into several layers in terms of material type, media type and source of such materials as shown in Table One (Appendix). From Table One, in general, the first layer is divided into two main categories of text and audiovisuals where include books / periodicals (serials) and CD / LCD / VCD / Web based respectively. Based on the first layer, the second layer will focus on the specific categories by type of media delivered, such as printed, CD-ROM, Web-based or microform, etc. When entering the third layer, library materials can be divided into different sub-categories based on the source of that material. For example, in each category from the second layer, it can be divided into subscription, exchange (loan) or collective shared from consortium.

### 5.2.2 Following GAAP.

To obtain the effectiveness of an annual report, upon accounting classification properly clarified, this paper suggests that an annual report matches GAAP for accounting practices, such as when reporting bundling (combination) expense, depreciation and intangibles. Normally, all categories and sub accounts tend to remain the same for the convenience of comparisons year to year. However, in order to reflect rapid changes in publishing industry and / or vendor ownership, in particular for electronic resource and service, adding new categories or eliminating existing ones are suggested to meet such changes. Nevertheless, it always bears in mind that no matter to what extent those changes may be; all categories adjustments must be in compliance with GAAP to ensure clear and comparable results.

### 5.2.3 Forming a Committee on Accounting Procedure .

Since the rapid changing nature of electronic resources no matter in format or delivery, another suggestion would be to erect an appropriate organization where can periodically review accounting practices and procedures so as to establish generally accepted practices for reporting library materials.

## 6. Concluding Remarks

In seeking to the effectiveness of a library annual

report showing electronic resource and service expenditure, an appropriate direction for accounting classification while preparing library annual report is paramount importance. In examining issues highlighted, it is noted that the baseline work to alleviate such issues would be relying on clarifying the accounting classification for electronic resource and service categories. In contrast to traditional category model, the new concept would focus on multi-layer structure wherein may have specific categories represented by type of materials, media for delivery and source of information. The structure also considers “intangibles” such as digital right incurred by the electronic resource transactions as well as the situation of complex pricing scheme under various combination of electronic resource purchased.

Based on that, it is concluded that an emerged framework of line item structure for library materials can be utilized as a guideline to set out a justified GAAP for non-for-profits organizations like library services. However, since the rapid changes of the information technology, a formal organization of committee on accounting procedure should be in place to accommodate accounting practices and support librarians' concern over the formulation and acceptance of Generally Accepted Accounting Principles. As a result, the effectiveness of a library annual report can be achieved to benefit library management where is in pursuit of continuous sufficient funding, high quality of service and better communication with all relevant parties internally and externally.

Note: The paper is based on the findings made by Koh, Lin, Nguyen, and Soegiarto during the Nanyang Business School (NBS) Business Study Mission (BSM) to Seoul, Korea, in June 2001. NBS is part of Nanyang Technological University in Singapore, and one of the leading business schools in the Asia-Pacific region. The four persons were MBA students at NBS at that time. The BSM dissertation they have written under the supervision of A/P Park incorporates their BSM findings.

## Abstract

Korea has recently experienced explosive growth in online stock trading, to the extent that the country is now one of the global leaders in this area. In this paper, we examine the implications of this phenomenon on the competitive environment facing retail brokerage firms in Korea as well as their potential strategic responses. Online trading entails low entry barriers and more demanding customers, and thus creates intense competitive pressures. Only those brokers that adapt their business models flexibly and quickly to the new environment, in particular by relying more on customized, fee-based services and less on trading commissions, will make the grade. Although our study is focused on Korea, most of its lessons, particularly those relating to strategic responses for brokers, are applicable to other markets as well.

## 1. Introduction

Figures 1 and 2 below summarize the growth of online stock trading in Korea, which has now become a global leader in this area. The speed and magnitude of the growth can be best described as extraordinary.

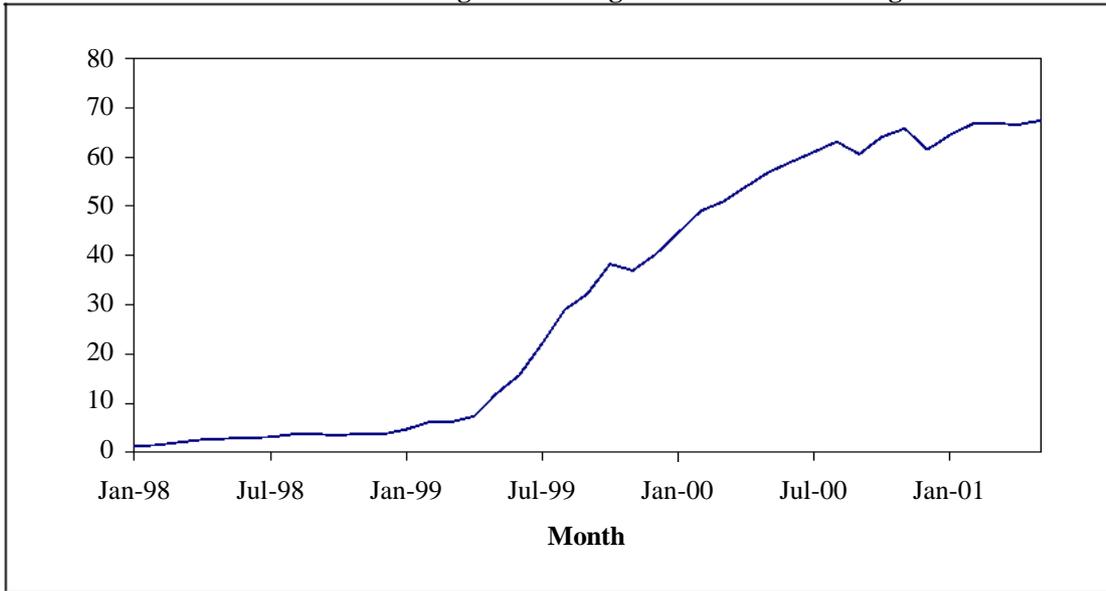

It was not until April 1997 that the Korean government amended the *Securities and Exchange Act* to allow trade orders by telephone, telegram, fax, computers or other electronic communications devices in addition to traditional document-based orders, thus making online securities trading possible. In January of 1998, only 1.3% of total trades were conducted electronically. By May 2001, the figure had soared to 67.4%, the highest in the world, with online trading

value surging 280-fold from 0.5 trillion won to 141 trillion won (Korean Industry Update, 2001).

As the interest of Koreans in online trading intensify, the number of online trading accounts continues to explode. In January 1998, there were only about 78,340 online securities accounts, but by May 2001, South Korea had some 4.17 million online securities accounts, a growth of 53 times. These accounts already accounted for 48.2% of all active securities trading accounts. Meanwhile, the monthly average online securities trading per account in 2000 was 30.94 million won, with the monthly average order number per account being 12.8 (Korea Securities Dealers Association, 2001b). In fact, a recent survey revealed that 92% of Korean retail investors preferred online trading to using traditional brokerages (*Asiaweek*, 2001).

With an online trading penetration rate in excess of 67%, Korea is the undisputed leader of Internet stock trading in the whole world. Its online trading percentage is higher than even the United States, which an online penetration rate of around 40% (Yiu, 2000). This is quite remarkable in light of the fact that the United States has a significantly longer history of discount brokerage services than Korea. Among the 13 members of ICOSA, an international securities industry association, Korea has the highest online trading percentage, surpassing second-place Canada's 40% and third-place France's 28%. Korea is also substantially ahead of high-income East Asian economies such as Japan, Taiwan, Singapore and Taiwan (Yiu, 2001).

Korea Securities Dealers Association (2001a)

The main part of our paper deals with the implications of this online trading boom on the retail brokerage industry in Korea. Since the Buttonwood Tree exchange that took place in New York in 1790s, the brokerage industry has undergone numerous evolutionary changes, many of them attributable to the emergence of new technologies. With the advent of Internet technologies and the subsequent Internet trading in the last few years,

a brand new industry has emerged, the Online Brokerage.

In the second section, we attempt to analyze the changing value proposition of the brokerage industry and predict what the future holds. In the third section, we examine the changing competitive environment of the industry using Porter's Five Forces model. In the fourth section, we look at how existing online brokerage

can ensure long-term sustainability in the face of tumultuous change. The fifth section concludes.

## **2. Changes in the Value Proposition of the Brokerage Industry**

At its simplest, the securities industry is composed of exchanges, clearing houses, brokerages consisting of brokers and financial advisors, sellers/borrowers, and buyers/investors. Brokerages engage in the purchase, sale, and intermediation of securities. Securities firms serve four major functions in the financial market. First, they serve as financial intermediaries, matching individual/institutional investors with individual/institutional sellers, and corporate/governmental borrowers. Second, they provide a means of pricing and valuing investments by making timely information about investments available to the marketplace. Third, securities firms furnish a vehicle for the liquidation of investors' assets, as brokers and dealers trade securities for investors efficiently. Finally, they provide investment advice and customer-tailored financial instruments.

Many securities firms serve as both brokers and dealers, with the former trading on behalf of clients and the latter trading on its own account to make a profit. Most broker-dealer firms have headquarters to handle administration, and branch offices to sell and market company services, and assist clients. The type and extent of services offered beyond brokerage and dealing activities determine what category the security firm falls under, namely full-service or discount brokerage. Full-service firms provide a range of services for both retail and institutional customers (see Figure 3 below), while discount brokers usually act as the primary access channel for retail customers to reach the stock market (see Figure 4 below).

With the advent of the Internet, the brokerage industry has shifted to a new paradigm, electronic brokerage services (henceforth e-brokerage.) E-brokerage adds a new factor to the value-proposition of off-line traditional brokerages, regardless of whether they are full-service or discount: the Internet medium (see Figure 5 below).

This medium can help the dependent investors do their own research, and get informed about new initial public offerings (IPOs). It could also provide asset management tools. All in all, the Internet makes transaction more apparent with its speed and availability. In this environment, the investors' expectation from the

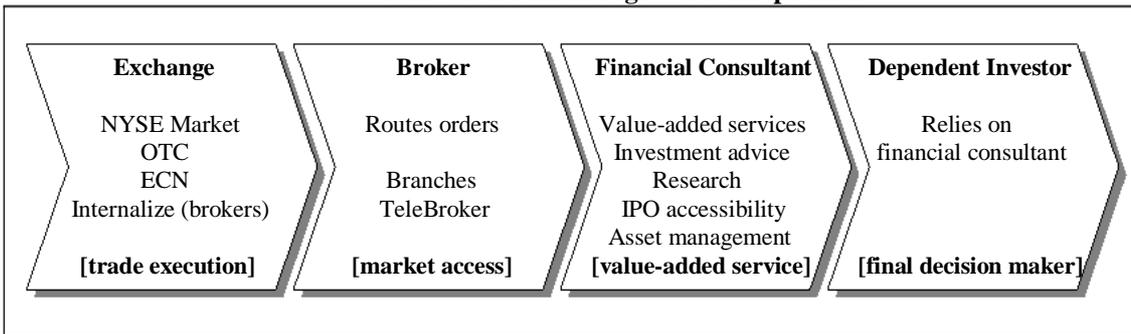

e-brokerages are more demanding than ever before. The most common belief is that e-brokerages must provide hassle-free automated transaction execution along with other products at a reduced price. Those products and services should be available 24 hours a day, seven days a week. Moreover, with the high automation capability of the medium, the services must be customised to match the tastes and styles of each investor. These could include easy and low-cost access to research reports, resource links, tools and analysis, charts and news, customizable portfolio views, and checking and banking services.

While offering new value propositions for the investors, both e-brokerage and traditional brokerage house can also benefit from the Internet. First of all, the Internet has become a new channel to acquire new customers and sell products and services. The Internet is an ideal medium to help brokerage firms to expose themselves to potential buyers globally and achieve efficient dissemination of product and service information. It expands the opportunity to participate in the customer acquisition processes and improve target customer identification. It facilitates new sales and delivery directly to consumers without time and place constraints. Online stock purchasing is a good example of a new channel that reduces transaction costs both for the seller and the buyer. The Internet also creates new products and services, such as the ability to transfer funds from bank accounts.

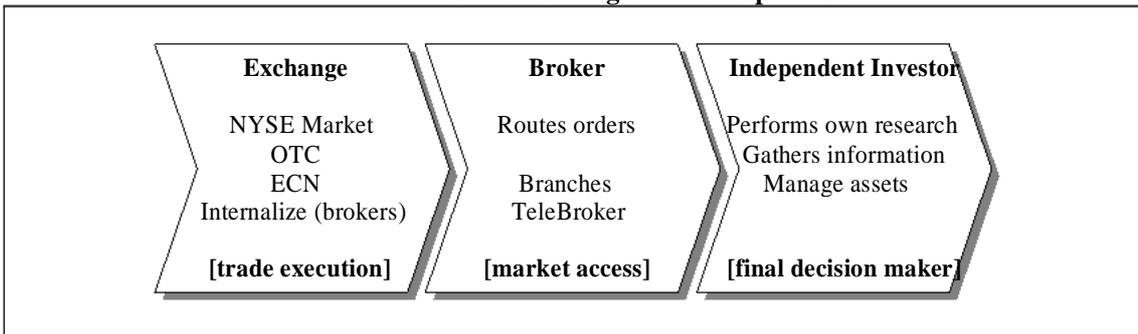

The Internet could help increase customer satisfaction as well. Because it is capable of mass customisation, the Internet allows custom marketing and personalized products, which translates into greater customer satisfaction and more transactions. Customized service requires an enriched understanding of the ways in which products are used, usage rates, and precise performance metrics, which is now possible via the Internet. Automation web sites can expand and improve customer support 24 hours a day, seven days a week.

Finally, the Internet is providing brokerages cost savings in overhead, labour, transactions, and customer services. It reduces the costs of providing customer support services by providing a cheaper communications medium (cheaper than telephone support) and lowers transaction cost by eliminating store fronts and improving business processes. Opportunities to streamline payment/receivables processes become a reality, thanks to the rapid development of online transaction technologies.

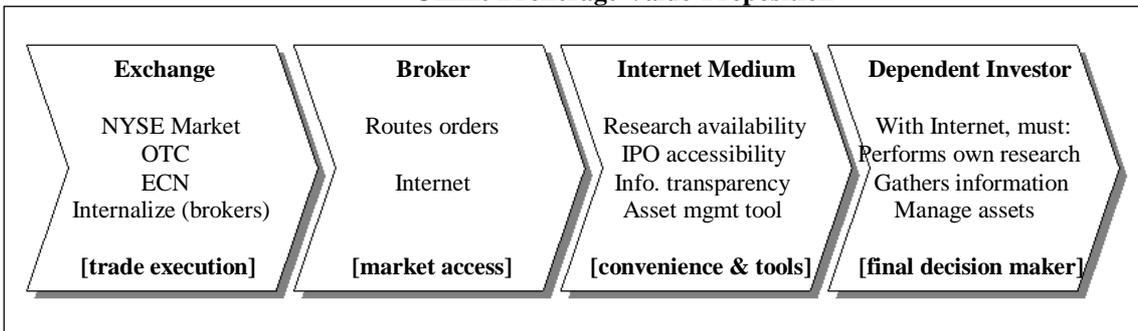

**Figure 3  
Full-Service Brokerage Value-Proposition**

**Figure 4  
Discount Brokerage Value-Proposition**

**Figure 5  
Online Brokerage Value-Proposition**

In conclusion, brokerage firms are positioned to capture a larger share of the customer's wallet. One thing appears certain: in general, e-brokerage will continue to grow in popularity (Yoo, 2001).

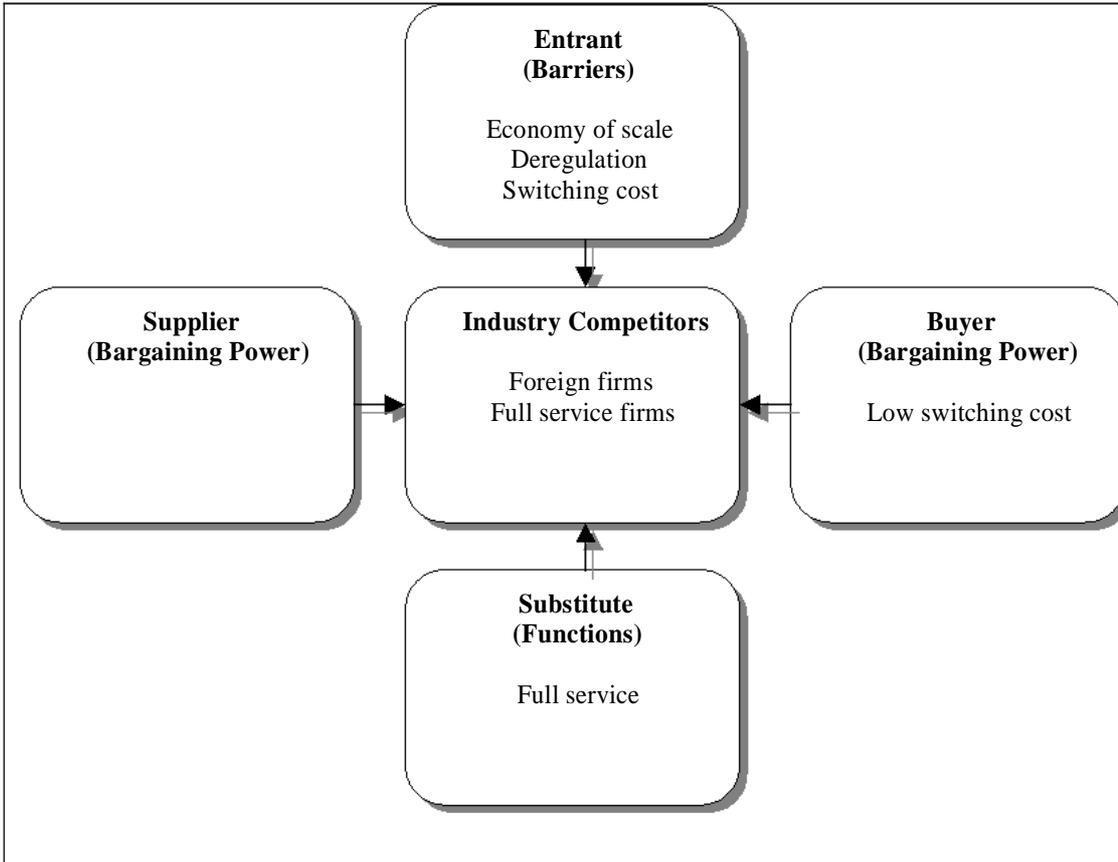

### **3. Changes in the Competitive Environment of the Brokerage Industry in Korea**

Despite the advantages of an online business model, the e-brokerages are facing many new challenges. We will analyze the changing competitive landscape using Porter's Five Forces Model (see Figure 6 below).

