# Welcome Messages from Conference Chair

On behalf of the Institute of Information Management of the National Chiao Tung University, I am pleased to welcome you to Taipei and the Second International Conference on Electronic Business. I would like to thank you for choosing to participate in the conference, and hope all of you to find this city full of exciting events, including fabulous Chinese art treasure exhibitions and fascinating night markets.

The Second ICEB conference continues to be a unique venue bringing together leading researchers and practitioners in all areas of e-Business. We have received well over 284 paper submissions and have accepted and included 205 papers in the proceedings. We would like to thank all the authors for submitting to ICEB 2002. This conference provides a major forum for e-Business researchers, practitioners, developers, and users to present their work and discuss critical issues and views on leading-edge e-Business management, practices and opportunities. We certainly hope this conference will provide an excellent overview of the concerns and results of frontier e-business research.

We are greatly honored to announce that Prof. Chun-Yen Chang, President of National Chiao Tung University, has agreed to attend the opening ceremony. Also, three prominent speakers, Prof. Chiang Kao, President of National Cheng Kung University; Prof. Che-Ho Wei, Chairman, National Science Council; and Dr. Quincy Lin, Senior Vice President and CIO, Taiwan Semiconductor Manufacturing Company (TSMC) are going to give keynote speeches in our conference. Prof. Phillip Ein-Dor, Tel-Aviv University, Founding Editor, Journal of AIS; Steve Chang, Founder, Chairman and CEO of Trend Micro Inc.; Prof. Edgar H. Sibley, George Mason University, Editor, Information & Management; and Prof. Po-Lung Yu, Distinguished Professor, National Chiao Tung University will give special presentations in the joint sessions of keynote & panel. Also, seven journal editors, Professors Phillip Ein-Dor, Edgar H. Sibley, G. S. Kuo, Eldon Y. Li, Jos Lemmink, Timon C. Du, and HsiuJu Rebecca Yen have agreed to serve as panelists in the journal editor panel. Moreover, in collaboration with this conference, several journals such as Decision Support Systems and International Journal of Electronic Business, etc., have dedicated special issues/sections for outstanding papers presented in the conference.

The conference would not have been a success without help from so many people. I would like to express my sincere thanks to Faculty of Business Administration, The Chinese University of Hong Kong; Centre for E-Business, National University of Singapore; and Research Center for Contemporary Management, Tsinghua University for co-organizing this conference. I would also like to thank Professors Eldon Li, Jian Chen and Duen-Ren Liu for coordinating paper review, Professors Baoding Liu, Eldon Li, Waiman Cheung, Lihua Huang, and James Ang for promotion and program organization, Duen-Ren Liu for the production of the proceedings, and Ms. Susan Chen for all the administrative supports. Also, I would like to express my deepest gratitude to conference sponsors, National Science Council, Ministry of Education, HP Taiwan, Trend Micro Inc., IBM, Polaris Securities Group, TSMC, UMC, ZyXEL Communications Corp., Computer & Communications Research Laboratories / ITRI, and Institute for Information Industry, Taiwan.

We sincerely hope you experience the warm feeling of hospitality extended by Institute of Information Management, National Chiao Tung University. Finally, enjoy your stay at the Grand Hotel, and the forums provided in the conference.

**Chi-Chun Lo, Ph.D.**  
Conference Chair

# Organizing Committee

## Organizer

Institute of Information Management, National Chiao Tung University, Taiwan

## Co-organizers

The Chinese University of Hong Kong, Hong Kong  
National University of Singapore, Singapore  
Tsinghua University, China  
International Consortium for Electronic Business

## Conference Advisors

Han-Lin Li, Dean, College of Management, National Chiao Tung University, Taiwan  
Tien-Sheng Lee, Dean, Faculty of Business Administration, The Chinese University of Hong Kong, Hong Kong  
Christopher Tang, Dean, Faculty of Business, National University of Singapore, Singapore  
Chunjun Zhao, Dean, School of Economics and Management, Tsinghua University, Beijing, China

## Conference Chair

Chi-Chun Lo, National Chiao Tung University, Taiwan

## Conference Coordinators

Waiman Cheung, The Chinese University of Hong Kong, Hong Kong  
James Ang, National University of Singapore, Singapore  
Jian Chen, Tsinghua University, China  
Lihua Huang, Fudan University, China  
Eldon Y. Li, California Polytechnic State University, USA

## Program Committee Co-chairs

Chyan Yang, National Chiao Tung University, Taiwan  
Duen-Ren Liu, National Chiao Tung University, Taiwan

## Proceedings Editor

Duen-Ren Liu, National Chiao Tung University, Taiwan

## Local Arrangements Chair

An-Pin Chen, National Chiao Tung University, Taiwan

## Local Arrangements Committee

Ruey-Shun Chen, National Chiao Tung University, Taiwan  
Duen-Ren Liu, National Chiao Tung University, Taiwan  
Lee-Ing Tong, National Chiao Tung University, Taiwan  
Min-Jen Tsai, National Chiao Tung University, Taiwan  
Hsiao-Cheng Yu, National Chiao Tung University, Taiwan

## Conference Secretary

Ms. Susan Chen, Miss Vickie Perng, National Chiao Tung University, Taiwan

# Keynotes & Panels

## **Keynote Speech: Technology and Management Aspects in Electronic Business**

Prof. Chiang Kao, President, National Cheng Kung University

## **Keynote Speech: Scientific Research in Taiwan**

Prof. Che-Ho We, Chairman, National Science Council, Taiwan

## **Keynote Speech: Challenges and Opportunities of e-Business in the Next Decade**

Dr. Quincy Lin, Senior Vice President & CIO, TSMC, Taiwan Semiconductor Manufacturing Company Ltd

## **Keynote & Panel Discussion I**

### **Keynote: Fifty Years On – Business Computing in 2051**

Prof. Phillip Ein-Dor, Tel-Aviv University; President, Association for Information Systems;  
Founding Editor, Journal of the Association of Information Systems

**Moderator:** Prof. Waiman Cheung, The Chinese University of Hong Kong

**Panelists:** Hemant Jain, Wisconsin Distinguished Professor, University of Wisconsin – Milwaukee;  
Jian Chen, Tsinghua University;  
Chyan Yang, National Chiao Tung University

## **Keynote & Panel Discussion II**

### **Keynote: A World Safe for Exchanging Digital Information**

Steve Chang, Founder, Chairman and CEO of Trend Micro Inc.

**Moderator:** Dr. Jyh-Sheng Ke, Vice President, Institute for Information Industry, Taiwan

**Panelists:** Shun-I Chu, President, ZyXEL Communications Corporation;  
Wayne Pai, President, Polaris Securities Group;  
Terence Liao, General Manager of Business Critical System and Software Group of HP Taiwan

## **Keynote & Panel Discussion III**

### **Keynote: Problems and Research Aspects of Web Security**

Prof. Edgar H. Sibley, Eminent Scholar, George Mason University; Editor, Information & Management

**Moderator:** Dr. Bao-Shuh Paul Lin, Vice President & General Director, Computer & Communications Research Laboratories, Industrial Technology Research Institute, Taiwan

**Panelists:** Shrane Koungh Chou, National Chengchi University;  
Baoding Liu, Tsinghua University;  
Jing-Jang Hwang, Chang Gung University

## **Keynote & Panel Discussion IV**

### **Keynote: Human Aspects: An Important Factor for Successful e-Business**

Prof. Po-Lung Yu, Distinguished Professor, National Chiao Tung University;

C. A. Scupin Distinguished Professor, KU Business School, University of Kansas

**Moderator:** Prof. Han-Lin Li, Dean, College of Management, National Chiao Tung University

**Panelists:** James Ang, National University of Singapore;

Ting-Peng Liang, National Sun Yat-Sen University / The Chinese University of Hong Kong

## **Journal Editor Panel Discussion**

**Moderator:** Prof. Eldon Y. Li, Founding Editor, International Journal of Electronic Business

**Panelists:** Timon C. Du, Managing Editor, International Journal of Internet and Enterprise Management;

Phillip Ein-Dor, Founding Editor, Journal of AIS;

G. S. Kuo, Editor-in-Chief, IEEE Communications Magazine;

Jos Lemmink, Editor, International Journal of Service Industry Management;

Edgar H. Sibley, Editor, Information & Management;

HsiuJu Rebecca Yen, Managing Editor, International Journal of Internet Marketing and Advertising

## **Industrial Presentation: What is e-Business? And Why is it crucial to the future success of your business?**

Dr. Mike H. C. Lee, President & COO of Com2B Corp.

# Technology and Management Aspects in Electronic Business

Chiang Kao

President of National Cheng Kung University, Tainan, Taiwan

Technology has been considered by most people as a key factor to the success of economic development of a country and productivity improvement of an industry. An argument is that without the support of sound management systems, the contribution of technology would be limited. In an empirical study, it is found that the productivity of the machinery firms in Taiwan is affected by both technology and management. The mathematical relation is  $Productivity = 1.7836(Technology)^{0.0449}(Management)^{0.3357}$ . The exponent of Management is approximately 7.5 times of that of Technology, indicating that the former is 7.5 times effective than the latter in improving productivity. With that equation, a firm is able to derive suitable strategies to improve productivity taking into account the constraint on time and budget. The same concept should be applicable to Electronic Business. A research topic will be developing proper measurements for technology, management, and performance indicators for Electronic Business.

## **Fifty Years On – Business Computing in 2051**

Phillip Ein-Dor

Professor and Chair of New Economy Information Systems

Faculty of Management

Tel-Aviv University

eindor@tau.ac.il

It is now just over 50 years since the deployment of LEO – the first business computer and application – in 1951. This presentation will attempt to look 50 years ahead in order to discern the nature and effects of business computing in 2051.

Scenarios will be offered of some possible business applications fifty years hence. These include the business information systems in space, the nature of manufacturing, and social effects.

The scenarios will serve as a basis for addressing a number of issues. These include the availability of technology to support the scenarios presented, the nature of organizations shaped by future information systems, the nature of employment in the new organizational structure, consumer-vendor relations in the new economy, the effects of the new information technology on the nature of national governments, and the effect of information technologies on the structure of the global economy.

## **Problems and Research Aspects of Web Security**

Edgar H. Sibley

University Professor, Eminent Scholar  
Information and Software Systems Engineering  
George Mason University  
esibley@gmu.edu

There are many different users of Web technology today, from people buying through electronic commerce systems to those using collaboration technology to work at a distance. Users assume a safe and uninterrupted session. The consequence of hackers, crackers, and denial of service attacks therefore becomes a major problem to organizations today. Research in the field is, however, complex and sometimes difficult.

The Keynote Speech will therefore deal with secure systems research, including:

- The difficulty in setting up a laboratory to perform such research and defining "normal" and "abnormal" traffic, tagging one so that it can be identified when analyzing the flow, both in front of and behind the firewall of an enclave;
- The detection of and partial relief from such attacks as mail bombs, viruses, and Distributed Denial of Service;
- Providing safe conversations across country boundaries for situations needing disclosure of material at designated times to participants; and
- Policy aspects that control such operations and their analysis.

# Human Aspects: An Important Factor for Successful e-Business

Po-Lung Yu

Distinguished Professor, National Chiao Tung University

C. A. Scupin Distinguished Professor, KU Business School, University of Kansas

yupl@cc.nctu.edu.tw

Information technology has changed the landscape of doing business, streamlined the information processing and changed the logistics of the flows of information, materials, cash and product designs of product and service. In this increasingly competitive business world, information technology plays a vital role in business management. However, decision making, strategic planning, consuming and designing are done by humans. If the products or services cannot satisfy the customers' needs or release their pains and frustrations, the product and service could not sell. The business will fail.

In order to have a competitive edge, a company must be able to have insight into potential customers' needs both currently and in the future. A business must understand customers' real pains and desires and produce and deliver products or services that satisfy their needs and relieve their pains and frustrations. In order to reach such a state of competitiveness, a company must become insightful about potential customers' needs and changes in those needs. In addition, it must have maximum flexibility and liquidity to reorganize resources—including human resources, skills, and information—to produce excellent, low-cost goods and services that satisfy the customers' needs ahead of its competitors. A company can compete and survive only by continuously renovating and improving. The company needs to be effective and efficient to design and produce products or services with a lower cost but higher quality. To do so, the company needs to continuously innovate in all areas, including designing, production skills, production procedures, channels of distribution, services and management reengineering, etc., so that it can be ahead of its competitors.

Our thoughts and thinking paradigms are represented by circuit patterns of our billions of neuron cells. These circuit patterns are our mental programs or human software, which drive our brains (a very super computer) to work. The totality of these circuit patterns and their operation are known as our habitual domains or human software. Our habitual domain or software goes with us wherever we go and has a great impact on our behavior and on our competitiveness. We can say that in ever-intensifying competitive situations, the key factor for organizations, industries, societies or nations to succeed and prosper is to continuously upgrade, expand and enrich their competence or habitual domains.

In this talk, we will introduce the concepts of behavior mechanism and habitual domain as to show how we can continuously innovate, enrich and upgrade our competence and competitiveness as to prosper in this very competitive e-era business.

# Paper Sessions

## Session 1A: e-Service & Service Operations on the Web

### **Building E-Service Systems: From Planning to Implementation**

Hiroshi Tsuji, Osaka Prefecture University  
Masato Terada, Hitachi Ltd.

### **Cost and Benefit Analysis for E-Service Applications**

Jie Lu, Guangquan Zhang, University of Technology, Sydney

### **Internal Customer Service: The Potential for E-Service**

Simon Croom, Robert Johnston, University of Warwick

### **In-Depth Revealing Grid Based Web Service Provision Model: Grid Service Provision (GSP)**

Huinan Xu, University of Surrey  
Xiaoming Cong, University of Luton  
Phil Seltsikas, University of Surrey  
Kaushik Pandya, University of Luton

## Session 1B: Collaborative Commerce & Group Support

### **Planning and Deployment of Collaborative Commerce: A Conceptual Framework**

Ta-Tao Chuang, Gonzaga University  
Kazuo Nakatani, Florida Gulf Coast University

### **Reciprocal Effect of Team Commitment and Media Richness in eCollaboration: A Conceptual Model**

Suprasith Jarupathirun, Hemant Jain, University of Wisconsin – Milwaukee

### **Building and Managing Social Capital in Virtual Communities**

Shafiz A. Mohd Yusof, Liaquat Hossain, Syracuse University

### **Research on Role-Centric Collaborative Technology**

Wei-Dong Zhao, Bin Cai, Fudan University

## Session 1C: SCM & e-Logistics

### **Perceived Importance of Success Factors of Firms Practicing E-Logistics in Supply Chain: An Exploratory Study on Extranet**

Wing S. Chow, Hong Kong Baptist University

### **Collaborative Integration between IT Industry and Logistics Industry in Taiwan: A Case Study on T Company's E-Logistics Plan**

Huei-Huang Chen, Yu-Chung Hung, Ching-Chuan Hsieh, Tatung University

### **Impact of Information Sharing in Supply Chain Management**

Takahiro Tsuksihama, Hitachi, Ltd  
Hisashi Onari, Waseda University  
Toshimitsu Hamada, Nasu University

### **Upstream R&D Competition and Cooperation in a Two-Tier Supply Chain**

Pei-Jun Huo, Jian Chen, Tsinghua University  
Ji-Xiang Chen, Shanghai Jiao Tong University

## **Session 1D: Decision Support & Intelligent Systems**

### **A Decision Support System for Construction Project Risk Assessment**

Shih-Tong Lu, National Central University

Gwo-Hshiung Tzeng, National Chiao Tung University

### **An On-Line Personalized Promotion Decision Support System for Electronic Commerce**

Chin-Feng Lee, S. Wesley Changchien, Yu-Jung Hsu, Chaoyang University of Technology

### **Efficiency Increase of Export On-Line Systems by Applying Multiple Criteria Decision Support Systems**

Arturas Kaklauskas, Edmundas Kazimieras Zavadskas, Vilnius Gediminas Technical University

Antanas Zenonas Kaminskas, Lithuanian Government

Vaidotas Trinkunas, Jurate Kaklauskienė, Vilnius Gediminas Technical University

### **A Detailed Procedure for Using Copulas to Classify E-Business Data**

Victor L. Berardi, B. Eddy Patuwo, Michael Y. Hu, Kent State University

## **Session 1E: Technology Management**

### **Measuring IT Contribution to Company's Competitive Advantages**

Edward Cheong-Tsair Ho, Harchand Singh Thandi, Swinburne University of Technology

### **Collectivism, Machiavellianism, Perceived Organizational Justice and Organizational Citizenship Behavior: An Empirical Study of Chinese Employees**

Ruolian Fang, Vivien K.G. Lim, National University of Singapore

### **Applying Business Models for Risk Management in E-Business**

Andrew Finegan, RMIT University

### **Implications of Virtual Interviews as a Global Recruitment Tool**

Stevina Evuleocha, California State University, Hayward

## **Session 1F: Internet Marketing**

### **The Internet Shopping Process: An Empirical Model, Research Findings, and Financial Implications**

Tung-Zong Chang, Su-Jane Chen, Metropolitan State College

### **Internet Advertising: A Comparison of Pricing Strategy**

Seng-Su Tsang, Jung-Kuo Chuang, Yuan Ze University

### **4Ws E-Marketing Strategy: A Conceptual Framework of its Antecedents and its Consequences on Web Performance**

Luís Filipe Lages, Universidade Nova de Lisboa

Carmen Lages, Paulo Rita, ISCTE- Instituto Superior das Ciências do Trabalho e da Empresa

### **Consumer Perceptions of Traditional and Electronic Markets**

Nitaya Wongpinunwatana, Thammasat University

Chanchai Buratavorn, Bank of Thailand

Panchama Vipamas, Siam Steel Cycle Company Limited

Sorajak Jantarabenjakul, Bank of Thailand

## **Session 2A: e-Business Entrepreneurship**

### **E-Government Deployment for the 21st Century**

Manual Avitia, Jonathan Lee, California Polytechnic & State University

### **E-Government and Lessons from E-Commerce: A Preliminary Study**

Grace Zhaohui Liu, American Management Systems, Inc.

Russell K.H. Ching, Nancy Tsai, California State University, Sacramento

### **Taxation of Electronic Commerce**

Peter Horn, L' Ecole Nationale des Ponts et Chaussees

### **The Systematic Thinking on the Development of Chinese E-Business**

Shanchong Shi, Tianjin University

Zhanping Zuo, Kuan Han, Hebei University of Economy & Trade

## **Session 2B: Electronic Commerce Management**

### **A New Business Model of Electronic Commerce with Innovative Strategies**

Ming-Hsien Yang, Wen-Shiu Lin, Mei-Hua Fan, Shang-Chia Liu, Fu-Jen Catholic University

### **A Measurement Model of Trust in Internet Stores**

Liping Liu, Cathy C. Li, University of Akron

Steven J. Karau, Southern Illinois University

### **Designing E-Commerce Product Innovation Strategies to Disrupt Existing Industries**

George M. Puia, Saginaw Valley State University

Xiaohua Yang, Bond University

### **Classifying E-Commerce Trust Seals: An Analytical Framework**

Te-Wei Wang, Chih-Chen Lee, Ena Rose-Green, Florida International University

## **Session 2C: SCM & e-Logistics**

### **Collaboration: Spirit of Supply Chain Management**

Babak Akhgar, Jawed Siddiqi, Saadat M. Al-Hashmi, Sheffield Hallam University

### **The Impact of Internet-Based Technologies on the Procurement Strategy**

Margaret L. Sheng, National Chi Nan University

### **Integrate the Information Technology with Supply Chain Management: A Trend of the Electronic Business in the New Century**

Liuying Yin, Youle Fan, South China University of Technology

### **Some Models for Understanding the Incentives for Supply Chain Collaboration**

Henry C. Co, California Polytechnic & State University

Sharafali Moosa, National University of Singapore

## **Session 2D: Decision Support & Intelligent Systems**

### **A Multiple Criteria Decision Support Web-based System for Facilities Management**

Edmundas Kazimieras Zavadskas, Arturas Kaklauskas, Vilnius Gediminas Technical University

Antanas Zenonas Kaminskas, Lithuanian Government

Andrius Gulbinas, Natalija Lepkova, Jurate Kaklauskienė, Vilnius Gediminas Technical University

**The Design of a Web Snapshot Management System for Decision Support Applications**

David Chao, San Francisco State University

**Group Decision Making for a Fuzzy Software Quality Assessment Model to Evaluate User Satisfaction**

Shu-Yen Lee, China Engineering Consultants, INC.

Tsung-Yen Lee, National Taiwan University

Yeh-Jui Fey, Ling Tung College

Huey-Ming Lee, Chinese Culture University

**Development of a DSS to Estimate the Sales for the Retailing Industry in Taiwan**

Ching-Chin Chern, David Ming-Huang Chiang, National Taiwan University

Ting-Wei Ho, Industrial Technology Research Institute

**On the Accuracy of Judgments in the AHP**

Hong Ling, Limin Lin, Mingxing Han, Lianliang Tan, Fudan University

**Session 2E: Technology Management**

**Reexamining the Benefits of Information Systems in Japanese Manufacturing Companies**

Osam Sato, Tokyo Keizai University

Yoshiki Matsui, Yokohama National University

**An Empirical Study of Business Strategy and Performance**

Choong Y. Lee, Pittsburg State University

**Reconsidering Adoption Behavior: Models Beyond Diffusion**

Steven J. Dick, Southern Illinois University

**Taiwan Internet Diffusion: An Empirical Study of Internet Interactive Effects**

Hsiang-Chi Huang, Institute for Information Industry

**Allying BPR with Strategy: A New Perspective for BPR**

Xiao-Xia Huang, Shao-Zu Mei, University of Science and Technology Beijing

**Session 2F: Internet Marketing**

**Optimal Online Interactive Service Policy and Pricing Decision with Negative Network Externality**

David C. Teng, David M. Chiang, National Taiwan University

**Use of Graphic Images and Text Characters in Internet Banners as an Effective Marketing Tool**

Eric Kin Wai Lau, City University of Hong Kong

**Why People Forward Emails to Others?**

Tom M. Y. Lin, Heng-Hui Wu, National Taiwan University of Science and Technology

**Motivation and Consumer Knowledge on Processing Online Advertisement**

Alex Wang, Emerson College

**Cyber-Marketing will Become the Mainstream of E-Commerce Development in Future**

Xuping Jiang, Tsinghua University

Aiqun Yao, Agriculture University of China

### **Session 3A: e-Business Entrepreneurship**

#### **E-Business Investment in the Travel Industry: A Preliminary Study**

Sophia Wang, National Dong Hwa University  
Waiman Cheung, The Chinese University of Hong Kong

#### **A Proposed Framework for Influencing Factors of Partnership in E-Marketplace**

Hsueh-Foo Lin, National Pingtung Institute of Commerce  
Shin-Yi Lai, China Development Industrial Bank  
Fu-Hsuan Ting, Makalot Industrial Co., Ltd.

#### **Winning in Digital Economy**

Nikhil Agarwal, A.M Sherry, Institute of Management Technology, Ghaziabad

#### **'Do It Yourself (DIY)' E-Business Solutions for Small and Medium Enterprises**

George Q. Huang, JB Zhao, University of Hong Kong

### **Session 3B: Electronic Commerce Management**

#### **A Loss-Free Micropayment Protocol for Multimedia Services**

Jing-Jang Hwang, Chang Gung University  
Jung-Bin Li, National Chiao Tung University

#### **Planning and Decision-Making Process of a Strategic IT Investment: A Case of a Web Content Management System in a Financial Organization**

Petri Hallikainen, Hilikka Merisalo-Rantanen, Kari Nurmimäki, Helsinki School of Economics

#### **An Example of E-Commerce Platform in Anhui Tobacco Corporation**

Bin Ding, Xiaojian Chen, Qinglong Tang, Xiaomin He, University of Science and Technology of China

#### **ePrice Comparator: An Automated Internet Price Comparison System**

Drew Hwang, California State Polytechnic University  
Amy Chen, ACME Portable Machines, Inc.

### **Session 3C: SCM & e-Logistics**

#### **The Impact of Early Order Commitment on the Performance of a Simple Supply Chain**

Xiande Zhao, The Chinese University of Hong Kong  
Jinxing Xie, Tsinghua University  
Jerry C. Wei, The University of Notre Dame

#### **Multiple Objective Planning for Production and Distribution Model of Supply Chain: Case of Bicycle Manufacturer**

Gwo-Hshiung Tzeng, Yu-Min Hung, Min-Lan Chang, National Chiao Tung University

#### **E-Supply Chain Integration for Inter-Enterprise Business Practices**

Chian-Hsueng Chao, National University of Kaohsiung

#### **The Integration of the Third Party Information Resources: The Informationalization Breakthrough for Enterprises Based on the Star Supply Chain Management**

Bo Jiang, Nan He, Na Zhao, Zhao Zhao, Xin-Lu Yang, Northern Jiaotong University

### **Session 3D: Decision Support & Intelligent Systems**

#### **Modeling Decision Systems via Uncertain Programming**

Baoding Liu, Tsinghua University

#### **A Kind of Parallel Evolutionary Algorithms and Its Application in E-Business**

Yan Zhu, Jian Chen, Tsinghua University

#### **The Evolution of Internal Representation**

Ray Tsaih, Wen-Chyan Ke, Chia-Yu Liu, National Chengchi University

#### **A Feature Weighting Method by Multimedia Data Model on E-Business**

Young-Jun Kim, Cheonan College of Foreign Studies

### **Session 3E: Information Technology & Management**

#### **A Comparative Research on Competitiveness of Information Industry of China vs. Korea**

Chang'en Zheng, Yimin Han, Qiwen Wang, Peking University

#### **Standard Single Data Table Web Management Information System Through ASP**

Yuan-Hsi Hsu, Feng Chia University

#### **The Role of the Relational Database Model in E-Business**

Terrence D. Quinn, California Polytechnic & State University

#### **Application Service Provisioning in SMEs: The Tough Job after the Hype**

Marco Cantamessa, Emilio Paolucci, Politecnico di Torino – DSPEA

Davide Tosco, Istituto Superiore Mario Boella

#### **ENAT-PT: An Enhanced NAT-PT Model**

Li-An Zeng, Zhao-Hui Cheng, Li Ling, Songrong Qian, Xu Liao, Fudan University

### **Session 3F: Service Quality & Customer Relationship Management**

#### **A Virtual Prototyping Application (Let Customers Reveal Their "True" Preference)**

Lionel Wang, Marketing and Innovation, L.L.C

#### **Impact of Electronic Commerce Customer Relationship Management on Competitive Advantage: A Research Model and Issues**

Timothy Paul O'Keefe, Assion Lawson-Body, University of North Dakota

Abdou Illia, Eastern Illinois University

#### **Why are Self-Service Customers Loyal? -- A Relational Benefits Perspective**

HsiuJu Rebecca Yen, Yuan-Ze University

#### **CRM Implementation in PR China: A Preliminary Evaluation**

Satya P. Chattopadhyay, University of Scranton

### **Session 4A: e-Business Entrepreneurship**

#### **A Holistic Approach for E-Business Engineering**

Holger Luczak, Stefan Bleck, Tomaso Forzi, Peter Laing, Aachen University of Technology

#### **eBPS: A Strategic Framework for Successful Blueprint of E-Business Development**

Irene S.Y. Kwan, Lingnan University

**The Key Successful Factors of Internet Business: The Study of Online Bookshop**

Shu-Fang Chen, Dauw-Song Zhu, Tzy-Wen Tang, National Dong Hwa University

**Study on the Present Condition, Tendency and Countermeasure of E-Business in China**

Jianzhong Xu, Yunxiu Peng, Bing Li, Harbin Engineering University

**Session 4B: Electronic Commerce Management**

**A SMIL-Based Catalog Presentation System in Electronic Commerce**

Sheng-Tun Li, Hung-Chi Chen, Huang-Chih Hsieh, National Kaohsiung First University of Science and Technology

**Influences of New Trend in Development of American and Canadian E-Business upon Mainland Enterprises and Our Development Strategies**

Danyang Zhu, Guangdong Textiles Imp. & Exp. Corp.

**Tourism Website Development and User Requirements: Who are Tourism Website Users and What are Their Requirements in China**

Zi Lu, Hebei Teacher's University; University of Technology, Sydney

Jie Lu, University of Technology, Sydney

**The Yield Management of Tourist Enterprises**

Rong Kang, Northwest University, Xi'An

Yue Wu, Shaanxi Supply Industry Group Co. Ltd

Bingyang Liu, Northwest University, Xi'An

**Session 4C: SCM & e-Logistics**

**Inventory Management with the Internet-Based Direct Channel in a Two-Echelon Supply Chain System**

Wei-Yu Kevin Chiang, University of Maryland, Baltimore County

George E. Monahan, University of Illinois at Urbana-Champaign

**The Realization of a Stochastic Optimization Model for the Empty Container Inventory Based on EDI Information**

Xin Shi, Shanghai Maritime University

**A Fuzzy Logic and Genetic Algorithm based Supplier Performance Evaluation Methodology for an Effective Supply Chain**

Rajkumar Ohdar, Pradip Kumar Ray, Indian Institute of Technology

**Inventory Policy Implications of On-Line Customer Purchase Behavior**

Harry Groenevelt, University of Rochester

Pranab Majumder, Duke University

**Common Replenishment Strategies in Supply Chain under Uncertainty Demand Environment**

Huiying Zhang, Min-Qiang Li, Ji-Song Kou, Tianjin University

**Session 4D: Decision Support & Intelligent Systems**

**E-Mail as a Decision Tool for Asynchronous Group**

Hsu-Hsiu Cheng, Jyun-Cheng Wang, Chui-Chen Chiu, National Chung Cheng University

**Definable Strategies and Equilibria for Games**

Michel de Rougemont, University Paris II & LRI-CNRS

**Determining Successful Negotiation Strategies: The Evolution of Intelligent Agents**

Jong Yih Kuo, Fu Jen Catholic University

**Overcoming the Fixed-Pie Bias in Multi-Issue Negotiation**

Raymund Lin, Seng-Cho T. Chou, National Taiwan University

**Session 4E: e-Learning & Innovations in Teaching & Learning**

**E-Learning: A Study of Issues and Perspectives**

Andrew Finegan, RMIT University

**How to Setup a Successful E-Learning System for E-Business**

Tzu-Hsin Yang, Min-Jen Tsai, National Chiao Tung University

**Making a Case for Collaborative Business Planning: Educating Information Management and Systems Graduates for the Knowledge-Based Economy**

Angela Lin, Jonathan Foster, University of Sheffield

**Teaching Internet Entrepreneurship**

Gail Ross Waters, California State Polytechnic University, Pomona

**Teaching a Comprehensive Web Based Application within an IS Curriculum**

David C. Wallace, Illinois State University

**Session 4F: Service Quality & Customer Relationship Management**

**E-Business: Customer Acceptance**

Patrick Jaska, University of Mary Hardin-Baylor

Patrick T. Hogan, Columbus State University

**A Quality of Service Framework for Internet Share Trading**

Hong Xu, Jairo Gutierrez, Qiang Lu, University of Auckland

**Beyond Customer Relationship Management: Selling Chain Management for E-Business Practices**

Chian-Hsueng Chao, National University of Kaohsiung

**Towards Customer Knowledge Management: Integrating Customer Relationship Management and Knowledge Management Concepts**

Henning Gebert, Malte Geib, Lutz Kolbe, Gerold Riempp, University of St. Gallen

**Session 5A: Case Study in e-Business**

**How to Transition from a Traditional to an E-Business Enabled Real Estate Agency**

John Hamilton, James Cook University

Willem Selen, Macquarie University

**Value Creation in E-Business: The Case Study of Trend Micro**

Shih-Chang Hung, Tzu-Hsin Liu, Yee-Yeen Chu, National Tsing Hua University

**Approach to E-Business: A Case Study of Shanghai Tobacco Group Corporation**

Kun Zhao, Donghui Yu, Zhongming Chen, Lihua Huang, Fudan University

**Offline Empowerment: Key to the Success of E-Business in India**

Kalpana Mathur, Dhrupad Mathur, Jai Narain Vyas University

## **Session 5B: Electronic Commerce Management**

### **Cost-Benefit Analyses of Internet Investments**

Michael Holm Larsen, Kim Viborg Andersen, Copenhagen Business School

### **Study on the Search Cost in the Electronic Market**

Jian Chen, Yingxia Lin, Tsinghua University

### **An Intelligent Interface Integrated Services Environment for Electronic Commerce**

Chien-Chang Hsu, Fu-Jen Catholic University

### **The Optimal Ordering Periods for Internet Shopping under Time Dependent Consumer Demand**

Chaug-Ing Hsu, Wei-Chieh Lee, National Chiao Tung University

## **Session 5C: Enterprise Resource Planning**

### **Critical Successful Factors of ERP Implementation: A Review**

Allen J. W. Lian, Jim T. M. Lin, National Central University

### **Integrated Collaborative Planning Within the Supply Chain: The Future of ERP**

Mark Richter, California Polytechnic Pomona University

### **A Case Study of ERP Implementation Issues**

Tom Bramorski, University of Wisconsin-Whitewater

### **A Single Item Lot Sizing with Backorder and a Finite Replenishment Rate in MRP**

Liang Liang, Yugang Yu, Hongying Wan, University of Science and Technology of China

### **ERP is the Key Point of Supply Chain Management**

Xiao Chen, Jiahui Cheng, Tsinghua University

## **Session 5D: Data Warehousing & Data Mining**

### **A Bi-Directional Approach for Developing Data Warehouses in Public Sectors**

Monica Lam, Russell Ching, California State University, Sacramento

### **Query Optimization Techniques for OLAP Applications: An ORACLE versus MS-SQL Server Comparative Study**

Ahmed El-Ragal, Yehia Thabet, Arab Academy For Science and Technology

### **User-Based Web Recommendation System: A Case Study of the National Museum of History**

Kwoting Fang, Jonen Liu, National Yunlin University Science of Technology

### **Clustering Graduate Theses Based on Key Phrases Using Agglomerative Hierarchical Methods: An Experiment**

Jau-Hwang Wang, Ju-Cheng Hsieh, Central Police University

## **Session 5E: e-Learning & Innovations in Teaching & Learning**

### **The Relationships between Individual Differences and the Quality of Learning Outcomes in Web-Based Instruction**

Sherry Y. Chen, Brunel University

**Leveraging Enterprise-Wide Information System's Curriculum to Teach E-Business Concepts**

Paul Hawking, Brendan McCarthy, Victoria University

**An Empirical Study of Knowledge Creation and Interaction in Argumentation Setting**

ChingMiin Duh, YungTA Institute of Technology and Commerce

LiarnRung Wen, Meiho Institute of Technology

**A Study on Using Internet to Implement Constructivist Scaffolding Teaching for "Research Method" Course**

Szu-Yuan Sun, Pei-Chen Sun, Ming-Ching Zeng, F-S Wang,

National Kaohsiung First University of Science and Technology

**Session 5F: Service Quality & Customer Relationship Management**

**Combining Clustering and MCDM Approach for Evaluating Customer Lifetime Value Ratings**

Ya-Yueh Shih, Duen-Ren Liu, Gwo-Hshiung Tzeng, National Chiao Tung University

**Applications of Knowledge-Enabled CRM**

YiChen Lin, Southern Taiwan University of Technology

JrJung Lyu, National Cheng Kung University

ChiuShuang Chan, Southern Taiwan University of Technology

**Analyzing the Functional Frame of eCRM Based on Customer Value**

Bing Liang, Bo-Cheng Chen, Tsinghua University

**Linking Customer Retention to Intelligent Technology: An Optimization Approach**

Li-Shang Yang, University of South Australia

Chaochang Chiu, Yuan Ze University

Arthur Preston, University of South Australia

**Session 6A: Case Study in e-Business**

**Strategic Implementation of E-Procurement: A Case Study of an Australian Firm**

Xueli Huang, Rob Welsh, Edith Cowan University

**Performance Evaluation for 59 Listed Electronic Corporations in Taiwan**

Chien-Ta Ho, Lan-Yang Institute of Technology

**e-beauty: A Successful Model for B2C Business**

Rong Chen, The Chinese University of Hong Kong

Feng He, Shaanxi Normal University

**Payment Barriers in China's B2C Business**

Bin Qiu, Southeast University, Nanjing

Shu-Jen Chen, California State University, Fullerton

**Session 6B: Electronic Commerce Management**

**A Blueprint for Applications in Enterprise Information Portals**

Chyan Yang, Kuang-Ming Chen, Jun-Wei Yu, Chen-Hua Fu, Szu-Hui Wu, Fan-Pyn Liu,

National Chiao Tung University

**Atomicity Implementation in E-Commerce Systems**

Lars Frank, Uffe Kofod, Copenhagen Business School

**English as the Infrastructure Language for a Multilingual Internet**

Garry White, Southwest Texas State University

**Business Integration for the Hospital Medical History Database System by Using the Java Server Page and SQL Technique**

Ching-Liang Su, Song-Nan Hong, Jian-Mu Ke, Zhi-Ying Chen, Da Yeh University

**Session 6C: Operations Strategy for e-Commerce**

**Assessing the Impact of Internet Adoption Levels on Competitive Advantage**

Thompson S.H. Teo, Vivien K.G. Lim, National University of Singapore

**Investigating the Antecedents and Consequences of Attitude toward Web Site: A Web Content Attribute Perspective**

Kuo-Fang Peng, National Central University

Tong-An Hsu, Chung Yuan Christian University

**A Taxonomy of Operation Priorities in China**

Xiande Zhao, Tien-Sheng Lee, Yinan Qi, The Chinese University of Hong Kong

Huiying Zhang, Tianjin University

Chee-Chuong Sum, National University of Singapore

**Research on the Individuation of Client-Centered Ecommerce**

Xinsheng Ke, Yongqing Shen, Xuwei Li, Northern Jiaotong University

**Session 6D: Data Warehousing & Data Mining**

**Dynamic Pattern Matching Using Temporal Data Mining for Demand Forecasting**

Wen-Bin Yu, James H. Graham, Hokey Min, University of Louisville

**A Mining Algorithm under Fuzzy Taxonomic Structures**

Tzung-Pei Hong, National University of Kaohsiung

Kuei-Ying Lin, Chunghwa Telecom Co., Ltd.

Been-Chian Chien, I-Shou University

**OMARS: The Framework of an Online Multi-Dimensional Association Rules Mining System**

Wen-Yang Lin, Ja-Hwung Su, Ming-Cheng Tseng, I-Shou University

**Application of Text (Idea) Mining to Internet Surveys: Electronic Capture of the Structure of Ideas and Semantic Concepts**

Jeffrey E. Danes, California Polytechnic State University

**Knowledge Discovery Model in Chinese Industrial News**

Ju-Yu Huang, Jin-Wen Institute of Technology

Huey-Ming Lee, Chinese Culture University

**Session 6E: e-Learning & Innovations in Teaching & Learning**

**A Curriculum Development Project for IBM Linux in Academia Program**

Chih-Yang Tsai, Andrew Pletch, State University of New York at New Paltz

Arthur Palmiotti, Gerri Peper, Michael Wuest, Chris Rohrbach, Kevin Curley, IBM

**Moderators in the Adoption of E-Learning: An Investigation of the Role of Gender**

Yao-Kuei Lee, Tajen Institute of Technology

Keenan Pituch, The University of Texas at Austin

**The E-Commerce Application Experience in Selected Asian MBA Programmes**

Kin-Yu Cheung, Ping Zhao, Tsinghua University

**Importance of the Internet in University Curriculums: A Case Study at Sam Houston State University**

Mark R. Leipnik, Gurinderjit B. Mehta, Virginia Wilder, Sanjay S. Mehta, Sam Houston State University

**Considerations for Computer Ownership Policies**

Elena Salas, California State Polytechnic University of Pomona

**Session 6F: Service Quality & Customer Relationship Management**

**An Empirical Study of the Impact of IT Intensity and Organizational Absorptive Capacity on Customer Relationship Management Performance**

Ja-Shen Chen, Yuan-Ze University

Russell K.H. Ching, California State University, Sacramento

**Implement Innovative Proactive-Service-Center to Enhance Service Performance in Customer Site**

Richard Chiang, Frank H Chin, Applied Materials Taiwan

**Quality Management for an E-Commerce Network under Budget Constraint**

Yi-Kuei Lin, Van Nung Institute of Technology

**Customers' Acceptance of a Web Site for Product Information Search**

Ling-Ling Wu, Shi-Yi Su, National Taiwan University

**The Customer Resource Management in the Internet Age**

Minxue Huang, Yinfeng Song, Wuhan University

**Session 7A: e-Business Integration**

**The MTO-Framework for Implementation of E-Business Models**

Michael Holm Larsen, Heller Zinner Henriksen, Niels Bjørn-Andersen, Copenhagen Business School

**The Invisible Borders in Internet Transactions: An Empirical Study of eBay's Auction System**

Ruth L. Wang, Chien-Hua Li, Mike Lee, California State University, Sacramento

**Adaptive Inter-Organizational Workflow Management for E-Business Integration**

Han-Seup Kim, Sungjoo Park, Korea Advanced Institute of Science and Technology

**"Nothing Changes Overnight": The Diffusion and Acceptance of E-Business Experiences with New Ways of Working and Communication Processes**

Michael Jäckel, Christoph Rövekamp, University of Trier

**Session 7B: Electronic Commerce Management**

**Foundation for a Successful Web Site**

Aren Vartanian, California State Polytechnic University

**Missions for Executives in Developing an E-Management Platform**

Yen Zen Wang, Sheng Chung Chen, Far East College

**Global Geo-Demographic Data and GIS for E-Business**

Mark R. Leipnik, Sanjay S. Mehta, Rose Seidel, Sam Houston State University

**Utilize E-Commerce to Further Open the Door of China**  
Shan He, Zhongshan University

### **Session 7C: Operations Strategy for e-Commerce**

**Current Information Technology Infrastructure for E-Business**  
Nancy Tsai, Russell K.H. Ching, California State University, Sacramento

**Electronic Commerce Strategy for Small and Medium Enterprises: Case Studies of Korean Firms**  
Se-Hyung Cho, Konyang University  
Yong-Kyun Chung, Hankuk University of Foreign Studies  
Seung-Chul Kim, Hanyang University

**The Comparison in Cognition on Outsourcing Decision for Accounting and Taxation between Cross Straits**  
Chiung Feng Ko, Soochow University

**Adaptive Strategies of Firms in High-Velocity Environments: The Case of B2B Electronic Marketplaces**  
Jai Ganesh, T R Madanmohan, P D Jose, Indian Institute of Management Bangalore

### **Session 7D: Knowledge Management**

**Using Association Rule Techniques to Improve Document Retrieval**  
Timon C. Du, Jacqueline Wong, Honglei Li, The Chinese University of Hong Kong

**Peer-to-Peer Knowledge Management: Overcoming Bottlenecks and Improving Information Quality**  
Andreas Neus, Philipp Scherf, IBM Unternehmensberatung GmbH

**A Framework for Enterprise Knowledge Discovery from Databases**  
S. Wesley Changchien, Wen-Jie Lee, Chaoyang University of Technology

**The Feasibility and Method of News Mass Customization (NMC)**  
Youqin Zhu, Yongxian Wang, Tsinghua University

**Factors Influence Information and Knowledge Sharing in Organization**  
Jen-Ruei Fu, Van Nung Institute of Technology  
C.K. Farn, National Central University

### **Session 7E: e-Finance & Real Estate**

**An Overview of Financial E-Commerce**  
Dannel Te-Shan Wang, Shin-Herng Chu, Drew Hwang, California State Polytechnic University – Pomona

**The Impact of ECN on the Trading Structure of Taiwan's Securities Market**  
Chichang Jou, Ming-Hung Chen, Tamkang University

**Using Hidden Markov Model for Stock Day Trade Forecasting**  
Wen-Chih Tsai, An-Pin Chen, National Chiao Tung University

**E-Banking in Italy: An Analysis of the Evolution of Prices, Services and Competition Strategies**  
Emilio Paolucci, Gessica Balsamo, Politecnico di Torino – DSPEA

**Simulating the Investor's Behavior in Stock Market with an Intelligent Agent**  
FengYu Chang, DengYiv Chiu, Chung Hua University

## **Session 7F: Mobile Commerce & Business**

## Abstract

For building e-service systems, this paper discusses the difference between traditional system integration and e-service system integration. First, e-service systems should be planned by more than two companies who have different core competences. Second, project manager who builds an e-service system should integrate not only hardware nor software but also digital contents. Third, e-service systems are developed not for cost reduction but for customers' satisfaction. Paying attention to these points, this paper presents components, risks, building procedure, and office role for building e-service systems, and reviews our experiences.

## 1. Introduction

System integration is to build an application system by selecting components and connecting them. It is an important activity for system engineers. It includes system planning, transaction analysis, data base design, function design, implementation, and maintenance.

At current Internet era, there are new views for system integration. For building traditional systems such as banking system and inventory system, water-fall model [1] and rapid prototyping model [5] were well known to the project managers. Then there is the decisive question whether or not traditional project management works also for e-service project. Stoehr, T. provides 99 key success factors for managing e-business projects [9].

From our perspective, the traditional models can not be applied to e-service system integration because of three reasons while the target of e-service system is to transform our current life style and work style to new styles by using Internet technology (IT):

- (1) The e-service should be planned by more than two companies who have different core competences. Some companies have competence for system building while others have competence for electronic payment, logistics, system operation, human resources and so on [2]. In fact, Nikkei newspaper in Japan delivers new alliance articles everyday.
- (2) For building an e-service system, a project manager should integrate not only hardware nor software but also digital contents. Currently a variety of digital contents for education and entertainment are provided. Contents aggregation from a volume of contents

holders is attractive movement for customers [10].

- (3) In general, the traditional systems were developed for restructuring companies' business process [3]. There were chances for cost reduction assessment. Therefore, it is possible to calculate cost analysis for investment. However, e-service systems are developed for customers' satisfaction and their convenience [8]. The price for service is often not decided by its cost but consumers' value [8]. Then we should pay attention on business risk. So, methodology for risk/chance analysis is indispensable for building e-service systems.

Paying attention to these reasons, we develop new framework and concept for physical office for building e-service systems. Without framework, the system integrator misses the project management. With framework, the system integrator can recognize his capability maturity for building e-service systems. Our framework presents the components, the risks, and the procedure for building e-service systems while the e-service creation center is a physical office for an e-service development.

## 2. Components for e-Service System Integration

Let us review the difference on components between the traditional systems and the e-service systems first.

For the traditional system integration, a system integrator selects hardware and software for the system infrastructure. Then he designs application program. For his selection, he has to analyze cost/effect and transaction volumes. Of course, the system integrator may outsource program development resources.

Comparing to the traditional system integration, we have identified four points for the e-service components as follows:

- (1) A project manager should integrate not only hardware and software but also digital contents. Digital contents should be identified widely. In fact, there are digital contents not only for the entertainment and the education but also those for the hotel room reservation and the airline ticket reservation. To integrate a variety of contents from a volume of contents holders is called contents aggregation.
- (2) User interface design is important issue because the user is not a professional person but a general consumer. There are variety of user terminals such as personal computers, mobile phones, personal data

assistant, and internet appliances. Data synchronization among them is an important function for mobile computing. The ubiquitous computing concept that allows us to use computer anywhere and anytime is also important.

- (3) Resource outsourcing is a key factor for early service development and risk sharing. Not only application development but also system operation requires professionals. For the system operation, both iDC(internet Data Center) and customer support center are generally outsourced. A system integrator should understand the core competences of outsourcers and subcontractors, and should evaluate them.

- (4)SLA(ServiceLevelAgreement) is an important concept for pricing. A service integrator should clarify the service level for customers and pay the penalty if the service level is degraded. Sometimes customer may prefer the price to the quality. Excellent quality is not always key factor for service selection nor customer satisfaction. Then SLA becomes a clue for service selection.

We propose the components in our framework as shown in Figure 1: Elements for integration, implementation outsourcing, operation outsourcing, and customers/sales channels. “Aggregation” and “Service level agreement” are keywords for integration.

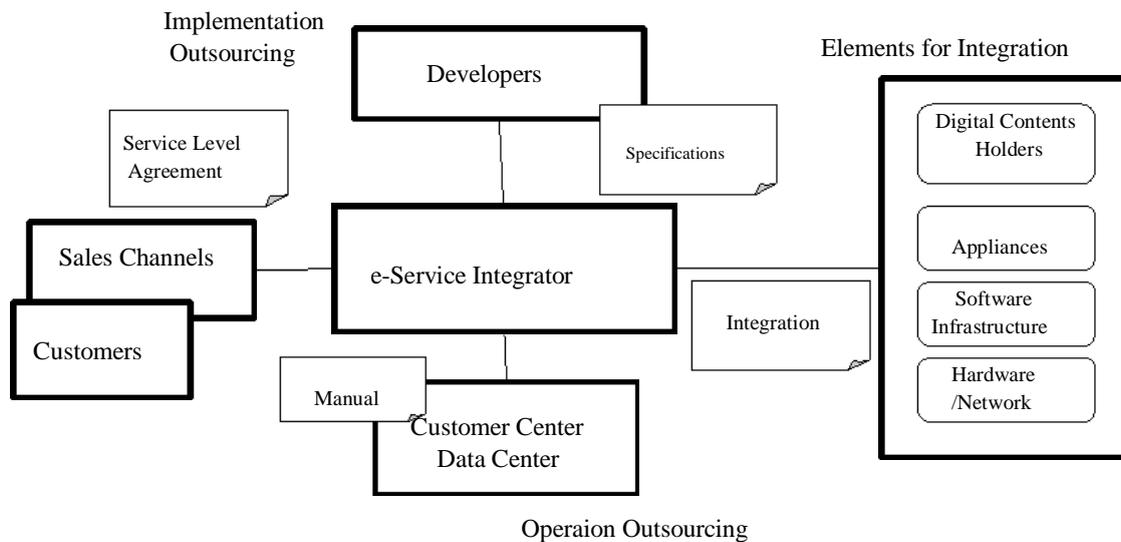

Figure 1. Components for building e-Service Systems

### 3. Risks for e-Service Integration

While e-service is attractive for current era, there are risks for business creation. We should recognize that there should be risks. To avoid risks is meaningless. We should know what the risks are, and what their probabilities of the risk are [11]. To recognize the existence of risk, let us consider the changes in the current market. There are two big changes as follows:

- (a) As mentioned in section 1, most e-services are implemented by more than two companies. Each company has its unique core competence. Figure 2 shows the alliance network among companies for e-service integration. Note that the traditional alliances were done by the companies that have the same (or similar) competence.
- (b) The consumers have gotten the power to collect and deliver information via internet. Sometimes, the consumers make an electronic community to exchange information among special interest group [4]. Without load, time, and money, the internet users are able to know the product differentiation, their inventory, and their price [8].

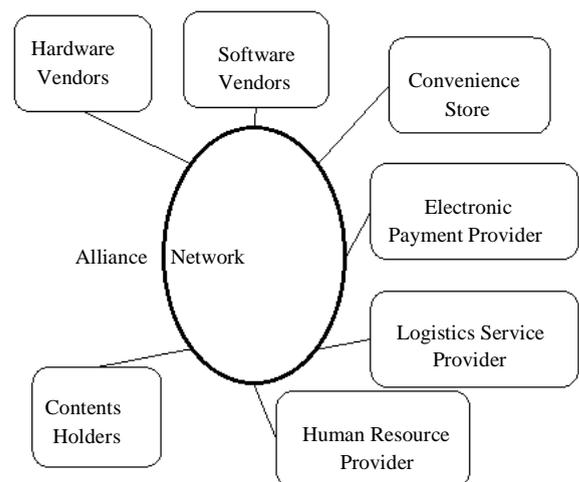

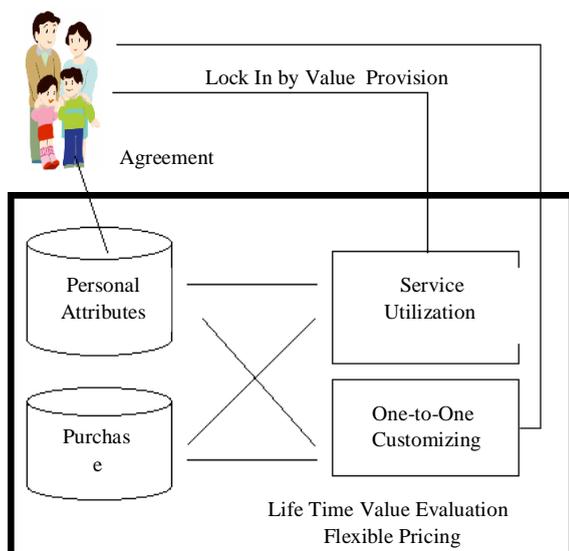

Figure 2 Alliance for Building e-Service Systems.

Understanding these changes, the e-service integrators should create business models. To prevent other company from imitating the new business model, the company should claim business model patents.

For (a), the protocol among allied companies should be defined so that transaction data should be exchanged securely. However, there are few global standards for the service connection. In general, each company has its own system, its culture, its business protocol, and so on. Therefore, there is risk for communication. Further, if a company is declared bankrupt, the business will fail. This is also risk. So a company has means to monitor allied companies status continually.

For (b), we know the price in e-service is decided not by its cost but by its value [8]. The value is defined by customers. Auction site is an example for the electronic community and flexible price. Sometimes, the price is defined by customers LTV (life time value) where LTV is evaluated by total contribution of each customer. However, it is not easy to estimate LTV. Therefore, there is also risk. To estimate LTV as correct as possible, a service integrator build customer database as shown in Figure 3.

**Figure 3 Personal information in e-Service.**

While the customer database stores private information including name, home address, birth date, interests, favorite, purchase history, and so on, there should be privacy protection policy. If the e-service fails to handle privacy information, it will be purged out from the market. Thus, there is risk.

Therefore, the risk management including monitoring, measuring, hedging that has not been necessary for traditional system integration is indispensable for e-business integration.

#### 4. Procedures for e-Service Integration

Based on the discussion in section 2 and section 3, let

us describe our procedure for e-service integration. For building e-service, the business model establishment is the first step. There are three issues in building business model as follows:

- (1) The business model is claimed for the customer satisfaction. The cost/effect analysis that is important in building traditional systems is not possible for starting the e-business. Our framework offers six types of business models: intermediary exclusion model, aggregator model, multi sales channels model, specific service model, cross-sales portal model, and communication portal model. These are discussed elsewhere [9].
- (2) The target customer should be defined. Note that the interest of the aged people is different from that of the young people. Behavior of the married people is different from that of the single people. The life style and the work style should be carefully analyzed. The target customer analysis induces what kind of the user terminal is appropriate for the business.
- (3) The shopping style should be defined. There are three types of shopping: for purchasing daily goods such as books and foods, customers prefer time-saving shopping. For selecting luxurious goods such as dresses, jewels, and watch, the customers would like to enjoy window shopping. They would like to check as many goods as possible even if they are busy. Finally, there is non-daily product shopping. Real estate and car are examples.

Traditionally, the products have been lined up by the company competence (the company's view). In fact, an electronic company provides a variety of electronic equipments while a chemical company provides a variety of goods from oils.

However, the menu of the e-service should be defined by the consumers' view. For example, a consumer who likes driving a car may be interested not only in car information but also in road information, car goods information, and gas station information. Thus, the contents in the e-business should be aggregated not by one company competence but by the consumers' convenience. The followings are example of the e-service vision:

- (a) My company allows working women to live comfortably,
- (b) Our Mission is to give a good circumstance for the aged people,
- (c) We have children learn pleasantly,
- (d) We are happy if the handicapped persons enjoy the internet shopping.

To allow the consumers to handle the contents easily, contents aggregation, ASP (Application Service Provider) aggregation and account aggregation are key factors.

Then business plan should be described. The following should be defined: who are partners? How much is the possible investment? When is the deadline for recovering debts? The business plan should include the annual interest and the accumulated interest.

Currently, a guideline says that the annual interest

should be balanced in three years and the accumulated interest should be balanced in five years. We think it is a reasonable guideline. To calculating the interest, the pricing model and the number of target customer should be assumed.

Then risk/chance analysis is indispensable as shown in Figure 4. The subject in the analysis includes the risk factors of the novelty, the market acceptability, the brand, and the potential market growth. The service integrator should prepare the monitoring method and hedging method for the risks. Assigning the probability to each risk, the service integrator assumes the optimistic scenario and the permissive scenario. The scenarios should be shared among the allied companies and the project members.

Once business model is established, the service integrator should study on the feasibility from the view of the business as follows:

- (1) FS (feasibility test) is promoted for verifying the scenario of the e-business. The service integrator should initiate FS as soon as possible. Then FS is executed as follows: (a) there may be limited service level, (b) the evaluation item is well defined, (c) the period for testing is clear.

The access log that shows the transaction volumes, the transaction bias, the total visitors, the unique visitors, the repeaters behavior and so on is the clue for the evaluation. The test campaign and the event promotion are useful method for measuring customer's reaction.

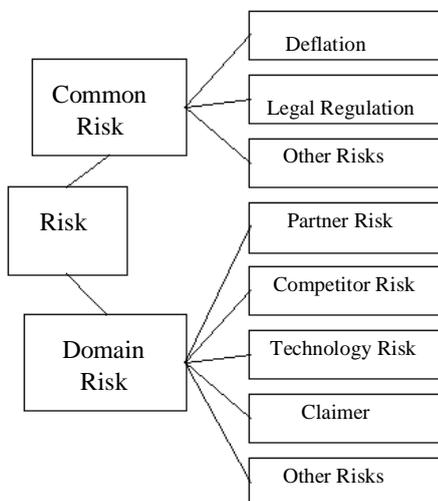

Figure 4 Tree for risk analysis.

- (2) In the case that the FS gets the affirmative result for the business plan, the service integrator designs the service level in detail. The service level including the following items is designed for the business plan: (a) service contents (usability), (b) service time (availability), (c) privacy policy, (d) customer's obligation, (e) disclaimer of warranties, and (f) limitation of liability.
- (3) Using two-dimension axis (free vs. charge, subscription

vs. no-subscription), the framework introduces the evolution process for the e-service. "Repeaters" and "life time value" are the keywords for evolution map. To make new visitors into frequent visitors there should be strategies that provide incentives. The value for the customers should not be evaluated in the short terms. Once an e-service site succeeds to rock in volumes of customers, there will be more chances to get new customers (profit). Figure 5 shows the evolution process for the e-service sites.

- (4) Finally, the service operation policy is designed. The service level designed in step 2 shows the guideline for the computer operation and the customer support operation. The former includes security policy while the latter includes media for the customer channels. Our framework has guideline for the operation outsourcing.

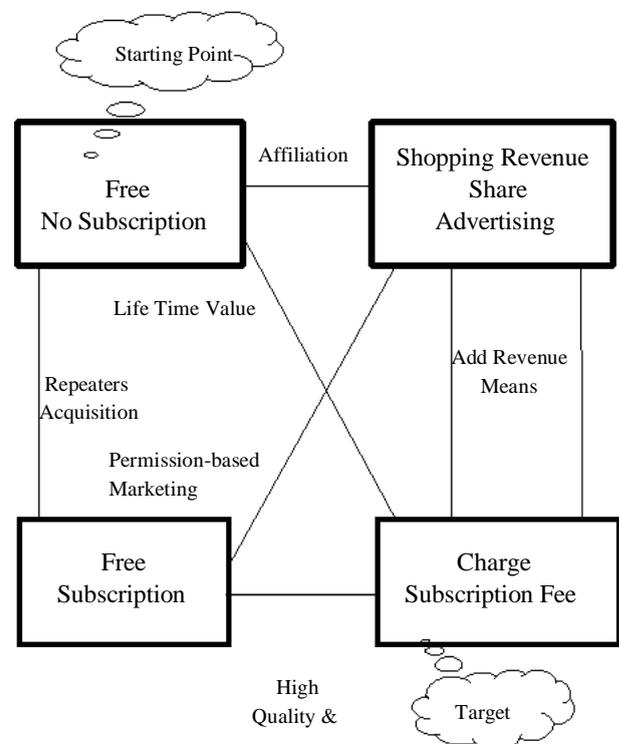

Figure 5 Evolution Transition for e-Service.

## 5. Office for e-Service Development

To integrate the e-service systems by the framework mentioned in the previous section, the physical place plays an important role. Analyzing the requisite of the physical place, we designed e-service creation center. Our e-service creation center that was founded in October of 2000 consists of the meeting rooms, the concept exhibition room, the presentation room and mini iDC (internet data centers). Figure 6 shows the layout of our e-service creation center.

The e-service creation center is open to persons and organizations that are interested in creating e-services. The vendors, the contents holders, the outsourcers, the carriers

and so on are the guests of the center. They exchange their competences, their vision, and their brand in order to create the business ideas at our meeting rooms.

To disclose one's competence and to make business alliances, our concept exhibition room and mini iDC are powerful. The mini iDC that is equipped with fundamental hardware, software and network is ready for starting feasibility study on business idea. The created business idea is introduced at the presentation room. The usability test is also done at the e-service creation center.

The concept exhibition room demonstrates the attraction of CDN (Contents Delivery Network) which allows persons to enjoy rich contents on internet such as streaming media. Then the contents holders who are not accustomed to CDN become to be tempted to deliver their contents via internet. Thus, there are chances for the contents aggregation.

## 6. Conclusion

We have described the e-service integration. We identified the difference between the traditional system integration and the e-service integration. Paying attention the difference, we develop a new framework. However, it is not easy to establish the new project management. In general, any organization has the capability maturity level for project management. To identify the level of the capability maturity is important.

CMM (Capability Maturity Model) presented by CMU [7] shows a guideline for capability maturity. There are five stages in CMM: Inconsistent Management, Project Management, Process Management, Capability Management, and Change Management.

Although in October of 2000 our capability maturity level was "Inconsistent Management" because we do not have know-how on e-service building, our current level of capability maturity is "Project Management" because we have experienced for building e-service [12][13]. For the future work, we will clarify the issues for "Process Management", "Capability Management" (Observable and Controllable), and "Change Management" for the e-service integration.

## 7. Acknowledgement

This work was done while the first author worked with Hitachi, Ltd. The authors would like to express sincere

thanks to the colleagues of e-Service and Business Development of Hitachi, Ltd. for their useful advice and valuable discussion.

## Abstract

Companies are adopting Internet-based electronic services (E-services) attracting customers, sharing of business information, maintaining business relationships and conducting business transactions. Companies in the earlier stages of employing E-services have little information and knowledge on its potential organizational and relational impacts. Through few years practice of E-services, companies have obtained related knowledge. They urgently need to assess the costs to move service online against the benefits received via adopting E-service, and identify the impact of E-service adoption in companies' relationships with their customers as a result of innovative use of E-services.

The initial objective of the research is to explore the relationships between cost factors, benefit factors and customer satisfaction for an E-service application. A further objective is to find a potential path for developing a customer oriented E-service application from its current implementation through identifying the types of changes taking place in the service functions and operations as a result of increased use of E-services. Though conducting a survey, this paper, as a stage report of the project, presents a research framework for E-service evaluation, identifies main cost and benefit factors of E-service and analyses the relationships between these factors. Finally, a cost benefit relationship model is proposed.

**Keywords:** E-services, Evaluation, Cost benefit analysis, Customer satisfaction, Assessment framework

## 1. Introduction

The Internet is being used as a platform through which services are delivered to businesses and customers [3]. Companies are adopting Internet-based electronic services (E-services) attracting customers, sharing of business information, maintaining business relationships and conducting business transactions. More recently, companies have started using the E-service as means to automate relationships between their business processes to allow customers to form alliances, joining their applications, databases, and systems in order to share their costs .

E-service applications in Australia have had rapid growth in past few years. International benchmarks consistently place Australia among the top ten countries in the world in the terms of adoption and use of E-business (E-service has been extraordinarily affected by the development of E-business). Through assessing connectivity, business environment, E-commerce consumer and business adoption, legal and regulatory environment, supporting an E-service, and social and cultural infrastructure, the US based Economist Intelligence Unit [6] published its second set of "E-business Readiness Rankings" for over 60 countries in May 2001, Australia was placed 2<sup>nd</sup> to the US [22]. As the results presented in 'The current state of play-June 2001' [22], 50% of Australian adults accessed the Internet in the 12 months to November 2000 and 37% of Australian households were connected to the Internet at November 2000 [21]. On business online use, 56% of employing businesses were connected to the Internet at June 2000 (an increase of 93% since June 1998). On the aspect of business E-service activity, the use of online banking and shopping by Australians has grown considerably. An estimated 13% of adults paid bills or transferred funds in the three months to November 2000 (an increase of 225% since November 1999), and 10% purchased or ordered goods or services via the Internet. The value of Internet-based E-service in Australia at June 2000 was estimated to be \$A5.1 billion [22]. The ability of E-service to fulfill customers' demands for service is helping businesses to reduce costs and obtain benefits. Service is an important measure of success in competitive markets and the Internet marketplace will be no exception. As researchers noted, E-business success is determined less by business models than by delivering topnotch, repeatable service that creates satisfied customers [19].

Recent reports concerning the quality, usability and benefits of E-services have led researchers to express increasing interests in conducting evaluation for E-services [9]. These studies used various research methods, such as survey, case study and conceptual modelling, to conduct research in E-service websites or applications assessment, evaluation frameworks, cost/benefit analysis and customer satisfaction measurement. Ng et al. [20] reported a desk survey of business websites and discussed the benefits of Internet. Giaglis et al. [7] presented a case study of E-commerce investment evaluation by developing a model of E-

commerce business value. Tang et al. [25] proposed a conceptual model to demonstrate the rationale of the buyer-supplier interaction with the information service provider's mediation in the E-commerce environment. Lee et al. [13] created a framework for evaluating the business value of Internet-based B2B E-service through five propositions. Helander and Khalid [11] used a system model to illustrate the relationships between three subsystems in E-commerce: store environment, customer and web technology. Drinjak, Altmann & Joyce [5] investigated the perceived benefits of investing in E-service applications. More recently, Hahn et al [10] summarized three major traditional approaches to E-commerce website evaluation: testing, inspection and inquiry, and presented a value-driven framework for E-commerce website evaluation.

However, exist evaluation models and frameworks from literature have orientation either from a web customer perspective or web supplier perspective only. The project intends to explore the relationships between customer perspective and supplier perspective for specific E-service applications. This project attempts to develop a conceptual framework to evaluate E-service applications by identifying the relationships among E-service functions, customer satisfaction for E-service applications, business benefits received via adopting E-service and costs to move service operations to online. It will then identify the types of changes taking place in the service functions and operations as a result of increased use of E-service, examine the impact of increased sharing of information via online collaboration between companies and their customers on management approaches. The research results will be expressed into a factors relationship model. Based on the model, recommendations for developing and maintaining E-service applications will be proposed, which will have the potential to improve the competitiveness, flexibility and strategic planning of companies engaging in E-service by reducing costs, increasing benefits and making E-service activities better.

This paper, as a stage report of the project, describes the research framework in Section 2. Research methodology used in the study is given in Section 3. Section 4 analyses main cost benefit factors and their relationships for the development of an E-service application, and then expresses the findings into a cost benefit relationship model.

## 2. Research Framework

Based on the pervious works shown in Lu at el [17], Lu [15, 16] and a broad range review of literature (such as [5] [8] and [23]), four categories are identified to compose a conceptual research framework for assessing E-service applications. The four categories are E-service function (F), E-service cost (C), E-service benefit (B) and customer satisfaction (S)(FCBS). *E-*

*service function* concerns with the capability and quality of E-services. *E-service cost* concerns with the costs of adopting E-services. *E-service benefit* concerns with the benefits received through employing E-services. *Customer satisfaction* is about the results of individuals taking outcomes that have been received. Each category consists of a set of factors.

The number, types and functions of E-services increase day by day and E-services are typically delivered individually. In *E-service function* category, typical function factors include general information publicity, email require, delivery of customized information, advertising products and price, online ordering/booking and on-line transaction. These functions also imply the levels of E-service complexity. For example, online payment has higher level than only advertising products. Each E-service application may contain several or all of these functions.

Drinjak, Altmann & Joyce [5] listed a number of benefit items within three categories of web applications and their rankings. These items include: providing access 24 hours a day and seven days a week (24\*7), effective promotion of the company together with the products and services it produces, enhance quality and speed of customer service, create competitive advantage and subsequently avoid competitive disadvantage, entice shoppers and encourage customer interaction, supporting core business functions which are integral to business strategy, provide new business opportunities, increase market presence and facilitate on-line purchasing. The research also indicated that the item access 24\*7, effective promotion of the company, enhancing customer service, supporting core business functions, and providing new business opportunities have relatively high rankings. Lu [16] listed 21 benefit factors and identified eight factors as the core benefit factors through a survey conducted in New Zealand. They are: accessing to a greater customer base, broadening market reach, lowering of entry barrier to new markets and cost of acquiring new customers, alternative communication channel to customers, increasing services to customers, enhancing perceived company image, gaining competitive advantages, and potential for increasing customer knowledge. Based on the two research results, 16 main E-service benefit factors are identified and used in the study.

Lu [16] also tested 19 cost factors and identified eight core costs factors: expense of setting up applications, maintaining applications, internet connection, hardware/software, security concerns, legal issues, training and rapid technology changes. The eight cost items are used in the study as cost factors.

E-service is altering the way in which businesses operate and interact with customers. One of the major challenges companies face today is to meet increasing

customer demands, including efficient processes and improved customer services. The judgment on the quality of service has been shifted from the business to the individual customers. Customer satisfaction has become one of the dominant factors to E-service success [4]. As Terry & Standing [26] observed 'while there is no direct measure for the success of an information system, empirical researchers have commonly used user satisfaction as the dependent variable'. A successful E-service is one that attracts customers, makes them feel the service is trustworthy, dependable, reliable, and satisfactory [14] [12].

Generally there are three types of customer measures to be used: the relative importance of attributes, dimension of customer satisfaction and added customer value [1]. *Attribute importance* means every service attribute contributes diversely to the overall satisfaction of the customers. *Dimension of customer satisfaction* means every dimension of satisfaction gets its own score, which then can be compared to evaluate the strengths and weaknesses of the applications. *Added*

*customer value* is generated through dividing the business' overall customer satisfaction by the scores of all businesses competing in a certain market. This project applies a composition of the three types of customer measures in customer satisfaction category. It includes information content satisfaction, usability satisfaction, security satisfaction, convenience satisfaction, efficiency satisfaction and flexibility satisfaction. Each of the factors may imply more detail criteria. For example, usability satisfaction involves user satisfaction in information up-to-date, clear language style and links to appropriate resources. E-service website format design, facilitated browsing, search engine provided, accessing speed and customer control of a transaction process [24] are considered as sub-criteria for convenience satisfaction.

Figure 1 shows the factors of E-service function, cost, benefit and customer satisfaction, called FCBS research framework.

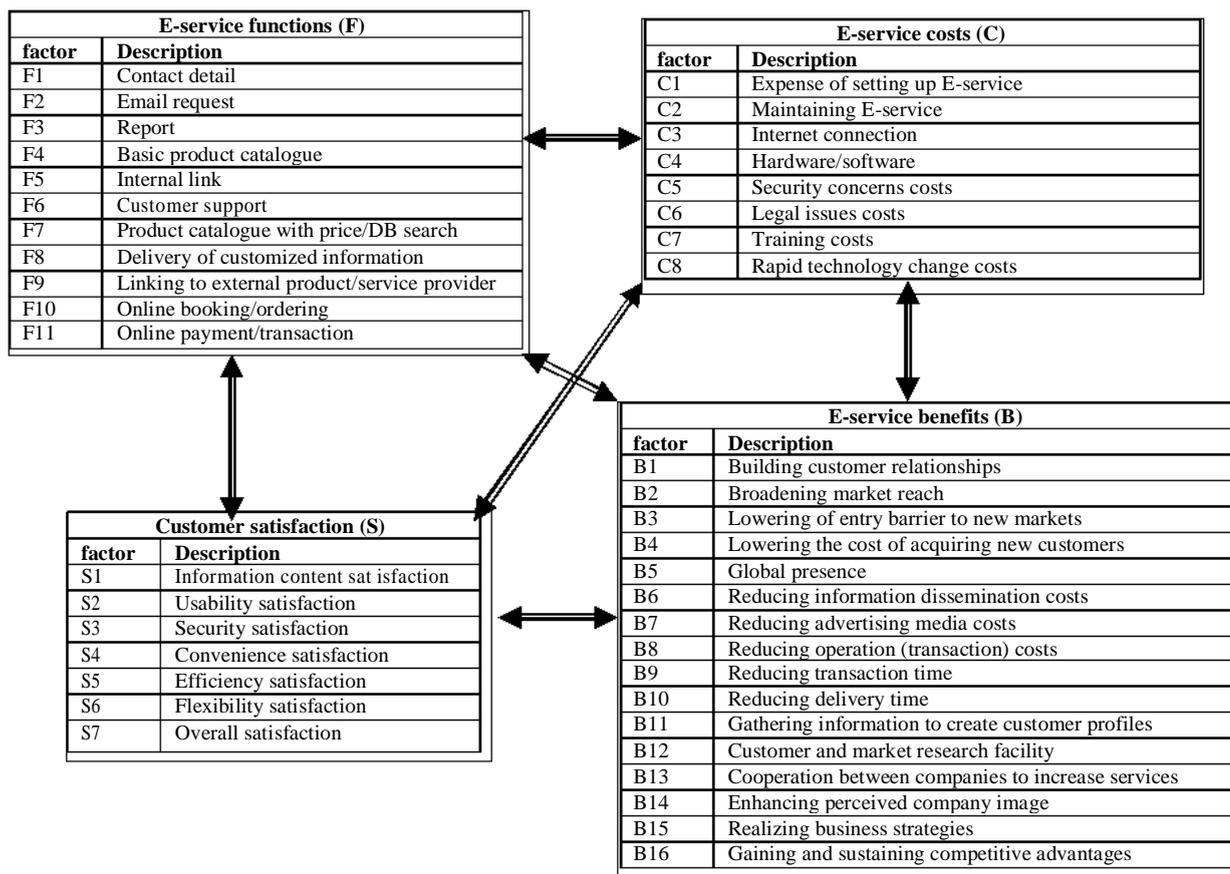

Fig. 1 FCBS research framework with factors

### 3. Research Methodology

This study focuses on two main industry sectors: Tourism/Travel and IT/Communication services in Australia. This study needs to conduct a company (E-service provider) oriented survey and a customer oriented survey respectively. It then explores the relationships among survey results by using statistical analysis method. Why the project develop two surveys is that it needs to get customer satisfaction from customer side and company cost benefit assessment from company side. The statistical analysis aims to find useful aggregation results in investigate dependency and correlation relationships between factors shown in the research framework. The surveys assume that respondents represent their colleagues and should not be asked directly about hypotheses.

In order to identify company sample a *web search* was first conducted. The purpose of the web search is to find which companies have adopted E-services on an appropriate level and get volunteers from these companies. A total of 100 websites were randomly selected from the company websites registered in the Yellow Pages Online (NSW, Australia) <http://www.yellowpages.com.au>, under Tourism/Travel and IT/Communication categories, conditional on their reaching for an appropriate level of E-service development. The sample companies involved a number of industry sectors: Accommodation, Community Services, Information Technology, Retail, Transport, Attractions and Travel Agents.

A *company-oriented questionnaire survey* was conducted in the sample companies from February to March 2002. As a pre-test survey, an initial questionnaire was sent to three subjects aimed getting responses' feedback. Based on the pre-test results, the questionnaire was refined. The finalized questionnaire was then posted/emailed/faxed to the 100 selected sample companies. Out of 34 questions in the questionnaire, eight items are related to E-service functions and development, 10 are related to the costs of setting up and maintaining E-service applications and 16 are related to business benefits of E-service applications. A total of 50 responses were obtained and the results shown in this paper is based on 48 completed responses. All questions listed in the questionnaire use five-point Likert scales or giving a statement that is responded by choosing or not choosing. This survey attempts to identify why companies adopt E-service applications, how do evaluate an E-service application, what are the main benefit factors and what kinds of benefits have been obtained, what are the major costs and barriers towards E-service applications, and how the relationships are changing between E-service costs and benefits.

Finally, a *customer-oriented survey* was conducted in September 2002 to identify customers' major

facilitators and barriers in relation to receive E-services, customers satisfaction in information content, usability, security, convenience, efficient and flexibility for E-services. By the length limitation, the paper only shows the results conducted in the company oriented survey.

### 4. Data Analysis

#### 4.1 Why do companies adopt E-service applications?

The survey results show that the 48 companies sampled have employed Internet doing E-service for 3.1 years on average. There are 49% of the companies sampled indicate the reason to develop E-services is 'currently it is the way to do business', 27% indicate that their competitors are adopting E-services, 41% mention that their customers want E-service based business relationships, and 73% explain that doing E-services is a part of their organization's strategies. Some companies gave more reasons for doing E-services such as this is 'another way to reach new customers', 'online knowledge management' and 'E-service is a cost-effective solution'. One company indicates the reason is that 'we are an Internet technology company'.

#### 4.2 Are companies satisfied with their current E-service applications?

Out of the 48 sampled companies, about 26% of sampled companies think that their E-service applications are 'very successful', 36% of 'successful', 28% of 'moderate', 8% of 'very little' and only one company marked 'not beneficial'. The result shows that most companies are satisfied with their E-service development.

The data shows that about 40% of E-service applications were developed by in-house staff, 20% by web developers or contractors, and 39% by both internal and external people. Through comparing the 'successful' level in the three groups of websites, there is no significant difference in satisfaction levels for E-service applications developed among different groups.

This survey also explored the barriers when company adopting an E-service application. 35% of companies sampled indicate that 'lack of staff expertise' is one of main barriers. 33% indicate 'difficulty in integrating web with internal applications' is a main barrier. 'Expense of setting up E-service' is marked as one of main barriers by 41% of companies. 'Expense of maintaining E-service', 'Lack of adequate training', 'Lack of web capable business partners', 'Resistance to structural changes within your company', and 'Security problems associated with using E-service' are marked as barriers by 16%, 12%, 6%, 14% and 16% of companies respectively. This result shows that expertise, technique, and expenses are still main barriers for E-service development.

It is found that companies that mark their E-service applications as 'very little benefit' or 'not beneficial' almost mark 'expense of setting up web-based E-service applications' and 'difficulty in integrating web with internal applications' as main barriers. This finding means obviously that such companies must overcome barriers in setting up and integrating E-services to obtain ideal benefits.

### 4.3 What functions are provided in E-service websites?

Totally 11 function factors listed in Figure 1 were tested. The results show that over 90% of sample companies provided contact details, reports, basic product catalogue and internal links. About 40% of companies offered online booking and 67% made product catalogue with price/DB search available. Only three companies kept sending information to customers and only seven allowed online payment.

What factors/functions are more important to online customers in their decision to purchase at a website? The survey shows that 51% of companies sampled thinks 'guarantees transaction security' is an important factor. 49% of indicate 'guarantees services or products offered' is important. 67% of indicate 'provides useful information' and 59% of expresses their concerns on 'provides user-friendly navigation to information'. There are 59% of companies marking p' rovides fast service' and 35% of 'provides lower cost than traditional methods'. About 33% of companies mentions that

'provides more options to customer services or products selection' is one of important factors.

### 4.4 What are the main benefits for adopting an E-service?

The questionnaire is designed to cover proposed factors at an appropriate level and with an appropriate form. The respondents were asked to indicate their present benefits assessment and ideal rating for each of the benefit factors. The current benefit assessment is regarding to the assessment of the status of respondents' E-service application, comparing with where they would ideally like it to be. The ideal rating for benefit factors is tested on a 5-point scale. Here '1' means not important at all, and '5' very important. For example, if a company considers that one of the most important benefits is to enhance perceived company image, the company would score perhaps 5 on the Ideal Rating of factor 'enhancing perceived company image'. Table 1 shows the result of ideal rating for benefit factors. It is found that B14 (Enhancing perceived company image), B16 (Gaining and sustaining competitive advantages), B1 (Building customer relationships), B2 (Broadening market reach), B15 (Realizing business strategies) and B4 (Lowering the cost of acquiring new customers) received higher scores respectively. These factors are thus identified as major benefit factors. That means businesses have a higher expects to get benefits on these aspects.