#### **3.1 Low Barriers to Entry Lead to More Competition**

The most important difference between e-brokers and traditional brokers is that e-brokers lack of a physical presence (including the branch office and financial consultants) and the associated costs of development such as building cost, overhead, and employee wages. The second key difference is the brokers' strategic approach. While established companies have attempted to retain an established customer base, electronic brokers must follow a customer acquisition strategy. This means they must differentiate themselves, whether through low costs or value added services (Dong, 2001).

**Figure 6**  
**Korea Retail Online Brokerage Industry Analysis**

Beyond the physical and strategic differences, e-brokers resemble discount brokers in several ways. They offer discounted prices and pass control of portfolio management to the investor and collect revenue from trade commissions, interest income, and service fees.

Competition is even more intense in the aftermath of the financial reforms that took hold after the economic crisis. The commission fee is now subject to fierce price wars between competitors. Deregulation also opens the market to global competition, allowing the participation of the foreign brokerage houses in the local market, making things even tougher for local players.

### **3.2 Customers' Greater Bargaining Power**

Brokerage service firms must be aware of the modern consumer who has exposure to the Internet and technology. He or she has greater challenge of balancing personal and professional priorities and has less time and energy to select brokerage service providers. The Internet provides access to a much wider potential client base than a physical brick and mortar structure, but also makes it much easier for consumers to compare different service providers. Consumers have both less time to devote to selection of brokerage service provider and much greater control over the

selling process. This can make the cost of attracting and retaining customers become more significant as stiff competition forces e-brokers to offer more innovative and better products and services to win business (Lim, 2001).

### **3.3 More Intense Rivalry**

E-brokers have delivered revolutionary products to the market with online trading. However, with more new participants coming to the market, it is extremely difficult for any player to differentiate itself from others through distinctive products. Moreover e-brokers are also facing increasing composition from the existing traditional full-service players, who can offer more comprehensive services for dependent investors. The inevitable maturing of the consumer market for online trading will thus force e-brokers to shift gears and move into non-trading investment business or try to appeal to a wider market.

### **3.4 Other Considerations**

The fierce competition in the market has led to a situation in which most online brokerage houses depend on fee-per-trade for their revenue. Thus, this business

model is fundamentally in conflict with customers' best interest. The incentives to provide investors with stable long-term blue-chip securities are weak when revenues increase with the frequency of transactions. Because of this, some vendors are unbundling their products and services, such as research and access to IPOs. The day traders are the exception. However, they are attracting more regulatory scrutiny, which could have negative spillover effects for mainstream brokers. In addition to those challenges, traditional brokers, who decide to jump on the e-brokerage bandwagon, face substantial channel conflict with their network of dealers and brokers.

In conclusion, there are two main implications of online trading for the brokerage industry: severe competition and pricing pressure in certain segments. This is likely to continue, as the online brokerage space becomes more crowded with new entrants and traditional brokerage firms moving online and into new segments of the market. However, growth in the number of online trades should provide volume growth. Furthermore, it is possible that some market segments may experience price increases. We foresee a divergence of business models catering to either the asset management model or the high-volume trading model (or, in some cases, both). As competition continues to heat up and more emphasis is placed on assets, not trading volume, other value-added services will become an important component of e-brokerage. Consequently, only companies who actively change their business models to adapt to the changing environment will do well (Kang K.T., 2001).

#### **4. Strategies for Long-term Success for Online Retail Brokerage in Korea**

One thing we can be certain is that the advancement of technology is going to continuously transform the brokerage. The future is going to be very different from the present. In the words of Hamel and Prahalad, failure to anticipate and participate in the opportunities of the future will impoverish the firms. In an emerging industry with no precedents, anticipating the future is an enormously complex task. To compete more effectively for the future, it is necessary to build the best possible assumption base about the future and thereby develop the prescience needed to proactively shape industry evolution. Industry foresight will give a company the potential to get to the future first and control its evolution and thereby control its own destiny (Hamel & Prahalad, 2001). In particular, the online brokerage should ask itself three essential questions. First, what new types of customer benefit should the company provides in five, ten or fifteen years? Second, what new competencies should the company build or acquire to offer the benefits to the customer? Lastly, how should it reconfigure the interface with the customer?

Realizing that the future is very different from the present, the management should be made aware that it

takes "thinking of the box" to plot the future direction. Invoking economist Joseph A. Schumpeter's notion of capitalism's "creative destruction", the management should not cling to the past but always look for ways to improve on its existing business model. It is therefore crucial that there is a management in place that understands both the trend of new emerging technologies and how the needs of customers will evolve in the future.

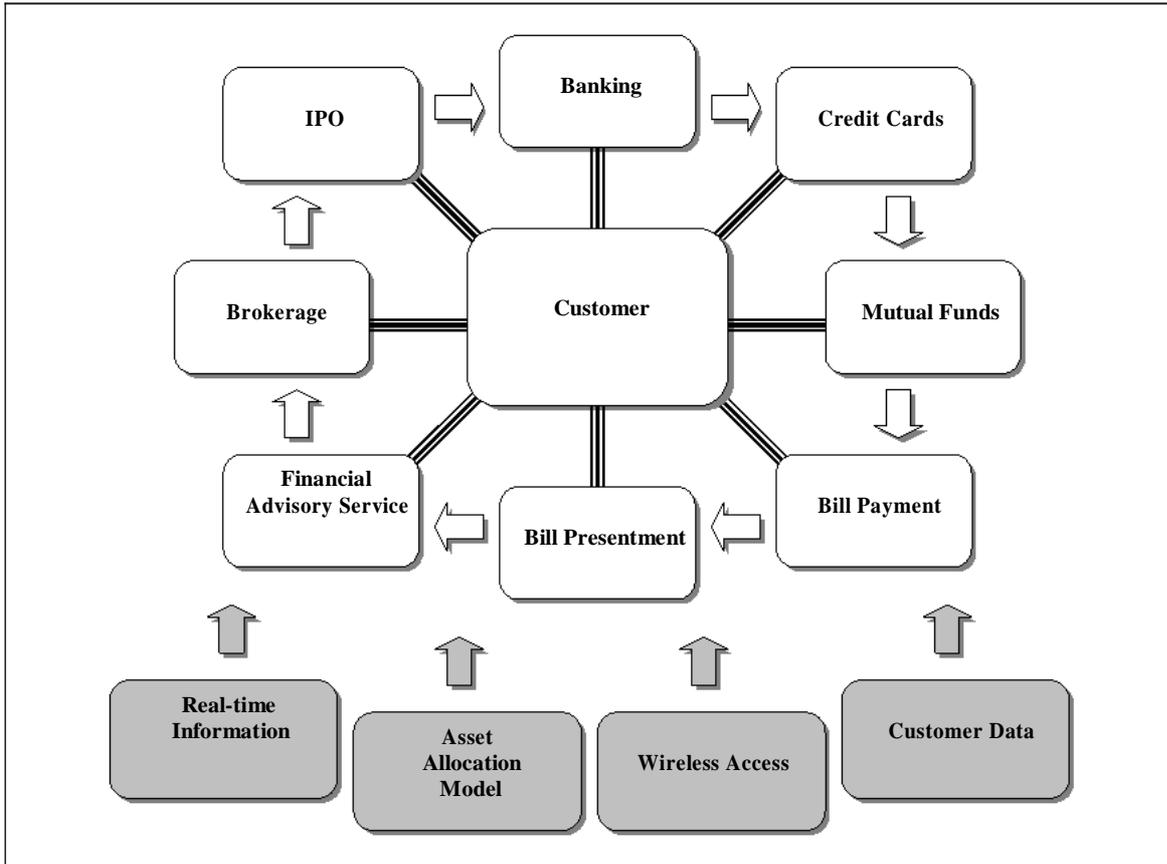

Online trading in Korea is expected to continue its growth as securities firms continue to engage in aggressive marketing, reduce commissions fees and develop advanced communication technologies. The number of new entrants coupled with the increasing use of online trading by institutional investors will also contribute to the growth of online trading. FSC anticipates that with the current razor thin commission, there will be probably a watershed of the securities business community. Many smaller and unprofitable brokers will be forced to close down. FSC has since moved to remove regulatory obstacles that limit the incentives of securities firm to go beyond merely satisfying regulatory requirements. This means shifting of their knowledge and resources from mere brokerage services and securities investment activities toward sophisticated corporate finance and investment banking activities (Jin, 2001).

Through value chain analysis, we predict that customers of the future will most likely demand the best of both worlds, that is low commissions and rich financial advisory services in a reliable and convenient transaction platform. Acknowledging that the customer is at the core of all strategies, we have developed the hub and spoke model to explore how online brokerage can excel in the long term (see Figure 7 below).

##### **4.1 Execution and Advice**

With the lowering of entry barriers and lifting of foreign participation in the brokering industry as a result of financial liberalisation, the commission rate has been facing strong downward pressure. Examples from the US market also point to the inevitable entry of the full service firms, local and foreign, to embrace the digital opportunities (*Business Week*, 2001). Online brokerage firms have to recognise that they have to offer more than low price execution to interact more meaningfully with customers. Most customers of online brokerage prefer it to the traditional broker due to lower transaction cost. However, transaction-related revenues are very volatile. To illustrate this point, the total online stock trading amount in March 2001 was down 47.1% as compared to March 2000 (Korea Securities Dealers Association, 2001b). Therefore it is critical for firms to move away from excessive reliance on brokerage transaction and more towards more stable income sources such as service fees, account fees and interest income.

**Figure 7**  
**Hub and Spoke Model with Customer as the Core**

One effective way to increase revenues from a customer is to take advantage of the entire customer-wealth cycle. E-brokers can broaden their services by improving on their financial advisory services. As a customer moves into different stages of his wealth life cycle, his investment outlook will change accordingly. The crash of the dot.com and many other technology related stocks in the last year has made many investor realise that while submitting a trade may be quick, easy and simple, the process of making sound appropriate investment decisions has not become any quicker, easier or simpler. Charles Schwab, the top U.S. discount broker, understood this principle and has moved to take advantage of the customer wealth cycle early by adding investment advisory offerings via its acquisition of U.S. Trust & Co., an old-line private client bank, and CyberCorp, a technology and day trading firm (Coffin, 2001). With this move Charles Schwab sought to cater to the needs of customers in various stages of their wealth life cycles, and continue to earn their devotion and loyalty. In fact, hybrid firms such as Schwab that provide a wider range of services at a reasonable price will experience faster growth than the no frills online discount broker or full service broker.

#### **4.2 Rise of the Assets Play**

Another important benefit of exploiting the customer's wealth life cycle is asset accumulation. Although assets may come and go in good and bad markets, assets make for a more sustainable and less volatile franchise (Meyer, 2001). As the online brokerage moves into maturity, the performance metrics is no longer the number of customer accounts. Instead it becomes the total asset volume under management. In fact, Charles Schwab had US\$219 billion in assets and collected US\$180 million of mutual fund service fees in the second quarter of 1999 alone (Junnarkar, 2001). One effective way for Korean brokerage houses to accumulate assets is to expand beyond their brokering services to include services such as bill presentment and payment, credit cards, mutual funds and access to initial public offerings (IPOs). Becoming the single source supplier for all banking and investment related products and services will enhance the stickiness of the web sites, expand customer base and increase financial leverage.

#### **4.3 Partnerships and Alliances**

We have earlier illustrated through the hub and spoke model the concept of developing products and services with the customer at the core centre. However,

few firms will have the financial strength and intellectual bandwidth to create high quality financial content across the spectrum. Instead, the brokering house should act as an aggregator and presenter of market information and products rather than a creator of content. Content – such as mutual funds, asset allocation models, and IPO access – will be created by niche players with specific expertise in those areas. A smart brokerage firm will pull the content from a variety of sources, aggregate, package and sell it at the lowest cost and highest quality. Forming strategic partnership and alliances with well-known and trusted online players can expedite the account aggregation and also lend credibility to the brokerage house.

#### **4.4 Harnessing Technology**

One advantage of the Internet is the tracking abilities that it offers. Korean brokerages should recognise that they have an enormous database on their hand – data obtained from their customers' trading behaviour and activities, such as the types of web site visits. Through advanced data mining tools, financial companies can tailor complex offerings to their customers. Companies that utilise customer data effectively can develop a customer relationship that increases loyalty and cross-selling capability.

The emergence of broadband wireless applications has opened up many new possibilities of interface between customer and the financial companies. Applications such as wireless application protocol has enabled an investor to access the latest financial information through gadgets such as mobile phones, and personal organisers 24 hours, seven days a week. Financial companies should be aware of the latest development in communication technologies and learn to exploit those technologies to their advantage.

#### **4.5 Building Brand Name**

In the U.S. context, E\*Trade has become the second largest online broker in terms of number of average daily trades, third in the number of accounts and fourth in client assets in a short span of four years. E\*Trade strategy has focused on customer acquisition and building a strong brand through aggressive advertising campaign. Its marketing budget of US\$ 300 million in 2000 is even bigger than that of Schwab, which is 11 times bigger. Similarly, other online players have also spent substantial amount on advertising. A big part of this battle is to compete for brand awareness and market share, which most believe will lead to marketplace dominance. All the online trading players aim to be the power brand that is recognized to represent the entire category of online broking. Likewise, Korean online brokers should also invest heavily in marketing to build a strong brand name to capitalize on the growth of the equity culture in Korea after the economic crisis.

But having said that, the Korean online brokerage should not make the same mistake as their counterparts

in the U.S. One of the major complaints against the U.S. online brokers is the frequent disruption of service, which contradicts their advertising message of fast and reliable system. In 1996, AOL launched an aggressive advertising campaign yet only added a modest number of modems to service these new online accounts. As a result, an overwhelming number of new subscribers were unable to access to AOL and this created a huge public backlash against the company (Spitzer, 2001). Korean online brokerage players should make sure that they have sufficient system capacity to serve their customers before embarking on any big advertising campaign.

#### **4.6 Summary of Strategies for Online Securities Firms**

We have thus suggested that an online broker should provide its customers with services based on their needs. As customer needs change through his wealth life cycle, the financial company will replace one offering shown in the hub and spoke model with another shaped by new efficiencies and demand. Technological innovations permit the financial intermediaries to reach out into the market place and provide these services at a lower price than building the offering themselves. Strategic alliances and partnership also allow the companies to be nimble and react fast to customer changing needs and demands at a lower cost and more efficiently than competitors. In the long term, such efficiencies and cost reduction will translate into a sustainable competitive advantage for the company (Kang K.T., 2001).

#### **5. Concluding Remarks**

The emergence of Internet technology and the many innovative applications that are built on its foundation has rewritten many existing business rules and assumptions. In particular, the brokerage industry has undergone a major shake up in the last decade. The introduction of online brokerage has redefined the rules of the game and that has put many traditional brokerages scrambling for solutions or facing extinction. Such heightened competitive pressures are very much in Korea, which has experienced explosive growth of online stock trading and is now a world leader in this area.

The focus of our paper has been the impact of Korea's online trading boom on the competitive environment facing brokerage firms and their potential strategic responses. Since it entails a combination of low entry barriers for new e-brokers and customers who have more information and are therefore more demanding, online trading creates intense competitive pressures. Only companies who actively change their business models to adapt to the changing environment will make the grade. More specifically, the most viable business models probably involve focusing more on financial advice and other customized, fee-based services and away from high-volume trading. Brokers should

provide such services throughout the customer's wealth life cycle, which entails different needs at different times.

With the proliferation of Internet, online trading will eventually spread to all stock markets, the only difference being the timing and magnitude of penetration. Our paper will be useful to anyone who wishes to have a better understanding of online trading. In particular, we hope our section on long-term strategies for online brokerage will provide valuable suggestions to online brokers in other markets since they will face the same kind of intense competitive environment associated with the advent of online trading in Korea.

## Abstract

Constant Proportion Portfolio Insurance (CPPI) is the most popular portfolio insurance strategy using hedging strategy to protect principal while a wave upward or downward trend in the market is noted. Nevertheless, since the original CPPI was proposed, its performance has been limited to relevant parameters of strategy. And since there is no clear, definite and systematic rule of decision has get been proposed, it also has unstable performance and worse upside capture, especially for the multiplier ( $M_t$ ) in model parameters, it has far great influence to end-of-period return. If  $M_t$  can be decided with its initial value setting and dynamic tuning via certain appropriate approach, under a decent mechanism of market timing selection, the strategy can therefore acquire excess return of min-max operation due to sharp improvement of upside capture, and also can provide hedging function within the insured volume when the market declines. This paper presents a systematic method using the value-at-risk control method to dynamically adjust the CPPI strategy parameter  $M_t$ , called asset allocation insurance strategy value-at-risk based asset allocation insurance strategy model (VALIS). We proof that the proposed model is a dynamic asset allocation insurance strategy, which is conservative but also aggressive; and shows that it is in compliance with the characteristics of idea portfolio insurance strategy, and is feasible and effective. From an empirical study of the Pan-Pacific market, we found that in any type of market or trend it is clearly better than the major benchmark indices, and it outperform other traditional portfolio insurance strategy.