**Table 1: Ideal rating for benefit factors**

Ideal rating	B1	B2	B3	B4	B5	B6	B7	B8	B9	B10	B11	B12	B13	B14	B15	B16
1	0	0	3	1	5	5	3	5	5	5	4	2	4	1	1	1
2	2	4	6	2	7	3	4	3	2	4	5	4	5	2	3	2
3	8	9	9	9	12	6	9	9	6	9	4	11	6	3	8	5
4	10	12	15	16	5	16	15	13	14	6	16	12	11	9	10	8
5	27	21	12	18	17	16	15	15	19	19	15	15	18	30	23	29
NA	0	47	2	1	1	1	1	2	1	4	3	3	3	2	2	2
AV	4.3	4.1	3.6	4.0	3.5	3.8	3.8	3.6	3.9	3.7	3.8	3.8	3.8	4.4	4.1	4.4

### 4.5 What benefits have been obtained through developing an E-service application?

Companies are all interested in maximizing business value of E-services. They have made business strategies to address the requirements of interoperability, quality of customer service, evolution and dependability. They expect to know what factors are affecting E-service benefits and how E-service can increase real business benefits, by comparing its costs with those of the associated investments. In order to complete such analysis, this study not only explores which benefit factors are more important to business benefit and also seeks to find in which aspects companies have obtained

higher benefits, and which one is lower. The 5-point scale is also used for present benefit assessment: 1-low benefit, 5-very high benefit. For example, if a company considers that currently E-service only build very basic customer relationships but the company would ideally prefer to build more closed relationships with customers. Then the company would score perhaps 3 on the present benefit assessment for B1. The assessment result shown in Table 2 indicates that companies have obtained higher benefits on B14 (Enhancing perceived company image), B16 (Gaining and sustaining competitive advantages), B1 (Build customer relationships) and B2 (Broadening market reach).

**Table 2: Current benefit assessment**

Benefit assessment	B1	B2	B3	B4	B5	B6	B7	B8	B9	B10	B11	B12	B13	B14	B15	B16
1	2	1	6	4	9	5	6	7	7	7	10	9	7	1	3	2
2	7	6	13	14	10	8	7	7	10	9	7	12	8	5	7	8
3	16	21	18	14	8	17	13	18	12	13	10	17	12	12	18	15
4	14	12	7	9	13	12	15	8	10	8	14	3	13	12	12	12
5	9	8	3	6	8	5	6	7	9	9	5	5	6	17	7	10
NA	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0	0
AV	3.4	3.4	2.7	3.0	3.0	3.1	3.2	3.0	3.1	3.1	2.9	2.6	3.1	3.8	3.3	3.5

**4.6 What are the main cost factors for adopting an E-service application?**

Same as benefit factor identification, this study identifies major cost factors by 5-point scale: 1- not important at all, 5- very important. For example, if a company thinks the cost of maintaining an E-service is not important it should mark the degree of importance as 1 or 2. Table 3 shows that C2 (Maintaining E-services) is the most important factor and C5 (Security concerns costs) is the second as they received a high average value (3.9, 3.7). This finding implies that companies have had or would have higher investment on these important cost items.

**Table 3. Weights of cost factors**

weight	C1	C2	C3	C4	C5	C6	C7	C8	C9	C10
1	4	1	4	2	3	8	4	4	4	5
2	6	7	8	5	7	6	9	4	2	4
3	10	7	12	13	7	10	10	15	13	17
4	13	15	11	16	10	11	17	14	20	12
5	14	17	12	9	18	10	5	10	8	9
N/A	0	0	0	2	2	2	2	0	0	0
AV	3.6	3.9	3.4	3.6	3.7	3.3	3.2	3.5	3.6	3.3

**4.7 What costs are higher than estimated in developing an E-service application?**

This study also explores which items cause a higher cost, and which one lower. Here ‘1’ means very low cost, and ‘5’ very high. The assessment result is shown in Table 4. It is found that there are higher costs on C9 (time spent on E-service development) and C1 (expense of setting up E-service) in the sampled companies.

**Table 4. Current cost assessment**

cost	C1	C2	C3	C4	C5	C6	C7	C8	C9	C10
1	6	6	15	5	7	9	9	8	6	6
2	5	10	13	7	9	12	9	7	3	8
3	10	12	11	16	9	11	15	9	13	14
4	17	16	7	12	13	8	10	19	14	14
5	9	3	1	7	7	4	2	3	10	4
N/A	0	0	0	0	2	3	2	1	1	1
AV	3.4	3.0	2.3	3.2	3.1	2.7	2.7	3.0	3.4	3.0

**4.8 What cost factors affect E-service benefits?**

In order to exam the relationships between individual cost and benefit factors, a number of hypotheses are designed [18]. This paper only presents three hypotheses and discusses related test result details.

**H1:** There is a significant difference in the benefit 'Broadening market reach' (B2) for different groups of companies that have different levels in the cost of 'Maintaining E-service' applications (C2).

**H2:** There is a significant difference in the benefit 'Gaining and sustaining competitive advantages' (B16) for different groups of companies that have different levels in the cost of 'Maintaining E-service' applications (C2).

**H3:** There is a significant difference in the benefit 'Enhancing perceived company image' (B14) for different groups of companies that have different levels in the 'Legal issues costs' (C6).

Let 'Maintaining E-service' (C2) be an independent variable with five levels, 'B' roadening market reach' (B2) and 'Gaining and sustaining competitive advantages' (B16) be dependent variables. Let 'Legal issues costs' (C6) be an independent variable with five levels, 'Enhancing perceived company image' be a dependent variable. Three one factor fixed effects ANOVA models (1), (2) and (3) were built to determine the effect of the independent variables on the dependent measures in individuals.

$$[Broadening\_market\_reach]_i = \alpha + \beta [Maintaining\_E-service]_i + e_i \quad (1)$$

$$[Gaining\_compet\_advantages]_i = \alpha + \beta [Maintaining\_E-service]_i + e_i \quad (2)$$

$$[Enhancing\_perceived\_company\_image]_i = \alpha + \beta [Legal\_issues\_costs]_i + e_i \quad (3)$$

The ANOVA results show that the 'Broadening market reach' and 'Gaining and sustaining competitive advantages' are significantly different across different groups of the cost of 'Maintaining E-service' ( $p < 0.05$  in Table 5 and 6). The findings mean that the E-service applications where company spent more time on maintenance will contribute directly to the benefit factors B' roadening market reach' and G' aining and sustaining competitive advantages'. The result supports H1 and H2. However, Table 7 shows that the 'Enhancing perceived company image' is not significantly different across different groups of the cost of 'Legal issues costs'. It is not support H3's claim.

**Table 5. Summary & ANOVA results for the effects on Broadening market reach (B2)**

Cost 2 groups	Cont	Sum	Ave	F	P-value
C2=1 very low	6	21	3.5	2.7	0.0461
C2=2	10	27	2.7		
C2=3	12	43	3.5		
C2=4	16	55	3.4		
C2=5 very high	3	14	4.6		

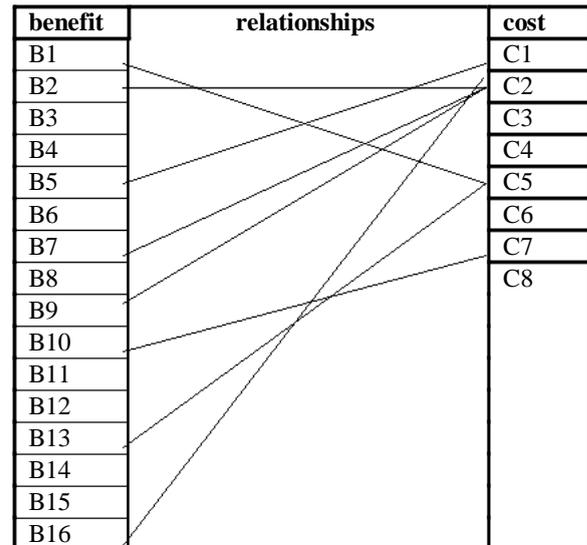

**Table 6. Summary & ANOVA results for the effects on Gaining and sustaining competitive advantages (B16)**

Cost 2 groups	Cot	Sum	Ave	F	P-value
C2=1 verylow	6	16	2.7	5.3	0.0015
C2=2	9	27	3.1		
C2=3	12	36	3		
C2=4	16	67	4.2		
C2=5 veryhigh	3	14	4.7		

**Table 7. Summary & ANOVA results for the effects on Enhancing perceived company image (B14)**

Cost 6 groups	Cont	Sum	Ave	Source of variation	df	MS	F	P-value
C6= 1 very low	9	34	3.78	Between Groups	4	2.7	2.4	0.0643
C6= 2	12	40	3.38	Within Groups	38	1.1		
C6= 3	10	43	4.3					
C6= 4	8	36	4.5					
C6= 5 very high	4	12	3					

By using ANOVA model to test other hypotheses, a set of relationships between cost and benefit factors are explored. The results are presented in a cost benefit relationship model (Figure 2). The lines in the model express dependency relationships between related factors.

**Fig. 2. Relationships between cost and benefit factors**

## 5. Further Research

This study is applying Structural equation modeling method [2] to analyze the relationships between multiple cost benefit factors.

This study has just completed a customer oriented survey. Data analysis is being completed to test those hypotheses that relevant to customer satisfaction. For example, in order to explore whether or not customer satisfaction is dependent on cost item 'maintaining E-service', let 'customer\_satisfaction' be an independent variable and 'maintaining\_E-service' a dependent variable, then test the effect of *customer satisfaction* on the *maintaining E-services* in individuals.

Through testing more hypotheses, findings will be presented into an integrated E-service factor relationship model (Figure 2 is a part of the model) which involves all the relationships among the four groups of constructs shown in FCBS research framework: *E-service functions, costs, benefits and customer satisfaction, with kinds of relationships: dependent, correlated and non-correlated.* The relationship model is intended as a mechanism for clearly identifying options, opportunities and their implementations for E-service development. The findings shown in the relationship model will have the potential to help companies to improve the competitiveness of companies engaging in E-services by reducing costs, increasing benefits and improving E-service quality. Based on the findings, the project will propose recommendations for designing, maintaining and improving E-service to take full advantages of Internet.

### Abstract

This empirically based paper is concerned with the application of the notion of internal customer service, purchasing and procurement, to e-services. It contends that much of the recent research into e-business, and e-service in particular, has taken a primarily external customer focus. Reports suggest that the greatest potential of e-business comes from applications within and between businesses. The findings are based on data collected in an extensive research programme from interviews, cases and focus groups in 97 organisations. It has shown that contrary to views of the traditional purchasing and procurement functions, e-service improved customer perceptions of service through faster and easier service with speedier resolution of problems, improved process reliability with reduced mean time between failures together with overall cost reductions.

### 1. E-Service and the External Customer

Recent e-service research has been primarily concerned with the provision and development of service between an organisation and its *external* customers. Voss [1] for example developed ten key steps in the development of an e-service strategy to help create outstanding web-based services. Mieczkowska and Barnes [2] investigated issues of customer participation in the delivery of library services. Sousa [3] whilst concerned with the quality of the customer's experience considered the issues for service design. Verma et al [4] investigated the value added features e-services need to provide to gain market share and profits. Zhu et al [5] developed a model linking consumer-perceived quality with e-service to the SERVQUAL dimensions. Walker et al [6] investigated the reasons why consumers accept or reject technology. Electronic customer relationship management (CRM) whilst recognising the potential for data mining, improved segmentation and one-to-one marketing appears to have been primarily concerned with managing the relationship and indeed the contact with customers [7] [8].

It is interesting to note that the manufacturing-based electronic commerce literature has been much more internally focused concerned with, in particular, the implications for process design [9] [10] [11] [12]. Even more interesting is the conclusion reached by such authors, summarised by Barnes et al [11] "e-commerce is tending to automate, rather than redesign existing

processes: e-commerce operations tend to be run as discrete processes, with little or no integration between traditional and e-commerce business processes and their respective information systems .... organisations often display confused and often contradictory motives for e-commerce; there is little measurement and evaluation of e-commerce performance". Despite the internal focus of much of this work the internal customer service perspective seems to be missing.

### 2. The Importance of an Internal Customer Perspective in E-Services

Although understanding the impact of e-service on the external customer is important and not in dispute, data from research organisations such as Forrester Research and Gartner, has demonstrated that the greatest potential from e-business will be in B2B applications both within (i.e. internal services) and outside the organisation.

Recognising the importance of internal services is not new. The importance of the internal customer has long been accepted as a key issue in operations design and improvement. "For an organisation to be truly effective, every single part of it, each department, each activity and each person and each level, must work properly together, because every person and every activity affects and in turn is affected by others" [13]. Central to this is the notion of the internal customer "every part of an organisation contributes to external customer satisfaction by satisfying its own internal customers" [14]. From a marketing perspective this internal customer notion is also well-accepted [15] and has led to the concept of internal marketing [16]. However the application of the notion of the internal customer to e-business, and e-service in particular, is relatively new.

The object of this paper is to evaluate an application of e-service to internal services in order to assess if such developments can not only improve the quality of service provided but also reduce the cost of doing business.

### 3. E-Procurement

E-procurement has been the subject of a great deal of research but again this has focused on the development of inter-organisational electronic networks. Malone, Yates and Benjamin [17] argued that the developing inter-organisational electronic networks would improve co-

ordination between firms to reduce the costs of searching for appropriate goods and services (they call these *electronic brokerage effects*). Consequently, they claimed that one of the major effects of inter-organisational networks would be a shift from hierarchical to market relationships. “Some of the initial providers of electronic markets have attempted ... to capture customers in a system biased towards a particular supplier. We believe that, in the long run, the significant additional benefits to buyers possible from the electronic brokerage effect will drive almost all electronic markets toward being unbiased channels for products from many suppliers” [17,p.492]. Brousseau [18] reviewed 26 inter-organisational networks, finding that most were used to reduce production or distribution costs and served to reinforce already existing hierarchical relationships among firms. Only in two, the petroleum business and textiles, was the use of inter-organisational networks associated with buyers gaining advantage by having more suppliers from which to choose. Evans and Wurster [19] claimed that the low infrastructure and transaction costs of Internet-based systems allow organisations to exploit the increased opportunities for complex information exchange with multiple partners, but also recognised the value to be gained through closer relationships between trading partners (‘affiliation’). Amit and Zott [20] likewise discussed the importance of close relationships (‘lock-in’) between trading partners as a key source of advantage to both buyer and seller, whilst Barratt and Rosdahl [21] claimed that ease of search and transparency acts as an advantage to the buyer but may be a disadvantage for the seller.

#### 4. E-Service – The Impact of E-Procurement

The procurement function of public and private sector organisations typically operates at the interface between the organisation’s operational processes and the external supplier marketplace. The function’s role is clearly a dichotomous one – it acts as both a customer and a supplier. Many elements of the procurement process are analogous to a typical marketing process: including - identification of (internal customer’s) needs, translation of those needs into specification, management of the delivery of goods and services to the internal customer and evaluation of the internal customers’ satisfaction. The other elements of the process involve communication with suppliers – requests for tenders, price negotiation, ordering receipt and invoicing. Electronic procurement systems mirror the procurement process through the provision of two distinct, but connected, infrastructures - internal processing (via, for example, corporate intranet) and external communication with the supply base (via, for example, Internet-based platforms) [22]. Each of these provides opportunities to enhance customer service – internally and externally.

Three service-related phenomena are of interest to our internally focused paper:

1. **Customer perceptions:** Internal customers perceive the quality of service offered by the traditional purchasing function to be poor. Consequently the function is held in low regard [23]
2. **Process compliance:** The traditional procurement process for indirect supplies for internal customer is characterised by low internal compliance [22]
3. **Cost reduction:** Cost of procurement is a key concern effected by trying to minimise transaction costs by limiting the number of suppliers [24] [25].

#### 5. Method

In this paper we report on the findings from our ongoing research into the nature and impact of electronic procurement (e-procurement) systems on internal customer service. This research programme has been concerned with building knowledge in e-procurement and has so far consisted of a series of interviews, cases and surveys conducted over the last two years with adopters and users of e-procurement systems. Ninety-seven organisations in total have been studied, including public sector bodies and a range of private sector organisations. All have participated in an extensive telephone survey, many have participated in focus group workshops and 16 have contributed to the development of more detailed case analyses.

In analysing internal e-service relationships we employed service quality criteria identified by Johnston [26] as the codes for labelling and presenting our data. These criteria are:

Attentiveness	Communication
Responsiveness	Competence
Care	Functionality
Availability	Commitment
Reliability	Access
Integrity	Flexibility
Friendliness	Security
Courtesy	

#### 6. Findings

In assessing the impact of e-procurement on internal customer satisfaction we investigated the impact of on-line requisitioning and ordering using on-line catalogues and procurement cards. We also examined the implications of the financial modules of e-procurement on improved budgetary control and management reporting (see table 1).

In this respect we found that the use of an accessible (i.e. available at the desktop) and centrally specified service process produced clear *operational* improvement in terms of process performance such as: speed of processing (measured from requisition to order acknowledgement); system reliability (measured in terms

**Table 1: Improvements from e-service**

<i>Criteria</i>	<i>Characteristics</i>	<i>Significance</i>
<b>On-Line</b> Responsiveness, Availability, Reliability, Flexibility, Functionality, Access	<b><i>(Decouples user-provider interactions)</i></b> Mean time between failure of system key requirement (infrastructure reliability). 300% increase in speed of response from request to order (process time) Increased range of goods and services available on-line Reconciliation of expense to budget (integration between systems) Price savings (better sourcing)	<ul style="list-style-type: none"> <li><input type="checkbox"/> Process design and reliability a critical element of the delivery of e-service.</li> <li><input type="checkbox"/> MTBF a vital area – this was found to vary between cases according to network reliability and 24/7 support.</li> <li><input type="checkbox"/> Speed of response is seen as key order winner – increasing compliance and thus reduces off-contract buying.</li> </ul>
<b>Helpline</b> Friendliness, Care, Courtesy, Flexibility, Attentiveness, Access	<b><i>(High contact)</i></b> Service interaction a key factor in satisfaction. Speed of resolution to queries and problems seen as important element of effective support. Customisation of support to deal with range of user knowledge and variety of system queries.	<ul style="list-style-type: none"> <li><input type="checkbox"/> Helpline staff capability, particularly the use of technically expert frontline help staff a significant contribution.</li> <li><input type="checkbox"/> Call-centre management a critical element of the delivery of e-service.</li> </ul>
<b>Expectations and Perceptions</b> Communication, Competence, Commitment	<b><i>(Explicit service process design)</i></b> Behavioural shift (changing practices) Cultural shift (changing perception) Technological focus –rather than business process change. Control – e-procurement allows ‘invisible control’	<ul style="list-style-type: none"> <li><input type="checkbox"/> Managing internal service relationships a key factor for effective e-procurement.</li> <li><input type="checkbox"/> Technology focus can improve compliance for technically capable staff, but acts as a barrier if not.</li> </ul>

of mean time between failure); greater range flexibility (larger catalogues). Additionally, users ability to improve budgetary information through on-line reconciliation and allocation of expenditure was seen as a significant benefit to their ability to control their own budgets whilst also reducing the burden on the Finance department. Finally, price improvements through consolidation of centralised purchases delivered increased budgetary efficiency – although in a number of cases this actually proved to be a disincentive! A fundamental concern here was that many managers are measured and evaluated according to the size of their budget – any significant reduction in purchase price leads to a reduction in the size of their budget. This was viewed as a real barrier to some of the fundamental changes needed to ensure compliance and buy-in with the systems.

Since, in many cases, user help was provided by a range of methods (including on-line, telephone and face-to-face) we have identified the characteristics and consequences of generic helpline support for the development and maintenance of internal service. The speed of resolution of queries was found to be a critical issue during e-procurement implementation and has a positive relationship to the extent of compliance by users. As the level of compliance is a primary performance measure of effective implementation, helpline design and delivery is critical to achieving high levels of compliance

and the consequent improved control over the procurement process. One of the most direct influences on speed of resolution was the use of expert frontline help staff. By deploying highly trained staff as the first point of contact a far larger proportion of queries are resolved through a single call (as there is less need for referral) than where junior staff were used as the initial contact point.

The third area of interest related to what was broadly described by respondents as ‘cultural shift’. An explicit focus on internal customer service, through mechanisms such as newsletters, intranet web sites and other internal marketing as well as cross departmental briefings and presentations, all highlight the value and contribution of effective service communication. In a number of our respondents the communication had concentrated almost exclusively on the technical characteristics of the systems and on user training. Almost paradoxically the response from such users was strong only where they were already technically competent (or ‘computer literate’). The perception in such organisations was that unless the training was well designed and part of a customer-focused service it acted as a disincentive to the user.

## 7. Conclusions and Implications for Internal E-Services

This paper has provided some evidence that there is a role for e-service, in particular e-procurement in helping improve internal customer service and reduce costs.

1. **Customer perceptions:** The application of e-service to internal purchasing and procurement improved customers perceptions of service - service was faster, easier with speedier problem resolution and control of budgets
2. **Process compliance:** The reliability of the process improved through reductions in MTBF together with high levels of compliance and control using help-line support.
3. **Cost reduction:** e-service applied to procurement enabled a restructuring of overall costs through the consolidation of centralised purchasing without the need to restrict the supplier base.

## Abstract

Current development of network infrastructures is undergoing rapid transformation. With the emergence of the Open Grid Service Architecture and Globus Toolkit as incubators for evolving ASP business model to maintain profitability, this paper presents an in-depth analysis of the hypothetical Grid Service Provision (GSP) model by firstly giving an historical account of evolutionary factors in Internet architectures leading to Grid and P2P and secondly, investigating GSP model in the contexts of Service Level Agreements metrics and GSP implementation details. It is acknowledged by some experts that this hypothetical model is technologically feasible in reality.

## 1. Introduction

Application Service Provision (ASP) which is regarded as alternative and primary software application delivery model to Small or Medium Enterprises (SMEs) has been reaching maturity [1]. The ASP model, typically a 'one-to-many' model, often delivers web-enabled applications to SMEs using IP-based telecom infrastructure. Compared to the more numerous studies on the decision to outsource or not in the context of a client relationship [3] and ASPs marketing strategies, few studies have looked at the influence of new networking technology on the ASP

business model, and how this might optimize an ASP's Quality of Service (QoS). With the increasing migration towards the trend of interoperability and collaborative-work between individuals and corporations to conduct the electronic business (E-business) on Internet, a higher demand that shifting the internet service networks away from best-effort, vertical network architectures to a more intelligent and enhanced networking service to enable end-to-end service-aware network paradigm is claimed by both business practitioners and users [3]. With the

emergence of Web Service [4] and WSDL<sup>1</sup> which have come to be known as an interface and description language in which software operations are network-accessible through standardized XML messaging, the attractive features of Web Service are showing potentials for xSPs to broaden the scope of QoS they deliver to end-users and also increase the skill to serve the business computing market. Today's business computing pattern features a collaborative ecosystem of corporations and individuals that can exist in a holistic computing process. Since Web Service makes it reality that the software applications can be platform-independent and also execution-independent of the programming language [4] in which it is written, Web Service technology offers the business computing users an alternative way to receive the software application service not only from xSPs' server farm, but also from the peer users' computers. This significant technical improvement progress provides users with chances to obtain the high QoS from a bigger and broader dimension of networking and computing environment, including Peer-to-Peer (P2P) computing. Consequently, one curiosity for requiring a feasible and ideal networking infrastructure underpinning and optimizing Web Service to function is arising to both academic researchers and service provision business practitioners. The emerging Grid Computing technologies with its unbeatable advantages are now expected to meet this requirement.

## 2. Related Work

Service providers of all types (xSPs), including ASPs, must deal with many issues if they hope to become long-term survivors in this fast-changing ecosystem. xSPs need compelling services to sell – and rock-solid infrastructure platforms on which to host those services [7]. xSPs need to monitor and measure service use and

---

<sup>1</sup> WSDL - Web Service Description Language.

the quality of the services (QoS) they deliver. Due to the fact that no single service provider can do all of this alone, xSPs need to form alliances, which usually include Independent Software Vendors (ISV), platform vendors, Internet Connection Vendors (ICV), and also infrastructure vendors. Each stakeholder plays a complementary role in delivering the service.

Focus of debates in prior research has been on the (re)allocation of the xSPs resources and also the alliance of the xSPs to offer the clients better QoS, as well as to enhance their competency to prevent the customers from turning to rival providers. Moreover, many academic researchers are now 'hyping' the development and deployment of the web service technology as the encouraging transition for ASPs; from web-accessible software-as-service to higher-level integrated collections of software operations that will finally operationalise successful ASP delivery for customers. Compared to pre-packaged applications, the unique aspects of web services can be summarized as:

- Web service-based applications are loosely coupled;
- Application component-oriented;
- Cross-technology implementations;
- Available to be used alone to carry out a complex aggregation or business transaction.

A leading IT consultancy, Ovum has released findings of its research on this latest development in computing and communications: [8,9]: "Within the next five years Web services will mean the death of the pre-packaged application, known to - and even occasionally loved by - users around the world today". However, all of these discussions are based on WWW protocols and IP-based telecom infrastructures. Hence, they miss the unprecedented advantages that Grid computing can bring to the IS world. In the Web Service era, old-fashioned ASP/xSPs software-as-service delivery pattern on the HTTP-IP based networking infrastructure is not likely to achieve interoperability due to the xSPs' intrinsic characteristic of "one-to-many" relationship between service providers and users.

## 2.1 JXTA vs. Microsoft.NET

To achieve the business process interoperability, P2P computing signifies a decentralized architecture [10]. The most mature application areas for P2P computing are file sharing and instant messaging in the users' space. P2P takes a class of advantage of resources available at the edges of the Internet including: Storage; Cycles; Content and Human presence. Web Services, on the other hand, is an attempt to take the Web model for publishing - loosely coupled components with a simple "request-and-response" model - and apply it to computing using XML messages instead of HTML documents [11]. Due to its insistence on well-defined

standards such as XML-RPC, SOAP<sup>2</sup>, WSDL and UDDI<sup>3</sup>, Web service applications are able to communicate between client and server, and different Web Services are also designed to work together, in order to achieve the fundamental goal of interoperability.

The stumbling block for current P2P computing is that two P2P applications using HTTP transport mechanisms are not guaranteed to communicate due to the little progress that has been made so far in adopting general standards. For example, two Napster users must install the same application so that they can share MP3 songs. Likewise, another typical example of P2P collaborative work groupware [12] (requests all the users to install a class of software to organize their activity) is Groove [13], made by Groove Networks. Groove allows co-workers to expose data directly to other users while they are working at their computers, and when they are off-line, the other user can continue working on the file that has been saved on the shared "workspace". Users can get resynchronised once they reconnect to the shared "workspace" again. Although Groove equips users with an impressive array of tools for getting group work done over the Internet, users still need to install this software to form a virtual workspace to achieve interoperability.

### 2.1.1 Microsoft.NET

Two leading P2P practitioners in business computing like Microsoft and SUN Microsystems are pioneers in exploiting the great potential for combining Web Service with P2P computing.

Microsoft HailStorm (which is now called Microsoft .NET My Services) announcement brings a light to the dawn of increasing the two areas of overlap. Microsoft plans to bring new convenience and richness to the lives of consumers by increasing the utility and value of devices, applications, and the Internet. Building upon the proven capabilities of Microsoft .NET Alerts and Microsoft .NET Passport. .NET My Services will allow businesses to build stronger customer relationships by improving web sites and web services, offering operational efficiencies that can cut costs and increase profits, and provide new business opportunities for the industry<sup>4</sup>. From a customer's perspective, .NET My

---

<sup>2</sup> Simple Object Access Protocol - provides a means of messaging between a service provider and a service requestor.

<sup>3</sup> Universal Description, Discovery, and Integration.

<sup>4</sup> The .NET My Services platform is a collection of XML Web services that are invoked over the Internet by means of industry-standard protocols including SOAP, XML, and Universal Description, Discovery, and Integration (UDDI). The instant messaging system is undergoing changes so it can be used as a platform for Web services. The associated 'Passport' will provide identity services and Microsoft Messenger will offer presence management for networked applications, such as personal information storing, including contacts, e-mail,

Services ensures that the information is private, secure, and available. By default, personal information is only accessible to the user. Once information is placed in the .NET My Services “Digital Safe Deposit Box”, a user can control it with fine granularity; choose to share that information with friends, family, groups with which they have an association, or with businesses. In addition, from the business perspective, Microsoft .NET My Services makes Mobile E-commerce a reality in which users can sign up to receive alerts on any of a number of desktop or mobile devices, enabled by XML cross-platform transaction functionality.

So far, the overlap area in which P2P and Web Services seem to be converging is XML messaging. P2P technology still needs to focus on general standards on which to build the conversation. Moreover, P2P is a narrow scope technique term referring to locating files in small-world networks. Locating files in an environment with potentially hundreds of thousands of geographically distributed nodes is challenging because of scale and dynamism. In such an environment, the system has multiple sources of variation over time:

- Files are created and removed frequently;
- Nodes join and leave the system without a predictable pattern,
- A large number of components may aggregate into frequent group level changes.

Notwithstanding this added opportunity, P2P is still under development; the benefits of decentralization have been recognized.

Decentralization was an architectural principle of the Internet itself, but over a period of 10 years, the Internet has changed significantly. The concept of the ASP model as major software application delivery pattern has been widely accepted and this has caused a shift in thinking of the Web/Internet as becoming increasingly centralized. Paradoxically, this is just what the internet and computing tenets often try to reverse.

### 2.1.2 SUN JXTA

With respect to progress has been made so far in infrastructure, Sun Microsystems developed a set of protocols in their Project JXTA for ad hoc, pervasive, peer-to-peer computing [15]. Project JXTA was designed to standardize a common set of protocol needed to build peer-to-peer applications that enable peers to discover each other, self-organize into peer groups, advertise and discover network resources, communicate, and monitor one another.

Project JXTA significantly differentiates itself with .NET by a set of creative features [15] that are appealing academics’ interests:

- Achieved decentralization;

---

calendar, profile, lists, electronic wallet, physical location, document stores, application settings, favourite Web sites, devices owned, and preferences for receiving alerts [14].

- Exploitation of increased bandwidth;
- Processing and storage available on devices connected at the edge of the Internet

Project JXTA presents a successful example of an optimization solution in the absence of general standards that early P2P computing might need to adopt. Decentralized computing systems constructed on JXTA architecture present the experience [15] of a community environment where members propagate and share information in a decentralized, self-organizing and open manner, as shown in Figure 1.

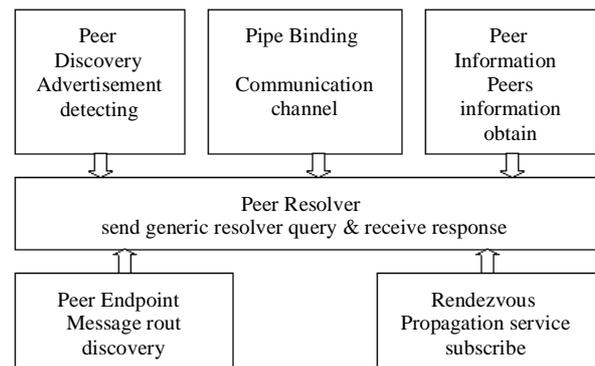

Figure 1. The Project JXTA Protocols

(Source: Project JXTA Virtual Network. Sun Microsystems. 2002)

JXTA protocols work together hierarchically by equipping Peer-to-Peer computing with generic infrastructure that is likely to be able to achieve the goal:

- Develop and deploy P2P services;
- Applications in a virtual self-adapting community;
- Enable a diversity of P2P application and services to be implemented.

### 2.2 Grid Computing and OGSA

Peer-to-Peer computing developments however try to build P2P applications and communications based on a standardized common set of protocols. The characteristic of P2P infrastructure (including all types of enablement) may intrinsically assign no dictating policies, nor dominant peers amongst the virtual community. P2P computing allows client computers to bypass traditional database stores and exchange data directly client-to-client, hence peer-to-peer. Nevertheless, P2P has a dark side [16]: P2P is considered by some to be a ‘socialist computing platform’ whose existence and survival relies largely on trust. The concerns that users can be trusted in P2P deployments and to securely transfer information are currently important questions asked by both academics and enterprises. Likewise, Peer-to-Peer virtual communities are based on decentralized organization

structures and without centralized monitoring could lead to networking-and-technology anarchism.

### 2.2.1 Grid Computing Origination

There is a bewildering debate concerning increasing and maximising computing efficiency by means of workflow decentralization, so that the computing pattern will comply with computing science principle: computing happens where the data is! But a certain degree of centralization is still inevitably necessary. However, this argument will fortunately not become a new fallacy at all. It depends on how we look at the definition of centralization. In today's e-business and e-science, we often need to integrate services across distributed, heterogeneous and dynamic communities formed from the disparate resources within a single enterprise and/or from external resource sharing and service provider relationships. This integration can be technically challenging because of the need to achieve various qualities of service (QoS) when running on top of different native platforms. Foster et al summarized that the ideal target environment for application developers should be:

- Homogeneous;
- Reliable;
- Secure;
- Centrally managed.

Business needs to deliver software applications and services to a vast customer base through distributed networks. There is also the requirement to integrate distributed resources to provide customers with higher Quality of Service. These requirements demand a large-scale, precise and advanced technical computing framework and this development now has led to the emergence of Grid technologies [17,18].

A Grid infrastructure is extremely intricate in terms of the scale and complexity of the services it must provide. The 'Grid Problem' or Grid challenge is defined as the flexible, secure, coordinated resource sharing among dynamic collections of individuals, institutions and resources. These collective organisations are referred to as 'Virtual Organisations (VOs) [19]. Despite their intricacy, Grids present many opportunities for applications in such areas as the World Wide Web, Enterprise Computing, Internet and Peer-to-Peer computing, Application Service Provision and other generic service provision schemas (xSP) [19]. Nevertheless, Grid computing is not simply a broader concept than that of Peer-to-Peer, there are fundamental differences in different contexts. Table 1 shows the Grid and P2P computing comparison and their primary diversity.

### 2.2.2 OGSA Architecture

With the infrastructure of P2P computing for building a virtual community, similarly with Grids, there are a set of infrastructure elements, which now are known as

Open Grid Service Architecture (OGSA) that is being used to construct virtual organizations.

OGSA as a holistic grid service architecture uses the Web Service Description Language (WSDL) to achieve self-describing, discoverable service and interoperable protocols, with extensions to support multiple coordinated interfaces and change management. In addition, OGSA uses the Globus Toolkit to define conventions and WSDL interfaces for a Grid service, which is a (potentially transient) service that can support reliable and secure invocation, lifetime management, notification, policy management, credential management, and virtualization [18]. As a result, OGSA provides a standards-based distributed service system that supports the creation of the sophisticated distributed services required in modern enterprises and inter-organizational computing environments.

Context	Grids	Peer-to-Peer
Enablement	<ul style="list-style-type: none"> <li>• Enable Communities to share resources (computer power, data, storage)</li> <li>• Enable new Applications by the coordinated use of geographically distributed resources</li> <li>• Enable controlled and coordinated sharing of resources among "virtual organisations"</li> </ul>	<ul style="list-style-type: none"> <li>• Computers (PCs) in a P2P network share resources directly (bypassing a central server)</li> </ul>
Infrastructure Type	<ul style="list-style-type: none"> <li>• Persistent infrastructure for Computing</li> <li>• The Internet as a Computing Platform</li> </ul>	<ul style="list-style-type: none"> <li>• Distributed Computing File sharing, Instant messaging, Enterprise Collaboration, People-to-People</li> </ul>
Original Motivation	<ul style="list-style-type: none"> <li>• High-end science and engineering</li> </ul>	<ul style="list-style-type: none"> <li>• Distributed Computation, Sharing, Business</li> </ul>

Table 1. Grids and Peer-to-Peer Comparison.

From the standardized common set of protocols prospective, the creation of large-scale infrastructure requires the definition and acceptance of standard protocols and services, just as the Internet Protocol (TCP-IP) which is at the heart of the Internet [20]. Thus far, no formal standards process has been developed for Grids, however, the Grid Forum [21] is working to create one. Nonetheless, currently there is a remarkable degree of consensus on core technologies. Essentially all major Grid projects are being built on protocols and services provided by the Globus Toolkit [22], which was developed by a group of scientists<sup>5</sup> in the United States and other institutions.

<sup>5</sup> Ian Foster's team at Argonne National Laboratory [29] (operated by the University of Chicago) in collaboration with Carl Kesselman's team at Information Sciences Institute, the University of Southern California.

### 3. New Generation Service Provision building on OGSA and Web Service

Taking advantages of both Grid and Web services technologies, the Open Grid Service Architecture (OGSA) defines mechanisms for creating, managing and exchanging information among entities which is emerging as new generation services delivery pattern – Grid Service. Briefly summarized, a Grid Service is a Web service that conforms to a set of conventions (interfaces and behaviours) that define how a client interacts with a Grid service [23]. The Web Service Definition Language (WSDL) has common application interfaces, and conventions (behaviours that include: dynamic service creation, interface address naming and discovery, controlled fault resilient, notification, manageability, and upgradeability of the distributed long-lived state). This and the OGSA infrastructure together define a Grid Service.

#### 3.1 The Enabling Environment to Implement Grid Service within a VO

The collective organisations in a VO typically maintain not merely a static set of persistent services that handle complex activity requests from clients<sup>6</sup>, they often need to instantiate new transient service instances dynamically, which then handle the management and interactions associated with the state of particular requested activities [18]. The OGSA conventions, protocols, and infrastructures underlie the Grid web service in service implementation. The WSDL application interfaces enable the specific execution in the hosting environments or with more sophistication the containers such as J2EE, IBM Websphere, Microsoft.NET and Sun One. The containers here refer to an implementation-programming model, programming language, development tools, and debugging tools.

#### 3.2 Hypothetical GSP Model

Work [5] on the hypothetical Grid Service Provision (GSP) model so far that provides quality of service in Web Service Application delivery with Open Grid Service Architecture (OGSA) support is still in an embryonic phase. Current work on GSP can be divided into two stages: GSP definition and futuristic scenario simulating analysis in the context of Service Level Agreement (SLA) metrics.

The ASPs/xSPs applications and services provision model can embrace a new lifecycle. The key to reaching this new horizon is to move to a common program-to-program interaction model. New applications are being developed with programming models (such as the Enterprise Java Beans component model [24]) that

---

<sup>6</sup> Clients here refer to service requestors, in the context of “resource-sharing relationship” in a VO.

insulate the application from the underlying computing platform and support portable deployment across multiple platforms. The Open Grid Service Architecture provides a broad set of protocols as low-level infrastructure to communicate and manage the pervasive computational edge resource of a VO. Meanwhile, the development of programming models which comply with Web Service Description Language (WSDL) and Extensible Markup Language (XML) specifications are building blocks to enable the ASP software application delivery model to evolve. As a result, unlike the scientific Grid service architecture such as SETI@home [26] or Grids in Aerospace industry [25], developing and deploying Grids in business computing are pledged to harness new opportunities and market niches in the Grid era. Figure 2 is a hypothetical Grid Service Provision model and is shown at the end of this paper.

From the physical fabric point of view, OGSA is an extension of HTTP-IP based networking. After applying Grid computing to the current networking physical infrastructure using OGSA mechanisms to build a VO, the decentralization and distribution of software, hardware, and human resources would make it essential that the desired quality of service (QoS) are achieved. This type of ubiquity in computing and service patterns will largely change the traditional way that enterprises do business, especially e-Business. The impact of Grid computing, whether measured in terms of common security semantics, distributed workflow and resource management performance, coordinated fail-over, problem determination services, or other metrics – on resource assembled dynamically from enterprise systems, service provider systems, and customer systems [18] – will all alter our perception and understanding of computing.

### 4. Analysis and Implication

In old-fashioned ASP/xSP models, customers receive the software application through web, and host their business data on the xSP’s server farm. Customers are confined to the relationship with the ASP/xSP on a long-term or short-term subscription basis and this depends on whether they decide to rent or lease the service [27]. Despite Service Level Agreements (SLAs), customers have to accept the “as is” quality of services provided by vendors with very little customizability. Furthermore, there are also several problems with the services: based around imperfect connectivity, ASPs’ remote management and resource management.

Grid technologies support the sharing and coordinated use of diverse resources in dynamic VOs, from geographically and organizationally distributed components to highly integrated creations to achieve the desired QoS [19]. Enterprises are also now expanding the scope and scale of their enterprise resource planning (ERP) projects as they try to provide better integration with customer relationship management (CRM), integrated supply chain management and existing systems. Grid Service Provision may help to release this

significant pressure on the enterprise IT infrastructure as well as to achieve the following:

- Supports dynamic resources allocation in accordance with the service-level-agreement (SLA) policies, efficient sharing and reuse of IT infrastructure at high utilization levels, and distributed security from edge of network to application and data servers.
- Deliver consistent response times and high level of availability, which in turn drives a need for end-to-end performance monitoring and real-time reconfiguration.
- In addition, assure the security, auditability, SLA and complex transaction processing flows of multi-organizational supply chain management, B2B integration in cross-enterprise business-to-business collaboration.

#### 4.1 Analysis of Grid Service Provision (GSP) model

Peer-to-Peer computing evangelises the current business computing pattern into interoperability paradigm, built on Grid computing and OGSA architecture. With the development of software engineering, the traditional software-as-service can be integrated with web pages and delivered via internet. .NET and J2EE as popular implementation-programming model, programming language, development and debugging tools that can help realize the Web Service which can be simply understood as “functioning-web-pages”. With this functionality, web service can be simply and easily delivered by xSPs and received by users without pre-installed software-running supporting systems. From the users’ prospective, Web Service largely reduces the cost of IT investment and the complexity of maintenance – the commonly and broadly used web browser can carry out this implementation of Web Service.

The functionality-encapsulated web service contributes feasibility to developing and deploying interactive and cooperative interoperability in today’s collaborative electronic business ecosystems. Business and individual users can receive software applications (web service) from service providers, as well as from peer users alternatively. SMEs, as major marketing target for xSPs, are given flexibility to acquire web service from multi resources: xSPs’ server farm and/or Peers users.

Due to the fact that web service can be hosted at various places, users do not need to shuffle raw data around a network to wait for processing by a centralised mainstream computer at an ASP’s server farm, and furthermore, ASPs do not need to bear the overload work for user’s computing requests - there is a large waste of resources, considering bandwidth, user idle time; data secure transferring issues, etc.

With the emergence of distributed computing, in which Grid computing has marked an important new phase; the ASP model can evolve by using the advanced networking architecture to deliver software applications. The convergence of web services and Grid computing

technologies is expected as an approach to solving and resolving current ASP delivery problems. Moreover, such new technologies may bring a revolution to the current software application delivery pattern, and this could have a pervasive impact on the IS world, like IP based WWW (World Wide Web) did in the last two decades of the 20<sup>th</sup> century.

As a result, academic researchers [5] are attempting to evolve the old fashioned ASP business model into Grid Service Provision (GSP) model by combining and converging Web Service technology and OGSA architecture to achieve the fundamental goal of interoperability.

#### 4.2 Inside GSP Model

GSP is not only an xSP technical framework, it is also likely going to be spoiled by business practitioners as a good business model that begins with an insight into human motivations and ends in a rich stream of profits [28].

When ASP evolves into GSP, users (SMEs) are regarded as VO members, who can inherit all VO’s features: flexible, secure, coordinated resource sharing among dynamic collections of individuals, institutions and resources. Once users sign in VO to start each service session/transaction, at the same time, GSP begin to monitor and measure the quality of service using Java-based intelligent agents [29] to ensure end-to-end QoS specifications and service price negotiations in such an environment. Java-based SLA/Pricing Agents are used to process user’s service request including identity verification, customised SLA specifications, and commit the service to be delivered to the requestor (user). Open Grid Service Architecture/Grid Engine/Container are used as application implementation platform and service interpreter/search/delivery engine to communicate both users and (Grid) Service Providers to ensure the service quality and SLA fulfilment.

(Grid) Service Providers are responsible for managing security issues, user information, resource discovery and advertising, data storage, etc. When a service request is accepted, GSP will search the resources throughout the whole VO and GSP itself in order to respond to this request. This responsive process is hidden and transparent from a user’s point of view because the resources can be stored on GSP’s server and also peer-users’ computers. This responsiveness mechanism guarantees quick and efficient service response to the request. One of significant attributes of GSP model is the ability to create added-value that benefits peer users: members in a VO, who have spare resources such as storage space, can share the extra computational ability with GSP to help host web services and deliver to the other peer users. Both spare resource provider members and GSP benefit the profit from this sharing.

Compared to old fashioned ASP, GSP model presents many opportunities to improve the level of QoS and increase the profit margin, as shown in Table 2.

## 5. Conclusion and Discussion

Traditional ASPs have focused on economy-of-scale in the past a few years, and some successful players have achieved this goal. In today's Web service and Grid environments, vendors are being given the opportunity to embrace achievement of both economy-of-scale and skill. Current trend of Electronic Commerce (E-Commerce) is to accelerate the shift of power toward the consumer (Adrian J. Slywotzky). Some advantages of Grid-enabled P2P networking will allow SMEs to reduce fees,

operational complexity, and increase interoperability. Grid computing and OGSA as originated for solving the scientific computing problems are now showing the potential to serve the business computing market. However, GSP is a hypothetical model which is lack of empirical evidence and study. It is consistent with technology development in reality. Hence, this model still needs to be tested and implemented by both academic researchers and business practitioners for further development.

Context	GSP	ASP(old-fashioned )
Service Delivery Pattern	Peer-to-Peer (Many-to-Many)	One-to-Many
Infrastructure Type	Extended HTTP-IP Networking	HTTP-IP, WWW Networking
Motivation	<ul style="list-style-type: none"> <li>• Better QoS</li> <li>• Customised service for user</li> </ul>	<ul style="list-style-type: none"> <li>• 'as is' products</li> <li>• Pre-packaged service</li> </ul>
Relationship with user	<ul style="list-style-type: none"> <li>• Peer-to-Peer relationship</li> <li>• VO members</li> </ul>	Server/Client
Interoperability	High	Low
Service Charge Method	per Session/Transaction	User's Subscription
User's accessibility	Easy access (Join the VO)	Need technical support
Networking Control/Monitoring	Difficult	Easy
User's Cost	Reduced(Low)	High
Providers' Investment	Reduced cost by resource sharing	Incremental investment
Organisation Architecture	Decentralised	Centralised

## Abstract

This article proposes a conceptual framework for planning and deploying collaborative-commerce (c-commerce). The framework consists of two dimensions: the type of inter-organizational relationships and the level of engagement that involved organizations want to achieve. The combination of these two dimensions generates nine categories of collaborative-commerce. Each category designates an opportunity for c-commerce initiates. The article characterizes each category with two concepts: focus and linkage interface. Focus means the interest or benefits that one type of c-commerce is expected to achieve. Linkage interface refers to major elements that facilitate the type of c-commerce to move forward and keep the involved parties as a whole. Examples are identified to illustrate the nature of each category.

Practitioners can use the framework as a roadmap to assess the commitment and trust level and subsequently, determine the type of c-commerce. Researchers can use the framework to identify issues specific to each category and specify features of enterprise application pertaining to each category. Three main directions are also identified for future research to further understand the phenomenon of c-commerce.

## 1. Introduction

As the competition of business environment becomes more intense and information technologies (IT) become more sophisticated than ever, firms are rapidly adopting innovative use of IT to outreaching customers, building partnerships, and creating new forms of organizations. Ramifications of this trend include the creation of various new forms of commerce, such as electronic-commerce, electronic-business, and mobile commerce. According to a recent report [2], the next stage of growth in the enterprise application software business is collaborative commerce (c-commerce). The report estimated that the size of the c-commerce market would grow from \$5.8 billion in 1999 to \$36.5 billion in 2004 (estimated by AMR and IDC). Several successful cases of c-commerce have been reported in various industries, such as the aviation and aeronautics, automobile manufacturing, and telecommunication. For example, Boeing improved its production productivity from 228 airplanes per year in 1992 to 620 expected in 2002 by using collaborative e-marketplace [5].

As many firms start adopting c-commerce, issues surrounding c-commerce have caught researchers' attention. For example, Welty and Becerra-Fernandez (2001) investigated the issue of managing trust and commitment in collaborative relationships. Kumar [13] delineated the features of information and communication technologies for supporting c-commerce.

Although sporadic research about c-commerce has been reported, an examination of extant research shows that there is a lack of systematic research into the phenomenon of c-commerce. The purpose of this article is to propose a conceptual framework for planning and deploying c-commerce at the firm and industry level. We believe that, in the early stage of c-commerce, such a conceptual framework is crucial for understanding the phenomenon of c-commerce. With the conceptual framework, researchers could synthesize previous studies and identify issues specific to different types of c-commerce. The framework can also be used by practitioners as a roadmap to take into account relevant issues when they consider investing in c-commerce.

## 2. Literature Review

C-commerce is claimed as the next generation of enterprise software applications, yet the practice of collaboration is not new. In fact, collaboration is part of human life. By working together, people could overcome challenges imposed by the nature and survived from acts of the nature. As a result, while research in c-commerce in the field of IT is still in its infancy, the topic of collaboration has caught researchers' attention in a variety of disciplines. For example, researchers in the field of social services have investigated how business, government, and stakeholders form collaborative alliance to generate constructive solutions to social problems [8]. In the field of marketing, researchers examined the factors that affect the development of collaborative relationship between buyers and sellers [24] and how to develop and sustain collaborative supply chain relationships [23].

Meantime, only limited research in c-commerce has been conducted in the field of IT. Those existing studies focused on two themes: (1) reporting successful anecdotes and (2) IT infrastructures for building c-commerce. Examples of successful stories [5] [12] are available in companies in various industries: those are Boeing Co., Lockheed Martin Aeronautics, Co., General

Motors Corp., Juniper Networks Inc., and Toshiba Canada Office Corp.

The emphasis of IT infrastructure prevails in the extant literature of c-commerce. For example, Bellini, Gravitt and Diana [2] define the c-commerce market by three categories of enterprise application software: supplier relationship management, knowledge management, and product lifecycle management. They assert that the demand for software in these three categories will grow when companies look for ways to close the loop of product development value chain. They report that the collaborative capabilities of those applications usually leverage the Internet, rather than an enterprise proprietary nationwide network. Also, the collaborative capabilities require an environment to “facilitate inter-company business processes and community management with integration to extend the enterprise in a unique and ubiquitous way” [2, p. 7].

Fou [7] claims that the ultimate aim of c-commerce is to maximize return on intellectual capital investment, improve business agility, and provide better quality of customer experience. In order to achieve the objective, Fou believes that the next stage of c-commerce must be built on web services, and he proposes a Web-service-based collaborative architecture that consists of four tiers: c-commerce vendors, web services, business rule engine, and multi-dimensional c-commerce enterprise web portal. Furthermore, Fou classifies the evolution of c-commerce into three stages: (1) web-enabled single-dimensional and single-process c-commerce, (2) B2B exchanges-based, single-dimensional and multiple-process c-commerce, and (3) web service-based, multiple-dimensional and multiple-process c-commerce.

In contrast, Derome [4] downplays the importance of state-of-the-art technologies in developing collaborative relationship. For example, according to him, e-mail is a c-commerce tool, as are Electronic Data Interchange (EDI) and Extensible Markup Language (XML). Thus, Derome [4] believes that c-commerce capabilities should be depicted from a functional standpoint. He defines c-commerce as a three-layer architecture: Free-form collaborative services, process collaboration layer, and the structured data exchange category. The IT environment, duration of collaboration, and goal of collaboration vary from category to category. Although Derome suggests a variety of technologies (so-called collaboration over Internet Protocol, CoIP) for each of the three categories, he emphasizes the importance of deriving value propositions from the development of a collaborative relationship. However, the value propositions he proposes are mainly from transaction-focused applications.

Li and Williams [16] examined six case studies and found that companies that had established a successful cooperative relationship at the transactional level by creating interfirm network (via proprietary or open systems) tended to develop new and collaborative partnership at the strategic level. They observed similar evidence in the sectors of retailing and manufacturing. Their studies show that further developed collaborative

relationship could occur in the existing transactional application or a new application devoted to the new partnership. However, they found that different types of applications were more often developed on different IT infrastructures.

In addition to studies regarding successful c-commerce cases and IT infrastructures for c-commerce, several other studies have been reported. For example, Alexander [1] reported benefits of c-commerce and barriers of deploying c-commerce from a practitioner’s point of view. Mulani and Matchette [18] propose a total lifecycle collaboration framework that ties the mutual strategic objectives of two companies to actual inter-company execution. The connection between strategic objectives and actual executions is realized by developing critical decisions and metrics for various types of collaboration in different stages of the lifecycle of new product development. Ramachandran and Tiwari [20] studied the air cargo industry and reported that collaborative supply chain providing economic global air cargo services should be based on a business model that consists of three layers: connectivity layer, knowledge layer, and functionality layer.

As shown by the above review, research studies of c-commerce are scarce. Reporting successful cases and IT infrastructure for c-commerce dominate the extant research. Although the selection of appropriate IT infrastructures is critical for developing successful c-commerce, yet it is not sufficient. This is because collaboration is not a purely technological issue. As indicated in several studies, successful c-commerce depends on trust and commitment among partners, as well as individual partner’s capability of providing required services. We believe that a framework for planning and deploying c-commerce that considers those aspects should be developed.

### **3. Framework for Planning and Deploying C-Commerce**

#### **3.1 Rationale**

Before we delve into the detail of a framework that we propose, it seems appropriate to address the rationale for those factors we consider in the framework. Himmelman defines organizational collaboration as “a process in which organizations exchange information, alter activities, share resources and enhance each other’s capacity for mutual benefit and a common purpose by sharing risks, responsibilities and rewards” [9, p. 28]. This definition suggests that the development of collaborative relationship has a profound impact on the involving parties. Thus, firms that plan to invest resources into a collaborative relationship should consider c-commerce as gradually progressive applications of enterprise-level IT that attain and support the collaborative relationship. They should evaluate their relationships with business partners and the level of engagement that they would like to be involved. While inter-organizational relationship depends on objective factors, such as the industry sector, and the nature of the

business, the level of engagement is determined by trust and commitment held by the firm on its business partners.

Trust and commitment are generally considered as premises for establishing a collaborative relationship [23]. Trust could be broadly defined as the belief that others will act or react in a predictable way [17]. Trust is important for the creation of partnership because it could reduce uncertainty and provide certain extent of assurance for managers' decisions. Consequently, it might determine the commitment we assert on a partner relationship. Trust and commitment are a relative concept. Just like relationship between individuals, relationships between companies begin, grow and develop [11]. The level of trust and commitment grows following the development process of relationship between two parties. The trust level built from an acquaintance is presumably lower than that acquired from a friendship. The level of trust and commitment will determine the level of involvement that one party is willing to engage with another party and as a result, it will indirectly determine the level of e-commerce that one party would like to establish.

In practice, previous studies [16] also show that the first step of developing interfirm collaboration seems to be developing a routine application so that trust and commitment could be nurtured. Consequently, a framework for planning and deploying e-commerce should take into account the variation of trust and commitment between organizations and provide sufficient granularity of choices so that firms could determine the type of e-commerce to create.

### 3.2 Dimensions of the Framework

Our conceptual framework for planning and deploying e-commerce is based on two factors: (1) type of inter-organizational relationship (IOR) and (2) the level of engagement determined by trust and commitment. There are several classifications of IOR available in literature of organization sciences. We believe the classification proposed by Whetten [28] is sufficient to serve the purpose of our study. Whetten classified IOR into four categories: dyadic linkages, organization sets, action sets and network.

Dyadic linkage is the simplest form of interaction between organizations, and this linkage occurs "when two organizations find it mutually beneficial to collaborate in accomplishing a common goal" [28, p. 5]. A typical example of this type of IOR is a joint venture by two organizations. Another example of this linkage can be simple coordination that one organization performs some part of production activities while the other performs the rest to achieve higher efficiency.

Organization sets are the total sum of inter-organizational linkages between a focal organization and its trading partners [28]. There is only one focal organization that mainly manages the interactions and conflicts. In this IOR, relations among non-focal organizations are minimal and thus can be ignored. A typical example is a big manufacturer that coordinates its product design effort with several small parts suppliers.

Another example is a manufacturer whose parts or work-in-process are supplied by multiple suppliers.

Action sets are coalitions of organizations working together to accomplish a specific purpose [28]. Action sets are networked interacting group of organizations. Unlike organization sets, there is no one clear focal point in action sets; however, it is still possible that one, two or more organizations play roles of leaders in this type of IOR. An example of this type of IOR is coalition of small banks to provide shared ATMs to their customers. It should be noted that this is one type of networked IOR, which will be described below, since there are direct interactions among partners without going through a focal organization.

The last form of IOR is a business network. A business network is defined as "the structure of interdependent relationships between the activities of a given firm and those of other firms in its competitive environment that influence each other's strategies" [10, p. 60]. A business network, thus, usually represents all interactions that occur among trading partners [28]. A typical example is the supply chain of manufacturers, distributors, wholesalers, and customer-facing firms at the retail level for any commercial products [13]. As mentioned before, action sets are a special type of network IOR, and thus we treat both action sets and business network as "network" type of IOR in our framework.

The three stages of organizational evolution in using IT [22] are employed to differentiate the level of engagement. Those three are: Automate, Informate, and Transform. "Automation" means using IT to reduce the cost of production. Here production has a broader meaning, including the production of physical goods, information processing, and any other forms of human activities. Typically, traditional, manual and paper-based operations are computerized to reduce manpower necessary to carry out the operations.

A company in the "informate" stage is to empower managers with IT. The empowerment is mainly achieved by providing managers with information generated by IT tools. Meanwhile, a company may create economic value of information that is the by-product of automation. Typical examples include using decision support systems to "informate" managers to make better decisions or using data mining techniques to identify patterns and trends of customer purchasing behavior from transaction data for better planning. A company at this stage needs workers who have ability to interpret and analyze information that generated from basic transactions.

A company in the "transform" stage might have successfully gone through the first two stages and been ready to capture opportunities presented by the environment by transforming its organization and/or by changing the rules of the games of the market. Companies in this stage are characterized by strong IT leadership, vision, and a sustained process of organization empowerment. In other words, a company in this stage is committed to align business and IT strategies well and exploit IT-enabled opportunities.

### 3.3 The Framework

Using these two dimensions, we propose a conceptual of framework as shown in Table 1. We will discuss each category in terms of concept, focus, and linkage interface. Focus means the interest or benefits that one type of c-commerce is expected to achieve. Linkage interface refers to major elements that facilitate the type of c-commerce to move forward and keep the involved parties as a whole.

#### 3.3.1 Automatic Dyadic Relationship

The main concept of automatic dyadic relationship is to use IT to automate existing interactions between two companies in order to improve the efficiency and other benefits of the interaction. The main focus of this c-commerce application is to improve the efficiency of business transactions, such as reduction in time, reduction in labor, and increase in transaction accuracy. The

linkage interface in this type is structured data format, which may be based on proprietary or open standards. Because the linkage interface is structured data format, this type of automatic relationship seldom causes changes in internal processes of the firms, although it may change job descriptions and requirements for skills. This is the most basic or simplest form of c-commerce. As a matter of fact, this type of relationship dated back to 1970s when companies started to use electronic data interchange (EDI) to automate highly structured transactions. Wal-Mart's continuous replenishment system (CRS) is an example of automated dyadic relationship [14] (It should be noted that even though a retailer like Wal-Mart apparently has many suppliers, since those suppliers are relatively independent of one another, the relationship between Wal-Mart and each of its suppliers could be considered as dyadic relationship.) The continuous replenishment system enables Wal-Mart to reduce its inventory cost to a minimum level with a stockless

**Table 1. A conceptual framework for planning and deploying c-commerce**

Types of Inter-Organizational Relationship					
		Dyadic	Organization sets	Networks	
	Automatic Dyadic Relationship	Concept	Automate existing interactions between two companies	Automate interactions among partners via a focal company	Automate linkages among members of the business network
		Focus	Efficiency	Efficiency of individual relationships and a group seen by a focal partner and timely action	Efficiency of flows and effectiveness of managing uncertainty
		Linkage interface	Structured Data	Structured data/information	Data/information/algorithms
	Informative Relationship	Concept	Informing partners with IT products	Informate and strengthen critical relationship	Informate partners and strengthen all partners as a group or redesign the business network.
		Focus	Effectiveness	Efficiently and effectively identify and strengthen critical relationships	Efficiency, effectiveness, and competitive success
		Linkage interface	Information/know-how	Knowledge about its business, partners, and products	Information/knowledge, experience, and insight.
	Virtual Organization	Concept	Transform relationship b/w partners	Transform relationships and create miniature community around a focal partner or function as a virtual organization	Change the scope, boundary, and/or structure of the business network
		Focus	Efficiency, effectiveness, new value, & new opportunity	Efficiency, effectiveness, values, and new opportunity	Collaborative advantage/competitive advantage, new economic opportunity, efficiency of the whole industry
		Linkage interface	Knowledge/division of labor & rewards	Complementary partnership/compatibility between skills/knowledge/division of labor/vision of a focal partner	Value, vision, and potential external threats.

business model. This allows Wal-Mart to implement its low cost strategy and thus, to create competitive advantages over its rivals.

In the past, because most of EDI systems were based on proprietary technologies, investment in EDI systems reflected a high level of engagement companies committed to this type of relationship. However, as open standards (such as TCP/IP, XML) become popular, companies could adopt a technology based on those standards to automate a dyadic relationship. Because of lower switching cost with technologies based on open standards, the company could relatively easily switch from a relationship to another and, consequently, the engagement level will not be as strong as it used to be.

### **3.3.2 Informed Dyadic Relationship**

The main concept of informed dyadic relationship is that one company uses information generated from its applications of IT to inform its partner so that its partner will make necessary arrangement to respond to anticipated future events. The focus of the relationship is to effectively respond to changes in the environment. Information that could be helpful for responding to plausible events in the future is the interface that holds involved firms together. The sharing and use of the information might cause minor changes in internal operations in one party. In an even closer relationship, one party of a dyadic relationship might even share the know-how of forecasting and/or its historical data set.

An example of informed dyadic relationship is the continuous replenishment program (CRP) in Procter & Gamble, Co. The CRP has similar functions as those of CRS in Wal-Mart. The CRP is capable of analyzing changes in customer buying habits and, subsequently, Procter & Gamble adjusts its product schedules to both and actual purchases and anticipated demand. Furthermore, Procter & Gamble kept its retail customers informed by sharing the analysis result to improve supply chain efficiency and effectively respond to changes in the needs of customers.

The engagement level of this type is high because companies must share their proprietary information as well as how to use the information. Sharing this type of information not only reflects the engagement level that one party is committed to the relationship, but also paves a foundation for further enhancement of confidence and trust. As the nature and sharing of information is the linkage interface, the type of technologies becomes less an issue.

### **3.3.3 Transformed Dyadic Relationship**

The main concept of transformed dyadic relationship is that companies use IT to transform its relationship with its partners. The focus of transformed dyadic relationship is creating new value to existing market or capturing new opportunities, while it may include improvement in efficiency and/or effectiveness. The linkage interface is knowledge. Examples of knowledge include an understanding about the business that one firm is in and/or knowledge of division of labor when a new

opportunity opens. The firm and its partner will be able to divide the work and fully take advantages of their strengths. Another scenario is that a firm changes the structure of its relationships with partners and invite them work together. For example, a personal computer maker has an OEM company. In the past, the PC maker sells products (computers) to its customers via transportation service that it arranged. With the assistance from IT, the PC maker may change the structure in terms of division of labor by providing information about its customers to its OEM and the OEM is in charge of the delivery of products. The level of trust and commitment between the PC maker and its OEM is stronger than that between them in informed/automated dyadic relationship because in the present case, the PC maker firm will need to provide specific information about its customers and know-how of customer service and delivery to its OEM.

The engagement level of this type is very high because two companies must be willing to share responsibility and risk involved in the transformation of their relationship. The transformation of their relationship may require them to align their business strategies and IT strategies for common goals. Typically, if and after going through the automated and informed stages together, both companies might possess well-compatible IT infrastructure and are well ready for transformed dyadic relationship. The adoption of complicated, customized, enterprise-wide applications can be planned.

### **3.3.4 Automatic Organization Set**

The main concept of automatic organization set is that the focal firm uses IT to automate its interaction with partners. An example of automatic organization set is that a builder (or a construction company) who deals with several contractors in the construction industry may use IT to coordinate its interactions with contractors. In this case, after being commissioned to construct a building, the focal firm (i.e., the builder) might need to consult the architect for any doubt in the blueprint, to solicit constructors with different skills and techniques, and to make a plan to accomplish the project on time under budget. The main focus of the focal firm (i.e., the builder) is to maximize efficiency of its interactions with individual contractors as well as the efficiency of the group as a whole. In order to maximize the efficiency of the group as a whole, the builder could employ coordination technologies (e.g., groupware) to coordinate tasks performed by different contractors, to monitor the progress of tasks, and to keep contractors informed. Another example of automatic organization set is that a company may implement an electronic bidding system, which selects the best bidder following predefined criteria from a pool of suppliers.

This type of e-commerce focuses on efficiency of each relationship and the overall efficiency seen by the focal organization. The focus of automatic organization set is to efficiently exchange data among partners and take actions efficiently and effectively. The linkage interface is data and/or information about business transactions.

In this type, more partners are involved than the dyadic IOR and thus managing IT is more complicated. However, since there is a clear focal firm in this relationship, the means of data/information exchange is usually selected by the focal firm and partners follow the rules and protocols selected. The engagement level of this type is not high. Thus, industry standard or open standard should be used to avoid unnecessary switching costs on partners.

### 3.3.5 Informed Organization Set

The main concept of informed organization set is that the focal firm uses information generated from its application of IT and know-how's to enhance and strengthen its critical relationships with partners in its organization set. As Kanter [11] indicates, "Successful partnerships manage the relationship, not just the deal." [11, p. 96]. Thus, the focus of informed organization set is to effectively identify and manage relationships with those partners that are critical to the success of the firm. The linkage interface of informed organization set is to disseminate knowledge about the business, its partnership, products and/or its customers that is critical for the focal firm to identify and strengthen critical relationship with its partners. An example of informed organization set is the development of a Collaborative Planning, Forecasting, and Replenishment (CRFR) system in Procter & Gamble, Co. Based on inputs from its partnerships with retail customers, Procter & Gamble, Co. created an instrument called CPFR Capability Assessment for the baseline evaluation of the partnership's four core CPFR processes in eight key elements. The CPFR Capability Assessment is used to assess the strength and weakness of the partnership and actions needed to improve the development process of CPFR [26]. There are two purposes of developing a CPFR system: (1) providing inputs to further fine tune the CPFR Capability Assessment; and (2) improving inventory and reducing out-of-stocks through the supply chain from the manufacturing plants to customers' distribution centers to customers' retail store shelves to consumer homes.

A focal firm's main concern in this type is to handle conflicting interests of partners, enhancing the effectiveness of individual relationship and the overall effectiveness of the group simultaneously. Reasoning of its decision making must be shared with the partners, each of which compromises its own short-term interest, if necessary, for a long-term prosperity.

### 3.3.6 Transformed Organization Set

The main concept of transformed organization set is that the focal firm uses IT to transform its relationships with its partners, or enable itself function as a virtual organization. A focal firm needs to find critical complementary partners and divide the work so that a group can work toward the shared value and exploit an opportunity. The focus is to respond efficiently and effectively to the need of customers and to add value to the whole organization set and to capture economic

opportunity as a group. One possible scenario of transformed organization set is that with the accumulation of experience in using IT to automate and informate its linkages, the focal firm might gradually outsource its activities in design, production, and delivery to its partners and eventually becomes a virtual enterprise. In this case, the linkage interface includes knowledge about its products, customers, and the business that the focal firm is in, as well as guiding goals, strategies and values established by the focal firm. Even more important linkage interface is the knowledge about how to manage a virtual enterprise, how to make and execute plan, and how to coordinate independent activities in the virtual environment. For a focal firm to share those with its partners openly, a group can form a community around a focal firm. Thus IT applied in this relationship must be able to support planning and execution of a plan, as well as sharing information and exchanging transactional data. An example of transformed organization set is the case of Lockheed Martin Aeronautics Co. [12]. Lockheed used Net-collaboration technology to bring more than 80 suppliers that scattered in 187 locations to design and build components of a new family of supersonic stealth fighter planes for the Department of Defense. The Net-collaboration technology employed allowed Lockheed and its partners to keep all parts in sync by sharing designs, tracking the exchange of documents, and monitoring the progress of the project. While the impact of using this type of technology is at operational level in this case, in the long term, it may change the role of Lockheed because Lockheed will be able to tap the best talent, employ new business processes, and redefine roles of partners.

The above descriptions about automatic, informed, and transformed organization set highlight an important point: new and usually "soft" management skills and techniques are progressively more important when a company moves from automatic stage to transformation stage. As a result, how to overcome challenges imposed by a new environment that the firm is in becomes an important issue.

### 3.3.7 Automatic Business Network

The main concept of automatic business network is that all group partners use IT to automate existing linkages among partners. In order to make the business network work efficiently as a whole unit, involved companies usually need to exchange transaction data with its partners without a focal firm. Participating partners must share common goals and understand their roles in a network so a group can achieve maximum efficiency. This feature differentiates this relationship from the automatic organization set and from automatic dyadic relationships. The major objective is to make necessary adjustments in participating firms' internal operations so that the business network, as a unit, becomes able to move goods, information, and payment as smooth as possible. Efficiency in terms of flows and effectiveness in terms of the management of demand uncertainty is the focus of this relationship. The linkage interface of this

relationship is data and algorithms that could smooth the ripple effect generated from disturbances that may occur in one node in the network. Technologies often named “advanced planning systems” (APS) provide techniques, such as forecasting, time series analysis and linear programming, to analyze and optimize the flows of the network [13]. Those applications work best in a relatively stable environment because in such an environment, the structure of the business network will be stable enough to be modeled and optimized [13].

Although a leading firm (“lord of the chain” in Kumar’s word [13]) or a coordinator might appear in a business network in the long term, there is generally no dominating firm in the network. The commitment level, compared to other types of business network, is relatively low; however, the investment in those model-based technologies could be significant. Furthermore, sharing and assuming responsibility and risk in the network is critical for the whole network to function as a whole. As a result, the commitment level might be higher than automatic dyadic relationship.

### 3.3.8 Informed Business Network

Informed business network means that firms in a business network use IT to create values for themselves and partners in the same network by informing each other or redesigning the business network as a knowledge network [25]. Although information derived from historical data might be critical for informing partners to make necessary adjustments so that the flows of payment, goods, and information can move smoothly, the major drive of informed business network might be from experiences in the field, insight for the business, and intuitive judgments [13]. As a result, although data mining and optimization techniques might still be employed to manage demand uncertainty, experiences, insight, and expertise from different companies might be used to create “collective wisdom” to grasp the market opportunity. This scenario is particularly plausible when the business network faces the crisis of survival. The example of battle between the supply chain of buggies, buggy whips, stables and roadside carriage-hostelries against automobile described by Kumar [13] well illustrates the scenario. In this scenario, because the competitive success of a firm is no longer dependent on the firm’s effort, companies in the same business network will be more willing to share risk and obligations by informing its partners and being informed by its partners. The focus of this type of relationship would be efficiency, effectiveness, and competitive success of the business network. The interface linkage of informed business network will be information, knowledge, experiences, and insight.

### 3.3.9 Transformed Business Network

The notion of transformed business network is that the structure, scope, or boundary of a business network is changed with the introduction of IT into the network. Transformation may occur in the form of redefining the scope of the business network [25], creating an IT-

enabled value-net [3], or organizing as an E-Hub in an industry [19]. The scope of the business network could be redefined with new products, new markets, and/or new partners that are brought about by IT. Developing an IT-enabled value-net is intended to create collaborative advantage as well as competitive advantage [21]. The creation of an E-Hub might improve the efficiency of transactions for the whole industry, provide a forum in which industry-wide issues can be addressed and expertise and knowledge can be shared. Those purposes are all concerned with the development of the industry. Therefore, the focus of transformed business network is to create collaborative advantage, capture new economic opportunity, identify potential threats, and/or foster the growth of the industry by exploiting the capability of information technology as the network. The linkage interface of transformed business network is value, vision, and external threats.

An example of transformed business network is the transformation in the tax return preparation network [10]. The transformation of the tax return preparation is characterized by the expansion of the network, addition of new players, changes in roles of existing players and re-structure of the network [12].

## 4. Research Agenda

There are many issues that need to be addressed before we can truly understand c-commerce. In this section, we make an attempt to identifying several issues that we believe deserve researchers’ attention in the near future.

1. Conceptualization of coordination mechanisms in c-commerce: The process of c-commerce involves communication, cooperation, and coordination among partners. Various IT infrastructures proposed by extant research in c-commerce as well as advanced information technology, such as enterprise systems, might have sufficiently paved a foundation for serving the purposes of communication and cooperation. In order to depict the complete picture of c-commerce, conceptualization of coordination mechanisms in c-commerce is crucial. Answers to the following questions are critical to understand the phenomena of c-commerce: What coordination mechanisms are available? How do those firms coordinate their activities? On what ground do they choose one coordination mechanism over another? How does IT support selected coordination mechanisms? What c-commerce applications are best suited to support a particular coordination mechanism?
2. Evolution of c-commerce process: The creation and sustain of c-commerce involves tremendous investment in resources and commitment. The relationship among partners is usually not temporary. Our position is that those partners that progressively go through the automated, informed, and transformed stages over time will have greater success possibility, because mutual trust and commitment would be gradually built up in each stage and because partners could gradually cultivate

skills and techniques for managing their partnership. In this case, what enables and/or inhibits the transition and how an IT-enabled partnership evolves from one stage to another is an important topic to study. Meanwhile, we believe that other factors might offer opportunity for companies to engage in one particular type of collaboration rather than starting their relationship with automated relationship. As a result, what causes the evolution of intra-stage process and how the intra-stage process evolves is also essential for understanding c-commerce. Both inter-stage or intra-stage evolution can be examined by investigating into changes in properties of links (such as strength of the link and symmetry), roles participating firms play, position participating firms occupy, and properties of the network (such as connectedness, density, and reachability) [6].

3. Typology of collaborative network: Although it is claimed that the basic architecture of collaborative networks would be in the form of hub and spoke [19], we believe that the form of hub and spoke will not completely take the place of peer-to-peer communication. We further assert that although the form of hub and spoke is a preferable architecture of collaborative network at the firm or industry level, specific topology varies depending on the nature of projects, groups, and tasks. Also, the topology may vary depending on the stage of the life cycle of a project.

## 5. Summary

C-commerce creates a new form of commerce. Extant literature has focused on the issues of IT infrastructure and benefits. In this article, we proposed a conceptual framework for planning and deploying c-commerce at the firm or industry level based on two dimensions: the evolution of organizational computing capability and commitment, and the type of inter-organizational relationship. This framework allows researchers to classifying commercial applications of computer and communication technologies for c-commerce. It can be also used to identify issues specific to each type of c-commerce, and help practitioners to examine their standing in terms of planning and deploying c-commerce. Moreover, in the early stage of the development of c-commerce, we also identified several key issues that we believe need to be addressed to understand c-commerce better.

## Abstract

One of the major areas of E-Business applications is the sourcing of expert human resources globally with the help of virtual teams operating in various parts of the world. Major corporations are increasingly using eCollaboration technologies to make the functioning of these teams economical and effective. The tasks performed by these teams can vary from software design and development to providing back office services like call center support, technical support, transcription services etc. Additionally, after 9/11 corporations have embarked on major initiatives to implement eCollaboration technologies at the global level to help reduce travel.

Extensive work has been done to study the decision-making performance of face-to-face and virtual teams. However, previous studies have found conflicting results regarding the impact of media richness on decision-making performances of teams. This paper posits the significant role of media type on the communication richness when team members have low commitment to the collaborative team projects. A conceptual model that depicts the influence of media type on satisfaction, team conflict, social influence, and supportiveness that influences the team commitment has been developed. The influence of team commitment on communication richness is also examined. A controlled lab experiment is designed to test the research model.

## 1. Introduction

Team or group work is widely practiced in an organization to accomplish various tasks. With the advent of Internet technology organizations are increasingly using, virtual teams, whose members need not be present at the same location or at the same time [3] [19]. Researchers have investigated issues related to the virtual team practices [34] and the factors that influence virtual team performance [20]. One of the key factors contributing to team performance is effective communication [8], which is the focus of this study.

Virtual teams by definition do not have the luxury of a face-to-face meeting, but require the use of communication technology or “new media” as a medium to coordinate the work and share/exchange information among their members [20]. According to media richness

theory [8], “new media” should be used appropriately by matching characteristics related to media richness with a task’s requirements. However, communication effectiveness is affected not only by the match between media and task, but also by other factors, such as willingness and capability of the participants to adapt and use new media [25] [27] and social influence [39].

Using the Hermeneutic Interpretation approach to examine the actual exchange of e-mail messages among a group of managers, Lee [27] found that in addition to other factors, communication effectiveness requires the willingness and capabilities of members, and support from their organizations. Similarly, Kock [25] studied the use of computer-mediated meetings in a small group and found that “lean media” like e-mail (according to the classification of media richness theory) can be used as effectively as “rich media” like face-to-face for tasks that require high richness, if members using lean media are motivated enough. These findings are parallel to the organization literature on the affect of team commitment on team performance.

The studies of team commitment in organization literatures have addressed both the linkage between team commitment and performance [14] and the antecedents like perceived task interdependence, inter sender conflict, and satisfaction with co-workers. The antecedents are related to the level of team commitment [2]. Studies of organization communication and communication technology, consequently, have focused on the impact of communication medium, and other factors- mentioned earlier, on the team performance. However, none of these studies has specifically explored the possibility of media richness influencing the levels of team commitment.

The Social Influence Model can be used to explain the choice and use of media [39]. Similarly, based on team commitment literature, we argue that an individual using the same media can have either rich communication or lean communication with other members depending on the level of commitment to their team. We, thus, assert that team commitment influences the richness outcome of the media use. The purpose of this study is to determine the communication effectiveness (rich communication) in lean media usage under different levels of team commitment and to examine the effect of media characteristics on the level of team commitment. Thus, we posit that team commitment and media usage is not a one-way relationship. Extending upon the previous study

of Bishop and Scott [2] and on media richness and social presence theories [8], we argue that team commitment is not static and can also be influenced by the ability of medium to transmit multiple cues, immediacy of feedback, language variety, and the personal focus of the medium.

## 2. Theories and Model Development

### 2.1 Goal Commitment

One of the plausible explanations of why some people perform better than others when they all have equal abilities is their motivation to work harder [30]. According to goal setting theory, different goal levels motivate people to behave differently that results in performance differences. Researchers have shown evidence of a significant positive relationship between goal difficulty (high goals) and performance [29] [31] [41]. However, the goal difficulty does not have an effect on performance without commitment [17] [28] [42] [46]. Locke and colleagues considered commitment as an important factor in goal setting theory. Goal commitment can be defined as the resistance to change a goal over time [28] or the determination to try for a goal and the persistence to attain the goal over time [18] [32]. Locke [28] suggested that commitment influences how people expense their cognitive/physical effort to achieve a goal and hypothesize commitment to moderate or strengthen the relationship between goal and performance. Lock et al [32] suggested that the difficulty of the goal affects goal commitment. The moderating effect of goal commitment was also found to be stronger when a difficult goal is assigned [24]. However, prior study by Donovan and Radosevich [11] found that the moderating role of goal commitment on the goal difficulty-performance relationship accounted for less than 3% of the variance in task performance. This small effect might have been the result of the use of easy tasks for difficult goals in the study. The results of Martin and Manning [33] study suggest that commitment is important only when a difficult goal and a difficult task are used.