## 1. Introduction

In general, portfolio insurance strategies can be categorized into two types: the first type is the portfolio insurance strategies which do not involve underlying options including Buy and Hold, B&H [1], Constant Mix, CM, Constant-Proportion Portfolios Insurance, CPPI [2], Time-Invariant Portfolio Protection, TIPP, [3] etc. The second type is the Option-Based Portfolio Insurance (OBPI) which is derived from the basis of option pricing

formulas, such as PBPI (Participation-based Portfolio Insurance), CBPI (Capped-Based Portfolio Insurance), Covered Put, Synthetic Put and Dynamic Hedging, etc. In the aforementioned portfolio insurance strategies, based on the considerations to avoid the misallocation effect, mispricing effect, insurance performance uncertainty effect [4], inadequate substitution of financial instruments and sour liquidity, etc., which are derived from over dependence on complicated option evaluation models [5], basis risk and risk of missing pricing of derivatives, interest rate and transaction cost modified bias [6], variance estimation error, etc., though the constant superior strategy is not concluded yet, the proportion protection insurance strategy, which is relatively simple and easy to operate and maintain, has become the rebalance strategy which is preferred by the majority of conservative fund managers and asset allocation management institutions [7].

The constant proportion protection insurance strategy features the effects of buy-low and sell-high. If there is sign of the trend and when there is judgment on whether there is rise or fall in the market, it outperforms other similar insurance strategies. However, since the constant proportion protection insurance strategy mode was proposed, its performance has been limited the parameters of model which lack precise and systematic determinant rules, thereby leading to instability and poor upside capture. Especially, the parameter in model of strategies, Multiplier,  $M_t$ , affect the entire accumulated profit of the rebalance strategy of enormously. If  $M_t$  can be applied via suitable method to determine its initial value and dynamic tuning, then because of the large enhancement of upward catching rate, it will enable that strategy to obtain excess return of Min-Max operation. At the same time it also possesses risk prevention function provided under insured amount when the market drops.

Thus, the original constant proportion protection insurance strategy assumes that  $M_t$  is a constant value. For works of later related scholars, practical market operators and research reports etc, mostly they based on experience to conduct rough estimate so as to establish the

parameter setting of strategy model. Till now there is still not one (General) setting or adjustment method [8]. As the portfolio insurance strategy must possess both capital insurance and profit making property, therefore the consideration of this property is to bring in estimation on the maximum loss of a certain future period to assets allocation strategy. Then by means of Value-at-Risk control model dynamic tuning  $M$ , and by proving that the proposed dynamic tuning strategy model possesses also excess return obtained from active operation as well as essentials of insurance for avoidance of downside risk insurance.

This research combines risk metric method and historical data simulation method as the Value-at-Risk estimating model. In empirical research, the result proves the robustness and validity of the proposed strategy model. The conclusions of results also show proof and discussion that supports this paper and the same time it is discovered that it also possess considerably high real world market operation feasibility.

This paper is organized as follows: in the first section, we describe the research background and motives of this research, and present a complete paper review; in the second section, we first introduce the Value-at-Risk control model, which is quoted in the paper, as the deductive theory basis of the proposed model and as the basic concept of the empirical study; from the third section, we start to conduct the deduction and verification of the proposed Value-at-Risk assets allocation insurance model, and also begin to introduce the Value-at-Risk concept into the portfolio insurance model; We then apply the deduced model in the fourth section and conduct market empirical study and analysis; finally, in the fifth section, we present the conclusions and discussions of this research; in the final part, we present our views in the future developments and visions, offering an arena to be further developed and discussed by subsequent researchers. In the following we begin by explaining the Value-at-Risk estimation method adopted by this research.

## 2. The Adoption of the Value-at-Risk Measurement and Evaluation Methods

### 2.1 The Value-at-Risk Measurement

In 1730, Abraham de-Moivre first proved: "Within a preset error range, the observation values of a random sampling are presented in a bell-shape curve, with the right and left wings being symmetrical and the values averagely being distributed in the both sides of the mean. It is so called the Normal Distribution." And de-Moivre further established the concept of standard deviation. The two concepts are now generally referred to the Law of Average, which has placed a significant foundation for the development of the modern quantitative risk.

The Value-at-Risk is the methodology proposed by modern statistics, and has been widely applied as a tool to measure risk of late. Its main concepts are also originated from the Law of Average. Its definition is stated as follows:

The approaches adopted by the study are briefly illustrated as follows:

### 2.2 Parametric Form (Analytic Variance-Covariance)

Currently the most frequently used by the industries and the most well known solution is the Risk Metrics developed by JP Morgan. The assumption premise is the portfolio return is a normal probability distribution, and its relation with the change of risk factors is linear. Thus, the Value-at-Risk of the portfolio can be obtained by calculating the standard deviation and the association degree of the risk factors. Consequently, with only two presumed simple linear portfolios, which are in accordance with the aforementioned such as negotiable securities, spot and forward exchanges and notes etc., a crisp value can be generated through the said method. Its advantages are: (1) there is no need of any pricing model; (2) market data can be accessed at any time. And its disadvantages include the difficulty to conduct a sensitivity analysis etc.

Assuming the assets in a portfolio features a normal distribution return, the combination of the normal distribution variables can be defined by

$$aX + bY \quad (1)$$

Where,  $a, b$  are the Mark to Market, MTM, of the assets  $X, Y$ ; and  $X, Y$  are the securities which feature a normal distribution return, hence the standard deviation of the combination can be defined by

$$\sigma_p = \sqrt{a^2\sigma_x^2 + b^2\sigma_y^2 + 2ab\rho_{xy}\sigma_x\sigma_y} \quad (2)$$

## 3. The Theory Modeling and Verification of Dynamic Asset Allocation Strategy

In this section, we first introduce the Value-at-Risk theorem into the insurance strategy, and then verify whether the strategy formed by the established model is in compliance with the two properties of an ideal investing portfolio insurance strategy proposed by Rubinstein.

### 3.1 The introduction process of VALIS risk model

Let  $M$  be multiplier. In time  $t$ , the insurance premium  $F$  can be demonstrated as

$$F = F_0 e^{rt} \quad (3)$$

where  $r$  represents the risk free rate or treasure bond (or notes);  $F_0$  is the initial insurance premium. If we calculate the payoff in time  $t$ , then

$$W(t) = F + [W(t) - F_0] \left(\frac{S}{S_0}\right)^{M_v(t)} e^{(1-M_v(t))(r+0.5M_v(t)\sigma^2(t))} \quad (4)$$

Where,  $W(t)$  is the wealth in time  $t$ ;  $W$  is the initial wealth;  $S$  is the stock price in time  $t$ ;  $S_0$  is the initial stock price level. Then the exposure,  $V(t)$ , of risky assets can be demonstrated as

$$V_s(t) = M_v(t)[W(t) - F(t)] \quad (5)$$

Considering the situation where no leverage is available, then Equ. (5) can be demonstrated as Equ. (6)

$$V_s(t) = \text{Min}\{W(t), M_v(t)[W(t) - F]\} \quad (6)$$

Considering the market risk [9], if  $\Delta P(\Delta t)$  is the asset position price volatility volume during time length  $\Delta t$ , then if we demonstrate the Cumulative Distribution Function, CDF, of  $\Delta P(\Delta t)$  as  $F_{\Delta P}(x)$ , thus in the Probability,  $P$ , the Value-at-Risk of Long Position during  $\Delta t$  can be shown as the following equation:

$$P(t) = \mathbb{P}[\Delta P \leq t \mid \text{VaR}(t)] = F_{\Delta P}(\text{VaR}(t)) \quad (7)$$

The VaR of Equ. (7) in this research is based on the RiskMetrics™ method developed by J.P. Morgan [10][11]. Assuming the continuously compounded daily return of the assets portfolio possessed follows the conditional normal distribution, if daily log return is denoted as  $r(t)$  and the information set acquired in time  $t-1$  as  $\phi(t-1)$ , under the hypothesis that there is no drift phenomenon in random walk, then  $r(t) \mid \phi(t-1)$  can be demonstrated as Equ. (8)

$$r(t) \mid \phi(t-1) \sim N(\mu(t), \sigma^2(t)) \quad (8)$$

Where,  $\mu(t)$  is conditional mean, and  $\sigma^2(t)$  is conditional variance of  $r(t)$ .  $\mu(t)$  and  $\sigma^2(t)$  can be described using a simple model as shown in Equ. (9).

$$\mu(t) = \alpha_0 + \alpha_1 r(t-1), \sigma^2(t) = \alpha_2 + \alpha_3 r^2(t-1), 1 > \alpha > 0 \quad (9)$$

Where the implied daily spot price  $P(t)$  is log value, i.e.  $\ln(P(t))$ , which satisfies IGARCH(1,1) (Integrated Generalized Autoregressive Conditional Heteroscedastic) (Engle, 1982; Bellerose, 1986, 1992, 1994; Nelson, 1991; Tsay, 1987) Process different

equation  $P(t) - P(t-1) = a(t) + \sigma(t)\varepsilon(t)$ , where  $\{\varepsilon(t)\}$  is iid (independent and identically distributed) random variable series; and  $a_0 > 0$ , mean is equal to one and variance is equal to one. From the property of IGARCH model,  $h$  period log return from time  $t$  to time  $t+h$  can be denoted as

$$r_h(t) = r(t+h) + r(t+h-1) + \dots + r(t+1) \quad (10)$$

Thus, from Equ. (10), we know that  $r_h(t) \mid \phi(t)$  in Equ. (9) is a normal distribution, and its mean is equal to be 0. As for  $\sigma_h^2(t)$  under the assumption that  $\varepsilon_t$  is independent, we can acquire as shown in Equ. (11)

$$\sigma_h^2(t) = \text{Var}[r_h(t) \mid \phi(t)] = \sum_{i=1}^h \text{Var}[r(t+i) \mid \phi(t)] \quad (11)$$

Where  $\text{Var}[r(t+i) \mid \phi(t)] = E[\sigma^2(t+i) \mid \phi(t)]$  solved recursively.

Applying  $r(t-1) = a(t-1) + \sigma(t-1)\varepsilon(t-1)$ , Equ. (9) can be rewritten as below:

$$\sigma^2(t) = \sigma^2(t-1) + (1-\alpha)\sigma^2(t-1)(\varepsilon^2(t-1) - 1), \text{ for } \forall t \quad (12)$$

Since  $E[\varepsilon^2(t+i) - 1 \mid \phi(t)] = 0$ , for  $i \geq 1$ , this Equ. (12) can be formulated as

$$E[\sigma^2(t+i) \mid \phi(t)] = E[\sigma^2(t+i-1) \mid \phi(t)], \text{ for } i \geq 2 \quad (13)$$

Then from Equ. (18), we can estimate  $\sigma^2(t+1)$  of next period in Equ. (14), and  $\text{Var}[r(t+i) \mid \phi(t)] = \sigma^2(t+1)$ , for  $i \geq 1$  we can conclude as below

$$\sigma_h^2(t) = h\sigma^2(t+1) \quad (14)$$

Referring to Equ. (8), we can infer as below

$$r_h(t) \mid \phi(t) \sim N(0, h\sigma^2(t+1)) \quad (15)$$

Thus, the log return conditional standard deviation of  $h$  period can be denoted as

$$h^{1/2}\sigma(t+1) \quad (16)$$

Thus, in Long Position, if the probability is set to be 5%, then we can acquire that  $\lambda_1 = 1.65$ , where  $l = 0.05$ . If we want to estimate the Value-at-Risk after  $h$  period,  $\text{VaR}_h$  we can denote  $\text{VaR}_h$  whose mean equal to 0 and standard deviation is  $\sigma(t+1)$  as

$$\text{VaR}_h(t+1) = \lambda_1 h^{1/2} \sigma(t+1) A, \quad A: \text{long position} \quad (17)$$

If we hold more than k types of asset positions and the return is likely to feature cross-correlation, then we estimate the overall  $\text{VaR}_h(t+1)$  as Equ. (18)

$$\text{VaR}_h(t+1) = \left[ \sum_{i=1}^k \text{VaR}_i^2(t) + 2 \sum_{i<j}^k \rho_{ij} \text{VaR}_i(t) \text{VaR}_j(t) \right]^{1/2} \quad (18)$$

Where,  $\rho_{ij}$  is the correlation coefficient among assets; i, j represent different assets.

If we consider there is a drift phenomenon in random walk, then Equ. (17)  $\mu_h(t)$  must be modified as

$$\left| \mu_h(t) - \lambda_1 h^{1/2} \sigma(t-1) \right| \quad (19)$$

Equ. (18) should be modified as well following Equ. (18).

Thus from Equ. (5), in time t, holding risky assets,  $V_s(t)$  and risk free assets,  $V_b(t)$ , and set  $W(t) = V_s(t) + V_b(t)$ , then we can acquire

$$\begin{aligned} V_s(t) &= \text{Min}[M_v(t-1) * (V_s(t-1) + V_b(t-1) - F)] \\ V_b(t) &= W(t) - V_s(t) \end{aligned} \quad (20)$$

With the introduction of Value-at-Risk into Equ. (17) or Equ. (19), we can formulate the Value-at-Risk dynamic asset allocation strategy model as shown in Equ. (21)

$$V_s(t) = M_v(t)(W(t) - F) \quad (21)$$

$$\begin{aligned} M_v(t) &= [W(t) - \text{VaR}(t)] / [(V_s(t) + V_b(t)) - F] \\ &= [W(t) - \lambda_1 h^{1/2} \sigma(t) W(t)] / [W(t) - F] \\ &= W(t) [1 - \lambda_1 h^{1/2} \sigma(t)] / [W(t) - F] \end{aligned} \quad (22)$$

With the same reason we can prove that risk consideration can be introduced into Equ. (18) and we can formulate as per Equ. (22)

$$\begin{aligned} M_{v,d}(t) &= W(t) \left[ 1 - \left( \sum_{i=1}^k \text{VaR}_i^2(t) + 2 \sum_{i<j}^k \rho_{ij} \text{VaR}_i \text{VaR}_j(t) \right)^{1/2} \right] \\ &= W(t) \left[ 1 - \left( \sum_{i=1}^k \lambda_i h^{1/2} \sigma_i(t) A \right)^2 + 2 \sum_{i<j}^k \lambda_i \lambda_j h^{1/2} \sigma_i(t) \sigma_j(t) - \lambda_1 h^{1/2} \sigma_j(t) \right]^{1/2} \end{aligned} \quad (23)$$

Readers can also refer to Theorem 1, Chebyshev's Theorem, to decide  $\lambda_1$  according to confidence interval.

Of course, the empirical rule or so-called 68-95-99 rules can also be a rough estimation method.

[Theorem 1] Proportion (or fraction) of any data gathered together and fell on the mean plus or minus x proportions (or fraction) within the standard deviation

shall have at least  $(1-1/x^2)$ , where x is any positive number larger than one.

### 3.2 Verification of Rubinstein's Idea Portfolio Insurance Properties of VALIS

According to Rubinstein (1985) points out that idea portfolio insurance should feature two properties. We hereby verify VALIS proposed by this research as follows:

Property 1:

Under idea portfolio insurance, the probability of suffering loss from bottom breaking is equal to zero.

Proof:

From Equ. (20), we introduce Equ. (23) into it and it becomes

$$V_s(t) = \text{Min}[M_v(t-1) * (V_s(t-1) + V_b(t-1) - F), FM_v(t)(M_v(t) - F - \lambda_1 h^{1/2} \sigma(t))^{1/2}] \quad (24)$$

Thus, from Equ. (24), investing risky assets in the worst case is equal to the security position of an underlying portfolio plus an insurance policy that is guaranteed not to suffer loss, that complies the property 1. It is hereby proved. (Q.E.D.)

Property 2:

The return of the said position totally depends on the end value of the underlying portfolio, and is irrelative with the spot price before expiration of the underlying portfolio.

Proof:

From Equ. (23), we can acquire

$$\begin{aligned} M_v(t)(W(t) - F) &= W(t) [1 - \lambda_1 h^{1/2} \sigma(t)] \\ W(t) [M_v(t) - F - \lambda_1 h^{1/2} \sigma(t)] &= FM_v(t) \\ W(t) &= FM_v(t) / [M_v(t) - F - \lambda_1 h^{1/2} \sigma(t)] \end{aligned} \quad (25)$$

From Equ. (25), it is proved that in the proposed strategy model, the holding return is irrelative with the spot price before expiration of assets allocation portfolio. (Q.E.D.)

3.3 The property is comparatively traditional that by means of options-basis insurance strategies it possesses Floor- Breaking moderation effect and occurrence probability

The operation of static portfolio insurance and dynamic portfolio insurance strategy mainly arises from the Black-Scholes model. Nevertheless, in the Black-Scholes model, one of the important assumptions is the relative price of risky assets, such as stocks.  $\ln(R/P-1)$

must demonstrate the lognormal distribution model and no serial independence under lognormal distribution model, and spot price variation behaviors are continuous, i.e. minimal volatility. Thus, there should also be huge jump spot price variation behaviors. So, the investing portfolio insurance strategy which is options-basis can be effective; on the contrary, if spot price often moves up and down sharply or even comes to a crash, then the function of investing portfolio insurance strategy model will drop down more or even the effect will be lost, Floor-breaking. As shown in the below equation, the insured portfolio, DPI, under dynamic insurance strategy, is composed by the risky assets,  $S$ , and the loan fund,  $P$ .

$$\begin{aligned}
 \text{DPI} &= S + P \\
 &= S[-N(-d_1)]S + N(-d_2)Ee^{-rT} \\
 &= [1 - N(-d_1)]S + N(-d_2)Ee^{-rT} \quad (26) \\
 &= W_1S + W_2Ee^{-rT}
 \end{aligned}$$

Where,  $d_1 = [\ln(S/E) + (r + 0.5\sigma^2)T] / \sigma T^{1/2}$ ;  $d_2 = d_1 - \sigma T^{1/2}$ ;  $\sigma^2$ : variance of strike assets price;  $T$ : Put Option contract expiration Annualized length;  $r$ : continuous compound rate, risk-free Rate;  $E$ : exercise price;  $N(-d_1)$ : under accumulated standard normal distribution, the probability from  $-\infty$  to  $-d_1$ ;  $N(-d_2)$ : under accumulated standard normal distribution, the probability from  $-\infty$  to  $-d_2$ .