The commitment to accomplish a goal is classified on two dimensions - the expectancy and the attractiveness [17] [31]. Variables that affect both of these dimensions of goal commitment are: authority, peers/supervisors influence, supportiveness, monetary incentive, feedback, expectancy, self-efficacy, individuals' need for achievement, and past success.

Hollenbeck and Klein [17] classified the above variables into situation factors and personal factors affecting both attractiveness and expectancy of goal attainment. They suggested that the situation factors affecting attractiveness of goal attainment would be *publicness, volition, explicitness, reward structure, and competition*. Publicness refers to the awareness of others about one's goal. They argued that it is difficult to abandon publicly known goals because such behavior appears unattractive to other people. In a team context where all members know their team goal, members of a

team are unlikely be happy with a member who abandons a team goal.

Volition is defined as the individual's free time and energy to engage in a behavior. Low volition implies that people will easily abandon a difficult goal that requires more time and energy than they are willing to give. In an environment where people are involved in more than one team projects or have many responsibilities, time and energy become scarce resources and are not enough to accomplish all goals; thus, people may choose to accomplish some of their personal and team goals and abandon or change the level of remaining goals. In other words, goals that require less energy and time are more attractive than goals that require more resources.

The reward structure also influences the attractiveness of the goals. People prefer goals that have higher rewards than the goals that have low potential rewards. Therefore, high reward goals can be more attractive even though they require lot of energy and time. Unclear description of the goal or vague goals can lead people to believe that the goal is attractive, however, vague goals are not as effective in generating high performance [28]. Competition with other groups or team members, which creates a pressure or desire to accomplish a goal, is another important factor that influences the attractiveness of a goal.

Hollenbeck and Klein [17] also proposed several personal factors that would affect the attractiveness of goal attainment. For example, they argued that high *Need for achievement* personality was related to the commitment to difficult goals. Their arguments are based on the findings of a study [5] that people with high need for achievement set more difficult goals than people with a low need for achievement. Other personality variables that are relevant to goal commitment are *endurance* and *type A personality*. People with high endurance are willing to work longer hours, and do not give up quickly on a problem; thus they are unlikely to abandon difficult goals. Similarly, people with a type A personality, being aggressive and competitive, setting high standards, and putting themselves under time pressure, are more likely to set more difficult goals and put more effort to accomplish those goals.

Situation factors that would affect the expectancy of goal commitment are social influence, task complexity, performance constraint, and supervisor supportiveness [17]. Social influence with respect to others' performance, others' goals, and others' goal commitment, has shown a strong impact on goal commitment [17]. They suggested that individuals are unlikely to maintain their goal commitment when the majority of team members appeared to either abandon their goals or lower their goal level. An individuals' commitment level would be higher when team members have the similar goal level.

Martin and Manning [33] manipulated the level of normative information on, how others have performed (others did well/ others did poorly). They found that there was no significant difference in the performance of high and low goal commitment subjects when they were told

that others did not perform well. On the other hand, there was a significant difference in performance when subjects were assigned with different level of goal difficulty and were told that others performed well. The findings suggest the moderating effect of goal commitment on the relationship between the task performance and the normative information. However, the study did not examine whether there is an effect of normative information on goal commitment.

Additionally, Martin and Manning [33] examined the relationship among goal levels, performance, and goal commitment. They found that people with a low goal commitment could perform as well as people with a high goal commitment when easy tasks were used. However, when difficult tasks were assigned, the performance of people with high goal commitment was significantly better than the performance of people with a low goal commitment. These findings indicate that low goal commitment does not mean that people would attempt to fail or not accomplish the goal [33]. However, for people with low goal commitment assignment of difficult tasks may lead to frustration and high-level of anxiety, which may result in the goal abandonment.

Hollenbeck and Klein [17] identified high self-efficacy, past success experience, high self-esteems, and locus of control as personal factors affecting the expectancy of goal commitment. Their literature reviews (c.f. [15] [16] [29] [45]) indirectly supported the propositions of the relationship between the personality variables and goal commitment. Klein et al [24] found a correlation (0.38) between supervisor supportiveness and goal commitment.

Locke et al [30] asserted that goal commitment directly influences the performance of the team members. The strength of this relationship depends on the amount of variance in the goal commitment. Internal factors, external factors, and interactive factors that determine the variance of the goal commitment were identified. Internal factors include the expectancy of success and self-efficacy. External factors include legitimate authority, trust in authority, peer (group) influence, values, incentive, and rewards. Interactive factors include the participation of individuals in setting up their goal and competition.

Studies show that an authority's instruction need not always be obeyed [1]. In this case, the goal assigned should be legitimate (such as possible to be accomplished or reasonable). Legitimate authority and trust in the authority influences individuals to commit to the assigned goal. Social pressures or peer influence has a positive effect on commitment [12]. According to expectancy theory, the value of the outcomes and the estimated probability of effort and performance will affect commitment/choice and thereby performance. The values of outcome, however, may include both recognition and monetary reward.

A study by Mueller [36] found that the relationship between competition and goal difficulty leads to better performance, but there was no evidence of a relationship between commitment and competition. The above

described internal factors, external factors, and interactive factors are used during cognitive processing to judge the value of goal commitment. Locke et al [30] adopted a different approach to categorize the distal antecedent factors of goal commitment. The antecedent variables in Locke et al [30], however, are very similar to those proposed by Hollenbeck and Klein [17].

Klein et al [24] conducted a meta-analysis of the distal antecedents of goal commitment. They found that situation factors had a higher correlation with goal commitment than personal factors. Task complexity, social influence, supervisor supportiveness, and volition have significant correlations of -0.50, 0.45, 0.38, and 0.37 respectively, while other variables had correlations smaller than 0.20. Thus, this study will focus on task complexity, social influence, supervisor supportiveness, and volition influencing the goal commitment.

## 2.2 Team Commitment

The present study focuses on commitment to a goal and also on commitment to a team membership. Team commitment characteristics, accordingly, include the determination and the persistence to achieving a team's goals and the strong desire to maintain membership in a team. Bishop and Scott [2] suggested that satisfaction with co-workers and intersender conflict influences the desire to maintain membership in a team, which in turn impacts the team commitment. In a situation where team performance benefits each member, individuals are likely to replicate the effort of teammates to create an equitable exchange relationship. Experiencing a good social relationship with team members will enhance team commitment.

Bishop and Scott [2] examined two types of role conflict: Intersender and Resource-related conflict. Intersender conflict is posited to have a negative relationship with team commitment either directly or through satisfaction with teammates. Resource-related conflict is posited to have a negative relationship with organization commitment and satisfaction with supervisors. Intersender conflict occurs when members cannot behave in a way that will satisfy incompatible expectations among teammates about their members. Bishop and Scott [2] also argued that high perceived task interdependence would lead members to be more aware of the importance of their contribution to the team as well as to the organization; members, thus, increase their positive affect on the team and their effort on the task [35].

In summary, the factors that will influence team commitment are those that have an impact on the persistence to achieving team's goals and the strong desire to maintain membership in a team. We suggest integrating the factors satisfaction, intersender conflict, and perceived task interdependence, included in the model of Bishop and Scott [2], with the factors task complexity, social influence, supervisor supportiveness, and volition, included in goal setting theory.

## 2.3 Media Selection and performance

Over the last two decades, researchers in organization communication have developed theories to understand and explain the choice of communication media in an organization [7]. Carlson and Davis [6] in their study of a public agency found that ease of accessibility is the default selection criterion for media choice. People, therefore, view the chosen media to be effective enough to be used in a particular situation or for a particular task if it achieves the expected outcomes/performance. As a result, they do not choose the most effective media. Another explanation based on cost minimization was provided by Swanson [40], people are likely to choose inferior quality information because its use requires less effort or work than the use of high quality information. These explanations, however, may not apply to all situations. Other plausible variables that can explain the selection of media are, information quality, message personalization, and social influence.

Even though, there are many plausible explanations for media choice, the main reason for using a particular media is that it allows people to successfully exchange or acquire the meaning of information. Exchange of the meaning of information and subjective views is required in equivocality situation<sup>1</sup> such as problem definition or resolution of disagreement. Acquisition of the meaning of information, on the other hand, is required when the members are in the uncertainty situation<sup>2</sup>. Media richness theory [8] hypothesizes that communication would be effective if the media used is congruent with the task. The theory measures the richness of each medium based on its ability to give immediate feedback, the variety of communication cues, the personalization of the medium, and the language variety. Thus, rich media enable users to provide quick feedback about their understanding or ambiguity of opposing parties' messages, and to transmit cues in multiple, concurrent ways. Similarly, social presence theory views the capabilities of each medium to permit users to perceive others as being psychologically present [9]. Therefore, rich media usually can be viewed as a media that also provides a high degree of social presence.

Several studies that examined the central hypothesis of richness theory that matching media with the task leads to communication effectiveness, however, found that in some situations, a mismatch of media with the task demand still resulted in high performance. Dennis and Kinney [9] found that the success of communication might not be determined by the richness construct but the more fundamental constructs of feedback and social presence cues. Other factors that influence the performance are organizational norms, personal characteristics and shared histories among group

---

<sup>1</sup> Equivocality Situation means ambiguity, confusing, disagreement, and lack of understanding tasks and information.

<sup>2</sup> Uncertainty Situation means that there is not enough information to make a decision or to perform a task.

members [13] [37] [38]. Kock [25] suggest that the reasons subjects using lean media have the same level of performance, as subjects using rich media are that with lean media, an extra effort to overcome problems due to the limitations of media capabilities is necessary.

Using Hermeneutic concepts to interpret a collection of exchanged e-mail messages among a group of managers, Lee [27] concluded that electronic mail is neither rich nor lean media because richness or leanness is not a property of the e-mail medium, but a property of the interaction of the user with e-mail medium in organizational context. Lee suggested that, to have rich communication using e-mail, e-mail receivers must not be passive recipients of data but active producers of the meaning.

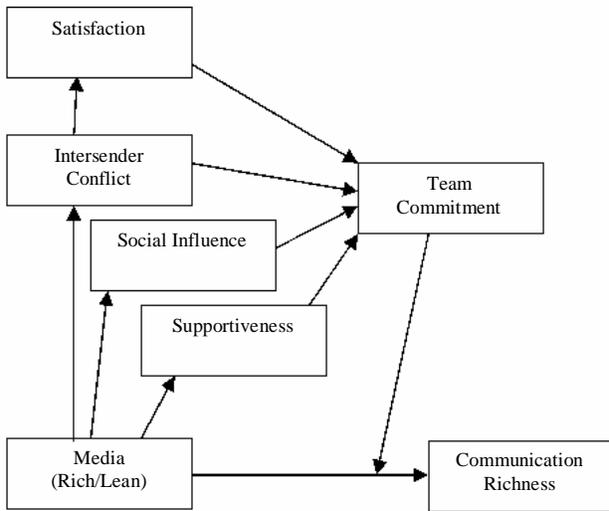

In summary, we can conclude that people usually select the media that are easier to access and are effective enough to get the job done. In some situations, however, people require more effort to interpret the meaning of information or interact with counterparts during the decision making if one medium is used over another. Thus, it is interesting to examine team performance under use of different media when one or more members of the team have a low commitment to the team. Also it will be interesting to examine how the richness/social presence of media affects the team commitment.

## 2.4 Research Model

Based on the foregoing discussions and extending the theoretical bases, we propose a research model (shown in figure 1) to examine the role of media type on the communication richness when team members have low commitment to the collaborative team projects in eCollaboration environment. The study by Kock [25] found that subjects using lean media put an extra effort to collaborate on equivocal tasks. Burke and Chidambaram [4] found that subjects using lean media are focused on the task at hand that leads to better performance. The behaviors of subjects in both studies can be explained when all subjects accept and are committed to the assigned tasks and goals.

We argue that individuals who are members of multiple different teams and are working on individual projects/tasks concurrently are unlikely to put the same intensity and focus in every task. According to goal setting theory, given that all teams have the same ability and use the same technology, performance of teams/groups varies due to the difference in the level of effort intensity. The goals that the team sets to pursue will influence the intensity of effort required to accomplish the goal. For goals to have an impact on performance, however, every team member must accept and commit to the goals (e.g. [30] [31] [32]).

Commitment and acceptance of team goals influences and motivate individuals to expense their cognitive/physical effort. Research in Group Decision Support Systems (GDSS) has shown that group members with the focus and attention on the task at hand would lead to higher decision quality [10]. Thus, we believe

**Figure 1: A Research Model**

that individuals using lean media can put effort and focus to successfully collaborate on equivocal tasks, when the individuals have a high commitment to the team goals.

On the contrary, individuals using lean media will not put enough effort and focus to successfully collaborate on equivocal tasks when they do not have commitment or have low commitment to the team goals. A sign of low commitment is, for example, when individuals delay their response to the team members or ignore the requests of others. We posit that team members will perceive the rich communication with individuals who have high commitment and will perceive the lean communication with individual who have low commitment to the team goal. Thus, team commitment has a moderating effect on the communication richness achieved by the media (as shown in figure one). As discussed earlier based on the previous research important factors affecting team commitments are: Satisfaction, Intersender conflict, Social Influence, and supportiveness (as shown in figure one). These factors in turn are affected by richness of the communication media in eCollaboration environment. Thus, there exists a reciprocal relationship as shown in figure 1. The next section proposes a set of Hypotheses and briefly describes a planned experimental study.

### 3. Hypotheses & Proposed study

Based on commitment literature, individuals with high commitment will put more effort in collaborating among team members to achieve a team goal than those with low commitment, hence our first hypothesis is:

*H1: Use of lean media under high commitment situation will be perceived as richer communication than use of lean media under low commitment situation.*

Discrepancies in feedback between performance and effort are an important factor affecting goal commitment (e.g. [22] [44]). The tasks with the lowest discrepancy

will receive priority if the tasks have the same amount of incentives. Large discrepancies in feedback may indicate that the goal is impossible or very difficult to attain. With limited resources (time and effort), individuals have to lower goal commitment of other tasks to meet the commitment required by a task that is determined to be more important. We can conclude that the feedback using either rich media or lean media should not differ in their impact on team commitment.

In the GDSS research, however, social presence has a significant effect on individual involvement in generating and evaluating ideas. In meetings anonymous individuals generate more ideas than those with names identified [21]. Jessup et al. [21] also found that individuals in a face-to-face meeting are more threatened by possible criticism. In addition, social factors such as social pressures and social norms are shown to influence individual behaviors in selecting media use. Social impact theory [26] suggests that pressure to act is a function of the interpersonal power, immediacy, and group member status. Based on these studies, we can imply that the feedback and praise in high social presence environments are more persuasive or have a greater effect on individuals' behavior than the feedback and praise in a low social presence environment.

According to media richness and social presence theories, each media has a different capacity to transmit information, which in turn exhibits differences in social presence and richness (e.g. [4] [8]). The theory ranged the richness of each medium based on its abilities to give immediate feedback, the variety of communication cues, the personalization of the medium and the language variety. The rich media exhibit more social presence and awareness of other participants. We argue that rich media are likely to create more pressure for individuals to follow group norms than lean media does. Team members and the "team leader" can use the feedback and a variety of communication cues to convey the supportiveness and social influence to affect individual's commitment to the team, which will be confounded when they are using rich media instead of lean media. Thus, we hypothesize that:

*H2.a: Individuals with low commitment using rich media will feel greater social influence from team members than those with low commitment using lean media.*

*H2.b: Individuals with low commitment using rich media will feel more support from team members and team leaders than those with low commitment using lean media.*

*H2.c: The perceived social influence will have an effect on individual's commitment to the team goal.*

*H2.d: The perceived team supportiveness will have an effect on individual's commitment to the team goal.*

Bishop and Scott [2] found that intersender conflict has significant indirect effect on team commitment and significant direct effect on satisfaction with the team members. Satisfaction was also found to significantly

influence team commitment. Individuals perceive to have intersender conflicts in a team when they feel that two or more members give them different requests, answers, or agreements. These differences or conflicts may leave team members in a state of confusion and unsure about what to do next, which leads to a lowering of the goal expectation, the effort, and the team commitment [2]. We propose that the faster the intersender conflicts are resolved, the less effect the conflict will have on the team commitment and the satisfaction with team members. Rich media, which provides a variety of cues and immediate feedback, should help individuals in resolving these conflicts faster than with lean media. Since, in case of lean media individuals can postpone or delay their response, especially when they already have a low commitment to the team. In addition, the slow response to the request and to the slow conflict resolution process will lead to individuals' frustration and adversely effect satisfaction with the team members. Thus, we can posit that intersender conflicts will have less confounding effect on the satisfaction with team members when rich media is used.

*H3a: Teams using rich media have smaller negative effects of the intersender conflicts on satisfaction with the team members than teams using lean media.*

*H3b: The intersender conflicts will have a negative effect on team commitment.*

In situations where individual with low team commitment decides not to respond at all - e.g. do not show up at the meeting, show up at the meeting but do not participate, or do not reply back, team members using rich media will feel more offense to the low commitment individuals' behavior than team member using lean media. As a result, we anticipate that we will not find the effect proposed in the hypothesis 3 if the individuals decide not to respond to the requests of the team members.

To test the proposed hypotheses, about 180 student subjects who are enrolled in internet and non internet classes will be used for this study. The design of planned research study is a 2 (high commitment, low commitment) x 2 (rich media, lean media) matrix with a between subject design for the team commitment. Subjects will be assigned randomly to a team. Subjects will be manipulated using incentive, task difficulty, and perceived task independence to have high commitment to the first project and have low commitment to the second project.

## 4. Conclusions

With the increasing interest in application of eCollaboration technology at the global level for a variety of tasks it is important to understand the factors that affects the performance of these global teams. Even though many studies have focused on media richness the

impact of team commitment in eCollaboration have not been studied. As can be seen form the conceptual model presented in this paper there is a reciprocal relationship between the media richness and team commitment. Based on the theoretical model a set of hypothesis has been derived. The model explains intricate relationships between various factors affecting team commitment and how media richness can impact these factors.

## Abstract

We suggest that the development and sustainability of social capital is related to the social context in which individuals, groups or firms operate. Therefore, we argue that there is a direct relationship between how one party conceives to be benefited from being part of another group or network and its implication for the development of social capital. In this paper, we use a social exchange metaphor for understanding the challenges related to the management of social capital in a virtual community. First, we provide an overview of virtual community and discuss the application of Information and Communication Technology (ICT) for supporting this type of community. Second, we address the management challenges for the development process of social capital from a sociological standpoint. Lastly, we suggest the implications of study for the management of social capital in virtual community. The following research questions guide this study—What is/are the key strategic challenges for the management of social capital in virtual community? How do establish an effective knowledge sharing process for supporting the development of social capital in a virtual community? How can the social exchange metaphor help in managing the strategic challenges related to the formation of social capital in a virtual community?

## 1. Introduction

Internet is increasingly seen as a useful mode to share data, collaborate on research, and exchange messages for both the organizational and virtual community (VC). A set of rules as a guiding principle for individuals to act or participate is common to both VC and organizational community [29][55]. VC evolved as a result of the implementation of Electronic Information Exchange (EIES) systems for computerized conferencing in 1976 [26]. It is observed for the case of EIES that a collective intelligence capability for decision-making was cultivated through this implementation. However, understanding how individuals interact and exchange information through the use of Internet and its implications on the formation of social capital is limited. Social capital can be essentially viewed as network of contacts of the individuals or participating organizations in an exchange [55]. Therefore, we highlight the need for understanding

the mechanics of exchange, coercion and conflict between contacts or network of contacts as a useful paradigm for this social capital formation research in VC.

A study by Turoff [52] and Burnett [9] suggests that the expansion of computer-mediated communication (CMC) provides a platform for individuals to meet, communicate, collaborate, socialize, and shop. Smith [48] highlights that the sense of belonging and concrete experience of social networks (and the relationships of trust and tolerance) can bring great benefits to people. This eventually serves as motivating factors for people participating in a VC. Recent studies on VC also suggests that gaining access to new knowledge of product, process, competitors and markets can also be seen as motivating factors for people participating in VC [1]. Walther [55] further highlights that ICT infrastructure needs to be in place so that the VC can emerge. However, this study also argued that social structure of the networks needs careful examination, which serves as a basis for understanding the utilization of ICT for supporting the VC [55]. We argue here that knowledge sharing or KS is an important part in the formation process of social capital. KS involves a relationship between actors (same as people or individuals) that is embedded in a structure of other social relationships [17][3]. Boer et al. [3] suggests that these ongoing social relationships provide the constraints and opportunities for individuals, organizations and knowledge, and provides a basis for understanding the dynamics of KS in VC. Individuals establish their network of contacts through this sharing. Therefore, KS is seen as essentially a social phenomenon. Social capital is increasingly considered as significant part of other organizational asset such as financial, human, intellectual, and other capitals in today's communities. It is regarded as the social fabric or glue that holds communities and other social networks together [8]. Smith [48] suggests that the process for fostering and sustaining social capital lies in the interaction, which enables people to build communities, to commit themselves to each other, and to knit the social fabric. Prior studies have examined social capital from three perspectives: (i) the density of social networks that people are involve in; (ii) the extent to which they are engaged with others in informal social activities; and (iii) their membership of groups and associations [7][13][48]. Therefore, we suggest that an effective knowledge

sharing or KS is critical to the development and sustainability of social capital in VC. In this paper, we address the process for building social capital through KS in VC. We first define the concept of VC and suggest that this study on VC can essentially follow the patterns of organizational community building research. Second, we present the significance of KS as an activity for fostering the development and sustainability of social capital in VC. Why is the understanding of KS critical for the development and sustainability of social capital in VC? And how can this new form of informal community establish its social network in order to build and sustain the social capital? Understanding this phenomenon from both a theoretical and an applied perspective calls for an examination of the conceptual issues related to the formation of community and in particular VC.

## 2. Conceptual Issues for Understanding Virtual Communities

We first introduce the concept of *community* before addressing the conceptual issues for VC. Community is associated with a place and a name in his thought [35]. Nelson et al. [35] further added that community is where one goes to shop, to attend a show, to meet friends, or simply to loaf. The common-sense concept of community is that it involves an area, people, and the relationships among people (e.g. structure). The elements of structure in a community consist of groups, formal organizations, institutions, division of labor, values, social differentiation, and functions. Therefore, community may be formally defined as the structuring of elements and dimensions to solve problems that can be solved within the local area [35].

VC is defined as a social entity where a number of people relate to one another by the use of a specific technology [45][24][28][47][49]. In addition, a VC is considered to be a source from which individuals seek social support using computer-supported communications [53][22]. Hiltz and Wellman [20] argued that the difference between communities' off-line and computer-supported communities is that VC is more dispersed in space and time, but more closely knit. It is further suggested that the members of a VC is more heterogeneous in their characteristics and homogeneous in their attitudes [20]. Furthermore, Igbaria [22] suggests that VC is a group of people who may or may not meet one another face-to-face, and who exchange words and ideas through the mediation of computer networks and bulletin boards. VC is therefore defined as information technology based system which supports the communication and social relationships between people whether individuals or groups of people.

## 3. Building Social Capital Through Knowledge Sharing

In this section, we discuss three issues related to the development and sustainability of social capital in a VC. We provide an introduction to social capital first. Secondly, we discuss KS in the context of developing and sustaining social capital in VC. Thirdly, we provide a conceptual framework highlighting the process involved in the formation of social capital.

The notion of social capital was first introduced by Lyda Judson Hanifan's discussions of rural school community centers [48]. The term 'social capital' was used to describe tangible substances, which count for most in the daily lives of people. The major concern was on the cultivation of good will, fellowship, sympathy and social intercourse among those that make up a social unit [48]. Most recently, Putnam [41][43] initiated social capital as a focus for research and policy discussion. However, other prominent contributions came from [23] study in relation to urban life and neighborliness. Bourdieu [4] first used the term to refer to the advantages and opportunities accruing to people through membership in certain communities. With regards to social theory, Coleman [10] used the term social capital in his discussions of the social context of education. Social capital is also used to describe resource of individuals, which emerges from their social ties [10]. Coleman [10] argued that social capital differs from the financial capital found in bank accounts and the human capital inside people's heads. It is further suggested that social capital inheres in interpersonal relations and describes the durable networks, which form social resources through individuals, and groups strive for mutual recognition [10]. As such, social capital is the necessary infrastructure of civic and community life that generates 'norms of reciprocity and civic engagement.'

Social capital is seen as a core concept in business, political science, healthcare, and sociology. It can be viewed as a common framework for understanding the depth of a community's social connectedness. Putnam [42] suggests that social capital refers to features of social organization such as networks, norms, and social trust, which facilitates coordination and cooperation for mutual benefit. It can also be referred to as institutions, relationships, and norms that shape the quality and quantity of a society's social interactions [50][51]. Social capital is not just the sum of the institutions, which underpin a society-it is the glue that holds them together [51]. Furthermore, Cohen and Prusak [12] suggests that social capital consists of the stock of active connections among people--the trust, mutual understanding, and shared values and behaviors, which bind the members of human networks and communities and make cooperative action possible. Jacobs [23] defines social capital as neighborhood networks. Networks are not merely the

result of historical accident; they came about as individuals spend time and energy to connect with others.

So, why is the understanding of knowledge sharing (KS) important to the formation of social capital? What is relationship between KS and formation of social capital? How can the effective KS systems help develop and sustain social capital in VC? According to the *theory of organizational knowledge creation*, knowledge is generated through a process of interaction of tacit and explicit knowledge [36][37][27]. Knowledge is either transformed within one single person or among a group of people. Therefore, it is important to note that knowledge is neither given nor pre-defined, but created through a process of individual interpretation and personal construction [44].

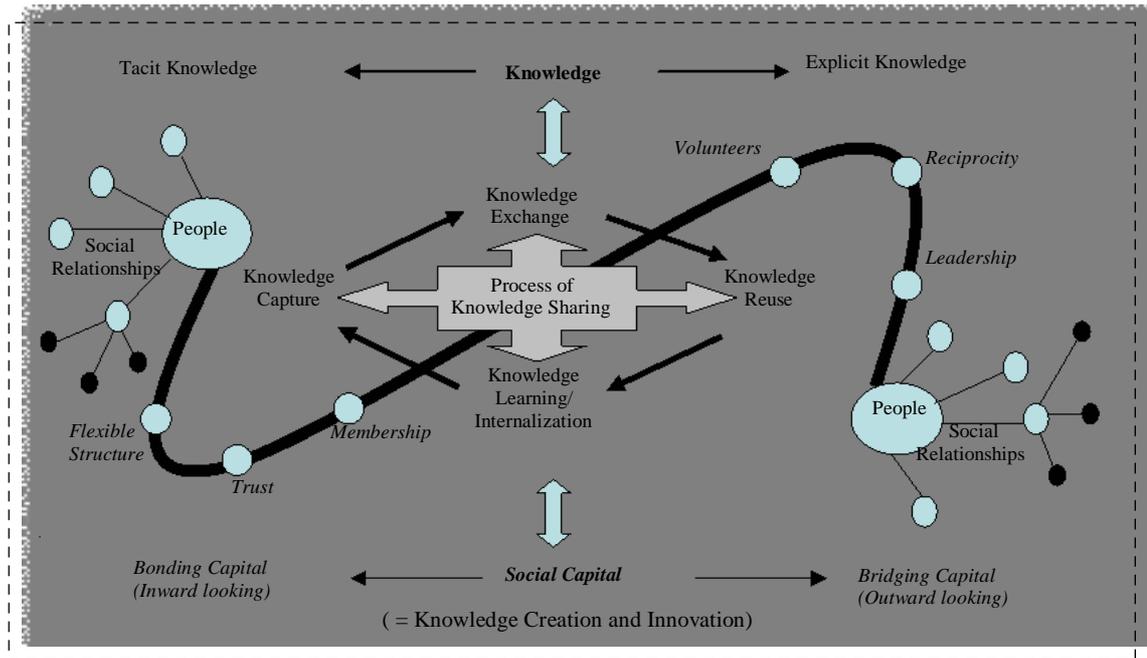

Here, we discuss two broad types of knowledge-- explicit and tacit [37]. Explicit knowledge is knowledge that can be expressed in words and numbers, and shared in the form of data, scientific formula, specifications, and manuals [21]. Explicit knowledge is packaged, easily codified, communicable and transferable. An example of explicit knowledge is the manuals, which accompanies the purchase of electrical goods--microwave oven. On the other hand, tacit knowledge is considered to be highly personal, hard to formalized and difficult to communicate or share with others [21]. Subjective insights, intuitions, and hunches fall into this category of knowledge. Tacit knowledge deals with individual's actions and experience, as well as in the ideals, values, or emotions he or she embraces. An example of tacit knowledge is knowledge a chemistry professor may have on carrying out experiments of certain substance.

We suggested earlier that the development and sustainability of social capital for both the organizational and virtual community is essentially a social process. Social capital is developed through the community who shares knowledge about certain products, services, and markets to a group of people interested in common goals. It is therefore through an effective KS which individuals or organizations are able to develop and sustain the social capital in VC.

So, what is the process for building a sustainable social capital for VC? Here, we provide a conceptual framework called "*Process of building social capital*" in the context of virtual community (refer to Figure 1). This framework was adapted from an organizational context, and by integrating the ideas, we attempt to explore and apply it in the context of VC. This framework begins with the first layer of the types of knowledge-- tacit and explicit. We argue that a full understanding of these two types of knowledge will facilitate differentiating how knowledge is exchanged and shared among people in organizations. To illustrate this further, we introduce the KS process developed by [33]. We highlight here that a framework for evaluating and incorporating new experiences and information is thus crucial. This is crucial as knowledge can be viewed as a mix of experience, values, contextual information, and expert insights.

The case of MITRE [33] suggests four perspectives for understanding knowledge flows and collections-- individuals or groups exchange it with each other (e. g. knowledge exchange), record it or capture it (e. g. knowledge capture), reuse the recorded knowledge assets (e. g. knowledge reuse), and finally, generate new knowledge as they internalize learning into the way they think and know (e. g. knowledge internalization).

Giddens [15] suggests that structuration is important as it integrates the concept of knowledge and social relationships. He further argued that the relationship between people is established as soon as they share knowledge with one another [15]. This relationship between people consequently influences the way knowledge is being shared. Knowledge can be shared between people through face-to-face, or through technology either asynchronous or synchronous (which is known as virtual community). In our model (see Figure 1), we explicitly show "people" linked to several nodes indicating the networks based on the establishment of social exchanges of goods and behaviors where they are assumed to have the reciprocal element when they determine the value of knowledge each of them has. The exchange of knowledge is further been moderated by the elements of power, control and benefits by each exchanging party as highlighted in the elementary theory of the social structure [54].

**Figure 1. A conceptual framework for building social capital [55]**

In Figure 1, there is a dark line with several key nodes representing the ‘social capital’ variables, which is directly connected to the people with their own social bonds, norms and networks, is presented. We suggest that these antecedents consisting of six key variables in turn will facilitate the final process--the knowledge sharing and creation of social networks and exchanges for building social capital in VC. Subsequently, this outcome--social capital is framed as the last layer of our proposed conceptual framework (see figure 1) where social capital can be seen as having two additional dimensions--bonding (or exclusive) and bridging (or inclusive). The former may be more inward looking and have a tendency to reinforce exclusive identities and homogeneous groups. While the latter may be more outward looking and encompass people across different social divides [43]. Putnam [43] further explains that bonding capital is good for under girding specific reciprocity and mobilizing solidarity while bridging networks, by contrast, are better for linkage to external assets and for information diffusion. Further, bridging social capital can generate broader identities and reciprocity, whereas bonding social capital bolsters our narrower selves [43, p. 22]. In the next section, we discuss the dimensions of social capital.

#### **4. Understanding the Dimensions of social Capital**

Nahapiet and Ghoshal [34] divide social capital into three dimensions (different from Putnam’s dimensions)--

structure, cognitive and relational in their comprehensive review of the conceptual literature. Structural social capital refers to the ways in which motivated recipients gain access to actors with desired sets of knowledge and intellectual capital. This dimension of social capital is usually studied using a network approach. In the network approach, the frequency of contact and resulting social distance among actors in a particular firm or organizational field are plotted to form a web-like diagram illustrating actor interaction patterns. The objective of this type of research is to determine the central nodes of the network or the critical communicators, which is helpful in understanding communication patterns as well as resultant organizational behaviors such as power positioning and knowledge flows [5][13].

In contrast, cognitive social capital approach recognizes that exchange occurs within a social context, which is both created and sustained through ongoing relationships [34]. Similar to the notion of community of practice [6] and some aspects of virtual community, cognitive social capital refers to the shared meanings which can be created through stories and continual discussions within a specific, often clearly defined group. These shared meanings are self-reinforcing in that participation as the community is dependent upon an *a priori* understanding of the context and continual contribution to the on-going dialogues.

The third dimension of social capital deals with the relational aspects, which is concerned with the underlying

normative dimensions that guide exchange relationship behaviors. Norms exist when the socially defined right to control an action is not held by the individual actor, but instead is held by others [11]. Therefore, norms represent degrees of consensus and hence are powerful although fragile form of social capital [34].

## 5. Managing the Challenges of Social Capital

There are a few challenges that exist in each of the dimensions mentioned above for virtual communities seeking to create, sustain, and exploit their social capital. As we understand, connections made through face-to-face interactions are necessary for building social capital. Due to the fact that face-to-face interactions are not always practical or possible in virtual communities, we must look for ways to build and leverage social capital virtually [31].

### 5.1 Structural Challenges

A study by Rocco [46] suggests that the level of trust that exists in virtual workgroups could be measurably improved by even a single face-to-face interaction at the beginning of the project. But barriers of time, distance, and physical setting can make such interactions difficult to accomplish.

Another aspect of this challenge is that when people are across multiple virtual communities, it is difficult for them to make connections with others having a specific expertise. Organizations have attempted to solve the problem by developing an electronic “yellow pages” and dedicated skill directories where individual could provide data regarding their level of expertise on a variety of topics. While some of these efforts proved useful, many of them did not achieve their desired results [31]. This is because these repositories require users to manually update their expertise profiles regularly, which individuals often failed to do so.

### 5.2 Cognitive Challenges

One of the greatest disappointments encountered in large organizations is the difficulty of ensuring everyone is “reading off the same page.” Shared understanding is not guaranteed even when people are physically together, observing and discussing in the same environment [31].

In a virtual world, a number of barriers make it difficult to ensure that each member in a conversation has appropriate contextual clues necessary to develop mutual understanding and share knowledge. First, communicating across time and space often introduces cultural and linguistic differences that can distort the intended meaning. Talking with someone who is less familiar with your language can be difficult in face-to-

face setting; but trying to do so without any facial expressions, and gestures would be even more difficult.

Lesser and Cothrel [31] points out that another barrier facing the development of social capital in a virtual community is the difficulty associated with building a common set of assumptions and understandings. In physical settings, the interaction around common artifacts makes it easier to develop reference points that everyone in a conversation can share.

### 5.3 Relational Challenges

The last challenge involves relationships in virtual environments. As Lesser and Cothrel [31] states that connections are easy but relationships are hard. The Internet age has given rise to a whole range of questions about how we evaluate the trustworthiness of others that we cannot see, and perhaps have never met. In this regard, [cited in 31,p.73] suggest that “these issues have to do with information quality, bias, endorsement, privacy, and trust – the fundamental values of society, much misunderstood on the web, and also highly susceptible to exploitation by those who can find a way.” Furthermore, the public nature of many virtual conversations, such as chatting, can leave individuals exposed to attacks by others, many of them anonymous and not controlled by the norms and responsibilities of traditional social interactions. According to Blanchard and Horan [2], this form of attack known as “flaming,” can lower the level of social trust within a virtual environment and can inhibit the participation of individuals seeking more forthright relationships. In the next section, we suggest some implications in building social capital in virtual communities.

## 6. Implications for Social Capital Building in Virtual Communities

Nahapiet and Ghoshal [34], and Burt [8] suggests that key idea behind social capital building is that networks of relationship involve a valuable resource for providing people with privilege access to information and opportunities. The interpersonal dynamics between individual of networks are equally important as having the social network of individuals. Thus, the implication of positive interactions that take place between individuals in the network is significant. This leads to the success of building the social capital in both the organizational context as well as the VC [30]. We suggest that the development of social capital implies creating the opportunity, the motivation and the ability for knowledge sharing in VC. Therefore, our propositions have some complex implications in the sense that VC emerges as a new form of community, which exists without a formal structure and it transcends across space, time and distance. Furthermore, framing these antecedents based on the

organizational perspectives presents and contributes a new outlook of the key idea of social capital building and social exchange network. But more importantly, it helps to promote a better understanding of the process of building the social capital in a VC.

A study by Fairtlough [14] suggest that when a high degree of innovation and speed is required, the elimination of job descriptions, enhanced flexibility and initiative, as well as increased self-motivation would be the key success to effective organization. In line with these suggestions, we thus propose:

Po: Flexibility and mobility of a VC structure allows sharing of knowledge when exchange, conflict, and coercive relations exist through sanctions and thus able to build successful social capital.

Putnam [43] promotes trust as an essential component of building and sustaining social capital as it helps increasing cooperation. The greater the level of trust within the communities, the greater the likelihood of cooperation in which the end result all leads to enhanced trust among members or social actors. Nahapiet and Ghoshal [34] also emphasize that over time a culture of cooperation would surface among this trusted group of people, which can be strengthened through social interactions. However, this social relationship can wither if it is not maintained. Thus, interaction is a precondition for the development and maintenance of social capital [4].

P1: Trustworthiness and interactions among members involve preferences and beliefs among members for effective knowledge exchange and social capital building in VC.

P2: A high level of trust and cooperative spirit among members promotes lower transaction costs, stronger social relationships, and stronger social structure in VC.

There is also a relationship between trust and membership. Membership reflects the degree of civic engagement and the nature of horizontal relations between individuals as members who has established the necessary trust between them. Additionally, membership describes the element of cohesiveness, which is expected to exist in any social relationship. This acts as glue, which bonds the members together. McGrail et al. [32] stipulates that membership measures have not focused on membership of national organizations such as environmental groups or union because they are considered hierarchical and bureaucratic that is though as not to generate much social capital.

P3: A non-hierarchical and informal structure of VC promotes cohesive membership in order to establish a strong social and trusting relationship in social capital building.

The commitment to the community increases when people continue to volunteer [16]. Volunteerism represents selfless actions that promote community spirit and civic participation; while at the same time, changes the volunteer's self-concept to promote further volunteerism [38]. Active volunteers are those who are motivated because they perceive equitable and rewarding relationship and thus are more likely to continue their services [39]. Therefore, this act of volunteerism is a precondition to promote and sustain loyalty and commitment of the members.

P4: An active role of volunteers to facilitate and support knowledge sharing activities in VC emerges when there are elements of benefit and control in their social exchanges.

Reciprocity increases trust and refers to the simultaneous exchange of items of roughly equal value and continuous relationship of exchanges at any given time--repaid and balanced [11][41]. Furthermore, Bullen and Onyx [7] highlights that social capital is a combination of short term altruism and long term self interest as it does not only imply the immediate and formally accounted exchange of legal or business contract. The individual provides a service to others or acts for the benefit of others at a personal cost. Yet, based on general expectations of human nature, there is always a need for reciprocal acts where their kindness would be returned at some undefined time in the future. Additionally, when a community has a strong reciprocal relationship, people express their care and interest for each other more often. In turn, this relationship encourages the knowledge sharing that form the social capital.

P5: The higher reciprocal element exists among weak power members than equal and strong power members with regards to sharing of knowledge.

Only effective management and efficient role played by a leader will reduce the costs and accelerate the development of new products and services in an organization. Furthermore, organizations will need to react faster and use its resources such as social capital more efficiently in order to enhance knowledge sharing. Likewise, effective creation of knowledge sharing by the leader promotes efficient distribution of the social capital in an organization.

P6: The role of leadership facilitates the integration and distribution of knowledge sharing activities among members in order to form social capital in VC.

## 7. Conclusion

Social capital is an important resource for the sustainability of virtual communities. Virtual community provides a new platform for researchers to understand the dynamics of social networks that takes place in the virtual space. It also provides opportunities for understanding the process of social groups formation by taking into considerations the antecedents, which are expected to promote greater exchanges of knowledge and then translated as their fundamental assets such as social capital. We suggest that community can exist in both the physical as well as virtual space. We first conclude that social capital provides opportunities for societies to resolve collective problems more easily by sharing knowledge. Each member of the community accomplishes this by doing his or her share. This adds more synergistic values when people cooperate and are committed. Second, social capital facilitates communities to advance smoothly when they are bonded with trust, produce less everyday business and social transactions cost when they have repeat interactions with other fellow members of the community. Third, social capital creates enhanced awareness of the many ways in which ideas and knowledge are interlinked to develop character traits that are good for the rest of society [43].

## Abstract

With the development of e-business, the collaboration between enterprises is increasingly strengthened, which, at the same time, challenges coordination technologies in distributed enterprise transactions. Workflow management has as its priority the support of coordination functions and workflow interoperability points the way towards collaborative business environments. Though WfMC, Workflow Management Coalition, specifies the abstract interoperability, differences such as workflow concept models, ontology etc. cannot be dealt with effectively because the specification is only technical. On the other hand, portal technology focuses on the integration of information and application services customized according to roles. It can provide support for the interoperability of workflows. In this paper, workflows are integrated with portal technology. And a role centric collaborative environment is proposed which is a way out for problems existing in workflow interoperability.

**Key words:** Role, Workflow, Interoperability, Ontology, Portal

## 1. Introduction

New economies and global markets with their accompanying intense competition have generated the need for organizations to develop and adopt new IT infrastructure to support double-win or multi-win collaborative business environments. An enterprise can hardly survive by itself facing such many global competitors. Furthermore, competitions have extended to a more macro-level, which is usually between supply chains, even value chains. In the information society environment, enterprises also need Internet technology to support their business collaboration. How to collaborate efficiently so complex business activities between organizations is a new problem facing business change management. As one of the recent IT research focuses, cross-organizational workflow technology mainly deals with the resources integration by multi-organization collaboration. It aims to establish a seamless process integration environment, to widen the business information scope, to improve the flexibility of the whole supply chain or value chain, and to ultimately improve the level of customer satisfaction.

A single organization usually cannot satisfy all customers' needs in electronic business environments, where necessary resources are highly distributive. Business organizations make great efforts to improve the quality of collaboration among suppliers, customers, and

business partners, with a view to improve their own core competence. Based on role theory, the importance of collaborative technology in Internet-enabled business environments is firstly analyzed in this paper. Then it focuses on two important potential technologies for the interoperability, i.e. portal and workflow technology. At last, a role-centric collaboration environment integrating with portal and workflow technology is proposed, which can partially solve the problem of the interoperability of cross organization processes.

## 2. Role theory basic

Role is defined as comprehensive feature abstraction of a class of entities, which can be described by common structure, behavior, property, function, tendency etc. [1] Role is used as a reasonable standard to differentiate entities for their high competence to comprehensively describe entities. The role an actor plays is not static in cross-organizational processes, because which role an actor needs to play is determined by real cases. For example, an actor in a value chain, its upstream suppliers can view it as a customer, while its downstream customers also can view it as a supplier. From a more macro view of point, a value chain is composed of a series of links between customers and suppliers. Within an organization, intra-organization processes can also be viewed as a customer chain, which links all involved departments. Customer-driven is the most popular concept in nowadays business practice, in which customers' needs are various and need to be customized. Market is getting dynamic. Traditional linear value chains have evolved into a complex, flexible, refined, and agile value-net system. Sometimes they are referred to as value networks, which are woven by value threads [2]. Organization structures tend to be networked and business operations tend to be virtual. A networked organization is usually composed of a core enterprise ,its contractors and sub-contractors. The main duty of the core enterprise is to coordinate all members of the networked organization. How to define roles of participants in a networked organization is even more complex. Usually, multi-role property needs to be assumed to a participant.

Role theory has been widely used in the access control of databases and information systems in previous researches. It is used herein to analyze the business collaboration, in order to show the importance of coordination technology. As the initiator of an activity, role is the basic component of an enterprise or a virtual organization. In process change management, role is also the main object to be reengineered. In BPR, the change

of activities and the relation between them can be viewed as the reengineering of roles and the collaboration between them. That is, process management can be seen as the analysis and adjustment of roles and their relation. Every role in the process has four basic attributes: rights, responsibilities, protocols and capabilities. When a participant acts as a role, its knowledge, capabilities and rights should meet the requirements of the role. He should also take the related responsibilities and risks, which result from his activities. The participant must act according to a special protocol, and need collaboration with other participants who take on the corresponding roles and try to complete all tasks defined by the roles within the limitation of resources, information, and rules.

From the object-oriented perspective, a role is similar to an object class, and it can be viewed as the abstraction of a class of agent objects. In system planning, roles provide templates for agents. Using roles to configure the agents can solve the problem of prematurely determining the role of a participant. Thus it can improve system flexibility to fit well with the challenge from dynamic market changes.

The formation and features of business collaboration will be further discussed from three aspects of roles, that is, competence, knowledge, and protocol.

## 2.1 Competence

According to the theory of organization competence [3], competence is the main resource of an organization, whose business scope is also decided by its competence. The core competence of an organization is the origin of its long-term competitive advantages. It includes some accumulated knowledge, especially that knowledge of how to organize processes and coordinate various participants and their different skills. This also means that an organization can be viewed as a combination of roles with various competences. Work dividing and collaboration between roles can improve individuals' competence and bring the improvement of organizational creativity. At the same time, work dividing can set up the organization boundary as a foundation for collaboration.

Organizational operations are composed of various basic activities. These activities are related to each other. Roles possess different competence to support its operations. Nowadays, a single enterprise cannot meet customers' various needs, which usually involve complex production and customized services. Businesses, therefore, need seamless collaboration and real-time interaction among R&D, suppliers, manufacturers, distributors, retailers, and customers so that the cross-organizational processes become the most important character of business operations in the e-business environment. On the other hand, enterprises can focus their resources on their core processes, and outsourcing other business operations. E-business enterprises will improve their whole competence by the collaboration and profit distribution between enterprises through the infrastructure of cross-organizational processes.

## 2.2 Knowledge

The theory of organization competence regards knowledge as the inner factors of organization competence [3]. Organizational activities need the coordination between professional individuals holding different knowledge. An organization runs as a system for knowledge integration. Its innovations are achieved by the knowledge sharing among roles.

Cross-organizational knowledge sharing brings more affluent resources of knowledge and intelligence, which will promote the technology and service innovation.

## 2.3 Collaboration

The rapid development of global economy intensifies competition among enterprises. An enterprise can hardly survive in the increasingly competitive environment without the efficient collaboration with other enterprises because its resources and competence are limited. Thus it has to focus resources on its core processes. That is to say, in order to effectively react to dynamic market changes, enterprises should concentrate on its most potential business domains, by integrating its intra- and extra-resources, outsourcing part of non-core business processes. These cross-organizational business processes aim to improve the whole competences of all member enterprises through seamless coordination.

## 3. Role-centric collaboration

### 3.1 Business collaboration

With the rapid development of electronic business, enterprises transfer their activities from traditional, direct market transactions to the whole process of value increasing, which involves the collaboration among participants on the value chain, besides the collaboration among departments and roles within enterprises. The concept of business collaboration mainly deals with the business activities and their interoperation between different enterprises. There is still no widely accepted common definition on *business collaboration*. Different definitions emphasize different scope and level of collaboration. In general, most definitions propose a well-organized combination structure of different enterprises in order to integrate suppliers, business partners, customers, and distributors on the supply chain widely into a virtual organization by Internet-enabled collaborative IT supports. Each of these member enterprises usually owns different core competence and resources. In such disparate business collaboration environments, newly emerging business models need a series of reconstruction of business collaboration structure, communication channel, and relation with customers and suppliers. The key of success of these models lay in the sharing and exchanging of information and knowledge, which are the basic needs of enterprise competence integration and coordination in this cross-organizational process management and change scenario.

In collaborative business environments, the whole supply chain or value chain becomes a collaboration system based on network and collaboration technologies.

Participants on the chain can share knowledge and information, and act in seamlessly connected cross-organizational processes, which aim to improve the response speed to customers' dynamic needs. Actually either partner enterprises, or their constitutive departments, or personnel of these enterprises can take on the collaboration roles. Such complex collaboration needs an interoperable platform to facilitate real-time information exchanges and knowledge sharing. This platform makes participants on the chain can share accurate information about their products and service in time.

Networked organizations operate through the collaboration among roles. Cross-organizational processes connect member enterprises by means of some activity points. It ensures accurate decision-making and high operation efficiency. The whole system of a networked organization can be highly effective and efficient, when roles collaborate well.

Besides those technical factors, cultural differences between collaboration partners are also very important. In some cases, the collaboration difficulty comes from partners' different business tradition. For example, some enterprises are not willing to share information with other enterprises by its traditional business practice. Furthermore, many enterprises may use different modeling methods to describe their processes, or may manage their processes in different ways. According to social psychology theory, most enterprises tend to put an enlarged importance on their own business practice, which is usually supported by their past successful experience. The difference of ontology of different enterprises brings even more challenge for designing and implementing the cross-organizational process management. Interoperability and communication between these partners having different cultural background are even difficult to be overcome both technically and culturally in these environments.

The key of successful collaborative business is the tight cooperation among roles in the form of knowledge and information sharing. Some researchers regard collaborative business as the next generation of electronic business. Electronic business model is concerned with the abstraction of roles and their relations among an enterprise, its customers, suppliers, and business partners. The flow of production, information, and capital can be clearly described in business model. One of the main research areas on collaborative business is to solve the problem of how to establish a collaborative platform for different roles with the support of Internet-based information technology. According to current technical level, cross-organizational workflows or distributed workflows are feasible solutions to this problem.

### **3.2 Cross-organizational workflow technology**

Workflow management technology is a tool for process automation and standardization. Since its first emerging in 1970's and fast development in 1990's, Workflow technology has been successfully adopted by

many enterprises of different industries. Most of these workflow application cases are limited to intra-enterprise, where it is usually applied in a relatively unified application environment or at least within a common business culture background. Although the *WfMC* (Workflow Management Coalition) has proposed a series of workflow standards, the interoperability between different *WfMSs* (workflow management systems) is limited to messaging mechanism. Sheth et al. estimate that the number of readily available workflow systems is between 200 and 300 [4]. It is nearly impossible to enforce all members in a networked organization to use a unified *WfMS*. Many enterprises use different workflow conceptual model, which is called as ontology by some researchers. This difference brings the problem of interoperability of different workflow systems used by different enterprises.

Two important collaboration technologies, i.e. the cross-organizational workflow and portal technology is discussed in this section and next section 3.3. Then, in the section 3.4, their integration is discussed. It is suggested to be a very effective support technology to cross-organizational workflow management.

Increasing customer needs on tailored service and the complexity of production process require the tight cooperation and real-time interaction between roles of R&D, Suppliers, manufacturers, distributors, retailers, and consumers. These activities need corresponding cross-organizational processes for role coordination and some standardization prescription on communication and interface protocols. More and more business processes become cross-organizational. The main research purpose of cross-organizational process management is on how to coordinate their activities in distributed and heterogeneous dynamic environments.

Cross-organizational workflows are one of the most important tools to support cooperation between roles. Current solutions for cross-organizational process coordination are mainly dependent on the interoperability of workflows. While different enterprises usually have their own organization structure, business practice, and their special ontology, the workflow integration sometimes becomes very intractable. Ontology describes basic concepts and their relation in a domain. It acts as intermediary for knowledge integration, sharing, communication and abstraction, usually domain dependent. One of the solutions for the discrepancy between enterprises' ontology is to comply with a unified ontology for all members. But this solution is too expensive to be put into practice, especially for those large-scale networked organizations, which usually have invested in a great volume of legacy systems. Another more feasible solution is to define a high level common ontology, which is changed into all members' local ontology and vice versa. Using this method, the information senders packet data and information according to the common ontology; then the information receivers decode the package in the form of common ontology into their own ontology. The transformation rules for different ontology is a valuable area for further

research. In the area of information and knowledge sharing among different roles, our recent research has conducted on how to use high-level ontology as a commonly understandable and acceptable term set for cross-organizational process communication between different enterprises.

Cross-organizational process research originates from the increasing needs for the cooperation between different enterprises. The most popular form of this cooperation is outsourcing, which is usually contract-based. Besides its legal meaning, contract is also one of the main ways to abstract cross-organizational process interaction, which includes most ontology of cross-organizational activities, such as searching for partners, interconnecting related workflows, controlling outsourced workflows, sharing workflows, etc [5]. It is a relatively practical way to solve the problem of heterogeneous ontology. One of the European Esprit FP4 program, CrossFlow [6] carries a deep research on contract-based cross-organizational workflow coordination standard and its basic structure, which becomes a candidate standard of WfMC. Contract is regarded as a common understandable describing language for cross-organizational process and process interoperation. Either WfMC standards or XML (Extensible Markup Language) can be used as the describing language for contract making and enactment. The main task of workflow interaction is to transfer right information to right participants in right time. The shortage of information sharing usually results in weak interoperability of cross-organizational workflows. Fortunately, it can be partially solved by portal technology.

### 3.3 Portal technology

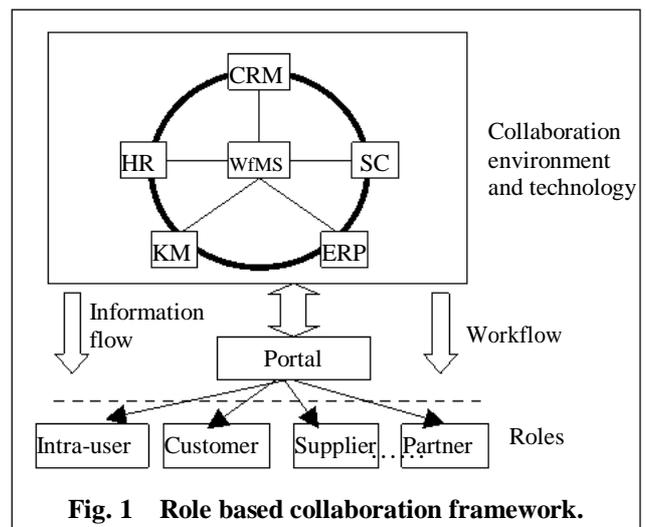

Some problems, such as drowning in data but starving for information, lack of personalized information service, and lack of proper information consistency by dynamic data association, all result in difficulties of the interoperability of cross-organizational process. It need a competent and consistent collaboration platform to provide inter-organizational information exchange service and workflow interoperability for different business roles. From a technical viewpoint, collaboration platform is a dynamic cooperation environment for dynamic information exchange between enterprises. It can be used as a basic integration framework for information and services.

As an Enterprise collaboration platform, portal can integrate many services, such as information obtaining and sharing to ensure the consistency between intra-organizational and inter-organizational collaboration. Every role can obtain all information and services from a fully personalized portal. It is an important foundation for roles to participate in collaborative activities actively.

The fundamental of portal technology is to integrate enterprises' all data resources, applications, and services by a unified information portal, which can provide personalized information and service to various

participants according to their different role, referred to as role-based access control. This information sharing mechanism also involves some security and customized service applications to provide services to all participants such as customers, suppliers, and business partners.

Portal also provides a unified access interface between users and integrated functional systems and various cross-functional applications. Enterprise portal usually consists of a unified interface and various information or service resources. Users consist of intra-organizational employees, customers, suppliers, and business partners. They can obtain information searching service through the interface. This portal-based method of information integration offers clear and unified resources for decision-making by providing a whole view of all information within an enterprise or a networked organization. The portal technology integrates existing legacy systems such as ERP, EC (electronic commerce), SCM (supply chain management), CRM (customer relation management), and HRM (human resource management), KM (knowledge management) systems etc., for all intra- and extra- participants. A true portal can act as the workflow management infrastructure for information exchange and business process interoperation. See Figure 1.

**Fig. 1 Role based collaboration framework.**

Intra-organizational employees, customers, suppliers, can effectively collaborate on different levels, such as employee-to-employee, department-to-department, and enterprise-to-enterprise, through customized portal services. Nowadays, most of enterprise information are distributed, various and vast. All these features bring the difficulty to get proper, consistent, and accurate information in time. The portal technology provides a solution by integrating different data sources and presents information in a unified, clear, and understandable form to participants according to their current roles [7]. Thus it can effectively support decision-making and improve work efficiency. The main characteristics of the portal technology are discussed as following.

#### z Role-based technology

Different participants need diverse information,

applications, and interfaces to support their activities. The role a participant plays can be changed in different business circumstances. Portal should be able to change their service portfolios according to participants' roles. The introduction of role theory to portal technology aims to simplify personalized portal service management. Role-based portal technology can provide more enough information to participants in need, with personalized interface and service portfolios, as well as access authority.

Different roles obtain content information in their personal ways. Portal designers need to analyze business scenarios and abstract types of roles. Usually there are three main types, i.e. intra-organizational users, customers, suppliers and business partners. Every type can be further divided into sub-types. Portal is not only the integrating point of applications and services, but also an environment for describing roles' responsibility. Roles can access intra- and extra-enterprise data on the basis of their authority through portal, which operates as an information intermediary. Take the CRM system as an example, CRM system integrates customers into R&D, manufacturing, marketing, and service management. Thus it can provide an effective and efficient way to manage existing customers, potential customers, and business partners. The portal system offers an information-exchanging channel for customers, distributors, retailers, suppliers, and intra-organizational users. The integrated portal service also can provide channels for cross-organizational process interaction. For example, marketing personnel can access customer information to have customized service portfolios for customers and other extra-organizational users. Marketing personnel can also use portal technology to provide differentiated production and price lists to distinct types of customers or retailers. Intra-organizational users can also access knowledge base through the portal to get necessary knowledge. The portal services can be dynamically adjusted in order to fit for each user's knowledge accumulation process. It provides a knowledge management platform especially for learning organization.

#### **z Integrating both content and functions**

Portal technology is characterized by flexibility and openness. It can collect many forms of information, such as XML, HTML, JAVA and other proprietary forms, from distributed network, to provide tailored information services. With the help of web technology, information association is achieved. For example, when an information point is found, all related information could be tracked by hyperlinks.

A true portal should create a full service collaboration environment, which integrates all applications and the applications can be dynamically connected according to users' changing needs. By virtue of portal, roles can obtain intra- and extra- enterprise information and functional supports, which can be used to facilitate workflow coordination. Thus the value of portal is fully realized. Portal is not only the interface between

application and service, but also the interaction window between roles. From the perspective of role theory, workflows can be viewed as a series of interaction between roles. This property just coincides with the function of portal. So, portal can be regarded as an intermediary for workflow interoperation. For example, in the process of production designing, all participants can exchange information through portal, to realize a concurrent designing process, which usually involves different departments or organizations.

Portal technology can integrate with other enterprise applications, such as CRM, SCM, KM systems, etc., to improve the quality of decision-making and collaboration. Portal is also based on collaboration management theory. As a collaborative support platform, portal enables a strong association among integrated function into its portal logic, which suits well with collaborative work in present business environments.

Collaborative support platform breaks down the boundary between enterprises in order to send right information to right participants in right time. Every role's tailored portal service usually involves a variety of distributed applications. A cross-organizational workflow also involves collaboration of different roles from many organizations. So it may need long time to establish the final collaboration environment by various forms of cooperation. In general, an enterprise on the value chain establishes its own applications, which are related to its workflow activities, according to the role it play in the chain. Then portal integrates these distributed applications. This solution evolves from the traditional intra-organizational integration, such as EEP, to a total integration of both intra-organizational and inter-organizational applications, which is based on some new technology standards, such as XML.

#### **3.4 Integrating portal with cross-organizational workflow technology**

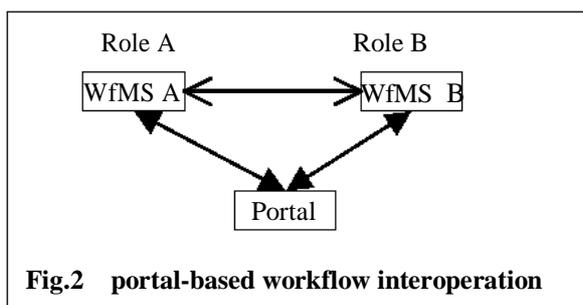

WfMS is a groupware to support collaboration between different roles involved in workflows. Currently, most existing WfMSs mainly use activity lists and alarm mechanism to support roles' activity during workflow processes, but they are lack of the ability to support role-based access control over information from different participants. Customers, suppliers, business partners apply different ontology, which is difficult to be unified, since they use different conception models, especially in the case of cross-organizational processes. The interpretability of current WfMSs is only technical, which results in the difficulty of knowledge sharing between different participants. As discussed in 3.3, portal technology can support cross-organizational workflow management. Workflow technology is complementary to portal technology. The integration of workflow technology with portal technology can improve participants' work efficiency as well as effective communication. Portal technology can work as an integrator to provide comprehensive activity lists by decomposing and re-compounding distributed activity

lists induced from different systems. Thus, roles can allocate proper resources and time for activities according to their priority.

The interoperability of traditional workflows usually has recourse to a messaging-based method by the mechanism of request and response. It only supports simple workflow interoperation, while portal technology is more versatile, that it can deal with more complex workflow interoperation. As illustrated in figure 1, WfMS is the center of the business collaboration system. It works as a neural system, which links all participants and their systems. WfMS transfers all tasks to personalized portal of every participant. By role based access mechanism, all intra-organizational users, suppliers, customers, distributors, business partners, can be integrated into E-business processes, where participants can exchange information for seamless process interoperation.

In general, the portal technology can integrate with workflow technology at least in the following three ways:

- z Portal provides customized function and information support. It sets different access priority for different roles.
- z Workflows can be used in portal technology [8]. For example, Peoplesoft co. designs portal as a hub-and-spoke WfMS integrator by the XML-based application messaging mechanism. It can integrate different WfMSs and other systems, providing comprehensive lists of activities allotted to participants so that they can properly allocate resource and time to activities, according to their importance.
- z Portal can be used as an intermediary for the interoperation of different WfMSs. As a collaboration support module, portal can also called by WfMSs as illustrated in Figure 2. This partially solves the

problem of direct interoperation between different workflows. In agent-enhanced workflow architecture, the interoperation of cross-organizational workflows is supported by the broker mechanism, which mainly deals with the bilateral ontology translation [9]. In this sense, portal can be regarded as an extended broker, which provides more affluent supports in addition to information transformation.

#### 4. Conclusion

With the development of E-business, one of the most competitive business strategies is to form alliance among enterprises according to their special core competence.

The collaboration between alliance partners usually involves many cross-organizational processes, which break down traditional enterprise boundary. It results in the urgent need of a new collaboration environment to fit for cross-organizational interoperation, especially in strongly coupled cases. Improving the workflow interoperability is one of the main tasks for this challenge. In doing so, WfMC has published some specifications on the issue of workflow interoperability.

Due to the technical limitations of current process modeling and management, as well as workflow technology in its fancy, it is still difficult to effectively deal with the interoperability problem, which also results from the difference between heterogeneous workflows and their ontology. Some distributed WfMSs are still under experiment. The key to solve the interoperability of cross-organizational processes is to design an effective method for information sharing and distribution. Fortunately, portal technology provides a partial solution as an effective tool for workflow interoperability with its customerized service portfolios according to the need of roles. At last, the integration of portal technology with workflows is proposed. It is a feasible solution for building up cross-organizational workflow collaboration.

Future research will focus on developing a prototype system to demonstrate the ideas.

# Perceived Importance of Success Factors of Firms Practicing E-Logistics in Supply Chain: An Exploratory Study on Extranet

Wing S. Chow  
Department of Finance and Decision Sciences  
School of Business  
Hong Kong Baptist University, Hong Kong  
Vwschow@hkbu.edu.hk

## Abstract

One way to enhance the success of supply chain is through the adoption of e-logistics. Much literature discuss the success stories of supply chain, it is however lacked of the determination of its success factors in the e-logistics environment. Extranet is considered as an enabler/system that could enrich the betterment of service quality in e-logistics. This paper identifies four success factors influencing to the success of Extranet; namely the quality of system, information, service and work performance. Furthermore, the analysis on its significant decision variables in each success factor through the concept of SERVQUAL is also presented.

## 1. Introduction

Traditionally, the focus of supply chain was on connection, transaction, and delivery. In today's faster-paced markets, the focus has shifted to meet market demands rapidly, correctly, and profitably. With materials flowing downstream from suppliers, manufacturers, warehouses, stores to customers and information flowing in both directions, supply chain must maintain and sustain technology-based and quality-driven capabilities in order to minimize systemwide costs, reduce lead time and transit time, and improve customer service levels. To this end, supply chain must be managed effectively. Thus, it reveals in many supply chain literature that the focus of quality-based paradigm has also shifted from the traditional company-centered setting to complete supply chain system with the implementation of e-logistics [3]. This phenomenon is especially true for the Hong Kong environment whereby it is highly critical competitive advantage of being to access the low cost production capabilities in China [5]. The adoption of e-logistics in supply chain in a form of Extranet (External Intranet), such as e-fulfillment, is a mean to which most companies seeking it as an enabler to enrich their betterment of service quality with their customers or trading partners.

Extranet is an extension version of Intranet application that applying Web technologies on the public Internet, but restricts access to a group of registered users only. With the extensive use of Extranet in the B-B environment, registered customers could gain a better understanding on the need of demand and supply of the procurement or

operations events with their trading partners. Most Extranet systems made available in the supply chain environment may also enhance the three basic functions of Intranets including (1) to create internal bulletin board that publishes information electronically, (2) to establish a distribution platform that enhances information exchanges between partners, and (3) to support daily business functions such as decision-making and training. The study of success factors and its quality of services in Intranet is plentiful in literature, such as Lai [4]. However, the success factors that influencing the Extranet has not been properly addressed in literature.

The objective of this paper is thus to remedy this deficiency by studying the success factors of Extranet in the supply chain. This paper proposes to firstly identify a set of decision variables from relevant literature and then collect data to determine its success factors. This paper adopts the exploratory factor analysis method to determine its success factors. In next section, this paper will first present the study design and measures, and then follow with the results, discussion and conclusion of our findings.

## 2. Study Design and Measures

### 2.1 Data Collection Procedure

A structured questionnaire with a cover letter was used to collect data through direct e-mails and telephone interviews. The method of telephone interview was to follow to those respondents who did not reply within four weeks after the mails were sent. 380 respondents were randomly selected from the URL homepage of <http://www.tdctrade.com>. This database is selected mainly because it provides a comprehensive web database that consists of companies adopting e-logistics and Extranet systems after the phone-calls confirmation. A total of 105 participated, with 2 incomplete questionnaires were discarded from the returned mails. Therefore, a total of 103 questionnaires was used for the data analysis, which constitutes of response rate of 27.6%. The average working experience with Extranet of our respondents was reported as 2.95 years with standard deviation of 0.51 year. Participants have been with the present company for

average of 5.46 years. These information show that the participants are conversant with the Extranet in their company. Our participants are from the industries of delivery services (including air cargo services), freight, transportation, wholesalers, trading, and logistics firms. All of our participants are presently holding a managerial position.

## 2.2 Data Analysis

This paper adopted the following methods for data analysis:

- 1) Construct validity. This paper adopted KMO (Kaiser-Meyer-Olkin) values to measure the adequacy of the samples. KMO values are typically used to judge if a group of decision variables is suitable for analyzing as the success factors when the exploration factor analysis method is used. The KMO value of 0.5 is considered to be acceptable condition.
- 2) Reliability test. This paper adopted internal consistency method to test if a set of decision variables in a cluster is homogeneous. A reliability coefficient  $\lambda \geq 0.6$  in a cluster is considered as sufficient condition to conclude a high consistency of decision variables.
- 3) Exploratory factor analysis. A general guideline is that a value of factor loading  $\geq \pm 0.5$  for a decision variable is considered as practically and significantly contribution to that factor.
- 4) SERVQUAL measure. This paper adopted the SERVQUAL measure Kettinger and Choong [2]. The service quality of Extranet can be measured by computing firstly Extranet perceptual scores by subtracting values of Extranet Performance scores of the company from scores collected from their customers. Gap correlation is then obtained by studying the correlation of Extranet Perceptual scores with the Overall Extranet User Satisfaction scores.

## 2.3 Measures

Compiling a list of relevant decision variables is firstly needed in prior to the determination of success factors for the Extranet in e-logistics. However, it is indisputable that its relevant literature is limited. In such, this paper proposes to concentrate and identify its relevant decision variables that frequently addressed in the Intranet literature. This approach is justified mainly because both these two systems share many similar features. In total, a total of eighteen decision variables that are commonly applied to Extranet environment are identified and they are: X1 = The system maintains consistently and regularly, X2= The system provides user-menu/instructions, X3= The system enhances the collaboration among group members, X4= The systems produces accurate search results/information, X5= The system gives a standardized display format (screen layout), X6= The system adopts Data security/privacy, X7= The system improves personal productivity, X8= The organization provides technical

support competently, X9= The system improves the business communication, X10= The system enhances fast response time, X11= The system provides standardized retrieval procedure, X12= The organization provides training, X13= The system provides most up-to-date information, X14= The system provides standardized search procedure, X15= The system eases to use, X16= The system improves the quality of decision-making, X17= The system helps to make decision faster, and X18= The system allows faster exchange of information.

These eighteen decision variables are used to develop two sets of questionnaire. The first set is to ask participants to evaluate their expected performance of their Extranet system in a measurement scale 1 to 5; where a value 5 represents as most important one, and value 1 as least important one. The second measurement is to ask their customers/trading partners to rate the actual Extranet performance based on the criterion of each decision variable, in a measurement scale of 1 to 5; where a value 5 represents strongly agree, a value 1 as strong disagree. In addition, we also adopted three questions to ask their customers/trading partners to evaluate the overall satisfactory of the Extranet system in a measurement scale of 1 to 5, with value 5 as excellent, and value 1 as poor performance. These three questions are used to performance the correlation described in the SERVQUAL measurement. These three questions are adopted with modification from the paper of Chow and Lui [1]. In the questionnaire, we also asked participants to consider the term "The system" be treated as "The Extranet system" and that they could consider e-fulfillment system adopted in their company is an example for such a system in the e-logistics environment.

## 3. Results and Discussions

Table 1 shows the result findings of our proposed study of success factors for the Extranet. In this table, there are three information included in each row of column one, namely labels of the success factor for the Extranet, reliability values  $\lambda$ , and KMO values. Column 2 represents the coded decision variables shown in the above section. Column 3 is the factor loadings of each decision variable. Expected and actual performance of Extranet are shown in columns 4 and 5. Perceptual performance, that is (expected performance value - Actual performance value), is listed in column 6. The correlation between perceptual performance of Extranet with overall Extranet user satisfaction is shown in the last column.

In column one, all KMO values are great then 0.5. It is therefore concluded that samples adopted in this study have reached to a sufficient condition to perform further analysis. Similarly, all reliability values  $\lambda \geq 0.6$ , and thus it shown that that decision variables included in each grouping is highly consistent. In analyzing factor loadings within each grouping, column 3 shows that all factor loadings  $\geq \pm 0.5$ , which implied that each decision

variable is significantly and practically contributed to each grouping. All expectation values in the above table have values great than 3, which implied that all these decision variables are significantly important to the success of Extranet. The perceptual scores are all negative values, which indicated that the performance of Extranet does not match perfectly with their customers' expectation.

In the last column, values with "\*" or "\*\*" representing decision variables that are considered as good potential indicators to the overall Extranet satisfaction. However, one must clear that those remaining ones do not representing insignificant to the contribution on the success of Extranet.

There are four success factors that contributing as success factors of Extranet. The first one is system quality. Decision variables related to this success factor are X2 = The system provides user-menu/instructions, X6= The systems adopts data security/privacy, X10 = The system enhances fast response time, X11 = The system provides standardized retrieval procedure, and X14 = The systems provides standardized search procedure, and X15 = The system eases to use. Second success factor of Extranet is information quality, which consists decision variables of X4 = The system produces accurate search results/information, X5 = The system gives a standardized display format (screen layout), and X13 = The system provides most up-to-date information. Third success factor is service quality. Decision variables are X1 = The system maintains consistently and regularly maintained, X8 = The organization provides technical support competently, and X12 = The organization provides training. Forth success factor is work performance quality. The corresponding decision variables are X3 = The system enhances the collaboration among group members, X7 = The system improves personal productivity, X9 = The system improves the business communication, X16 = The system improves the quality of decision-making, X17 = The system helps to make decision faster, and X18 = The system allows faster exchange of information. These four success factors are crucial and needed to be carefully considered when launching an Extranet system in the e-Business environment.

In analyzing the indicators of overall Extranet user satisfaction, four decision variables are significant in system quality success factor. These four decision variables are X10 = The system enhances fast response time, X11 = The system provides standardized retrieval procedure, X14 = The system provides standardized search procedure, and X15 = The system eases to use. In information quality success factor, two indicators of overall Extranet user satisfaction are X4 = The system produces accurate search results/information, X5 = The

system gives a standardized display format (screen layout). However, there is only one good indicator in service quality success factor, namely, X8 = The organization provides technical support competently. At last, there are three good indicators can be identified in work performance quality. They are X9 = The system improves the business communication, X17 = The system helps to make decision faster, and X18 = The system allows faster exchange of information.

Organizations should emphasize on these decision variables so that the overall user satisfaction of Extranet can further be enhanced.

#### 4. Conclusion

This paper has two contributions. First, it has identified four success factors of Extranet in e-logistics. These four success factors are system quality, information quality, service quality, and work performance quality. Second, it has determined a set of good indicators to enhance the overall user satisfaction on Extranet. A total of 10 decision variables are identified as good indicators. These indicators are 1) fast response time is enhanced, 2) Extranet system is easy to use, 3) search procedure is standardized, 4) retrieval procedure is standardized, 5) display format (screen layout) is standardized, 6) search results are accurate, 7) system support staff are technical competence. 8) Extranet system allows faster exchange of information, 9) Extranet system improves the business communication, and 10) Extranet system helps to make decision faster.

## Abstract

The IT industry is Taiwan's most thoroughly globalized industry. In the IT industry, suppliers and customers are spread all over the world, so making logistics management more efficient is very important. With government's sponsorship, Taiwan's IT industry has introduced e-Procurement (Plans A and B) to make the whole procurement process among enterprises an electronic one. Thus e-Procurement became the fundamentals of e-SCM. In order to extend the benefits of e-procurement, Taiwan government continuously promote the IT industry to introduce e-Logistics (Plan D).

The objectives of this paper are to study the collaborative integration between IT industry and logistics industry in Taiwan, and to investigate the progress of introducing e-Logistics into the IT industry. A PC manufacturer, T Company was selected for use in the case study. It was found that the logistics visibility elevation through "Track and Trace" and the achievement of VMI (Vendor Managed Inventory) are the objectives of e-Logistics implementation. IT manufacturers worked out common business models. Then each supply chain can follow the common specification and implement their e-Logistics individually. This study found that not only the IT manufacturers gain the competitive advantages, but LSPs (Logistics service providers) also learn from collaborative commerce and provide better service for customers with the implementation of e-Logistics. Then eight guidelines were induced as the reference for other industries to implement e-Logistics afterward. Besides, some suggestions were proposed to IT industry, logistics industry, and government.

## 1. Introduction

Business nowadays is moving toward globalization due to the specialization and convenience of traffic channels. Recently, the booming of the Internet and other modern communication devices further serve to speed up globalization. Enterprises in Taiwan inevitably move toward global arrangements due to the limited territory and few natural resources of the country. In particular, Taiwan's companies, which are famous worldwide for manufacturing and focus on ODM and OEM, are forced to use resource from other regions to develop their products. The IT industry is now faced with not only volatile customer demands, but also a series of challenges, such as intense global competition, shortened product life cycle

and delivery, and difficult global coordination between sources of raw materials and manufacturing, this situation takes the supply network a great deal of time to integrate. Due to the time pressures caused by the vast supply network, enterprises must develop an integrated process management system to efficiently respond to fast changes within the commercial cycle.

With government's sponsorship, Taiwan's IT industry has introduced e-Procurement (Plan A and Plan B of IT applications promotion project), to make the whole procurement process between enterprises an electronic one. In order to extend the benefits of e-Procurement, Taiwan government continuously promotes the IT industry to introduce e-Logistics (Plan D). Helping more than 15 industry systems to introduce e-Logistics is the target of Plan D. Logistics costs account for 10% an enterprise's total cost[1]. The more globalized industry, the more logistics costs. So the e-Logistics plan aims to apply information technology to logistics management. In addition to extend and expand benefits of e-Procurement, it is also the critical field that companies can save costs, especially for the manufacturing industry. Enterprises can build efficient response systems to reduce inventories with information. Furthermore, they can enforce the ability of global operations and logistics with e-Logistics.

## 2. Related Works

One of the objectives of supply chain management is to make information flow among participating companies in the supply chain efficient and accurate. The information technologies such as EDI (Electronic Data Interchange) and barcode system can improve the efficiency of supply chain. These technologies can secure and distribute related trading information for buyers and sellers. It makes the trading information transfer smooth. Therefore, the efficiency of business activities among manufacturers, customers, banks, and suppliers can be improved. Nowadays, EDI has been replaced with XML-based B2B application integration. The expected benefits are greater than the EDI.

### 2.1 Quick Response

"Quick Response" is a main strategy to redesign the supply chain and make the whole process a best practice. The target is to create a quick response system based on customers' requirement. It makes the suppliers and manufacturers cooperate to satisfy customers and reduce

cost. Utilizing a paperless system from the stage of production to payment, continuously input precise data to the system, and reduce data error and data miss that can realize QR.

A study in the food industry supply chain concludes that using EDI can lead the potential cost reduction annually up to US\$27 billion [2]. Further, the study foresees inventory reductions of more than 40% with the application of innovative logistics concepts. In addition, Loebbecke and Powell [3] had investigated that through an integrated transport tracking system can gain competitive advantages. They use central information data center, communications networks, and EDI to implement the system. Every party in the logistics can easily access the logistics information. The system provides savings of more than US\$24.5 million in five years. It does not account for competitive advantage through better customer service, not for additional monetary advantages, either. Actually, every transaction can save at least US\$2.5.

## 2.2 Vendor Managed Inventory

VMI (Vendor Managed Inventory) is a program of inventory management. It is a solution to forecast the requirements and replenish by mastering the sales data and the quantity of inventories. Suppliers can more effectively response to the changes of market and requirements of customers. Thus VMI can reduce the inventories, increase inventory turnover rate, and then maintain the appropriate quantity of inventory. Because manufacturers share important information with suppliers, both of them can improve requirement forecast plan, replenishment plan, transportation and shipment plan, and so on. VMI is changed from traditional replenishment according to purchase orders to replenishment according to actual consumption and forecast. Therefore, VMI model is well suited the dynamic business environment today.

There were many real practices in American, such as Wal-Mart, Campbell Soup, Johnson and Johnson, and Procter and Gamble [4]. They have reduced the inventory with mastering accurate consumption information.

## 3. Case Study

T Company is an IT manufacturer. It focuses on personal computer manufacturing. In addition, it is an OEM/ODM company serving major brand-name customers. Confronting both international and domestic intensive competition and challenges, T Company has deployed manufacturing factories, assembling factories, and research and service centers worldwide. In addition to headquarter in Taiwan, T Company has established factories in Thailand, Mexico, the U.S., Netherlands, the U.K., and Mainland China. And it established JIT (Just in Time) warehouse in El Paso near the boundary between the U.S. and Mexico. All of the arrangements construct the foundation of global operations and logistics.

In the past, T Company had developed the MRP

system and MRP II system to elevate the manufacturing ability. After focusing on the development of 3C business and the global operations, it introduced J. D. Edwards' ERP system successively in the U.S., Mexico, and Netherlands, to meet the major brand-name customers' information requirement and integrate all the business functions. The MRP system and the J. D. Edwards' ERP system are the backbone of the global operations network now. In the past two years, T Company had implemented e-Procurement, the fundamentals of e-SCM, under the sponsorship of the Ministry of Economic Affairs of Taiwan.

Recently, T Company is aware that focusing on manufacturing may meet some limitation in gaining competitive synergy. Therefore, it plans to provide major brand-name customers with integrated product services (IPS) that cover advanced research, product development, fast-prototyping, manufacturing, and global logistics throughout North America, Europe and Asia. Therefore, T Company applied for the sponsorship of Plan D and began to implement e-Logistics.

### 3.1 The Foundation of Taiwan IT Industry e-Alliance

Early in October 2001, the IT companies applying for government's Plan D sponsorship started establishing a users group. The shippers (IT manufacturers), LSPs (logistics service providers) and logistics information ASPs (applications service providers) were invited to join the users group. The target of Plan D users group was to hold conferences to strike out common business models and information technology infrastructure as early as possible. Members of Plan D users group have to follow the outcomes that the Plan D users group decided in deploying the business models and IT infrastructure on their corporations to enable them to do business with other companies via the common manner. After several months, Taiwan IT Industry e-Alliance was set up based on the Plan D users group.

The mission of Taiwan IT Industry e-Alliance is to develop the common specifications and the acceptance criteria for validating implementation results, and to promote the developed specifications and criteria. Members of Taiwan IT Industry e-Alliance used the scenario proposed by RosettaNet for e-Logistics as reference model and discussed how to modify it to fit all the members' need. They may add some PIPs into the scenario and take off some PIPs from the scenario. Once the modified scenario is decided, members can follow the common scenario to determine the specifications of PIPs. The last stage is to figure out IT architecture to fulfill these business processes.

### 3.2 Implement e-Logistics

T Company has confronted the following requirements in logistics management.

- z VISIBILITY (make the material flow visible)
- z OPTIMIZATION (make the material flow routes

optimal)

z MANAGEMENT (make the logistics efficient)  
Therefore, T Company proposes to implement its e-Logistics system with following core information technology.

z ASP

ASPs (Application Service Providers) are third-party entities that manage and distribute software-based services and solutions to customers across a wide area network from a central data center.

z RosettaNet

For the issues of supply chain process standard, some large information enterprises established RosettaNet organization, a nonprofit organization that strove to define the standard in IT industry supply chain management. The first target of RosettaNet is to make the standard in business processes, and the second one is to make the standard in message syntax. The RosettaNet standard is composed of PIPs, RNIF, and dictionaries. PIPs (Partner Interface Processes)[5] are specialized system-to-system XML-based dialogs that define business processes between trading partners. The RNIF (RosettaNet Implementation Framework) Core Specification provides exchange protocols for quick and efficient implementation of RosettaNet standards. Dictionaries reduce confusion in the procurement process due to each company's uniquely defined terminology.

The architecture of T Company's e-Logistics System is shown in figure 1. ASP provides a public information exchange center. T Company constructs its virtual private logistics information center under the public information exchange center. The private hub can provide logistics information for every site of T Company, including factories in Thailand, Mexico and distribution center in El Paso via the Internet. In addition, T Company's suppliers and LSPs can access information in the hub with browser or through gateway. The brand-name customers and international LSPs use the international logistics information ASP for information exchange. T Company's private hub connects with the international logistics information ASP directly or through Taiwan public logistics information hub. This makes information share among all the partners of supply chain network.

Furthermore, data gathered in the hub can be used in planning. Managers can reconcile supply with demand, and make production planning according to the status of each node in the global logistics pipeline. Thus FPS (Factory Planning Simulation) system can generate simulation reports in accordance with logistics information in the e-Logistics hub and data generated from ERP in each factory.

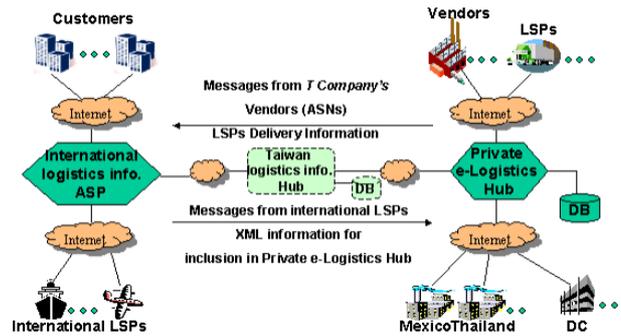

Figure 1: Architecture of T Company's e-Logistics System [6]

T Company provides three different interconnection manners for their partners as shown in figure 2. Thus its trading partners can select one way and implement their systems based on their requirements and IT ability.

z System Integration with Open Standard (Class A integration):

Companies with higher IT capability can implement RosettaNet compliant system to integrate the processes among buyers and sellers. Both messages and processes follow the common standard.

z Electronic Data Interchange through Turnkey System (Class B Integration):

Companies use this kind of integration to streamline two companies' backend ERP with document exchanging. It is similar to traditional EDI. Companies use turnkey solution that ASPs provided to achieve standard message exchange.

z Web Access (Class C Integration):

Users connect to the website that central manufacturers provided with browser. This kind of connection doesn't have system connection, and only exchange with common XML standard.

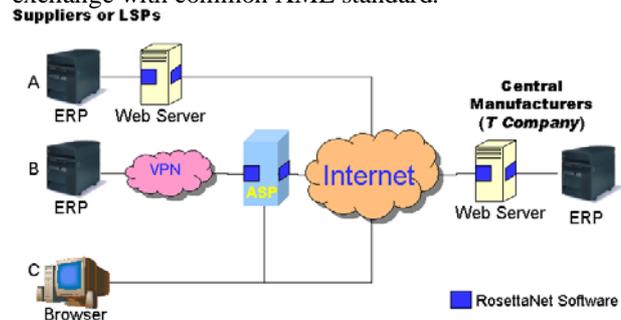

Figure 2: The Frameworks of Introducing RosettaNet Standard [7]

### 3.3 Business Process and Expected Benefits

In the logistics management, T Company still use fax, telephone, or e-mail as the media of information exchange. It is hard to master actual logistics situation, such as the quality and efficiency of logistics. The maximum synergy of e-SCM can't be achieved. T Company consequently introduces e-Logistics so as to seamless streamline the processes of all the partners in supply chain network.

The scenario illustrated below not only represents the situation that T Company meets; but also represents the situation that many other companies may meet. It is

time consuming and inefficiency.

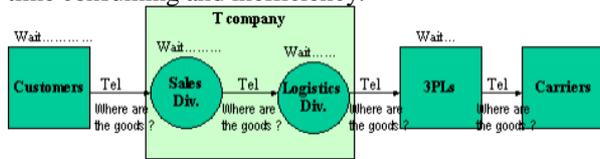

Figure 3: Original Track and Trace Process

Taiwan IT Industry e-Business Alliance had decided to use RosettaNet logistics related PIPs (Partner Interface Processes) as the common standard. Members of alliance must follow the common business processes and implement the infrastructure to exchange messages. The concluded business models including two main functions, “track & trace” and VMI (Vendor Managed Inventory). Track & trace can be further divided into two parts, shipping order management and shipment status.

Table 1: Functions and Related RosettaNet PIPs

Function		RosettaNet Partner Interface Process
Track & Trace	Shipping Order Management	PIP 3B12 Request Shipping Order PIP 3B18 Notify of Shipment Documentation PIP 3B13 Notify of Shipment Confirmation
	Shipping Status	PIP 3B3 Distribute Shipment Status
VMI (Vendor Managed Inventory)		PIP 4A2 Notify of Embedded Release Forecast PIP 4A3 Notify of Threshold Release Forecast PIP 4A5 Notify of Forecast Reply PIP 3B2 Notify of Advance Shipment PIP 4C1 Distribute Inventory Report PIP 4B2 Notify of Shipment Receipt

Source: Taiwan IT Industry e-Business Alliance, sorted by this study

#### z Track and trace

The scenario of tracking and tracing is shown in Figure 4. The supplier create shipping order request (specifies which products to ship, how to ship them, the origin and destination locations, and other related information). Then the message (PIP3B12) is sent to LSPs. The LSPs create order confirmation to reply. Suppliers create shipping notification with the shipment. Suppliers need to request LSPs to ship the components to customers whenever a sales order is received. It is required to provide delivery documentation. The LSPs inform the supplier when the shipment has been sent with PIP3B13.

Shipping status information has to be sent to the supplier or the consignee according the agreement.

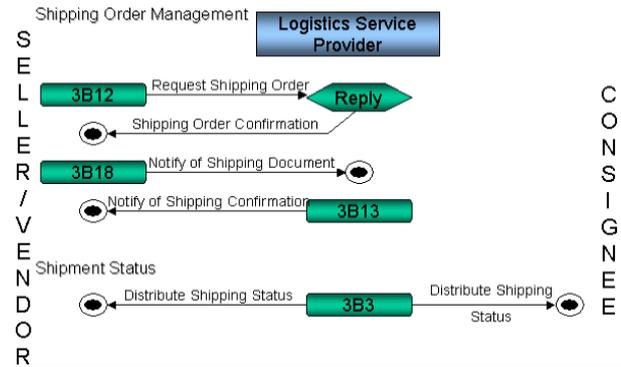

Figure 4: Trace & Track Using RosettaNet PIPs [5]

#### z Vendor Managed Inventory

The scenario of tracking and tracing is shown in Figure 5. The customer create a release forecast with product demand information (PIP4A2) or create threshold release forecast (PIP4A3) with product demand information, current product inventory levels, and target product inventory levels and send the message. The distribution center creates an inventory report to both the seller and the customer. The supplier notifies the receiver that a shipment has been assigned and created the detail Advance Shipment Notification. Then the physical distribution is conducted. When the goods enter into the distribution center, the distribution center creates a shipment receipt with receipt information. When the customer needs materials, the customer sends pull signal to the distribution center. Furthermore, the distribution center can replenish. The customer sends consumption reporting to the seller with PIP4B2.

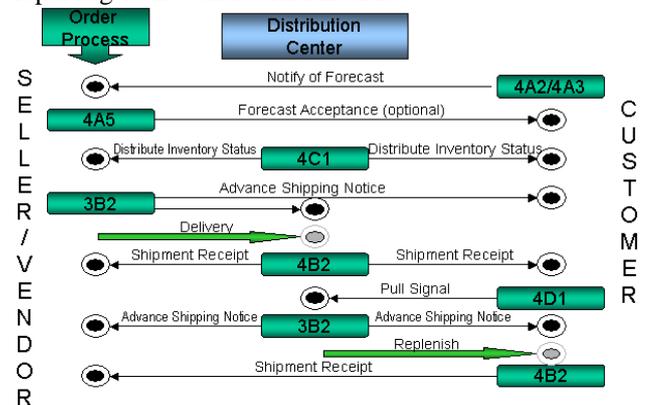

Figure 5: VMI Scenario Using RosettaNet PIPs [5]

Therefore, T Company can elevate the visibility of logistics with business automation and the operation of e-Logistics hub. And the VMI model can be achieved by automating processes.

## 4. Findings and Exemplary Effects Investigation

### 4.1 Findings

During the execution process of this plan, this study discovers that large gap exists between the scale of the logistics companies as well as their capabilities on utilizing information technology. How to lead all the

logistics companies into electronic operations would be a tough issue. It is a good way to classify the on-line connections of a system into three levels. The advantages of this classification include: 1. Provide different connection models in accordance with the different demand levels of IT ability for different users. 2. Every logistics companies can join the entirety of the e-Logistics.

Moreover, T Company also plans to help several LSPs to adopt B2BI. T Company has experience in adoption B2BI (e-procurement), and it also could impart their own experience in adopting them and sufficient orders to drive them to accept new technology, thus, the time of adoption and the possibility of failure would be reduced. For the LSPs, in addition of the orders from T Company, the introduction of new IT technology could not only enforce the IT capability but also reduce the cost and the necessary time responding the demand of the customer through this new operation.

#### 4.2 The Issues and Corresponding Measures

During the introduction of Plan B, the late launching of users group caused the progress of introduction highly delayed. Besides, they had spent a lot of cost long before the common range and standard identifying. As so, the Plan D learned the lessons. In the initiation of the plan, the enterprises form a user group. Under the discussion, they determine the specification of message exchanging, and standard. IT manufacturers and LSPs can implement e-Logistics early.

From the result of the investigation of the current industry application by Electronic Commerce Resources Center of Institute for Information Industry designated by Taiwan IT Industry e-Business Alliance; the RosetteNet has developed several scenarios. Therefore, the domestic enterprises could choose scenarios those are fitting them. It not only saves plenty time and cost but also could connect with the international enterprises directly.

From the past experience of the introduction cases and the researches that focus on KSFs (Key Success Factors) of introducing enterprise information systems[8], it can be found that the high-level managers play a very important role, especially for large-sized plans, they even could be crucial for the success or the failure.

Most of the central manufacturers that participate in the e-Logistics plan are the multi-national enterprises. Hence, the choice for designation of the domestic logistic operations which means from domestic suppliers to the domestic assemble factories or manufactories of the domestic central manufacturers is only among the domestic logistics companies, and the choice for designation of international or cross-national logistic operations is among the large-scaled international logistics companies or the international third party logistics service providers. On the opposite, the information processing and the delivery status recall still not get involved deep enough or even not established yet for our domestic logistic corporations. Probably their customers, such as the domestic IT enterprises or the

component suppliers, could check the delivery status by phone calls, but still is short of a spontaneous recall service. Few of the international logistic corporations, for example, UPS, they generally already digitalization in depth, have high cooperation attitude toward this plan and showing their determined support for the introduction of international standard – RosettaNet. Besides, they also have enough IT ability for this introduction. A large part of the logistics service providers or freight forwarders have already sensed the importance of tracking and tracing. In the past, they solved it by outsourcing the establishment of the web site for providing the requiring service but still lack of the abilities in maintenance for the continuing service. So the e-Logistics plan is very welcomed by them as long as the plan gets the support from the central manufacturers.

In general, the enterprises that participate in the plan would designate the logistic assignments to the international third party logistics service providers and they, again, outsource the practical delivery assignments to other companies, including the domestic land carriers, the international land carriers, ocean carriers, and air carriers. Those land carriers usually have not built up the tracking and tracing mechanism yet. Thus, the delivery tracking and tracing is obviously difficult and the information of the responsible department is always behind the latest one. This issue relies on the international third party LSPs to be solved.

Another issue is that the logistics industry has the controversy of the RosettaNet standard proposed by the IT industry. They thought that the standard is particularly set up based on the conditions of IT, EC and semiconductor without considering other industries. Especially, this standard does not include all required processes for the logistics industry. The practical solution is that building up a common standard inside the industry so that the only assignment for logistics corporations would be mapping when integrating the IT process. Actually, this solution should be derived from the logistics industry itself.

#### 4.3 Effects

BPR teams should be conducted simultaneously once the Plan D started in order to re-engineer the organizational structure and all business processes.

A comprehensive education and training program for this plan is essential. From real experience, it is found that many employees have defensive attitude toward the plan without fully understanding. However, this system could reduce their job load and let them put more efforts in a more meaningful duty with more additional value. For example, the traditional tracking and tracing process cost a lot of manpower. From the beginning, the customer needs the delivery status. Then, they make the phone calls to the internal purchase department; the purchase department inquires the logistics department; then, the logistics department contact with LSP; then, LSPs contact with Carrier, and so on. Under the Plan, those level-by-level inquiring could be solved at once by web site directly from the customers. The duty for the

purchase department, logistics department, etc could shift to higher value-added jobs, such as analysis.

A good communication is also necessary. This plan needs wide involvement, and the participants may contact with various departments or countries. For practical experience, unpleasant cooperation has occurred because some departments were not informed in advance. The precedent communications among all involved departments are dispensable.

#### 4.4 Exemplary Effects Investigation

The IT industry is chosen as the pilot of the B2B integration introduction by the government and thus, gains the assistance. The purpose of this pilot project is to spray the experience to other industries that would like to join the plan afterward. No matter it is success or fail, the most important function of this plan is to keep the conclusion and provide to other industries in order to avoid similar mistakes and unnecessary time-consumption in implementation. That is what we called the spirit of demonstrative "Information Technology Applications Promotion Project". Here are some findings and suggestions that may be applicable for other industries interested in introducing the similar plan in the future.

##### 1. Organize users group as early as possible

The foremost condition for a successful plan is the foundation of User Group that could provide a mutual communication mechanism together with the establishment of the relevant standard. To reach the common sense of the participants is the purpose of the users group so as to corresponding the coming of an era of group competition.

##### 2. The manufacturers drive the participation of the upstream suppliers of the supply chain and the logistics service providers

From the experience of Plans A and B, the success is owed to a key point caught by the Department of Industrial Technology of The Ministry of Economic Affairs— start from those center manufacturers of a supply chain. It just likes to hold a bunch of sweet corn. To hold the knot means to hold the whole bunches. Consequently, the Plan D follows the same model, except some of the large-scale LSPs join users group spontaneously; the center manufacturers are in charge of the drive the participation of the cooperated LSPs for the discussion and establishment of the business process and the specification of the information technology.

##### 3. Build up a common partner interface process and message standard

Standardization is still the spirit of Plan D. The implementation of the interactive dialogue of e-business and the operations process of the enterprises are possible only after standardization. The common standard that followed by all participants is on the list of the primaries in integration introductions. There are two ways to set up the standard: the first choice should be the current international standard; if not, then set up a new one according to their own by the way of imitating the current successful model such as RosettaNet, for example: its

RNIF, PIPs, Dictionaries and the methodology of the process integration is suit to be the reference for other industry. Besides, XML could be a good basic tool when set up the standard for the integration of business-to-business on the angles of its excellent self-description.

##### 4. Participate in the discussion of the international industry standard

If we analyze the past rules showing in the IT industry, we could easily found that the standard has become a weapon of these international major enterprises and caused a clear boundary between different systems. The competition start far from choosing the standard if a group of major IT corporations decide to follow some certain standard. All the relevant product is deem to follow the decision of theirs. In short, the future is a war of the standard. As far as the Taiwan domestic corporation on the position of suppliers to be concerned, lost the opportunities to participate establishment of the standard, it means to risk the possibility of the replacement. For example, the current standard, RosettaNet and Oasis etc, are dominated by foreign enterprises. Thus, they may not put our consideration on the list. The IT industry hopes that the assistance in regularizing standard and striving against the dominancy from the government could be more active. At that time, we, the suppliers, could own more negotiation power than the customers and the strength for a long-term prospect of the IT industry.

##### 5. Establish common business model and process

The principle for establishing common business model should be focus on coordinating a proper one for everybody based on the original one owned by each one. The business model could modify the process situation set up by IT industry that could reduce the necessary effort of introduction.

##### 6. Draw up the relevant IT support

For the necessary IT supporting this standard business model and process, the participants should looking for the IT corporations that fit for the process of the corporations. However, the framework proposed by the IT industry is possible a good choice, the participants afterwards might follow as well.

##### 7. Seek support from high-level managers

As we mention in the last section, the high-level managers holds crucial element in a large-scale plan.

##### 8. Implement BPR in accordance with the plan

To adopt the needs of the common business models demand great modifications in internal process so we could not neglect the importance of the internal BPR when we introduce B2BI system.

However, what kind of industry is particularly suit for this model in e-Logistics introduction? The nature is more similar to the IT industry, the more possible for the participant to adopt this plan and the less cost in modification it would need during the introduction. From the observations, among of all the industry, the auto industry is the most close to those of the IT industry. For example, the earliest application model is from the one of

the TOYOTA in the respect of JIT. We suggest that the auto manufacturers are the best choice for government for the option of popularizing the demonstrative model. The other option could be mechanical and electrical industry, flight and space mechanic industry, or the medical equipment manufacturer etc., with slide modification of the model to fit the individual needs of the industry.

## 5. Conclusions and Suggestions

### 5.1 Conclusions

The crucial point for achieving and holding the No. 1 market share in the current global business market is the speed of information integration – The faster, the better. As the information is getting visible and instant, the competition of each industry is getting serious. The only chance for the corporation to survive is rely on the ability to respond the market demand instantly and put the customer satisfaction on the top of the list.

Another important element for a successful enterprise in this era is choosing the ways of the efficient alliance, instead of standing along. Only the cooperation and pursuing the mutual beneficial of the corporations could create the best benefit for themselves, as the market in the future would be a competition of the whole supplier chain, instead of just the corporations in the past.

Plans A and B has integrated the upstream suppliers, the central manufacturers, and the downstream customers in an entirety of electronic supply chain and Plan D also has brought into the logistics industry, a kind of bridge between the enterprises, in this entirety, at the same time, the conjunction of Plan C with those two plan could form a complete integration of supply chain with “information flow”, “material flow” and “cash flow”. Then, this integrated chain definitely could increase the overall competition of our IT manufacturer industry and furthermore, drive the whole domestic industry to advance into a new boundary.

### 5.2 The suggestions for the industry

#### 1. The suggestion for the IT industry —Enforce ERP

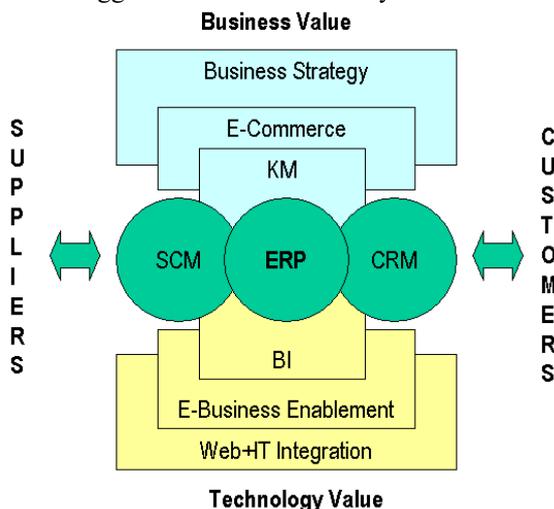

Figure 6: Malecki's view of e-Business [9]

ERP is the core for the operation of the e-Business, the pivot of all applications. Form the view of Malecki in the e-Business as shown in figure 6, we know, the most overall effect is from the coordination between the B2BI introduction and the internal IT system. The introduction of ERP develops from “the predomination of the competition”, “the necessity of the competition” to “the foundation of the competition” until now. Before introducing the business-to-business application integration, the enterprises should, first, has a robust ERP system.

#### 2. The suggestion for logistics industry

z The standardization of logistics process in accordance with the IT introduction

The IT industry has already own mature IT in internal facilities and went through the phase of rationalization. As we mentioned before, the issues should be the different depth of information processing in logistics industry. The most effect of B2BI introduction relies on the standardization of logistics industry.

z The integrations of their own IT system

During the process of introducing the Plan D, we could observed that the logistics choose passive attitude toward providing the relevant information to the IT manufacturers, that brings more convenience to the latter but more burden to the former. The logistics industry should conduct an internal system integration (Enterprise Application Integration) and enforcement in its own information system so as to connect with B2BI system by the way of automation. An overall automation is an important element for a best overall effect of the business-to-business application integration.

z Enforce the understanding of e-business

For the whole environment of e-business, the key point is the connections between upstream and downstream corporations. It will reduce the individual character of the logistics industry from the angle of pursuing the best effect of the whole supplier chain, instead of individual benefit. In the future, in addition to the demand of a fast order process and transportation, the accuracy in controlling the amount and type of the goods, the integrity of controlling the inspections, and the goal of zero stock amount and shortage are also the criterion of a standard B2B logistics service.

z Participate in relevant projects sponsored by the government

Our government also provides relevant electronic project for domestic logistics industry. The demonstrative “mobilized logistics information system” sponsored by Department of Commerce under the Ministry of Economic Affairs in 2002 is an example. The aims of this project is to drive the applications of wireless communication technology into logistics industry in accordance with the goal of business automation and e-business by helping them to introducing “mobile information technology” so as to increase the efficiency of the transportation and the utilization of the fleet, increase the service quality and decrease the transportation cost. It is a good opportunity for logistics industry to offer a better service by enforcing

its infrastructure and introducing e-Logistics.

### 5.3 The suggestions for government

This plan is expected to advance the logistics industry from the respect of IT. However, we still have several suggestions as below for the government:

#### 1. Encourage the establishment of public hub

We suggest that government could encourage the establishment of public hub by the ways of demonstrative applications system or other reward investment program.

The spirit of the public hub is: As long as you connect with the hub, you connect with numerous enterprises that join with the hub. Save the cost and increase the effect are the major advantages of this model.

Nevertheless, the participants of the Plan D has many concern and criteria and is suspect with the neutrality of any central manufacturers since the hub is a convergence owned all the details of the participants. It is possible to estimate the operation status of the participants from the information saved in the hub if someone intend to. We suggest the government assist to establish the hub under a third party with a reputation of just. Moreover, the government could offer preferential measures and for those who are willing to adopt the public hub. Besides, the public hub is not only established for IT industry but also could provide for other industries to use.

#### 2. The strategy of international logistics set by the government still has rooms for improvement

The current global strategy of our government still focuses on the manufacturers with less consideration of assistance in logistics industry. For the domestic logistics, the major concern is usually the cost. The government could lead them entering the international logistics under the special project. Besides, IT manufacturers may assistance logistics firms to enter the international logistics.

#### 3. Cross-industry integration needs Cross-industry plan

Plan D is sponsored by the Department of Industrial Technology of the Ministry of Economic Affairs; while the Department of Commerce of the Ministry of Economic Affairs and the Ministry of Transportation and Communications are jointly responsible for servicing and supporting the logistics industry. When the IT industry and the logistics industry make effort in such collaborative integration, all the responsible departments of the government should set up a joint supporting framework to provide strong assistance to the Plan participants.

#### 4. Sponsor the development of Taiwan-based R&D center and global logistics and operations center

Taiwan is a small place. In the recent, we face the pressure of industry moving outward. In the past, the development country, such as U.S.A. or Japan, has been gone through and it turns out an expansion of IT industry, instead of reduction. Besides, that the manufacturing base shift to Mainland China should be regard as a global expansion, instead of a view of industry emigration since the advantage of low-cost has disappeared in domestic environment. The assistance for the corporations in developing the Taiwan as the center of R&D and global

operation could start from the outstanding the features of our industry and product, then, cooperated the proper global operation plan of the central manufacturers of supply chain as the schedule and encourage the coordination of the satellite enterprises for the purpose of a competitive regional supply network.

### 5.4 Suggestions for Future Research

The advance of IT is at a tremendous pace. During the process of the e-Logistics, we discovered that many technologies in the applications of business are discussed enthusiastically, for example: Web Services, ebXML...etc. The relevant technology may not be mature enough but those ideals are fantastic. The progress of the IT would never stop and it is a good topic for the researcher afterwards to study.

For the logistics operations, the visibility of the material flow is only an initiation. The most important steps should be the application strategy after obtaining the visibility information. Until the research is closed, this part still remains on the paperwork without practical performance or implementation. This is also a good topic for further study.

Once Plan D is finished, whether the benefits could be achieved as expected is another potential topic for further study.

Reviewing from the e-procurement in Taiwan's IT manufacturers to the e-Logistics and e-financing after e-procurement, the trend of the future, the Plan E – engineering collaboration and the relevant knowledge management, can be peeped. Likewise, the Plan E and the relevant knowledge management are worth of future researches.

# Impact of Information Sharing in Supply Chain Management

Takahiro Tsukihama\*, Hisashi Onari \*\*, Toshimitsu Hamada \*\*\*

\* Production Engineering Research Lab. Hitachi, Ltd Japan tsuki@perl.hitachi.co.jp

\*\* Department of IMSE Waseda University Japan onari@mn.waseda.ac.jp

\*\*\* Nasu University Japan

## Abstract

It has been pointed out that a vital element of SCM systems is the sharing of information such as sales figures and delivery plans between multiple companies or between different divisions of a company. However, the potential benefits of SCM for individual companies that actually share information has yet to be properly investigated.

In view of this, the present study modeled company activities in a way that considered decision-making not just over the execution-level, but also over the tactics- and strategy-level. Simulation was then used to investigate the impact of information sharing on company gross profits.

In this study on supply chains in the electronics industry, we confirmed that sharing information such as product plan and procurement plan between a component manufacturer and assembly manufacturer can lead to improved gross profits for all companies involved. We demonstrated that the benefit of sharing strategy-level plans is greater than in the case of sharing execution- and tactics-level information. The increase in gross profit was seen to be particularly large in the case of declining demand. In addition, while earlier studies evaluated the impact of information sharing by looking at inventory levels, this study confirms that reducing inventory does not necessarily lead to improved gross profits, thereby highlighting the importance of gross profits as a measure for assessing the impact of information sharing.

## 1. Background and objectives

Supply Chain Management (SCM) systems for integrating and controlling entire chains of supply processes - from suppliers to manufacturers to wholesalers to retailers and through to customers - have drawn a lot of attention in recent years.

It has been pointed out that a vital element of such systems is the sharing of information such as sales figures and delivery plans between multiple companies or between different divisions of a company. However, the potential benefits (management impact) of SCM for individual companies that actually share information has yet to be properly investigated.

The present study therefore examines SCM in the electronics industry, with the aim of investigating the impact of information sharing between manufacturers.

## 2. Positioning of the study

This study focused on assembly manufacturers,

component manufacturers and parts manufacturers involved in the production of electronics goods such as personal computers, mobile phones and digital home appliances. From the results of a survey of such companies, their supply chain-related activities can be classified into the three categories listed below.

- Supply activities: How to sell/supply products
- Transform activities: How to make products
- Procurement activities: How to purchase raw materials and production capacity

Generally speaking, supply chain is the chain of those activities over company, and each company assumes demand and uses it for decision-making, exchanging or adjusting plan information between activities as shown in Fig.1. However, it has been recognized that this independent demand model is easy to cause the bullwhip effect that each demand is amplified along the upper stream of supply chain and excess inventories arise.

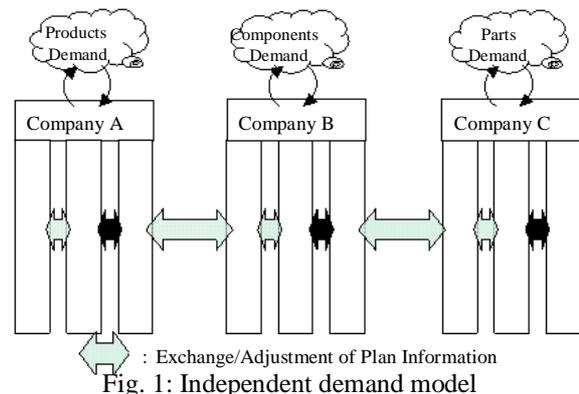

Fig. 1: Independent demand model

Some earlier studies have quantitatively analyzed the effects of information sharing in supply chains [1][2]. Most of these studies have simulated companies using simple inventory models, to forecast demand using information such as inventory on hand at preceding companies in the supply chain (e.g. for suppliers, manufacturers), sales figures and buffer inventory as shown in Fig. 2. These forecasts are then used to determine inventory replenishment levels. Thus, these studies have demonstrated how information sharing can improve inventory efficiency and eliminate lost sales opportunities.

However, these studies have examined only the benefits of information sharing (reducing inventory and lost sales opportunities) for decision-making over the execution- to tactics-level, as shown in Table 1.

They have not investigated the benefits of information sharing on tactics- to strategy-level decision-making for

determining optimum use of production resources (increasing utilization efficiency of production resources). Furthermore, they have not shown the impact of SCM on company gross profits.

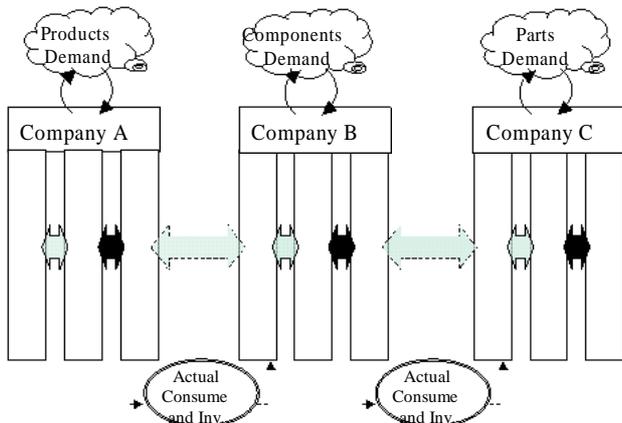

Fig. 2: Information sharing model of current SCM

Table 1: Planning level and positioning of this study

	Planning Period	Time Bucket	Planning Cycle	Aim	Effect of Info.Share
Strategy Level	6 months to Several years	Months	Monthly /yearly	Planning suitable equipment and human resources	Improved ROI
Tactics Level	1-3 months	Weeks	Weekly /monthly	Planning within the possessed resources and ensuring raw materials	Improved ROA (The rate of Operation)
Execution Level	1-14 days	Days	Daily /weekly	Planning day-to-day operations	Reduced inventory levels / loss of sales opportunities

Dependent demand model that each plan information is calculated by MRP based on the demand of the lowest reaches of the supply chain as shown in Fig. 3, is recognized as the model in which each company shares the tactics- to strategy-level information.

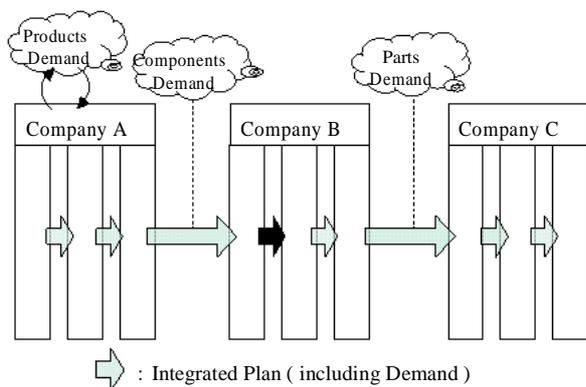

Fig. 3: Dependent demand model

However, this dependent demand model manages whole supply chain as one enterprise, and each company has no right to decide their own plan. Therefore, it is hard to apply it except a company group that has a capital relation each other.

We propose a new supply chain model as shown in

Fig.4. In this e-Community Model, the demand and supply information service center is set up. The service center feeds back demand /supply information which is calculated based on the latest plan information that is provided by each member company in this community. Each company can use that demand / supply information for their own decision-making of plan and provide the updated plan for the service center again.

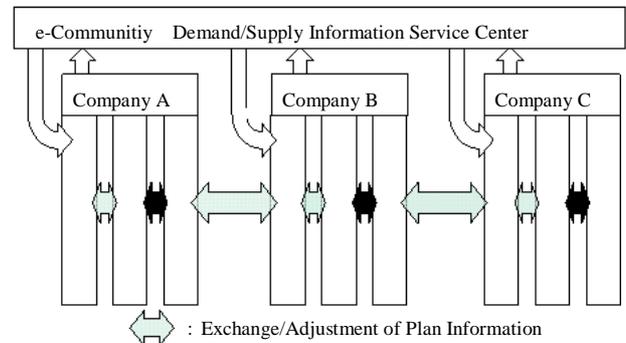

Fig. 4: e-Community Model

The features of this e-Community Model is as follows;

- 1) Each company can keep independency
- 2) Each company can share all plan information over whole supply chain through the service center

Especially in 2) above, each company can share tactics- to strategy-level information. The upper stream company can get demand information calculated based on the procurement plan of the lower stream companies, while the lower stream company can get the supply constraints calculated based on the supply plan of the upper stream company.

As the first step in our analysis for proposed e-Community Model, the present study modeled company activities in a way that considered decision-making not just over the execution-level, but also over the tactics- and strategy-level. Simulation was then used to investigate the impact of information sharing on company gross profits.

### 3. Modeling company activities

Based on the above supply chain-related activities - that is supply, transform and procurement - we developed a model to describe the activities of a typical company in the manufacturing industry. We then created a framework (Fig. 5) for the essential planning and decision-making activities of such a company, i.e. sales planning, production planning and procurement planning.

Activities were defined as planning activities (strategy-level, tactics-level and execution-level), instruction and results management activities, and logistics activities. An outline of each of these types of activities is given in Table 2.

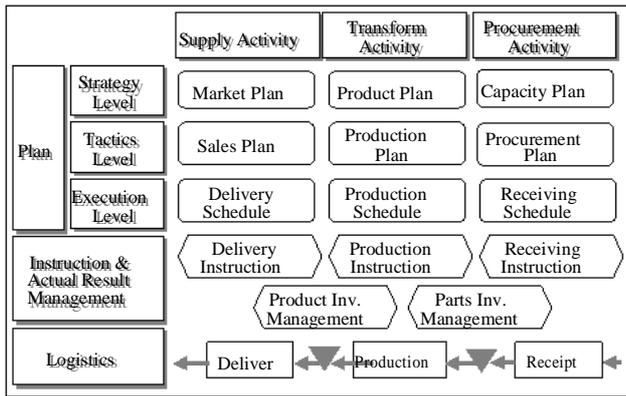

Fig. 5: Essential company activities for SCM

Table 2: Planning activities

Level	Activity	Description
Strategy Level	Market Plan	Make forecasts of future demand for applicable products based on long-term perspectives
	Product Plan	Develop a production prospect for applicable products over the relevant time frame on the basis of market plan
	Capacity Plan	On the basis of product plan, plan for the necessary production capacity (equipment and human resources)
Tactics Level	Sales Plan	Forecast sales volume from medium-term perspective Sales Plan
	Production Plan	Create a production plan in accordance with the sales plan, within the limits of capacity plan
	Procurement Plan	To achieve the production plan, calculate the quantity of parts and materials needed for relevant periods
Execution Level	Delivery Schedule	Determine product delivery dates, according to received orders
	Production Schedule	Determine manufacturing volume and dates according to the delivery schedule and production plans
	Receiving Schedule	In accordance with the production schedule, determine the delivery quantities and dates for parts orders placed

#### 4. Profit and loss evaluation model

In order to investigate the effect of information sharing on company gross profits, we created a profit and loss evaluation model (as shown in Fig. 6). The model breaks down costs into variable and fixed components and takes into account sales (according to received orders) and expenses for a given period. The unit prices for products, parts and labor used in calculating profit and loss are set on the basis of a product cost price structure (proportion of sales income for fixed costs such as direct material costs and labor costs).

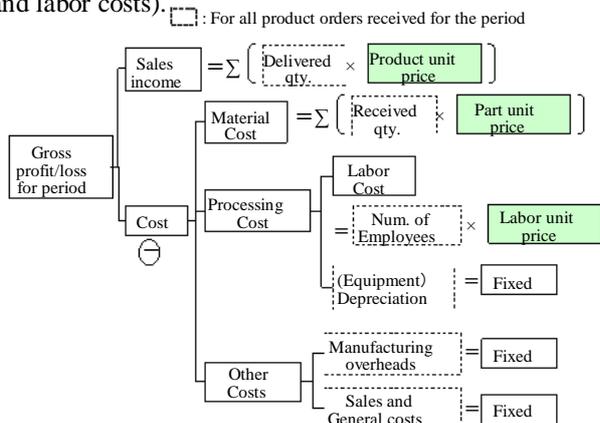

Fig. 6: Profit and loss evaluation model

#### 5. Information sharing models

We consider that information sharing between an assembly manufacturer and component manufacturer would work as shown in Fig. 7 below. In this study we investigated an information sharing system in which a component maker utilizes information from an assembly maker for forecasting demand

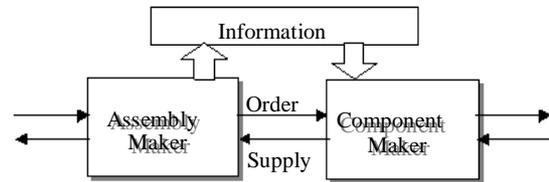

Fig. 7: Shared information flow between companies

##### 5.1 Information from the assembly maker

The assembly maker creates strategy-level and tactics-level plans of its operations. Thus, when the component maker needs to forecast demand for its products, it can utilize not only execution-level information from the assembly maker, such as inventory in hand and sales figures, but also tactics- and strategy-level planning information, as shown in Fig. 8. Examples of strategy-, tactics- and execution-level information used in this study are given in the table 3.

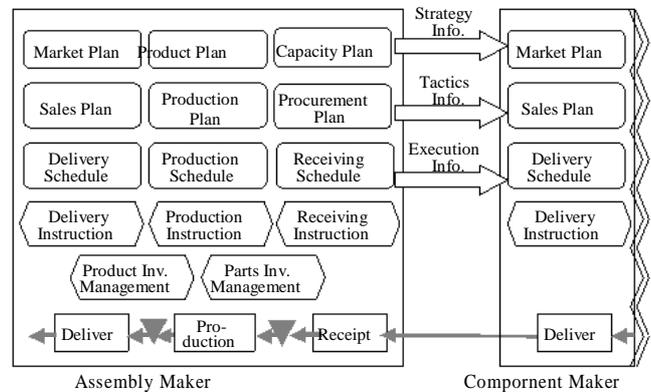

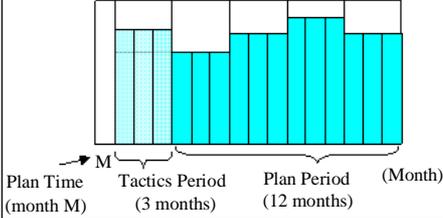

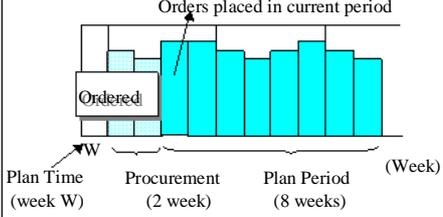

Fig. 8: Information from an assembly maker for use in demand forecasting by a component maker

The component maker can improve its capacity plan using the product plan of itself and monitoring the strategy-level product plan of the assembly maker, thus making more efficient use of production resources. In addition, by keeping track of the of assembly maker's procurement plan, the component maker can improve the efficiency of its own parts and materials ordering.

Table 3: Examples of information used in this study

<b>Strategy Information</b>	<p>Product Plan (long-term production plan of customers)</p>  <p>Plan Time (month M)    Tactics Period (3 months)    Plan Period (12 months)    (Month)</p>
<b>Tactics Information</b>	<p>Procurement Plan (future orders planned by customers)</p>  <p>Plan Time (week W)    Procurement (2 week)    Plan Period (8 weeks)    (Week)</p>
<b>Execution Information</b>	<p>Actual Inventory on hand Actual Sales figures</p>

### 5.2 Demand forecast method, using information from the assembly maker

In this study, we performed a demand forecast based on the assembly maker information listed in Table 3. Specifically, we did this using the market plan (strategy-level activity), sales plan (tactical-level activity) and delivery plan (execution-level activity). (See Fig. 4.)

The market plan quantity of component maker uses the product plan quantity of assembly maker as it is, while the sales plan quantity of component uses the procurement plan quantity of assembly maker as it is. Furthermore, the delivery schedule quantity of component maker is predicted based on the assembly maker’s sales figures and inventory on hand. Now, if the component maker does not make use of information from the assembly maker, it must determine plan quantities by making predictions based on orders received in the past.

## 6. Analysis of the impact of information sharing on gross profit

### 6.1 Outline of analysis

- No information: Information is not shared
- Execution-level information sharing: Only short-term information is shared
- Tactics-level information sharing: Tactics- and execution-level information is shared
- Strategy-level information sharing: Strategy-, Tactics- and execution-level information is shared

We analyzed how gross profits of the component maker and assembly maker vary with each of the above information-sharing methods.

### 6.2 Experimental conditions

This experiment was conducted based on the conditions below.

<Experimental conditions>

- 1 product = 1 component = 1 part
- Each maker operates by assembling and processing products after receiving orders.
- Evaluation period is 48 weeks (12 months)
- Capacity planning involves forecasting for human resources only, i.e. “equipment” capacity is assumed to be fixed.
- The costs of each maker as a percentage of revenue are assumed to be as follows: direct material costs 70%; labor costs 10%; other fixed costs 15%

The experiment was conducted for all four cases below, each representing a different demand pattern for the assembly maker. As shown in Table 4 below, each of the demand patterns is defined by monthly demand change rate, volatility and cycle.

Table 4: Demand patterns and parameters

Demand Pattern	Monthly Demand Change Rate	Volatility	Cycle
1. Up trend	+5%	10%	None
2. Down trend	-5%	10%	None
3. Cyclical trend	±5%	10%	9month
4. No trend	0%	10%	None

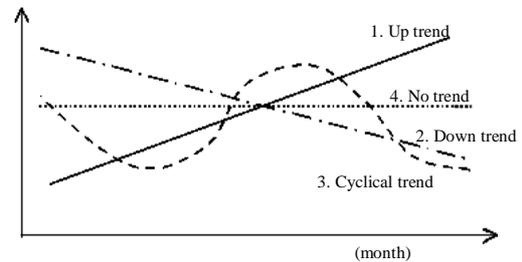

Fig. 9: Demand patterns

### 6.3 Impact on component maker gross profits

We analyzed how different information sharing methods (execution-, tactics- and strategy-level) affected the gross profits of the component maker.

The graph in Fig. 10 confirms that all three information sharing methods increase the gross profit of a component maker. In addition, for all demand patterns except “no trend” the impact on gross profit increases with the length of the planning period. The benefit of strategy-level information sharing is particularly large in the case of a “down trend” demand pattern. As shown by Fig. 11, this is due to the fact that strategy-level information sharing greatly improves resource utilization efficiency (=gross profit/ (labor cost + other fixed costs).

Clearly, the reason that strategy-level information sharing exerts very little effect on gross profits and resource utilization efficiency in the case of a “no trend”

pattern is that demand can be predicted quite accurately without information sharing, since there is essentially no change in demand.

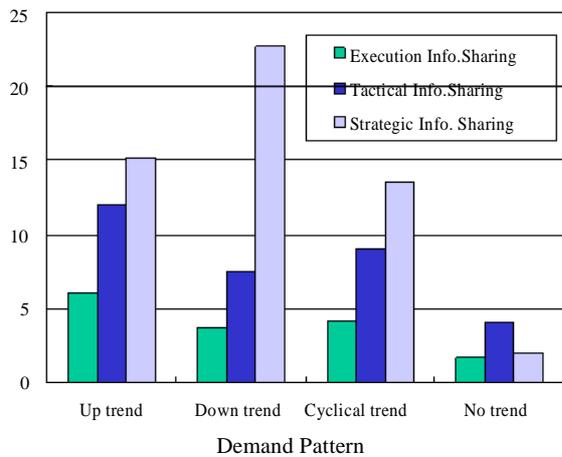

Fig. 10: Impact of information sharing on component maker gross profits

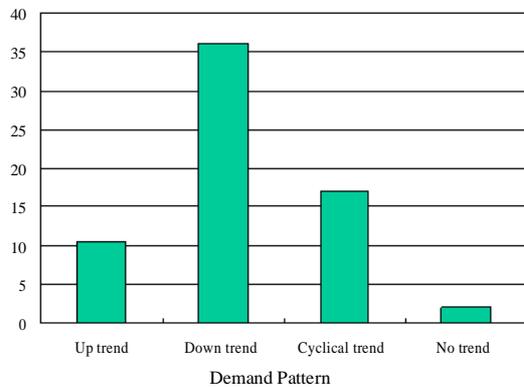

Fig. 11: Influence of strategy-level information sharing on resource utilization efficiency

#### 6.4 Impact on assembly maker gross profits

We analyzed how different information sharing methods (execution-, tactics- and strategy-level) affected gross profits of assembly makers.

Although the increase in gross profits for the assembly maker is less than that of the component maker, Fig. 12 shows that information sharing provides benefits even to the side supplying the information (the assembly maker in this case). The benefit is particularly large for the case of “up trend” demand.

As Fig. 13 shows, information sharing tends to reduce the order loss rate for the assembly maker. Thus, by providing its planning information to the component maker, the assembly maker can ensure a reliable supply of parts and materials and therefore reduce lost sales opportunities. This explains how benefits are gained from providing information.

Furthermore, despite the fact that tactics-level information sharing results in increased gross profits for the component maker (Fig. 10), average inventory has actually increased for this case (Fig. 13). This shows that even if average inventory is reduced, it does not

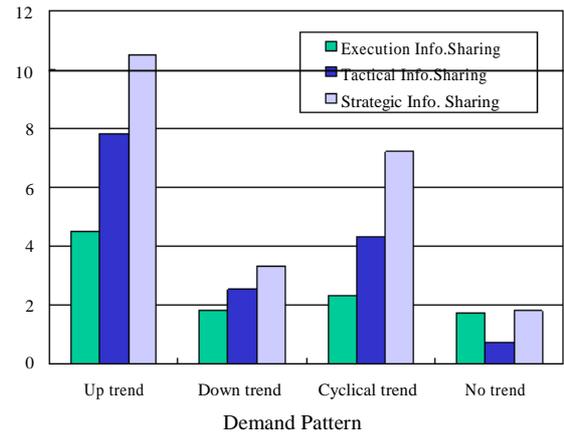

Fig. 12: Impact of information sharing on component maker gross profits

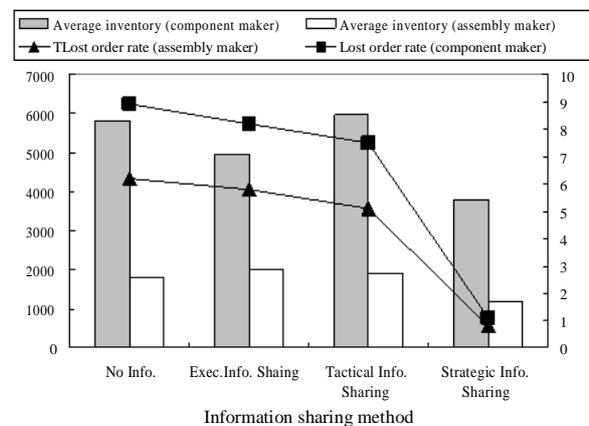

Fig. 13: Influence of information sharing on average inventory and lost order rate (“up trend” demand pattern)

necessarily follow that gross profits will increase. From this, we can conclude that the impact of information sharing needs to be evaluated by looking at gross profits not inventory.

#### 7. Conclusion

In this study on supply chains in the electronics industry, we confirmed that sharing information such as product plan and procurement plan between a component manufacturer and assembly manufacturer can lead to improved gross profits for all companies involved.

We demonstrated that the benefit of sharing information is greater in almost liner fashion as long as sharing information level is deeper from execution- and tactics- to strategy-level.

The increase in gross profit was seen to be particularly large in the case of declining demand. In addition, while earlier studies evaluated the impact of information sharing by looking at inventory levels, this study confirms that reducing inventory does not necessarily lead to improved gross profits, thereby highlighting the importance of gross profits as a measure for assessing the impact of information sharing.

## Abstract

This paper derives a two-tier supply chain model with many firms in each tier. The upstream firms engage in cost-reducing R&D activities. Under the case of R&D competition, the paper discusses how the changes in R&D spillover, R&D efficiency and the numbers of the manufacturers and the suppliers affect the R&D expenditures, the quantities and the profits. Then, R&D cooperation is considered. And what effects arise with the changes in the R&D spillover and the degree of cooperation are studied.

**Key words:** supply chain, upstream firm, downstream firm, R&D competition, R&D cooperation

## 1. Introduction

The subject of R&D competition and cooperation has gained a lot of attention from researchers in a variety of settings. Such literature usually uses a two-stage game that firms choose their R&D expenditures before making decisions on production. [1] examines the impact of multinational presence on domestic firms' innovative efforts in a model focusing on the strategic dimension of R&D. [2] addresses the question about the optimal degree of spillovers and the number of rival firms necessary for obtaining the maximum amount of effective R&D. Both [1] and [2] only consider R&D competition between firms. Meanwhile, many papers consider R&D competition and cooperation simultaneously and make comparisons between them. [3] presents an interesting analysis of cooperative and non-cooperative R&D and compares the R&D investment and output under cooperative R&D with those under non-cooperative R&D. [4] extends the results in [3] to the case of more than two firms and more general demand and cost assumptions. [5]

extends the analytical framework in [3] to a two-industry, two-firm-per-industry model allowing for R&D spillovers to occur within industries as well as between industries. [6] compares duopoly outcomes between two alternative models of independent R&D and non-cooperative R&D, where there are complementarities between firm-specific R&D resources.

Besides the two-stage models, some papers introduce another stage game before the other games occur. [7] derives the non-cooperative, optimal policy towards international R&D cooperation. In the model, the governments simultaneously announce their R&D subsidy rates before the firms choose their R&D expenditures and quantities. [8] examines the impact of the firms' mode of foreign expansion on the incentive to innovate as well as the effects of R&D activities and technological spillovers on the firms' international strategy. [8] considers a two country imperfect competition model where the firms face three different type of decisions: how to expand abroad, how much to spend on R&D and how much to sell in each market.

Although there exist a lot of papers about R&D competition and cooperation, we can hardly find one under the case of supply chain. An exception may be [9] which derives a model that an integrated firm produces the input and engages in R&D to reduce the input production cost. The integrated firm sells the input to its rival at a regulated price and competes with it in the final product market. [9] examines input price regulation's effects on R&D and output. In our paper, we consider a two-tier supply chain with many firms in each tier. The upstream firms, the suppliers, conduct R&D activities that result in reduction in marginal cost. We use a parameter  $\beta$  to capture R&D spillovers between the

suppliers.<sup>1</sup> We first consider R&D competition and then R&D cooperation. Concerning R&D competition, we discuss how the changes in R&D spillover, R&D efficiency and the numbers of the manufacturers and the suppliers affect the R&D expenditures, the quantities and the profits. Under R&D cooperation, we study what effects arise with the changes in the R&D spillover and the degree of cooperation.

The two-tier-supply-chain structure with many firms in each tier in the paper is similar to that of [10]. Such kind of structure also appears in [11] and [12]. [10] examines the impact of fixed and variable costs on the structure and competitiveness. [11] examines vertical integration as an equilibrium phenomenon and consider the issue of private profitability versus collective profitability. [12] analyses the effects of different institutional arrangements of union-firm bargaining.

## 2. The Model

Consider a two-tier supply chain with  $n_1$  firms, the manufacturers, in the downstream tier, and  $n_2$  firms, the suppliers, in the upstream tier. The firms in the same tier engage in Cournot competition. The suppliers sell a homogeneous input at price  $p_2$  to the manufacturers which use it to produce a final product. Without loss of generality, we assume that one unit of final product requires one unit of input. The inverse demand function of the final product is  $p_1 = a - bQ_1$ , where  $p_1$  is the price and  $Q_1$  is the total output. Denote the output of manufacturer  $i$  as  $q_{1,i}$ , then  $Q_1 = \sum_{l=1}^{n_1} q_{1,l}$ . The profit of a representative manufacturer is

$$\Pi_{1,i} = (p_1 - v_1 - p_2)q_{1,i} \quad (1)$$

where  $v_1$  is the constant marginal cost of the final

<sup>1</sup> The spillovers are often important parameters in the R&D literature and almost all the aforementioned papers consider the spillovers. [9] ignores the spillovers since only one firm conducts R&D activity and it is no need to consider them. It should also be noted that the spillover in [7] has the different meaning from other papers and ours. [7] uses the spillover effect to capture the degree of R&D collaboration while such parameters in other papers indicates the involuntary technological information leakage.

product.

The suppliers conduct R&D activities that result in reduction in marginal cost. Let  $x_j$  be the level of R&D investment undertaken by supplier  $j$  and let  $v_{2,j}$  denote supplier  $j$ 's marginal cost. In order to model the possibility of imperfect appropriability (i.e., technological spillovers between the suppliers), we introduce a spillover parameter  $\beta \in [0,1]$ . This means that the magnitude of supplier  $j$ 's cost reduction is determined by its own technological knowledge and by a fraction  $\beta$  of the sum of the other suppliers' knowledge. More specifically

$$v_{2,j} = v_2^0 - \sqrt{gx_j} - \beta \sum_{\substack{m=1 \\ m \neq j}}^{n_2} \sqrt{gx_m} \quad (2)$$

where the parameters  $g$  and  $v_2^0$  describe the efficiency of the R&D process and the initial marginal production cost of the suppliers. The expression  $\sqrt{gx_j}$  is an R&D production function which reflects the existence of diminishing return to R&D expenditures and can be seen in many papers<sup>[3][8][13][14]</sup>. The profit of supplier  $j$  is

$$\Pi_{2,j} = (p_2 - v_{2,j})q_{2,j} \quad (3)$$

where  $q_{2,j}$  is supplier  $j$ 's output.

Now, we consider the decision problem of the manufacturers. Manufacturer  $i$  chooses its output to maximize its profit by taking the other manufacturers' output as given. The first-order condition can be derived from (1), which is

$$a - v_1 - p_2 - b(Q_1 + q_{1,i}) = 0$$

Since the manufacturers are identical, we can get

$$q_{1,i} = q_1 = \frac{a - v_1 - p_2}{b(n_1 + 1)}$$

and

$$Q_1 = n_1 q_1 = \frac{n_1(a - v_1 - p_2)}{b(n_1 + 1)} \quad (4)$$

In equilibrium, the overall output of the manufacturers and the suppliers must be equal. Substituting  $Q_2$  for  $Q_1$ , (4) can be rearranged to

$$p_2 = (a - v_1) - \frac{b(n_1 + 1)}{n_1} Q_2 \quad (5)$$

where  $Q_2 = \sum_{m=1}^{n_2} q_{2,m}$  is the overall output of the suppliers. Supplier  $j$  chooses  $q_{2,j}$  to maximize its profit.

From (3) and (5) we get the first-order condition as follows

$$a - v_1 - v_{2,j} - \frac{b(n_1 + 1)}{n_1} (Q_2 + q_{2,j}) = 0 \quad (6)$$

We can get  $n_2$  equations from (6) since  $j$  varies from 1 to  $n_2$ . Then, we can, respectively, derive the suppliers' total output and supplier  $j$ 's output as follows

$$Q_2 = \frac{n_1}{b(n_1 + 1)(n_2 + 1)} [n_2(a - v_1) - \sum_{m=1}^{n_2} v_{2,m}] \quad (7)$$

$$q_{2,j} = \frac{n_1}{b(n_1 + 1)(n_2 + 1)} [(a - v_1) - (n_2 + 1)v_{2,j} + \sum_{m=1}^{n_2} v_{2,m}] \quad (8)$$

Substituting (5), (7) and (8) into (3), we get

$$\Pi_{2,j} = \frac{n_1}{b(n_1 + 1)(n_2 + 1)^2} [(a - v_1) - (n_2 + 1)v_{2,j} + \sum_{m=1}^{n_2} v_{2,m}]^2 - x_j \quad (9)$$

### 3. R&D Competition

In this section, we first derive the equilibrium when the suppliers independently decide R&D expenditures to maximize their individual profits. Then we discuss what effects arise with changes in some parameters.

Substituting (2) into (9) results in

$$\Pi_{2,j} = \frac{n_1}{b(n_1 + 1)(n_2 + 1)^2} [(a - v_1 - v_2^0) + (n_2 + \beta - n_2\beta)\sqrt{gx_j} + (2\beta - 1)\sum_{\substack{m=1 \\ m \neq j}}^{n_2} \sqrt{gx_m}]^2 - x_j \quad (10)$$

Supplier  $j$  chooses its R&D investment,  $x_j$ , to maximize its profit. The first-order condition is

$$\frac{\partial \Pi_{2,j}}{\partial x_j} = \frac{n_1}{b(n_1 + 1)(n_2 + 1)^2} [(a - v_1 - v_2^0) + (n_2 + \beta - n_2\beta)\sqrt{gx_j} + (2\beta - 1)\sum_{\substack{m=1 \\ m \neq j}}^{n_2} \sqrt{gx_m}] \frac{(n_2 + \beta - n_2\beta)g}{\sqrt{gx_j}} - 1 = 0$$

from which we get

$$\sqrt{gx_j} = \sqrt{gx} = \frac{n_1 g (n_2 + \beta - n_2\beta) (a - v_1 - v_2^0)}{b(n_1 + 1)(n_2 + 1)^2 - n_1 g (1 - \beta + n_2\beta)(n_2 + \beta - n_2\beta)}$$

or

$$x_j = x = \frac{n_1^2 g (n_2 + \beta - n_2\beta)^2 (a - v_1 - v_2^0)^2}{[b(n_1 + 1)(n_2 + 1)^2 - n_1 g (1 - \beta + n_2\beta)(n_2 + \beta - n_2\beta)]^2} \quad (11)$$

We need the following condition

$$b(n_1 + 1)(n_2 + 1)^2 > n_1 g (1 - \beta + n_2\beta)(n_2 + \beta - n_2\beta) \quad (12)$$

to ensure that the discussions are practical.

Now, we get

$$\Pi_{2,j} = \Pi_2 = \frac{n_1 [b(n_1 + 1)(n_2 + 1)^2 - n_1 g (n_2 + \beta - n_2\beta)^2] (a - v_1 - v_2^0)^2}{[b(n_1 + 1)(n_2 + 1)^2 - n_1 g (1 - \beta + n_2\beta)(n_2 + \beta - n_2\beta)]^2} \quad (13)$$

$$Q_1 = Q_2 = Q = \frac{n_1 n_2 (n_2 + 1) (a - v_1 - v_2^0)}{[b(n_1 + 1)(n_2 + 1)^2 - n_1 g (1 - \beta + n_2\beta)(n_2 + \beta - n_2\beta)]}$$

$$q_{1,i} = q_1 = \frac{n_2(n_2+1)(a-v_1-v_2^0)}{[b(n_1+1)(n_2+1)^2 - n_1g(1-\beta+n_2\beta)]}$$

$$q_{2,j} = q_2 = \frac{n_1(n_2+1)(a-v_1-v_2^0)}{[b(n_1+1)(n_2+1)^2 - n_1g(1-\beta+n_2\beta)]}$$

$$\Pi_{1,i} = \Pi_1 - bq_1^2$$

**Proposition 1** Each supplier's R&D expenditure increases with R&D efficiency and the number of the manufacturers and decreases with the number of the suppliers.

**Proof** From (11) we can immediately get  $\frac{\partial x}{\partial g} > 0$  and  $\frac{\partial x}{\partial n_1} > 0$ . Thus, the R&D effort of the suppliers increases if R&D activities are more efficient or there are more manufacturers.

Partially differentiating (11) with respect to  $n_2$ , we get

$$\text{Sign}\left\{\frac{\partial x}{\partial n_2}\right\} = \text{Sign}\{n_1g\beta(n_2 + \beta - n_2\beta)^2 - b(n_1+1)(n_2+1)(n_2 - n_2\beta + 3\beta - 1)\} \quad (14)$$

After some simple manipulations, we can show that

$$\begin{aligned} & b(n_1+1)(n_2+1)(n_2 - n_2\beta + 3\beta - 1) \\ & \geq \frac{b(n_1+1)(n_2+1)^2(n_2 + \beta - n_2\beta)}{1 - \beta + n_2\beta} \end{aligned} \quad (15)$$

always holds since it is equivalent to  $(n_2 - 1)(2\beta - 1)^2 \geq 0$ , which is undoubtedly true.

Substituting the inequality in (12) into (15) yields

$$\begin{aligned} & b(n_1+1)(n_2+1)(n_2 - n_2\beta + 3\beta - 1) \\ & > n_1g\beta(n_2 + \beta - n_2\beta)^2 \end{aligned}$$

which leads to  $\frac{\partial x}{\partial n_2} < 0$  from (14). Thus, each supplier

invests less in R&D if more firms exist in the upstream tier.

**Proposition 2** (1) For large spillovers ( $\beta \geq 0.5$ ), the suppliers reduce their R&D expenditures when the spillover increases. (2) We can not unambiguously indicate how the R&D investments vary with the spillover if  $\beta < 0.5$ . However, the less the numbers of the manufacturers and the suppliers, the lower the R&D efficiency and the higher the spillover are, the more likely that the R&D investments decrease.

**Proof** Partially differentiating (11) with respect to  $\beta$ , we have

$$\text{Sign}\left\{\frac{\partial x}{\partial \beta}\right\} = \text{Sign}\{n_1g(n_2 + \beta - n_2\beta)^2 - b(n_1+1)(n_2+1)^2\} \quad (16)$$

For  $\beta \geq 0.5$ , we get

$$\begin{aligned} & b(n_1+1)(n_2+1)^2 > n_1g(1-\beta+n_2\beta)(n_2+\beta-n_2\beta) \\ & \geq n_1g(n_2+\beta-n_2\beta)^2 \end{aligned} \quad (17)$$

from (12). Thus, we obtain  $\frac{\partial x}{\partial \beta} < 0$  from (16) and (17) for  $\beta \geq 0.5$ .

For  $\beta < 0.5$ ,  $\frac{\partial x}{\partial \beta} < 0$  holds only if

$$b(n_1+1)(n_2+1)^2 > n_1g(n_2 + \beta - n_2\beta)^2 \quad (18)$$

which ensures that the condition in (12) satisfies. (18) can be rewritten as

$$\frac{b(n_1+1)}{n_1} > \frac{g(n_2 + \beta - n_2\beta)^2}{(n_2+1)^2} \quad (19)$$

It can be seen that the left-hand side of (19) decreases with  $n_1$  while the right-hand side decreases with  $\beta$  and increases with  $g$  and  $n_2$  if  $\beta < 0.5$ . Hence, if  $\beta < 0.5$ , the greater  $\beta$  and the smaller  $n_1$ ,  $n_2$  and  $g$  are, the more likely that  $x$  decreases with  $\beta$ .

**Proposition 3** If an increase in the spillover occurs,

the quantity of each tier and each firm and the profit of each manufacturer increases if  $\beta < 0.5$  and decreases if  $\beta > 0.5$ .

**Proof** It is easily to get

$$\begin{aligned} \text{Sign}\left\{\frac{\partial Q}{\partial \beta}\right\} &= \text{Sign}\left\{\frac{\partial q_1}{\partial \beta}\right\} = \text{Sign}\left\{\frac{\partial q_2}{\partial \beta}\right\} \\ &= \text{Sign}\left\{\frac{\partial \Pi_1}{\partial \beta}\right\} = \text{Sign}\{1-2\beta\} \end{aligned}$$

which leads to Proposition 3 immediately.

**Proposition 4** (a) Each supplier's profit decreases with the spillover if  $\beta \geq \frac{2n_2-1}{3(n_2-1)}$ . (b) It can not generally concluded how the profit varies with the spillover if  $\beta < \frac{2n_2-1}{3(n_2-1)}$ . However, the greater  $g$ ,  $n_1$ ,  $n_2$  and  $|0.5-\beta|$  are, the more likely that the profit decreases with  $\beta$ .

**Proof** Partially differentiating (13) with respect to  $\beta$  leads to

$$\begin{aligned} \text{Sign}\left\{\frac{\partial \Pi_2}{\partial \beta}\right\} &= \text{Sign}\{b(n_1+1)(n_2+1)^2[(2n_2-1)- \\ & 3(n_2-1)\beta] - n_1g(n_2+\beta-n_2\beta)^3\} \end{aligned} \quad (20)$$

The term in the square brackets of the right-hand side of (20) is negative if  $\beta \geq \frac{2n_2-1}{3(n_2-1)}$ . This proves the first part of Proposition 4.

If  $\beta < \frac{2n_2-1}{3(n_2-1)}$ , we can get from (20) that

$$\begin{aligned} \text{Sign}\left\{\frac{\partial \Pi_2}{\partial \beta}\right\} &= \text{Sign}\{\phi_1\} \\ \phi_1 &\equiv \frac{b(n_2+1)^2[(2n_2-1)-3(n_2-1)\beta]}{(n_2+\beta-n_2\beta)^3} - \frac{n_1}{n_1+1}g \end{aligned}$$

We have

$$\frac{\partial \phi_1}{\partial g} < 0, \quad \frac{\partial \phi_1}{\partial n_1} < 0, \quad \frac{\partial \phi_1}{\partial n_2} < 0$$

$$\text{Sign}\left\{\frac{\partial \phi_1}{\partial \beta}\right\} = \text{Sign}\{1-2\beta\}$$

Therefore, the greater  $g$ ,  $n_1$ ,  $n_2$  and  $|0.5-\beta|$  are, the more likely that the profit decreases with  $\beta$ .

**Proposition 5** The quantity of each tier and each supplier increases with  $n_1$ . Each incumbent supplier's quantity decreases if new suppliers enter the market, i.e.,  $n_2$  increases.

**Proof** It is easy to get

$$\frac{\partial Q}{\partial n_1} > 0, \quad \frac{\partial q_2}{\partial n_1} > 0$$

$$\begin{aligned} \text{Sign}\left\{\frac{\partial q_2}{\partial n_2}\right\} &= \text{Sign}\{-b(n_1+1)(n_2+1)^2 + \\ & n_1g[1+(n_2+3)(n_2-1)(1-\beta\beta)]\} \end{aligned}$$

Noting that

$$\begin{aligned} & n_1g[1+(n_2+3)(n_2-1)(1-\beta\beta)] \\ & < n_1g(1-\beta+n_2\beta)(n_2+\beta-n_2\beta) \end{aligned}$$

and the condition in (12), we get  $\frac{\partial q_2}{\partial n_2} < 0$ .

**Proposition 6** (a) The total quantity of each tier increases with  $n_2$  if  $\beta=0.5$ . (b) It can not generally concluded how the number of the suppliers affects the quantity of each tier if  $\beta \neq 0.5$ . However, the greater  $n_1$ ,  $n_2$  and  $|0.5-\beta|$  are, the more likely that the total quantity decreases with  $n_2$ .

**Proof** It is easy to get

$$\text{Sign}\left\{\frac{\partial Q}{\partial n_2}\right\} = \text{Sign}\{\xi_1\}$$

$$\begin{aligned} \xi_1 &\equiv b(n_1+1)(n_2+1)^2 - \\ & n_1g[n_2^2 - (3n_2+1)(n_2-1)(1-\beta\beta)] \end{aligned}$$

If  $\beta=0.5$ , we can get  $\xi_1 > 0$  from condition (12) and hence  $\frac{\partial Q}{\partial n_2} > 0$ .

If  $\beta \neq 0.5$ , noting that

$$n_1 g [n_2^2 - (3n_2 + 1)(n_2 - 1)(1 - \beta)] > n_1 g (1 - \beta + n_2 \beta)(n_2 + \beta - n_2 \beta)$$

we can not unambiguously sign  $\xi_1$  from condition (12). However, if

$$\phi_2 \equiv b \frac{n_1 g [n_2^2 - (3n_2 + 1)(n_2 - 1)(1 - \beta)]}{n_1 + 1 (n_2 + 1)^2} > 0$$

we can get  $\frac{\partial Q}{\partial n_2} > 0$ . Noting that  $\frac{\partial \phi_2}{\partial n_1} < 0$ ,  $\frac{\partial \phi_2}{\partial n_2} < 0$

and  $\text{Sign}\{\frac{\partial \phi_2}{\partial n_2}\} = \text{Sign}\{1 - 2\beta\}$ , we know that the

greater  $n_1$ ,  $n_2$  and  $|0.5 - \beta|$  are, the more likely that  $Q$  decreases with  $n_2$ .

**Proposition 7** It can not generally concluded how the number of the manufacturers affects each incumbent manufacturer's quantity. However, the greater  $n_2$  and  $|0.5 - \beta|$  and the smaller  $g$  are, the more likely that each incumbent manufacturer's quantity decreases with  $n_1$ .

**Proof** It is easy to get

$$\text{Sign}\{\frac{\partial q_1}{\partial n_1}\} = \text{Sign}\{\xi_2\}$$

$$\xi_2 \equiv g(1 - \beta + n_2 \beta) \eta \left( \frac{1}{2} + n_2 \beta - \frac{1}{2} b \right) n_1 (n_2 + 1)^2 \quad (21)$$

We can not unambiguously indicate the sign of  $\xi_2$  from (12) and (21). However, if

$$g(1 - \beta + n_2 \beta) \eta \left( \frac{1}{2} + n_2 \beta - \frac{1}{2} b \right) n_1 (n_2 + 1)^2 < 0$$

i.e.  $\phi_3 \equiv \frac{g(1 - \beta + n_2 \beta) \eta \left( \frac{1}{2} + n_2 \beta - \frac{1}{2} b \right) n_1 (n_2 + 1)^2}{(n_2 + 1)^2} < 0$ , we

have  $\frac{\partial q_1}{\partial n_1} < 0$ . Noting that  $\frac{\partial \phi_3}{\partial g} > 0$ ,  $\frac{\partial \phi_3}{\partial n_2} < 0$  and

$\text{Sign}\{\frac{\partial \phi_3}{\partial n_2}\} = \text{Sign}\{1 - 2\beta\}$ , we know that the greater

$n_2$  and  $|0.5 - \beta|$  and the smaller  $g$  are, the more likely that  $q_1$  decreases with  $n_1$ .

#### 4. R&D Cooperation

In this section, we consider the case that the suppliers cooperate in R&D and remain competition in production.

Each supplier  $j$  chooses its R&D expenditure  $x_j$  to

maximize  $\Pi_{2,j} + \lambda \sum_{\substack{m=1 \\ m \neq j}}^{n_2} \Pi_{2,m}$ , where  $\lambda \in [0, 1]$

captures all possible degrees of R&D cooperation. In the extreme case of full cooperation (when  $\lambda=1$ ), each supplier chooses its R&D expenditure level to maximize their joint profits.

The decisions of the manufactures and suppliers on quantities keep the same as R&D competition in Section 2. However, supplier  $j$  chooses  $x_j$  to maximize

$\Pi_{2,j} + \lambda \sum_{\substack{m=1 \\ m \neq j}}^{n_2} \Pi_{2,m}$ . From (10), we get

$$\frac{\partial \Pi_{2,k}}{\partial x_j} = \frac{n_1}{b(n_1 + 1)(n_2 + 1)^2} [(a - v_1 - v_2^0) + (n_2 + \beta - n_2 \beta) \sqrt{g x_k} + (2\beta - 1) \sum_{\substack{m=1 \\ m \neq k}}^{n_2} \sqrt{g x_m}] \frac{(2\beta - 1)g}{\sqrt{g x_j}} \quad (22)$$

$$\frac{\partial \sum_{\substack{m=1 \\ m \neq j}}^{n_2} \Pi_{2,m}}{\partial x_j} = \frac{n_1}{b(n_1 + 1)(n_2 + 1)^2} [(n_2 - 1)(a - v_1 - v_2^0) + (n_2 + \beta - n_2 \beta) \sum_{\substack{m=1 \\ m \neq j}}^{n_2} \sqrt{g x_m} + (2\beta - 1)(\sqrt{g x_j} + (n_2 - 2) \sum_{\substack{m=1 \\ m \neq j}}^{n_2} \sqrt{g x_m})] \frac{(2\beta - 1)g}{\sqrt{g x_j}} \quad (23)$$

Supplier  $j$  will choose its R&D investment level according to the following first-order condition

$$\frac{\partial (\Pi_{2,j} + \lambda \sum_{\substack{m=1 \\ m \neq j}}^{n_2} \Pi_{2,m})}{\partial x_j} = 0$$

We can get the first-order condition as the function of each supplier's R&D level from (22) and (23). Since the suppliers are identical, the subscript of  $x$  can be deleted and the first-order condition is reduced to

$$\frac{n_1 g [(n_2 + \beta - n_2 \beta) + \lambda (n_2 - 1)(2\beta - 1)] \times}{b(n_1 + 1)(n_2 + 1)^2 \sqrt{g x^*}} \times [(a - v_1 - v_2^0) + (1 - \beta + n_2 \beta) \sqrt{g x^*}] - F = 0$$

Then we get

$$\sqrt{g x^*} = \frac{n_1 g [(n_2 + \beta - n_2 \beta) + \lambda (n_2 - 1)(2\beta - 1)] (a - v_1 - v_2^0)}{b(n_1 + 1)(n_2 + 1)^2 - n_1 g (1 - \beta + n_2 \beta) [(n_2 + \beta - n_2 \beta) + \lambda (n_2 - 1)(2\beta - 1)]} \quad (24)$$

We need the following condition

$$b(n_1 + 1)(n_2 + 1)^2 > n_1 g (1 - \beta + n_2 \beta) [(n_2 + \beta - n_2 \beta) + \lambda (n_2 - 1)(2\beta - 1)]$$

to ensure that the discussions are practical.

Substituting (24) into (7) yields

$$Q_1^* = Q_2^* = Q^* = \frac{n_1 n_2 (n_2 + 1) (a - v_1 - v_2^0)}{b(n_1 + 1)(n_2 + 1)^2 - n_1 g (1 - \beta + n_2 \beta) [(n_2 + \beta - n_2 \beta) + \lambda (n_2 - 1)(2\beta - 1)]} \quad (25)$$

We can also get

$$q_{1,i}^* = q_1^* = Q^* / n_1 \quad (26)$$

$$q_{2,j}^* = q_2^* = Q^* / n_2 \quad (27)$$

**Proposition 8** The R&D expenditures increases with  $\lambda$ , the degree of R&D cooperation.

**Proof** The proof is immediately followed from the

fact that  $\frac{\partial \sqrt{g x^*}}{\partial \lambda} > 0$ .

Noting that  $\lambda=0$  is actually the case that the suppliers do not cooperate in R&D, we know from Proposition 8 that the R&D investment level under cooperation is higher than that under competition. Furthermore, the larger the degree of cooperation is, the larger the gap of R&D level between cooperation and competition is. The gap reaches the largest value if the suppliers engage in full cooperation.

**Proposition 9** (a) The R&D investments increase with the spillover if the degree of cooperation is appropriately large, i.e.,  $\lambda \geq 0.5$ . (b) We can not generally indicate how the change in the spillover affects the R&D investment if  $0 < \lambda < 0.5$ . However, the greater  $\lambda$  and  $g$  and the smaller  $n_1$  and  $\beta$  are, the more likely that the R&D investments increase with  $\beta$ . If  $\beta < 0.5$ , the greater  $n_2$  is, the more likely that the R&D investment increases with  $\beta$ . If  $\beta > 0.5$ , the

smaller  $n_2$  is, the more likely that the R&D investment increases with  $\beta$ .

**Proof** Differentiating (24) with respect to  $\beta$  yields

$$\text{Sign}\left\{\frac{\partial \sqrt{g x^*}}{\partial \beta}\right\} = \text{Sign}\{\xi_3\} \quad (28)$$

$$\xi_3 \equiv b(2\lambda - 1)(n_1 + 1)(n_2 + 1)^2 + n_1 g (1 - \beta + n_2 \beta) [(n_2 + \beta - n_2 \beta) + \lambda (n_2 - 1)(2\beta - 1)]^2 \quad (29)$$

(a) If  $\lambda \geq 0.5$ , it can be easily shown that  $\xi_3 > 0$  and

hence  $\frac{\partial \sqrt{g x^*}}{\partial \beta} > 0$ .

(b) If  $0 < \lambda < 0.5$ , the first and second term on the right-hand side of (29) are, respectively, negative and positive. Thus, we can not unambiguously indicate the sign of  $\xi_3$ . We can rewrite (28) as

$$\text{Sign}\left\{\frac{\partial \sqrt{g x^*}}{\partial \beta}\right\} = \text{Sign}\{\phi_4\}$$

$$\phi_4 \equiv g + \frac{b(n_1 + 1)}{n_1} \times \frac{(2\lambda - 1)(n_2 + 1)^2}{(1 - \beta + n_2 \beta) [(n_2 + \beta - n_2 \beta) + \lambda (n_2 - 1)(2\beta - 1)]^2}$$

We obtain

$$\frac{\partial \phi_4}{\partial g} > 0, \quad \frac{\partial \phi_4}{\partial n_1} < 0$$

$$\text{Sign}\left\{\frac{\partial \phi_4}{\partial \beta}\right\} = \text{Sign}\{-(n_2 - 1)(2\lambda - 1)^2\}$$

$$\text{Sign}\left\{\frac{\partial \phi_4}{\partial \lambda}\right\} = \text{Sign}\{(n_2 + \beta - n_2\beta) + (n_2 - 1)(2\beta - 1)(1 - \lambda)\}$$

$$\text{Sign}\left\{\frac{\partial \phi_4}{\partial n_2}\right\} = \text{Sign}\{(1 - 2\beta)(2\lambda - 1)^2\}$$

Since  $0 < \lambda < 0.5$ , we can readily get  $\frac{\partial \phi_4}{\partial \beta} < 0$  and

$\frac{\partial \phi_4}{\partial \lambda} > 0$ . In addition,  $\frac{\partial \phi_4}{\partial n_2} > 0$  if  $\beta < 0.5$  and

$\frac{\partial \phi_4}{\partial n_2} < 0$  if  $\beta > 0.5$ .