$W_1$  and  $W_2$  are the weights, percentage of the risky assets,  $S$ , and the loan fund,  $P$ , respectively, and have to be adjusted at any time following the variation of the portfolio value and time. When the downward adjustment variation of  $S$  is closing to zero,  $S \rightarrow 0$ , then  $d_1 \rightarrow -\infty, d_2 \rightarrow -\infty$ . Thus,  $N(d_1) = N(-\infty) = 0, N(-d_2) = N(\infty) = 1, W_1 = 0, W_2 = 1$ . Therefore, from Equ. (26), when  $S \rightarrow 0, T > 0$ , Floor is  $Ee^{-rT}$ ; when  $T = 0, \text{DPI} \geq E$ . When there is any major variation to  $S$ , then DPI will not be able to adjust  $S$  position to  $P$  in time and thus face the danger that insurance premium breaks bottom in the beginning of the period.

However, in the VALIS model proposed in this research, because for the future portfolio value, the risk has been introduced into the insurance model by means of estimating Value-at-Risk. Thus, facing volatile circumstances, the model will be able to provide the protection and enhancement of insurance function against huge variations, and such enhance arises from the risk consideration of portfolio value adjustment to lower the short-term urgent demand on liquidity. For example, on Oct. 19, 1987, the United States stock market indexes dropped sharply, and the traditional portfolio insurance strategies all failed. The main reason is inadequate consideration of portfolio value risk that caused the

inability to buy in or sell out, thereby failing to protect the invested principal.

#### 4. Empirical Research and Analysis

The empirical research is composed by two parts. The first part is to conduct test on simulated normal status return data. The second part is to operate based on Taiwan weighted index as the asset portfolio insurance underlying content.

##### 4.1 Simulated Random Normal Return

Firstly, test is conducted based on the simulated return data generated by random method under normal distribution. Total observed return data is 112 sets ((Rand(.)-0.5)\*0.5). The descriptive statistical excerpt of return is as Table 1:

Table 1 Statistical excerpt description of return data

	Mean	Standard Deviation (S.D.)	Kurtosis	Skewness	Mean Confidence Interval (95%)
Random return	0.00348387	0.12930241	0.03186368	0.03186368	0.02421063
	6		2	2	5

Set wealth as 100, insurance premium is 80, insurance tool including stocks,  $W_1$  and risk free assets, fixed income securities, or bond,  $W_2$ , initial weights are set as  $W_1=0.6, W_2=0.4, \lambda_1 = 0.65, h = 3$ , rebalance frequency is adjusted daily, data frequency is simulated random daily return data, insurance period is the entire return observations data. Observe the multiplier,  $M_t$ , If insurance period based on experience value is set as  $M_v = 2$  and  $M_v = 3$  respectively, and  $M_t$  turning rule of the proposed VALIS in this research, then it can be clearly seen that  $M_t$  turning rule of VALIS is superior than fixed multiplier rules set in CPPI. In this case study, in respect of its performance in its insurance period, its rebalance strategy is shown in Figure 1

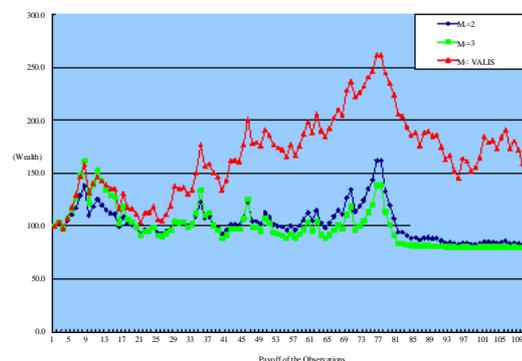

Fig. 1 Comparison of performance of  $M_t(t)$  tuning rule of VALIS and fixed multiplier rebalance strategy during the insurance period

In Figure 1, it is not difficult to discover that the  $M_i(t)$  turning rule of VALIS actually went through the estimate on the future Value-at-Risk. In respect of upside, the upside capture can be enhanced and furthermore the insurance performance can be greatly enhanced and that is the main source of excess return. In respect of downside, position can be adjusted earlier through Value-at-Risk estimation so as to avoid loss continuously due to dropping trend. This empirical study also tried comparisons between various random return types and between different kinds of fixed multiplier setting and the results tends to be uniform. That means the method of fixed multiplier has no significant difference and it also shows that there is actual proof and support on the thinking of induction of Value-at-Risk into insurance strategy. Coping with the rebalance performance in Figure 1,  $M_i$  turning rule value of tuning process and insurance period return observation data are in Figure 2

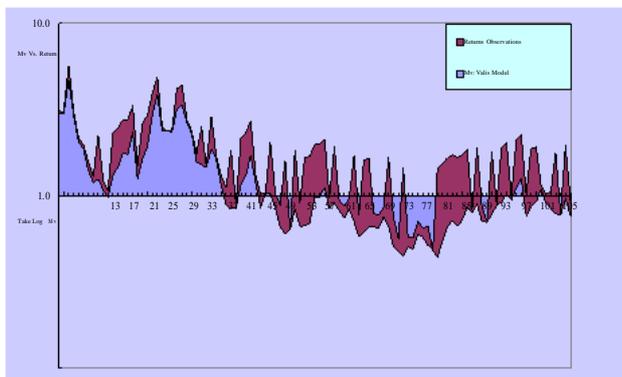

Fig. 2  $M_i(t)$  tuning rule of  $M_i(t)$  tuning process and insurance period return observation data display

Contrary to Figure 2.2,  $M_v(t)$  tuning rule of Value-at-Risk calculation and  $M_i(t)$  tuning process display is in Table 2. Table 2 shows related data of VALIS strategy applied in actually proved cases.

Table 2 Summary of VALIS strategy relevant parameters adjustment process

VALIS Strategy Model			
Return[R(t)]	VaR(t) (95%)	$M_i(t)$	Wealth[W(t)]
0.096548069	--	3.0	100.0
0.063129099	--	3.0	103.8
-0.080851495	0.2	4.7	98.0
0.174454076	0.2	2.9	107.4
0.097807636	0.2	2.1	118.0
0.106811134	0.1	1.9	129.6
0.166378286	0.1	1.4	146.7
0.091646545	0.1	1.2	158.1
-0.244630284	0.4	1.2	131.2
0.144857928	0.3	1.1	140.1
VALIS Strategy Model			
Return[R(t)]	VaR(t) (95%)	$M_i(t)$	Wealth[W(t)]

0.088742409	0.3	1.0	146.7
-0.058244264	0.2	1.3	142.5
-0.061619378	0.1	1.5	138.8
-0.041917043	0.0	1.8	135.5
-0.006938966	0.0	1.7	134.9
-0.197190979	0.2	2.3	115.8
0.241696074	0.4	1.3	130.8
-0.112041948	0.4	1.6	117.5
-0.026445139	0.3	1.9	116.3
-0.073885766	0.1	2.9	111.9

Final performance of various types of portfolios insurance strategy model with same properties are shown in Figure 3 and from the results it shows that VALIS has quite a good rebalance performance.

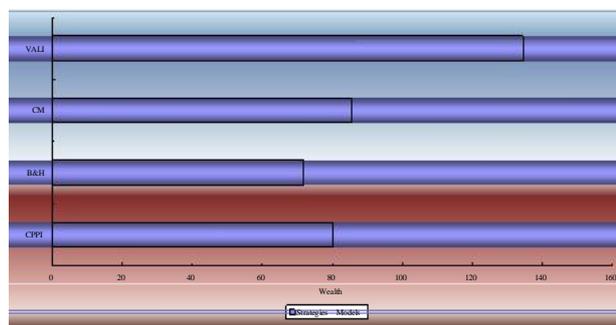

Fig. 3 Final performance comparison between operations of various types of investment group insurance strategy model

#### 4.2. Evidence from Pan-Pacific Markets

This section illustration the performance while investigating various assets in PanPacific markets. The comprehensive results show the proposed VALIS model outperforms other insurance strategy models.

The insurance period is 12 months (commencement date: 1994/01/04 ~ expiry date: 1995/01/04) and total number of business day is 244 business days. Wealth is set at 100, insurance premium is 80, insurance instruments including stocks,  $V_s$ , and risk -free asset or fixed income securities: bond,  $V_b$ , initial weights are set at  $W_1=0.6$ ,  $W_2=0.4$ ,  $\lambda_1 = 0.65$  and rebalance frequency shall be adjusted daily and insurance period covers all return observation material. Comparisons of annualized return between difference strategy models around insurance period is shown in Table 3:

Table 3 Comparisons of annualized return between difference strategy models

Annualized return for various strategy models				
Bloomberg Code	VALIS	CPPI	Constant -Mix	B & H
Japan	10.9%*	6.1%	10.1%	9.8%
$V_s$ (NKY)	$V_b$ (JPMUJPN)			
Hong Kong	12.2%*	-13.6%	-20%	-18.4%
$V_s$ (HSI)	$V_b$ (JPMUJPN)

## 5. Conclusions

In respect of theorem model establishment, this research infers the concept of Value-at-Risk into the portfolio insurance strategy model VALIS so as to strengthen upside capture and through Value-at-Risk the future can be estimated conservatively and when the market is facing large fall, it will have better bottom breaking protection effect. In the essay, the characteristic of idea portfolio insurance proposed by Rubinstein is utilized to prove that VALIS conforms to the requirement of capital insurance strategy. In this empirical research, VALIS is being utilized to compare with famous traditional portfolio insurance strategy such as fixed multiplier of CPPI, B&H, CM so as to evaluate its performance.

In regard to the adoption of Value-at-Risk model, as appropriate selection has to be conducted based on investment underlying, amongst present several tens of values in risk calculation methods, each has its merits and demerits. Therefore, this essay has considered the application of the practicality of VALIS that the J.P. Morgan guidepost is considered for decision of proceeding. For induction and proof of other various types of Value-at-Risk, it can be based on the induction and proof with same reason in this essay and it can be inferred by investment operation underlying based on

separate options, exchange rate, futures, etc as foundation. In addition, in respect of evaluation period and sampling period of Value-at-Risk, they can also be adjusted based on practical requirement. If it is financial institution like bank then it can be based on the suggested number of days and thresholds of standard of Basel Capital Accord in 1988 and other plans in Capital Adequacy Directive, CAD, BIS of Europe in 1996. Then based on these related parameters can be set. If it is the periodical rights department of securities merchants, new financial products department or derivative department or assets allocation management institutions, etc, then it can refer the standard setting suggestion from the G30 meeting of International Derivative Financial Products. As starting from 1997, countries in G10 already adopted the above-mentioned plan, therefore the implementation of assets allocation insurance strategy based on that standard will be able to conform to international trend and standard.

## Abstract

To identify a mobile station (MS) and validate legal service requests, authentication functions are utilized in the location registration, call origination and call termination procedures. In GSM, the VLR requests the HLR for assistance in authenticating the visiting user. The authentication center (AuC) in the home network generates 3-tuples and sends them back to the VLR for subsequent authentications during the user's residence. If these 3-tuples are used up before the MS's leaving, another request is issued by the VLR. The request is expensive, because it needs to access the HLR/AuC. Traditionally, a fixed-K strategy is used. That is, K 3-tuples are sent to the VLR for each request. Larger K is preferred to reduce the number of the expensive requests for 3-tuples. However, much waste of 3-tuples is observed, especially when an inactive user is considered. Hence, K value should be determined based on the usage pattern of the user. We propose a dynamic-K (DK) strategy to reduce the waste and diminish the signaling traffic for authentication. Simulation results show that the DK strategy can effectively determine the appropriate K value. Not only the waste but also the number of requests are diminished efficiently.

## 1. Introduction

In Global System for Mobile (GSM) communications, the Mobile Station (MS) communicates with the Base Station (BS) by radio. BS are connected to the Mobile Switching Center (MSC) which communicates with the Public Switched Telephone Network (PSTN). There are two kinds of mobility databases for handling service provision. One is the Home Location Register (HLR), and the other is the Visitor Location Register (VLR). The HLR contains the information of all subscribers. The VLR stores the roaming users' records that are used to handle the location update, call origination and call termination [1]. The Authentication Center (AuC) generates security parameters upon the request from the HLR. The AuC may be co-located with the HLR. A simplified system architecture is shown as Fig. 1.

One of the core security issues in personal communication system is user authentication for providing the con-

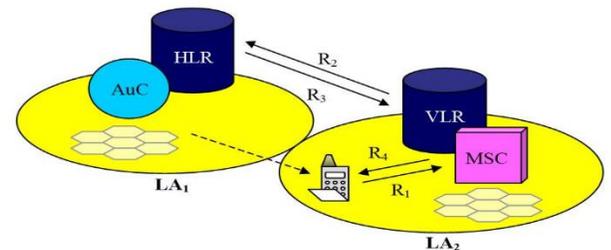

Figure 1: A simplified GSM architecture

tracted services. Another one is session key agreement for securing subsequent sessions. Both of the security issues are accomplished by the 3-tuples (RAND, SRES,  $K_c$ ) generated from AuC. When a roaming user arrives in a location area (LA), the VLR of the LA will need the assistance of the HLR to authenticate the roamer. In general, the HLR asks AuC to generate K 3-tuples and forwards them to the VLR for the subsequent utilization. Each of the location update, call origination and call termination needs one 3-tuple for authentication operation. If the 3-tuples are used up, the VLR will request again and the HLR offers K new 3-tuples. Such arrangement is called fixed-K strategy. The 3-tuples request is expensive, because it needs to access the HLR/AuC. Hence, an larger K is preferred to reduced the number of requests. A very similar mechanism is adopted by Universal Mobile Telecommunication (UMT) which is the third generation mobile service technology evolved from General Packet Radio Service (GPRS). In 3GPP TS 29.002, K=5 is recommended [2].

The 3-tuples transmissions from AuC to VLR may occupy much network bandwidth if larger K is used. Moreover, many 3-tuples are not used before he/she leaves the LA or becomes the victim user. These unused 3-tuples are discarded and becomes a waste. The victim user is the one whose VLR record is replaced due to VLR overflow [3]. The 3-tuples in the record will be lost under such condition. Especially, the inactive users are the more possible targets to be selected as a victim [4]. Because they seldom make/receive calls, the waste of 3-tuples is more serious.

Thus, it is desirable to select an appropriate K value to reduce the waste and minimize the signaling traffic for authentication. In this paper, a dynamic-K strategy is inves-

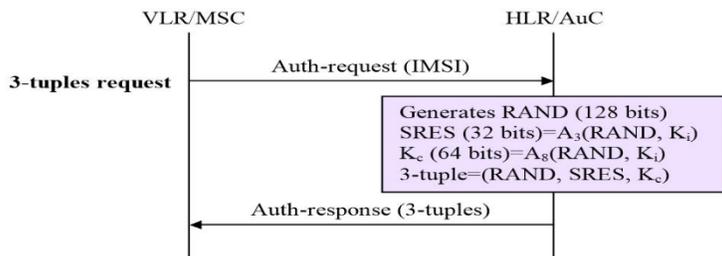

Figure 2: The 3-tuples request protocol between VLR and HLR/AuC

tigated. The authentication protocol in GSM is described in section II. Section II also explains the relationship between the waste of 3-tuples and the VLR overflow. The dynamic-K strategy is introduced in section III. According to various system parameters, the numerical analysis is investigated in section IV.

## 2. User Authentication and VLR Overflow

When a roaming user visits an LA, the service is provided by the system in the visited area. The visited system should verify the identity of the user to provide the contracted services. The verification is implemented with an authentication protocol between the MS and the VLR/MSC. For simplicity, we assume VLR is co-located with the MSC. For the security of the user, the authentication must be executed under the assistant of the user's HLR. The VLR cannot authenticates the roaming user itself. The details of the authentication is introduced in this section. Moreover, the VLR overflow control scheme may affect the authentication information. The affection is also described briefly in the subsection.

### 2.1 The Authentication Protocol in GSM

In GSM, each SIM card has a unique International Mobile Subscriber Identity (IMSI) and a secret key ( $K_i$ ). One-way functions  $A_3$  and  $A_8$  are used during the authentication. Fig. 2 diagrams the 3-tuples request protocol which is executed as the roaming user arrives in the LA or the 3-tuples are used up. The aim of the request is to gain  $K$  3-tuples computed by the HLR/AuC of the roaming user. The first 3-tuple is for the location registration that confirms the arriving of the user. Whenever he/she wants to take advantage of system services (call origination or termination), the remaining 3-tuples will be used for the authentication of the roaming user. One authentication for services needs one tuple.

Fig. 3 shows the authentication protocol between MS and VLR/MSC. To verify the identity of the roaming user, the VLR/MSC sends RAND to the user. RAND is a 128-bits random number. The roamer uses its secret key  $K_i$ , RAND, and  $A_3$  algorithm to compute SRES\* which is sent back to the VLR. If the stored SRES matches the received SRES\*, the authentication is successful and services will

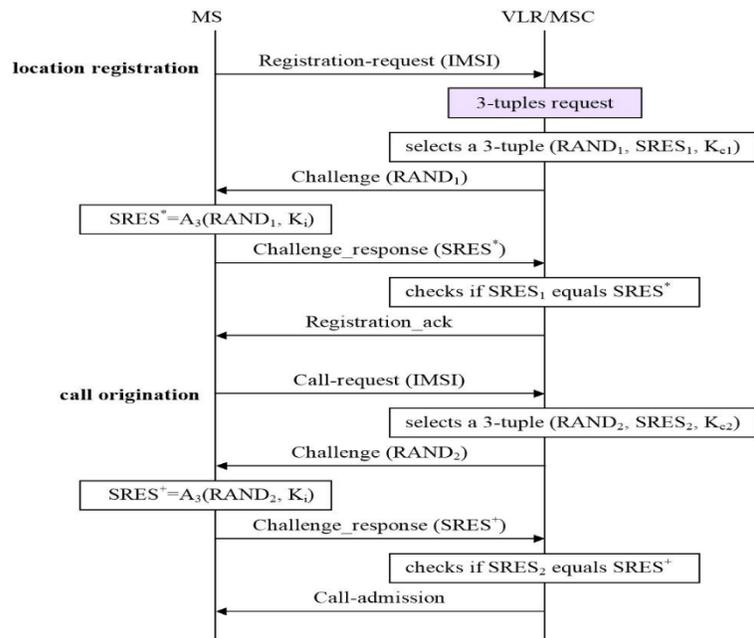

Figure 3: The authentication protocol between MS and VLR/MSC

be provided to the roaming user. Besides, the MS uses  $K_i$ , RAND, and  $A_8$  algorithm to compute the session key  $K_c$ . The  $K_c$  is utilized for encrypting/decrypting the subsequent session between MS and MSC.