**Proposition 10** When the degree of R&D cooperation changes, the quantity of each tier and each firm increases if  $\beta > 0.5$ , decreases if  $\beta < 0.5$  and remains unchanged if  $\beta = 0.5$ .

**Proof** From (25), (26) and (27), we have

$$\text{Sign}\left\{\frac{\partial Q^*}{\partial \lambda}\right\} = \text{Sign}\left\{\frac{\partial q_i^*}{\partial \lambda}\right\} = \text{Sign}\{2\beta - 1\}$$

which leads to the proposition immediately.

**Proposition 11** (a) If  $\lambda \geq \frac{n_2 - 1}{3n_2 - 1}$ , the quantity of each tier and each firm increases with  $\beta$ . (b) If  $\lambda < \frac{n_2 - 1}{3n_2 - 1}$ , the quantity may increase or decrease with  $\beta$ . The smaller  $\beta$  is, the more likely that the quantity increases with  $\beta$ .

**Proof** From (25), (26) and (27), we get

$$\text{Sign}\left\{\frac{\partial Q^*}{\partial \beta}\right\} = \text{Sign}\left\{\frac{\partial q_i^*}{\partial \beta}\right\} = \text{Sign}\{\xi_4\}$$

$$\xi_4 \equiv (n_2 - 1)n\lambda(1 - \beta) - 2(n_2 - 1)(2\lambda - 1)\beta$$

(a) If  $\lambda \geq 0.5$ , we have

$$\xi_4 \geq n(n_2 - 1)n(n_2 - 3) > 0$$

If  $\lambda < 0.5$ , we can obtain

$$\begin{aligned} \xi_4 &\geq (n_2 - 1) - \lambda(n_2 - 3) + 2(n_2 - 1)(2\lambda - 1) \\ &= (3n_2 - 1)\lambda - (n_2 - 1) \end{aligned} \quad (30)$$

If  $\frac{n_2 - 1}{3n_2 - 1} \leq \lambda < 0.5$ , from (30) we get  $\xi_4 \geq 0$  and the equation holds only when  $\beta = 1$ .

(b) If  $\lambda < \frac{n_2 - 1}{3n_2 - 1}$ , we obtain

$$\frac{\partial \xi_4}{\partial \beta} = 2(n_2 - 1)(2\lambda - 1) < 0$$

This completes the proof.

## 5. Conclusion

This paper has derived a model with upstream R&D in a two-tier supply chain. We considered R&D cooperation as well as R&D competition. Under R&D competition, we studied how the changes in R&D spillover, R&D efficiency and the numbers of the suppliers and the manufacturers affect R&D investments, quantities and profits. Under R&D cooperation, we showed that how R&D investments and quantities change with R&D spillover and the degree of R&D cooperation. The main results in the paper are given in eleven propositions.

## Abstract

This paper presents an integrated system in which a computer-based decision support system (DSS) for construction project risks assessment at stage of contracting and construction. The Analytic Hierarchy Process (AHP) method is used to determine the weightings of risk factors from subjective judgment of experts and practitioners, and Fuzzy Multiple Criteria Decision Making (FMCDM) is used to assess the synthetic judgment of risk degree for the main activities of a construction project in different phase. A simple case study illustrates the effectiveness of the proposed approach and developed system.

## 1. Introduction

Construction is one of the most dynamic, risky, challenging, and rewarding industrial sectors [16]. Accordingly, construction activities are uncertain and variable, and associated risks are often permanent and complex in construction projects. Especially, large-scale construction projects (such as high-rise commercial building projects and mass transit system projects, and mountain tunnel construction projects) are becoming increasingly complex and variable in nature, and many risk and uncertainty factors are inherent. However, the construction industry often has a poor reputation for dealing with risk and uncertainty adequately, resulting in poor performance with failure to meet schedule deadlines and budgets, and attendant loss to both contractors and owners [15] [27]. In this case, effective risk and uncertainty management is a form of incentive to the contractors, as their profit margin will often be secured or even improved. This is particularly significant as projects including large capital outlays, unbalanced cash flows, significant new technology, unusual legal or contractual arrangements and sensitive environmental or safety issues

[5]. However, construction risk and uncertainty can seldom, if ever, be eliminated. A comprehensive risk and uncertainty analysis is not necessary to prevent cost and schedule overruns but, at least, it will give those parties a more rational basis on which to make decision.

A number of analysis model reported in the literature that provide management knowledge on the risk and uncertainty inherent in a project and lead to better decision outcomes. These risk handle methods can be considered to fall into three categories: (1) probability analysis [11] [13] [28] [31]; (2) interval analysis [2] [7] [18]; and (3) fuzzy set analysis [15] [20] [25] [26]. Probabilistic analysis techniques include sensitivity analysis, basic probability analysis, decision-tree analysis, Monte Carlo simulation. However, some of literature studies and surveys reported indicate that probability risk analysis is not widely accepted [1]. Interval analysis uses ranges for input variables to estimate plausible ranges of the results. However, it is difficult to define the intervals of input variables when the boundaries of the intervals are uncertain. A fuzzy set approach, pioneered by Zadeh [32], is a means for modeling uncertainty (or imprecision) arising from mental phenomena, which are neither random nor stochastic [9]. It is useful for uncertainty analysis where a probabilistic data is not available or when interval values of input variables are uncertain. Thus, this study attempts to apply the Analytic Hierarchy Process (AHP) to determine the impact weights of risk factors from subjective judgment of experts and practitioners. Further, the Fuzzy Multiple Criteria Decision Making (FMCDM) was used to assess the synthetic judgment of degree of risk for the main activities of a construction project in different phase. On the other hand, due to advances in computer technologies and current information exchange capabilities, there exists a need to develop a decision support system (DSS) that will assist the contractors in making critical risk management decisions at the stages of contracting and construction. Thus, the aim of this paper is to present a

systemic approach of the implementation of DSS in risk assessment of construction project. Initially, the establishment of a hierarchical structure for tackling the problem of construction risk and uncertainty identification is discussed, and a brief introduction to FCMCDM methods. Then, introduce the DSS framework that we developed. Finally, concluding remarks are presented.

## 2. Construction Project Risk Assessment Model

The purpose of this section is to establish a hierarchical structure for tackling the problem of risk assessment of a construction project. The contents include three subsections: constructing the hierarchical structure of risk factors for a general construction project, determining the assessment factors weights, and getting the synthetic judgment value.

### 2.1 Constructing the Hierarchical Structure of Risk Assessment Factors

Many researchers have tried to tackle the problems of risk and uncertainty identification in construction projects. Chapman [7] define the sources of risk as a risk hierarchy composed of four “layers”: the environment, the industry, the client and the project. Wideman [30] has compiled a risk identification breakdown structure as a framework of the major sources of risk which is subdivided into five classifications of risk: external unpredictable, external predictable but uncertain, internal (non-technical), technical and legal. Smith and Bohn [24] classified project risk into eight broad categories: natural risks, design risks, logistic risks, financial risks, legal and regulatory risks, political risks, construction risks and environment risks. Raftery [21] considers that there are three separate areas of risk: risk internal to the project, risk external to the project, and the client/the project/project team and project documentation. Conroy and Soltan [10] refer to four categories of risk, namely human failings, organizational failings, design group failings and design process failings. Charoengnam and Yeh [8] categorized construction risks into six groups: construction related, performance related, physical, financial and economic, contractual and legal, political and societal. Tah and Carr [25] [26] built a hierarchical risk-breakdown structure, which separated project risk into two main groups: external risk (including economic, physical, political and technological change) and internal risk (including five sub-items in local risk and eleven items in global risk). Thompson and Perry [27] listed sixteen sources of risk, five of which related to construction and three to finance issues.

The assessing hierarchical structure for project risk and uncertainty should provide evaluators the convenience for practical usage and easy understanding. Therefore, the assessment structure should avoid too complex on risk factors and the hierarchy need to express the basic risk and uncertainty condition for a project. The key

dimensions and the factors for construction project risk assessing were derived through previous literature review, comprehensive investigation and consultation with several experts, including one professor in architectural engineering, one professor in civil engineering, one experienced contractor. There are five risk and uncertainty dimensions, including economic and financial, contractual and legal, physical and construction related, managerial and performance related, political and societal. From these, twenty assessing factors for the hierarchical structure were used in this study. The hierarchical structure adopted in this study is shown in Fig. 1.

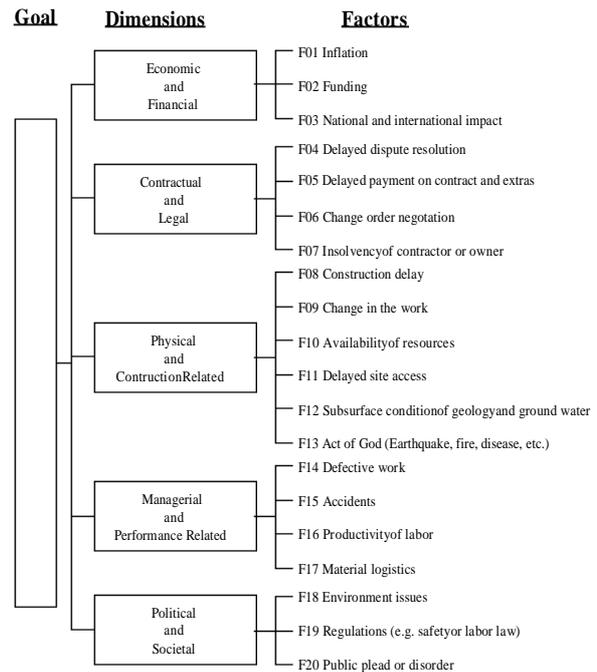

Fig. 1 The Hierarchical Structure for Risk Assessment of Construction Project

### 2.2 Determining the Risk Assessment Factors Weights

Several criteria are used in judging whether the level of risk is high or low, such as the degree of seriousness and the subsequent impact if this risk factor does occur. In this study the impact which is the degree of seriousness and the scale of the impact on project activities if the undesirable thing occurs [35]. However, the factors of project risk and uncertainty assessing have diverse significance and meanings, we cannot assume that each assessing factor is of equal importance. There are many methods that can be employed to determine weights [14] such as the eigenvector method, weighted least square method, entropy method, AHP, and LINMAP (linear programming techniques for Multidimensional of Analysis Preference). The selection of method depends on the nature of the problem. To assess project risk impact is both a complex and wide-ranging problem, so this problem requires the most inclusive and flexible method.

Since the AHP method can systematize complicated problems, is easy to operate, and integrates the experts' or evaluators' opinions. Therefore, in this study, the AHP method to assess the impact of risk factors is suggested. AHP weightings are mainly determined by evaluators who conduct pairwise comparisons of all factors with respect to certain criteria, deals with the relative priority or importance of each factor [22] [23]. The process of determining the importance order among criteria (risk assessment factors) is based on matrix computations and involves pairwise comparison of the various criteria in pairwise comparison matrix such as follow:

$$A = \begin{bmatrix} 1 & a_{12} & \dots & a_{1n} \\ 1/a_{12} & 1 & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ 1/a_{1n} & 1/a_{2n} & \dots & 1 \end{bmatrix}$$

A matrix  $A = (a_{ij})$  where  $i, j = 1, 2, \dots, n$ , is established for evaluation of criteria and each criterion,  $a_i$  is compared with another criterion,  $a_j$ . The importance of one criterion over the other is established by utilizing a predetermined scale (refer to Table 1), thus defining  $a_{ij} = w_i/w_j$ , where  $w_i/w_j$  signifies the importance (or weight) of criterion  $a_i$  over criterion  $a_j$  and  $i, j = 1, 2, \dots, n$ . All entries in this matrix are positive and by definition satisfy the condition for a reciprocal matrix,  $a_{ji} = 1/a_{ij}$

Table 1 Comparison scale

Degree of importance	Definition
1	Equal importance of elements
3	Weak importance of one element over another
5	Strong importance of one element over another
7	Demonstrated or very strong importance of one element over another
9	Absolute importance of one element over another
2, 4, 6, 8	Intermediate values between two adjacent degrees of importance

The pairwise comparison of criteria based on the predetermined scale and its organization in a matrix form facilitates further analysis of the information. The relative comparisons of various criteria represent the elements,  $a_{ij}$ , of the upper triangle of the comparison matrix. The lower triangle of the matrix is established by taking the corresponding reciprocals from the upper triangle. The relative importance of criteria or the priority vector is established by computing the eigenvector corresponding to the maximum eigenvalue of the comparison matrix. It

is important that consistency should be maintained during the pairwise comparisons, that is,  $a_{jk} = a_{ik}/a_{ij}$  where  $i, j, k = 1, 2, \dots, n$ . Analytical Hierarchy Process allows for reasonable deviations in consistent comparison and does not require the consistency to be in exact mathematical proportions. The consistency of  $(n \times n)$  matrix can be established by computing the consistency ratio (C.R.) for the matrix, as defined in Eqs. (1) and (2).

$$\text{Consistency Ratio (C.R.)} = \frac{\text{C.I.}}{\text{R.I.}} \tag{1}$$

$$\text{Consistency Index (C.I.)} = \frac{\lambda_{\max} - n}{n - 1} \tag{2}$$

where, Random Index (R.I.) is defined as the average C.I. for a large number of reciprocal matrices of the same order with random entries, and  $\lambda_{\max}$  is the maximum eigenvalue of the matrix under consideration. Empirical studies conducted by Saaty have indicated that a deviation in consistency ratio of less than 10% is acceptable without adversely affecting the results. If the consistency ratio for a matrix is greater than 0.1 then, either the values in the matrix should be rejected or else, steps should be taken to modify the pairwise comparisons till an acceptable consistency ratio is obtained. The procedure for AHP can be summarized in seven steps as follows:

- Step 1** Set up the hierarchy system by decomposing the problem into hierarchy of interrelated elements.
- Step 2** Construct pairwise comparison matrices among all the elements in the dimensions of the hierarchy system. Assign the ratio values to the pairwise comparisons by asking which is the more important of each two factors.
- Step 3** Solves the eigenvector of the comparison matrix and establishes the relative weight for the dimensions level.
- Step 4** Check for consistency of the matrix.
- Step 5** Repeat Steps 3 and 4 at all descending factor levels of the hierarchy.
- Step 6** Multiply the weights of the factors at the upper levels down to the factors at the lower levels along with their vertical relationship.
- Step 7** Determine the aggregate relative weights of the decision elements to arrive at a set of ratings for the decision alternatives/strategies.

The final importance weight of every factor provides a basis for considering the priority of the impact to the various risks in a certain kind of construction project.

### 2.3 Getting the Synthetic Judgment Value

In daily life, we often hear people to express their opinion with “not very clear”, “probably so”, or “very likely”, indicating that they have some uncertainty or imprecise judgment. With different daily decision-making problems of diverse intensity, the results can be

misleading if the fuzziness (vagueness/uncertainty) of human decision-making is not taken into account. However, since Zadeh put forward fuzzy theory [32], and Bellman and Zadeh [3] described the decision-making method in fuzzy environments, an increasing number of studies have dealt with uncertain fuzzy problems by applying fuzzy set theory. Owing to a construction project often belong to uniqueness, inconsistency and data incompleteness. It is not easy to search available numerical information related to risk factors from another projects since the lack of historical records reservation in many cases. Therefore, the main way to estimate possibility of a risk factor occurrence for an activity of project is subjective judgment by project managers or experts. Since the subjective judgment is a fuzzy behavior in decision-making. Thus, this study includes fuzzy decision-making theory, considering the possible fuzzy subjective judgment of the evaluators during their evaluation of the construction project activities. The applications of fuzzy theory in this study are elaborated as follows:

**a. Fuzzy Numbers**

Fuzzy numbers are a fuzzy subset of real numbers, representing the expansion of the idea of the confidence interval. According to the definition of Dubois and Prades [12], fuzzy numbers should possess the following basic features.

Fuzzy number  $\tilde{A}$  is of a fuzzy set, and its membership function is  $\mu_{\tilde{A}}(x): R \rightarrow [0,1]$ , and it is enshrined with the following characteristics:

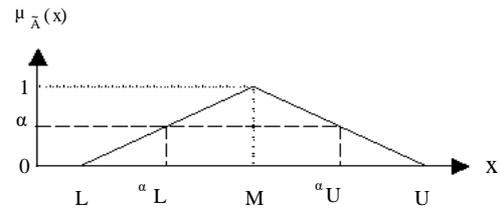

- (i)  $\mu_{\tilde{A}}(x)$  is a continuous mapping from R to the closed interval [0,1];
- (ii)  $\mu_{\tilde{A}}(x)$  is a convex fuzzy subset;
- (iii)  $\mu_{\tilde{A}}(x)$  is the normalization of a fuzzy subset, which means that there exists a number  $x_0$  that makes  $\max \mu_{\tilde{A}}(x_0) = 1$ .

Those numbers that can satisfy these requirements will then be called fuzzy numbers, and the following is an explanation for the characteristics and the operation of a triangular fuzzy number  $\mu_{\tilde{A}}(x)=(L, M, U)$  as shown in equation (3).

$$\mu_{\tilde{A}}(x) = \begin{cases} \frac{(x-L)}{(M-L)} & L \leq x \leq M \\ \frac{(U-x)}{(U-M)} & M \leq x \leq U \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

Moreover, the set of elements that belong to the fuzzy set  $\tilde{A}$  at least to the degree  $\alpha$  is called  $\alpha$ -level set :

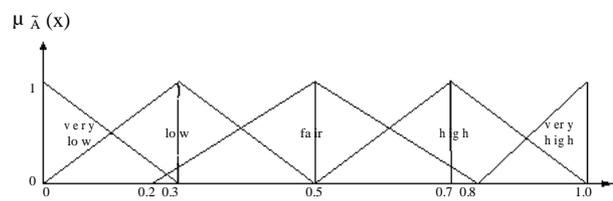

$$\forall \alpha \in [0,1], \tilde{A} \text{ of } \alpha\text{-cut shows } \alpha\tilde{A} \text{ and } \alpha\tilde{A} = [(M - L)\alpha + L, (U - M)\alpha + M] = [L, U] \quad (4)$$

**Figure 2. The membership function of the triangular fuzzy number**

**b. Linguistic Variable**

According to Zadeh [33], it is very difficult for conventional quantification to express reasonably those situations that are overtly complex or hard to define; thus, the notion of a linguistic variable is necessary in such situation. A linguistic variable is a variable whose values are words or sentences in a natural or artificial language. For example, the expressions of occurrence possibility of risk factors as “inflation,” “change order negotiation,” “delayed site access,” “accidents,” “public plead or disorder,” and so on all represent a linguistic variable in the context of this study. Linguistic variables may take on effect-values such as “very high”, “high”, “fair”, “low”, “very low”. Triangular fuzzy numbers, as shown in Fig. 3, can indicate the membership functions of the expression values. The use of linguistic variables is currently widespread, and the linguistic values found in this study are primarily used to assess the linguistic ratings given by the evaluators. Furthermore, linguistic variables are used as a way to measure the scope of occurrence possibility for each risk factor.

**Fig. 3 Membership Function of the Five Levels of Linguistic Variables**

**c. Fuzzy Multiple Criteria Decision-Making (FMCDM)**

Bellman and Zadeh[3] were the first to probe into the decision-making problem under a fuzzy environment, and they heralded the initiation of FMCDM. This study uses this method to evaluate and rank the degrees of risk for construction project activities. The following will be the method and procedures of the FMCDM theory.

- (1) Measurement criteria: Using the measurement of linguistic variables to demonstrate the risk factors possibility by expressions such as “very high”, “high”, “fair”, “low”, “very low”, the evaluators are asked for conduct their subjective judgments, and each linguistic variable can be indicated by a triangular fuzzy number (TFN) within the scale range of 0-1.0. In addition, the evaluators can subjectively assign their personal range of the linguistic variable. Take  $E_j^k$  to indicate the fuzzy possibility value of

evaluator  $k$  towards activity  $i$  under factor  $j$ , and all of the assessment factors will be indicated by set  $S$ , then,

$$E_{ij}^k = (LE_{ij}^k, ME_{ij}^k, UE_{ij}^k), \quad j \in S \quad (5)$$

Since the perception of each evaluator varies according to the evaluator's experience and knowledge, and the definitions of the linguistic variables vary as well, if there are several evaluators in assessment process, this study uses the notion of average value to integrate the fuzzy judgment values of  $m$  evaluators, that is,

$$E_{ij} = (1/m) \otimes (E_{ij}^1 \oplus E_{ij}^2 \oplus \dots \oplus E_{ij}^m) \quad (6)$$

The sign  $\otimes$  denotes fuzzy multiplication, the sign  $\oplus$  denotes fuzzy addition, and  $E_{ij}$  shows the average fuzzy number of the judgment of the decision-maker, which can be displayed by a triangular fuzzy number as follows:

$$E_{ij} = (LE_{ij}, ME_{ij}, UE_{ij}) \quad (7)$$

The preceding end-point values  $LE_{ij}$ ,  $ME_{ij}$ , and  $UE_{ij}$  can be solved by the method put forward by Buckley [4], that is,

$$LE_{ij} = \left( \sum_{k=1}^m LE_{ij}^k \right) / m \quad (8)$$

$$ME_{ij} = \left( \sum_{k=1}^m ME_{ij}^k \right) / m \quad (9)$$

$$UE_{ij} = \left( \sum_{k=1}^m UE_{ij}^k \right) / m \quad (10)$$

- (2) Fuzzy synthetic judgment: The weights of the each risk assessment factor of construction project as well as the fuzzy possibility values must be integrated by the calculation of fuzzy numbers so as to be located at the fuzzy synthetic judgment value (effect-value) of the integral assessment. According to the weight  $w_j$  derived by AHP, the weight vector can be obtained, whereas the fuzzy possibility matrix  $E$  of each of the activities can also be obtained from the fuzzy judgment value of each activity under  $n$  criteria, that is,

$$w = (w_1, \dots, w_j, \dots, w_n)^t \quad (11)$$

$$E = (E_{ij}), \quad \forall i, j \quad (12)$$

From the weight vector  $w$  and fuzzy possibility matrix  $E$ , the final fuzzy synthetic judgment can be conducted, and the derived result will be the fuzzy synthetic judgment matrix  $R$ , that is,

$$R = E \cdot w \quad (13)$$

The sign “ $\circ$ ” indicates the calculation of the fuzzy numbers, including fuzzy addition and fuzzy multiplication. Since the calculation of fuzzy multiplication is rather complex, it is usually denoted by the approximate multiplied result of the fuzzy multiplication, and the approximate fuzzy number  $R_i$  of the fuzzy synthetic decision of each alternative can be shown as follows:

$$R_i = (LR_i, MR_i, UR_i), \quad \forall i \quad (14)$$

$$LR_i = \sum_{j=1}^n LE_{ij} * w_j \quad (15)$$

$$MR_i = \sum_{j=1}^n ME_{ij} * w_j \quad (16)$$

$$UR_i = \sum_{j=1}^n UE_{ij} * w_j \quad (17)$$

- (3) Ranking the fuzzy number: The result of the fuzzy synthetic judgment reached by each activity is a fuzzy number. Therefore, it is necessary that a nonfuzzy ranking method for fuzzy numbers be used for during the project risk judgment for each activity. In other words, the procedure of defuzzification is to locate the Best Nonfuzzy Judgment value (BNJ). Methods of such defuzzified fuzzy ranking generally include mean of maximal (MOM), center of area (COA), and  $\alpha$ -cut [17][34]. To utilize the COA method to find out the BNJ is a simple and practical method, and there is no need to bring in the preferences of any evaluators, so it is used in this study. The BNJ value of the fuzzy number  $R_i$  can be found by the following equation:

$$BNJ_i = [(UR_i - LR_i) + (MR_i - LR_i)] / 3 + LR_i, \quad \forall i \quad (18)$$

According to the value of the derived  $BNJ_i$  for each of the project activities, it ranks the degrees of risk for the project activities and provides a basis for considering the priority of the response to the activities in a construction project.

### 3.FRAMEWORK OF THE SYSTEM

When developing a framework for the DSS, it is important to realize that various tasks must be assigned to either the computer or the user. In other word, it has to be determined which activities are the responsibility of the decision maker (user input) and which are the best handled by the computational system (system requirements)[19]. Based on the procedures mentioned in section above, we developed an integrated system of AHP and FMCDM to perform the assessment of construction project risk. Since iteration of the process is required, a spreadsheet application lends itself as a logic choice for the application tool. Microsoft Excel was selected as the spreadsheet application tool for the decision support

system. The process diagram of AHP and FMCDM for assessing the degree of risk of each activity in this study is shown as Fig 4. Then, the main interfaces of the system are shown as Fig.5 to Fig. 15.

#### 4.CONCLUSION

General speaking, more preparation in advance will get less loss on operation. Thus, this work provides a systemic model to assess the factors of risk of a

construction project may encounter, and according to the results of assessment to plan the risk management strategies for construction activities. It is helpful to contractor recognize what risk factors he will face and how to plan a risk management strategies when was awarding a large-scale construction contract. The purpose of this study was to develop a scientific framework and computer-based decision support system for the risk assessment of construction project. This work proposes a multi-criteria framework for risk assessment. To deal with the qualitative attributes in subjective judgment, this work employs Analytic Hierarchy Process (AHP) to determine the weights of risk factors. Then, the Fuzzy Multiple Criteria Decision Making (FMCDM) approach is adopted to synthesize the degree of risk of each activity. This process enables decision makers to formalize and effectively solve the complicated, multicriteria and fuzzy/vague perception problem of project risk assessment. An integrated decision support system that combines the AHP method and FMCDM approach to be effective and convenient for assessing the degree of risk by a popular program-EXCEL. It will assist the project managers in making critical decisions during the phase of project contracting and construction.

# An On-Line Personalized Promotion Decision Support System for Electronic Commerce

Chin-Feng Lee, S. Wesley Changchien, and Yu-Jung Hsu

Department of Information Management  
Chaoyang University of Technology  
Taichung, Taiwan  
{lcf, swc, s9014629}@mail.cyut.edu.tw

## Abstract

With the development of the Internet and Electronic Commerce (EC), enterprises have overcome the space and time barriers and are now capable of serving customers electronically. However, it is a great challenge to attract and retain the customers over Internet. One approach is to provide the responsive personalized service to satisfy the customer demand and promote sales at the first time. Hence, in this paper, we propose a decision support system which develops best promotion products based on combinations of different marketing strategies, pricing strategies, and customer behaviors evaluated in terms of multiple criteria. Data mining techniques are utilized to help the business discover patterns to develop on-line sales promotion products for each customer for enhancing customer satisfaction and loyalty.

The proposed system consists of four components: (1) establishing marketing strategies, (2) promotion pattern model, (3) personalized promotion products, and (4) on-line transaction model. A simple example is given to illustrate the implementation and application of proposed decision support system.

**Keywords:** Decision support systems, electronic commerce, personalized promotion, data mining

## 1. Introduction

The growth of the internet and the expansion of on-line shopping have forced traditional business to rethink over their marketing promotion programs because on-line shopping changes customer behavior dramatically. On-line personalized promotion provides business returns based on its ability to retain current customers and increase the value of customers [8].

On-line personalization of sales promotions can be executed at various levels of sophistication. There are two major approaches to provide personalized information [13]. In the content based approach, it provides items that are similar to what the user has favored in the past. In the collaborative filtering approach, it identifies other users that have showed similar preference to the given users and provides what they would like. The purpose of this research is to well formulate marketing strategies for offering customers promotions related to product categories they have

purchased.

Besides, the effectiveness of promotions can be expected to increase if customers receive promotions that most attract them. Another purpose of this research is to study how to use data mining techniques to analyze historical on-line purchase data of a large group of customers to characterize all customers, customer cluster, and individual customers' shopping behavior. Accordingly, an intelligent on-line personalized promotion decision support system is proposed in this paper.

Simply stated, data mining refers to extracting knowledge from large amounts of data [4]. Kleissner [7] defined that data mining is a new decision support analysis process to find buried knowledge in corporate data and deliver understanding to business professionals. Hence, decision makers can quickly and correctly make decisions via data mining analysis.

The organization of the paper is as follows. Section 2 proposes an intelligent on-line personalized promotion decision support system. It is classified into five parts: (1) system architecture, (2) establishing marketing strategies, (3) creating a promotion patterns model, (4) generating personalized promotion products, and (5) proceeding with on-line transaction model. Finally, we conclude the paper and present directions for future research in Section 3.

## 2. An Intelligent On-line Personalized Promotion Decision Support System

In this paper, we present an intelligent on-line personalized promotion decision support system, which uses the data mining techniques to help the business discover suitable promotion products for each individual customer.

### 2.1 System architecture

Figure 1 shows the architecture of the system, which consists of the following components: (1) marketing strategies, (2) promotion patterns model (3) personalized promotion products, and (4) on-line transaction model. Each component of the proposed system is described in details as follows.

### 2.2 Marketing strategies

The marketing strategies include promotion strategies and the pricing strategies with business life cycle.

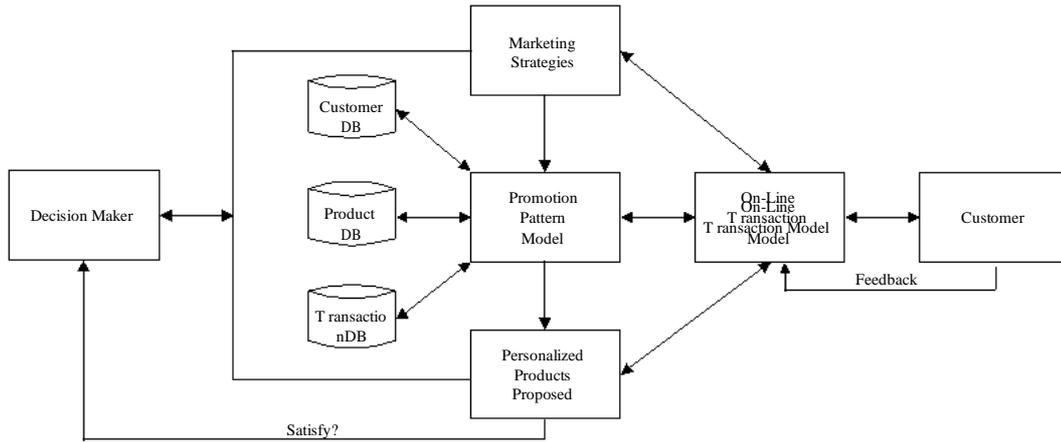

Figure 1. An intelligent on-line personalized promotion decision support system

### 2.2.1 promotion strategies

Most scholars believe that sales promotion can give the promoted objects immediate incentives and excite their interest. Davis [3] considered that sales promotion strengthens the marketed effect and increases the sales volume in short-term. Some other scholars subsumed the objects of sales promotion under the definition of promoted activities. Hence the promoted activities include customer promotion, trade promotion, and sales-force promotion.

In this paper, we focus on customer promotion in Internet. According to the classification of on-line customer promotion proposed by Hsu [5], on-line promotion models can be divided into cash discount, commodity presentation, and rewards drawing activities. Promotion models are listed in Table 1. Here, in our proposed system, sales promotion strategies including general promotion, cross-selling, and up-selling strategies are presented in Table 2. The three strategies utilize two promotion models, which are cash discount and commodity presentation.

Table 1. Promotion models [5]

Promotion model		Promotion manner
Cash discount	Universal price discount	Price-offs
		Price discount
	Differential price discount	Quality discount
		Total discount
Commodity presentation	Same kind Commodity presentation	Bonus packs
	Different kind Commodity presentation	Premiums
		Bundling
Rewards drawing activities		Trading stamps and sweepstakes

### 2.2.2 pricing strategies with business life cycle

For the pricing strategy, we define the promoted price based on two factors. One is the price strategy for each stage in business life cycle, and the other is the original price of product. In addition, the promoted price will be adjusted dynamically with time; that is to say, when the business situation or the product profit changes, the system will automatically, on the basis of the two factors, to refresh a new promoted price. First, we propose an approach which assesses business life cycle based on the capital growth ratio, employee growth ratio, and sales volume growth ratio and sets up the pricing strategies for each stage. The idea comes from the methods presented by Chow [2] and Smith et al.[11]. The pricing strategy for each stage of business life cycle strategy is shown in Table 3. It divides the business life cycle into four stages including introduction, growth, maturity, and decline stages. The value of growth ratio differentiates at each stage in the business life cycle. The growth ratio is defined by Chow [2] as the following formula.

$$R_i = \frac{G_i}{|G_{i-1}|}, \quad G_i = \frac{S_i - S_{i-1}}{S_{i-1}} \times 100\%$$

where  $R_i$  is the  $i$ -th period growth ratio,  $G_i$  is the  $i$ -th period growth rate, and  $S_i$  is the  $i$ -th period value of capital, employee and sales volume.

Next, we hope to consider two factors, pricing strategy for each stage and product price, in finalizing the final promoted price. Generally, the product price depends on the desired profit for business. Similarly, the promoted price should be adjusted according to the final profit that the business expects to yield. Here, let the final profit be  $P$ , the cost be  $C$  and the final promoted price be  $PP$ . Then  $PP = C(1+P)$ .

**Table 2. Proposed sales promotion strategies**

Strategy	Product categories	Promotion condition	Price manner	Applied technique
General promotion	† Best-selling	† Purchased quantity † Purchased total amount	† Price discount	† Cross analysis
	† Worst-selling			
Cross-selling	† Seasonal product † Festival product	† Bundling † Purchased total amount		† Association mining † Sequential pattern mining
Up-selling	† Association product † Sequential product	† Bundling † Purchased total amount	† Cross analysis	

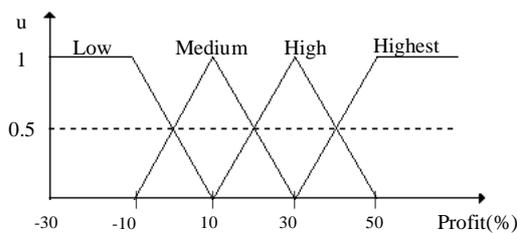

**Table 3. Pricing strategy for each stage of business life cycle**

Business life cycle	Introduction	Growth	Maturity	Decline
Characteristic				
Growth Ratio (Capital, Employee and Sales Volume)	$R_i \geq 2$	$2 > R_i \geq 1$	$1 > R_i \geq 0$	$R_i < 0$
Price strategy for each stage	Low	Highest	High	Medium

In this research, by using a fuzzy set theory [13], an approach is proposed to help the business to decide the final promoted price. Two steps involve in the decision of final promoted price. One is to define the membership function for the profit, and the other is to utilize the fuzzy rule-based inference to obtain the final profit.

(1) defining the membership function for the profit

In fuzzy logic, a fuzzy set A on universe X is defined by the ordered pair  $(x, \mu_A(x))$ , where x is the object on X, and  $\mu_A(x)$  is called the membership function of A. The membership function can be any value in the range of [0.0, 1.0]. Now, we define the membership function for profit as shown in Figure 2.

**Figure 2. Membership function for profit**

(2) utilizing the fuzzy rule-based inference to obtain the final profit

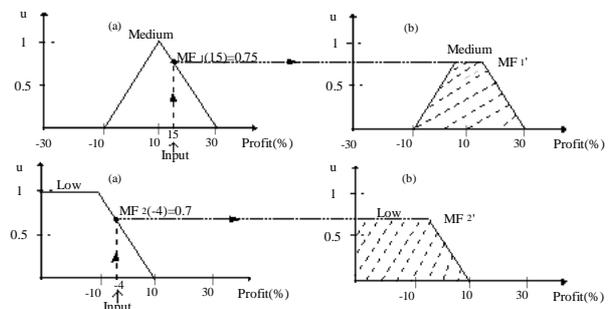

In this step, the promoted price will be obtained by combining the following two fuzzy rules. Firstly, assuming that a product ‘A’ has a profit of 15% and its cost is C. Secondly, assuming that the business life cycle stage is ‘Introduction’ and the pricing strategy for this stage is ‘Low.’ Therefore, the first fuzzy rule (say,  $MF_1$ ) is “if the profit of product ‘A’ is Medium then the final profit is Medium,” according to the membership function for profit of Figure 2. Then, the second fuzzy rule (say,  $MF_2$ ) is “if business profit is Low then the final profit is Low.”

Finally, an output value can be generated from a membership function merged from the two fuzzy rules

mentioned above. The inference process consists of three basis steps and one optional step [6]. The first three steps are fuzzy matching, inference, combination, and the optional one is defuzzification.

(a) fuzzy matching step

Firstly we define the fuzzy matching function as  $MF(p)=d$ , where  $MF()$  is a fuzzy membership function such as  $MF_1$  or  $MF_2$ , the original product profit p is an input of  $MF()$ , and the matching degree d is an output of  $MF()$ . We assume that two inputs are 15 and -4 respectively. Figure 3(a) illustrates that the outputs 0.75 and 0.7 are obtained by the mentioned two fuzzy rules  $MF_1$  and  $MF_2$ , respectively.

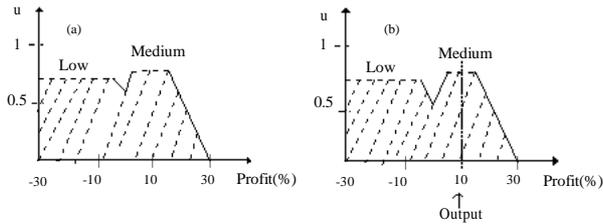

**Figure 3. (a) Fuzzy matching step (b) inference step**

(b) inference step

After the fuzzy matching step, we will calculate the rule’s conclusion based on its matching degree. Figure 3(b) using the clipping method, the matching degree 0.75 and 0.7 suppress the membership functions  $MF_1$  and  $MF_2$  into  $MF_1'$  and  $MF_2'$ .

(c) combination step

The step combines the conclusion inferred by all fuzzy rules into a final conclusion. This is illustrated in Figure 4(a) for combining two fuzzy conclusions  $MF_1'$  and  $MF_2'$  using the clipping method.

**Figure 4. (a) Combining fuzzy conclusions inferred by the clipping method (b) the result of MOM defuzzification.**

(d) defuzzification step

For the reason that we need a crisp output, an additional step is used to convert a fuzzy conclusion into a crisp one. This step is called defuzzification. The Mean of Maximum (MOM) method is used to calculate the average of all variable values with maximum membership degrees. Figure 4(b) shows the result of applying MOM defuzzification to a combined fuzzy conclusion. The value of final conclusion is 10%; that is, the final profit is 10%. Therefore, in this example, the final promoted price is  $C(1+10\%)$ .

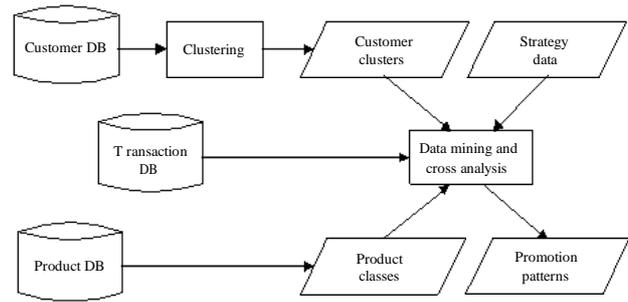

With the proposed price strategy, we have three opportunities for promotion discount.

- (1) general discount : The cross-selling and up-selling products will obtain the price discount based on the strategies above.
- (2) purchased quantity discount : The new, best-selling, worst-selling, seasonal or festival products in general promotion will obtain the price discount when the purchased quantity is greater than or equal to a decision-maker specified minimum quantity threshold.
- (3) purchased total amount discount : The customer will obtain the price discount when the purchased total amount is greater than or equal to a decision-maker specified minimum total amount threshold.

### 2.3 Promotion pattern model

In this stage, we propose a promotion pattern model which is illustrated in Figure 5. It utilizes data mining techniques and cross analysis to carry out the promotion strategies, as discussed in Section 2.2, from product, customer, and transaction databases. The purpose is to assist the business in discovering appropriate promotion patterns.

For the easy management and analysis consideration, all the products are classified into several categories in advance. For example, suppose that there are fifteen products, and all products are classified into five classes A, B, C, D, and E. The outcome is listed in Table 4. The product with Item\_ID '1' is classified into the class 'A.'

**Figure 5. Promotion pattern model**

**Table 4. Product classes**

Item ID	Class	Brand	Price	Cost	Status
1	A	IBM	\$740	\$643	-
2	A	ACER	\$1,250	\$937	-
3	A	ACER	\$1,567	\$1,160	New
4	B	TWINHEAD	\$2,293	\$1,700	-
5	B	IBM	\$1,829	\$1,460	-
6	C	EPSON	\$83	\$67	-
7	C	HP	\$153	\$127	-
8	C	HP	\$223	\$157	New
9	D	EPSON	\$183	\$153	-
10	D	HP	\$110	\$100	-
11	D	HP	\$170	\$143	-
12	E	LEMEL	\$87	\$70	-
13	E	PLEXTOR	\$100	\$83	-
14	E	PLEXTOR	\$200	\$153	New
15	E	RITEX	\$0.33	\$0.30	-

#### 2.3.1 data mining for customer database

Market segmentation divides a larger market into submarkets based upon different needs or product preferences. Clustering analysis is one of the most frequently used method for segmenting a market.

(1) clustering

All products were classified into five classes earlier. However, we don't know the exact number of customer categories. Hence, clustering technique becomes the choice. Here, we will utilize the automatically clustering feature of Adaptive Resonance Theory Network (ART) to cluster customers. It uses customers' demographic and behavior to segment customers. In other words, all the customers who are in the same cluster have the similar demographic and behavior.

ART is an unsupervised learning network developed by Carpenter and Grossberg [1]. It is capable of determining the number of clusters through progressive adaptation.

(a) ART allows a training example to modify an existing cluster only if the cluster is sufficiently close to the example; otherwise a new cluster is formed to handle the example.

(b) ART can determine when a new cluster should be formed by using a "Vigilance parameter" as a threshold of similarity between patterns and

clusters.

For example, there are five customers data shown in Table 5. Since the inputs of ART should be binary values, we must design the corresponding values for the inputs of the example in advance. Here, some discretization techniques [4] are used to divide customers' attributes Income, Age, and Total amount into the intervals labeled as Low, Medium, and High. Take attribute Income as an example. The Low interval is defined below 1000, and can be coded as "00." The Medium interval is defined between 1000 and 1700, and can be coded as "01." The High interval is defined above 1700, and can be coded as "11." Similarly, attributes Age and Total amount are discretized and encoded in the same way as in Table 6.

**Table 5. The customers data**

Customer ID	Name	Income	Age	Sex	Total amount
111	Sam	1,800	35	M	400
122	Mary	8,00	22	F	2,000
123	Annie	1,300	27	F	1,200
113	David	1,900	52	M	500
133	Jacky	1,400	55	M	1,500

**Table 6. Discretizing and encoding attributes as an ART input**

Attribute	Range		
	Code		
Income	<1,000	1,000-1,700	>1,700
	00	01	11
Age	<30	30-50	>50
	00	01	11
Sex	M	F	
	1	0	
Total amount	<300	300-1,000	>1,000
	00	01	11

According to the discretization and encoding method, five vectors corresponding to the five customers' data shown in Table 5 can be obtained as follows.

Attribute sets = {Income, Age, Sex, Total amount}  
 Sam = {11, 01, 1, 01}  
 Mary = {00, 00, 0, 11}  
 Annie = {01, 00, 0, 11}  
 David = {11, 11, 1, 01}  
 Jacky = {01, 11, 1, 11}

(2) customer clusters

Set the Vigilance parameter as 0.5, three clusters can be generated by ART. Mary and Annie belong to the first cluster, Sam and David belong to the second cluster, and the third cluster contains Jacky. Table 7 displays the cluster label and the corresponding customer ids. For example, the customer numbered 113 belongs to the cluster label of A.

**Table 7. Clusters of customers**

Cluster	Customer ID
A	{111, 113}
B	{122, 123}
C	{133}

**2.3.2 data mining and cross analysis for transaction database**

The above section discussed that the business divides customers into several different clusters based on a clustering technique. Therefore, we can take that as a basis to provide different promotions for different clusters. In this section, we will progress towards the data analysis of transaction database by data mining and cross analysis in order to find out different promotion fitting for the different clusters.

(1) data mining

Here, we will utilize association rule mining and sequential pattern mining respectively. Then we discover association products and sequential products which are purchased together and purchased in sequence respectively.

(a) association mining

It can be found that what kinds of products are purchased at the same time through association rules mining. In the paper, an association mining method [9] is used to find out the affinity of products purchased together from the transaction data of all customers. At the same time, the association mining method can also be applied to each customer cluster and individual customer to extract the purchasing patterns for each customer cluster and each individual customer.

Consider the transaction database in Table 8. Assume that the minimum support is 4. The association products {2, 7} and {13, 15} are obtained for all customers. That means that all the customers tend to buy items 2 and 7 together or buy items 13 and 15 together. From Table 8, customer 113 belongs to customer cluster A. By association mining on customer cluster "A," we discovered that the customers of this cluster tend to buy items 13 and 15 together. Similarly, applying association mining to each individual customer (say customer 113), we found that the customer loved to buy items 13 and 15 together as well. All the association product patterns for three customer categories (all customers, customer cluster and individual customer) in this example are shown in Table 9.

(b) sequential pattern mining

It can be found that what kinds of products are purchased after buying some item through sequential patterns mining. In the paper, sequential pattern mining methods [9] are used to find out the products frequently purchased in sequence over time from the transaction data of all customers. At the same time, the sequential pattern methods can also be applied to each customer cluster and individual customer to extract all the sequential purchase patterns.

**Table 8. Transaction data**

TID	Itemset	Customer ID	Cluster
1	{2,7,11}	111	A
2	{9,10,12}	111	A
3	{2,5,7}	112	A
4	{7,13,15}	113	A
5	{4,10,13,15}	113	A
6	{3,13}	121	B
7	{2,5,7}	122	B
8	{1,8,12,13}	122	B
9	{2,13,15}	123	B
10	{15}	123	B
11	{2,7}	131	C
12	{12}	131	C
13	{2,4,9}	132	C
14	{10,13}	132	C
15	{2,7,11,14}	133	C

**Table 9. Association product patterns for three customer categories**

All customers	{2,7}{13,15}
Customer cluster A	{13,15}
Individual customer (Customer 113)	{13,15}

Consider the transaction database in Table 8. Assume that the minimum support is 2. The sequential product patterns {2, 12} and {7, 12} are obtained for all customers. That means that all the customers have a trend to buy item 12 after buying item 2 and to buy item 12 after buying item 7. From Table 8, customer 113 belongs to customer cluster A. Similarly, by sequential pattern mining on customer cluster A, we found that the customers of this cluster tend to buy item 10 after buying item 7. All the sequential product patterns are shown in Table 10.

**Table 10. Sequential product patterns for three customer categories**

All customers	{2,12}{7,12}
Customer cluster A	{7,10}
Individual customer (Customer 113)	-

**(2) cross analysis**

We will utilize the cross analysis for best and worst selling and up-selling strategy. The best-selling and worst-selling products can be found based on the statistical analysis. The upgraded products can be found with up-selling strategy.

**(a) statistical analysis**

For each product class, cross analysis can be firstly carried out on the product data (as shown in Table 4) and transaction data (as shown in Table 8) of each kind of customer category for acquiring the best-selling (e.g., the ratio of sales volume is more than 50%) and worst-selling (e.g., the ratio of sales volume is 0%) products.

Here, cross analysis will not be carried out on

the products with the status labeled as “new” because no sufficient transaction data can be analyzed for those new products.

**(b) up-selling strategy**

A technique is applied to the association, sequential, and best-selling products for increasing sales of each customer category. For example, an item set {2, 7} is an association product pattern mined for the category of all customers. Up-selling analysis is firstly applied to item 2 which belongs to product class A. Then, item 3 will be obtained for up-selling because items 2 and 3 belong to the same class A and have the same characteristic.

**Table 11. Best-selling and worst-selling of all product classes for all customers, customer cluster A and customer 113**

Product class	All customers		Customer cluster A		Individual customer (Customer 113)	
	Best selling	Worst selling	Best selling	Worst selling	Best selling	Worst selling
A	{2}	-	{2}	{1}{3}	-	-
B	{4}{5}	-	{4}{5}	-	{4}	-
C	{7}	{6}	{7}	{6}	{7}	-
D	{10}	-	{10}	-	{10}	-
E	-	-	-	-	{13}{15}	-

Here, we use attribute “brand” as the characteristic of up-selling case. In the proposed up-selling strategy, we can consider combined items for up-selling if an up-selling item is combined to other items belonging to an extracted association product pattern. Therefore, the item set {3, 7} is also an up-selling product. All up-selling products are listed in Table 12 for each kind of customer categories.

**2.4 Personalized promotion products proposed**

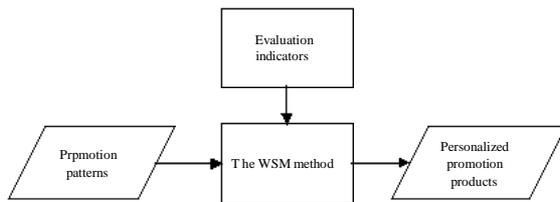

The proposed system will generate many promotion products such as those in Table 12, and we regard them as candidate promotion products. However, not all the candidate products should be offered for promotion. Some evaluation should be done for ordering all of the candidate promotion products. In this paper, WSM (Weighted Sum Model) is used for ranking. WSM is a multi-criteria decision making method.[12] Figure 6 illustrates the model of personalized promotion products proposed.

**2.4.1 promotion patterns**

Promotion patterns are discovered from product, customer, and transaction databases with data mining techniques. Table 12 shows the promotion products.

**Table 12. Promotion all product classes for all customers, customer cluster A, and customer 113**

All customers	Association products	{2,7}{13,15}	Up-selling products	{3}{3,7}{8}{2,8}{3,8}{14}{14,15}
	Sequential products	{2,12}{7,12}		{3}{3,12}{8}{8,12}
	Best-selling products	{2}		{3}
		{4}		-
		{5}		-
		{7}		{8}
Worst-selling products	{10}	{11}		
Customer cluster A	Association products	{13,15}	Up-selling products	{14}{14,15}
	Sequential products	{7,10}		{8}{11}{8,10}{7,11}{8,11}
	Best-selling products	{2}		{3}
		{4}		-
		{5}		-
		{7}		-
Worst-selling products	{10}	{11}		
Individual customer (Customer 113)	Association products	{13,15}	Up-selling products	{14}{14,15}
	Sequential products	-		-
	Best-selling products	{4}		-
		{7}		-
		{10}		{11}
		{13}		{14}
Worst-selling products	{15}	-		

**Figure 6. The model of personalized promotion products proposed**

#### 2.4.2 evaluation indicators

To evaluate the candidate products, we propose three evaluation indicators which are profit, customer satisfaction, and success indicators. All these indicator values should be first normalized by scaling its values to a small specified range, such as 0.0 to 1.0.

##### (a) profit indicator

Making money is the primary goal for the businesses. Therefore, they hope the promotion products with high profit should have a high priority when the products are promoted. For this reason, the profit should be included as an evaluation indicator.

##### (b) customer satisfaction indicator

Along with the customer relationship management (CRM) becoming more and more important recently, the customer satisfaction must be subsumed. The manner for evaluating customer satisfaction is to ask the customer whether they are satisfied with the promoted manners, including the product bundling, product price, and so on. The customer will be asked to carry out an evaluation after purchasing is made. The evaluation score is obtained as a feedback from the customer for

measuring the effectiveness of each promotion product.

##### (c) success ratio indicator

This indicator is used to estimate the acceptance ratio of promotion. The success ratio is defined as follows.

Success ratio = the number of promotions accepted / the number of promotions proposed

#### 2.4.3 the WSM method

We will calculate the score of each candidate promotion product by utilizing the WSM method to rank them and obviate those products with low scores. If there are  $m$  candidate promotion products and  $n$  indicators, then the WSM score of each product can be calculated as follows [12]:

$$A_{\text{WSM-score}} = \max_i \sum_{j=1}^n a_{ij} w_j, \text{ for } i = 1, 2, \dots, m, \quad (1)$$

where  $a_{ij}$  is the  $j$ -th actual indicator value of the  $i$ -th candidate promotion product and  $w_j$  is the importance of the  $j$ -th indicator.

We assume the weights of the three indicators are 0.2, 0.5, and 0.3, respectively. After applying the WSM method, the WSM score are showed in Table 13.

#### 2.4.4 personalized promotion products

After all the WSM scores for candidate promotion products, a filtering process follows.

Take the products in Table 13 and assume 0.5 is the filtering threshold. Finally, the final ranking of price discount promotion products is :  $\{11\} > \{14\} > \{8, 10\} = \{10\} > \{5\} > \{3, 7\} > \{2, 8\} = \{2\} > \{2, 7\} > \{7\}$ ; that is,

**Table 13. Each indicator score and final score of candidate promotion products**

Candidate promotion products	Profit indicator	Customer satisfy indicator	Success ratio indicator	Final score	
General discount products	{2,7}	0.27	0.5	0.7	0.51
	{13,15}	0.15	0.5	0.7	0.49
	{3}	0.35	0.5	0.3	0.41
	{8}	0.4	0.2	0.8	0.42
	{3,7}	0.28	0.5	0.8	0.55
	{2,8}	0.37	0.5	0.7	0.53
	{3,8}	0.38	0.4	0.5	0.43
	{14}	0.3	0.8	0.7	0.67
	{14,15}	0.2	0.5	0.4	0.41
	{2,12}	0.27	0.4	0.5	0.40
	{7,12}	0.2	0.3	0.7	0.40
	{3,12}	0.28	0.2	0.1	0.19
	{8,12}	0.3	0.2	0.2	0.22
	{11}	0.18	0.9	0.9	0.76
	{7,10}	0.15	0.3	0.6	0.36
	{8,10}	0.25	0.8	0.7	0.66
{7,11}	0.19	0.5	0.4	0.41	
{8,11}	0.29	0.1	0.5	0.26	
Purchased quantity discount	{2}	0.33	0.5	0.7	0.53
	{4}	0.35	0.4	0.3	0.36
	{5}	0.25	0.7	0.6	0.58
	{7}	0.2	0.5	0.7	0.50
	{10}	0.1	0.8	0.8	0.66
	{6}	0.2	0.2	0.8	0.38
	{13}	0.2	0.5	0.3	0.38
	{15}	0.1	0.5	0.7	0.48

customer 113 will obtain the price discount when he purchases the above products. He will obtain the general discount when he purchases general discount products; moreover, customer 113 will also obtain the purchased quantity discount when his purchase quantity is greater than or equal to a decision-maker’s specified minimum quantity threshold.

**2.5 On-Line transaction model**

Whenever a customer logons to the proposed system, the on-line transaction model is provided, illustrated as in Figure 7. In the model, the system responses immediately to a legal customer when he is in one of the three user statuses: “enter system,” “select a product,” and “shell out.” The response draws forth the corresponding responsive strategy according to which status the customer is.

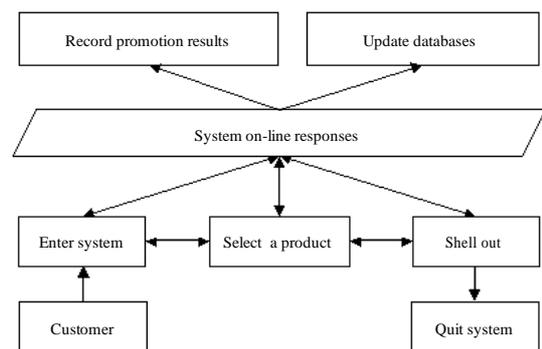

Finally, when a customer quits the system, it will update related database and record the promoted result for calculating success ratio as a basis to enhance the proposed on-line personalized promotion’s effectiveness.

**3. Conclusions and Future Work**

In this paper, we mentioned that the development of Internet has shortened the distance between business and customers. However, it is a bigger challenge that business will face because there are more competitors in Internet than in traditional market, and the customers’ loyalty is so low that it is a difficult problem for a business to attract and retain customers. Traditional mass marketing is no longer suitable; the business must

change to one-to-one marketing so as to provide personalized promotion products for each customer.

Hence, in this paper, different promotion products are proposed for different customers. We present a decision support system to assist business intelligently developing on-line promotion products suitable for each customer. The main concept of the system is that business can utilize data mining techniques to find out effective promotion products based on marketing strategies, pricing strategies, and customers’ purchasing behaviors, where customers may refer to all customers, customer clusters, or an individual customer. Best promotion products are

**Figure 7. On-line transaction model**

**Table 14. On-line responsive strategies**

Customer status	System on-line responsive strategies
Enter system	Select personalized promotion products
Select a product	Select associated products Select discount data for the amount
Shell out	Select discount data for the total

developed after all candidate promotion products are evaluated in terms of multiple criteria. It can increase customer satisfaction and loyalty and finally achieve the goal of strengthening business competitiveness. The system consists of four components: (1) marketing strategies, (2) promotion pattern model, (3) personalized promotion products, and (4) on-line transaction model.

In the future, we shall develop this decision support system and experiment on it in real world to achieve the goal of supporting e-business. In addition, it involves many kinds of techniques in our research. We will continue to devote to the improvement of the techniques later in order to shorten system's response time and then promote its effectiveness.

## Abstract

Within the frame of E-Commerce and Internet literature, decision support systems have drawn the attention of researchers from a wide spectrum of disciplines. Decision Support Systems can play a critical role, in export decision situations. This paper examines various on-line systems to help execute export business. A variety of export on-line systems have been analyzed to determine which export processes are being supported online. The results of this study provide useful insight for creating ones own Multiple Criteria On-Line Export Decision Support System (EDSS).

Theoretical and practical aspects of decision support systems in electronic commerce were dealt with in various research papers by D. G. Conway et al. (2000), R. Debreceny et al. (2002), F. Ramos et al. (2002), R. Kohlu et al. (2001), and others.

An analysis of e-commerce and on-line decision support systems that were developed by researchers from various countries assisted the authors to create one of their own Multiple Criteria On-Line Export Decision Support System (EDSS). EDSS differs from others in its use of new multiple criteria analysis methods as were developed by the authors.

International trade is an information business. Technological innovations mainly through changes in the availability of information and communication technology combined with calculators, analyzers, decision support, expert and e-commerce systems have been provided by a variety of new services that have been developed from the international trade sector.

International trade Web sites contains a variety of e-commerce systems [1] [2] [3] [4]. Various purposes export software can be used by the on-line regime.

Web sites with various purposes for International Trade contains a variety of calculators: Complete Export

Pricing Calculator [7], Import Calculator [8], Exposure Fee Calculator [9], Interest/Loan Payment Calculator [10], etc.

Web sites might also contain various purpose analyzers [3] [4] [11] which help customers to analyze various situations.

Various expert systems (Expert System for the Application of Import and Export Regulations, Trading Expert System, Business Valuation [1], Business Consultant [12], etc.) can be found on Web sites.

The major players in international trade Web sites can find various purpose decision support systems. That is, Export Analysis Tools and Decision Support System, Logistics Solution (export, dispatch, freight and import), Alternative Resource Base for Forest-Based Export Industries, Wine Producers Who Wish to Export their Products Overseas, State of the Art Decision Support System (GarmentSoft) [13], etc.

Above Web-based Systems for Export are seeking to find out how to make the most economic decisions, and most of all these decisions are intended only for economic objectives. Alternatives under evaluation have to be evaluated not only from the economic position, but take into consideration qualitative, technical, risk and other characteristics as well. Alternative solutions allow for a more rational and realistic assessment of economic, technical, qualitative conditions and traditions and for more satisfaction of different customer requirements. Therefore, applying multiple criteria decision support systems may increase the efficiency of e-business.

The models of gravity, econometrics, portfolio theory and multiple criteria analysis, etc. are used for the analysis of export and the forecast of its development trends. Depending on the subject and goals of the research, as well as the amount and objectivity of the available data, it is believed to be reasonable to use different models of export analysis.

Most of the world's countries use gravity models and export/import functions for the analysis and forecast of international trade. These models have been prepared by various institutions and therefore differ in terms of the level of their detailed descriptions and finish.

Gravity equations have widely been used in empirical studies addressing the issues in international trade (O.Havrylyshyn et al. (1991), M.Sanso et al. (1993), etc.). Four categories of gravity equations applications are most well-known: estimating the cost of the border, explaining trade patterns, identifying the effects related to regionalism and the calculation of trade potentials. The calculation of trade potentials has in particular been used widely for Central and Eastern European Countries (Z.Wang et al. (1991), O.Havrylyshyn (1991), R.Baldwin (1993), D.Schumacher (1997)). E. Leamer (2000), A. Harisson et al. (1999), and M. Slaughter (1998) analysed the relationship between trade and employment.

The modelling of Lithuanian export could be carried out (for certain remuneration) by various organizations, e.g. World Bank, UNCTAD, WTO, etc. While modelling exports of various countries the above-mentioned institutions apply gravity and econometrical models. However, they cause some additional problems. For example, only the final results of export modelling, with certain explanatory notes, are provided in the closing section of the analysis. As a rule, the physical implications remain obscure and insufficient, which worsens the reliability of the results. With the aim of avoiding the aforementioned drawbacks, we recommend using the methods of export analysis and EDSS as were developed by the authors of the paper by offering the following practical solutions: analysis of the competitiveness of export sectors; analysis of the competitiveness of Lithuanian export products; analysis of the prospective markets.

The worldwide largest trade database COMTRADE (the United Nations Statistical Division) is used for carrying out the above-mentioned analyses. The Database collects information on 184 countries and 3,500 products, which covers approximately 90% of the world trade.

The physical implications of the recommended methods for export analysis and EDSS are in this way absolutely clear. This would provide a basis for carrying out a Lithuanian export analysis by using different profiles on a regular basis.

Multiple Criteria On-Line Export Decision Support System (EDSS) comprises of the following three constituent parts: data (database and its management system), models (model base and its management system) and a user interface.

According to the user's needs, various models of EDSS may be provided by a model management system. When a certain model (i.e. determination of criteria weights) is used, the results obtained become the initial data for some other models (i.e. a model for multiple criteria analysis and for the setting priorities).

EDSS stores and processes information and data from various sources. The developed EDSS enables consumers to transform unprocessed data into information necessary

for the analysis of a particular problem and to be used for further decision-making.

The following multiple criteria analysis methods and models as developed by the authors (1998) are used by the EDSS in the analysis of the competitiveness of export sectors, exported products and prospective markets:

A new method and model of complex determination of the weight of the criteria taking into account their quantitative and qualitative characteristics was developed. This method allows to calculate and coordinate the weights of the quantitative and qualitative criteria according to the above characteristics.

A new method and model of multiple criteria complex proportional evaluation of the projects enabling the user to obtain a reduced criterion determining complex (overall) efficiency of the project was suggested. This generalized criterion is directly proportional to the relative effect of the values and weights of the criteria considered on the efficiency of the project.

In order to find what price will make an object being valued competitive on the market a method and model of determining the utility degree and market value of projects based on the complex analysis of all their benefits and drawbacks was suggested. According to this method the objects utility degree and the market value of an project being estimated are directly proportional to the system of the criteria adequately describing them and the values and weights of these criteria.

A new method and model of multiple criteria multivariant design of a project life cycle enabling the user to make computer-aided design of up to 100,000 alternative project versions was developed. Any project life cycle variant obtained in this way is based on quantitative and conceptual information.

While analysing export, the main issue that should be solved in this regard, is the determination of the system of criteria, giving a detailed definition of the export.

The formation of systems of criteria describing sectors, products and markets was based on thoughts of different authors. This is because the goals of interested groups and systems of criteria describing sectors, products and markets by some means are relatively subjective. Therefore, in order to increase the level of objectivity of this analysis, the formation of systems of criteria describing sectors, products and markets was based on ideas of professionals and different literature from within the field.

Systems of criteria exhaustively reflect the sectors analyzed products and markets at this moment in time and the prospects of their development.

Analysis of the competitiveness of export sectors of a country under consideration is carried out in a complex way by using comparisons with other countries, at this moment in time and according to changes in performance.

On the basis of the COMTRADE database (of the United Nations Statistics Division), a database of international competitiveness analysis of export sectors of 7 countries (Denmark, Finland, France, Germany, Lithuania, Portugal, UK) was formed.

The results of the comparative analysis of export sectors are presented as a grouped decision making matrix where columns contain n export sectors of a country under consideration.

The diversity of aspects being assessed should include a variety of presented data needed for decision-making.

After a multiple criteria analysis of the export sectors, the following will be determined: priority of the sectors; tendencies.

The results of the multiple criteria analysis of the UK's export sectors carried out by the EDSS coincide with ITS calculations was based on COMTRADE.

In order to determine the most effective exported products of a country under consideration, their competitiveness analysis was carried out, both statically and dynamically.

The results of the comparative analysis of exported products are presented as a grouped decision making.

After completing a multiple criteria analysis of exported products of a country under consideration, the following will be determined: priority of products of a country under consideration; tendencies.

The results of the multiple criteria analysis of the Danish export products carried out by the EDSS coincide with ITS calculations was based on COMTRADE of UNSD. The 2nd alternative (Petroleum oils and oils obtained from bituminous minerals, crude; utility degree  $N_2=23.44$ ) is better than the 1st alternative (Meat from swine that was fresh, chilled or frozen;  $N_1=22.04$ ), i.e. export of the 2nd alternative (Petroleum oils and oils obtained from bituminous minerals, crude) is 1.06 ( $N_2 : N_1 = 23.44 : 22.04 = 1.6$ ) times more efficient than the export of the 1st alternative (Meat from swine that was fresh, chilled or frozen).

On the basis of the COMTRADE database, a database of market analysis of exact exported Lithuanian product was formed.

During a market analysis of each of the exact exported Lithuanian product, such a database has to be filled in.

After a multiple criteria analysis of the sectors, the following will be determined: priority of the market for each product; tendencies.

Having exhaustive conceptual and quantitative information, as well as the results of multiple criteria analysis of sectors, products and markets, as stated above, it is then possible to take them into consideration and more effectively carry out negotiations with the prospective importers.

## Conclusions

Different export on-line systems have been used in recent years to solve a wide variety of export problems. The purpose of this paper is to examine the current status of on-line export systems and indicate how multiple criteria on-line decision support systems can overcome some of the limitations of existing systems. Current on-line export systems is lacking of multiple criteria analysis

possibilities. In this paper we consider a Multiple Criteria On-Line Export Decision Support System (EDSS) as was developed by the authors (<http://193.219.145.94/>) and show how this system can be used for solving different export problems. In the paper a short description of the EDSS in the analysis of sectors, products and markets is provided. EDSS was developed to help exporters make decisions when faced with rapidly changing export conditions and to strengthen their problem-solving abilities. The EDSS, designed for export analysis, includes three basic units: data (database and its management system), models (model base and its management system) and a user interface.

# A Detailed Procedure for Using Copulas to Classify E-Business Data

Victor L. Berardi, B. Eddy Patuwo, Michael Y. Hu

Graduate School of Management

Kent State University

Kent, Ohio 44224

epatuwo@bsa3.kent.edu

## Abstract

Decision support systems are widely implemented to effectively utilize the tremendous amount of data generated by information systems throughout an organization. In one common implementation, the goal is to correctly classify a customer so that appropriate action can take place. This may take the form of a customized purchase incentive given to increase the probability that a transaction is completed, while enhancing profitability. Intelligent agents employing neural network technology that function as Bayesian classifiers are one approach used here.

Another approach that has been around for decades, called copulas, to our knowledge has yet to be utilized for classification in e-business applications. Copulas are functions that can describe the dependence among random variables. The very fact that copulas directly address codependence among variables may make them especially attractive in e-business applications where large numbers of correlated attributes may be present that could negatively affect the performance of other methods. In this paper, the basics of Bayesian decision making and posterior probabilities are reviewed. A detailed procedure for using copulas as Bayesian classifiers for e-business data is presented. The emphasis in describing the method is placed upon practitioner understanding to facilitate replication in real situations while maintaining technical rigor to ease computerized implementation.

## 1. Introduction

The impact of technology is being felt throughout the organization. Information technology is redefining not only how organizations develop strategies but the concepts of organizational learning and the nature of the organizational forms that are possible (e.g., [5] [14] [19]). At the tactical and operational levels, processes throughout the organization are rapidly being reengineered to incorporate the e-business approach.

All these information systems generate a tremendous amount of data for use in organizational decision processes. Effectively utilizing these data repositories is a key to not only meeting articulated business needs but to maximizing an organization's return on investment as well. For example, consider a common e-commerce application. Web-based retailers often track customer search and browsing records in addition to purchase information. This data can then be linked with internal databases, with external affiliate sources, and with readily available

demographic data to provide sophisticated customer profiles. As a result, individualized purchase incentives, suggested add-on purchase items, customized advertising schemes and email distributions can quickly be created to increase sales, enhance profitability, and develop customer loyalty (e.g., [5] [11] [18] [20]).

The goal in situations like the aforementioned is to accurately classify the customer (object) in question so that appropriate action can take place. Many technologies have been utilized to effect classifications in e-business applications. Some, such as data mining, intelligent agents, and neural computing are relatively new. Others, such as logistic regression, have been widely used for decades. Many times these methods are used in concert. For example, an intelligent agent may be employed to customize a follow-up email for a new customer. As attribute data is collected on the new customer, a neural computing model is used to estimate the probability of the customer making subsequent purchases. The intelligent agent, in turn, enters an appropriate enticement into the email.

Often, the approach employed by the classification method tries to estimate the probabilities, called posterior probabilities, associated with an object belonging to each of the possible groups based upon observed attributes. The classifier, in its simplest form, assigns the object as belonging to the group to which it has the highest probability of belonging. This is known as Bayesian classification and is often employed with neural networks and logistic regression applications.

Another approach that has been around for decades, called copulas, to our knowledge has yet to be utilized for classification in e-business applications. Copulas are functions that can describe the dependence among random variables and have been used in applications such as risk analysis [7], the analysis of accident precursor events [23], and for aggregating expert opinions [10]. In each of these situations, correlated events and variables are likely. As will be seen, copulas can be used to develop the likelihood functions that are integral to estimating the posterior probabilities used in Bayesian classification and seem promising for e-business applications. The very fact that copulas directly address codependence among variables may make them especially attractive in this realm where large numbers of correlated attributes may be present that could negatively affect the performance of regression models and neural networks.

The remainder of this paper is structured as follows. The next section reviews the basics of posterior

probabilities and Bayesian decision making. Then, three models that can function as Bayesian classifiers in e-business applications: logistic regression, neural networks, and copulas are discussed. The goal here is to illustrate how each model approaches the Bayesian classification problem in a distinctly different manner. Particular attention is paid to copulas as they are not as widely used as the other two in e-business applications. Next, a step-by-step process for building and using a copula-based approach in an e-business environment is detailed. The final section concludes the paper and discusses further considerations for interested readers.

## 2. Posterior Probability and Bayes

In a classification problem setting, the underlying population generating process characterizes the relationship between the input attributes and the output classes. This relationship defines what is called the posterior probability distribution. At this point, simply note that the posterior probability is a quantity giving the probability that an object belongs to a specified class after we have observed information related to the classification decision.

For example, consider a situation in which perhaps 50 percent of customers who begin the checkout process at a website actually complete the transaction. Without any information concerning a customer, the best we could say is that there is a 50 percent (prior) probability that the next customer will actually complete the transaction. However, after obtaining information on the customer, such as site visit history or previous purchases made, for example, we could modify our probability of transaction completion either up or down from 50 percent to reflect this newly obtained information. Appropriate action could then be taken to maximize expected sales and profits from the customer and transaction.

Posterior probability forms the basis of the well-known Bayesian classification theory [8]. An object's posterior probability is a quantity of great interest, since it allows us to make optimal decisions regarding the class membership of new data. Consider a case with  $J$  groups ( $w_j$ ) that are described by  $N$  variables ( $x_n$ ) where  $P(w_j)$  is the prior probability that a randomly selected object belongs to group  $j$ . According to Bayes rule, if we obtain information contained in an observation  $(x_1, \mathbf{K}, x_n)$ , the prior probability will be revised into the posterior probability,  $P(w_j | x_1, \mathbf{K}, x_n)$ , that the given object  $(x_1, \mathbf{K}, x_n)$  belongs to group  $j$ . That is,

$$P(w_j | x_1, x_2, \mathbf{K}, x_n) = \frac{f(x_1, x_2, \mathbf{K}, x_n | w_j) \cdot P(w_j)}{\sum_j f(x_1, x_2, \mathbf{K}, x_n | w_j) \cdot P(w_j)} \quad (1)$$

where  $f(x_1, x_2, \mathbf{K}, x_n | w_j)$  is the conditional likelihood function for each group,  $w_j$ , and the denominator represents the unconditional joint

distribution  $f(x_1, x_2, \mathbf{K}, x_n)$ . Bayes rule shows how observing the value of  $(x_1, \mathbf{K}, x_n)$ , the attributes for the object, changes the prior probability  $P(w_j)$  to the posterior probability  $P(w_j | x_1, \mathbf{K}, x_n)$  upon which the classification decision is based.

Furthermore, suppose that a particular  $(x_1, \mathbf{K}, x_n)$  is observed and is to be assigned to a group. Let  $\lambda_{ij}(x_1, \mathbf{K}, x_n)$  be the cost of misclassifying  $(x_1, \mathbf{K}, x_n)$  to group  $i$  when it actually belongs to group  $j$ . Since  $P(w_j | x_1, \mathbf{K}, x_n)$  is the probability that the object belongs to group  $j$  given attributes  $(x_1, \mathbf{K}, x_n)$ , the expected loss associated with assigning  $(x_1, \mathbf{K}, x_n)$  to group  $i$  can be minimized by following the Bayesian decision rule for classification,

Decide  $w_k$  for  $(x_1, \mathbf{K}, x_n)$  if  $L_k(x_1, \mathbf{K}, x_n)$

$$= \min_{i=1,2,\mathbf{K},M} \sum_{j=1}^M \lambda_{ij}(x_1, \mathbf{K}, x_n) P(w_j | x_1, \mathbf{K}, x_n) \quad (2)$$

A loss function of particular interest in the literature is known as the symmetrical or zero-one loss function. The zero-one loss function is specified as  $\lambda_{ij}(x_1, \mathbf{K}, x_n) = 1$  for  $i \neq j$ , and 0 otherwise. This binary loss function assigns a zero cost to a correct decision while assigning a unit loss to all misclassifications. In this case, the Bayesian decision rule is to assign an object to the group associated with the maximum posterior probability:

Decide  $w_k$  for  $(x_1, \mathbf{K}, x_n)$  if  $P(w_k | x_1, \mathbf{K}, x_n)$

$$= \max_{j=1,2,\mathbf{K},M} P(w_j | x_1, \mathbf{K}, x_n) \quad (3)$$

This decision rule yields a minimum expected misclassification rate or, in other words, the maximum overall number of correct classifications in the long run.

## 3. Models for Estimating Posterior Probabilities

The above discussion clearly shows the important role of posterior probabilities in the Bayesian classification decision. It is readily apparent from Bayes rule, that accurately estimating the likelihood functions is a key to obtaining reliable posterior probability estimates for objects. Logistic regression, neural networks, and copula-based methods can all be used as Bayesian classifiers as discussed next.

### 3.1 Logistic Regression

Logistic regression attempts to estimate posterior probabilities and likelihood functions based on the Bernoulli distribution by utilizing a logistic response function of the general form

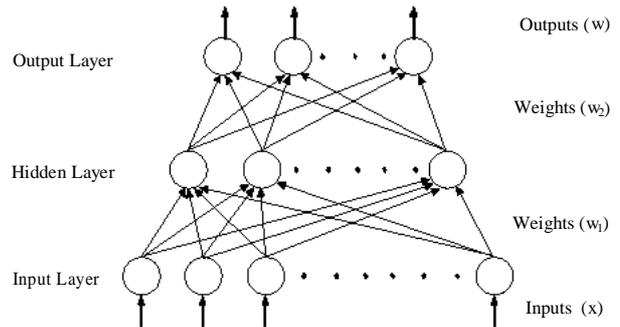

$$E(w) = \frac{\exp(\beta_0 + \beta_1 X_1 + L + \beta_n X_n)}{1 + \exp(\beta_0 + \beta_1 X_1 + L + \beta_n X_n)}. \quad (4)$$

where  $E(w | x_1, K, x_n) = P(w | x_1, K, x_n)$ . The maximum likelihood estimates for the  $\beta$ 's are determined via iterative numerical search procedures. Logistic regression is readily available in statistical packages such as SAS or SPSS and quickly yields a model for given data with minimal computational delay. Logistic regression is well understood by practitioners and has enjoyed success in a wide range of classification problem settings. Neter, Kutner, Nachtsheim, & Wasserman [17] contains an excellent discussion of logistic regression for interested readers.

Logistic regression does have limitations worth noting. Perhaps the most significant one is the a priori specification of the logistic response function, which may restrict the utility of the regression to model in the presence of complex relationships. For example, correlated inputs are known to impact model performance. Also, performance degradation may be seen in situations where the input attributes variance-covariance matrix is not constant between groups. As a practical matter, often a variable selection process is used to overcome such problems but adds another dimension of complexity to this fixed-form approach.

### 3.2 Neural Networks

Neural networks take a fundamentally different approach to estimating posterior probabilities for classification. A neural network is a parallel system of interconnected computing elements called nodes. Information is processed via the interaction between nodes where knowledge is represented by the weights of the connections between them. Figure 1 shows a simple three-layer feedforward network representative of those used in this research. The first or lowest layer is called the input layer where external information enters the network while the last or top layer is called the output layer where the network produces the model solution. The middle layer or hidden layer provides the connections necessary for neural networks to identify complex patterns in the data. All nodes in adjacent layers are connected by acyclic arcs from the input layer to the hidden layer and from the hidden layer to the output layer [2].

**Figure 1. Multi-layer feedforward neural network.**

An optimization process is utilized to minimize the difference between the targets—typically zero and one, representing the true groups to which the objects belong—and the neural network estimates of group membership. The theoretical relationship linking estimation of Bayesian posterior probabilities to neural networks has long been known (e.g., [1] [4] [9]). For an excellent discussion of designing and using neural networks for estimating posterior probabilities, interested readers are directed to [3].

Often neural networks are said to be parameter-free or data-dependent models. This means that the form of the neural network employed is not prespecified as in logistic regression. Rather, through experimentation with various numbers of hidden nodes, in conjunction with weight matrix determination via nonlinear optimization, the data itself determines the model form to be used. In this way, neural networks directly estimate the posterior probabilities associated with the observed objects and the likelihood functions they represent. This allows neural networks to model complex relationships in a wide array of problem settings and is a primary reason for their recent usage and success.

While neural networks are theoretically flexible they are not without practical limitation. The hidden node determination is not trivial, requiring multiple training and testing activities. In addition, the neural network optimization is sensitive to the initial weight values. This necessitates using multiple random initializations and optimizations at each hidden node to increase the probability of finding an acceptable solution. These factors combine to make model building quite time consuming and calculation intensive, even for less complex problems. Because the data are so integral to determining appropriate model form, with neural networks it is especially important to segregate some of the data to make selecting the best number of hidden nodes independent of neural network training.

### 3.3 Copulas

A copula approach to classification is fundamentally different from these other methods, and as such, holds potential as an alternative when other methods do not perform well or in combination with them. In general, the copula approach described in this paper attempts to

decompose the joint cumulative distribution function represented by the data set into two components. First, the joint distribution is split into independent marginal cumulative distribution functions. Next, a second function, called a copula, is developed that specifies the interrelationship between the random variables. Then, these components are used to estimate the posterior probabilities associated with the objects in the data set. This copula approach to classification relies upon Sklar's Theorem, which is expressed as

Sklar's Theorem [22]. Given a joint cumulative distribution function  $F(x_1, \mathbf{K}, x_n)$  for random variables  $X_1, \mathbf{K}, X_n$  with marginal cumulative distribution functions (CDFs)  $F_1(x_1), \mathbf{K}, F_n(x_n)$ ,  $F$  can be written as a function of its marginals:

$$F(x_1, \mathbf{K}, x_n) = C[F_1(x_1), \mathbf{K}, F_n(x_n)],$$

where  $C(u_1, \mathbf{K}, u_n)$  is a joint distribution with uniform marginals. Moreover, if each  $F_i$  is continuous, then  $C$  is unique, and if  $F_i$  is discrete, then  $C$  is unique on  $\text{Ran}(F_1) \times \mathbf{L} \times \text{Ran}(F_n)$ , where  $\text{Ran}(F_i)$  is the range of  $F_i$ .

The function  $C$  is called a copula and describes the interrelationship between the random variables. Sklar's Theorem is especially useful because any joint distribution can be written in copula form without limitation.

To facilitate presentation and to ease understanding, consider the case where each  $F_i$  is continuous and differentiable, where the joint density  $f(x_1, \mathbf{K}, x_n)$  is written as

$$f(x_1, \mathbf{K}, x_n) = f_1(x_1) \times \mathbf{L} \times f_n(x_n) \cdot c[F_1(x_1), \mathbf{K}, F_n(x_n)]. \quad (5)$$

$f_i(x_i)$  is the density that corresponds to  $F_i(x_i)$  and  $c = \partial^2 C / (\partial F_1 \partial F_n)$  and is known as the copula density. This shows that the joint density can be represented as a function of the marginal densities and the copula density [7]. For independent random variables,  $c = 1$  indicates no dependence among the variables as the above equation simplifies to  $f(x_1, \mathbf{K}, x_n) = f_1(x_1) \times \mathbf{L} \times f_n(x_n)$ . When dependence among variables is present,  $c \neq 1$  thereby encoding the interrelationship between variables. If a group  $w_j$  is specified, then  $f(x_1, \mathbf{K}, x_n)$  becomes  $f(x_1, \mathbf{K}, x_n | w_j)$  and the relationship to posterior probabilities via Bayes rule is clear.

Equation (5), therefore, provides a clear path on how to use the copula approach for estimating posterior probabilities in (1) for use in Bayesian classification per equations (2) and (3).

The copula density concept is likely to be unfamiliar to

most readers, though, and deserves further discussion. The focus in this paper is on the multivariate normal copula family. It is called multivariate normal because it uses pairwise correlations between variables to represent dependence among variables in the same manner that the multivariate normal distribution is parameterized in terms of Pearson product-moment correlations [7]. By using a nonparametric correlation measure, such as the Spearman's  $\rho$  or Kendall's  $\tau$ , however, multivariate normal copulas are flexible in that they can allow any marginal distribution for the input attributes. Steps 3 – 8 in the procedure below, detail precisely how this is accomplished.

As a result, the copula approach provides a flexible and useful approach to describing complex relationships among variables that can be used in conjunction with Bayes rule to develop Bayesian classifiers. Copulas have been underutilized given recent advances in the ease of data acquisition, the great speed of computational capabilities, and the availability of commercial packages enabling probability distribution fitting and estimation. Therefore, a primary goal of this paper is to detail a procedure for using a copula-based approach in decision making processes.

The copula approach to classification represents an exciting addition to the tool chest of techniques available for e-business applications. The novelty of its approach clearly distinguishes it from the other two. Copulas are by no means a panacea or guaranteed to perform better than the other methods. Copulas require estimates of marginal distributions and correlations between variables. This makes them more computationally intensive than logistic regression but less so than neural networks. In addition, many copula families exist and must be user specified. The multivariate normal copula family is particularly flexible and is used in the example problem as detailed in the procedure described next.

#### 4. Procedure for Using Copulas with E-Business Data

In this section, a general procedure for developing and using multivariate copulas for classifying objects is presented. The goal is to clarify how copulas can be implemented with e-business data to improve decision making. The focus is on facilitating practitioner understanding with an acknowledged tradeoff in brevity and computational efficiency. Readers interested in detailed theoretical development and proofs relating to copulas are directed to [7] [10] [16] [21].

There are four phases to using copulas in e-business applications. Phase one consists of collecting and processing the raw data. Phase two focuses on building the copula model. Phase three describes how to use the copula model to estimate posterior probabilities. Phase four, meanwhile, discusses using the copula model with newly acquired data.

#### 4.1 Phase One—Collecting and Processing Data

STEP 1: Collect data on objects (e.g., customers) of interest from system.

STEP 2: Segment the objects into  $j$  groups ( $w_j$ ) as appropriate for decision making.

#### 4.2 Phase Two—Building a Copula Model to Couple the Marginal Distributions

STEP 3: Calculate correlation matrix ( $R_j$ ) for the independent variables  $X_1, K, X_n$  for each group  $w_j$ . While the multivariate normal copula is parameterized in terms of the Pearson product-moment correlations, to avoid the limitation of normally distributed independent variables, use nonparametric approaches such as Spearman's  $\rho$  or Kendall's  $\tau$  thereby creating  $R_j^*$ . Next, convert  $R_j^*$  into  $R_j$  via a simple transformation. For Spearman's, the conversion for each element  $r_{ij}$  is  $r_{ij} = 2 \sin(\pi \rho_{ij}/6)$ . For Kendall's, the conversion is  $r_{ij} = \sin(\pi \tau_{ij}/2)$ . For example, in a two-group case with three input variables, two, 3x3 correlation matrices will be generated.

STEP 4: For each  $R_j$  calculate the inverse ( $R_j^{-1}$ ) and the square root of the determinant ( $\sqrt{|R_j|}$ ). These will be used for copula calculations in STEP 8.

STEP 5: Fit marginal distributions to each independent variable  $X_i$  for each group  $w_j$ . Save the distribution information for use in subsequent steps (e.g., Normal( $\mu, \sigma$ )). This can be accomplished using packages such as MatLab, SPSS, SAS, or using a distribution fitting program such as ExpertFit [12]. Law and Kelton [13], Morgan and Henrion [15], and Clemen [6] provide more information on this issue for interested readers. For a two-group three-input case, each of the three variables will be fitted twice.

STEP 6: For each object (realization) ( $x_1^k, K, x_n^k$ ), compute the cumulative density functions (CDFs) and probability density functions (PDFs) associated with each of the marginal distributions found in STEP 5. Call the CDFs ( $F_{11}^k, F_{12}^k, L, F_{1n}^k$ ) ... ( $F_{j1}^k, F_{j2}^k, L, F_{jn}^k$ ) for each of the  $j$  groups and  $n$  variables. Call the PDFs ( $f_{11}^k, f_{12}^k, L, f_{1n}^k$ ) ... ( $f_{j1}^k, f_{j2}^k, L, f_{jn}^k$ ). Therefore, for a two-group case, each object will have two CDFs and two PDFs estimated for each variable.

STEP 7: For each of the  $k$  objects, compute the inverse univariate standard normal from the  $n$  CDFs found in STEP 6 as  $y_{jn}^k = \Phi^{-1}(F_{jn}^k)$  where  $\Phi \sim \text{Normal}(0,1)$ . Let  $y_j^k$  be the column vector  $y_j^k = [y_{j1}^k, y_{j2}^k, K, y_{jn}^k]$  of object  $k$  for group  $w_j$ . For a two-group case, each object will have two estimates,  $y_1^k$

and  $y_2^k$ .

STEP 8: Calculate the point estimate of the copula density of each object  $k$  for every group  $w_j$ . The copula density is found as

$$C_j^k = e^{-\frac{1}{2} (y_j^k)^t R_j^{-1} y_j^k} / \sqrt{|R_j|}$$

where  $y_j^{k,t}$  is the transpose of  $y_j^k$ .

#### 4.3 Phase Three—Using the Copula Model to Estimate Posterior Probabilities

STEP 9: For each object (realization) ( $x_1^k, K, x_n^k$ ), compute the likelihood function for every group  $w_j$ . The likelihood function is calculated as

$$f^k(x_1, x_2, K, x_n | w_j) = f_{j1}^k(x_1) \times f_{j2}^k(x_2) \times L \times f_{jn}^k(x_n) \times C_j^k.$$

STEP 10: Compute the unconditional joint distribution for each object. This is found as

$$f^k(x_1, x_2, K, x_n) = \sum_{j=1}^j f^k(x_1, x_2, K, x_n | w_j) \cdot P(w_j)$$

where  $P(w_j)$  is the prior proportion of group  $w_j$  objects in the data.

STEP 11: Compute the posterior probabilities of each object belonging to each group. The posterior probabilities are calculated as

$$P^k(w_j | x_1, x_2, K, x_n) = \frac{f^k(x_1, x_2, K, x_n | w_j) \cdot P(w_j)}{f^k(x_1, x_2, K, x_n)}$$

These probability estimates are then used in Bayesian decision making for classification as shown in equations (2) and (3). When an equal cost of misclassification assumption is used, the objects are assigned to the group corresponding to the highest posterior probability. Make appropriate decisions for each classification, such as offer a purchase enticement to objects classified as group  $w_2$ , a customer unlikely to purchase again.

The copula model has just been finalized and utilized to calculate posterior probabilities associate with the known objects. Next, we turn to the issue of how to use a copula model for classifying future observations.

#### 4.4 Phase Four—Using Copula Model with New Data

STEP 12: Collect additional data on objects (e.g., customers) of interest from the system to be used to make immediate classification decisions and to take appropriate actions.

STEP 13: Repeat STEPS 6 – 11 for each newly obtained object. Use information calculated previously from STEPS 3–5, but do not recalculate these steps. Make appropriate decisions in STEP 11 based upon the group to which the object is assigned.

### 5. Conclusion

Information systems are generating a tremendous amount of data for use in e-business decision processes. Effectively utilizing these data repositories to make

decisions consistent with the organizations tactical and strategic objectives can be a key to achieving and sustaining competitive advantage. E-business decision support systems have frequently employed data mining, neural computing, intelligent agents, and regression approaches, alone or in concert to turn these data into information and knowledge.

Copulas are another approach that is promising for e-business applications. Like neural networks or logistic regression, copulas can be used to accomplish Bayesian decision making as part of a decision support system. Fundamentally, though, the copula approach to analyzing the data is quite different from these other methods. In particular, a copula approach directly addresses the codependence among variables. This may be especially desirable in e-business applications where large numbers of correlated variables exist that may negatively impact the performance of other methods.

In this paper, the basics of Bayesian decision making and posterior probabilities are reviewed. Next, the neural networks, logistic regression, and copula approaches to estimating the posterior probabilities upon which Bayesian decision making is based in discussed. The focus is on understanding how each method works so that the differences can be understood. Finally, a detailed method for using copulas to classify e-business data is presented. The emphasis is placed upon practitioner understanding to facilitate replication in real situations while maintaining technical rigor to ease computerized implementation.

Swinburne University of Technology  
Hawthorn, Victoria, Australia  
edwardho@iee.org      hthandi@swin.edu.au

## Abstract

The objectives of this research are to detail the history of business-IT alignment and develop a model to measure business-IT strategic alignment. The methodology involved defining and developing measures for the predictor variables of environmental uncertainty and importance of IT to the firm. A conceptual framework or strategic alignment model integrating key practices espoused by academics and practitioners regarding strategic alignment was developed. Measures for the strategic alignment model were defined and developed, and the relationships of the predictor variables with the degree of alignment as well as technology's contribution to organizational performance assessed.

## 1. Introduction

Business strategy and IT alignments and their contributions to business competitive advantages or performance have been much researched the early 1990s. Though most companies know that alignment is needed to facilitate optimum business benefit, it is difficult for them to know whether they have the strategy and technology aligned.

The literature review indicates that, to date, there does not appear to be a 'one-size-fits-all' solution to achieving agreement, coordination, and close cooperation between business strategy and IT strategy. Hence, this paper explores the history of business strategy-technology alignment (strategic alignment in short) and outlines the study being conducted by the authors to increase our knowledge of what the influences are upon business strategy-technology alignment and what impact such alignment has upon the organization. It reports only the preliminary findings as the research is still ongoing as this paper was written.

The overarching research objectives were set as

s define and develop measures for the predictor variables environmental uncertainty and importance of IT to the firm;

s develop a consolidated conceptual framework or

model based on the key practices espoused by academics and practitioners that influence strategic alignment;

s define and develop measures for the strategic alignment model; and

s assess the relationship of the predictor variables with the degree of alignment and the degree of alignment with technology contribution to organizational performance.

Specific benefits of the research were seen as the following:

s This study's contribution to practice will result primarily from identifying key practices with organizational outcomes given the influence of the contingency variables. Identification and measurement of the relationships between the variables and the linkages in the consolidated strategy alignment model should have important consequences for practitioners seeking ways to improve their contribution.

s Contributions to research will derive from the completeness of the model, use of the model's IT's importance to the firm as a contingency variable, and the use of the Key IT practices construct to provide relationships heretofore unexplored. It is expected that the degree of IT and Business Strategy alignment and the impact of key IT practices upon organizational performance will be moderated by the importance of IT to the firm.

s The strength of these relationships should provide directions for future research. For example, studies could be undertaken on why is there a strong relationship between customer service level and the alignment of IT and business. Future research would also benefit from examining the feedback effect of outcomes on the importance of IT to the firm as proposed in the research model.

## 2. Literature review and conceptual framework

### 2.1 History of the strategic alignment model

Alignment of the information systems plan with a company's business plan has been the subject of much research and has been cited as one of the chief problems facing business and IT planners and managers [4][6][14]; The first attempt could be traced back to 1991, when the results of the MIT research program *Management in the 1990s* were published [12]. Among them, a rudimentary framework emerged whereby information technology (IT) was regarded as a variable linked with other variables such as strategy, organization and culture.

The strategic alignment model that was first proposed and which became a body of thought for leading researchers until today was postulated by Henderson and Venkatraman in 1993. In that year, a special issue of the IBM Systems Journal featured a series of articles on the concept of 'strategic alignment', including the leading article by Henderson and Venkatraman [5]. These authors developed the idea stemming from their research within the *Management in the 1990s* project, conducted under a grant by the IBM Consulting Group. The model that they created gained widespread following in the profession.

The *Henderson and Venkatraman* model expresses the interrelationship between business and IT. It is based on two distinct linkages: strategic fit and functional integration. Strategic fit is the linkage concerned with the integration of the external environment in which the firm competes (e.g., business partners, clients and customers, government agencies, regulatory bodies, financial or lending institutions, key suppliers) and the internal environment in which the firm performs (e.g., process technology, organizational structure, human resources, innovative processes). Functional integration is the corresponding link between business and IT. This linkage extends the notion of internal and external fit to IT. These two linkages are used to determine the relationships between IT and business. The model is divided into quadrants, comprising business strategy, IT strategy, organizational infrastructure and processes, and IT infrastructure and processes. These quadrants are interrelated; how they relate represents the organization's 'perspective' or alignment orientation. Effecting a change in any single domain requires the use of three out of the four domains to assure that both strategic fit and functional integration are properly addressed.

Between 1995 and 1997, many studies were conducted based on the Henderson and Venkatraman strategic alignment model. The model was developed further and enhanced by some major researchers such as Papp, Brier and Luftman [7][8]. In 1995, the latter identified a total of

twelve perspectives. These included eight individual perspectives of strategy execution, technology potential, competitive potential, service level, organizational IT infrastructure, IT infrastructure strategy, IT organization infrastructure, and organization infrastructure strategy. In addition, four fusion perspectives were identified, namely, 'organization strategy fusion, IT strategy fusion, organization infrastructure fusion, IT infrastructure fusion' [7][8].

### 2.2 Maes'generic framework

Maes [9] felt that the Henderson and Venkatraman strategic alignment model was not perfect and proposed a modified strategic alignment framework, called the generic framework [9] in an attempt to counter the weaknesses in Henderson and Venkatraman model. Maes argued that the Henderson and Venkatraman model was incomplete because it only dealt with choices regarding organizational and technological infrastructure and processes. Because of this, Maes extended the 'information/communication' and 'operations' layers in the Henderson and Venkatraman strategic alignment model to include the critical links among the various quadrants.

### 2.3 CAP Gemini's Framework of Alignment

In May 2000, a white paper was published jointly by University of Amsterdam and CAP Gemini Institute that included the implementation component of the model and renamed the Unified Framework of Alignment [10]. In this paper, Maes' generic framework was enhanced to include the implementation components; namely, contextual, conceptual, logical, physical and transformational. This framework was created as a design tool aimed at development of mutually aligned business and IT systems through a unified architecture. Whilst Maes' generic framework is a tool for information management, the unified framework of alignment was created as a design tool aimed at development of a mutually aligned business and IT system through a unified architecture. Maes and CAP Gemini argued that business and IT alignment is a combined management and design concern. Thus, the combination of these two frameworks creates a complimentary of results. For example, Maes' framework would be further enhanced when it includes the design components; namely, the contextual, conceptual, logical, physical and transformational phases.

While the researchers cited above have claimed that measurements are important to the usefulness of the model, no studies have been conducted to justify the claims. Bruce [3] claimed that successful alignment could be accomplished via coordination of strategic objectives with

a number of key components: resources, management processes, decision-making mechanisms, performance measures, rewards, and incentives. Measures of alignment will thus be different for firms of different sizes, in different growth phases, and in different industries.

Further, Bruce argued that, most likely, these measures would fall into the following categories - cost leadership, product leadership and outstanding customer service. Bruce's scorecards included the three categories above and were further broken down into following measures: price, quality, customers, markets, cost of operations, channels as well as goods and services. Almost simultaneously, the Balanced Scorecard organization came up with a performance measurement framework for IT and business outcomes [1] [2] which showed areas where IT could add value to existing activities of an organization, as shown in table 1 below.

**Table 1: The value of corporate IT initiatives**

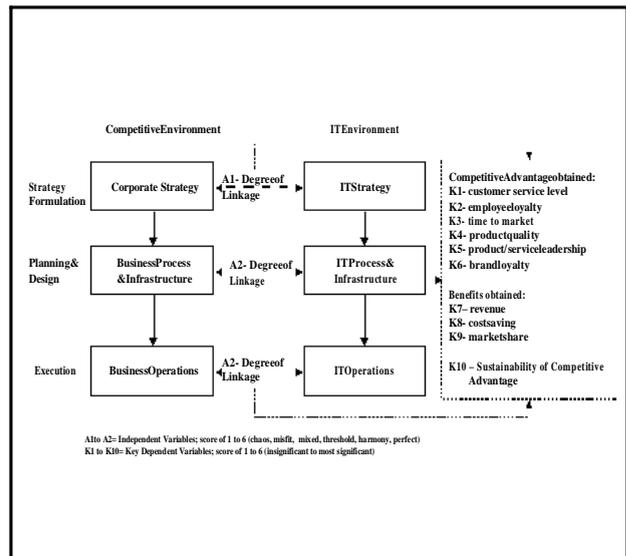

Representative systems	Competitive advantage - Value metrics
Electronic commerce (EDI, supplier management, electronic shopping, secure protocols)	Market share; Price premium for products/services
Information-based products and services (financial, market, and industry-specific information services)	Operating margins, New business revenues, cash flow, knowledge retention
Information value added to existing products and services (customer information networks, electronic catalogue)	Relative return on equity

Source: The Balanced Scorecard Institute

### 2.3 Development of alignment model

Because of the lack of measurements of strategic alignment, the managers today are not fully aware of the implication of strategic alignment. This is a window of opportunity for research in order to create management awareness and to address the competency gap. An attempt was made by the present authors to develop and 'measure' an eclectic strategic alignment model developed using various schools of thought; namely, Henderson & Venkatraman 1993, Maes' Generic Framework and CAP Gemini's Unified Framework of Alignment.

For ease of measurement, a modified 'consolidated' strategic alignment model or CSA model (refer to figure 1 below) was produced that merges the key concepts of the models discussed.

**Figure 1: The CSA model**

It closely resembles the McGeeand Prusak [11] model, with adaptations to include the links as proposed by Henderson and Venkatraman, Maes and CAP Gemini and common variables on competitive advantages and benefits.

*s Independent variables:* The primary independent variables were constructed to identify the strategic alignment at the corporate strategy, business process/infrastructure and operation/implementation level ('A' variables: The measures of tightness of linkage between IT and business strategies and operations. The higher the score, the more the firm demonstrates greater strategic sustainability).

*s Dependent variables:* Combining Bruce's [3] measures of strategic alignment with the metrics of the Balanced Scorecard Institute yielded key dependent variables for potential competitive advantage or benefits obtained. These include revenue, cost saving, customer service level, employee loyalty and job satisfaction, time to market, market share, product quality, market/product/service leadership and brand loyalty ('K' variables: The dependent variables that were generated as a result of degree of linkage in the A variables).

*s Moderator variables:* Moderator variables introduced comprised the computer systems used at different levels of strategy planning; i.e. corporate, business unit or operations.

*s Control variables:* Control variables used comprised manufacturing companies, namely companies with more than five years' profitable operation and companies with turnover of more than AUD 20 million per year.

### 3. Methodology

#### 3.1 Research approach

This research being an empirical study on the relationship between information technology, strategy planning and business processes design, the analytical survey method was adopted. Questionnaires were directed at senior information technology managers to obtain an organisational context and an understanding of the aims and critical success factors and their relationship to information technology strategy. In-depth questionnaire surveys were conducted for certain companies to provide contextual and broad understanding of business process and operation levels details.

The research methodology adopted for the pilot test was a field survey employing questionnaires. The latter were sent to senior IT executives and members of top management, within the same firm, in private corporations within Australia. This was hoped to facilitate statistical testing across a wide variety of organizations and reduce the effects of common source variance by measuring the independent and dependent variables from different respondents. Operationalisations of constructs was in the form of survey questions based on an extensive literature review and consideration of existing validated measures. Confirmatory factor analysis was used to measure the relationships among the variables.

#### 3.2 Data gathering

The sample of firms that participated in the study included manufacturing companies located in Australia. Several criteria were employed to determine the specific population from which the sample was drawn: (1) to ensure a minimal degree of homogeneity among the respondents, the firms included in the sample were restricted to manufacturing firms; (2) to reduce the confounding effects of diversification, the sample was limited to those firms that generate at least 70 per cent of their sales from a single industry [13].

Rather than relying on secondary data, and following practice common in many 'empirical' studies, questionnaires were used to collect data directly from senior information technology managers. Managerial opinion and perceptions were hoped to provide information that secondary data would not necessarily reveal. In the first stage of the survey instrument development, extant literature was perused to generate a pool of items and variables describing information technology-enabled strategic advantages. In addition to this, some industry expert advice was sought to assess the validity of the measures, the conceptual and functional equivalence of the constructs. The items or variables generated from the measurement development processes

were grouped, based on the literature review, into three categories:

s *Category 1*: Organisational arrangements: to understand organisational structure, policies, procedures, systems, and general corporate strategies.

s *Category 2*: Linkage between information technology and corporate strategy: to understand the strategic intent, the type of systems used, the degree of alignment and its associated benefits and any competitive advantages obtained at this level.

s *Category 3*: Linkage between information technology and business processes/operations: to understand the strategic intent, the type of systems used, the degree of alignment and its associated benefits and any competitive advantages obtained at this level.

The degree of linkage was measured on a 6-point Likert scale, ranging from 'chaotic' to 'perfect'. The degree of competitive advantage and benefits obtained due to the strength of the A1 and A2 variables was measured also on a 6-point Likert scale, ranging from 'insignificant' to 'most significant'.

The pre-test was conducted with IT personnel working in selected manufacturing companies, producing the pilot questionnaire. Two main groups of questions were asked. The first group of questions was posed to identify variables A1 and A2, and the executives were asked how strong the current alignment was in their companies between business strategies and IT strategies, and between business processes/operations and IT processes/operations. The second group of questions focused on aspects such as the current performance on variables K1 to K10. The main aim of this second group of questions was to obtain ratings on qualitative variables such as customer services and sustainability of competitiveness.

In the second stage, the questionnaire was test-run to ensure that the format was clear and logical and that the questions could be answered within half an hour. The refined questionnaire led to the actual implementation of data collection procedures.

To establish the significance of all the variables defined in the model and their effects on each other, data was collected by conducting in-depth interviews and by field surveys employing questionnaires sent to senior IT executives and members of top management within the selected firms. Quantitative data such as market share and revenue was obtained from the participating companies' financial statements and industry reports. As indicated above, information from various well-represented parties was obtained so as to facilitate statistical testing across a

wide variety of sources and to reduce the effects of common source variance by measuring the independent and dependent variables from different and informed respondents.

### 3.3 Data analysis

At the time of this analysis, of 200 survey questionnaires sent out, 37 responses had been received, yielding a response rate of 18.5%. The average number of years an IT manager had been in that position is 3.25 and for the CEO, it is 6.56. Based on simple descriptive statistical analysis, the strength of strategic alignment 'A1', at corporate strategy level, was found to be between mixed (rating 3) and threshold (rating 4) with a mean of 3.65; whereas strategic alignment 'A2', at business processes/operations level, was quite significant with a mean of 4.05, an above average score (rating 6 signifies most significant alignment). Analysing the means of data captured showed that K1 (customer services), K4 (product quality), K5 (product/service leadership), K7 (revenue gain), K8 (cost saving) and K10 (sustainability of competitive advantages) were accorded above average (i.e., higher than rating 3) scores. The frequency distributions of the scores for 'A' and 'K' variables were also analysed to find out the frequencies of the ratings on A1 and A2 variables (the strength of business and IT linkage) and the rating on the effect of IT Systems on competitive advantage (K1-K9) and benefits (K10).

Correlations between the dependent and independent variables were analysed using the one-tailed Pearson method. It was found that K1 (customer services) had a significant correlation with A1 (strategic alignment at corporate strategy level); K4 (product quality) and K10 (sustainability of competitive advantages) had a significant correlation (at 0.05 level) with A2 (strategic alignment at business processes/operations level). It is to be noted that, when other data have been collected and collated, some inferential statistical methods will be used for further analyses in order to derive other meaningful relationships among the variables; for example, the relationship between cost saving and revenue generation and their impact on business-IT strategic alignment.

### 4. Findings and discussion

As indicated earlier, descriptive statistical analysis shows that the respondents perceived that their IT-strategy and IT-processes /operations alignment was above average (where, individually, A1 had a mean score of 3.65 and A2 had a mean score of 4.05). Most respondents appeared to be of the view that IT could bring above average benefits to business performance in the area of customer service, (K1 – mean score 3.59), product quality (K4 – mean score 3.92),

product & service leadership (K5 – mean score 3.03), revenue gain (K7 – mean score 3.19), cost saving (K8 – mean score 4.62) and sustainability of competitive advantages (K10 – mean score 3.24).

The frequency distributions analysis indicates that a total of 51% of the respondents regarded the alignment of IT strategy to corporate strategy as chaotic in their organisations, whilst a smaller number (27%) perceived the alignment of business process and operation to IT process and operation as chaotic. Only 14% of the respondents regarded the alignment of IT strategy to corporate strategy as harmonious in their organisations, whilst a larger number, at 41%, perceived the alignment of business process and infrastructure to IT process and infrastructure as harmonious or ideal in their organisations. The total score distributions among the K1 to K10 variables indicate that more than 40% of respondents thought IT could help them achieve better customer service (K1), product quality (K4), product/service leadership (K5), revenue gain (K7) and cost saving (K8). More than 50% said IT had no effect on employee loyalty (K2), time to market (K3), brand loyalty (K6), market share (K9) or on sustainability of competitive advantages or benefits obtained (K10).

When the relationships between strategic alignment (A1 and A2) and performance outcomes (competitive advantages, benefits and sustainability 'K' variables) were analysed, respondents were found to perceive that customer service (K1) had a direct positive relationship or link with IT-business alignment at corporate strategy level (A1); and product quality (K4) and competitive advantages sustainability (K10) were directly related with IT-business alignment at the process/operation level (A2).

The fourth research objective was posed as two hypotheses, namely:

- s *Hypothesis 1*: Tighter integration of IT-business at strategic level has a positive relationship with business performance.
- s *Hypothesis 2*: Tighter integration of IT-business at process/operation level has a positive relationship with business performance.

Table 2 below summarises the hypotheses tests.

**Table 2: Summary of hypothesis testing**

Competitive Advantages or Benefits	Hypothesis 1: tighter integration of IT-business at strategic level has a positive relationship with business performance	Hypothesis 2: tighter integration of IT-business at process/operation level has a positive relationship with business performance
K1	Supported	Not Supported
K2	Not Supported	Not Supported
K3	Not Supported	Not Supported
K4	Not Supported	Supported
K5	Not Supported	Not Supported
K6	Not Supported	Not Supported
K7	Not Supported	Not Supported
K8	Not Supported	Not Supported
K9	Not Supported	Not Supported
K10	Not Supported	Supported

It shows that even though more than 40% of respondents thought that IT could improve customer service (K1), product quality (K4), product/service leadership (K5), revenue gain (K7) and cost saving (K8), the correlation indicated that, with the exception of customer service (K1), there was no evidence to suggest that tighter integration of strategy and IT planning would yield higher performance outcomes for product quality (K4), product/service leadership (K5), revenue gain (K7) and cost saving (K8). Similarly, with the exception of product quality (K4) and competitive advantages sustainability (K10), there was no proof to suggest tighter integration between IT and business processes/operations would bring higher business performance outcome for customer service (K1), product/service leadership (K5), revenue gain (K7) and cost saving (K8).

## 5. Conclusions

In most cases, ensuring right inputs for the program or services, together with efficient activities and processes and effective outputs and outcomes performance measures is no guarantee for the success of a particular program or service. The recognition of logic before measurement will be a key element in the future success of performance management initiatives. The CSA model aims to provide a logic that integrates all the elements in the performance measures from inputs and processes through to outcome measures.

## Abstract

This study examined the relationship between perceived organizational justice and two individual differences, namely, (i) within-culture collectivism and (ii) Machiavellianism. In addition, this study also examined the influence of perceived organizational justice on organizational citizenship behavior (OCB). Previous research suggests that individual differences influence perceived organizational justice, which in turn have an effect on subsequent behaviors. However, much of the research was done in the western context. The present research seeks to examine the generalizability of findings based on the western context by investigating the relationships among within-culture collectivism, Machiavellianism, perceived organizational justice and OCB in a non-western context, specifically, among a group of employees from People's Republic of China. Results suggested that within-culture collectivism and Machiavellianism were significantly associated with perceived organizational justice. Consistent with previous research, perceived organizational justice was positively related to OCB. Implications of the study were discussed.

## 1. Introduction

Organizational justice refers to the degree to which the conduct of an organization toward its employees is perceived to be fair. It has attracted considerable attention from researchers in the area of organizational behavior in recent years. Two main issues have largely dominated research on organizational justice. First, researchers focused on individuals' reactions to situations of perceived organizational justice. Individuals' perceptions of "what is fair" determine their attitudes and behaviors toward organizations and supervisors, such as organizational citizenship behavior [2] [34], organizational commitment [33] [50, p.77], withdrawal [33] and retaliation [43]. Second, researchers have explored the antecedents of perceived organizational justice. As a kind of perception formed in organizational settings, perceived organizational justice is affected by perceivers' individual characteristics, such as personality [43], gender [21] [42] [46] and ethical frameworks [19]. However, research on this issue is still very limited.

The purpose of this study is to test prior theoretical assertions with regard to the influence of individual

characteristics on perceived organizational justice by examining whether two individual characteristics, namely, within-culture collectivism and Machiavellianism, affect perceived organizational justice.

In addition, the majority of research designed to address these two main issues was conducted in the western context. However, studies of the effects of perceived organizational justice do not provide consistent and mutually supportive conclusions as to the generalizability across cultures [27]. For example, findings in the American literature suggest that distributive justice more strongly related to job satisfaction than is procedural justice [31]. However, Yoon [57] found that among Korean employees procedural justice was more strongly related to job satisfaction than distributive justice. In a similar vein, Leung, Smith, Wang and Sun [30] found that the relationship between procedural justice and job satisfaction was more significant than that between distributive justice and job satisfaction in joint venture companies in China. The present research examined the relationship between perceived organizational justice and OCB among a group of Chinese employees.

## 2. Theoretical Background and Hypotheses

### 2.1 Perceived Organizational Justice

In the area of organizational behavior, perception is the process by which individuals select, organize and interpret the input from their senses to give meaning and order to the whole around them [23, p.108]. Through perception, people try to make sense of their environment and the objects, and other people in it. However, organizational researchers note that perception is influenced by characteristics of the perceiver. Among the characteristics are motivational states [23, p.108] [24, p.31]. Specifically, the perceiver's needs, values and desires influence his perception of the objects that he perceives.

Perceived organizational justice is a kind of perception that reflects employees' senses of decisions, decision-making procedures and supervisors in organizational settings. There are three dimensions of organizational justice, i.e., distributive, procedural and interactional justice. Distributive justice refers to the fairness of outcomes or allocations that an individual receives [20].

It reflects employees' perception of whether they are fairly paid in comparison with their input into work. Further, a substantial amount of research on organizational justice has suggested that people, when reacting to organizational decisions that affect them, are influenced by the procedures used to determine the decision outcomes. In other words, people concern with the fairness of the decision-making procedures, labeled as procedural justice [28] [47]. The most recent advance in the justice literature is to focus on the importance of the quality of the interpersonal treatment people receive when procedures are implemented, labeled as interactional justice [4]. Interactional justice reflects supervisors' respect and consideration to employees.

Since a perceiver's motivational states influence his perception, it is suitable for this study to examine effects of within-culture collectivism and Machiavellianism on organizational justice perception. As illustrated in the following section, both within-culture collectivism and Machiavellianism fully reflect individual internal values and desires. Thus they are expected to influence employees' different understanding of the organizational decisions, decision-making procedures and supervisors.

## 2.2 Individual Differences and Perceived Organizational Justice

Individualism-collectivism (IC) has been regarded as a way to distinguish between individuals who are oriented towards self-interests and concern with achieving their own goals and individuals who are oriented toward the collective and focus on the social system rather than themselves [40]. Although prior research suggests that IC is a cross-cultural variable, many cross-cultural researchers note that there may be considerable within country variability along cultural dimensions [14] [32] [49]. IC has been directly measured within culture to indicate individualistic or collectivistic characteristic and further to predict changes in the outcomes of interests [16] [17] [36]. In general, collectivists place collective interests and interpersonal harmony above self-interests. In contrast, the pursuit of individual outcomes and independence is a principal motivation of individualists [48, p.41].

To date, distributive justice researchers have investigated different preferences among reward allocation norms (e.g., equity, equality, and need) across individualistic and collectivistic cultures. They found that collectivists tend to prefer equality and/or need norms to equity norm while individualists tend to prefer equity norm to quality or need norms. Although the specific relationship between IC and perceived distributive justice has not been empirically examined, researchers proposed that the value system of collectivists determines their tendency to seek collective outcomes instead of pursuing individual outcomes. In contrast, individualists tend to place their priority on the recognition of individual achievement and contribution [6]. Further, Choi [6] suggested that outcomes of decision-making be grouped into individual outcomes and group outcomes in order to

explore the influence of IC on perceived distributive justice.

The distributive justice scale in the extant organizational justice literature is used to measure employees' fairness perception of their individual outcomes (e.g., individual payment and bonus) and does not reflect that of the group outcomes (e.g., group bonus). Building upon Choi's proposition about the classification of group and individual outcomes, and collectivists' value system of concerning with collective interests, this study will examine the specific relationship between collectivism and employees' perception of their individual payment, as is assessed by the distributive justice scale in the majority of justice literature. It is expected that collectivists would care less about individual outcomes than about group outcomes. Thus, it is hypothesized that:

H1a: Collectivism is negatively associated with perceived distributive justice.

Cross-cultural research on procedural justice has addressed the question that non-westerners (i.e., collectivists) also care about the procedural justice issues [45]. In addition, some research examined the different preference for conflict resolution procedures between individualists and collectivists [29]. Although these studies did not demonstrate the specific association between IC and perceived procedural justice, they did suggest that collectivism would influence perception of procedural justice.

Research on the different information-processing styles of individualists and collectivists can help us better understand how collectivism is related to perceived procedural justice [15] [16] [18]. According to Earley et al [18] the information processing styles of collectivists and individualists determine the relative salience of self or group. In contrast to individualists, collectivists tend to focus on group-orientated information and display group-related cognition, for example, their value as a group member.

Further, group value theory helps to provide insights regarding the process which link procedural justice and group membership within the organization [26]. Group value theory suggests that people have a sense of affiliation with groups and they assess their value as a group member by the organizational procedures [51]. In an organization when both collectivistic and individualistic employees are influenced by the same organizational procedures, collectivists' stronger sense of affiliation with groups is expected to motivate a correspondingly stronger perception of procedural justice than that of individualists. Thus, it is hypothesized:

H1b: Collectivism is positively associated with perceived procedural justice.

Collectivists value interpersonal harmony with other group members, especially with supervisors. This value motivates them to pay attention to the information about the quality of the interpersonal treatment from the supervisors. In contrast, individualists value independence more than interpersonal relationship. Given that supervisor treat every employee equally with respect

and consideration, the tendency of collectivistic employees to focus on the information about the quality of their relationship with the supervisors will motivate them to form a stronger perception of interactional justice than does the tendency of individualistic employees. Thus, it is hypothesized that:

H1c: Collectivism is positively associated with perceived interactional justice.

Another motivational variable we want to examine is Machiavellianism, a construct that has been rather extensively examined in the psychological literature. Machiavellianism refers to a strategy of social conduct that involves manipulating others for personal gains, often against the interests of others [55]. Previous research has often associated Machiavellianism with such characteristics as selfishness, deceit and manipulateness [13] [22] [55]. Both the definition and the description of Machiavellianism suggest its association with the self-interest value system and the tendency to exploit others. Machiavellianism is found to bear the following characteristics: (1) a lack of affect in interpersonal relationships; (2) a lack of concern with conventional morality; and (3) low ideological commitment [10, p.1].

Christie and Geis [8, p.959] [9] [11, p.163] were among the first scholars to measure individuals' Machiavellianism tendencies. People with high Machiavellianism, namely, high-Machs, tend to focus on potential gains for themselves. They are not concerned with conventional morality and are particularly likely to lie and cheat when given opportunities [13]. High-Machs' focus on their potential and individual interests reflects their strong desire for individual outcomes and achievements. Because high-Machs are not easily satisfied, it is reasonable for us to expect that high-Machs always feel that they are unfairly paid. Thus, it is hypothesized that:

H2a: Machiavellianism is negatively associated with perceived distributive justice.

Further, high-Machs tend to focus on direct and visible individual outcomes (e.g., material reward) and are not interested in the intangible benefits contained in the decision-making procedures, for example, their value as group members to voice. When the procedures cannot bring high-Machs direct and visible material benefits in the near future, they are more likely than low-Machs to perceive the procedures to be unjust. Thus, it is hypothesized that:

H2b: Machiavellianism is negatively associated with perceived procedural justice.

An important characteristic of high-Machs is their tendency to manipulate others. Research has found that high-Machs employ deceptive strategy of exploitation in their short-term social interaction. In other words, high-Machs always want to be in a dominant position in their interpersonal relationship with others. However, this desire to dominate other people in social interaction clearly conflicts with the existing hierarchical subordinate-supervisor relationship in organizations. We note that the fair treatment and respect from a supervisor does not mean that the hierarchal relationship between

supervisors and employees no longer exists. It is supervisors who always stay in a dominant position in the hierarchical relationship. Thus, when high-Machs' desire of dominant status in social interaction cannot be met, we can expect that high-Machs tend to feel an unfair treatment from the supervisors. Thus, it is hypothesized that:

H2c: Machiavellianism is negatively associated with perceived interactional justice.

## 2.3 Perceived Organizational Justice and Organizational Citizenship Behavior (OCB)

Organizational citizenship behavior (OCB) refers to discretionary behavior that is not part of an employee's job description. OCB is not explicitly related to the formal reward system of an organization but is conducive to its effective functioning [38]. Organ [39] posited that citizenship behaviors are driven largely by perceptions of justice. Previous research suggests that employees who believe that they are fairly treated are more likely to hold positive attitudes about their work, their coworkers and supervisors. In turn, they are also more likely to reciprocate by engaging in citizenship behaviors to benefit their organization [35]. Empirical research has demonstrated significant relationship between three dimensions of organizational justice and OCB [1] [33] [37]. Moreover, research on OCB has consistently demonstrated stronger linkages between perceived procedural justice and OCB than between perceived distributive justice and OCB [2] [34]. For example, Moorman [34] reported that perceived procedural justices influenced four of five OCB dimensions, whereas perceived distributive justice did not affect any of justice dimensions [12].

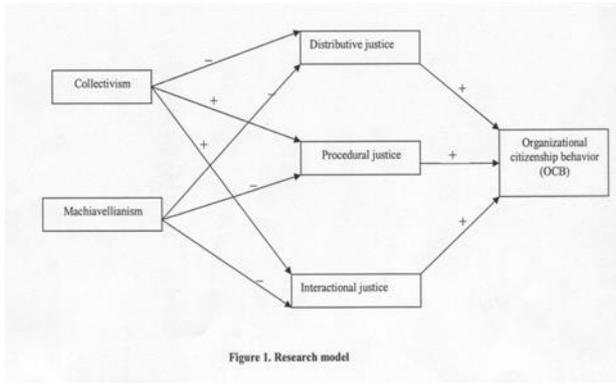

At the same time, we note that the majority of research on these relationships was conducted in the western context. Further examination of these relationships in the eastern context will enable us to understand the impact of perceived organizational justice on work-related outcomes. It is hypothesized that:

H3a: Perceived distributive justice is positively associated with organizational citizenship behavior.

H3b: Perceived procedural justice is positively associated with organizational citizenship behavior.

H3c: Perceived interactional justice is positively associated with organizational citizenship behavior.

Figure 1 illustrates the proposed relationships among two individual differences (i.e., within-culture collectivism and Machiavellianism), three dimensions of perceived organizational justice (i.e., distributive, procedural and interactional justice) and organizational citizenship behavior (OCB). It provides an overview of this study.

### 3. Method

#### 3.1 Sample

Data were collected via the use of electronic questionnaire. Respondents were professional employees from 10 IT-related companies in Xiamen city of the mainland China. The electronic questionnaire containing a cover letter to explain the aim of this survey was sent to respondents.

A total of 97 completed surveys were collected. About 51% of the respondents were women. The average age of respondents was about 30 years (S.D. = 5.29). The average organizational tenure was 4.54 years (S.D. = 4.38).

#### 3.2 Measures

**Collectivism.** An eight-item scale ( $\alpha = 0.65$ ) developed by Earley [17] was used to measure the respondent's tendencies to be collectivistic or individualistic within culture. Items were scored from (1) Strongly Disagree to (5) Strongly Agree. Examples of items in this scale include: 'If the group is slowing me down, it is better to leave it and work alone'; 'One does better work working alone than in a group'; and 'I would rather struggle through a personal problem by myself than discuss it with my friends'. High scores on this scale suggest high level of collectivism.

**Machiavellianism.** A twenty-item scale ( $\alpha = 0.77$ ) developed by Christie and Geis [10, p.1] was used to assess respondents' Machiavellianism. Items were scored from (1) Very Strongly Disagree to (7) Very Strongly Agree and tapped respondents' opinions on three substantive areas, namely, Machiavellian views, tactics and morality. Examples of items include: 'Never tell anyone the real reason you did something unless it is useful to do so'; 'The best way to handle people is to tell them what they want to hear'; and 'Honesty is the best policy in all cases'. The higher the scores, the stronger the respondents' Machiavellianism orientation.

**Organizational justice.** The three justice variables were measured using scales developed by Moorman [34]. Distributive justice was measured with five items ( $\alpha = 0.92$ ) pertaining to individuals' perceptions of the extent to which they have been fairly rewarded by their

organizations based on times such as: 'The responsibilities you have'; 'The stress and strains of your job'; and 'The work that you have done well'.

Procedural justice was assessed with seven items ( $\alpha = 0.93$ ) pertaining to respondents' perceptions regarding the fairness of organizational procedures. Examples of items include: 'How fairly are the organizational procedures designed to (a) provide opportunities to appeal against or challenge a company's decision; (b) hear the concerns of everyone affected by a company's decision; and (c) generate standards so that decisions can be made with consistency'. Items were scored on a five-point scale ranging from (1) Very Unfair to (5) Very Fair.

The scale for interactional justice included six items ( $\alpha = 0.93$ ) pertaining to whether organizational procedures were enacted properly and fairly by supervisors. Items, which were scored on a 5-point scale ranging from (1) Strongly Disagree to (5) Strongly Agree, include: 'My supervisor (1) provides me with timely feedback about decisions and their implications; (2) is able to suppress personal bias; and (3) treats me with kindness and consideration'.

**Organizational citizenship behavior (OCB).** This variable was assessed through a self-report version of 16-item scale ( $\alpha = 0.78$ ) developed by Smith, Organ, and Near [44]. Items were scored from (1) Strongly Disagree to (5) Strongly Agree. Examples of items include: 'Help others who have been absent'; 'Make innovative suggestions to improve department'; and 'Attend functions which are not required of me but help to improve company's image'. High scores on this scale mean respondents' high engagement in citizenship behaviors.

### 4. Results

Descriptive statistics, correlations and Cronbach's alpha values are reported in Table 1.

Variables	M	S.D.	1	2	3	4	5	6
1. Collectivism	3.26	0.50	(0.65)					
2. Machiavellianism	3.93	0.53	-0.46**	(0.77)				
3. Distributive justice	2.96	0.75	0.33**	-0.40**	(0.92)			
4. Procedural justice	3.27	0.89	0.20*	-0.28**	0.40**	(0.93)		
5. Interactional justice	3.29	0.75	0.42**	-0.40**	0.42**	0.53**	(0.93)	
6. OCB	3.62	0.41	0.31**	-0.48**	0.16	0.33**	0.42**	(0.78)

N=97. The numbers in parentheses on the diagonal are coefficient alphas.  
\* Correlation is significant at the 0.05 level (1-tailed).  
\*\* Correlation is significant at the 0.01 level (1-tailed).

Hypothesis 1a, which predicted that collectivism was negatively associated with perceived distributive justice of individual outcomes, was not supported. In contrast, collectivism was positively related to respondents' justice perception of their individual outcomes ( $r = 0.33$ ,  $p < 0.01$ ). Hypothesis 3a about the positive relationship between perceived distributive justice and OCB was not significant ( $r = 0.16$ ,  $p > 0.05$ ). As predicted, all the other hypotheses were significantly supported. Results suggest that collectivism has a significant positive association

with OCB ( $r = 0.31, p < 0.01$ ) yet Machiavellianism has a negative association with OCB ( $r = -0.48, p < 0.01$ ).

**Table 2. Results of hierarchically regressing perceived organizational justice on the control and independent variables (N = 97)**

Variables	Distributive justice		Procedural justice		Interactional justice	
	Beta*	$\Delta R^2$	Beta	$\Delta R^2$	Beta	$\Delta R^2$
<b>Control</b>						
Gender	0.04		-0.16		-0.06	
Age	0.17		-0.20		0.11	
Tenure	-0.03	0.02	-0.05	0.07	-0.33*	0.07
<b>Individual differences</b>						
Collectivism	0.20*		0.22*		0.29**	
Machiavellianism	-0.29*	0.18	-0.29*	0.10	-0.26*	0.21
$R^2 = 0.20$ ; Adj. $R^2 = 0.15$ $R^2 = 0.17$ ; Adj. $R^2 = 0.13$ $R^2 = 0.28$ ; Adj. $R^2 = 0.24$ $F = 9.60$ (2, 88), $p = 0.00$ $F = 5.36$ (2, 88), $p = 0.00$ $F = 12.96$ (2, 88), $p = 0.00$						

\* Standardized beta coefficients in the overall regression equation.  
\*  $p < 0.05$ , \*\*  $p < 0.01$ .

The hypothesized relationships between the individual characteristics, namely, within-culture collectivism and Machiavellianism, and perceived organizational justice were further examined using hierarchical regression analyses. The results in Table 2 suggest that the influences of collectivism and Machiavellianism on perceived organizational justice were still very significant, even with the control of the three demographic variables. Collectivism and Machiavellianism totally accounted for 18% of the variance in distributive justice, 10% in procedural justice and 21% in interactional justice.

**Table 3. Results of hierarchically regressing organizational citizenship behavior on the control and independent variables (N = 97)**

Variables	Organizational citizenship behavior (OCB)	
	Beta*	$\Delta R^2$
<b>Control</b>		
Gender	0.05	
Age	0.25*	
Tenure	-0.07	0.05
<b>Organizational justice</b>		
Distributive justice	0.11	
Procedural justice	0.27*	
Interactional justice	0.40**	0.25
$R^2 = 0.30$ ; Adj. $R^2 = 0.25$ $F = 10.51$ (3, 87), $p = 0.00$		

\* Standardized beta coefficients in the overall regression equation.  
\*  $p < 0.05$ , \*\*  $p < 0.01$ .

Results of hierarchical regression analysis in Table 3 suggest that perceived distributive justice has no effect on OCB (Beta = 0.11,  $p > 0.05$ ). However, both procedural justice and interactional justice are strong predictors of employees' engagement in OCB. Even after the demographic variables were controlled, these two dimensions of justice perception explained 25% of the variance in OCB.

## 5. Discussion

First, results of this study suggest that individual differences can significantly influence perceived organizational justice. Specifically, within-cultural

collectivism and Machiavellianism have a significant association with three dimensions of perceived organizational justice. Given that collectivistic and individualistic employees stay in the same organization with equal decision-making procedures and equal treatment from supervisors, collectivistic employees are more likely than their counterparts to form fairness perception.

Statistical analyses showed that there is a significant relationship between within-culture collectivism and perceived organizational justice. The significant positive association between collectivism and procedural justice as well as interactional justice exactly reflects the value system of collectivists. However, collectivism was found to be positively related to distributive justice which measured respondents' perception of their individual payment in this study. This result is completely contrary to Choi's proposition [6] about the relationship between collectivism and individual outcomes. In other words, this study showed that collectivistic employees also concerned with individual outcomes. There are two possible explanations for this result. First, the distributive justice scale to assess employees' perception of their individual payment actually reflects an organization's distribution system that affects every employee equally. In other words, the fairness of the distribution system is a common interest to all employees. Thus, it is reasonable for collectivistic employees to form fairness perception of the distribution system for individual payment. Earley et al [18] argued that a collectivist's sense of self is based on both personal and group-based information. Not only does a collectivist benefit from knowing that his or her work group has been successful, but he or she needs to know about personal success as well. In a similar vein, it is reasonable for this study to find that collectivism has a positive association with justice perception of individual outcomes. Second, the respondents in this study were Chinese employees, whose value system increasingly changed with the goal priority shift in Chinese enterprises during the two decades of economic reforms in China [7]. Before the economic reforms in 1978, the objectives of Chinese enterprises were more sociopolitical and ideological than economic [25] [53]. This goal priority of Chinese enterprise was accompanied with individual payment to be officially determined by the bureaucracy. Thus, it was impossible for Chinese employees to care about their individual outcomes. Since 1978, the economic reforms have reduced traditional state protection for Chinese enterprises and motivated them to take responsibility for their own survival in the increasingly competitive open markets. Simultaneously, the drastic shift from sociopolitical to economic goals in Chinese enterprises has generated enormous psychological effects on Chinese employees. Chinese employees are allowed to focus on individual outcomes, which generally reflect their performance or ability. At the same time, we should note that Chinese employees still keep the traditionality to consider collective interest and interpersonal harmony of importance. Thus, the simultaneous influence of both the collectivistic tradition

and the economic reforms in modern China makes it reasonable that Chinese employees not only care about individual outcomes as well as group outcomes.

To date, little is known about the relationship between Machiavellianism and perceived organizational justice. As an important psychological construct that reflects individual inner value, Machiavellianism should be promising to predict perception. The result of this study fully demonstrated a significant negative effect of Machiavellianism on perceived organizational justice. High-Machs' focus on self-interests and their nature to manipulate others determine their tendencies to form unfair perception of outcome distribution, decision-making procedures and supervisor treatment in an organization.

Second, the result of the relationship between perceived organizational justice and OCB provides support for previous western-based research. Specifically, this study demonstrated a stronger predictive power of procedural justice than of distributive justice. Therefore, western-based findings about the relationship between perceived organizational justice and OCB are generalizable to the eastern context.

Third, this study provides insights into individual differences, namely, within-culture collectivism and Machiavellianism, as predictors of OCB, although we did not illustrate the relationships between individual differences and OCB in detail. The significant positive correlation between within-culture collectivism and OCB ( $r = 0.31, p < 0.01$ ) provides strong support for previous research on the influence of within-culture collectivism on OCB [36] [52]. Moorman and Blakely [36] found that within-culture collectivism is positively related to specific dimensions of OCB. Van Dyne et al [52] confirmed the result. Likewise, the additional finding about the significant negative relationship between Machiavellianism and OCB ( $r = -0.48, p < 0.01$ ) casts light on the possibility to examine whether Machiavellianism is a possible predictor of OCB. Wilson, Near and Miller [55] pointed out that high-Machs and low-Machs differ in many aspects of their behaviors. Moreover, previous research on workplace deviance has demonstrated a positive correlation between Machiavellianism and deviant behaviors, i.e., the anti-citizenship behaviors [3]. Therefore, it is reasonable for future study to examine the specific influence of Machiavellianism on OCB.

## 6. Implications

## References

[2] Ball, G.A., Trevino, L.K. & Sims, H.P. "Justice and unjust punishment: Influences on subordinate performance and citizenship," *Academy of Management Journal*, 1994, 37(2), 299-322.

Results of this study have both theoretical and practical implications. In terms of the theoretical implications, this study extends previous research on the influence of individual differences on perceived organizational justice by examining the association between within-culture collectivism and Machiavellianism and perceived organizational justice. Moreover, findings of this study do not differ from those based on the western context and provide support for the theoretical argument that justice perception is a potent predictor of OCB.

In terms of the practical implications, organizations may want to increase employees' justice perception because it plays a key role in motivating employees to engage in OCB while reducing deviant behaviors. Justice perceptions are influenced not only by individual differences but also by organizational structures, procedures and organizations. Therefore, organizations should create a favorable working environment, which sets stage for employees' perceived organizational justice. Organizations can, to some degree, assess job candidates' individual differences in recruitment process to predict their tendencies to engage in citizenship behaviors as well.

## 7. Limitations and Future Research

One limitation of this study is that data were self-reported. Although self-report has been used by research on OCB [5] [41], it would be ideal to obtain data from multiple sources. The problem with the use of self-reports is self-serving bias on the part of the respondents who wish to appear to be good citizens [38] and a ceiling effect, whereby OCB scores are clustered at the positive end of the scale.

This study examined the effect of individual differences, namely, within-culture collectivism and Machiavellianism, on perceived organizational justice and the relationship between justice perception and OCB among a group of Chinese employees. Future studies can examine whether organizational justice is a mediator of the relationship between individual differences and OCB. Niehoff and Moorman [37] demonstrated that justice mediated the relationship between methods of monitoring and OCB. Their study found that methods of monitoring had a negative direct effect on OCB and a positive indirect effect through three dimensions of perceived organizational justice as well. Future studies can also examine whether Machiavellianism is predictor of employees' reluctance to engage in citizenship behaviors.

# Applying Business Models for Risk Management in E-Business

Andrew Finegan  
School of Business Information Technology  
RMIT University  
Melbourne, Australia  
andrew.finegan@rmit.edu.au

## Abstract

This paper presents a case study of the application of business models for managing risk in the development of operational strategies for e-business. It includes issues of security, transaction protection, customer relationships, and data and content ownership. The investment that an e-business project is willing to make in risk management activities depends on the business model adopted, the experience of the project team, and the constraints imposed on both. This is particularly important when planning to use technology to do business in the global economy.

## 1. Introduction

In this paper e-business models, e-business development and operation strategies are examined within the framework of project risk management. A case study of a practical approach to project risk management is used to illustrate a specific project development strategy available to organisations working within the e-business environment.

## 2. Defining Project Risk

Project risk management is the practice of identifying, assigning, and responding to risk throughout the life of a project and with the goal of meeting project objectives [8, p.302]. Risk management can improve the process of selecting projects, determining the scope of project, and developing schedules and cost estimates. It assists project stakeholders understand the nature of the project, and encourages integration of the other project management knowledge areas.

Risk in itself is not bad; risk is essential to progress, and failure is often a key part of learning [3, p.172]. A project must balance the possible negative consequences of risk against the potential benefits of its associated opportunity. In many respects, risk management is similar to insurance. Schwalbe [8, p.303] defines it as an activity undertaken to lessen the impact of potentially adverse events on a project. Like insurance, risk management is an investment with associated costs. The level of this investment is dependent upon the nature of the project, the experience of the project team, and the constraints imposed on both.

Why do organisations continue to undertake e-business projects if they are subject to risk and may cause loss or injury? Schwalbe [8, pp.303-304] observes that many companies are in business today because they took

risks that created great opportunities. Organisations survive over the long term when they pursue opportunities based upon innovation [5]. E-business may now be a key part of a business's strategy; without it many businesses might not survive. However, Greenstein and Feinman [3, p. 172] warn "In the rush to deploy client/server and Web-related technologies and perhaps gain competitive advantage or generate higher revenue along the way few companies stop to consider that these systems may expose them to some operational and financial risks".

## 3. E-Business and Risk

Faced with the necessity to engage in new forms for business based upon information technology, organisations are finding that there are two major e-business risk issues - security and the protection of transactions. In addition, these organisations must also consider the potential difficulties that they may have in adopting e-business technology and the specific threats that e-business present to the organisations.

### 3.1 Security

Currently, the major barrier to e-business is the consumer's lack of confidence in Internet security [7, p.158]. For e-business to be trustworthy, it must be secure and reliable. Users must feel confident when revealing sensitive information like credit card details that this information will be kept safe and secure.

Security is a constant consideration of any network-based application. It must address the following issues while still providing users access to the information:

- Authentication,
- Access control,
- Firewalls, and
- Encryption.

Firewalls are a combination of software and hardware, which manage access between a company's internal system and the Internet [3, pp.158-159]. A firewall allows a network administrator to determine which services and types of information are accessible through your Internet connection. Firewalls must be used in conjunction with an overall security policy to be most effective.

Encryption can be used after data has left an internal system. Encryption renders the data unreadable by using a mathematical formula known as a key. The data is turned back into readable form, i.e. deciphered, by

applying the correct key. Secure payment systems that people trust are pivotal to the continued growth of e-business. New payment systems like digital checks and electronic wallets are currently being developed, but credit cards are still the most common form of payment [7, p.239]. To set up a credit card payment system on your web site you need:

- An acquiring bank that will establish an Internet merchant account
- Payment processing software to transfer the credit card details between your bank and web site
- A secure certificate for data encryption

The most common encryption protocol in current use is SSL (Secure Sockets Layer) that was developed by Netscape [6]. SET (Secure Electronic Transactions) sponsored by Visa and MasterCard is another encryption technology, which is a new standard to enable secure credit card transactions on the Internet [9].

However, Greenstein and Feinman [3, p.158] and Schneider and Perry [7, p. 162] emphasise that effective Internet security requires policy as well as technology. A good security policy will ensure:

- Safety - that sensitive information sent across the Internet is protected during transit
- Trust - that information reaches its destination without tampering
- Privacy - that personal information stored is available only to authorised personnel

Questions to ask when developing your policy include:

- Who needs to have Internet and e-mail access?
- Do staff check email and fax numbers before sending confidential information?
- Are sensitive documents encrypted before being transmitted?
- Are parts of your internal computer system restricted?
- What do you do when employees leave? Do you have a password policy?

Security is about an approach to information management. In particular, protection of confidential client information is going to become more important as companies gather more information about clients through doing business on the Internet.

### 3.2 Protection of Transactions

In any e-business Weill and Vitale [10, pp.315-317] argue that the important question is "Who owns the transaction?" Organisations owning the customer transaction are able to set a fee or collect a profit margin for the service provided. The service could be for the sale of products, the provision of information or advice, or the provision of a professional service. Therefore, owning the customer transaction has the potential to generate customer revenue for the service. Owning the transaction also implies that the organisation owns the customer data related to those transactions. However, perhaps no other customer data will be owned unless the organisation also

owns the customer relationship. Owning the customer relationship provides influence where the customer looks to the relationship holder for trust, recommendations, and specialist advice.

The strength of the relationship with the customer will often determine the success of the business. The relationship will be determined by the strength the value of the service to the customer and the ability to deliver. This strength of will involve the brand, the breadth of offerings, the price-value equation, and the completeness of the consolidation into a single point of contact. Information is the lifeblood of e-business. The viability of many businesses will depend on access to information about customers' products, markets, and costs. The organisations ability to identify, capture, share, and exploit the key information strongly influences business profitability [10, pp.259-261].

Content providers are organisations that create and provide information products or services in digital form to be used by customers via third parties. In general the content provider owns none of the end-customer relationship, transaction, or data. Therefore, to be successful the content provider must be highly desirable and in demand as a supplier of content. Furthermore, not owning any of the customer assets - relationship, data, or transaction - makes the content provider very reliant on third parties. On the other hand, content providers typically have a relatively small number of direct customers, and therefore they do not incur the costs of managing relationships with a large number of customers [10, pp.253-256].

### 3.3 Potential difficulties

Many traditional and profitable businesses are challenged by the need to respond to the threats and opportunities of e-business.

Most large traditional firms are successful and profitable, and they achieved their success via strong leadership and cultures suited to their industry. Weill and Vitale [10, p.13] argue that these leaders are often poorly prepared to make major strategic commitments necessary for e-business, and are reluctant to take the initiative, preferring to wait and see. This attitude actively works against new initiatives that threaten the status quo. The challenge is that senior management must actively work to shape the e-business vision, their employees, and the organisational culture into a new model for the way business is undertaken.

Channel conflict is a real risk with e-business. The Internet offers a new channel to the customer, and businesses can choose to bypass existing channel partners, leading to channel conflict. Particularly difficult to handle is channel conflict where the customer is offered very similar value propositions directly, and alternatively by an intermediary, but at different prices. Steps to help avoid channel conflict include [10, pp. 306-307]:

- Segment the channels by customer by targeting the customers for online selling.

- Segment the channels by product by distributing some products online, and other products via traditional channels.
- Refine the dealers' role by defining the role of the retailer as one of display, test-drive, and configure the product or service.
- Develop a new brand or re-badge the existing product to sell directly, giving these items a different value proposition to the products sold by the retailers.
- Establish an information Web site with product description, and perhaps a virtual community, and pass all leads to the retail channel (the distributors).
- Retreat from selling similar products, and avoid an un-winnable price war.

Weill and Vitale [10, p.15] also argue that infrastructure requirements for e-business are stretching the capabilities of many organisations' IT portfolios. Traditional organisations are struggling with B2B e-business implementations that may require integrating their recently installed and expensive enterprise resource planning systems (ERPs) with their Web sites and the Web sites of partner firms. Also, one of the major challenges for the direct-to-customer organisation selling a physical product is getting the right product to the right address, reliably and economically. Many innovative businesses have developed attractive Web sites, but have not developed a clear understanding of the complex logistics involved in e-business. In response, some logistics companies see delivery of goods ordered via e-business as an opportunity to expand their influence (FedEx).

The use of multiple business models across an organisation can cause confusion for customers, especially if the customer needs to adopt a variety of different business practices within the organisation. Where various business units within the organisation use different models, confusion can arise if the customer is treated as a different entity by each business unit. Furthermore, implementing more than one model can lead to the further problems described above, including channel conflict, competency conflict, infrastructure conflict, and information conflict [10, p.82].

### 3.4 Threats from e-business

Organisations must also consider the specific threats that e-business make to the continued successful conduct of business. A number of questions should be addressed.

How large is the potential for competitors to undermine the loyalty of the organisation's customers? Weill and Vitale [10, p.294] observe that loyalty has two important components - brand identification, and switching costs. If customers have high brand identification, based on lifestyles and other personal traits, they will be more loyal. If the switching cost for a

customer to change brands is high, then they will also be more loyal.

How large is the gap between the current and the potential customer self-service?

Customer self-service is defined as providing an attractive value alternative to customers who can serve themselves. An important question asked by Weill and Vitale [10, pp.294-295] is: "How much does your customer dislike dealing with your organisation in person."

What is the difference between your organisations current geographical reach and its potential reach with the Internet? Weill and Vitale [10, p.295] observe that the larger the gap, the greater the threat or opportunity from e-business. However, many organisations' geographical reach is limited by external constraints, including other countries' regulations, tariffs and the cost of transportation.

## 4. Case Study - Razoredge Limited

The following is a case study that is based upon a real world organisation - RazorEdge Limited. It illustrates a particular project approach to e-business development with attention to risk management issues.

The case is of an Australian buying group for retail business with the following profile:

- 700 Members (independent retailers) located throughout Australia.
- 500 Suppliers (manufacturers and/or importers).
- Au\$150 Million annual turnover.
- Gross profit margin is 2.5 - 3.5% (very lean!!!).
- 55 Suppliers use electronic data interchange (EDI)
- These suppliers contribute 65% to 75% of business.
- 70% of members have access to a computer.
- Employs about 40 staff in two groups - Marketing, and Finance and Management.

The major challenge faced by RazorEdge Limited is the fear that suppliers or others will use technology to exclude the company from the loop. Also, business models are changing, as are relationships due to technology. Specifically RazorEdge Limited seeks to achieve the following objectives:

- Greater efficiencies and reduction in costs.
- Better communication with our members, suppliers, and the wider industry.
- Form alliances with key suppliers without risking loss of business, especially direct trading between suppliers and members.
- Increase revenue through special products, supplier links, and bulk order taking.
- The new bottom line - "Branding" is essential - RazorEdge Limited - the business and the brand must be leaders in the market, both "real" and "electronic".

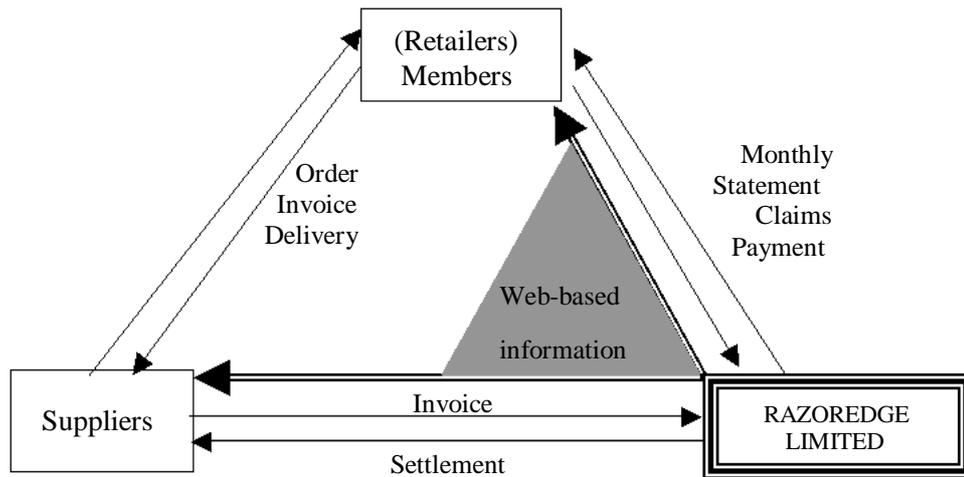

Figure 1 - RazorEdge Limited current business model

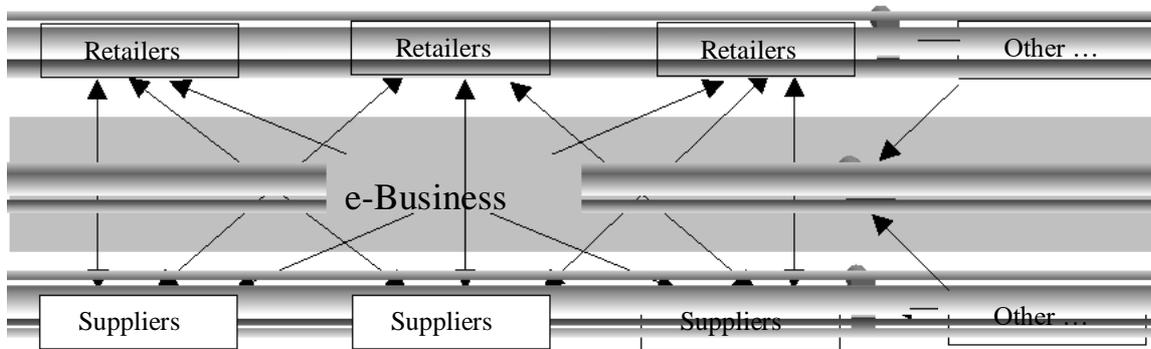

Figure 2 - Model of the Electronic Market  
(Adapted from Baron, Shaw, and Bailey, [1, p.94] & Weill and Vitale, [10, p.186])

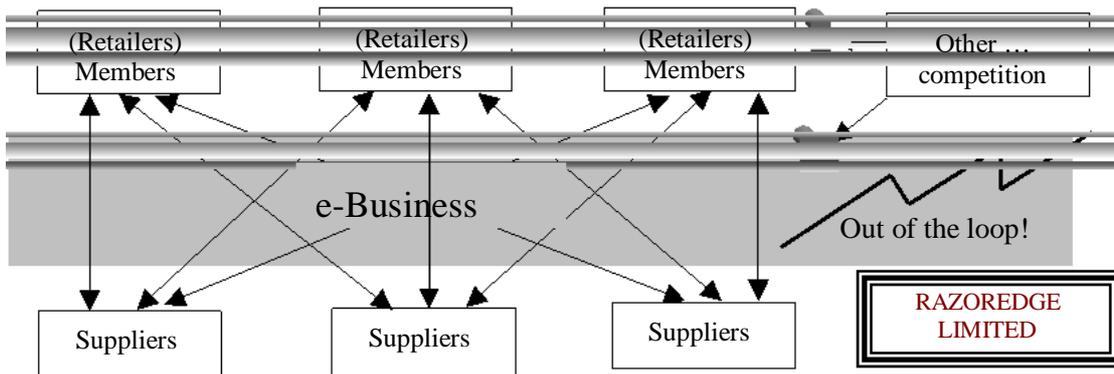

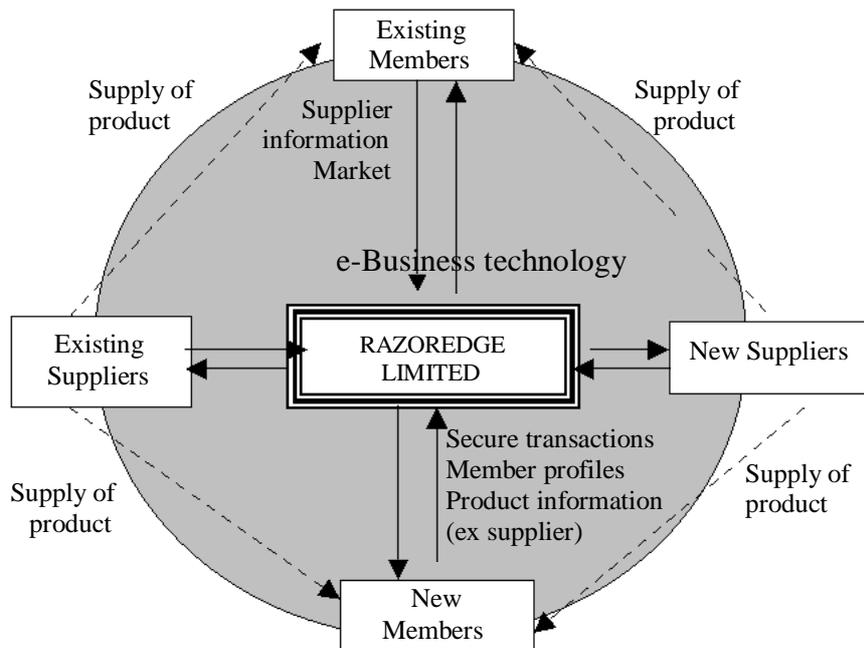

Figure 3 - The threat of the Electronic Market

The above model (Figure 1) represents RazorEdge Limited's current operations. It illustrates the major relationships that the company has maintained to achieve its business goals.

In evaluating the risk faced by RazorEdge Limited, the model of the electronic market (Figure 2) is an important consideration. This model has information technology

serving as a key component in creating the market. Individual firms operate within the electronic market using technology as an intermediary to interact with end customers. It allows firms to compete in an open market, while allowing customers to select from a variety of potential suppliers.

**Figure 4 - Suggested model for RazorEdge Limited**

As can be seen in the model in Figure 3, the Electronic Market is a potential threat to the continued operations of RazorEdge Limited. Therefore Figure 4 is a suggested model for RazorEdge Limited to minimise risk while achieving the key objectives.

In planning an implementation strategy based upon this model, RazorEdge Limited took into account that the e-business environment is characterised by rapid change in two critical areas:

- Information technology, the Web, and associated applications are constantly being developed and improved.
- The “users” understanding of their needs and the potential of e-business is also subject to growth. This can lead to considerable change in the system requirements.

Therefore traditional system implementation approaches are not ideal in this situation. Rather, it is recommended that prioritised initiatives be undertaken in a series of “short time-boxes” – one month duration – development cycles. This is an approach that has been developed for object-oriented systems development, which is closely aligned with e-business [4, pp.21-22]. These short development cycles, and the opportunity for frequent replanning are the critical elements for success. The suggested process is as follows:

- Identify the initiatives to be undertaken, and using these set priorities. The initiatives with the highest priority will be the first to be undertaken. Generally speaking, this will include review of the extendibility of the system architecture, as this will provide a component of the framework for future development.
- Plan the “project activities” for the next two months. Need to consider:

- Which knowledge elements to start with?
- What to develop first?
- What platforms to use?
- What roles and policy to establish?
- Regularly – 3 monthly or sooner if needed – review the initiatives and reset the priorities as required by the “current reality”.

Applying this to the RazorEdge Limited case, the following prioritised initiatives were established:

1. Product information - must be accurate, relevant and up-to-date.
2. Company information - including member profiles and supplier details.
3. Push information – trial intelligent agents to push product to market.
4. Develop membership community - with the focus on RazorEdge Limited.
5. Develop communication and negotiation support.
6. Information management - details of member history, delivery of orders, and claims.
7. Transactions capture – collecting details of transactions at line-item level.

The first three initiatives were successfully undertaken and implemented. The project was then reviewed and subsequent priorities replanned to accommodate the changing business conditions.

## 5. Conclusion

Before committing an organisation to an e-business project the following risk-oriented questions should be examined.

1. What is the combination (if any) of e-business models? This should also consider the sources of revenue, and whether they are realistic.
2. What customer segments are targeted, and what is the value proposition to each customer segments?
3. Who owns the relationship, data, and transactions, and what is the likely intimacy of the customer relationship? There is also a need to identify what are the channels to the customers and are they capable of supporting the required richness of information provision and capture?
4. What are the critical success factors, core competencies, IT infrastructure capability and the key information necessary to succeed?
5. What conflicts are inherent in the e-business initiatives?

# Implications of Virtual Interviews as a Global Recruitment Tool

Stevina Evuleocha  
Department of Marketing & Entrepreneurship  
School of Business & Economics  
California State University, Hayward  
Hayward, CA 94542  
sevuleocha@bay.csuhayward.edu

## Abstract

Global business environments have become increasingly competitive. Consequently, businesses are seeking newer methods to improve efficiency, reduce costs, market new products faster, and retain customers for the long haul. One of the methods that has emerged to aid businesses accomplish all these goals is computer-mediated communication (CMC) applications. Computer-mediated communication applications in employment interviewing have received some attention from businesses since the emergence of the Internet. Existing technology makes it feasible for employers to screen and interview prospective employees without these applicants leaving their homes globally. Current trends suggest that electronic recruiting will constitute a significant portion of human resource management activity in the future. This paper discusses (1) the employment interview and its role in virtual recruiting, (2) virtual interviewing within the framework of computer-mediated communication (CMC), (3) organizational applications of virtual recruiting systems, (4) virtual organizational communication and how its attributes lend themselves to implementing virtual interviewing in organizations, (5) the relationship between virtual organizational communication and virtual recruitment, (6) Internet-based interviewing in the context of transaction economics, (7) whether or not virtual interviews will replace traditional interviews, and (8) managerial implications of virtual recruitment and interviewing in organizations. This paper concludes by proposing areas for further research.

## 1. Introduction

Global business environments have become increasingly competitive. Consequently, businesses are seeking newer methods to improve efficiency, reduce costs, market new products faster, and retain customers for the long haul. One of the methods that has emerged to aid businesses accomplish all these goals is technology-based applications such as computer-mediated communication (CMC), multimedia, and the Internet, among many other indications.

The dynamic business environment in which companies operate also requires efficient allocation of resources among the various functions that a company must perform to remain competitive. Therefore, companies must decide which of their core functions they need to maintain in-house, and which ones they need to outsource. As fast-growing start-up companies or even the well-established ones engage in the task of episodic recruiting to meet their expansion goals or simply to fill vacancies due to staff turnover, some have turned to "virtual recruitment" [25] as a means of curtailing recruitment expenditures of their human resource departments.

Virtual recruitment allows companies to outsource the search and selection of quality candidates without having to hire more permanent human resource staff, or increase spending for one of a company's non-core activities, the employee recruitment process. According to the International Association of Corporate and Professional Recruitment (IACPR), it takes, on the average, about 4.13 months, to find and recruit suitable candidates [20]. Many companies are now using virtual recruitment as a viable means for recruiting workers.

The concept of a "virtual organization," where a company completely or partially outsources one of its non-core activities, is not novel. Over the past few years, the concept of outsourcing has received mixed reviews from the business world in terms of its effectiveness [25, p. 853]. The information technology (IT) industry has embraced the idea; so has the Human Resource Management (HRM) industry. Many companies are now reducing their non-core business activities such as employee recruitment and outsourcing such functions to consulting firms. Functions typically outsourced in the IT industry tend to focus on internal support services, such as management of servers and desktop computer support. Other industries such as the pharmaceutical industry also contract with external consulting firms to carry out large-scale clinical trials on products without having to maintain a complete department that would not be used for long stretches of time once a particular clinical trial is completed. Similarly, in the sales environment, industries are increasingly relying on outsourcing.

Companies outsource their employee recruitment function at varying degrees from a simple company-consultant relationship to business partnership agreements with shared goals. Regardless of the business relationship, outsourcing can offer a commercially viable alternative to setting up and maintaining departments that may not be used constantly, an option which is particularly attractive to companies faced with massive budget cuts. A company's employee recruitment function is a prime example of how virtual recruiting can be beneficial to the company. Recruitment for most companies comes in waves. A company may wish to insulate itself against an eventual lull in recruitment activity and the necessity to lay off human resource staff by engaging in virtual recruitment.

Given the growing interest in virtual organizations in management literature, there is a preponderance of research on the possibilities of virtual meetings, work teams, offices, factories, firms, and alliances. However, little empirical research exists on virtual organizations [12], and surprisingly, very little has been done on virtual recruitment. This paper is an initial attempt at setting an agenda for possible sustained research on the impact of technology-based systems such as virtual recruitment systems on employment interviews. This paper discusses (1) the employment interview and its role in virtual recruiting, (2) virtual interviewing within the framework of computer-mediated communication (CMC), (3) organizational applications of virtual recruiting systems, (4) virtual organizational communication and how its attributes lend themselves to implementing virtual interviewing in organizations, (5) the relationship between virtual organizational communication and virtual recruitment, (6) Internet-based interviewing in the context of transaction economics, (7) whether or not virtual interviews will replace traditional interviews, and (8) managerial implications of virtual recruitment and interviewing in organizations. This paper concludes by proposing areas for further research.