### 2.2 The Waste of 3-tuples in VLR Overflow

When a mobile user roams from his/her home system to another system, a temporary record for the user is created in the VLR of the visited system. The record includes information for handling calls to or from the user. In order to generate the important VLR record, the roamer must inform the VLR about his coming by registration. When the user leaves the visited system, deregistration is necessary to cancel the corresponding record in the VLR [5]. The number of VLR records changes dynamically when the visitor moves in or out. Due to the limited capacity, the VLR may become full if too many mobile users enter a VLR during a short period. As a VLR is full, the arriving mobile users will fail to register in the VLR. In such condition, these users cannot receive any service. The phenomenon is called *VLR overflow*. These users are called *overflow users*.

To resolve the VLR overflow problem, an overflow control scheme selects a record from the overflow VLR as a victim. The victim will be replaced with the record of the overflow user. The approach enables overflow users to receive services even when a VLR overflows. The inactive users are the mobile subscribers with low probability to issue/receive calls. Hence, the inactive users are the better targets to be selected as victims. [3]

The 3-tuples are stored in the VLR record. Once the

record is replaced, the remaining 3-tuples will be lost. When the victim user would like to make/receive calls, his/her record must be reconstructed again. Another 3-tuples request is issued from VLR to HLR for  $K$  new 3-tuples. Even if the record of an inactive user is never replaced, the remaining 3-tuples are still discarded when he/she leaves the LA. The waste of the 3-tuples is considerable for the inactive users. In next section, we propose a dynamic-K strategy to diminish the waste of 3-tuples and the authentication traffic load in signaling network.

### 3. The Dynamic-K Strategy

The main idea of the dynamic-K (DK) strategy is that the number of 3-tuples should be determined according to the call frequency of the roaming user. A user with high call frequency should be given more 3-tuples. On the other hand, less 3-tuples are enough for the inactive user. In this method, a simple call counter is maintained in the VLR record of the user. When a call origination/termination occurs, the call counter  $cn$  increases by one. If the user has no call for a period of time, the call counter  $cn$  decreases by one. As a roaming user arrives an LA, the registration procedure enables the VLR to request 3-tuples from the HLR/AuC of the user. Because no historic analysis of the user's call activity, three 3-tuples are generated and transferred to the VLR. If the user is an active user, the three 3-tuples will be used up soon. Then,  $K$  is computed with  $K = cn + m$ , where  $m$  is the system parameter preset by the system manager. The next request for 3-tuples will be responded with  $K$  3-tuples. To compare the DK strategy and fixed-K strategy, we designed simulation models for both of them. For approximating true condition, the overflow control scheme with second chance replacement policy is also added in our simulation models [3]. We made the following assumptions in our experiments [6, 7].

- There are two classes of mobile users. Class 1 users have a low call connection rate  $\lambda_{c,1}$ , and class 2 users have a high call connection rate  $\lambda_{c,2}$ .
- The user arrival rates of the class 1 and class 2 users are  $\lambda_{u,1}$  and  $\lambda_{u,2}$ , respectively.
- The call connections are Poisson processes [8].
- The user arrivals are assumed to be Poisson processes, too.
- The residence time distributions of all users have the Gamma distribution with mean  $1/\lambda_m$  and variance  $V_m$  [9].

The second and third assumptions can be easily relaxed to fit general distributions in our simulation experiments. For the stable simulation result, 1,000,000 roaming users are simulated in each simulation run [10]. The output of the simulations are the number of waste 3-tuples  $N_w$  and the number of the request for 3-tuples  $N_r$ . The analysis of the DK strategy and the fixed-K strategy is investigated according the simulation results.

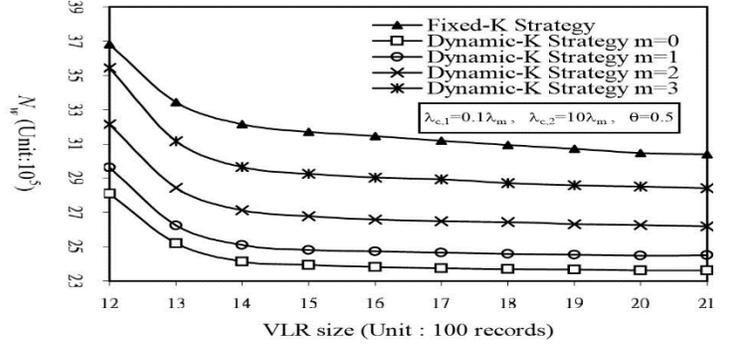

Figure 4: Effects of  $V$  on  $N_w$

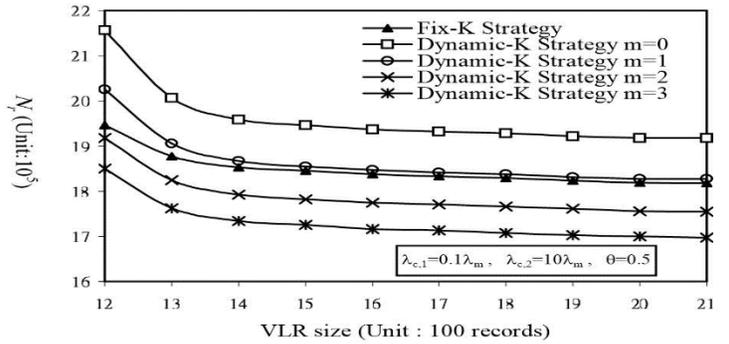

Figure 5: Effects of  $V$  on  $N_r$

### 4. Numerical Analysis

As mentioned above, the VLR residence time distributions for both classes of users are assumed to have the Gamma distribution with mean  $1/\lambda_m$  and variance  $V_m$ . In our simulation,  $V_m = 1/\lambda_m^2$ ,  $\lambda_{c,1} = 0.1\lambda_m$  and  $\lambda_{c,2} = 10\lambda_m$  are considered. We also assume that the total user arrival rate  $\lambda_u$  to a VLR area is a fixed value  $2000\lambda_m$ , where  $\lambda_u = \lambda_{u,1} + \lambda_{u,2}$ .  $V$  represents the VLR size.

Fig. 4 plots  $N_w$  as functions of VLR size  $V$ . In this experiment, we assume that  $\theta = 0.5$ , where  $\theta = \frac{\lambda_{u,1}}{\lambda_{u,1} + \lambda_{u,2}}$ . That is, half of the roaming users are class 1 and the other half are class 2. Compared with the fixed-K strategy, this figure demonstrates that the DK strategy can always reduce the waste of the 3-tuples. As VLR size increases, the waste decreases for both DK strategy and fixed-K strategy. Due to the larger VLR size, the frequency of discarding the 3-tuples drops off with the probability of record replacement. Another interesting phenomenon is that greater system parameter  $m$  seems to reduce the performance of the DK strategy. A straightforward judgment is that  $m = 0$  is the best choice. However, the answer will be quite different when the number of 3-tuple requests  $N_r$  is considered below.

The relationship between  $N_r$  and VLR size is illustrated in Fig. 5. For the same reason in previous discussion,  $N_r$  decreases as VLR size increases. Moreover, another im-

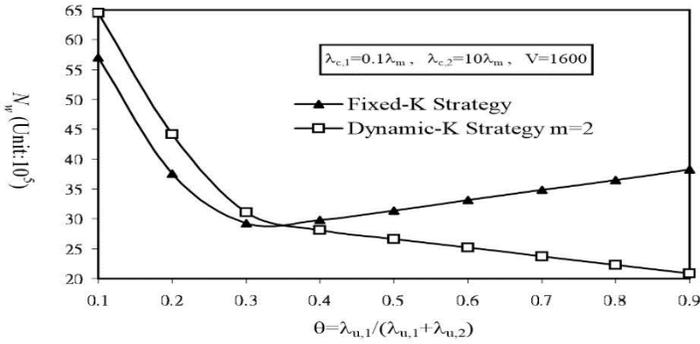

Figure 6: Effects of  $\theta$  on  $N_w$

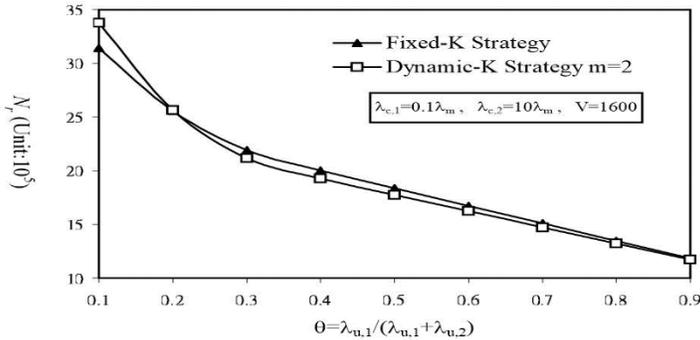

Figure 7: Effects of  $\theta$  on  $N_r$

important phenomenon is noticed. When  $m$  is greater than 1, the DK strategy needs less  $N_r$  than the fixed-K strategy. The request for 3-tuples is expensive, because it needs to access the HLR/AuC. Therefore, any strategy to reduce the waste of the 3-tuples should not increase  $N_r$ . From Fig. 4 and Fig. 5, we know that  $n=2$  is a good choice for DK strategy which can diminish both  $N_w$  and  $N_r$ .

The effects of  $\lambda_{u,1}$  and  $\lambda_{u,2}$  are shown in Fig. 6. It plots  $N_w$  as functions of the ratio  $\theta$ . As  $\theta$  increases, the class 1 users increases. It means that the average number of the calls per user decreases. A significant phenomenon is that the waste caused by fixed-K strategy increases for  $\theta > 0.3$ . Obviously, it is inefficient to set  $K=5$  fixedly. A contrasting result gained by the DK strategy. The waste always decreases as  $\theta$  increases. For  $\theta > 0.35$ , the DK strategy outperforms the fixed-K strategy. If  $\theta < 0.35$ , most of the user are active and their  $K$  value will be increased by DK strategy. Once they leaves, the average of waste is  $K/2$  which has high probability to be larger than  $5/2$ . Under such condition, the system manager can adjust  $m=1$  or  $0$  to get better performance than fixed-K strategy.

The relationship between  $N_r$  and  $\theta$  is illustrated in Fig. 7.  $\theta < 0.1$  is the extreme case. Under such condition, almost all users have high probability to make/receive calls. The  $N_r$  becomes very high. In other words, most users need to make more than one request for 3-tuples. Because three 3-tuples are given for the first request in the DK strategy, it has higher probability to require the second re-

quest than the fixed-K strategy which gives five 3-tuples. However, this is an abnormal condition and seldom happens. For  $\theta > 0.2$ , the DK strategy always needs fewer 3-tuples requests than the fixed-K strategy.

## 5. Conclusion

The 3-tuples (RAND, SRES,  $K_c$ ) are generated from the HLR/AuC, which enable the VLR to authenticate the roaming user. A similar protocol is adopted by the third generation mobile service technology. The fixed-K strategy is used in GSM and 3G communication systems. Since the cost for accessing HLR/AuC is expensive,  $K=5$  is recommended for the fixed-K strategy to prevent too many requests for the 3-tuples. It means that five 3-tuples are sent back to the VLR from HLR/AuC for each request. However, this strategy is inflexible. Much waste of the 3-tuples is observed. In this paper, we propose a dynamic-K (DK) strategy to diminish the waste. Most importantly, the DK strategy can reduce the number of the expensive requests for 3-tuples at the same time.

The main idea of the DK strategy is that  $K$  should be adjusted dynamically based on the call pattern of each user. The active user makes/receives calls often, so higher  $K$  is appropriate for them. On the other hand, the inactive user needs only smaller  $K$  value to prevent the waste of 3-tuples. The DK strategy can provide appropriate  $K$  value for each user. Simulation results show that the DK strategy gains better performance than the fixed-K strategy in most scenarios investigated in our study. The DK strategy reduces not only the waste of 3-tuples but also the number of the expensive requests for 3-tuples. Furthermore, a parameter  $m$  is provided to the system manager for adjusting the tradeoff between the waste of 3-tuples and the number of requests according to various population of resident users. The DK strategy is efficient and flexible to diminish the signaling traffic for authentication in GSM and 3G mobile communication systems.

## Abstract

The security of transactions in mobile commerce is moving away from being just an IT concern to being a business concern because of the potential loss of revenue to businesses due to lack of privacy, integrity or confidentiality, system slowdown or downtime. While most security procedures are limited to corporate IT infrastructure, in mobile commerce, issues concerned with transaction security appear to have extended beyond the corporate network to embrace the complete business process. Any lapse in procedures that maintain the confidentiality of data or the violation of privacy could affect corporate image and hence would impact on customer relationships. In turn, any adverse effect on customer relationships would impact negatively on business revenue. In addition to existing security problems in a wired commerce environment, the emergence of mobile devices has renewed calls for addressing security threats to financial transactions. These problems are discussed in this paper as key issues in terms of an organization's architectural and procedural approaches to the security, reliability and availability of business transactions.

**Keywords:** Mobile commerce, security threats, IT security, risks, business transactions.

## 1. Introduction

In the past, the majority of the computer security officers have had difficulty in convincing management to allocate financial resources for IT security. However, with the emergence of electronic commerce and various legislations, organizations appear to have understood the necessity for computer security, especially data security [5]. The current trend in most organizations, therefore, appears to be one of security officers focussing on IT security – namely – hardware security, software security and access security [5]. Access security involves both physical access and logical access. What appears to be missing from these security procedures is the proper integration of business transactions. Ghosh [11] states that

while various security measures have dealt independently with business transactions, electronic commerce and the emerging mobile commerce have changed the perception that an independent IT infrastructure security alone can protect an organization in terms of its business needs. To support Ghosh's statement, Deise et. al. [7] has identified the shift in the focus of IT security in organizations, resulting in new security policies to focus on reliable, available and trusted business transactions.

Initially in this paper, the new security threats arising from mobile commerce are highlighted. These threats are then linked to financial transactions in order to highlight the potential loss or damage to an organization's revenue. The organizational IT requirements are assessed with a view to providing support for financial transactions in a mobile commerce environment. This organizational support is then formed into an 'architecture' and the architecture is discussed in terms of how it supports an organization and what it does to support financial transactions in particular. This architecture is subsequently elaborated in terms of a series of action items so that transaction security in an organization can be guaranteed. It is hoped that these action items would then enable organizations to tighten their current security strategies.

## 2. Security Threats Arising from Mobile Commerce

Security threats in mobile commerce can range from the passive eavesdropping of messages to actively stealing data [19]. In a radio frequency operated mobile commerce environment, it is possible to listen to conversations with minimum difficulty. This has an impact on consumers causing concern about their data and about voice messages from unauthorized access. At the other end of the problem is the inherent security risk involved in transferring information over networks. This problem consists of two components: *identification integrity*, and *message integrity*. Identification integrity refers to the signature elements found in the messages which establish where the

message originates. Message integrity refers to details to establish that the message is received as sent and that no third party has attempted to open, modify or alter the contents. According to Zhang & Lee [25], these two items appear to cause a lot of concern to both senders and receivers. While the senders risk the theft or misuse of their personnel information such as account and bank details, the receivers (usually a merchant) risk repudiation of the transactions and the resultant non-payment.

Further security concerns in mobile commerce arise from the development in the technology itself [25]. It is envisaged that mobile technology will be offered with payment for the range of services offered. This is already emerging in the domain of mobile telephones. For instance, when a mobile telephone user accesses other network carriers, a special charge is levied on the user. Therefore, it is safe to assume that there will not be any "free services" in the future. The technology is developing in such a way that the payment for such services will be through some form of "smart card". The details stored in the smart card will need to be transmitted via the networks for validation and verification in order to determine service levels. If these networks are not fully secure, security breaches may occur.

One major security breach that can happen in mobile commerce is when user details are transformed from one mobile network to another [13]. When this transformation occurs, any encrypted data needs to be decrypted for transparency. In mobile commerce, when mobile devices make requests to the web pages of a network server, a four-stage process is followed. First, the requests arise from the originating Wireless Transport Security Layer (WTSL) protocol. Second, the requests are translated at the originating Wireless Application Protocol (WAP) gateway. Third, they are sent to the standard Session Security Layer (SSL) protocol of the destination network. Fourth, the translated information reaches the Hyper Text Transfer Protocol (HTTP) modules in the new network in order for the requests to be processed. In the course of translating one protocol to another, the data is decrypted and then re-encrypted. This process is commonly known as the "WAP Gap". If an attacker is able to have access to the mobile network at this point, then simply capturing the data when it is decrypted can compromise the security of the session.

Data in the Mobile Commerce environment is secured using encryption technology. According to Ghosh [11], it has already been proven that this technology is vulnerable to attack. Hackers have broken some of the existing algorithms for encryption, so there is nothing like complete security. Further, there is no international regulatory framework available to enforce certain security related problems. For example, in the current climate, no individual organization or government can guarantee security to consumers. When a security breach appears in an international transaction, no one country will be able to assume responsibility to prosecute the perpetrators. While these problems have been recognised and solutions are being proposed, organizations are losing consumer

confidence. This has the potential to impact the revenue generated by these organizations.