## **2. The Employment Interview and Virtual Recruiting**

The employment interview is an interactive process in which the prospective employer and the applicant assess and select each other. Organizations typically use the interview to recruit and select employees. Even though extensive research exists concerning the selection of applicants, recent changes in competitive markets have made the ability to attract and retain the very best employees more critical to organizational success. Organizations are constantly looking for the most efficient and cost-effective means of conducting employment interviews. Given recent advances in computer-mediated communications (CMC), especially the pervasiveness of technological advances such as multimedia and the Internet, personnel recruitment vendors are busy

developing new virtual (electronic) recruiting systems to enable both companies and applicants participate in the employment screening and selection process quickly and in the most cost-effective manner. Recruiters can also conduct global recruitment using technology-based solutions.

Of particular significance to using virtual recruitment systems to select candidates is the risk which traveling to distant locations has now imposed on recruiters and applicants given the current climate of global terrorism, exacerbated by the September 11, 2001, attacks in both New York City and Washington, D.C.

Other issues which have motivated companies to consider using technology-based recruitment systems, in addition to the simple objective of selecting the best candidate who has a great "fit" with the organization, have become paramount. These issues include the proximity of the applicant to the recruiter (the location of the applicant and the recruiter which attenuates the specter of potential terrorist attacks against the applicant and the corporate recruiter), the most appropriate channel to use in conducting the interview (written, interpersonal, or virtual), and which medium affords the participants the best opportunity to evaluate each other.

Employment interviewing and recruiting is an expensive, high-stakes game. Even for relatively unskilled employees search costs can amount to several thousand dollars. The U.S. Department of Labor estimates that it costs a company one-third of a new hire's annual salary to replace the previous individual [37], while other sources propose figures in the range of 1.5 to 2.5 times annual salary [7]. Moreover, unsuitable employees waste valuable firm resources, including compensation, training, and supervisory effort. Simple, comprehensive, and effective methods of identifying and screening potential employees are an attractive tool for employers.

Technology-based recruitment applications have received significant attention from businesses since the emergence of the Internet. Existing technology makes it feasible for employers to screen and interview prospective employees in geographically dispersed locations nationwide and globally. Current trends suggest that virtual recruiting will constitute a significant portion of human resource management activity in the future.

One of the major activities involved in recruiting high-caliber employees is the employment interview. Employment interviews fall under the rubric of interpersonal communication which will be impacted by the all the elements of the communication process: sender, receiver, message, channel/medium, feedback, and environment. While trade publications, college Web sites abound with information about virtual recruiting, very little research-based studies exist which explain the extent to which technology-based systems will impact employment interviews conducted in a "virtual" or electronic environment.

### **3. Computer-Mediated Communication and Virtual Interviews**

Computer-mediated communication (CMC) systems have now become an integral part of society, since they span education, industry, and government. In order to appreciate fully the impact of CMC on various organizational processes, it is necessary to define the term, since CMC means different things to different people.

Computer-mediated communication (CMC) refers to both task-oriented and interpersonal communication systems conducted using computer. This includes asynchronous communication (via e-mail or electronic bulleting boards); and synchronous communication ("chatting" or group software); and information manipulation, retrieval and storage through computers and electronic databases [17]. CMC is a process of human communication via computers, involving people, situated in particular contexts, engaging in processes to shape media for a variety of purposes [10]. Other researchers have attempted to reconcile the various attempts at defining CMC by offering this perspective--CMC comes in increasing number of forms; the technologies for mediating CMC are changing rapidly; diversity of users and uses is increasing; and many forms of CMC, particularly where interpersonal communication is concerned, seem to explicitly or implicitly serve multiple purposes. For instance, Murray presents an approach to CMC which treats CMC as a form of communication that is socially constructed, is subject to multiple research methods, and renders any attempt at overt generalization meaningless [27].

Virtual interviewing (VI) is an umbrella term which refers to a variety of computer-mediated communication (CMC) tools used to screen, recruit, and hire employees in geographically dispersed locations. Whereas electronic mail has been a frequent subject area for previous communication research, the global Internet today offers a more diverse set of tools and contexts for communication than it has in the past.

The drive to improve efficiency has given rise to an elevated interest in technology management ranging from ownership to use of new technologies. While many technologies tend to be of primary interest to one or two industries, almost all industries have an interest in information technology (IT). Most companies today cannot function without a computer system. These have been employed in all business areas, from education to manufacturing to construction. Management personnel are realizing that their competitive edge may hinge on the ability of their computer and communication systems to respond quickly to changing business needs. Consequently, business has to stay abreast of competitive moves in the use of CMCS and in many cases, be prepared to stay ahead of the competition [19].

A growing consensus amongst scholars, politicians, business leaders and the news media is that technologies traditionally referred to as new media are indispensable to the sum activities now referred to as electronic-commerce (e-commerce) and business-to-business (B2B) [32]. New media incorporates what is commonly known as multimedia. The term multimedia generally refers to the convergence of images, graphics, sound, voice, videotext and tubular information within a human interface that uses capabilities to access and present information. The primary marketing advantage of CMCS these days is the inclusion of multimedia facilities [21]. Such facilities may be used for videoconferencing, personnel training, as well as an interactive mechanism between management and employees or potential employees.

In contrast to long-distance telephone interviews, videoconferencing enables the candidate and the interviewer to see each other on screen. Moreover, better cameras and clearer links have improved videoconferencing in recent years. Even employers who prefer the traditional face-to-face interview concede that video technology is useful for weeding out undesirable job candidates. The employer is able to study the interviews in close detail and can replay parts of the interview to assess reaction or response—something not possible in a conventional interview. The next section discusses some applications of virtual recruiting systems which various organizations are now using to satisfy their employee recruitment needs.

### **4. Organizational Applications of Virtual Interviewing Systems**

Technology is changing how companies recruit and select applicants [36]. Even though virtual hiring technologies are still in their infancy, current virtual hiring technological advances have the potential to enable recruiters to reduce hiring cycle times by 90 percent, anticipate what skills will be in demand before they can be articulated, and call up information about a potential candidate on their computer screens.

The growth in the use of CMC during the last decade surpassed even the most optimistic predictions [13]. The pervasiveness of CMC has spurred intense competition among companies that produce "virtual" (electronic) employee recruitment solutions. These solutions vary in terms of their delivery modes and across a wide range of industries, companies, and applications.

One form of CMC content delivery is videoconferencing via the video. Its effectiveness has been well documented elsewhere [4] [9]. Videoconferencing enables geographically dispersed parties to communicate with each other in real time, and asynchronous video presentations enable participants to access the contents of the video from anywhere, and at any time [35]. Videoconferencing can slash recruiting travel expenditures by 20 percent [20, p. 87]. With enhancements in video quality (30 frames per second, on par with television), some companies are now making videoconferencing a part of their recruitment arsenal.

Best International, a computer recruiting company, regularly uses videoconferencing to conduct employment interviews overseas. The technology not only eliminates the cost of overseas travel but expands the firm's recruitment base and saves time in screening job candidates. These days, thousands of companies like Best are turning to technology as a recruitment tool. Businesses are conducting virtual interviews from remote locations by establishing videoconference links around the world. Some companies videotape interviews of overseas job candidates, transfer the tapes to CD-ROM, then view the interviews at their convenience. Others use electronic file transfers, downloading interviews as e-mail files; and computer experts predict that conducting interviews via real time Internet video chats will become commonplace in the near future.

AT&T, Dell Computers, Shell Oil, Compaq Computer, and Nike are using videoconferencing to screen and select candidates. Other companies are using in-house systems which cost anywhere from \$10,000 to \$35,000, to screen candidates around the country. Management Recruiters International (MRI) in Cleveland, Ohio, uses a videoconferencing system called ConferView, to screen job applicants in 380 MRI offices. Hire Intelligence, a web-based recruiting firm in Houston, Texas, provides a service which allows recruiters to videotape interviews to a website. Corporations log on to this site ([www.hiirs.com](http://www.hiirs.com)) and check out candidates for free [36]. Kinko's rents videoconferencing rooms at a quarter of its 900 stores for about \$150 per hour; National Career Center in Boulder, Colorado, offers similar services in a more intimate setting through its SearchLINC videoconferencing system. This system is available through deals with major hotel chains such as Radisson and Hilton, and is expected to increase in the next few years.

Another form of CMCS is Interactive Voice Response technology (IVR), which has been used for a long time, is now being integrated with other database technologies to capture information about potential employees, giving the company more flexibility and speeding up hiring decisions [36, p. 73]. Some companies have used is computer-assisted interviewing online to find the right hires.

Nike has used an AspenTree IVR technology product to hire employees for Niketowns, retail stores that showcase Nike products [36, p. 75]. The computer interview (which includes a video showing three scenarios for helping a customer and asks the applicant to choose the best one) is conducted in batches. A group of applicants is given 45 minutes to respond to the scenarios. As applicants complete their interviews, a printer in another room prints their responses. Areas that need to be probed further are flagged including indications of applicants' particular strengths. While applicants complete a virtual interview, the recruiter uses the applicant's printout to prepare for face-to-face, human interview. Since Nike uses behavior-based interviewing, virtual interviewing not only helps Nike's interviewers screen for applicants who lost their temper in work situations or who demonstrated other undesirable behaviors, it also helps interviewers to determine what to ask to reconcile inconsistencies in the virtual interviews or to probe applicant strengths in desired areas.

Coopers & Lybrand, one of the first companies to put its computer-assisted interviewing system on the Internet, also uses an Aspen Tree product. The company uses a website called Springboard. Applicants complete an employment application and four initial screening modules at their convenience by accessing the website and the Strategic Selection Advantage (SSA) Online application. The company has found a high correlation between high job performance ratings and superior performance in the SSA Online application. By taking the technology to the Internet, a company can reach prospective employers.

Innovex, Inc., a division of Quintiles Transnational Corp., a contract pharmaceutical company produces late-phase clinical studies to long-term marketing partnerships with pharmaceutical companies, uses an IVR product developed by TelServ of Cleveland, Ohio. Innovex uses IVR primarily to eliminate much of the labor of having people sift through large volumes of resumes. Applicants who respond to job advertisements call a toll-free number. They are asked a series of questions by a machine and those who meet the basic criteria are then referred to Innovex for face-to-face interviews.

Olsten also uses IVR technology developed by Wonderlic of Libertyville, Illinois, to prescreen applicants. According to Adrienne Plotch, vice president of professional service, IVR has saved the company significant staff time, and is accessible by applicants any time.

In spite of their widespread use, recruitment experts acknowledge that CMC systems use will increase, but it will not replace the personal interviews. Final interviews will always be face-to-face, in person.

## **5. Relationship Between Virtual Organizational Communication and Virtual Recruitment**

A virtual organization has been described as a collection of geographically distributed, functionally and/or culturally diverse entities that are linked by electronic forms of communication and rely on lateral, dynamic relationships for coordination [12]. The components that make up a virtual organization are geographically distributed, functionally or culturally diverse, electronically linked, and connected via lateral relationships. These attributes enable the organization to dynamically modify business processes to meet market demands, to coordinate via formal and informal contracts, to define the boundaries of the firm differently over time or for different customers or constituencies, and to re-arrange relationships among components as needed. These attributes lend themselves well to virtual recruitment whereby some organizations establish relationships at different levels to enable them carry out certain non-core organizational functions such as employee screening and recruitment.

Few pure virtual forms exist today [14]. Instead, aspects of virtuality occur in many business enterprises. For example, although most companies still maintain a divisional structure, they increasingly are forming external relationships with other firms in the form of strategic partnerships, alliances, and outsourcing contracts [26] [28]. In addition, rapid advancements in telecommunication technologies have enabled more telecommuting and cooperation among physically distributed employees [2]. These trends suggest that firms are acquiring more virtual characteristics than in the past. Even firms that may not look virtual on the surface are organizing selected activities and processes, such as employee recruitment virtually.

Communication is fundamental to any form of organizing, but it is preeminent in virtual organizations. Without communication, the boundary-spanning among virtual entities would not be possible.

Virtual (electronic) communication enables parties to link across distance, time, culture, departments, and organizations, thereby creating "anyone/anytime/anyplace" alternatives to the traditional same-time, same-place, functionally-centered, in-house forms of organizational experience [30]. Virtual communication loosens constraints of proximity and structure on communication, making it possible for spatially or organizationally distant parties to exchange messages with one another [16]. Further, virtual communication provides an opportunity to signal interest in forming connections that otherwise would be difficult or impossible to maintain [18].

The exact nature of communication processes in virtual forms, their antecedents and consequences are, of course, unknown as of yet. However, it is possible to glean some insight from the rich body of literature on synchronous and asynchronous electronic organizational communication. Employee recruitment will certainly continue to become more electronically mediated than in the past, and the vast set of empirical findings regarding mediated communication can foreshadow how employee recruitment will change as firms "go virtual" with their employee recruitment needs.

## **6. Internet-based Interviewing and Transaction Costs**

The strategic use of Human Resource Management (HRM) to enhance organizational performance has been examined in the literature. This approach "suggests that HR (both the function and the system) contributes directly to the implementation of the operating and strategic objectives of firms" [3]. The fact that progressive human resource practices which affect employee skills, motivation, and work design are associated with improved organizational performance, and an important component of those systems is "sophisticated selection procedures designed to screen out all but the very best potential employee" has been documented in empirical studies [11].

Although different conceptual models can be advanced to explain the links between HRM and organizational performance, transaction cost theory provides a particularly useful framework of analysis of the implications of new technologies in hiring employees. A fairly important issue of transaction cost economics is concerned with the nature of economic organizations as distinct from labor market exchanges. Therefore, transaction cost theory suggests that electronic recruiting could quite conceivably become the technological watershed of employment relations. This is because when viewed from a perspective of competitive advantage, Internet hiring for instance, will most certainly affect organizational strategies to maximize the value of limited labor resources [23].

According to transaction cost economics, organizations hire workers when the cost of purchasing labor on the open market surpasses the cost of long-term, relational contracting. At the core of this doctrine summarized is that "transaction cost economics is an effort to identify, explicate, and mitigate contractual hazards. In general, all hazards can be attributed to the twin behavioral assumptions from which transaction cost economics works: bounded rationality and opportunism" [38]. One can conclude from the behavioral assumptions, that an employment contract is necessitated when contingencies cannot be fully addressed through ex ante agreement.

Neither employers nor employees possess sufficient information to identify and negotiate over critical issues arising out of the labor purchase; thus, an independent contractor or market relationship is unacceptable to the parties [22]. Both employees and employers will strive to gain economic advantage from the relationship because of opportunism and the need to protect self-interest.

Two other characteristics that affect employment are: "fundamental transformation," and "asset specificity" [38]. In "fundamental transformations," even though the employment process starts out with large numbers bidding at the commencement of contracting, what happens later is ongoing dealings between parties. In "asset specificity," owners and workers come to a position of bilateral dependency through acquisition of firm-connected skills, unique technologies, and other idiosyncratic factors [38]. Because the costs of market transactions under such circumstances may be high, relational contracting through employment and its governance procedures minimizes contracting hazards [23]. Also, researchers have noted that internal corporate hierarchies and lavish upper management incentives inoculate organizations against hiring errors by restricting access to entry-level positions. Hence, opportunists are less likely to exploit firms by seeking lateral transfers. The preceding ideas are relevant to this analysis of the implications of virtual interviews as a global recruitment tool.

First, virtual interviews (VIs) expand the prospect of global recruiting. There are no effective geographical restrictions on the technology used for VIs. The potential reach for VIs offers the most expansive applicant pool with almost real time communication between buyers and sellers reminiscent of the large numbers bidding scenario that has been referred to as "fundamental transformations" [38]. The sheer size of the applicant pool that can be achieved using VIs guarantees organizations access to a wide pool of prospective applicants and quite likely, the most qualified. Invariably, competition for labor will subsequently generate repeat recruiting using VIs.

Secondly, the large number of potential applicants that VIs can attract calls for efficient methods of screening. VI is an efficient mechanism for rapidly eliminating unsuitable candidates thereby reflecting Williamson's earlier take on "fundamental transformation." Naturally, some problems cannot be fully eliminated. There is no foolproof way of ascertaining the truthfulness or accuracy of information on an audio tape or video tape, however, similar issues are encountered in traditional interviewing methods as well [24].

A third and final reference to transaction cost economics sheds more light on the relevance of employment trends. As Williamson points out, if markets could perform the "experience-rating functions," the need for entry level hiring and job progression would be mute. Recent research has documented apparent shifts in employment from job security and internal labor markets to flex work environments, virtual offices and outside contracting. These trends are driven by powerful forces undermining traditional employment practices [6]. To show how these trends are progressing with respect to white-collar employment, three factors driving the "transformation of managerial work" have been identified [31]. These factors are competitive pressures to reduce labor costs, new information technology, and the new ways of organizing work. A plausible implication is that these changes will likely affect the nature of managerial tasks and influence career patterns as ladders become shorter, the organization becomes flatter, and boundaries of all kinds become permeable.

Other researchers predict similar developments in work of all types. At the dawn of a new era in organizations, the boundaryless career has emerged as one of the new principles of employment. Some experts have even predicted the "end of the job" as employers shift toward contingent, short-term contracting [1] [5]. Others foresee a technological revolution which will generate massive upheavals in labor markets [33]. At the very least, job trends will probably result in a break with traditional approaches to HR functions [22]. One can reasonably conclude that organizations will become more sophisticated in acquiring and analyzing information about individuals and less reliant on long-term observation of work performance in evaluating employees. Technology will obviously play a prominent role in these changes.

It is clear then, that employers have reasonable motivation to use electronic technology for purposes of conducting job searches and recruiting qualified applicants. Although external factors create incentives for organizations to develop and implement strategic information systems, legal considerations may impose some constraints on the electronic job market.

## 6.1 A Basic Distinction

For practical reasons, a basic distinction about the possible tools for virtual interviews will be assumed. We will distinguish between real-time communication tools, such as Internet Relay Chat (IRC) and the forms of interpersonal communication allowed by Multi User Dimension, Object Oriented (MOO) and Multi-user Domains (MUDs) on one side; and delayed communication tools such as email, on the other. Real-time communication tools allow interactivity, the exchange of an immediate two-way flow of information. Delayed ones do not. This has certain implications for their performance.

IRC, MOOs and MUDs allow people to meet and interact. IRC is aimed at providing chat, enabling its users to literally talk to each other, in the sense that questions and answers actually follow each other. MOOs and MUDs are virtual environments where people can interact, based on Telnet.

The shortcomings of real-time communication tools are related to their interactivity. What we are used to, as real-time talk, is immediate question and answer. That is possible only partially on IRC, for instance. There still is a considerable delay between the subsequent messages, which sometimes makes the communication quite strange: you might ask a question and get an answer which was intended for the previous question. One has to type his/her message and submit it quickly, so it is not 100 % interactivity. However, the development is very fast and we are getting closer and closer to "true" real-time.

## 6.2 Interviewing via E-mail

The alternative to the previous methods of virtual interviewing is email. With email, interviewers formulate their questions, mail them to interviewees, and patiently wait for an answer. An email user does not expect any interactivity. He/she will formulate the questions as clearly as possible, and very straightforwardly, to reduce the chances of misunderstanding. Moreover, the interviewee has all the time to answer the questions, can reflect about it, and thoroughly explain details. E-mail is great for research interviews, dealing with complicated or controversial matters. Encryption technology now allows users to protect their messages.

E-mail also has a few shortcomings. Among them is of course the time delay between the mail containing interview questions, and the mail from your interviewee with answers to those questions. Moreover, nothing guarantees that your mail will be answered promptly.

## 7. Will Virtual Interviews Replace Traditional Interviews?

Videoconferencing is not a substitute for a face-to-face interview, and a personal meeting would always be the first preference. But the advantages sometimes outweigh the disadvantages. This technology saves time, money and allows several locations to connect at once, in spite of major time differences.

We are all living in a world where technology is changing practically every instance. The place we go to work is also experiencing radical changes due to similar reasons. Every organization is trying its very best to capture market shares using cutting-edge customized solutions. This trend has also affected the way organizations are structured. Recent trends in organization structure suggest that they will become increasingly distributed, flexible and responsible to environment and market changes. The networked organizations emphasize on the multidisciplinary work arrangements linking people across organizational boundaries, less clearly defined authorities and multidirectional communication patterns [33].

The benefit of using diverse means for human resource practices cannot be overemphasized. The term multimedia has been coined to encompass a document or presentation that includes several delivery modes, and in practice, is used almost exclusively for computer-based material [34].

The appeal of network videoconferencing as a virtual interview tool for instance, derives from the breadth of interaction it offers; the user can see as well as hear the individual or members of the group at the other end. Even low-end videoconferencing systems offer interesting features such as document/application sharing and whiteboard tools that work across electronic conferencing links. These tools and applications make collaboration easy and reduce travel expenses.

Other factors contributing to the growing interest in videoconferencing include better compression techniques, maturing standards that encourage interoperability, high-speed LANs and WANs that support the data requirements of video, and high-performance multimedia computers. In addition, operating systems are multimedia enabled. Microsoft Windows includes a videoconferencing package called NetMeeting.

New uses for videoconferencing are also helping to drive development. In work environments, it is being used for tech support, distance learning, telemedicine, job recruiting interviews, direct sales, legal work, telecommuting, and manufacturing.

Employers can now see and judge appearance and body language to get a deeper sense of what applicants have to offer before flying them cross-country for interviews. This includes the capability of viewing applicants at multiple sites, in various states and countries, at the same time.

The potential for savings is obvious. Renting a videoconferencing room - the preferred option for companies who lack their own remote facilities --rarely costs more than a few hundred dollars per hour. Travel and hotel costs can easily exceed \$3,000 [15]. Arguably, a more important benefit is the expanded labor pool that videoconferencing lets an organization reach.

## **8. Managerial Implications of Virtual Interviews**

The possibilities offered by virtual recruiting are great when it concerns social relations. Organizations can reach a lot of people in geographically-dispersed locations and gather first-hand information from job candidates--that is, by conducting virtual interviews with people wherever they are in the world, and at a very cheap price. In spite of the widespread applications of virtual interviewing, several managerial implications are noteworthy.

First, there is no consensus among recruiters regarding the efficacy of virtual interviewing in recruitment decisions. Some argue that virtual interviewing makes it fairer for everybody, helps the interviewer choose the right people for the job, streamlines the hiring process, and allows the company to capture data that can be used later in hiring waves or in employee development and succession processes [36, p. 78]. Other recruiters are uncomfortable with virtual interviewing since they consider it a form of in-depth electronic profiling. They fear that electronic profiling will exclude people who do not fall within the desired response range, even though the applicant may have skills the company really needs. In fact, they contend that Bill Gates would never had been hired for computer work if profiling had been used [36, p. 78-79].

Critics of virtual interviewing also contend that human interviewers may pick up cues that virtual interviewing could not. By factoring in information the computer cannot anticipate, interviewers would be able to make better selection decisions. If profiling selects people who have the same personality traits, diversity, which can be a company's asset, may be lost.

Even though vendors of computer profiling products claim that the profiling done is often a safeguard against exclusion, some critics see computer profiling as a way for companies to exclude minorities [36, p. 79]. These vendors claim that they continuously test their data to ensure that questions do not automatically exclude any group.

Secondly, virtual interviewing is vulnerable to charges of discrimination under Title VII [23, p. 160]. Civil right laws prohibit employment practices which have a differential or disparate impact on specific groups. On one level, virtual recruiting can produce adverse impacts in the same way as any other procedure, such as a written test or an educational credential. A second and more problematic aspect of online recruiting, however, is that the technology itself may select against certain protected groups. That is, access to employment on the Internet arguably excludes racial minorities, women, and older workers in greater relative numbers than young, white males for example.

The National Telecommunications and Information Administration (NTIA) used Census Bureau data to develop a profile of Americans' telecommunications access [29]. NTIA found that the "information have-nots" are disproportionately located in rural areas and central cities. Broken down by race, data indicate that rural black households have the lowest computer ownership of any group (6.4%), followed by Hispanic (12%) and Native American (15.3%). Rural whites and Asians have the highest ownership, at 24.6% and 33.7%, respectively. Similar disparities appear in the central city populations. When minority households do have computers, they are less likely than whites to have an Internet modem connection.

The NTIA survey also showed further differences in access to computers and modems by age, income and gender. Individuals under 25 and over 55 are the least likely to own computers. Among those owning computers, those between the ages of 25 and 34 have greatest access to modems. Moreover, as education and income increase, so does the likelihood of owning the necessary technology for Internet use. In a separate study analyzing the Census Bureau data, the author found that women are slightly less likely to live in households with computers [8]. Invariably, certain groups appear to have unequal access to the Internet.

While virtual interviewing holds great promise as a viable recruitment tool, this technology-based tool is not yet ready to replace the traditional face-to-face mode of interviewing. Also, even if groups which feel disenfranchised by virtual interviewing cannot successfully challenge virtual interviewing as unfair employment practice, the possibility presents a realistic threat to global implementation of virtual recruitment processes.

## 9. Conclusion

This paper has attempted to show proliferation of options available to organizations when they choose virtual interviews as a recruitment tool. It is apparent that VIs can help HR practitioners to locate and attract qualified applicants in a competitive labor market. The paper has argued that Internet-based recruiting will grow. By expanding HR procedures to include the Internet, recruiters can benefit from an inexpensive, convenient, and innovative process to attract potential employees. Employers can minimize the risk of discrimination claims by supplementing electronic recruiting with more traditional sources.

Virtual interviews will inevitably play a prominent role in human resource management activities. The Internet for instance, has the potential to profoundly reshape employee recruitment and selection, and its promise as a strategic tool in organizational staffing goals appear immense. If organizations are cautious, HR professionals can realize the benefit of using computer technology to identify and select employees while maintaining a diverse workforce and avoiding legal complications.

A pervasive theme in this paper the focus on communication volume and efficiency. Compared to face-to-face communication, virtual communication appears to increase the overall amount of communication between or among communicating parties. There is no doubt that people perceive significant differences in communication channels, but the hierarchy of preference is not clear. For example, will recruiters prefer face-to-face and telephone over computer-based conversations? What salient factors do recruiters consider in choosing communication media?

Assuming communication volume goes up in virtual organizations, it is safe to assume that intense pressures for communication efficiency will also occur. However gains in communication efficiency for a given task, especially employee recruitment, may be difficult to achieve electronically. The literature strongly suggests that problem solving and task completion are not faster when electronically mediated. Achieving efficiencies that are needed in the dynamic process design of virtual organizations will continue to be a challenge, requiring more systematic research.

changd@mscd.edu

## Abstract

Thanks to the tremendous growth of e-commerce, the U.S. economy has gone through rapid facelift. New start-up companies and existing retail power players compete for market position in the new millennium. Traditional retailers engage in business model reengineering to keep up with the changes in how customers acquire goods and services. How to attract on-line shoppers to their sites has become a fundamental task for Internet marketers. The present study examines how on-line shoppers perceive their on-line shopping experience in a major metropolitan area. An Internet shopping model, implications, and future research directions are offered.

## 1. Introduction

The explosion of e-commerce has dramatically changed the landscape of the U.S. economy. The combined monetary value for Internet-related businesses is expected to grow to around \$1.4 trillion by 2003. In the business-to-business sector, Internet technology facilitates numerous infrastructure changes in information exchange and procurement and distribution process. While the business sector accounts for most of the value of Internet commerce (estimated at \$1.3 trillion by 2003), rapid growth in the consumer sector propels traditional retailers to tap into this vast, yet unpredictable, business domain. In 2001, Web retail sales accounted for approximately 2% of total US retail sales. Although the U.S. economy have suffered significant decline since early 2001, the Internet sector continues to expand.

The fast development of the Internet infrastructure introduces new opportunities that are rarely seen in recent world economy. With assistance from the latest advancement in internet technology, on-line marketers rush to establish positions in newly identified niches and to acquire new competitive advantages. One distinct advantage for Internet marketers is the ability to reach a large number of consumers scattering around in various geographic locations, including hard-to-reach areas, in a matter of minutes or hours. Another advantage is its attractiveness to younger generations that are heavily sought after by many marketers, such as Pepsi, McDonald's, and major advertisers. Media spending on the Internet have been estimated to reach \$20 billion by the year of 2001. Adding Internet advertising to the

promotional mix has become a common strategy used by major advertising agencies and marketers. It has been reported that banner advertising on web pages is as effective as typical TV commercials. With more than 50% of the U.S. population are on-line in 2002, marketers have to contemplate how to connect with on-line users effectively and efficiently.

The dramatic growth in e-commerce also introduces new challenges in customer services. More consumers lodge complaints with various consumer agencies. The most common types of complaints concerned Internet marketers include refund and billing disputes, product return policies, defective products, inadequate infrastructure, and poor customer services. Consequently, an ensuing managerial issue is how to evaluate the quality of the consumer's on-line shopping experience. In the long run, on-line marketers who are able to maintain competitive advantage by providing superior shopping experience are more likely to prosper in the newly emerging marketing channel.

The present study examines consumers' on-line shopping experience based on various criteria and explores the determinants of customer satisfaction with on-line purchases. The results provide directions for future research for marketing researchers and managerial implications for on-line marketers. The following issues are examined:

- How do on-line shoppers describe their on-line shopping experience?
- What are the fundamental dimensions of the quality of one's on-line shopping experience?
- How do the underlying dimensions influence on-line shoppers' satisfaction?
- What are the financial consequences?
- Is there a common model of on-line shopping experience?

In-depth interviews were conducted with thirty-five consumers, who had purchased at least once from the Net in the past 12 months, from a major western metropolitan area to gain insight on consumers' perceptions and evaluation of their Internet shopping experience. Consumers were asked to elaborate on the following questions:

- past on-line purchases;
- reasons for buying from the Internet;
- self-described on-line shopping experience;

- intention for repeat purchase;
- issues and concerns for on-line purchases.

The results indicated that consumers bought a wide variety of products from the Net. Books, music CDs, airline tickets, computers, and computer peripherals and supplies were the most frequently mentioned products. When asked why shopped from the Internet, price and convenience were the two main reasons. In addition, respondents also mentioned it was fun to shop or browse on the Internet. For some hard-to-find items, such as supplies and replacement parts for out-of-date computer products, the Internet was the most efficient source. A few consumers also liked the large selection of products offered by Internet marketers.

A questionnaire was developed based on the results from the in-depth interviews. The questionnaire was revised and validated based on a pretest with a few experienced on-line shoppers. Prospective on-line shoppers were selected and recruited using a cluster sampling procedure. Interviewers were instructed to contact and recruit a number of respondents in their assigned neighborhood through telephone inquiries. Respondents were requested for referrals for other potential on-line shoppers from the same neighborhood. Data collection was completed a week before the Christmas shopping season. The procedure yielded 306 valid responses.

## 2. Results

Seven common attributes, price, convenience, quality, variety, immediacy (immediate interactive response), hard-to-find, and fun, were identified from in-depth interviews. Respondents were asked to choose the primary reason for shopping on-line and rank all listed reasons. Convenience was the most frequently chosen reason for shopping on-line, followed by price. When asked to rank all of the attributes, price was ranked as the most important factor, followed closely by convenience. Price and convenience were clearly the two main reasons that respondents chose to shop from the Internet.

Respondents' shopping experience was measured by a variety of items based on the findings from in-depth interviews. An overall satisfaction rating of 4.34 on a five-point scale (5=very satisfied) indicated a high level of satisfaction. Among all respondents, 87.1% indicated that they were satisfied or very satisfied with their on-line shopping experience. On various experience items, convenience-related items, such as ease of transaction and overall convenience, received high favorable ratings. While respondents generally believed that on-line transactions were of good value (with an average rating of 4.10), the relative cost comparison with those transactions made in regular stores was not as favorable as expected (an average of 3.89). In fact, 29% of respondents rated regular stores as less costly. Furthermore, most respondents considered shopping on-line was not as

secure as shopping at regular stores. It indicated a general security concern for on-line transactions. Their responses to follow-up questions on respondents' concern over a list of factors validated this result. Security, privacy, and fraud were the most concerned by the respondents.

To identify the underlying influential factors that determined one's overall satisfaction with on-line transactions, regression analyses were performed with overall satisfaction on each of the experience items respectively. The results indicate that twelve items have significant influence on overall satisfaction. Ease of transaction, comfort in transaction, and excitement were the top three factors that influenced customer satisfaction in the regression analysis. A stepwise regression was performed with customer satisfaction on the fourteen experience factors. The yielded regression model included three factors, ease of transaction, comfort in transaction, and excitement, with an R-square value of 0.47, consistent with the findings from simple regression analyses. Finally, on-line shoppers are more likely to shop more and pay more with merchants who provide superior shopping experience. The results indicate expected expenditure and profit margins increase with the level of positive experience. Overall, positive on-line shopping experience correlates with financial returns.

Overall, 70.5% of respondents indicated that they are very likely or likely to purchase from the Net again in the next six months. The results show strong increase across all product categories among respondents. Books, Music CDs and tapes, and airline tickets have the highest interest level. Overall, respondents anticipate making more purchases from the Internet in the next six months.

The results validate the findings from in-depth interviews. Three clusters of factors were identified. One cluster is related to Internet connection and quality of hardware and software. The second cluster is related to on-line interactive shopping experience. The third cluster is post-order fulfillment and service. They are named **Interactivity, transactional experience, and fulfillment and service**, respectively.

**Interactivity** factors determine the quality of interactive exchange between a shopper and a vendor's web site. It encompasses connection factors of consumers, ISPs, and e-tailers. The quality of personal computers used by a consumer and the speed of adopted connection methods as well as connection quality and website quality of both ISPs and e-tailers are identified as important factors.

**Transactional experience factors** are those involved in the on-line transactional process. A factor analysis reveals a factor structure with five common factors of value, assurance, entertainment, convenience, and evaluation.

**Fulfillment and service factors** are integral part of e-tailing as vendors have to rely on reliable shipping agents and superior service personnel to deliver high-quality on-line shopping experience. E-tailers who are able to offer efficient fulfillment and worry-free

services, such as convenient return and exchange policies, are more likely to proper than many hit-and-run on-line marketers who offer little service and warranty.

Factor analysis was employed to estimate the three components of on-line shopping experience: interactivity, transaction, and fulfillment. An overall interactivity measure was obtained via a single factor analysis, which explains 42% of the total variance. Similarly, two single factor solutions were obtained, explaining 39% of the total variation of the transaction factors and 45% of the total variation of the fulfillment factors, respectively. The single factor solutions were used in the subsequent analysis in testing the individual effects of interactivity, transaction, and fulfillment.

Regression analyses were employed to examine the effects of the interactivity, transaction, and fulfillment factors on the overall satisfaction. First, effects of the interactivity, transaction, and fulfillment factors were estimated separately by single regression analysis. The results indicate that transaction has the greatest effect among the three factors, while all three factors show a significant effect ( $p < 0.01$  for all three factors; see Table 1). When all three factors were included in a multiple regression model, only transaction and interactivity have a significant effect. This finding indicates a strong correlation among the three factors. The multiple regression model explains 31% of the total variation in overall satisfaction.

**Table 1: The Effects of Interactivity, Transaction, and Fulfillment**

Dependent Variable:	Overall Satisfaction			
Independent Variables:	??*	??*	??*	??*
<b>Interactivity</b>	0.425 <sup>a</sup>	0.218 <sup>a</sup>	---	---
<b>Transaction</b>	0.524 <sup>a</sup>	0.423 <sup>a</sup>	---	---
<i>Value</i>	---	---	0.463 <sup>a</sup>	0.199 <sup>a</sup>
<i>Convenience</i>	---	---	0.473 <sup>a</sup>	0.227 <sup>a</sup>
<i>Assurance</i>	---	---	0.382 <sup>a</sup>	0.038
<i>Evaluation</i>	---	---	0.422 <sup>a</sup>	0.163 <sup>b</sup>
<i>Entertainment</i>	---	---	0.324 <sup>a</sup>	0.025
<b>Fulfillment</b>	0.411 <sup>a</sup>	-0.008	---	---
R-square	---	0.310	---	0.290
n	306	306	306	306

\*Standardized beta coefficients based on single regression analysis

\*\*Standardized beta coefficients based on multiple regression analysis

a.  $p < 0.01$

b.  $p < 0.05$

Further analyses were conducted to examine the effects of the five transaction components on on-line shopping experience. Again, individual effects of the five components were estimated using simple regression analyses. All standardized betas are significant at the 0.01 level. As expected, convenience has the greatest effect, closely followed by value. When all five components were

included in a multiple regression model, only the convenience, value, and evaluation factors have a significant effect. The results suggest a strong correlation among the five components of the transaction factor.

## 2.1 Financial Implications

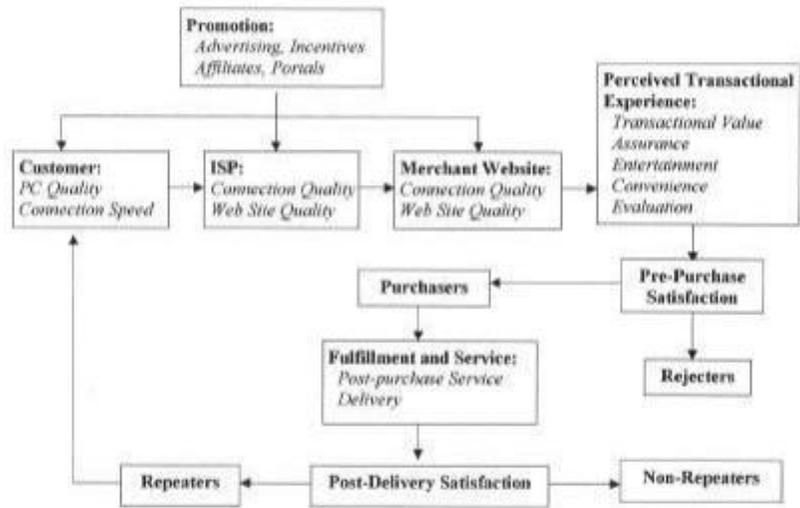

The final research question is how does one's overall satisfaction with the on-line shopping experience affect a company's performance based on anticipated financial returns. Respondents show unambiguous willingness to shop more frequently and pay a higher price in exchange for higher level of satisfaction. When group respondents based on their level of satisfaction, on average, respondents in the high satisfaction group indicate the willingness to pay a 14% premium than those in the low satisfaction group. In addition, respondents in high satisfaction group will purchase 2.5 times more frequently. Assuming a 20% profit margin, such high satisfaction will translate into a potential increase in profitability by 4.25 times for an on-line marketer who is able to provide high level of satisfaction.

## 3. Discussion

On-line shoppers from a major metropolitan area reported a high level of overall satisfaction and strong intention to repeat on-line purchases. Although convenience and price were rated as the two most important factors and security as the greatest concern for on-line transactions, the fun factor (excitement in on-line shopping) had the strongest simple effect on overall satisfaction. Ease of transaction and comfort in transaction were the other two significant determinants of satisfaction. Security had little marginal effect on one's overall satisfaction with on-line purchases. On-line merchants who offer superior shopping experience are likely to reap significant financial benefits because shoppers are willing to pay more and shop more frequently.

A model of the consumer on-line shopping process is proposed based on the findings. It is a general model that applies to most on-line shopping. Future research needs to address the fitness of the model and how this model can be used to predict customer satisfaction. The measurement issue on the quality of on-line shopping transactions or experience and how one's shopping experience and various factors determine future patronage are also important future research issues.

The Figure: NetShop - A Model of On-line Shopping Experience

# Internet Advertising: A Comparison of Pricing Strategy

Seng-Su Tsang      Jung-Kuo Chuang  
International Business Department, Yuan Ze University  
Chungli, Taoyuan, Taiwan  
sengsu@saturn.yzu.edu.tw

## Abstract

The primary objective of this study is to explore the various ways that Internet advertising provider (IAP) can charge firms to advertise. There are two pricing strategies that can be adopted. The first is called *uniform pricing*: Firms pay a fixed fee, depending on the size and location of the advertisement. The second strategy is known as *two-part tariff*: Firms pay a fixed charge and an additional per-click fee. IAPs may adopt one or both of these pricing strategies. Our model hypothesizes that there are two IAPs offering advertising space. The modeling shows that in cases where a uniform pricing strategy is adopted, the fee that each IAP can attain is monotonically decreasing over their substitutability. That is, IAPs that wish to maximize their revenue have to take measures to distinguish themselves from the competition in order to achieve zero substitutability. In cases where a two-part tariff pricing strategy is adopted, the revenue curve becomes convex. In other words, IAPs may choose to have either full substitutability or zero substitutability in order to maximize their profits.

## 1. Introduction

The ever-increasing expansion of the Internet has led to the dominance of Internet companies such as Amazon and Yahoo!. These companies offer not only their own services but also advertising space to firms wishing to promote their products or brands. Hereafter, these companies are referred as Internet Advertising Providers (IAPs). Visitors to these sites can access their services and also find themselves directed to other sites by simply clicking on banners on the Internet pages. For the surfer, these banners are no more than just icons offering access to other websites. However, for IAPs that go to great expense to construct and maintain these websites, these banners may be the only source of revenue. In other words, double clicking on those banners has becoming a new medium in advertising. This has led to the creation of a new advertising industry called Internet marketing.

In terms of the significance of Internet marketing, although its popularity began only a few years ago, its potential is tremendous. In

the US for example, the revenue from Internet advertising amounted to \$2 billion in 1998, according to a report by the Internet Advertising Bureau (IAB, 2000). The same report also estimates this may have exceeded \$4 billion in 1999. In Japan, the revenue from Internet advertising is estimated at ¥11.4 billion in 1998. In Taiwan, the Internet advertising revenue is estimated at NT\$100 million (Yeh, 2000). Compared to the annual advertising budget of NT\$80 billion in Taiwan, this is only a fairly small portion. Nevertheless, with a growth rate that has doubled annually in the past few years, this clearly should not be ignored.

Internet marketing is not only significant in this practical way but is also important in academic terms, with research into areas such as pricing and competition. Generally, IAPs may collect revenue from two sources: Advertisement Impression (AI) and Click Through Rate (CTR). AI represents an advertisement delivered successfully to a qualified visitor. A qualified visitor is one who has the opportunity to view the advertisement. Therefore, this does not include cases where sites bearing the advertisement are simply listed as results of a search. Clearly, visits to those sites by internal users are also excluded. CTR represents the number of times visitors click on an advertisement banner and are then directed to the target site. For payment purposes, firms that wish to have a banner on an IAP's web page are usually asked to pay a lump sum fee. Hereafter this lump sum fee is referred to as the AI fee. If a visitor clicks on their banner and is successfully directed to the target site, the provider may then collect a running payment according to the number of clicks each banner receives. Hereafter, this running payment is referred as the *referral fee*. (In some cases, however, the provider may choose not to charge unless this results in a business for the target site.) An interesting question is how the provider can set those fees. Do pricing strategies exist that can help providers maximize their revenue?

### 1.1. Internet vs. traditional advertising media

We begin our investigation of those questions by comparing the practice of Internet advertising with other traditional forms of

advertising media, such as magazine, TV and radio. It has always been a challenge in measuring the effectiveness of advertising with traditional media. This may be due to the lack of accurate ways to assess the link between traditional advertising and consumer purchasing behavior. Therefore, traditional media can only charge clients according to impression numbers. However, one significant difference we can see in Internet advertising is that CTR tracing technology provides a much better estimate of the power of advertisements. The server proxy offers a detail recording on Internet visitors' clicking actions. Furthermore, if firms can agree to inform providers when visitors make a purchase, then the effectiveness of advertisements can be measured with the utmost accuracy. In this case, firms can pay a referral fee only for "successful" advertising.

## 1.2. Non-linear pricing

Since the missing link in measuring the advertising effectiveness between advertising and purchase in traditional advertising media can be recovered with the CTR technology via Internet, the next question is what pricing strategy (uniform pricing or two-part tariff) will the IAPs employ to maximize their profit. Is two-part tariff a superior pricing strategy to uniform pricing, which is widely adopted in the area of traditional advertising media? Among the several tariff schemes in nonlinear pricing strategy, two-part tariff is the most widely used pricing strategy. Firms pay a fixed charge and an additional per-click fee. From the provider's viewpoint, the fixed fee is less attractive to firms but results in higher overall revenue (Wilson, 1992). Nahata, et al. (1999) show that "..., a fixed investment that ...reduces future transaction cost, a two-part tariff [or multi-part tariff]... becomes more profitable (than uniform price)." Compared with the huge investment involved in website development, the cost of putting a banner on a web page is negligible. In other words, the nature of Internet advertising may favor the two-part (or maybe multi-part) tariff system.

Since the introduction of the Internet, an impression has been created that the cost of doing things through the net is negligible. For example, to the providers the cost of placing advertisement banners on web pages is negligible. However, the space on a web page is limited and quite often for the same page there will be only one type of firm able to advertise. Consequently, firms may have to compete for the space, which drives the price up. Another difficulty is that when the impression rate or the CTR is high, this may use up the bandwidth and

slow down the transmission speed. This can cause visitors to lose patience. In this regards, providers do indeed have a variable (opportunity) cost. This gives a reference for us to model the marginal cost in the following sections.

Given that, however, in the Internet's very short history we have observed quite a few cases that uniform pricing (or sometimes referred to as "buffet pricing" in Nahata, et al. (1999)) is more viable than the two-part tariff. A significant example is the case of America Online. America Online is an Internet service provider (ISP). It was the first significant ISP to provide a flat rate for users to connect with the Internet. Other ISPs were then forced to provide a flat rate (uniform pricing) strategy to stay in the market. In Taiwan uniform pricing was implemented on the wide band system put on market in 1999. To some extent, this study explains the pricing behavior above.

The next section shows model without the referral fee, which follows the uniform pricing strategy. Section 3 shows the model that allows the use of referral fee, which follows the two-part tariff strategy. Related issues and future studies are addressed in Section 4.

## 2. Model without referral fee

For nonlinear pricing strategy, such as the two-part tariff, to be successful firms must be heterogeneous and providers must have monopolistic market power (Wilson, 1992; Oi, 1971). However, in practice very similar oligopolistic competitors may compete using the two-part tariff strategy. For example, China Times and United Daily News both provide web pages for advertisements, and they both price their banners on a two-part tariff basis. Hence, for simplicity, we will setup our model by assuming that the IAPs compete in duopoly and firms are assumed to be either light users or heavy users. □

Moving onto the modeling in a fashion of two-part tariff, it is necessary to set the demand profile of the buyers by assuming they are homogenous (Nahata, et al., 1999). Although the homogenous assumption seems unrealistic, the simplified situation may help to clarify this complexity. Furthermore, it may help to justify the results derived from the heterogeneous

---

<sup>1</sup> If providers have information in regard to the light and heavy usage, they may charge different fixed fees with respect the two types of firms. The fixed fees reflect the consumer surpluses of the firms. However, in most cases, the provider does not have this information. As a result, the provider may charge a fixed fee according to the surplus that the light users have, and set a per-unit price equal to the marginal cost for both types users.

assumption.

Next, according to Wilson (1992), if the following four preconditions are satisfied, sellers may adopt a nonlinear pricing strategy, such as two-part tariff. The four preconditions are as follows (Wilson, 1992, p.10) :

- The seller has a monopoly of power.
- Resale markets are limited or absent.
- The seller can monitor customers' purchases.
- The seller has disaggregated demand data.

Although in the Internet industry, IAPs are far from monopolistic in their areas, as long as the competition is imperfect the first precondition is not completely violated. Resale is also unlikely in the Internet advertising market, because the advertisements have to be placed directly with the provider. The firm is thus unlikely to resell its advertising space to a third party without releasing the resale information to the provider. As mentioned above, existing information technology can allow the provider to record the CTR precisely. That is, the third precondition can at least be partially satisfied. The last precondition is assumed in the present study. Therefore, a nonlinear pricing strategy is justified for our modeling of Internet advertising as follows.

Consider that there are two Internet advertisement providers (IAPs), say  $M_i, i = 1, 2$ . These two providers offer web pages for firms that need to place advertisements to promote their brand or increase sales. The two providers may compete with each other on price ( $p_i, i = 1, 2$ ). The price of an advertisement may depend on the web pages ( $q_i, i = 1, 2$ ) that are available. There may exist certain substitutability between web pages on the two providers' websites. Set  $\alpha$  the substitutability and assume the demands for the two as

$$p_1 = a_1 - b_1 q_1 - \alpha q_2, \text{ and}$$

$$p_2 = a_2 - b_2 q_2 - \alpha q_1$$

Assume the manufacturing costs are  $c_i, i = 1, 2$ . Then the profits for each provider are

$$\pi_i = (p_i - c_i) q_i, \text{ where } i = 1, 2.$$

This model is no different to that used for traditional advertising media. Hence we call it

<sup>2</sup> Further agreements between the firm and the provider would be needed to share information regarding final purchases if one would like to have a perfect measure of the link in advertising effectiveness mentioned earlier.

the benchmark model. Later we will use this benchmark to demonstrate the differences between traditional advertising media and Internet advertising.

The solutions to the benchmark model are

$$q_1^N = \frac{1}{b_1 - \alpha^2} (p_1 - c_1), \text{ and}$$

$$q_2^N = \frac{1}{b_2 - \alpha^2} (p_2 - c_2), \text{ where the } N \text{ stands}$$

for the Nash equilibrium.

In Appendix 1, we calculate the Nash prices as follows.

$$p_1^N = \frac{1}{4 - \alpha^2} (2a_1 - \alpha a_2 - 2c_1 - \alpha c_2)$$

$$p_2^N = \frac{1}{4 - \alpha^2} (2a_2 - \alpha a_1 - 2c_2 - \alpha c_1)$$

In addition to those results, we are particularly interested in profit changes over the choice of the level of substitutability ( $\alpha$ ). This derivative in the next equation is derived in Appendix 2.

$$\frac{\partial \pi_1}{\partial \alpha} = \frac{2(p_1^N - c_1) \alpha}{b_1 - \alpha^2} - \frac{2(p_1^N - c_1) \alpha}{4 - \alpha^2} - A_p \alpha B$$

where

$$A_p = \frac{2(p_1^N - c_1)}{b_1 - \alpha^2}$$

$$B = \frac{2(p_1^N - c_1) \alpha}{4 - \alpha^2} - \frac{2(p_1^N - c_1) \alpha}{b_1 - \alpha^2} - \frac{2(p_1^N - c_1) \alpha}{4 - \alpha^2} - \frac{2(p_1^N - c_1) \alpha}{b_1 - \alpha^2} - \frac{2(p_1^N - c_1) \alpha}{4 - \alpha^2} - \frac{2(p_1^N - c_1) \alpha}{b_1 - \alpha^2}$$

Set  $\frac{\partial \pi_1}{\partial \alpha} = 0$ , and we then have

$$\frac{2(p_1^N - c_1) \alpha}{b_1 - \alpha^2} - \frac{2(p_1^N - c_1) \alpha}{4 - \alpha^2} = 0$$

Assume  $A_p \alpha B = 0$ , that is  $\frac{2(p_1^N - c_1) \alpha}{b_1 - \alpha^2} = 0$ , then

$$\frac{2(p_1^N - c_1) \alpha}{b_1 - \alpha^2} - \frac{2(p_1^N - c_1) \alpha}{4 - \alpha^2} = 0$$

Reorganize the equation,

$$\Rightarrow \frac{2(p_1^N - c_1) \alpha}{1 - \alpha^2} = \frac{d(p_1^N - c_1)}{d\alpha}$$

To solve the equation, let

$$x = (p_1^N - c_1) \text{ and } x = \frac{2(p_1^N - c_1) \alpha}{1 - \alpha^2}, \text{ and}$$

we then have

$$1 - \alpha^2 = \frac{dx}{d\alpha} x$$

Through the reorganization of this

equation, we have

$$\frac{dx}{d\alpha} - 2\alpha x + \frac{dx}{d\alpha} = 0.$$

The solutions to the above equation are as follows.

$$\alpha_1^* = \frac{x \pm \sqrt{x^2 - 4x^2}}{2x} = 1, \quad \text{or}$$

$$\alpha_2^* = \frac{x \pm \sqrt{x^2 - 4x^2}}{2x} = 0.$$

Figure 1 shows a plot of  $\frac{\alpha_1}{\alpha}$  over  $\alpha$ .

This graph could be reversed into  $\alpha$  over  $\frac{\alpha_1}{\alpha}$  as shown in the graph below. Since the  $\alpha$  only makes sense between zero and one, according to the graph above, the provider's profit is maximized if  $\alpha$  is minimized. This result implies that if a referral fee does not exist between the provider and the advertiser, it is better for the provider to fully distinguish its market position from that of its competitors. Nevertheless, it might be interesting to study further the case in which one provider is the anchor and other providers move closer to its market position.

### 3. Model with referral fee

The next model is set to consider the way in which referral fee can be collected via the application of CTR technology. Typically, the provider may collect a one-off advertising fee at the outset. In addition, the provider may collect a referral fee for each visitor that clicks on the advertiser's banner and is directed to the advertiser's website.

In addition to the assumptions and notations we made in the benchmark model, we add the referral fee to our model as follows.

$$\begin{aligned} P_1 &= a_1 + b q_1 + q_2 & (1) \\ P_2 &= a_2 + b q_2 + q_1 & (2) \end{aligned} \quad \text{Macleod model}$$

$$q_1 = P_1 q_1 + C_1 q_1 + r_1 k_1 \quad (3)$$

$$q_2 = P_2 q_2 + C_2 q_2 + r_2 k_2 \quad (4)$$

$r_i, i = 1, 2$  represent the referral fee per click and  $k_i, i = 1, 2$  represent the number of clicks.

By reorganizing the equations (1) and (2), we have

$\Rightarrow$

$$q_1 = \frac{1}{b(1 - \alpha^2)} [a_1 + a_2 - P_2 - P_1]$$

$$q_2 = \frac{1}{b(1 - \alpha^2)} [a_2 + a_1 - P_1 - P_2]$$

Also, by substituting these equations into equations (3) and (4), we derive the profit functions as follows.

$$\pi_1 = P_1 C_1 q_1 + r_1 k_1 - \frac{1}{b(1 - \alpha^2)} [a_1 + a_2 - P_2 - P_1] P_1 C_1 + r_1 k_1$$

$$\pi_2 = P_2 C_2 q_2 + r_2 k_2 - \frac{1}{b(1 - \alpha^2)} [a_2 + a_1 - P_1 - P_2] P_2 C_2 + r_2 k_2$$

By setting  $\frac{\partial \pi_1}{\partial P_1} = 0$ , we derive the Nash

equilibria as follows.

$$q_1^N = \frac{1}{b(1 - \alpha^2)} [P_1 + C_1] - \frac{r_1}{P_1} k_1$$

$$q_2^N = \frac{1}{b(1 - \alpha^2)} [P_2 + C_2] - \frac{r_2}{P_2} k_2$$

Substitute the two equilibria into equations (1) and (2), and we get

$$\begin{aligned} a_1 + C_1 + a_2 + C_2 - P_2 - C_2 - 2P_1 &= 0 \\ 2C_1 + b(1 - \alpha^2) \frac{r_1}{P_1} k_1 - 0, r_1 &= \frac{r_1}{P_1} \\ a_2 + C_2 + a_1 + C_1 - P_1 - C_1 - 2P_2 &= 0 \\ 2C_2 + b(1 - \alpha^2) \frac{r_2}{P_2} k_2 - 0, r_2 &= \frac{r_2}{P_2} \end{aligned}$$

The Nash price equilibria are then arrived at as follows.

$$P_1^N = \frac{1}{4(1 - \alpha^2)} [2(a_1 + a_2) + 2C_1 + C_2 - b(1 - \alpha^2)(2r_1 k_1 + r_2 k_2)]$$

$$P_2^N = \frac{1}{4(1 - \alpha^2)} [2(a_2 + a_1) + 2C_2 + C_1 - b(1 - \alpha^2)(2r_2 k_2 + r_1 k_1)]$$

As in the benchmark model, we are interested in the profit change over the substitutability. That is,

is not possible to collect the referral fee. This may be one reason why the referral fee system is rarely employed. However, if there is technology that can tell if a purchase is made, then the referral fee system is actually superior to the click through rate from the viewpoint of performance-based pricing.

Perhaps the most significant case for using the two-part tariff strategy is in the area of franchising. According to the literature on franchise, the widely employed payment strategy between franchiser and franchisee includes the franchise fee (a fixed fee) and running royalty (per unit charge). This reflects an important consideration that the running royalty provides incentives for the franchisee to work diligently without close monitoring by the franchiser (Bhattacharyya and Lafontaine, 1992; Lal, 1990). In addition, this payment strategy can encourage franchisers to do their best to promote their trademark and products to increase franchisees' sales volume. For all these reasons, this may be why the two-part tariff is widely adopted in franchising. Nevertheless, the popularity of the uniform pricing strategy by ISPs provides a good reason for us to investigate this strategy in future study.

## Appendix 1

The price-reaction functions are as follows.

---

business is attained within IAP's websites. This design enables the IAP a perfectly monitoring whether or not a business is attained. Nevertheless, it will become a contractual problem, which is not a consideration of the present study.

$$\begin{aligned} & a_1 C_1 - a_2 C_2 - 2P_1 C_1 = 0 \\ & a_2 C_2 - a_1 C_1 - 2P_2 C_2 = 0 \\ \Rightarrow & a_1 C_1 - a_2 C_2 = 2P_1 C_1 \\ & a_2 C_2 - a_1 C_1 = 2P_2 C_2 \end{aligned}$$

If we take (a)  $\frac{1}{4} \frac{a_1^2}{a_2^2} (b)$ , then

$$\Rightarrow P_1^{Nash} = \frac{1}{4} \frac{a_1^2}{a_2^2} (2a_1 - a_2 - 2C_1 - C_2)$$

Same for

$$P_2^{Nash} = \frac{1}{4} \frac{a_2^2}{a_1^2} (2a_2 - a_1 - C_1 - 2C_2)$$

## Appendix 2

Following our definitions and the results in Appendix 1, we have the following in profit, Nash price and Nash quantity.

$$\begin{aligned} q_1 &= \frac{1}{b_1} \frac{P_1^N}{C_1} \\ P_1^N &= C_1 \frac{1}{4} \frac{a_1^2}{a_2^2} (2a_1 - a_2 - C_1 - C_2) \\ q_1^N &= \frac{1}{b_1} \frac{P_1^N}{C_1} \end{aligned}$$

Firstly, the derivative of the price to the substitutability is

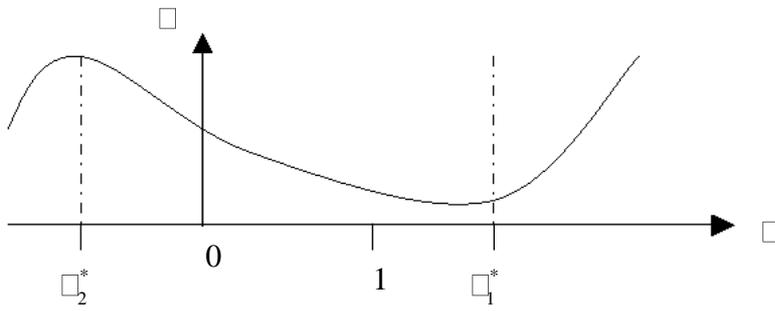

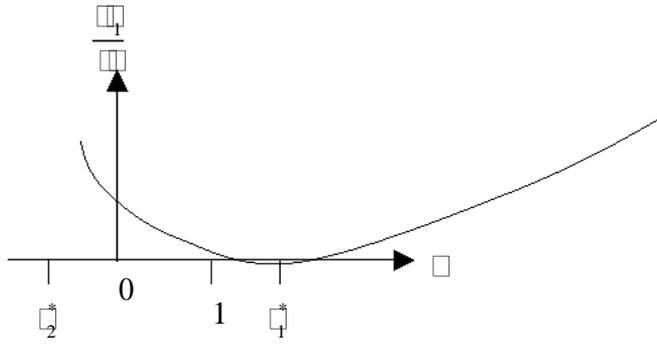

$$\begin{aligned} \frac{\partial P_1^N}{\partial C_1} &= \frac{2}{4} \frac{a_1^2}{a_2^2} (2a_1 - a_2 - C_1 - C_2) \\ &= \frac{1}{4} \frac{a_1^2}{a_2^2} (2a_1 - a_2 - C_1 - C_2) \\ &= \frac{2}{4} \frac{a_1^2}{a_2^2} \frac{1}{4} \frac{a_1^2}{a_2^2} (2a_1 - a_2 - C_1 - C_2) \end{aligned}$$

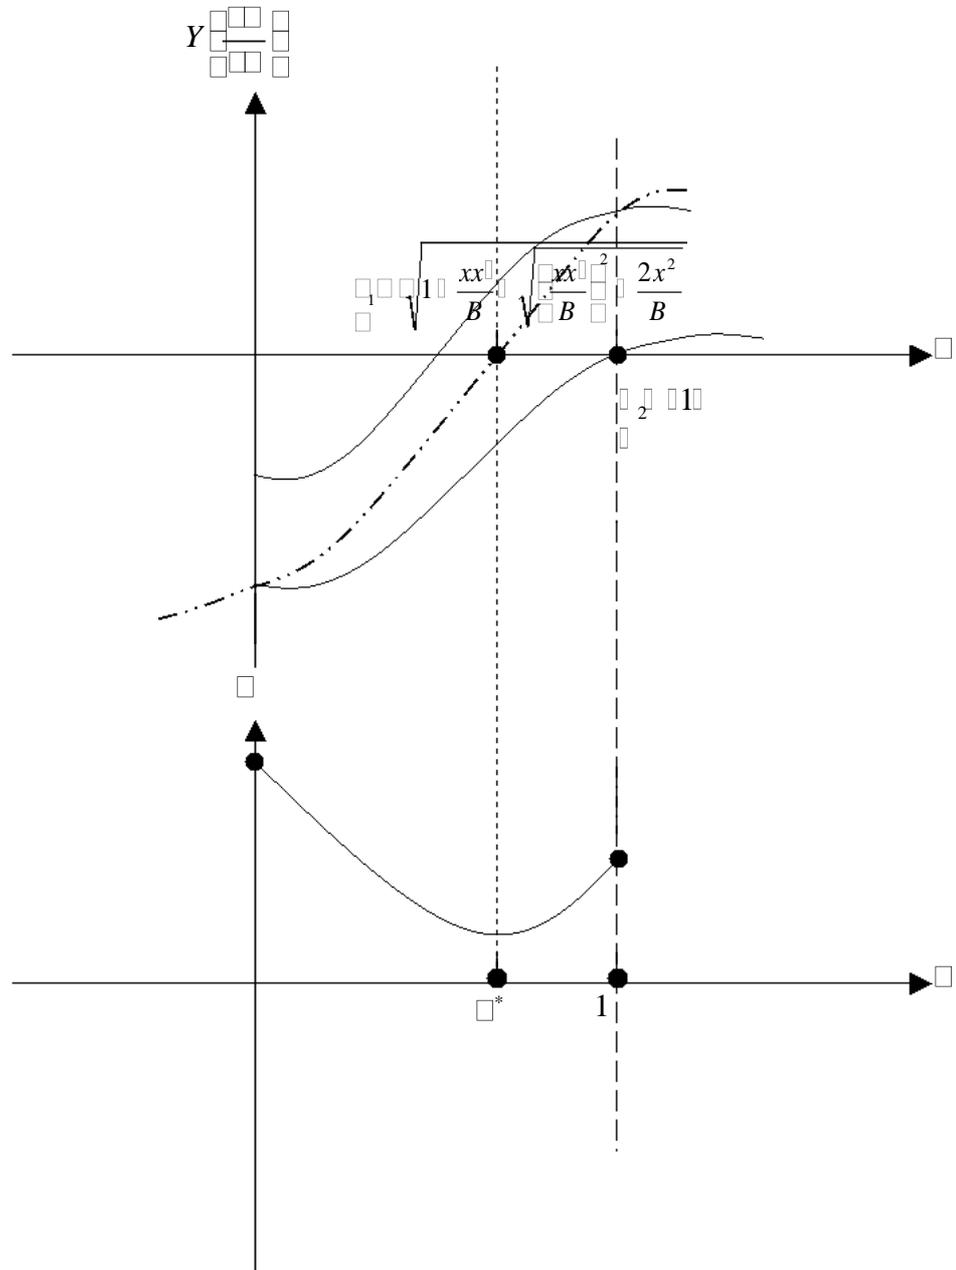

and the derivative of the quantity to the substitutability is

$$\begin{aligned} \frac{q_1^N}{b_1} &= \frac{1}{b_1} P_1^N C_1 \\ &= \frac{2}{b_1} P_1^N C_1 \frac{1}{b_1} P_1^N C_1 \\ &= \frac{1}{b_1} \frac{2}{1} P_1^N C_1 \frac{2}{4} P_1^N C_1 \frac{1}{4} [2 C_1 - 2 a_1 C_1 - C_2 a_2 C_2] \\ &= \frac{1}{b_1} \frac{2}{1} \frac{2}{4} P_1^N C_1 \frac{1}{4} [2 C_1 - 2 a_1 C_1 - C_2 a_2 C_2] \end{aligned}$$

The two jointly deliver the profit to substitutability derivative as follow.

$$\begin{aligned} \frac{q_1}{b_1} &= \frac{1}{b_1} P_1^N C_1^2 \\ &= \frac{2}{b_1} P_1^N C_1^2 \\ &= \frac{1}{b_1} \frac{2}{1} P_1^N C_1 \frac{P_1^N C_1}{1} \\ &= \frac{2 P_1^N C_1}{b_1} \frac{1}{1} P_1^N C_1 \frac{P_1^N C_1}{1} \\ &= \frac{2 P_1^N C_1}{b_1} \frac{1}{1} \frac{2}{4} P_1^N C_1 \frac{1}{4} [2 C_1 - 2 a_1 C_1 - C_2 a_2 C_2] \\ &= \frac{2 P_1^N C_1}{b_1} \frac{1}{1} \frac{2}{4} P_1^N C_1 \frac{1}{4} [2 C_1 - 2 a_1 C_1 - C_2 a_2 C_2] \end{aligned}$$

# 4Ws E-Marketing Strategy: A Conceptual Framework of its Antecedents and its Consequences on Web Performance

## Abstract

While building on the contingency theory, this paper proposes a conceptual framework that links five factors: a) internal forces, b) external forces, c) past web and firm performance, d) current web and firm performance, and e) e-marketing strategy in terms of the strategy defined for the 4Ws (Web-Design, Web-Promotion, Web-Price, and Web-CRM). These dimensions and respective variables are explored, and propositions about their relationships are presented. The role of past performance on strategy formulation in an internet context and on current performance is also considered. Future research is encouraged to build on this framework to test how internal and external forces of the firm, along with its past performance, influence the determination of e-marketing strategy and how in turn, e-marketing strategy impacts on performance at the web and firm levels. Ultimately, the present research seeks to identify effective e-marketing practices in order to help managers and in order to guide public policy makers deciding what to support.

## 1 Introduction

The Internet provides firms with an unprecedented ability to communicate directly with customers. With the relatively widespread adoption of the Internet, businesses of all sizes have the opportunity to build competitive advantage. But regardless of any technological opportunities, competitive advantage still rests on a business opportunity to provide outstanding customer service. The real opportunities for sustainable advantage lie with those who recognize the importance of using information technology to improve service in all phases of the customers' involvement with the firms' product or services.

The Internet is assumed to be an important channel for marketing and distribution of products and

services. This is, among other things, due to the cost-effectiveness of the Internet and the convenience for customers. With the Internet marketers can reach out to a broad customer base, locate target customers, identify their needs and communicate with them at a relatively low cost. The Internet provides an opportunity for market testing and optimization. Increasing digitalization will make it progressively easier to experimentally alter particular aspects of a business and quickly observe how customers respond [69]. As of February 2002, 544 million people had Internet access (www.nua.com).

Since the Web allows access to a plethora of information on different products, the organization must encourage the potential consumer to use the Web site as both an information tool as well as a purchase option. This combination of information search and purchase process is an advantage over traditional retailing as online consumers have stated that personalized targeting is a reason they shop online. When consumers are more involved in the buying process it significantly improves brand recognition and recall. According to Bontis and De Castro [4], the best customer-retailer Internet system possesses four characteristics: full product/service descriptions, customer purchase history, community information and facilitation of target marketing.

## 2 Research Objectives

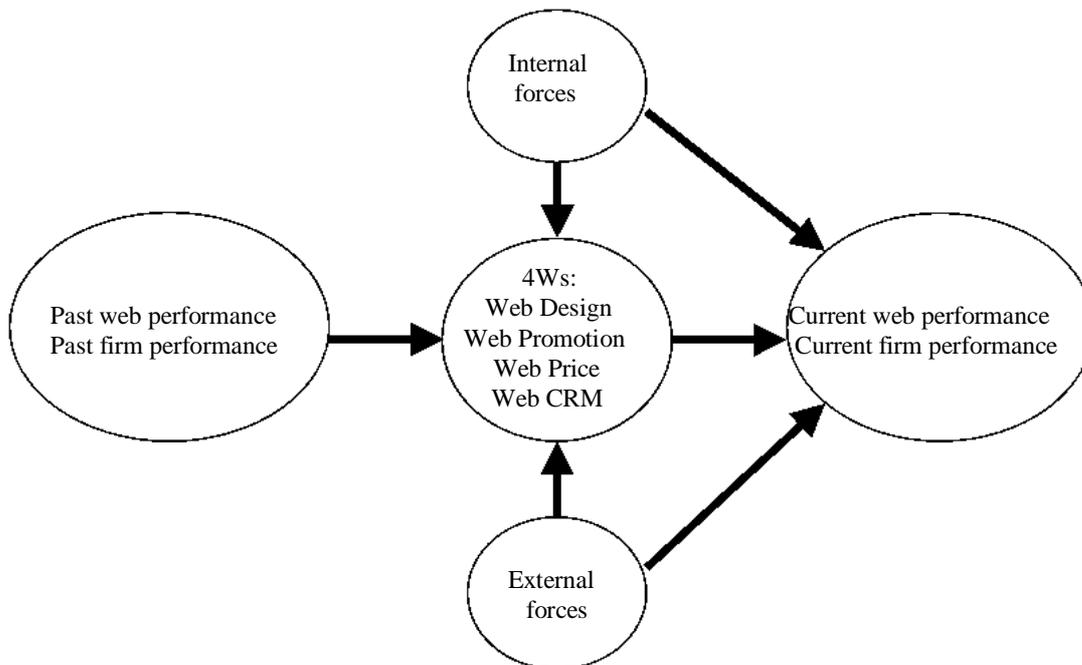

There are three main objectives of this research, the first of which is to extend our understanding of the contingency theory, particularly in an e-marketing context. This is accomplished by presenting a more comprehensive understanding of the simultaneous links among the internal and external forces of the firm, e-marketing strategy, and performance. Earlier marketing research has just focused on single relationships among these variables (e.g., the relationship between strategy and performance or the relationship between contingency

forces and strategy), while rarely considering their simultaneous effects. A contingency approach allows for a multi-faceted approach of the phenomenon. We also advance past work on marketing strategy, which traditionally focuses on a single marketing-mix element, to consider the full marketing mix in a web context.

The second objective of this work is to consider the role of past performance on marketing strategy formulation and on current performance in an internet context. Historically, marketing strategy formulation is viewed as an antecedent to performance outcomes [41]. A recent review of the top journals in strategy and organizational behavior indicates that 79% of the articles incorporating performance have cast it as a dependent variable, while only 9% of the studies have used it as an independent variable [48]. Past performance can be a critical variable in the determination of e-marketing strategy, and the evaluation of current period

performance. Research outside e-marketing e.g., [1][ 11], suggests that when firms experience poor performance they are more likely to search broadly for information and conduct in-depth analyses of their surrounding environments. In contrast, a good performance might promote more relaxed and effortless strategic decisions [24][ 40], as the firm may also become less critical about previous decisions [29], contributing to a narrow focus and preoccupation with the factors that contribute to performance at the expense of remaining responsive to all possible internal and external factors.

The third objective is to study how an articulated approach of four critical e-marketing strategy tasks – the 4 Ws (Web-Design, Web-Promotion, Web-Price and Web-CRM) – relates with current performance. Figure 1 presents the conceptual framework that incorporates past performance, internal and external forces of the firm, e-marketing strategy, and current performance.

**Figure 1 - A contingency framework of the relationship between e-marketing strategy and performance**

### 3 Theoretical Background

#### 3.1 The Contingency Theory

This paper is based in the contingency theory, which has its early roots in the general systems theory [5] [66] and in the behavioral theory of the firm [11][ 43][ 59]. Over the last four decades this perspective has been widely accepted in the field of marketing research [71].

This theory defends that does not exist the best strategy across situations. Performance levels result from the co-alignment among strategy and the firm’s context (i.e., the internal and external forces). Each strategy may be, or not, the best depending on the nature of the contingent forces. Hence, while building on the contingency approach, we propose the following research propositions (see figure 1).

Proposition 1: Depending on the nature of the internal factors, performance might be:

- positively or negatively affected by these factors;
- directly affected by these factors; and
- indirectly affected by these factors through their influence on e-marketing strategy.

Proposition 2: Depending on the nature of the external factors, performance might be:

- positively or negatively affected by these factors;
- directly affected by these factors; and
- indirectly affected by these factors through their influence on e-marketing strategy.

Proposition 3: There is a relationship between performance levels in the past year and performance levels in the current year. This relationship might be:

- positive or negative depending on the nature of the contingent forces;
- direct; and
- indirect, through the influence of past performance on e-marketing strategy.

Based on the marketing literature, we now propose some elements to operationalize internal and external forces, e-marketing strategy, and performance (see Figure 1).

## 3.2 Internal Forces

The marketing literature suggests a variety of internal forces, ie, corporate forces at the institutional and individual levels, which are relevant for e-marketing strategy and performance.

### 3.2.1 Organizational Innovation

Organizational innovation is a function of management that seeks to create new solutions for existing or potential problems. Many studies demonstrated the link between innovation and business performance [14] [ 16] [ 17]. Today's intensification of competition and of environmental uncertainty gives innovation an increasingly important role not only for growth but also for survival [31].

The concept of organizational innovation presents a dichotomy: technical Vs administrative [12] [ 15] [ 13]. Technical innovations "pertain to products, services and production process technology; they are related to basic work activities and can concern either product or process" [15, p.560]. Administrative innovations involve organizational structure and administrative process; they are indirectly related to the basic work activities of an organization" [15, p.560]. Trist [64] argues in favor of a balance between the technical system and the social structure of the organization, instead of the adoption of only one of this types of innovation.

### 3.2.2 Organizational Bureaucratization

Organizational bureaucratization is the degree to which procedures are required to be formalized. The contingency theory argues that bureaucratic structures – that rigidly institutionalize previous lessons from prior experience – can improve performance under stable conditions, but more organic structures are necessary in turbulent conditions [43] [ 52]. Either way, it seems reasonable to expect that the degree of bureaucratization of an organization developing e-marketing will affect performance.

### 3.2.3 Organizational Centralization

Centralization refers to the degree in which authority to take decisions concentrates at the highest levels of the organization [22]. There are two schools of thought about the impact of centralization on marketing strategy making. One traditional school argues that centralization leads to a better strategy making, suggesting that in centralized organizations the planning processes use specialized instruments, techniques and personnel [34]. This school also suggests that centralization diminishes the political activity, promoting the rational development of strategy. In contrast, another school defends that centralization is associated with more political activity [25]. From this perspective, centralization imposes time limits to senior decision makers, which consequently give less emphasis to situation analysis and comprehensive development of strategy making [51].

### 3.2.4 Organizational Formalization

Formalization refers to the degree in which rules, procedures, instructions and communications are written and standardized and the degree in which roles are clearly defined [56]. Previous research suggests that the more formalized the institution, the more the levels of rationality in planning and the more the formal systems, such as analysis and evaluation [28] [ 51]. Formalization can lead to ritualistic planning, with more concern in the development of the document than on a comprehensive action plan [46]. Formalization imposes objective criteria and objective procedures in resource allocation and commitment. Formalization increases information sharing and improves the quality of internal communication [36]. It may lead to less role conflict, less role stress and less role ambiguity among marketing staff [50].

### 3.2.5 Organizational Improvisation

Organizational improvisation is the development of mutually adaptive interactions in which knowledge of the work was developed as the work unfolded. Organizational improvisation includes improvisation by groups, departments and whole organizations [23]. Dougherty [23], described the development of new

products by teams that interacted in ways that did not follow established organizational routines.

### 3.2.6 Innovative Organizational Culture

An innovative culture refers to the complex group of beliefs and ways of doing things that influence the organization's perspective on how innovation and change should be managed. An innovative organizational culture refers to the degree to which there is, in the organization an emphasis on creativity, openness to new ideas, and quick decision making [49]. Previous research suggests that an innovative organizational culture motivates systematic attempts to develop, scrutinize and conciliate divergent perspectives about a strategic option [51]. An innovative organizational culture encourages cross-functional integration because it involves different groups in the decision process [57].

### 3.2.7 Market Orientation (competition orientation + client orientation+ inter-functional coordination)

According to Kohli and Jaworski [38], market orientation "is the organization wide generation of market intelligence pertaining to current and future customer needs, dissemination of the intelligence across departments, and organization wide responsiveness to it". Deshpandé and Farley [21] define market orientation as "the set of cross-functional processes and activities directed at creating and satisfying customers through continuous needs-assessment". Kohli and Jaworski [38] conceptualized market orientation as an organized set of marketing activities. A market orientation, as a corporate culture, characterizes an organization's disposition to deliver superior value to its customers continuously. Scholars of market orientation consider that a market-oriented corporate culture as a significant factor to achieve corporate performance. It has been shown that market orientation, is, in general, positively related with various business performance measures [36][ 58] [61].

Narver and Slater [53] suggested that market orientation consists of three behavioral components, each involved in the collection, dissemination and response to information: customer orientation, competitor orientation and inter-functional coordination, that constitute "the activities of market information acquisition and dissemination and the coordinated creation of customer value".

Customer orientation: under the perspective of the marketing concept - that argues for placing clients' interests first - a customer orientation is one of the most fundamental aspects of organizational culture e.g. [20] [44]. Following the organizational learning theory Huber [35] and Sinkula [60] see customer knowledge process as consisting on three sequential aspects: customer information acquisition, interpretation and integration. Competitor orientation: a focus on client alone can take

the institution to a reactive cycle, instead of proactive, if it does not consider equally the competitors actions [18]. A competitor-oriented company seeks to evaluate its strengths and weaknesses in relation to its main competitors with the objective of maintaining or winning advantage. Competitor knowledge process is the process of information collection about the strengths and weaknesses of competitions, analysis and integration in decision making. Like customer knowledge process, this process involves three behavioral aspects: competitor information acquisition, interpretation and integration. De Geus [19] argues that in the future the only competitive advantage of a company is its ability to know about the competition quicker than its rivals. Inter-functional coordination: Felton [27] insists that for the marketing concept to be implemented, there must be integration of the other organization's functions with marketing. Communication among the various functions of the company help the ability to respond to the client, which is harder to achieve if the various departments work within their routines without a common objective [70].

## 3.3 External Forces

### 3.3.1 Market Turbulence

Market turbulence is the degree of change in the clients composition and in its preferences [36]. The market turbulences are typically generated by the heterogeneity of consumer preferences [33].

Korgaonkar and Wolin [39] studied web users' motivations and concerns in relation to different types of usage. They found out that web users' motivations and concerns correlate significantly with the number of hours per day spent on the Web, the percentage of time spent on the Web for both personal and business purposes, and the user's purchasing behavior. The findings suggest the presence of seven motivations and concerns regarding web use: social escapism, transaction-based security and privacy, information, interactive control, socialization, nontransactional privacy, and economic motivation. Although the study asserts that Web users' behavior varies based on gender, education, income and age, motivations and concerns play a greater role than demographics alone in determining subjects' actions with respect to web usage.