Trust is central to any commercial transaction and more so in the case of mobile commerce [9]. Trust is normally generated through relationships between transacting parties, familiarity with procedures, or the redress of mechanisms. In the case of mobile commerce, the need for creating the trust in the consumer assumes extreme importance because of its virtual nature. It hinges on assuring consumers and businesses that their use of network services is secure and reliable, that their transactions are safe, that they will be able to verify important information about transactions and transacting parties such as origin, receipt and integrity of information, as well as the identification of parties dealt with. Therefore, the challenge is not to make mobile commerce foolproof, but to make the system reliable enough so that the value greatly exceeds the risk.

Any new development in technology in today's consumer mind creates both curiosity and reluctance. The informality and lack of overall control creates the perception that the Internet is inherently insecure [20]. This perception can trigger business and technological risks [21]. Business risks involve products and services, inadequate legal provisions, the reliability of trading partners, the behaviour of staff and the possible demise of the Internet service provider. Technological risks involve hacker attacks, computer viruses and data interception. To achieve satisfactory levels of trust, organisations have to think about managing both business and technological risks. Currently mobile commerce relies mostly on knowledge-based trust that is useful for Business-to-Business commerce [9]. However, there is a big surge in identification-based trust to satisfy consumers' concerns about their transaction details. In addition, the current architecture for mobile communications does not provide full security in terms of transaction integrity. Some of the models envisaged for mobile commerce are based on a smart card approach and hence the issue of financial transaction security needs greater examination.

### **3. Security Threats that Can Impact Financial Transactions**

Security risks in a mobile commerce environment associated with financial transactions can be categorised into traditional risks and non-traditional risks [14]. Traditional risks usually involve loss or damage to tangible physical assets and resulting economic loss. For example, loss of computer hardware may have an impact on incomplete transactions. Alternatively, a missing data disk, which is not fully protected from theft can place an organisation at risk. Treatment of traditional risks is usually addressed in risk management policies. Protecting tangible assets from traditional perils, even when those assets are devoted to mobile commerce, does not involve new and different techniques. These security treats are beyond the scope of this paper.

Non-traditional risks involve damage to organisations'

computer systems and electronic data [24]. These risks include stolen information, damage to web sites by hackers, the hijacking of web sites and viruses. An attack may be perpetrated for any number of reasons including financial gain involving credit card fraud, curiosity with no specific intent of harm, espionage by domestic or foreign competitors, or foreign governments, revenge by a terminated employee who is intent on wiping out files, disclosure of personal data to unauthorised institutions as in health related cases, thrill seeking, disruption to stop critical activities, and extortion for financial or political reasons. Any attack, internal or external, on a computer system is disruptive and forces the administrator to shut down the system resulting in revenue loss.

Non-traditional security breaches also include unauthorized access or the use of a company's computer system and data by an outsider or an insider [7]. For example, a hacker could break into a company's computer system and steal or destroy data. Widespread use of mobile commerce enhances the possibility of an outsider invading an organisation's computer system. Due to the reliance on computers for daily operations, breaches of a company's computer or information security system are a risk to almost all functional components of the business. Use of software to encrypt and, thus, safeguard communications provides some protection, but also adds the risk that a virus or other bug could damage the equipment or data. Further, according to Dang [6], theft of information such as critical electronic files including financial data, customer information, marketing and new product data, trade secrets, and personnel data may provide competitors with a strategic advantage, criminals with the means to commit fraud, and others the opportunity to disparage the company. Moreover, Dornan [8] states that the use of misappropriated information may harm third parties such as customers, employees, and business partners. The theft of information may undermine an acquisition or cause a public relations problem and hence potential loss of revenue.

Security breaches may be very costly to an organisation [10]. When an unauthorized access to the computer is gained for the purposes of committing a crime such as fraud, reputation is also at stake. Other security issues include the prohibition of high-level encryption technology by domestic or foreign governments so that agencies can break the codes if necessary for defence or law enforcement, changes in international standards, and loss of encryption key recovery.

#### **4. A Closer Look at Fraud and Crime Risks in Mobile Commerce**

The scope of computer fraud and crime is immense in mobile commerce. Among the most common crimes are malicious mischief, such as the insertion of viruses or Trojan horses into one or more computer systems; the fraudulent transfer of money to personal accounts; the use of forged electronic signatures; the theft of credit card information and credit card fraud; Medicare and Medicaid

fraud; the theft of intellectual property; illegal use of software; stock and commodity market manipulations; and similar illegal activities. Most losses are insurable, but premiums will be relatively exorbitant if security measures are not appropriately enacted [13].

A hacker may use a number of methods such as the insertion of viruses, spamming and web snatching to access computer systems and data and to cause damage. Damage may occur at data centers or in the transmission networks, routers, or power sources. Virus attacks may also come from innocent parties who pass on an infection without knowledge that the system is contaminated, usually by e-mail.

By using another technique, *distributed denial of service*, hackers have been able to attack some of the most well-known and highly secure web sites in the world, including Yahoo.com, eBay.com, and amazon.com. This technique hijacks numerous computers on the Internet and instructs each one to flood a target site with phoney data. The target site, trying to accommodate the phoney data, becomes overworked and soon begins to lose memory. The result is effectively slowing or shutting down the entire site to real customers.

*Web snatching* is a practice in which one party plants a virus in another party's Web site that automatically moves the viewer from the selected site to a site run by the web snatcher. This is done without the permission of the selected Web site owner or the site visitor. In many instances, the viewer is unable to get out of the unwanted site, short of turning off the computer, so is effectively held hostage to the new site. The diverted-from and diverted-to sites usually have nothing in common with each other.

Financial institutions and companies that have inadequate electronic security protection are more likely than not to suffer losses of money, information, or other corporate assets. Surveys have shown that most companies and institutions have incurred losses, and a substantial number have no idea whether they have come under electronic attack or not. Insiders or former insiders have committed most of the electronic crime and fraud, but there are many examples of third-party fraud and theft.

Mobile commerce can only be conducted if all parties believe there is adequate security. The majority of those who use the Internet, on which current mobile commerce technologies are built, are very concerned about security [11]. Some 40 percent of Internet consumers give false information when they use the Web because they do not trust the Internet's security [4]. Other users refuse to register at sites that require what the consumer believes to be personal information [1]. Many people want the government to legislate security on the Internet as they are not confident that businesses will do the job on their own [23]. Therefore, it is critical that businesses enhance both their security and their security image to combat crime on the Internet, as well as to increase customer confidence and participation in virtual business environments.

#### **5. Security Risks in Mobile Commerce**

## Emerging from Reliance on Third Parties

Today, most organisations rely on computers for their daily operations. Traditional and non-traditional security risks can interrupt a business or literally shut it down. For example, a security breach by a hacker can severely disrupt a business and those who depend on it. Most businesses in mobile commerce are dependent in several ways on the continued reliability and operation of computer controlled systems not within their control, such as the telephone network which is managed and controlled by computers. Businesses are dependent on their financial institutions that are also managed and controlled by computers. In mobile commerce, to accommodate home users, organisations are dependent on their Internet Service Providers (ISP). Suppliers and customers depend on each other's electronic data systems and on mutual systems, such as a third-party commodity exchange. When one system fails, it may cause the other systems to fail as well. Failure may be a slowdown in the dependent system, also called the 'brownout' or a total denial of service, also called the 'blackout' [11]

The above risks can result in many different types of losses [2] [8] [22]. Traditionally, property losses have meant damage to a building or other business property, including computer equipment. In the mobile commerce world, however, the focus is on damage to computer networks and, more importantly, to data. An important issue is whether data is considered tangible property under a typical property insurance policy. It appears that insurers are only beginning to address the issue of what is defined as 'covered property' under their policies at it is more likely that, in the long run, the courts will have to decide on this issue.

Property losses can also occur when an organisation's intangible or intellectual property is infringed or violated. Copyrighted materials can be copied without permission, trademarks can be infringed upon or diluted, and patented property or ideas can be stolen. Today, a firm's intellectual property may be its most valuable asset [7]. In mobile commerce, organisations need to be extra vigilant in protecting their intellectual property from hackers, crackers, competitors, and others, as well as make sure they do not infringe the intellectual property rights of third parties. This could potentially expose a firm to third-party liability.

Time losses typically include business interruption (BI) losses and service interruption losses. A BI loss is the economic loss resulting from the interruption of business activities. Business interruption losses may result from the inability to access data, the theft of data, or a threat to the integrity of a database. For example, a breach in the security of a credit card database may cause the database owner to curtail activity on the system until a damage assessment is completed and the system integrity is re-established. Not only is there a disruption of the database operations, there is also a consequential effect on all third-party users of the system.

Service interruption losses include economic losses

associated with the interruption of utilities. A service interruption incident can occur from an "off-site" exposure or event. There have been many incidents of communication cables inadvertently being cut. Long-distance telecommunication companies have experienced software problems in data routing that effectively crippled their networks for several days. According to Lee [17], service denials may cause a customer business interruption, network suspension, or a disruption in or delay of services. Service denials may result in damage claims or lawsuits for breach of a service contract.

Mobile commerce gives rise to new implications for doing business and being protected from interruptions [3]. Businesses suffering losses related to server outages face the risk of losing customers for extended periods of time. In mobile commerce, the increased reliance on suppliers is also exposing businesses to new risks for financial losses. These range from suppliers of goods (such as raw materials) to suppliers of services (such as server usage, delivery services, electricity, and telephones).

Business interruption may have several consequences - e.g., loss of income; extra expenses to recover; loss of customer, partner, and shareholder confidence; and, ultimately, reduced market capitalization. In some cases, business interruption may constitute a breach of contract and third parties harmed by the denial of service may sue, adding liability losses to first-party damages.

## 6. Expense Incurred by Organizations due to Business Interruptions

In the event of an interruption, a business may incur extraordinary expense to resume operations as quickly as possible. An example of extra expense might be increased freight charges to avoid delays in the production process associated with a loss event. In the mobile commerce area, there are new types of costs in the context of risk and insurance, including the costs of operating a web site from an alternative server, the costs of operating a web site through an alternative provider, the costs of repairing web sites damaged by hackers or equipment failures, and the costs of rebuilding other lost information [18]. Thus, various security risks arising from a combination of issues warrant closer scrutiny of the assessment of an organisation's IT requirements in order to facilitate secure financial transactions.

## 7. Assessment of Organization's IT Requirements

In order to guarantee the security of transactions in mobile commerce, the initial assessment of an organisation's IT requirement is essential for a number of reasons [16]. These include ever-changing customer requirements, changing hardware and software platforms, changing user needs and user experiences gained from innovative IT products. Therefore, such an assessment involves the four key components of mobile commerce.

They are (1) embedded computers in many everyday objects [12]; (2) next generation wireless networks [10]; (3) interfacing technologies for bi-directional communications [5]; and (4) design of an application that satisfies user needs [6].

The first key component, embedded computers, arises from the projected increase in wireless devices by 2005 and the prediction that, by 2005, mobile devices will outnumber wired devices [15]. These mobile devices would consist of some form of embedded system and hence the allocation of priority. The next component, wireless networks, follows from the first one which highlights the need for networks to be wireless (to support the concept of mobility and hence mobile devices). Users communicate via a number of different mobile devices and hence bi-directional communication is essential for an organisation to ensure that transactions are reliable and secure. Finally, the fourth component, application design, needs to accommodate diversity of user demands.

When an organisation's IT requirements are being assessed, importance should also be given to 'user experiences'. In the mobile commerce environment, user experiences typically involve cameras, music and other innovative technologies such as positioning systems and hence organisations should find a way to accommodate these ever changing user experiences. Organisations would then be tempted to add additional hardware and software resources to their existing infrastructure to accommodate these innovative technologies but this would increase their financial burden. One emerging suggestion appears to be the consideration of 'interface' facilities to enable the sharing of other third-party resources. This requires address and connectivity mechanisms that do not exist today. While recent newspaper articles forecast that such capabilities are emerging, the challenge for organisations is to create applications that truly have this multi-modal, multi-channel character because it is believed that the immediacy of wireless technology is great.

With this in mind, if we analyse an organisation's IT infrastructure, then we would be able to sort business needs to support secure transactions into four main groups. They are:

1. Technical infrastructure that can identify what IT consists of in an organisation;
2. Physical components of IT that can identify how these components support various workflow requirements in an organisation;
3. Logical components that can identify how IT components support various business processes; and
4. Real time measurement and control of security and service levels in real time.

While the first three points provide essential components of an application architecture in an organisation, the fourth provides the control and maintenance components of the application architecture. Real time control is essential in mobile commerce because

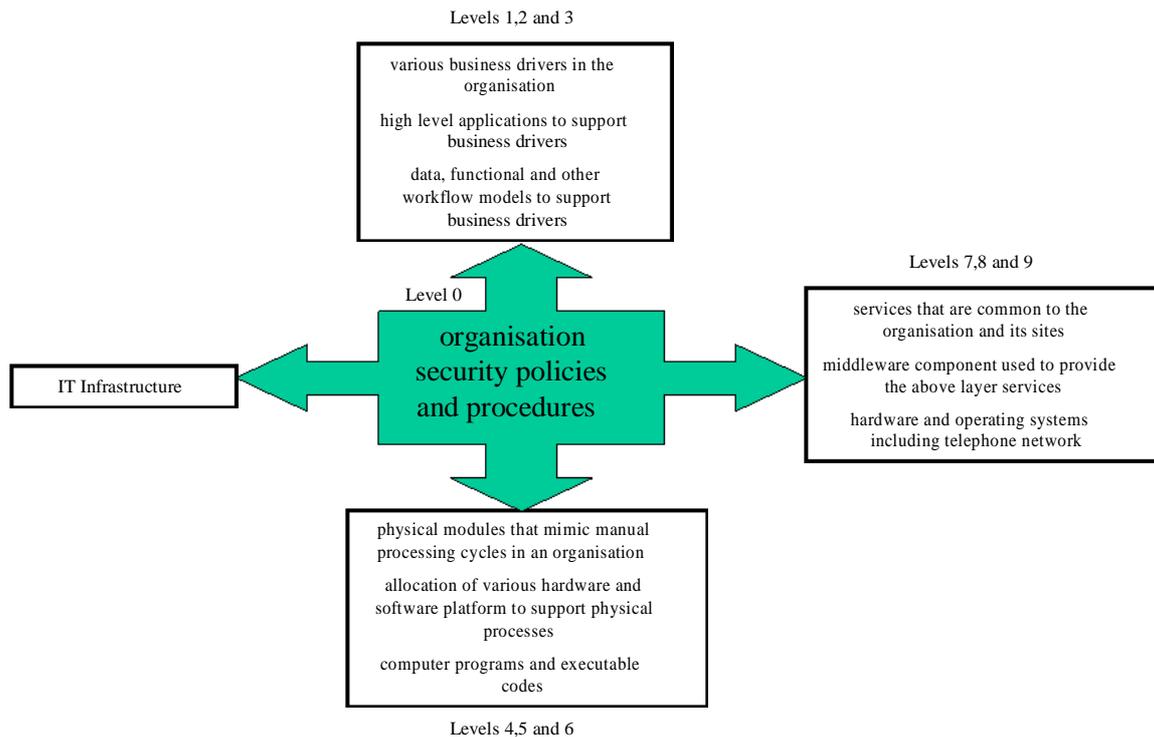

of the difficulty in describing complete security architecture to ensure security of transactions.

## 8. The Architecture

The architecture, shown in Figure 1, consists of 10 levels, starting from level 0. The level 0 is where all security policies that ensure transaction security are dealt with. This is a management component and independent of the organisation's IT infrastructure. This is because in the mobile commerce environment, due to changing user needs, it is difficult for the security officer alone to ensure the reliability of transactions. It is essential that management assumes the overall responsibility with security officers providing the necessary infrastructure because it is the managers who know the various processes involved in conducting financial transactions. This view is quite different from the current electronic commerce environment where security officers are responsible for data and information security. While this may be possible in a wired environment, due to importance given to the information and its origin in a mobile commerce environment, the view is totally different. Organisations will need to align their business processes with proper security policies because it will be difficult to track users in a mobile commerce environment due to the possibility of 'roaming'.

Further, in mobile commerce environment, users, systems and transactions change rapidly and unpredictably. This requires organisations to accommodate these needs and yet provide reliable and secure transactions. The current static authentication and authorisation process will be superseded in mobile commerce and the new dynamic privilege management will be an essential component. Therefore, risk management associated with an organisation's IT security will also need to be dynamic and to operate in real time to react to incidents and threats more pro-actively. In essence, level 0 of the architecture will ensure that customers, business partners, and other stakeholders of a transaction such as banks and governments interact directly with these business applications and their IT environments, especially in mobile environments. Level 0 architecture will ensure that the transaction environment is up and running, reliable and secure.

The levels 1-3 put the customer first and are specific to business needs. At these levels, several independent business activities are integrated through IT applications to ensure that the data, functions and workflow modules of an organisation are synchronised. Due to increasing demand from customers for mobile commerce, visibility and interaction across the supply chain to the customer are essential. Therefore, manual sub-transactions, usually found in a traditional transaction model (including weaker electronic commerce models), need to disappear and levels

**Figure 1 The Architecture**

1-3 will ensure that this happens. Levels 4-6 consist of the various physical modules to support the workflow. These levels also consist of the 'code' needed to support workflow and the integration of workflow. These levels are of extreme importance to businesses because these are where the integration of multiple segments of a business such as CRM and SCM takes place. Further, due to the physical nature of IT components, this is where the existing resources are integrated with new resources. To establish financial security, levels 4-6 need to be maintained properly because the transaction is split into multiple components at these levels before it is processed. Further, when the transaction is split into component sub-transactions, each of the sub-transaction may run on varied systems with different infrastructures. Organisations, therefore, should focus their 'security' on these levels for successful mobile-commerce. The last three levels are comprised of IT components in order to realise the various combinations of business needs. At these levels, IT components such as a computer are added to the existing infrastructure. While the previous levels 4-6 facilitate business needs, levels 7-9 actually implement them. Issues such as network speed and transaction completion time are essential characteristics at these levels. While the business performance is measured at the previous levels, response time measurement is controlled in the last three levels (7-9). These three levels are vulnerable to attack and the implementation of security procedures starts at these levels.

## 9. Discussion

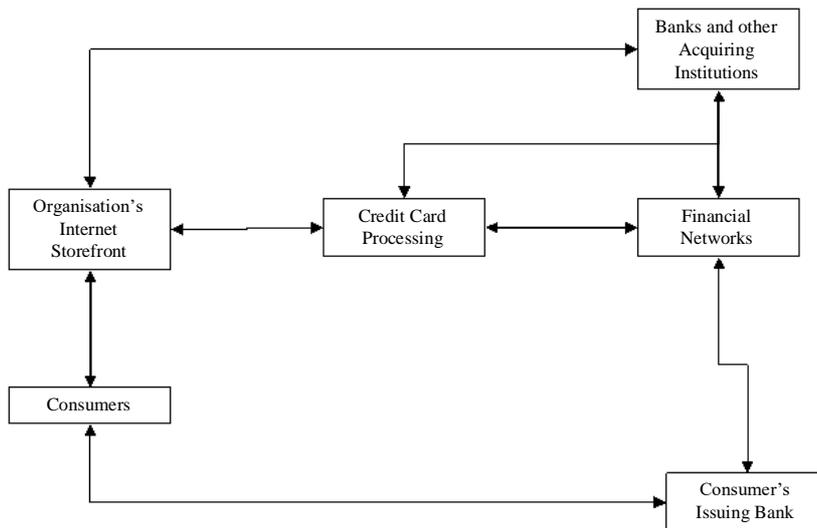

When a financial transaction is facilitated in a mobile

commerce environment, the consumer usually accesses the organisation's computer to search for appropriate details. Once the consumer is satisfied with his/her order, an order is placed. The consumer places an order using the infrastructure provided by the Internet storefront and using his or her payment method of choice. Once the order reaches the organisation, the transaction is processed. A number of security issues, such as, verifying the credentials of the consumer arise at this point. Provision for real-time security and connectivity to authorise payment via the Internet or wireless medium forms an integral component of the transaction. The organisation channels the transaction through various financial networks such as banks, ensuring that customers are authorized to make their purchase.

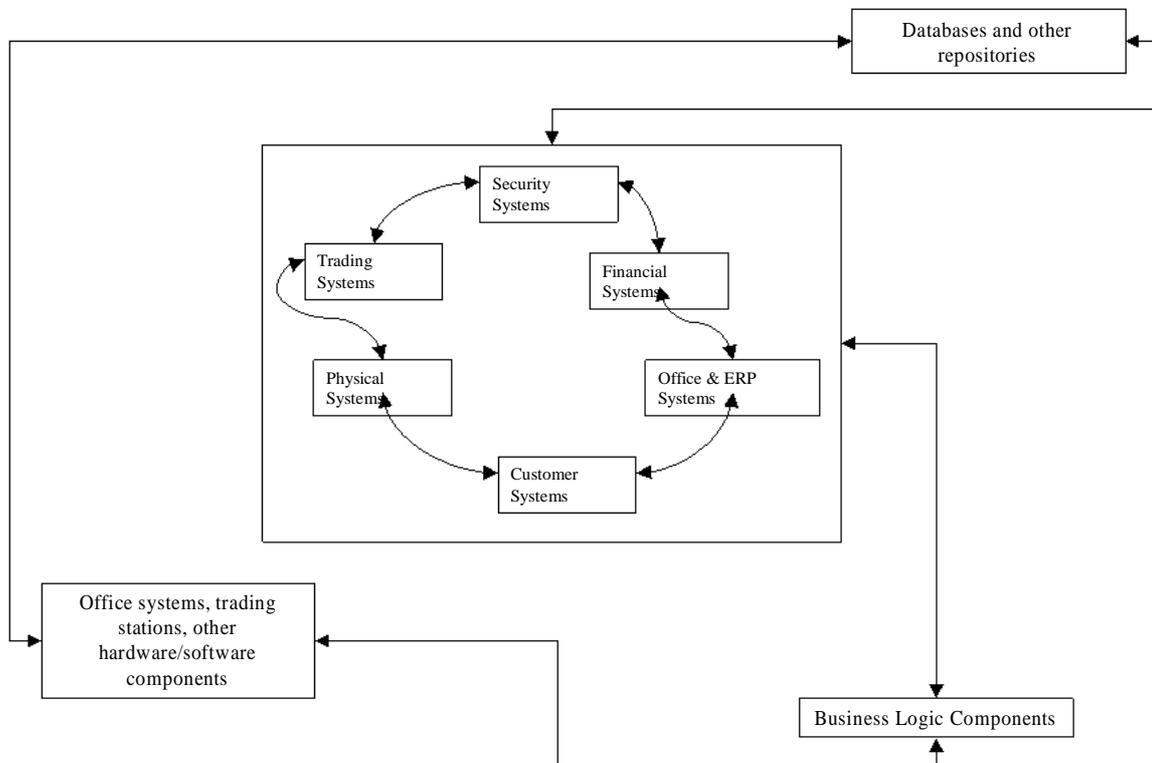

When security issues are applied to a transaction, the client/server architecture for transaction processing is usually used. The client is installed on the organisation's merchant site by the third-party providing user authentication for financial details and this client is integrated with mobile commerce application. The client is usually pre-integrated with store management systems including those for management reporting purposes.

For the purposes of transaction authorization, the client software establishes a secure link with the processing server over the Internet using an SSL connection, and transmits the encrypted transaction request. The server, which is a multi-threaded processing environment, receives the request and transmits it over a private network to the appropriate financial processing network.

Depending upon the consumer's financial status, the transaction is approved or denied. When the authorization response is received from the financial network, the response is returned via the same session to the client on

**Figure 2 Transaction Processing Cycle**

**Figure 3 Business Processing Facilitating Mobile Commerce Transaction**

the consumer's site. The client completes the transaction session by transparently sending a transaction receipt acknowledgment to the server before disconnecting the session.

The whole transaction is accomplished in few seconds, including confirmation back to the customer and the organisation. If the transaction is approved, funds will be transferred to the organisation's account. Once the transaction is confirmed, the transaction will be securely routed and processed. As proof of a securely processed transaction, both the customer and the organisation will

receive a transaction confirmation number. This is shown in Figure 2.

The architecture described in this paper supports almost all the elements of the transaction that can be conducted in the organisation. The security aspects not only involve the organisational IT infrastructure but also third-party security levels in order to approve a financial transaction. It should be remembered that consumers expect the organisation to facilitate a reliable and secure transaction and it is in the interests of the organisation that third parties involved in the transaction are reliable and capable of providing the necessary security for the consumer's

transactional details.

While the above diagram (Figure 2) portrays a complete financial transaction system, the subsystem in Figure 3 portrays the component that needs to be supported by an organisation. Components such as office systems, etc., form levels 7-9 in the architecture outlined in this paper. Components such as databases, etc., would form levels 4-6 in the architecture described above. Other components such as Business Logic Components form levels 1-3 in the architecture. The business processing for the facilitation of a transaction is also highlighted.

## 10. Conclusion

The architecture presented in this paper is an attempt to address various new security concerns in the emerging mobile commerce environment. The architecture has been constructed to accommodate various business processes as an integral component and security management system encompassing these business processes. It is believed that this architecture will assist in avoiding issues such as loss of transaction authenticity because the business process is integrated into the security procedures in the architecture. Further, the business processes are kept in the centre of the architecture to enable transaction confidentiality and integrity from an organisational point of view. Further, the interdependence of various systems within the architecture is expected to provide much needed real-time reaction to any cause of transaction unavailability in mobile commerce.

While the architecture is only conceptual, the inclusion of business processes along with IT security is expected to provide tighter controls in terms of financial transactions. This is rapidly becoming essential in the competitive world of mobile commerce where the volume of transactions ensures healthy revenue for organisations. Therefore, the architecture has been conceived with a focus on transaction security. It is hoped that this architecture helps organisations to get a head start in reviewing their security procedures and in establishing a better control on financial transactions.

## Abstract

The objective of this research is to analyze the correlation between consumers' adoption of MDA and some of its influential variables, namely innovativeness, procurement types, involvement, the degree of Internet used and the basic characteristics of consumers. This paper provides a new model to explain the influent effects between consumers' adoption of MDA and its influential factors mentioned above. The conclusions of this study are: (1) the curves of consumers' basic characteristics versus adoption of MDA are convex-type. (2) The consumers' age, name-list size, innovation adoption, goal-oriented and Internet usage frequency attributes have direct and positive effects on PDA adoption. (3) The innovativeness of consumers may be used to explain the reason of Consumers' procurement style. (4) The innovativeness of consumers may be used to exploit and design the product differentiation strategy. (5) The basic characteristics of consumers may be used to exploit and design the promotion and market segmentation strategies.

## 1. Introduction

As Internet gets widely used and digital devices get smaller and smarter, information appliances (IA) that are mobile, lightweight, versatile become popular and essential in market to suit for knowledge users daily usage. Although many products are named information appliances, the mobile digit assistant (MDA) is the representative category.

Consumer behavior is defined as the consumers' behavior to search, evaluate, procure, use and process some products, services and ideas. However consumers have many facets which affect the consumer adopting the MDA, like sex, education, occupation, innovativeness, attitude for impulsive or planning buying, the degree of Internet usage, etc. Many scholars apply single perspective to discuss consumer behavior. Like perspective of innovativeness [17], impulsive buying perspective [18] and information search perspective [21]. However since the fast progress of technology, the shorting of product life cycle, the highly changeability of consumers' demand, using single perspective to explain consumer behavior is not enough. Based on the consumer-oriented trend, this paper hopes to construct an integrated model to exploit the adoption MDA of

consumer behavior. Besides to understand more the consumer behavior when facing fast changeable or upgraded products, the conclusion of this paper also can provide more significant marketing strategy for the suppliers of MDA business.

## 2. Theory and Hypotheses

At past, some researchers view consumer behavior with focus on the action process of consuming [1] [14] [19]. Some other researchers refer consumer behavior as both the action process and the decision making process of consuming [3] [4] [24]. We may define the consumer behavior as "in order to satisfy ones need, consumers make consuming decision and take procurement action for some products or services". The processes include searching, evaluating, purchasing, and post purchase reevaluating. We may use the modified consumer decision model to describe the consumer procurement processes. And the basic characters of consumers (like sex, ages, education...) will affect the adoption of MDA.

Consumers' innovativeness and risk aversion also are very important factors for adoption of innovation products [2] [9] [15] [17]. Since Internet is a new channel for information search and procurement, the higher the perceived knowledge of Internet, the higher degree of Internet usage, and the higher the degree of MDA adoption. So the Internet perceived trend and Internet usage frequency are significant factors for adoption of MDA [11].

Impulsive buying is referring to impulsive, out of control and guilty procurement behavior [5] [16] [18] [22] [23]. Although the MDA procurement is also involved the impulsive character, the MDA buying behavior is based on need and affected by the mood at selling places, as well as sales and promotion strategy. We call this procurement behavior as "shopping around". The opposite procurement type is goal oriented buying [8]. Our research shows that both affect the adoption of MDA. The consumer's involvement is also an important factor on procurement of products and services [6] [13]. Especially from the perspective of information search [20] [21], the number of shopping mall, the number of brand and the number of product attributes are important factors of adoption MDA [10]. So, this paper uses

“brand-channel involvement” to represent the consumer involvement concept.

Mobile digital assistant (MDA) is referred to “the mobile digital equipment to assist and satisfy the customers’ life and work need”. In this research, we investigate the most technology and fashion influential products, namely, personal digital assistant (PDA) and cellular phone (CP). The objective of this research is to analyze the correlation between consumers’ adoption of MDA and some of its influential variables, namely innovativeness, procurement types, involvement, the degree of Internet usage and the basic characteristics of consumers.

The overall conceptual model of this paper is as figure.1. According to literature review, conceptual model and experience, we get two parts of hypotheses. One part is logic inference and the other is about conceptual model.

(1). Logic inference:

- H1: The curves of consumers’ ages versus adoption of MDA (PDA and CP) are first increasing then decreasing (convex-type), which should have a peak. The curve of consumers’ adoption of CP is higher than that of PDA.
- H2: The curves of consumers’ name-list-size versus adoption of MDA are convex-type. As consumers’ name-list-size increases, the number of PDA consumer is higher than that of CP consumer.
- H3: The growth curve of innovativeness of MDA is from bottom to up (market-oriented). The curve of CP adoption is closer to the diffusion of innovation theoretic curve than that of PDA.
- H4: For Internet users, the curve of consumers’ ages versus Internet usage frequency is convex-type, which should has a peak. But for non-Internet customers, the degree of Internet usage frequency decreases as the customers’ age increases.

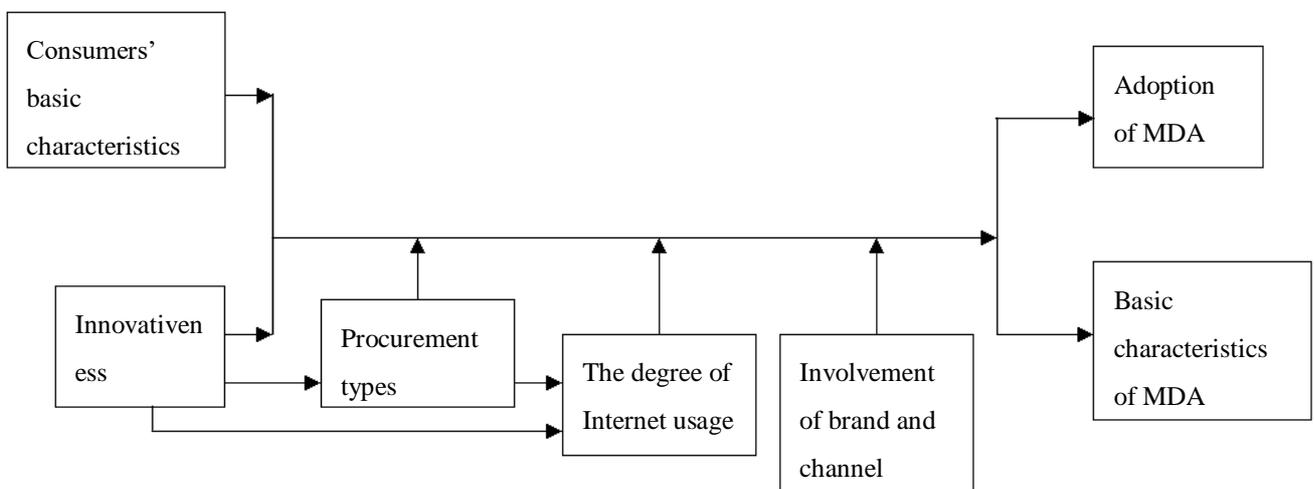

H5: As the degree of consumers’ goal-oriented increases, the Internet usage frequency increases. As the degree of consumers’ shopping-around increases, the Internet usage frequency increases.

(2). Conceptual model:

- H6: The adoption of MDA (PDA and CP) is no related with the consumers’ basic characteristics.
- H7: The adoption of MDA (PDA and CP) is no related with the consumer’s innovativeness.
- H8: The adoption of MDA (PDA and CP) is no related with the consumers’ procurement types.
- H9: The adoption of MDA (PDA and CP) is no related with the consumers’ Internet using frequency.
- H10: The adoption of MDA (PDA and CP) is no related with the consumers’ brand-channel involvement.
- H11: When adoption the MDA, the consumers’ innovativeness is no related with their Internet using frequency.
- H12: When adoption the MDA, the consumers’ innovativeness is no related with their procurement types.
- H13: When adoption the MDA, the consumers’ innovativeness is no related with the product and channel characters of MDA.
- H14: The consumers’ basic characteristics are not related with the product and channel characters of MDA.

3. Data and Research Method

This paper provides a new model to explain the influence effects between consumers’ adoption of MDA and its influential factors mentioned above. For effectiveness and cost consideration, this research using convenience sample. We totally sent 477 questionnaires and received 352 effective ones since 2001/4/20 to 2001/5/11. From 86 of these (24.4%), we received questionnaires from customers who both use the PDA and CP. From 307 of these (87.2%), we received questionnaires from customers who only use the CP.

Figuer1 : The overall conceptual model

The coefficients of reliability (Cronbach'  $\alpha$ ) for the variables (innovativeness, procurement types, etc.) are above 0.7 [12]. To test the construct validity of questionnaire perceptual measure, we use regression analysis and ANOVA. The coefficients of these relations are significant ( $p < .05$ ).

To test the conceptual model and corresponding hypothesis, we use LISREL model ( $\eta = \Gamma \xi + B \eta$

+  $\zeta$ , significant with GFI=.88, CFI=.93 and NNFI=.89), factor analysis, ANOVA and canonical correlation analysis.

#### 4. Results and Discussions

The results of testing hypotheses are summarized in tables 1 and 2.

Table1 Logic inference hypotheses testing table

Hypo	Relation	Results	Commend / Explanation
H1	Consumers' age vs. the adoption of MDA	Partial support	(1) Peaks are all at ages of 26~30 ; (2) Cp is higher than PDA ; But (3)peaks of CP and PDA at the same age level.
H2	Consumers' name-list-size vs. the adoption of MDA	Support	(1) Cp peak at no.25~34, PDA peak at no.21 ; (2)The name-list-size larger, the percentage of adoption PDA higher.
H3	Consumers' innovativeness vs. the adoption of MDA	Support	(1) The growth curve of innovativeness of MDA is market-oriented ; (2) The curve of CP adoption is closer to the diffusion of innovation theoretic curve than that of PDA.
H4	Consumers' age vs. Internet using frequency	Support	(1) For Internet users, the curve is convex-type and the peak at ages of 25~35 years old ; (2) For non-Internet users, the degree of Internet using frequency decreases as the customers' age increases.
H5	Consumers' procurement type vs. Internet using frequency	Partial support	(1) The goal-oriented users' Internet using frequency is higher than the shopping around users ; (2) The higher the degree of goal-oriented, the higher the Internet using frequency ; (3) But as the degree of consumers' shopping-around increases, the Internet usage frequency first increases then decreases.

Table2 Conceptual model hypotheses testing table

Hypo	Details	Relations	Results	Commend / Explanation
H6	H6	Basic characteristics→adoption of MDA	Support	Significant effect to PDA
	H6-1	Basic characteristics→adoption of PDA	Support	Significant effect of age, name-list-size
	H6-2	Basic characteristics→adoption of CP	Not support	Cp is a popular product
H7	H7	Innovativeness→adoption of MDA	Support	Significant effect to PDA
	H7-1	Innovativeness→adoption of PDA	Support	Significant effect of Innovativeness adoption
	H7-2	Innovativeness→adoption of CP	Not support	CP is a popular product
H8	H8	Procurement type→adoption of MDA	Support	Significant effect to PDA and CP
	H8-1	Procurement type→adoption of PDA	Support	Goal-oriented has significant effect to PDA
	H8-2	Procurement type→adoption of CP	Support	Shopping around has significant effect to CP
H9	H9	The degree of using Internet→adoption of MDA	Support	Significant effect to PDA
	H9-1	The degree of using Internet→adoption of PDA	Support	Significant effect to PDA
	H9-2	The degree of using Internet→adoption of CP	Not support	Internet is no business with CP's function

	H10	Brand-channel involvement → adoption of MDA	Support	Significant effect to CP
H10	H10-1	Brand-channel involvement → adoption of PDA	Not support	To accumulate knowledge about new product, so not have to buy it
	H10-2	Brand-channel involvement→adoption of CP	Support	Significant effect to CP
H11	H11	Innovativeness→Internet using frequency	Support	Significant effect
H12	H12	Innovativeness→Procurement type	Support	Significant effect
H13	H13	Innovativeness→the attributes of MDA product and channel	Support	Significant effect to PDA, CP
	H13-1	Innovativeness→PDA product attributes	Support	Significant effect
	H13-2	Innovativeness→PDA channel attributes	Support	Significant effect
	H13-3	Innovativeness→PDA upgrade attributes	Support	Significant effect
	H13-4	Innovativeness→CP product attributes	Support	Significant effect
	H13-5	Innovativeness→CP channel attributes	Support	Significant effect
	H13-6	Innovativeness→CP upgrade attributes	Support	Significant effect
H14	H14	Consumers' basic characteristics→the attributes of MDA product and channel	Support	Significant effect to PDA, CP
	H14-1	Basic characteristics→PDA product attributes	Support	Significant effect
	H14-2	Basic characteristics→PDA channel attributes	Support	Significant effect
	H14-3	Basic characteristics→PDA upgrade attributes	Support	Significant effect
	H14-4	Basic characteristics→CP product attributes	Support	Significant effect
	H14-5	Basic characteristics→CP channel attributes	Support	Significant effect
	H14-6	Basic characteristics→CP upgrade attributes	Support	Significant effect

Some results of hypotheses test are not significant. We now discuss the results as follow:

- (1)H1 : The statistics results show not exactly consistent with hypothesis 1. The reasonable explanation is that the most frequently usage computer person is about 25-35 years old. So the percentage to use PDA is also higher. However Cp becomes a popular product. The age of 25-35 also becomes the highest fashion pursuing and friends-communication groups. So adoption of CP is also highest.
- (2)H5 : The statistics results show not exactly consistent with hypothesis 5. The reasonable explanation is that Internet benefits (ex. fast searching and quick ordering) are an essential incentive for goal-oriented consumers. Therefore the higher customers' degree of goal oriented, the higher which degree of Internet used. But for shopping around trend customers, Internet just one of many sources of information. Yet person-to-person interactions are more attractive for shopping around trend customers than Internet bothering problems (like long-run waiting time, security, no physical tying).

Therefore the higher customers' degree of shopping around, the lower which degree of Internet used.

- (3)H6-2 : The statistics results not support hypothesis H6-2. According MIC [7] data shows that Taiwan customers use about eighteen million CPs. Almost everybody has over one CPs. Therefore CP become an ordinary and popular product. No some groups (like age, occupation, grade, or incomes) are special cases for adoption of CP.
- (4)H7-2 : The statistics results not support hypothesis H7-2. As (1), CP becomes an ordinary and popular product. There is no problem of adoption of CP. Yet there is a problem of adoption of CP about what type, what color and what special price. So innovativeness has nothing to do with adoption of CP.
- (5)H9-2 : The statistics results not support hypothesis H9-2. The reasonable explanation is that PDA functions are similar to PC or notebook. But CP main function is to communicate. The correlation about computer and Internet seems not significant. Especially using WAP to

download data is very slow and expensive. So the degree of Internet used has nothing to do with adoption of CP.

(6)H10-1 : The statistics results not support hypothesis H10-1. We may from social-psychology perspective to explain this result. Since PDA is an innovation so far. Even many customers haven't the need to buy one. They also collect and search PDA information. They not only enjoy shopping but also gather new knowledge to become a market expert. Therefore the brand-channel involvement may not have direct effect in procurement of PDA.

## 5. Conclusion and Suggestion

The main finding of this study are as follows :

### 5.1 The distribution of consumers behavior

(1)The curves of consumers' ages versus adoption of MDA are convex-type, which have peak at 26~30 ages. The curve of consumers' adoption of CP is higher than that of PDA. The curves are as figure 2.

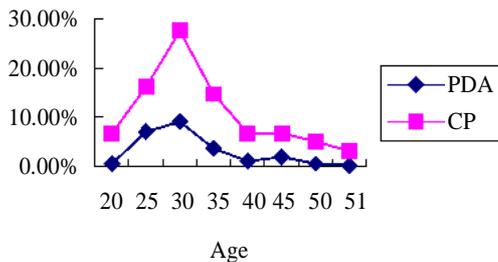

Figure 2. Consumer age and adoption of MDA

(2)The curves of consumers' name-list-size versus adoption of MDA are convex-type. As consumers' name-list-size increases, the number of PDA consumer increases, but that of CP consumer decreases. The curves are as figure 3.

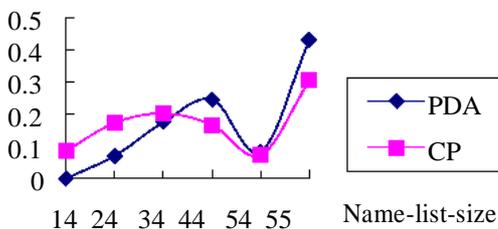

Figure 3. Consumers' name-list-size and adoption of MDA

(3)The growth curve of innovativeness of MDA is market-oriented. The curve of CP adoption is closer to

the diffusion theoretic curve than that of PDA. The curves are as figure 4.

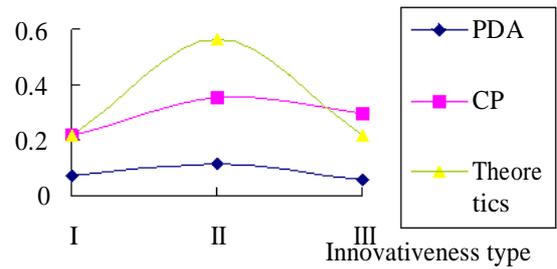

Figure 4. Consumers' innovativeness and adoption of MDA

(4)The curve of consumers' ages versus Internet using frequency is convex-type, which has peak at 26~35 ages. However, the elder age of consumers, the more rate of non-Internet user. The curves are as figure 5.

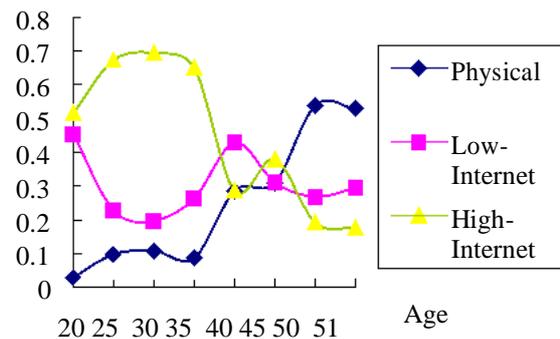

Figure 5. The customer's age and the Internet usage frequency

(5)The Internet usage frequency of the goal-oriented consumers is higher than that of the shopping-oriented. As the degree of consumers' goal-oriented increases, the Internet usage frequency increases. The curves are as figure 6.

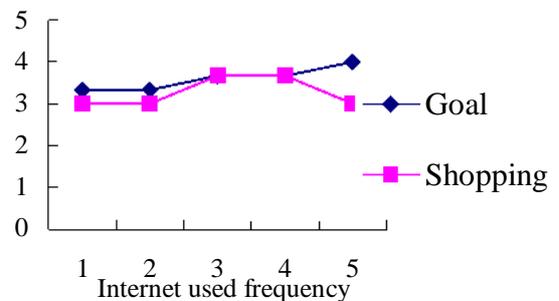

Figure 6. Procurement type and Internet usage

## 5.2 The results of statistics analysis

- (1) The consumers' age, name-list size, innovation adoption, goal-oriented and Internet usage frequency attributes have direct and positive effects on PDA adoption. The consumers' occupation, shopping-oriented and brand-channel involvement attributes have direct effects on CP adoption. The conclusions are summary in table 3.

Table 3. The summary of directly affective factors of adoption MDA

	Adoption of PDA	Adoption of CP
Age	X	
Occupation		X
Name-list-value	X	
Innovation adoption	X	
Risk aversion		
Goal-oriented	X	
Shopping around		X
Brand-channel involvement		X
Internet used trend		
Internet used frequency	X	

- (2) Innovativeness, procurement types and degree of Internet usage are intermediate variables.  
 (3) The innovativeness attribute of consumers has direct and positive effect on procurement type.  
 (4) The innovativeness and basic characteristics of consumers have statistical influence on MDA product

attributes, channel attributes and upgrade attributes.

The above findings are significant to the theoretical and managerial implication in the following aspects :

- (1) This research results are consistent with innovation diffusion theory, cost and efficiency theory and social-psychology theory of information searching.  
 (2) The innovativeness of consumers may be used to explain the reason of Consumers' procurement style.  
 (3) The innovativeness of consumers may be used to exploit and design the product differentiation strategy. Businesses may use new products, fashion style and high price strategy for consumers of high innovativeness, use brand-building, information service and advertise promotion for consumers of medium innovativeness and use brand-building, convenient procurement and low price strategy for consumers of low innovativeness. The conclusions are summary in table 4.  
 (4) The basic characteristics of consumers may be used to exploit and design the promotion and market segmentation strategies. For example, Businesses may offer high compatible and high expansive product for male or consumers of high innovativeness. Businesses may offer basic functional and integrated of hardware and software product for peoples ages from 46 to 50 or architects and builders or free-lancer or consumers of low innovativeness. Businesses may offer professional services and promotion for female or graduates or mouth incomes of seventy-eighty thousand or consumers of low innovativeness. Businesses may offer excellent repairs and guarantees for incomes of ninety-one hundred or consumers of low innovativeness, and offer additional information services and price discount which will produce more attractive effects for consumers of low innovativeness. The conclusions are summary in table 5.

Table 4. The summary of consumer's innovativeness and the degree of PDA product and channel attributes

PDA	Product attributes	Channel attributes	Upgrade attributes
Early adoption type	Product style (+) New/old machine (+) Chinese friendly (-)		
Early majority type	Famous (+) Size and function (+) Basic operation (-) Easy to use (-) Price (-)	Information service (+) Promotion (+)	Enlarging memory (+) Color LCD screen (-)
Late majority type	Price (+) Public praise of friends (+)	Price and discount (+) Store nearby (+) Convenience of return or exchange of goods (-)	

Table 5. The summary of consumers' basic characteristics and the degree of PDA product and channel attributes

PDA	Product attributes	Channel attributes	Upgrade attributes
Sex	Compatibility factor (male) Sources of information factor (female)		Compatibility factor (male)
Age	Function factor (46~50 years old)		
Education	Sources of information factor (graduate level)		Appearance and style factor (graduate level)
Occupation	Appearance and style factor (architects and builders) Function factor (architects and builders)		Compatibility factor (Bankers and insurer) Appearance and style factor (architects and builders)
Grade	Function factor (free-lancer)		
Income	Sources of information factor (70~80 thousand)	Excellent repairs and guarantees (90~100 thousand)	
Innovativeness	Compatibility factor (early majority) Function factor (Late majority) Sources of information factor (late majority)	Professional services and promotion (late majority) Excellent repairs and guarantees (late majority) Price discount (late majority)

## Abstract

The mobile Internet exists already in very many forms on the market. However, there are definitely still a lot of possibilities to improve the current concepts and solution, and thus a lot of room for future R&D activities. This paper is divided five parts as followings:

First of all, introduction; Secondly, the basic concept of mobile Internet is introduced, and its' development status is described simply; Thirdly, the process of come into being M-commerce based on Internet and the existing modes of M-commerce are discussed respectively; the differences between E-commerce and M-commerce are also shown in the paper; Fourthly, an M-commerce system model is presented, the model involves its' basic elements such as hierarchical architecture, management mechanism, system decision-making, application procedure etc; Fifthly, development trend and application fields for coming the new economics times are forecasted; Finally, how to build a M-commerce management system and make applications for business via CERNET\*\* (one of the biggest Internet platform in China) are introduced primarily in end of the paper.

## 1. Introduction

The booming Internet provides to people many conveniences and unlimited business chances. E-commerce has well known, for example, is one of the modern business models, nevertheless novelty mobile Internet is emitted today along with developing Internet & mobile communication technologies as well as people's imperious demands progressively. However, the mobile Internet is enlarging application fields of Internet-based E-commerce, at the same time, it opens up another way for suiting the future business. Therefore the mobile Internet-based named M-commerce (mobile commerce) is appeared slowly in the forefront of new economics times as a novel commerce mode. Nowadays "Mobile" has used widely in many fields with correlative daily life, such as mobile finance, mobile office, mobile mailbox, mobile classroom, mobile hospital, mobile bank, mobile phone, mobile computer, as well as mobile battle ..... so many "mobiles," they are popular in kinds of social and economical fields, and more and more press close to people's daily life, their mutual "mobility" is achieved by the mobile Internet. So we can regard justly the M-commerce as a capacious stage for the future business based on developing rapidly Internet, it is not only a

novel business mode but also a landmark effecting home social development and human behavior, and it can also supply an opportunity to span some stages of economical development for the developing countries.

In the near years, E-commerce has been discussed widely despite there isn't uniform appraise. However in the modern information society, E-commerce is an inevitable result of technique development and society progress, on the other hand it is also an innovation special for the developing counties, and its' progress is suffocated because of its' juvenility and imbalance in the global information industry. Whereas E-commerce is one of important step for the inevitable global information process, it is the means resource of new economics. In the new economics times, M-commerce will become a main mode of E-commerce, hereby it is important and necessary that understand and research M-commerce facing the coming "mobile times".

## 2. Mobile Internet and Its' Current Status

Mobile Internet is a large-scale and expansive application platform that be consisted of mobile communication system and Internet architecture, as well as relative advanced information technologies. The current status of M-commerce is shown by some characteristics as followings: Firstly, the M-commerce services is mushrooming to become a large-scale industry in some developed countries, but it is very imbalance over whole world, especially for developing countries such as the poor Africa country; Secondly, so far there isn't an integrated system architecture & uniform management model for M-commerce in the world; Thirdly, some factors such as techniques, management, society credit system, and so on, they can't yet ensure absolutely the reliability of some M-commerce applications, this is a very important factor that restrict farther development and enlarging application fields of M-commerce in the future. Fourthly, lack of uniform fare rules, for example, there isn't fair and reasonable model for measuring all M-commerce trades between company and company or company and customer, the existing incomplete model can't accept by all traders and customers yet.

## 3. Existing M-Commerce Mode

"Limited fast-moving" is an important character of existing M-commerce mode. The existing M-commerce mode is developed mainly from the original shape based

mobile interconnection, transmit speed and stability are not satisfied enough, input difficulties yet no solution and there is no rich, effective applications. If we cannot solve these problems, mobile Internet could only be remaining as a concept to affect M-commerce farther develop.

Altogether, some key factors for the M-commerce development in China could then be summarized as:

★ With the popularization, charge rate will become more and sensitive to utilization of M-Internet.

★ New technologies will bring opportunities for M-commerce.

★ Regulation policy and business model are both key issues for the growth of M-commerce in China.

## 6. CERNET Introduction

CERNET [6] is one of the biggest Internet platforms in China. Nowadays, the network is consisted of 8 GigaPop center nodes, 36 MigaPop main nodes, connecting cities over 160, members over 900, users over 9 million (latent users over 320 million). There are many testbeds such as IPv6 testbed between China and Japan, 3Tnet, NSFCNET, CERNET and CERNET2, they are connecting to Internet2 and APAN ect., it will become one of the most important application platform for M-commerce in the future in China.

## Autobiography

Qinghui Zeng (qhzheng@cernet.edu.cn, <http://www.edu.cn>) received the PhD degree in information & communication engineering from Huazhong University of Science & Technology, China in 2001.

He is currently a member of IEEE, IEEE-CS and CSEE. He is also a senior member of CSSE. He was awarded the top paper prize in information management engineering from National Information Center of China and second research prize in computer control and its application in electronics and information systems from CSEE, and top doctoral prize from Huazhong University of Science & Technology and the top graduate student prize from The Eastern Communication Co., LTD., He has published more than 50 papers in domestic and international journals such as IEEE, IEE, ICEE, Chinese Journal of Electronics, Computer Application, System Engineering, Decision Science & Application, High Technology Letter, Computer Engineering & Application and the proceedings of International conference on Management/Telecom/Industrial/ Engineering ect..

Dr. Zeng is currently studying in Network Research Center of Tsinghua University as an associate professor & senior engineer and working in Tsinghua University as a postdoctoral researcher of Department of Computer Science & Technology of Tsinghua University. His research interests are information & communication engineering, information management & decision-making system, mobile wireless Internet, network economics, mobile multimedia communication, intelligent information processing, hierarchical fuzzy control technology and their application.