### 3.3.2 Environmental Turbulence

Degree to which there is change in the environment. Previous research underlined the role that the external environment has on the development of strategy and performance [25]. When the environment in which an organization operates experiences a lot of change, the organization has several choices: It can ignore external demands or shocks that suggest the need to change plans and continue with previously planned activities; it can attempt to speed up its planning and

execution cycles so that they remain distinct but happen more quickly [26] or it can move toward an improvisational approach that merges planning and execution processes. Fast-changing environments can destroy the value of existing competencies [65]. Organizational scholars have argued that the increased pace of competition might require organizations to develop an improvisational competency to prosper [6]. Exogenous shocks and demands come along more rapidly than an organization can anticipate, and organizations often respond to such situations by improvising rather than not responding.

### 3.3.3 Technological Turbulence

Technological turbulence is the degree of change associated with new product technologies [30][36][68]. Technology change refers to the speed with which the technology is developed in a market product. On one hand, Day and Wensley [18] and Narver and Slater [53], argue that, when technologies change quickly, it is imperative to the companies to interact with clients because its preferences and needs can provide directions in a product market. On the other hand, Jaworski e Kohli [36] suggest that the importance of information from the client is lower because he knows little about the emergent technologies. In a product market, on which technology changes rapidly, the companies can have urgent needs to collect intelligence, because a close observation of competition gives early warnings about the competition's chance to use opportunities created by an emergent technology, winning competitive advantage in the development of new products.

### 3.3.4 Competitive Intensity

Competitive intensity is the degree of competitive force in a product market. In conditions of intensive competition, collection of information about competition can help the companies to anticipate better the changes in competitor strategies for new products and reduce "market unpredictability". With intensive competition in product advantage and market share became more volatile and neglect competition can damage more the position of the company in the market [18].

## 3.4 E-Marketing Strategy

The question challenging today's entrepreneur is not whether to have a web site but how to become the winner in Internet competition. The strategy chosen by the company is its answer of management to the perceived environment. Afterwards, the company communicates and implements a business strategy by stipulating specific performance goals, criteria and actions [9].

Strategy as a general direction of the company, reflects its response based on information from the

environment [37] and that can explain the magnitude of the relation between performance measures and a specific marketing response from the company (as for example market orientation). Walker and Ruekert [67] argue that strategic orientation, performance in specific dimensions and marketing activities have a contingent relation: the companies choose a type of strategy to obtain excellency in particular dimensions of performance, and execute each strategy by choosing marketing activities.

The current study will operationalize web strategy using four main constructs, in another words, will use the 4Ws: Web-Design, Web-Promotion, Web-Price and Web-CRM (Figure 1).

### 3.4.1 Web-Design

Attitude towards the web site has been researched as an important measure for how well a web site is doing. Chen and Wells [10] found out that entertainment, informativeness and organization profiles of web sites are descriptive dimensions correlated with attitude towards the site. When web sites are intended primarily to convey information, users put more weight on Informativeness and Organization, and less on Entertainment. Taken together, these dimensions complement each other and offer some clues on how to improve web site design and presentation. A good web site is one that delivers relevant and well-organized information in an engaging manner.

### 3.4.2 Web-Promotion

Stevenson et al. [62] have researched on the type of background that is most appropriate for positively affecting advertising effectiveness as measured by several common attitude measures, namely attitude towards the ad, attitude towards the brand, attention to the commercial, purchase intention, and attitude towards the web site. Their findings suggest that simpler web page backgrounds are more effective than more complex ones. Bruner and Kumar [7] further explored the advertising hierarchy of effects and its antecedents in the context of the web. Web experience was found to play an important role along with web page complexity and interestingness on attitude towards the web site, which in turn had significant effects on the web advertising hierarchy of effects.

### 3.4.3 Web-Price

The advent of the Internet as a new medium for buyer-seller interaction is changing the issue of price for both customers and suppliers in an unprecedented way. On the one hand, there are Internet dynamics that flatten the customer value pyramid because of technology that facilitates customer search, customer control over transactions and a return to one-on-one negotiation. On the other hand, firms may create customer switching

barriers, differentiate on other dimensions of the purchase decision and reduce transaction costs [55]. The fundamental value of the Internet lies not in lowering prices or making them consistent but in optimizing them [2].

#### **3.4.4 Web-CRM**

The Web can be used to establish direct marketing channels between firms and consumers [42].

Through data mining tools, it is possible to make use of the personal information on a visitor's web site and identify his or her interests and needs. Based on such understanding, firms can send e-mail messages and offer service packages especially designed for a potential customer, based on the marketer's assessment of the individual's interests.

Because of increased competition among actors offering their products and services on the Internet, generating revisits to companies's web sites has become a major challenge for many companies. In order to generate revisits, substantial amounts of resources are used in efforts to develop superior web sites that attract customers [63]. By structuring one's thinking about a firm's relationship with its customers, companies can identify their strengths and highlight areas in need of improvement [54].

### **3.5 Performance**

#### **3.5.1 Firm Performance**

Firm performance is a well-established measurement in the marketing literature. We will measure it through sales volume, profitability and market share for the current period (current firm performance), and perceived satisfaction with these measures when considering the previous year (past firm performance).

#### **3.5.2 E-Performance**

Although many e-commerce companies collect cost and usage data about their Web sites, few of them understand in any detail how well such information measures their sites' performance or how this performance compares with that of competing sites. However, since year 2000 investors have been insisting, if not on profits, at least on objective measures of a site's success in attracting, converting and retaining customers.

A key concern of this study is related with the conceptualization and measurement of performance. Overall the literature suggests that it is required a multidimensional scale. One approach that is increasingly relied upon is the aggregation of various performance measures into a single measure of performance. We incorporate this approach here by considering web site performance evaluation [8].

## **4 Implications**

### **4.1 Implications for Theory**

Considering the rapid growth of e-commerce in our marketplace, it seems to be a need to assess what is really happening in the managerial world. We believe that marketing researchers generally are ignoring a significant part of the marketing-performance phenomenon. Research should consider two sets of relationships: Performance→E-Marketing effects and E-Marketing→Performance effects. In other words research, has to identify if e-marketing strategy is not only an antecedent, but also an outcome, of performance. Furthermore, the existing research in marketing, which has focused exclusively on the study of direct relationships, has been inconclusive. In addition to the analysis of the direct relationships, future research may empirically test the conceptual framework presented here. This will add to previous research by showing how the contingent forces (i.e. internal and external forces) affect performance directly and indirectly, through their influence on the definition of the e-marketing strategies.

### **4.2 Implications for Public Policy and Management**

From the point of view of both firms and most national governments, the use of the Internet is extremely attractive because it reduces the firms' dependency on the domestic market, allows increase production through sales to foreign markets and consequently creates employment and enhances societal prosperity.

Public policy makers may play an active role in promoting the e-commerce activity, namely by providing support to business training. Thus, from the perspective of public policy makers, the following questions emerge: how can public policy makers help firms to compete in the electronic age and help them firms improve performance? What kind of support should be provided?

The present research seeks to identify effective e-marketing practices in order to help public policy makers to plan and refine the substance of their support. It is expected to help public policy makers to have a better notion of where to apply resources vis-à-vis e-commerce development.

In sum, the conceptual model presented in Figure 1 helps to systematize the e-marketing phenomenon and is expected to support public policy makers and managers in developing effective e-marketing strategies.

## Abstract

The objective of this study is to identify factors that are significantly associated with consumer in electronic or traditional market. The study uses consumer cost differences which are product price, product quality, after-sales service, product refund or exchange, variety and assortment of product offerings, time saving on buying product, convenience to buy product, distribution cost, sufficient law to protect consumer, security of payment by credit card to differentiate consumers from traditional and electronic markets. The result indicates that four of ten factors (product price, product quality, product refund or exchange, and time saving on buying product) can classify consumers in the two markets. Internet buyers' characteristics and behaviour are discussed.

## 1. Introduction

Internet has become an important medium for organizations desiring to market their products and services via electronic market. Although many organizations have claimed that Internet involves in their business success, little research has been conducted to prove the success of electronic market. Online shopping also has some limitations (i.e., the lack of variety of products, disappointing customer service, and wariness about unknown Internet retailers). Consumers may diffuse online shopping differently. Some consumers may still prefer traditional markets (i.e., retail stores) to electronic markets or vice versa. In addition, the Internet's effects on consumer behavior are unpredictable.

The electronic market in Thailand is still in its infancy. Survey on factors affecting the Internet usage by Chumchuan [2] revealed that Thai consumers are aware of sufficient law to protect transaction processed via Internet. In addition, the consumers are not confident in the quality of product/service bought from Internet and in the security of payment system [16]. Even though some Thai consumers are anxiety and unbelief in the electronic market, the others buy product on Internet. Therefore, additional research is needed to understand which factors (such as types of products,

costs relevant to traditional or electronic markets, and services from vendor etc.) are significantly associated with consumer perceptions of traditional and electronic markets. These factors can also be used to create model for predicting group membership (traditional versus electronic markets) from a set of predictors. The main purpose of this research is to investigate factors that influence individuals' decision to shop by either electronic or traditional markets.

## 2. Black Ground

Every buyer is engaged in continuous decision process which consists of five stages: need recognition, information search, evaluation of alternatives, purchase decision, and postpurchase behavior [7][8][1]. Many of these stages involve costs such as searching for sellers, delivering and monitoring product/service. As different marketing channels have some differently associated costs, a consumer normally compares relative advantage in each potential market. The relative advantage is often expressed in savings in time and effort, and cost reduction [15]. Therefore, a reasonable consumer usually attempts to minimize the relative costs involving the decision process [3]. Given the two types of marketing channels (traditional and electronic markets), the six costs associated with these markets include product price, search costs, risk costs, distribution costs, sales tax, and market costs [13]. However, as sales tax in Thailand is equal in each marketing channels, this study does not include sales tax in consideration.

### 2.1 Product Price

Product price is the sum of the production costs, coordination costs, and profits added to the product or service [13]. The benefits of electronic markets to both buyers and sellers are low cost and improved efficiencies [1]. The electronic marketing can reduce costs of order processing, inventory handling, delivery, and trade promotion because buyers deal directly with sellers. In addition, communicating electronically often costs less than communicating on paper through the mail.

## 2.2 Search Costs

Search costs are the time, effort, and money involved in obtaining and comparing the available brands and features of product demanded from various sellers [13]. Generally, a consumer will search on product price, product quality, and product features until he/she reaches the final purchase decision [13][1]. The product quality means the ability of the product to perform its functions, free from defects, and consistency in delivering a targeted level of performance. The electronic marketing provides benefits to buyer in term of convenience which, in turn, reduces buyers' search costs. The buyers do not have to go to various stores to find and examine products. In addition, the buyers can access to an abundance of comparative prices of competitive stores, products, or services that fit their needs from any location.

## 2.3 Risk Costs

Risk costs mean the costs involved economic, social, performance, personal, and privacy risks [13] [17]. The buyer decision process does not end when the product is bought. After purchasing the product, the consumer will be engage in postpurchase behaviour which is satisfaction or dissatisfaction. Normally, the buyer is disappointed when the delivered product fails to meet specifications. As the Internet buyers cannot touch or examine the products during evaluation stages, and they usually receive purchases via mail delivery, the buyer will require favourable terms such as warranty or replacement of products without difficulty and within a short time [3]. In addition, there are some risks associated with ensuring security of credit card transaction on the electronic market because information transmitted over Internet may be intercepted and misused. Therefore, the perception of security risk can be attributed to separate consumers from electronic to traditional markets.

## 2.4 Distribution Costs

Distribution costs refer to the costs involving the physical exchange of products or services from seller to the buyer [13][9]. The distribution costs are associated with types of products and services purchased over the Internet. The digital products such as electronic books and software can be delivered digitally and be used by the consumer straightaway. Sending the digital products or services online reduce the distribution costs. However, the distribution costs for tangible products are higher in electronic market than in traditional market because there is the need for the consumer to pay distribution costs to receive the product.

## 2.5 Market Costs

Market costs are the costs associated with participating in a market [13][3]. These costs include fee paid by buyers to access to the Internet and the costs paid to the firms that operate the electronic market. The

traditional market, however, are assumed these costs differently. The cost for traditional market is in the form of transportation to the shop.

This study applied the work by Strader and Shaw [13] on consumer cost difference for traditional and Internet markets. The costs associated with Thai consumers are examined. Thus, the aim of this paper is to provide the empirical answer to the following research question.

Research question : What are the factors that are significantly classified consumers into electronic or traditional market?

## 3. Research Methodology

### 3.1 Sample and Procedure

Five hundred questionnaires were distributed to participants in three main cities in Thailand (Bangkok, Chiang Mai, and Khon Kaen). Reason for limiting the study to the above participants was that participants in the main cities normally understand electronic market than participants in the small cities. In addition, the participants were universities' students and office staffs who have knowledge in e-commerce. The returned and usable results for further statistical analysis were 299 questionnaires. These questionnaires were divided into two groups, Internet buyers and non-Internet buyers. The groups were separated in term of whether participants used to purchase the products from Internet. The usable results were 73 questionnaires for Internet buyers group and 226 questionnaires for non-Internet buyers group. In addition, the questionnaires in two groups were split into analysis and holdout (validation) samples. The analysis sample was used to develop the discriminant function. Meanwhile, the holdout sample was used to test the discriminant function. This study used a 75-25 split to divide the sample into analysis and holdout groups. Moreover, the smallest group size must exceed the number of independent variables to ensure the minimum impact of sample size on the estimation of the discriminant function [4]. Finally, the purchase group contained 55 observations for analysis and 18 observations for validation. Meanwhile, the not purchase group was divided into 168 observations for analysis and 58 observations for validation. Sample sizes were quite different in the Internet buyers and non-Internet buyers groups in analysis and holdout data. However, with ratios of 1:3.05 in analysis group and 1:3.22 in holdout group, the discrepancy in sample sizes does not invalidate use of discriminant analysis [14].

The evaluation of assumptions of linearity, normality, multicollinearity or singularity, and homogeneity of variance-covariance matrices revealed no threat to multivariate analysis. The collected information was then analysed by using discriminant analysis with stepwise method. Ten variables were used as predictors of membership in two groups. The ten variables which identified Internet buyers from non-

Internet buyers were product price, product quality, after-sales service, product refund or exchange, variety and assortment of product offerings, time saving on buying product, convenience to buy product, distribution cost, sufficient law to protect consumer, security of payment by credit card.

### 3.2 Results

The results suggests that a discriminant function is significant at  $\chi^2(5) = 108.120$  with p value  $< 0.01$ . The discriminant function accounts for 81.60 percent of grouped cases (see table 2). The discriminant loadings, as seen in table 1, suggests that the best predictors for distinguishing between Internet buyers and non-Internet buyers were product price, product quality, product refund or exchange, and time saving on buying product.

Of the four variables in the discriminant function, product quality discriminates the most while time saving on buying product discriminated the least. Distribution cost is not included in the model, even though it showed statistical significance. The discriminant loading of this variable is less than an accepted level ( $\pm .30$ ). After distribution cost was deleted from the analysis, the group means (centroids) of the discriminant function is 1.339 for Internet buyers and -0.438 for non-Internet buyers. The results give the following estimated discriminant function.

$$D = -5.156 + 0.439 \text{ Product price} + 0.467 \text{ Product quality} + 0.364 \text{ Product refund or exchange} + 0.374 \text{ Time saving on buying product} \quad (1)$$

**Table 1 Summary of interpretive measures for consumer perceptions of traditional and electronic markets**

Dependent variables	Unstandardized coefficients	Discriminant loadings		F statistic	
	Value	Value	Rank	Value	Significance
Product price	.449	.582	2	34.618	.000
Product quality	.460	.642	1	54.466	.000
After-sales service	NI	.348	5	NI	
Product refund or exchange	.438	.464	3	30.067	.000
Variety and assortment of product offerings	NI	.290	6	NI	
Time saving on buying product	.371	.460	4	40.311	.000
Convenience to buy product	NI	-.119	10	NI	
Distribution cost	-.284	-.016	9	25.979	.000
Sufficient law to protect consumer	NI	.153	7	NI	
Security of payment by credit card	NI	.078	8	NI	
Constant	-4.644				

NI means this variable is not included in the stepwise solution.

The holdout samples have been used to examine the predictive accuracy of the discriminant function. The cutting score (-0.0002) is used as the criterion against each observation's discriminant Z score to determine group member for the observation. The classification matrices for consumer perceptions of traditional and electronic markets show in table 2. The analysis samples (with 81.60 percent classification accuracy) have higher prediction accuracy than the holdout samples (with 65.75 percent classification accuracy). As the discriminant function would classify a subject in the smaller group where the sample sizes are unequal, the prediction accuracy rate was compared with the two chance measures (proportional chance criterion or  $C_{pro}$

and Press's Q statistic) [4]. The purpose of comparison is to determine whether the prediction accuracy rate is in the acceptable level and the classification accuracy of group membership is not occurred by chance. The results show that the prediction accuracy (81.60 percent) is higher than the proportional chance criterion (42.19 percent) and the maximum chance criterion (61.89 percent). In addition, the values of Press's Q of analysis sample and holdout sample (89.15 and 5.26) exceed the critical value of 3.841 ( $\chi^2(1)$ ,  $p = 0.05$ ). Therefore, the predictions are significantly better than chance.

**Table 2 Classification matrices for consumer perceptions of traditional and electronic markets**

Actual group	Number of cases	Predicted group membership	
		Internet buyers	Non-Internet buyers
Analysis sample <sup>a</sup> :			
Internet buyers	55	44 80.00%	11 20.00%
Non-Internet buyers	168	30 17.90%	138 82.10%
Number of cases		74	149
Holdout sample <sup>b</sup> :			
Internet buyers	18	13 72.22%	5 27.78%
Non-Internet buyers	58	23 39.66%	35 60.34%
Number of cases		36	40

<sup>a</sup> Percent of grouped cases correctly classified is 81.60%.

<sup>b</sup> Percent of grouped cases correctly classified is 65.75%.

Table 3 shows the correctly classified and the misclassified cases from the analysis and holdout samples. Data in this table is used to identify specific differences on the independent variables that might identify either new variable to be added or common characteristics that should be considered. The eighteen cases misclassified in the Internet buyers group have significant differences on two of the four variables in the discriminant function. In addition, most variables, which were not included in the discriminant function, demonstrate significant differences. The non-Internet buyers group, however, shows a similar pattern, although with different variables. The statistically significant differences of some variables (product refund or exchange, time saving on buying product and variables not included in discriminant function) suggest that other variables would identify characteristic that identifies group membership.

Moreover, the Internet buyers' demographic characteristics, economic factors, and behaviour

towards the purchasing of products or services through the internet are summarized (see Table 4). In this study, the Internet buyers are younger. There are 36.5 percent of Internet buyers aged 20-26 years old; 28.4 percent of Internet buyers aged 27-33 years old; and 17.6 percent of Internet buyers aged 34-40 years old. The Internet buyers are more male (75.7 percent) than female (24.3 percent). A total of 75.7 percent of Internet buyers are single. In addition, most of Internet buyers are college graduates. They obtain a bachelor degree (51.4 percent) and a master degree (27.0 percent). The mean income of Internet buyers is 20,000 baht (around 476 US\$). Moreover, the Internet buyers spend a little time searching for the information before making purchase decision. The popular goods were publications and computer software. In addition, Thai Internet buyers prefer products with well-known brands. The product price, however, should be 10% cheaper than those available in shops. Usually, the products are paid by credit card.

**Table 3 Profiling correctly classified and misclassified observations in consumer perceptions of traditional and electronic markets**

Dependent variables	Mean scores			t test	
	Correctly classified	Misclassified	Difference	t value	Significance
<b>Internet buyers:</b>					
	(N = 55)	(N = 18)			
Product price <sup>a</sup>	4.00	2.29	1.71	3.667	.170
Product quality <sup>a</sup>	4.36	2.43	1.94	3.510	.177

**Table 4 Information on buying product/service on traditional and electronic markets**

Items	Response	Percentage
<b>Purchase product/service via Internet market:</b>		
1. Average number of Internet web sites searching for product/service before making purchase decision	1-3 web sites	41.9
2. Time used to search product/service before making purchase decision	Less than 2 hours	48.6
3. Product/service buying from internet	Book, article or magazine, and software	54.1
3.1 First ranking of high purchase		
3.2 Second ranking of high purchase	Computer and peripheral	17.6
3.3 Third ranking of high purchase	Toy and recreation	14.9
4. Consideration of product brand	Consider	81.1
5. Product price	Should less than buying product from traditional market 10%	33.8
6. Method of payment	Credit card	66.2
7. Method of product delivery	Mail	68.9
8. Satisfying product	Satisfy	91.9
9. Product delivery time	3-7 days	48.6
<b>Purchase product/service via traditional market:</b>		
1. Average number of places searching for product/service before making purchase decision	1-3 places	55.4
2. Time used to search product/service before making purchase decision	Less than 2 hours	41.9
3. Consideration of product brand	Consider	75.7

#### 4. Discussion

The results provide some preliminary answers to the main purpose of this paper. The findings suggest that product price and quality influence consumers. If the savings in transactions costs can be passed on to consumers in the forms of less price without compromising quality, it can be positive influence on consumers to buy products in electronic market. In addition, the result indicates that the Internet buyers in Thailand usually buy famous brands because the buyers are confident of the quality assurance of those products.

Moreover, tangibility of products is also the most important factors for Thai consumers. The survey by Wongpinunwatana and Achakulwisut [18] on the adoption of e-commerce of Small to Medium Enterprises (SME) in Thailand indicates that Thai consumers want to inspect products before making purchase decision. As the Internet buyers will visualize products from Internet, the buyers, therefore, require warranty on product refund or exchange in case of delivery products fails to meet their requirements [11]. The on decision to buy products in both marketing

channels, this factor is not indicate high influence on purchase decision. Income of Internet buyers in Thailand is quite low comparing to buyers from other developed countries. Therefore, these buyers will buy products with low cost. The frequently purchased products from Internet are books, articles or magazines, and computer software. Because the Internet buyers can download the previous purchased products from Internet, they do not consider much on the distribution costs. For computer software, Thai consumers will always look for freeware.

However, the factors of after-sales service, variety and assortment of product offerings, convenience to buy product, sufficient law to protect consumer, security of payment by credit card cannot use to identify Internet buyers from non-Internet buyers in Thailand. Several reasons can be used to explain these results. First, intangible products (i.e. books, articles or magazines, and computer software) are not required after-sales support or the warranty and variety of products. Second, many Internet buyers are college students and office staffs. Therefore, Internet access is essentially free for these consumers with access through school or work. If the consumers access the Internet from home, they have to pay for local telephone and Internet access charges. These charges, however, is quite low in Thailand. In addition, they spend less time on Internet and visit less web site before they make purchase decision. Therefore, the amount of participating costs in Internet market is quite equal to the amount of participating costs in traditional market which is costless. Third, contrary to expectations, Internet buyers do not indicate the awareness of security risk of credit card information transmitted over the Internet. The reason could be due to widely use of credit card in both marketing channels and trust with security of payment.

As the percentage of Internet buyers in this study (24.41%) is lower than the percentage of non-Internet buyers (75.59%). Consistent with this result, Ratpol [10] found that Thai consumers are likely to buy products from traditional market. As Internet is still new for Thai consumers, the sellers who want to use Internet as electronic market may have to consider using Internet as information provider.

## 5. Conclusion

In summary, the results from this study indicate that Internet and non-Internet buyers can be differentiated by product price, product quality, product refund or exchange, and time saving on buying product. This finding would be reasonable starting points for understanding types of transaction costs underlining consumers in both marketing channels (electronic and traditional markets) in Thailand. In addition, the organizations, which want to market their products via Internet, can use these results to understand their consumer cost differences for traditional and Internet

markets for an effective launch of this new marketing channel. There are a number of limitations in this study. First, participants in three main cities in Thailand may not be suitable representatives for the whole population. The other samples from other main cities such as Phuket city should be attempted. Second, electronic market in Thailand is still at the infant stage. This market is still in a period of learning. Thai people may not familiar with this new Internet technology. Therefore, information collected for analysis may be restricted.

Future research could be conducted by expanding sample to other cities. In addition, the study should include Thai culture factor. The need to understand how country's culture affects the success of business on the Internet must be considered [5][6][12][3]. The impact of culture has been an ongoing concern in electronic commerce research.

# E-Government Deployment for the 21<sup>st</sup> Century

Manual Avitia & Jonathan Lee  
E-Business Society  
California Polytechnic & State University  
3801 W. Temple Ave., Pomona. CA 91768  
[moavitia@aol.com](mailto:moavitia@aol.com) & [jonlee88@yahoo.com](mailto:jonlee88@yahoo.com)

## Abstract

E-Government leverages technology, specifically the Internet, to simplify the delivery of government services. Furthermore, e-Government improves the business of government by making government more efficient and convenient for the customers. Activities performed through e-Government can be in the nature of transactions, information, or education, to name a few.

## 1. Introduction

Electronic service delivery offers huge opportunities to improve public services for the benefit of citizens; more convenient, more joined-up, more responsive and more personalized. It is going to transform the way the public sector does business, in many cases replacing traditional channels for doing business with more efficient and effective electronic channels.

### 1.1 Value of E-Government

Government provides many opportunities to improve the quality service to the citizen. Citizens should be able to get service or information in minutes or hours, versus today's standard of days or weeks. Citizens, businesses should be able to file required reports without having to hire accountants and lawyers. Government employees should be able to do their work as easily, efficiently and effectively as their counterparts in the commercial world. An effective strategy will result in significant improvements in the government, including: Simplifying delivery of services to citizens;  
Eliminating layers of government management;

Making it possible for citizens, businesses, other levels of government and federal employees to easily find information and get services from the federal government;

Simplifying agencies' business processes and reducing costs through integrating and eliminating redundant systems;

Enabling achievement of the other elements of the President's management Agenda; and

Streamlining government operations to guarantee rapid response to citizen needs.

### 1.2 Business Case for E-Government

Electronic service delivery offers huge opportunities to improve public services for the benefit of citizens; more convenient, more joined-up, more responsive and more personalized. It is going to transform the way the public sector does business, in many cases replacing traditional channels for doing business with more efficient and effective electronic channels.

## 2. Benefits of E-Government

Less expensive – e-Government transactions eliminate the vast majority of brick and mortar and labor costs. E-Government transactions can be 65% less compared to OTC transactions. Using e-government leverages technology to reduce the cost of each transaction offered.

More convenient hours – e-Government transactions are available 24 hours a day, 7 days a week. This provides customers the flexibility to process transactions outside standard government office hours.

Reduced travel and waiting– Ubiquitous access is available from any home or off-site computer or from any phone. E-Government removes the travel time to a government office and eliminates the associated wait-time involved as well. An ancillary benefit is reduced wait-times for OTC transactions due to fewer customer visits.

Benefits all customers – e-Government benefits those that use the services and those that do not. As more and more transactions move from in-line to on-line, the customer that does not use e-Government is able to get better service while in a government office due to reduced wait time and ability of staff to focus on more complex transactions.

Reduction in bad check processing - Bad check processing time and expenses will decrease due to the fact that more customers will be utilizing credit cards to pay for their transactions.

Process improvement - e-Government often serves as a catalyst to perform business reengineering. Process improvement must continue when analyzing service for e-government.

## 2.1 Delivery of Services

Individuals/Citizens: Government-to-Citizens (G2C); Build easy to find, easy to use, one-stop points-of-service that make it easy for citizens to access high-quality government services.

Businesses: Government-to-Business (G2B); Reduce government's burden on businesses by eliminating redundant collection of data and better leveraging E-business technologies for communications.

Intergovernmental: Government-to-Government (G2G); Make it easier for states and localities to meet reporting requirements and participate as full partners with the government in citizen services, while enabling better performance measurement. Other levels of government program delivery because more accurate data is available in a timely fashion.

Intra-governmental: Internal Efficiency and Effectiveness; Make better use of modern technology to reduce costs and improve quality of federal government agency administration, by using industry best practices in areas such as supply-chain management; financial management and knowledge management. Agencies will be able to improve financial management and knowledge management. Agencies will be able to improve effectiveness and efficiency, eliminating delays in processing and improving employee satisfaction and retention.

## 3. What E-Government should be?

Easy to use, connecting people with governments according to their preferences and needs.

Available to everyone, at home, at work, in schools, in libraries and other convenient community locations.

Private and secure, with the appropriate standards for privacy, security, and authentication generating trust-required for e-government to grow and serve the public.

Innovative and results-oriented, emphasizing speeds and harnessing the latest advances in technology.

Collaborative, with solutions developed collectively and openly among public, private, nonprofit, and research partners, on the basis of their experience and expertise.

Cost-effective, through strategic investments that produce significant long-term efficiencies and savings.

Transformational, harnessing technology through personal and organizational leadership to change the way government works, rather than merely automate existing practices.

## 3.1 E-Government for the People

The big idea here is e-the-people. E-government links people not just to each other and the e-commerce marketplace, but also to the public marketplace of ideas, debate, priorities, initiatives, innovation, services, transactions, and results. It puts ownership of government truly in the hands of all citizens.

Imagine government truly of, and for the people, where individuals and organizations no longer wait in line between eight and five on weekdays only, but where they can be online at any time or place they wish. A place not only to get information but also to complete transactions with government, get services, talk with elected representatives-even to vote.

Imagine people in government who are excited about using the Internet to make a difference and produce results, answering questions instantly, using secure network that cross organizational boundaries to serve the public. Imagine people in business enjoying fast and easy interactions with government that produce results in the public interest.

Imagine people in all sectors-government, business, non-profits, and the research community working together to make this happen quickly, creatively, and cost effectively. This is e-government- our government of the future, not the government of the past. But don't stop there. E-government is not just about speed, efficiency, or accessing information online. It can also be tailed by individuals according to their preference and needs.

Imagine individual citizens creating customized, one-stop sites for themselves online, where they can choose to get information, conduct transactions, or communicate with their elected representatives. Imagine having your own self-designed, interactive site where you can directly conduct all your business with government whenever you wish. You can pay taxes, check your Social Security earnings, find out whether your building permit has been granted, renew your driver's license after your site has reminded you without being asked that it is coming due.

You can also participate in public hearings, create communities of interest with other online, monitor voting records, and express your views to your representatives. In short, you can choose how and when to connect with government, with the ability to choose appropriate levels of privacy and security.

#### **4. Conclusion**

The current pace of technological change means that there are few certainties about future service delivery. But we do know that government has the potential to offer truly citizen-focused services.

Citizens will choose when and where they interact with government. For many services, government will be open 24 hours a day, 7 days a week. Citizens will be able to interact with government from home, at work or on the move.

Services will be delivered through multiple channels. Traditional channels will compete with new electronic channels. As well as the public sector, the voluntary and private sector will offer new interfaces to government services. For example, you may pay tax through your electronic bank or renew your driver's license.

Government will be organized to deliver services that are customer focused. A government gateway will allow the aggregation of data across functions by users of that data in the private and voluntary sectors, and by new aggregators acting as wholesalers in government data and information. New citizen-facing government, voluntary and private sector intermediaries will compete to offer the best combinations of services.

## Abstract

As businesses become more involved and savvy with electronic commerce (e-commerce), electronic government (e-government) can learn many lessons from them. The tremendous growth in e-commerce will spur many governments to launch comparable e-government services. The recent passage of federal law in the US has institutionalized e-government. Thus, many government bodies will become greatly involved with the Internet and its associated technologies in providing an array of government services that were once confined to *brick and mortar* operations. However, in deciding which applications will be most effective in serving their constituents and given their limited resources, governments might learn from the practices of businesses. As in the case of business to business (B2B) e-commerce, the exchange of information within and between government agencies will comprise the bulk of interactions or transactions. The results of a preliminary e-commerce survey suggest several areas that may prove to be more effective for e-government Extranet and Intranet applications.

## 1. Introduction

The shift from goods to services has led to an information-based economy that has been fueled by rapid and continual advances in information technology (IT) [19]. Consequently, more organizations have become engaged in various forms of electronic commerce (e-commerce), and information has become their primary resource. As e-commerce expands at phenomenal rates in

the private sector, electronic government (e-government) is beginning to take a hold. Estimates placed business-to-business (B2B) e-commerce spending between \$92 and \$142 billion [1], [14], and business-to-customer (B2C) at \$33 billion in the US during 1999 [1]. By the year 2004, total e-commerce spending in the US is expected to exceed \$3.2 trillion [14]. Based on the projected general population estimates of the U.S. Census Bureau for 2002 and the estimated proportion of adult Internet users projected by Gartner [9], 45 percent, the current number of adult Internet users (in the US) is estimated at 93.2 million people. This represents approximately 42 percent of the global Internet users [8] and it is expected to double by 2005 [9]. In contrast, approximately 40 million people in the US sought information from government web sites in 1999. However, this was expected to increase to 68 million in 2001, a 70 percent jump in two years [21]. The vast difference in the number of users and the sheer volume of transactions as suggested by the value of electronic markets strongly suggest the existence of many untapped opportunities for e-government. However, capitalizing on these opportunities may pose major challenges for resource-constrained governments and their agencies.

Generally, e-government entails the delivery of government services and information via the Internet [6]. Its applications can be placed into four groups: government information to citizens, external interactions between government and citizens (i.e., submitting forms, registration and tax returns, voting, bidding on government contracts, etc.), internal interactions between government agencies and their employees (i.e., access personnel information, file forms, manage budget and

accounting functions, paychecks, etc.), and interaction between government agencies at the federal, state or local level to share information. Although many predict e-government will lead to a total government cost savings between 1 and 2.3 percent and a .2 to .4 percent increase in productivity [13], many challenges in determining where to begin lie ahead. Several development and implementation options can be pursued, but some applications may result in greater benefits than others. Given the private sector's experience and success with its development of e-commerce, government might closely examine what has been done to avoid costly mistakes and direct resources to those applications that will benefit both government and the public the most [4], [13]. Based on the responses of several organizations, Intranet applications on document management, the posting of electronic forms, education and training, and the broadcast of information prove to result in enhanced communication, increased efficiency and productivity, and improved decision making. Extranet portal applications provide one-stop e-government service that facilitates easy access to citizens and business.

The purpose of this paper is to identify some of the more successful applications in e-commerce and suggest their application to e-government. A preliminary survey was conducted with several private and public organizations to identify the categories in which Intranet and Extranet applications were developed and to gauge the perceived benefits that resulted from their applications. Experiences from a state-sponsored e-government implementation project will also be related and discussed.

## 2. Review

Although the convenience of e-government will quickly win the favor of most people, the real motivation may lie in legislative pressures to reduce the cost of government operations. For many state government agencies, budgetary constraints, a steadily increasing population, and freezes on government hires place added burdens on their ability to service the public. In essence, fewer resources are available to perform an increasing amount of work. A possible solution is e-government, adopting an IT-based business model to electronically managing their charges. Rather than gathering information or transacting business at a physical location or over the phone, people will be able to conduct these tasks online over the Internet with 24x7 (i.e., 24 hours, 7 days a week) accessibility from nearly anywhere in the world. In many cases, successful e-government applications have increased efficiency and resulted in reductions to the cost of processing a transaction [5], [7], [17].

E-government's growth in popularity can be attributed to many factors. Heeks [12] identifies three of them: an unsustainable level of public expenditure that has not produced efficient government services, a resurgence of neo-liberal thinking emphasizing the efficiency of market competition and the need make government more business like, and the rapid

development of IT and the increasing awareness of its value. Government wastes, project delays and cost overruns, mismanagement of resources, and inadequate organizational and management skills have motivated lawmakers to seek nontraditional solutions, such as electronic services (e-services) and e-government. As in the case of the private sector, current e-government initiatives focus on four relationships [3]: government to citizens (G2C), government to government (G2G), government to employees (G2E), and government to business (G2B). Although 34 percent of the initiatives concern providing G2C services, 63 percent involves G2G (20 percent), G2E (23 percent) and G2B (20 percent) e-government applications. This suggests that a majority of e-government will be developed for the Intra- and Extranet.

The long-term push toward an information economy has also fueled the demand for e-services over the Internet [19]. In the private sector, e-services focus on understanding the customers' needs, and responding with goods and services often tailored specifically toward meeting those needs. Many businesses have begun investing in customer relationship management (CRM) systems to manage their interactions with their customers through dialogs [18] and build loyalty [15]. In pursuing such ambitious endeavors, businesses have shifted their focus from being production-centric to service-centric [19]. In a similar move, e-services bring government services to citizens through e-government, but with the benefits people enjoy from e-commerce [2]. Asfaw et al. [2] cite three important e-government issues European nations face: citizens should benefit from e-government as they do from e-commerce, government agencies should benefit from the efficiencies reflected in lower Internet transactions costs, and e-government should be capable of providing a competitive advantage in attracting businesses to the government's jurisdiction by streamlining processes (i.e., securing licenses and permits, submitting tax and employee periodic reports, etc.). The applicability of these issues is ubiquitous and can be extended to all implementations of e-government. Thus, the objectives of e-government can parallel those of e-commerce, but from a different perspective.

Throughout the US, e-government has been gaining momentum. Recent developments in the U.S. Congress reflect greater interests in establishing an e-government stronghold. The E-Government Act of 2001 calls for creating a federal office for the country's chief information technology officer (CIO). Along with the functions of promoting e-government, the CIO would provide leadership and oversee the Internet access of government services and information, the implementation of government-wide information policies, and other functions prescribed by the Paperwork Reduction Act [21]. If enacted, the E-government Act will institutionalize e-government, and provide it with the necessary legislation to ensure its expansion.

Currently, the U.S. Patent and Trademark Office (USPTO) embraces e-government through its electronic trademark filing system that allows customers to interact

with the agency through the Internet [7]. The system also allows USPTO attorneys to conduct patent and trademark searches online and publish its gazette on the Internet. E-government has helped USPTO improve the quality of their interactions with customers, increase worker productivity, and retain highly trained examiners. By 2003, the office expects to handle 80 percent of its applications (for patents and trademarks) and communications electronically.

Another federal agency, the Department of Housing and Urban Development (HUD), has called on e-government to help improve its regulatory management requirements with owners and managers of government assisted housing [5]. HUD has divided its system to fit the needs of critical five areas: active partners performance system, mortgage delinquency and default monitoring, financial assessment subsystem, tenant assessment subsystem, and resident service and satisfaction survey. The system meets the three strategic objectives set by HUD: to reduce paperwork for HUD's partners and clients, to provide greater accessibility for clients to interact with HUD, and to improve HUD's affordable homes program's integrity. Overall, the system has improved HUD's operations and allowed it to keep participating owners and managers (of government assisted housing) abreast of federal and state regulatory requirements. Although limited in their scope when compared to the e-commerce applications in the private sector, the USPTO and HUD systems serve as a prelude to what can be achieved with e-government. To become fully e-government, organizational changes will have to be implemented to transition government agencies to information-centric business models that will allow them to take advantage and reap the benefits of e-government.

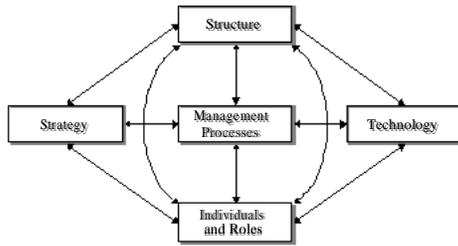

Many state governments have approached e-government through portals to promote e-services, integration and information sharing among agencies. Portals act as gateways that allow Internet users (i.e., constituents, government personnel) to access an array of government services and resources through a single web site in a similar manner to *one stop shopping*. In several cases, they will contain links to various agency web sites. For users, portals reduce their search costs as they provide a single point of contact for online government services [10]. Government agencies benefit from portals in many ways, such as to provide package services in a similar manner to those offered by businesses, reduce the service-processing costs, and improve government accessibility. Some of the recent developments (with portal web sites) include:

- MyGov in California allows people to personalized their e-government services (similar to MyYahoo) by selecting those most relevant to their needs;
- An ambitious e-government project in Hawaii will allow tax payers to file their income tax returns online. Not only will the system improve the tax agency's services to tax payers and its internal efficiency, but it may also increase tax revenues by increasing the accuracy

of the returns, reducing the time for the state to act upon delinquent tax returns, and decreasing the time to collect taxes owed to the state. The state anticipates similar processing cost savings on a single tax return to those reaped in the state of Texas where the cost dropped from \$1.66 to 33 cents [16];

- MyCalifornia extends several services to California citizens, including automobile registration, tax forms and refund status, fishing and hunting permits, hazardous waste disposal instructions, and state contracting information [17];
- NC@YourServices in North Carolina features e-procurement, online government purchasing, and involved the collaboration of many state and local agencies [17];
- PowerPort of Pennsylvania provides simplified online access to wide variety of government services, such as information and forms for business interested in locating to Pennsylvania, filing income tax returns, a calendar of state-wide events, the governor's press releases and more [17].

In spite of these instances of success, e-government still faces many challenges and management issues. As in the case of commercial enterprises entering e-commerce, government agencies will be confronted with organizational issues, especially those involved with the radical change from one business paradigm to another. Paradigms embodied in traditional (*bricks and mortar*) business models drastically differ from those in e-commerce business models. Whereas traditional business models concentrate on the physical acquisition of resources and placement of products and services, IT-enabled e-commerce business models focus on information (and its ensuing knowledge) as the organization's primary resource. Hence, the paradigm shift dictates that organizations engage in e-commerce develop their solutions through information leveraging, rather than methods, such as physical optimization models. The transition to e-government will hold the same challenges to government agencies, moving from solving problems with physical solutions to electronically leveraging information both within the agency and between it and its partners (i.e., other agencies). Led by changes to the agency's strategy and its adoption of Internet-enabled IT, changes to the organization structure, management processes, and the roles and individuals will be required to functionally realign them. The MIT90 framework [20] illustrates the interrelationships of these five components (Figure 1). Essentially, changes to any of the components will result in compensatory changes in the others.

**Figure 1. MIT90 framework**

Increasing interests in e-commerce and recent endorsements of the concept have raised the demand for e-government and ensured its future. Many of the current e-government applications, though, focus on supplying government information to citizens, and supporting external interactions between government and citizens (G2C). Little progress appears to have been made in developing applications for internal interactions between government agencies and their employees (G2E), and those between government agencies (G2G). Yet, in e-commerce, the greatest benefits (and profits) arise from B2B interactions and transactions. Most e-commerce activities appear concentrated on B2B with B2B spending anywhere between three to four times greater than that of B2C. Businesses that benefit the most from e-commerce tend to be organizationally e-commerce designed, particularly capable of leveraging information, distributing information both within itself and between partners in vertical and/or horizontal integration alliances. For e-government to achieve the same levels of success as e-commerce, perhaps governments should examine the factors contributing to its (e-commerce's) success and adopt (or adapt) them.

### 3. Lessons from an e-Commerce Survey

A preliminary e-commerce survey was conducted to determine the types of Intra- and Extranet applications that were most frequently pursued and the perceived results of their e-commerce applications. Fifty private companies and government agencies in California that were engaged in developing successful e-commerce applications were contacted. Of the 50 sent, 32 usable surveys (i. e., 23 from the private sector, 9 from government) were received for a return rate of 64 percent. The high return may be attributed to advance planning; organizations were contacted in advanced and agreed to participate in the survey. Because all organizations were well-established and experienced in developing e-commerce applications, their responses can be considered an accurate reflection of all organizations in the state.

Among the several items in the instrument, two groups focused on Intra- and Extranet applications. Intranet applications reside on an internal server, and are distributed through a network behind the organization's firewall and launched through a user's web-browser. Thus, they are private and can be accessed only from within the organization. Participants were asked of which

Intranet nine applications that were listed had their organizations implemented. The results appear in Table 1. The top four applications were document management (78.1 percent), post electronic forms (71.9 percent), education and training (71.9 percent), and broadcast information (65.6 percent). Based on these results, organizations are more inclined to develop informational Intranet applications.

Intranet Applications	Number Implemented (Percent)
Document management	25 (78.1)
Post electronic forms	23 (71.9)
Education and training	23 (71.9)
Broadcast information	21 (65.6)
Project management	19 (59.4)
Team collaboration	18 (56.3)
Software distribution	17 (53.1)
Inbound logistics	5 (15.6)
Other	2 (6.3)

**Table 1. Intranet applications**

The perceptions of Intranet benefits were measured on a seven-point Likert-type scale (1 = not benefited, 7 = greatly benefited). Table 2 shows the means and medians of the five items. The survey responses indicate that greatest perceived gains from Intranet applications are from enhanced communication (6.2), increased efficiency (5.6), increased productivity (5.5), and better decision making (5.3). Respondents benefited to a lesser extent from reduced cost (4.9). These perceptions suggest that most organizations develop Intranet applications to enhance and improve their distribution of information.

Perceived Intranet Benefits	Mean/Median (1 = not benefited, 7 = greatly benefited)
Enhanced communication	6.2/6
Increased efficiency	5.6/6
Increased productivity	5.5/6
Better decision making	5.3/5
Reduced costs	4.9/5

**Table 2. Perceived Intranet benefits**

Extranet applications tend to be directed toward supporting the interactions between organizations, often those engaged in partnerships or alliances. Characteristically, Extranets connect their individual Intranets together, therefore they are private. As in the case of Intranet applications, participants were asked to indicate which of the listed 12 Extranet applications their organizations had implemented. Table 3 displays the results. The results suggest that Extranet applications tend to involve interactive support and provide information. Customer service and support (65.5 percent), post electronic forms (46.9 percent), marketing and

advertising (46.9 percent) and products/services catalog information (43.8 percent) applications were more frequently implemented.

Extranet Applications	Number Implemented (percent)
Customer service and support	21 (65.6)
Post electronic forms	15 (46.9)
Marketing and advertising	15 (46.9)
Products/service catalog information	14 (43.8)
Electronic data interchange (EDI)	12 (37.5)
Collaboration between business partners	12 (37.5)
Portal	11 (34.4)
Sales	11 (34.4)
Publish information among business partners	10 (31.3)
Production and inventory control between business partners	9 (28.1)
Electronic funds transfer (EFT)	7 (21.9)

**Table 3. Extranet applications**

Participants were also asked to indicate the perceived benefits they received from Extranet applications. Table 4 summarizes the responses to the 11 items. Enhanced communication (6.2), increased productivity (5.5) and greater efficiency (5.5) ranked among the five highest perceived benefits as they did among those for Intranet benefits. Improved customer satisfaction (5.6) and better coordination between business partners (5.3) also appear among the top five.

Perceived Extranet Benefits	Mean/Median (1 = not benefited, 7 = greatly benefited)
Enhanced communication	6.2/6
Improved customer satisfaction	5.6/6
Increased productivity	5.5/6
Greater efficiency	5.5/6
Better coordination between business partners	5.3/6
Reduced costs	4.9/5
Increased profitability	4.8/5
Competitive advantage	4.8/4
Improved inventory control	4.8/4
Reduced production time	4.5/4
Increased sales and market share	4.4/5

**Table 4. Perceived Extranet benefits**

The responses from participants of the survey suggest general trends toward developing applications

that will result with the greatest acceptance, benefit and support of the organization's strategy. The perceived benefits can be translated to application objectives. Thus, both provide an insight to what governments should focus on with e-government.

#### 4. Discussion

While businesses have learned to use Intra- and Extranet applications to gain competitive advantages and efficiencies, interests in the public sector have been slow to develop. However, recent developments suggest that government has begun to take notice of their benefits. Traditionally, governments at all levels face constraints imposed by their bureaucratic structure and legislative rules. In contrast to businesses, governments are less motivated by the economic gains in adopting new technologies. Yet, in recent years increasing public pressures have led to the expansion of e-government. Most of the efforts to deploy e-government applications have primarily targeted supporting administrative tasks and automating governing functions. Given the vastness of e-commerce, e-government has many opportunities to explore and lessons to be learned.

Few differences separate government and private sector Intranet applications. As in the case of most businesses, government agencies can use the Intranet as a tool and arena for document management, posting electronic forms, training and broadcasting information. The nature of government often places burdensome demands on the physical movement of paper documents. Even simple, routine administrative tasks require enormous loads of paper work. Many government agencies have found that the Intranet provides an inexpensive, secure and convenient means for disseminating information. Using the Intranet for document management facilitates communications between employees, and in return, lends speed to complex decision making process. The paper-less flow of documents and information also results in enhanced efficiency and productivity as information is exchanged immediately.

Global businesses have relied upon the Intranet as an important communication link between geographically distributed sites. The same can be applied to e-government to link and bridge an agency's geographically disbursed districts. For example, the State of Hawaii relies upon its Intranet to distribute documents among its four districts, each of which is composed of one or more islands separated by miles of open seas. Before the implementation of their Intranet, hard copy documents were mailed among the districts. Physical delivery naturally means slower responses and longer waits than e-mail, Intranet-site access or document distribution over a Local Area Network (LAN). The Hawaii Department of Taxation takes advantage of Intranet technologies and now posts its tax codes and tax law changes through the Intranet. As a result, every tax clerk has immediate and complete access to them. Consequently, the easy access and convenience greatly bolsters their customer service and significantly improves

their responses, both in time and quality, to customer inquiries. The state also uses its Intranet to log production system incidents and reports. The department's system administrator and operators can now monitor the system from anywhere and at anytime through their Intranet website. These successful e-government applications reflect what many global companies, such as Intel, Hewlett-Packard and others, have learned in the past, and have helped e-government enhance communication within an agency, and improve efficiency and productivity through time savings.

A few of survey respondents noted that their organization's Intranet was often used for software distribution. Many organizations have found that sending a technician to upgrade a user's computer can be very expensive in terms of both the technician's time and employee downtime (i.e., productivity while the computer is down). A solution commonly used to overcome this problem in the private sector involves an Intranet approach. Intranet users can download software and software patches at anytime with no or very little assistance from the technical support staff. This helps reduce downtime since the upgrades can be implemented as soon after they are available (versus waiting for someone to install them). Many government agencies are also beginning to use the Intranet to inform the computer help desk staff of software problems and track the help ticket status, another common practice in the private sector. With a simple Intranet help desk application, users can log onto the Intranet site and write a help ticket; help desk staff will then be assigned to fix the problem and clear the ticket. The system maintains the history and the status of the help ticket. Thus, the ticket can be tracked and retrieved anytime. The Secretary of State's Office in California uses an expert system to determine the severity of the user's problem. Those problems that cannot be easily identified by the expert system are forwarded to technical experts. Otherwise, they are handled in a routine manner.

As with the Intranet, Extranet applications reap many benefits, such as enhanced communication through the collaboration and coordination between government agencies, greater efficiencies and productivity, and improved customer satisfaction. With e-government, the Extranet can serve to link government agencies at the local, state and federal levels. In the US, a viable business model using the Extranet has been proposed to enable a system for child support welfare monitoring. Under the current system, government agencies spend an enormous amount of taxpayer-resources to track noncompliant parents (i.e., parents who do not comply with court orders that require them to make child support payments) and provide welfare benefits. Benefits may be paid to the recipient through different agencies and funding sources, and their efforts may overlap or lead to inconsistent classifications. Problems in linking child support agencies at different levels are often blamed on the agencies use of different systems, and varied computer resources and expertise. If their Intranet applications can be designed to interface with each other

in their Extranet (as in the case of B2B partners), not only will child support agencies be able to coordinate and collaborate with one another in real time and anytime, and become more efficient, but their communication and productivity would be enhanced through the exchange (transfer) of information. In the end, the recipient would receive improved services.

Although businesses possess greater experiences with their e-commerce, differences between the (organizational) missions of business and government dictate differences in their delivery of services. In contrast to businesses, which deploy portal applications mainly within the organization boundary, e-government has seen a trend toward using portals to collaborate and coordinate among different government agencies and bundle government services together that are offered to citizens. Portals are single-point Web browser interfaces used to promote the gathering, sharing, and dissemination of information as well as the provision of services to communities of Interest [11]. Businesses tend to use portals to handle structured and/or unstructured data for business intelligence, knowledge management, training, and etc. With e-government, portals allow various government agencies share information to improve the efficiency of citizen searches for and access to services.

Successful implementations lead to a serious and positive impact on the company's bottom line. Companies can find off-the-shelf products from Brio Technology, Business Objects, DataChannel, IBM, Informix, Microsoft, Oracle and Sybase that can handle these tasks. Large consumer portals, such as Yahoo, also offer lessons and models for e-government projects to follow. Thus, businesses play an important role in the portal applications used in the public sector. In recent years, governments have been learning from businesses in the area of design and rollout of internal corporate portals for knowledge assimilation and distribution. Yet, interestingly, most government portal sites are designed and maintained by private companies, and lease by government agencies.

With more government agencies using portals as the gateway for government services, a trend has been seen to design the portal website around the life event of citizens. For example, MyGov in California can be customized by a citizen (user) to include major state government services such as birth certificate, driver license renewal, car registration, state tax returns, and etc. The advantage of this model is that it promises *one stop shopping* for government services.

Many lessons from businesses' use of their Intranets and Extranets can be learned to direct e-government toward developing more effective network applications. However, they (Intra- and Extranets) by themselves cannot revolutionize government, and planners should remember that technology may provide only partial solutions. First, the Internet technology should not just be used to refurbish government with cutting-edge technologies, but should be exploited to the full-length in automating administrative tasks and government services. Secondly, the e-government services should not stop at

just digitizing the existing work processes, but should be the redesign and re-engineering of work processes and government functions. Lastly, e-government initiatives should be proactive, strategic moves but not reactive, tactical decisions.

## 5. Summary and Conclusion

A few general conclusions can be reached from the lessons reflected in the survey results. Businesses' experience with development of e-commerce applications provides governments with a wealth of knowledge that can be used to avoid making the costly mistakes and better direct their limited resources to those applications that will be most effective. E-government as well as e-commerce will continue to grow because it offers real benefits. Intranet and Extranet applications will comprise the bulk of resources, yet they may yield insurmountable benefits. The lessons that surfaced from a preliminary e-commerce survey suggest that e-government Intranet should concentrate on document management, the posting of electronic forms, education and training, and the broadcast of information. The benefits that were reported include enhanced communication, increased efficiency and productivity, and improved decision making. For Extranet applications, most respondents indicated their organizations focused on customer service and support, electronic forms posting, marketing and advertising, and products/service catalog information. To a lesser degree, though, collaboration between business partners and portal were ranked in the middle. In contrast to Intranet responses, enhanced communication, improved customer satisfaction, increased productivity, greater efficiency, and better coordination between business partners were cited most frequently as Extranet benefits. The differences between business and government objectives may account for the difference in their actually applications.

## Abstract

No other innovation, or way of doing business, has revolutionized the international economy faster than the Internet. It took generations for the Industrial Revolution to play out around the world while the Internet Revolution has unfolded in less than a decade. The speed of this change has been astounding. In the Industrial Age, as change took place, governments were able to react accordingly. In the Internet Age, today's innovation is tomorrow's standard. Government are finding that they must act on Internet time, which is a daunting challenge.

This paper examines the current state of affairs with regards to the taxation of Internet commerce. It analysis the historical perspective of the United States of America, the OECD, the WTO, and the European Union; and attempts to answer the question "What happens next?" Is there an opportunity here for developing countries to increase their tax base?

## 1. Introduction

The biggest standards battle in the history of the digital revolution has again heated up and the fight is about taxes – taxes on e-commerce. The unprecedented growth in the Internet during the "internet bubble economy" highlighted the glaring problems with current taxation laws that address the remote purchases of goods and services. While these problems and concerns may have been sidelined during the past couple of years with the "busting of the internet bubble", the worsening of the worldwide economic slowdown and the surfacing of the global war on terror; they have not been adequately addressed.

And, Internet commerce is not dead. Recent statistics released from the US Census Bureau of the Department of Commerce (20) shows that Internet commerce has risen during the last quarter of 2001 and the first quarter of 2002 in comparison to the last quarter of 2000 and the first quarter of 2001. There estimate of U.S. retail e-commerce sales for the first quarter of 2002, not adjusted for seasonal, holiday, and trading-day differences, was \$9.849 billion, an increase of 19.3% from the first quarter of 2001 Fig.1

Total retail sales for the first quarter of 2002 were estimated at \$743.8 billion, and increase of only 2.7% from the same period a year ago. E-commerce sales in the first quarter of 2002 accounted for 1.3 % of the total sales while in the first quarter of 2001 e-commerce sales were 1.1% percent of total sales.

The United Kingdom statistics also show a startling increase in e-commerce sales (3). The Interactive Media

(2) Retail Group (an industry body for global retailing) is now collecting hard date on online sales to UK consumers. Their IMRG Index provides robust evidence that the UK e-retail market is significantly larger and growing faster than previously estimated. The Index rose to 262 in April 2001, up from 100 in April 2000 – giving an estimate of e-commerce retail sales for the month of April 2001 of 210 million pounds sterling (16).

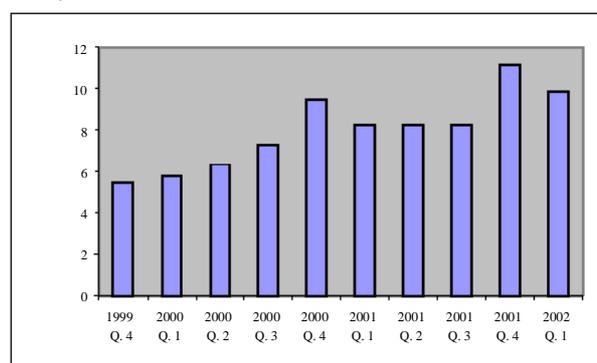

Figure 1: U.S. e-commerce retail sales

This increase of 162% in e-commerce retail sales compares with only a 5.9% increase in general retail sales. Figures from the Index similarly show an increase of 10.4% in March, 2002 compared with February, 2002 and the organization estimates that e-retail will continue to grow ten-times faster than mainstream retail, with no indication that any sector is beginning to plateau.

In a press release dated June 2002 (13), they stated "Half a billion people are online at home worldwide and a third of them shop online." They continued, "Europe now has more internet users than the US. The UK is responsible for a third of all e-retail sales in Europe, with online sales worth an estimated £507 million in May (2002) alone. Internet sales continue to surge, against the general retail trend, but while these direct sales are the most concrete manifestation of e-retail, and may reach 15% of all retail within a few years, they are only one element in the e-commerce equation."

They also highlighted that "throughout the first half of 2002 a steady stream of positive reports have been issued by e-retailers, whose ventures are showing profits - many for the first time - and experiencing rapid growth in sales. The UK e-retail market is currently growing at over 90% year-on-year, and is expected to be worth £7 billion this year (2002), representing almost 4% of the total retail market by the end of the year".

IDC Research confirms these figures (11). As the world's leading provider of technology intelligence, industry analysis, market data, and strategic and tactical

guidance to builders, providers, and users of information technology; their recent research suggests that more than 600 million people worldwide will have access to the Internet - spending more than \$1 trillion online. While the United States now accounts for 40 percent of the money spent online, they suggest that as residents of Asia and Western Europe increase their spending, The U.S. should only account for 38 percent by 2006. In some Asian nations, governments are lobbying to bring more citizens online, thus contributing to rapid Internet penetration in those markets. In Western Europe, e-commerce is expected to rise 68 percent this year as the adoption of the Euro brings better competition, price transparency, and improved deals for online buyers.

Accordingly, governments at all levels and all types of retailers are now addressing the best way to deal with legislative shortcomings surrounding the taxation of e-commerce; with local government groups pushing for tax assessment based on where the purchaser lives rather than the seller's location, and businesses lobbying for a neutral, fair and equitable, easily administered system. The EU recently acted unilaterally with their Electronic Commerce Directive.

## 2. The Problem

It is unquestionable that developments in e-commerce and new business models have allowed all kinds of businesses to change their trading practices in ways that were unimaginable when tax rules were developed for traditional business models. The emergence of the commercial Internet has opened new routes for the exchange of goods and services. Almost any goods that can be digitized can be bought, sold and distributed quickly and inexpensively through the Internet to consumers worldwide. Substantial questions remain, however, about how electronic commerce will be treated by the various laws of taxation.

Electronic commerce raises domestic and international tax issues. Specifically:

1. There are unique problems in tax administration posed by electronic commerce.
2. There are sales and use tax issues, such as nexus and the non-uniform (and sometimes inconsistent) manner in which tax laws treat electronic commerce-related activities.
3. There are international taxation issues arising under domestic taxation laws and foreign value added tax systems (with this changing business climate, tax authorities the world over have been particularly concerned that private customers would buy digital products and services from non domestic suppliers because no sales tax was due on these products).

Most nations have in place a system of tax laws and regulations which govern the tax treatment of goods and services crossing their borders and assert taxing jurisdiction on the basis of the "source" of income and the residence of the entity earning the income. For example, determining the source of income is important both to businesses in the United States and to foreign entities

doing business in the United States. Under the Internal Revenue Code (I.R.C.) (21), United States citizens and residents ordinarily are fully taxable in the United States on income which is derived from sources outside the United States, subject to certain exemptions and limitations. A corporation created or organized in the United States also is taxable on its worldwide income. Foreign entities, however, are generally only taxed in the United States on income generated from sources within the United States. For example, nonresident aliens in the United States and certain foreign corporations in the United States are taxed on income which is "effectively connected" to the conduct of a trade or business within the United States.

Taxation of international commerce also depends on the provisions of various international bilateral tax treaties. Among the most important concepts in these treaties is that of "permanent establishment," which is essentially a fixed place of business through which the business of an enterprise is wholly or partly carried on. To prevent double taxation of international activity, countries generally tend to restrict their taxation of business profits to those profits that are attributable to a permanent establishment in their jurisdiction.

The Internet raises difficult unresolved questions about how to determine whether an entity engaged in electronic commerce is engaged in a trade or business in a particular country or has a permanent establishment in that country for tax purposes. Parties engaged in electronic commerce, for example, may not have, or need, a physical place of business in a country in order to conduct extensive business online in that country. Thus, it is not always clear whether they have a permanent establishment which would give rise to any tax obligation. It is unlikely, however, that foreign electronic vendors who merely solicit orders within a country and then ship tangible goods into that country based on those orders will be considered as engaging in a trade or business in that country.

### 2.1 Where's the Nexus?

The power of a state to impose income taxes or sales or use taxes, or an obligation to collect taxes, depends on whether a "nexus" exists which would support a state's taxing jurisdiction. "Nexus" essentially means a "contact or link" – a contact or link which forms the legal basis for the imposition of taxes. Only those parties having sufficient contacts or links with a state are subject to taxes by that state - some minimum connection or link between the taxing state and the person, property, or transaction it seeks to tax. Where is the "nexus" in electronic commerce: is it between the seller and his home state, the seller and the state of the customer, the customer and the state of the seller, the customer and his/her state of residence, the internet service provider and their resident state, the internet service provider and the home state of the customer, or the internet service provider and the state of the seller? These questions still have to be answered.

In addition, if nexus exists for online transactions, the question of what, actually, is subject to sales and/or use tax remains. In general, this depends on how the transaction in question is classified under sales and use tax laws. Normally, governments distinguish between transactions in tangible personal property, services and intangibles and take a variety of approaches to classifying electronic activities under sales and use tax statutes, with little uniformity or guidance in their application. Sales and use taxes are normally imposed on retail sales of tangible personal property unless the law provides for a specific exemption or exclusion. "Tangible personal property" typically includes material goods that may be perceived by the senses. Services are not generally covered by sales and use tax unless the law specifically enumerates the services as taxed. Although services are less extensively taxed than tangible goods, over the years there has been a gradual broadening of the tax base for services. Intangibles, such as transfers of stocks and bonds or intellectual property rights, generally are not subject to sales tax. Sales and use taxation of intangible intellectual property rights has been an important issue in taxation and, given the important role that licensing plays in electronic commerce, promises to continue to be important in the future.

Taxation in connection with electronic commerce must also take into account the unique features of the Internet and other electronic networks. Most tax laws and regulations were established before the rise of electronic commerce, and are rooted in concepts of physical location or presence. Determining the identities of the parties who participate in a transaction, where a transaction is "sited," and identifying key "taxing points," for instance, are often important to the administration of taxes. These concepts, however, may be difficult to analogize to transactions occurring in cyberspace.

## 2.2 The Problem of Lost Revenue!

Not requiring internet-based merchants to collect sales and use taxes, places them at a significant advantage over traditional retailers. This inequity could have a profound negative impact on not only retailers but local communities because it risks governments' ability to collect the revenue needed for education, police, and other essential services, and could lead to increases in property or income taxes. In the United States nearly 40 percent of all state revenues come from the sales tax; it is the single most critical source of funding for public education. There is serious concern in the United States that unless the Congress moves to restore a level playing field by taxing internet commerce, current industry and academic studies project American States will lose between \$10-20 billion in sales tax revenues by 2003, \$45.2 in 2006 and as much as \$54.8 billion by 2011 – Figure 2 (5).

Given the above, it obvious why a central theme in the debate over the tax treatment of internet commerce centers around the extent to which the inability to tax them has eroded government sales tax collections.

Revenue losses from e-commerce generally arise because e-commerce enables a significant increase in remote sales, thereby causing a shift from collecting sales taxes at the point of sale to collecting use taxes for goods used, consumed, or stored in a jurisdiction. The resulting revenue losses are generally the result of tax evasion, not tax avoidance, since the use tax is due even if the sales tax cannot be collected.

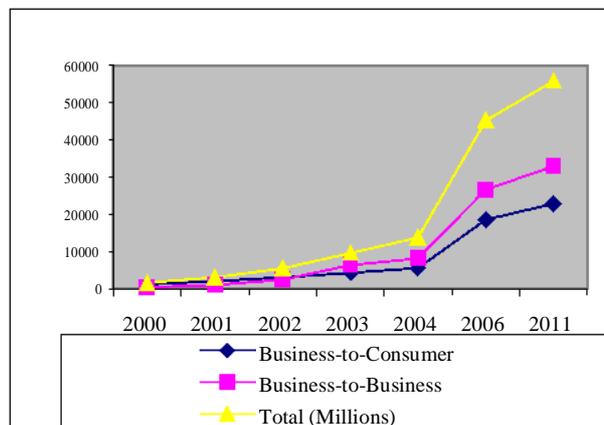

Figure 2: U.S. sales tax losses on electronic commerce

## 3. Are We Close to a Solution?

### 3.1 The Clinton Proposal:

In July 1997, the US discussion on e-commerce taxation was formalized in the Clinton Administration report entitled "A Framework for Global Electronic Commerce"(6). It articulated the United States government's view that governments should adopt a "non-regulatory, market-oriented approach to policy development around electronic commerce". The paper set forth five principles for facilitating the growth of commerce on the Internet:

1. The private sector should lead.
2. Governments should avoid undue restrictions on electronic commerce.
3. Where governmental involvement is needed, its aim should be to support and enforce a predictable, minimalist, consistent and simple legal environment for commerce.
4. Governments should recognize the unique qualities of the Internet,
5. And, electronic commerce over the Internet should be facilitated on an International basis.

It expressed the government's view that the Internet should be a tariff-free environment, and committed that the United States would advocate The World Trade Organization and other international groups to declare the Internet to be tariff-free "whenever it is used to deliver products or services". The Paper also stressed the US governments position that no new taxes should be imposed on electronic commerce and that taxation of such commerce should be consistent with established principles of international taxation. Further stating that

taxation of Internet sales should neither distort nor hinder commerce, be simple and transparent, and be able to accommodate tax systems used by the United States and its international trading partners.

### 3.2 The Internet Tax Freedom Act of 1998:

The Clinton Proposal was followed by the Internet Tax Freedom Act of 1998 (14). Concerned with the negative effect of taxation by local governments on the growth in online sales; the US Congress, with Clinton Administration backing and the support of John McCain in the Senate, attempted (with minor exceptions) to make the Internet a tax free zone. This legislation established a three-year moratorium on the state and local taxation of Internet access and "multiple or discriminatory taxes on electronic commerce". The Act's major e-commerce provisions included:

- A ban until October 1, 2001, on any new taxes on Internet commerce or access charges.
- Grand-fathering of existing taxes.
- And, the creation of an Advisory Commission on Electronic Commerce (ACEC), which found in their Report to Congress "governments should keep the tax and administrative burden on consumers and businesses as low as possible", and outlined "It should not be presumed that the collection of sales and use taxes on internet transactions is an inevitability" (1).

The ITFA's statutory language suggested several specific topics for the Commission to study, including an examination of:

- The collection and administration of consumption taxes on electronic commerce in other countries and the United States, and the impact of such collection on the global economy, including an examination of the relationship between the collection and administration of such taxes when the transaction uses the Internet and when it does not.
- The impact of the Internet and Internet access on the revenue base for telecommunications excise taxes.
- Model state legislation that would provide uniform definitions of transactions subject to or exempt from sales and use taxes and would ensure that Internet access, online services, and transactions using the Internet, Internet access or online service would be treated in a tax and technology neutral manner relative to other forms of remote sales.
- The effects of taxation, including the absence of taxation, on all interstate sales transactions, on retail businesses and on state and local governments to collect sales and use taxes owed on interstate purchases from out-of-state sellers.

A proposal submitted to The Commission by state and local governments (8), sought a uniform sales tax regime that would have applied to e-commerce and other remote-sales transactions where the seller does not have a presence "or nexus" in the state where the buyer is – although not uniformly applied, the US Supreme Court has upheld the "nexus" test.

This moratorium on (amongst other things) new, multiple and discriminatory taxes on internet commerce expired October 21, 2001 at midnight after the U.S. Senate successfully rejected an effort to take up legislation passed by the House to extend the ban for two years.

### 3.3 The US Streamlined Sales Tax Project:

The U.S. Streamlined Sales Tax Project began in early 2000 as an initiative by state governments (via the Committee on State Taxation – COST (7)), with input from local governments and the private sector, to simplify and modernize sales and use tax administration for all types of commerce.

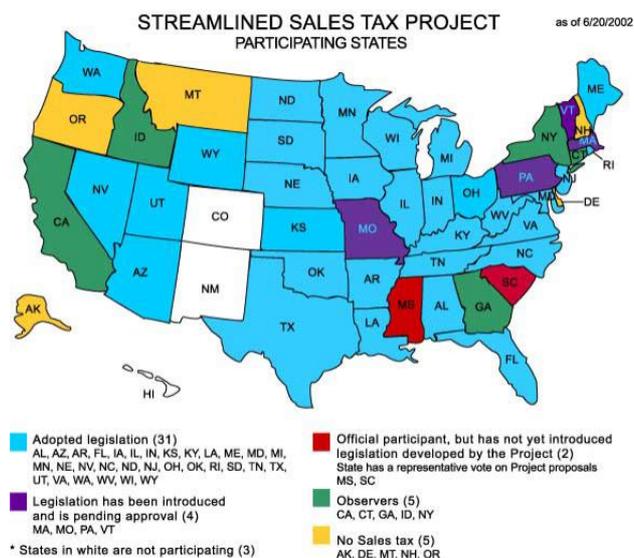

Figure 3: Streamlines sales tax project – participating states

This simplified system was to incorporate uniform definitions within tax bases, simplified audit and administrative procedures, and emerging technologies to substantially reduce the burdens of tax collection. The focus of the project is to improve sales and use tax collection and administration systems for both Main Street retailers, remote sellers, and for states. There are currently forty-two states involved in the project.

The project's main goal is to provide a sales and use tax systems that has the following characteristics:

- Neutrality – Taxability should be independent of the method of commerce used in a transaction.
- Efficiency – Administrative costs should be minimized for both business and government.
- Certainty and Simplicity – Tax rules should be clear and simple.
- Effectiveness and Fairness – Taxation systems should minimize the possibility of evasion.
- Flexibility – Taxation systems should keep pace with changes in the economy.

In January 2001, U.S. state leaders, working with more than 100 companies, unanimously adopted a model state streamlined sales and use tax legislation to remove

the burdens on business of compliance with thousands of different state and local sales tax systems. This new system proposes a 21<sup>st</sup> century, simplified tax system that would provide a single method of registration and a single means of reporting for all states, uniform rules and schedules for remittance to states, and uniform definitions of goods and services (15).

### 3.4 The European Union:

Although the US was undoubtedly the major player in e-commerce, American policy makers were not alone in their quest to define appropriate e-commerce taxation rules – Europe and other countries had equal concerns.

European Union members formally documented their own ‘plans’ for taxing Internet transactions, initially for example, in the Bonn Ministerial declaration and the European Commission’s 1997 “European Initiative in Electronic Commerce”. In the latter the principle of a “clear and neutral” tax environment was supported. However, the document clearly stated that “electronic trade in goods and services clearly falls within the scope of VAT” and pointed out that VAT would apply to the purchase of soft goods at the place of consumption.

In an extraordinary session on December 13, 2001, The EU Council of Economic and Finance Ministers met in Brussels and decided to move forward on two major tax initiatives - proposed directives on savings taxation and e-commerce VAT. On February 12, 2002 The Council reached a political agreement, on amending Regulation (EEC) 218/92 on administrative co-operation in the field of VAT and on amending the sixth Council Directive 77/388/EEC on VAT arrangements for certain services supplied by electronic means, as well as subscription-based and pay-per-view radio and television broadcasting. But these could only be formally adopted when all the language versions became available. This was done on May 7, 2002, when Council Directive 2002/38/EC was adopted. At the same time the Council adopted Council Regulation (EC)792/2002, temporarily amending Regulation 218/92 on administrative co-operation in the field of indirect taxation, to introduce additional measures necessary for the registering of foreign e-commerce traders for VAT purposes and for distributing the VAT receipts to the Member States where the services were actually used (9) (10).

The new rules aim to ensure that certain electronically delivered services are taxed at the place of consumption. They can be summarized as follows:

- Non-EU suppliers will have to charge VAT on services electronically supplied to EU customers at the VAT rate of the Member State where their customer usually resides. They can register in the Member State of their choice (so called Member State of identification) and pay all VAT due on a quarterly base. The State concerned will then re-allocate the VAT revenues to the Member States where the consumer is located. Registration will not be necessary for non-EU established traders whose

annual level of sales within the EU is below EUR 100 000.

- When these services are provided by an EU operator to a non-EU customer, the place of taxation will be where the customer is located and they will not be subject to EU VAT.
- When an EU operator provides these services to a taxable person (i.e., to another business) in another Member State, the place of supply will be the place where the customer is established.
- Where the same operator provides these services to a private individual in the EU, or to a taxable person in the same Member State, the place of supply will be where the supplier is located.

Additional measures can be summarized as follows:

- Tax on supplies to business customers will be accounted for by the customer. Registration for tax purposes will only therefore be necessary if supplies are made to private customers.
- A single place of registration (which will, in practice, normally be the Member State to where a first taxable supply is made) will be possible. This will enable the operator to discharge all obligations for EU VAT with a single administration. This latter measure effectively puts EU and non-EU operators on an equal basis when supplying to EU customers.
- It will also be possible to complete electronically all procedures in relation to registration and the making of tax returns.
- Tax administrations will provide operators with the means to distinguish easily the status of the customers (i.e. whether the customer is a VAT registered business or not) and this will normally provide the means whereby a supplier, acting with all possible diligence, can determine whether or not a transaction should be charged with tax.

Existing VAT rules for other transactions remained unchanged.

### 3.5 The OECD:

The OECD at its Turku meeting in 1997 presented its own “framework conditions” (document 25 from the Committee of Fiscal Affairs) for dealing with taxation and e-commerce. It outlined the general tax principles that should be applied to e-commerce. Specifically: neutrality; efficiency; certainty and simplicity; effectiveness and fairness; and flexibility.

Of primary concern to OECD member states was their belief that the Internet would facilitate increased cross-border commerce and increase the mobility of business and capital. Related tax administration and compliance issues were also of concern. Specifically:

- They feared the lack of any user control as to the location of the activity (vendors don’t know where their customers are, customers don’t know where their vendors are, and governments don’t know where either participant is).
- They feared being unable to identify users.

- They feared the reduced use of information reporting and withholding institutions (disintermediation).
- And, they had concerns regarding the development of electronic payment systems.

Members also believed, and were equally concerned, that tax havens and offshore banking facilities would become more accessible and, presumably, more widely used to avoid or evade tax.

Based on a consensus reached on the Taxation Framework Conditions at their Ottawa conference (October 1998), which included participation of a number of non-OECD countries, the OECD committee on fiscal Affairs (CFA) set up Technical Advisory Groups (TAGS), to produce recommendations on a variety of issues. It also issued a draft-revised commentary to article 12 of the model treaty addressing the tax treatment of software. In addition, they proposed a change to the commentary on Article 5 of its model tax convention with respect to the definition of "permanent establishment." Under this expanded definition, the presence of a server or Web page by itself generally would not satisfy the requirements for a permanent establishment. A server could be a permanent establishment if it performed significant activities that were more than "preparatory" or "auxiliary." It was left up to each member country to adopt clear and certain rules as to what would constitute significant activities for that purpose.

But their work continues! Since the agreement on the taxation Framework Conditions, the organization, through its Committee on Fiscal Affairs ("Committee"), has pursued an ambitious work program directed at effective implementation of the framework conditions. A key element of that work program has been an international dialogue, involving not only OECD member countries but also the international business community and a number of non-member economies. In March 2001, they published a progress report on the implementation of the Framework Conditions and a number of other "key documents" have emerged from that work program - on international direct tax issues, on consumption tax issues, and on tax administration issues.

On international direct tax issues:

- The full text of the agreed "Clarification on the Application of the Permanent Establishment Definition in E-Commerce: Changes to the Commentary on the Model Tax Convention on Article 5"
- The final report on "Treaty Characterization Issues Arising from E-Commerce, which was produced by the TAG (Technical Advisory Group) on Treaty Characterization of E-Commerce Payments".
- A Discussion Draft on "Attribution of Profit to a Permanent Establishment Involved in Electronic Commerce Transactions, prepared by the Business Profit TAG".
- A discussion draft on "The Impact of the Communications Revolution on the Application of "Place of Effective Management" as a Tie Breaker Rule", prepared by the Business Profits TAG.

- A report by the Business Profits TAG summarizing progress made in the context of its mandate, and proposed areas of future work.  
On consumption tax issues:
- A report by the Committee's Working Party No. 9 on Consumption Taxes: "Consumption Tax Aspects of Electronic Commerce".
- A report by the Consumption Tax TAG summarizing progress made in the context of its two-year mandate, and proposed areas of future work.
- A report by the Technology TAG summarizing, in particular, its advice on possible collection mechanism options for consumption taxes, and proposed areas of future work.  
On tax administration issues
- A report by the Committee's Forum on Strategic Management: "Tax Administration Aspects of Electronic Commerce: Responding to the Challenges and Opportunities".
- A report by the Professional Data Assessment TAG summarizing progress made in the context of its two-year mandate, and proposed areas of future work.

It is evident the OECD sees the development of appropriate Internet taxation policies as a major international issue (18).

### 3.6 The World Trade Organization:

In terms of The World Trade Organization (WTO); currently tariffs are not imposed on most electronic transactions but are normally only applied to the physical trade of goods. However, The General Agreement on Trade in Services (GATS) (22), the WTO agreement covering trade in services, does include under "Communications Services", some sub-sectors which relate to conduction of electronic commerce (including data transmission services, electronic mail, information and database retrieval, electronic data interchange, and online information and data processing – including transaction processing).

In their "Declaration on Global Electronic Commerce" adopted at the Second Session of the (Geneva) Ministerial Conference on May 20, 1998, the WTO Members agreed to establish a work programme to examine all trade-related issues relating to global electronic commerce (specifically taking into account the needs of developing countries) but, to continue their practice of not imposing customs duties on electronic transmissions. Implementation of the Work Programme was assigned to four WTO bodies, namely; the Council for Trade in Services; the Council for Trade in Goods; the Council for TRIPS; and the CTD. The General Council adopted the plan for this work programme on September 25, 1998, initiating discussions on issues of electronic commerce and trade by the Goods, Services and TRIPS (intellectual property) Councils and the Trade and Development Committee (23) (24).

The Doha Declaration resulting from the November 2001, Fourth Ministerial Conference in Doha, Qatar; endorsed the work already done by the work

program on electronic commerce sub groups and stated that the WTO members would continue their practice of not imposing customs duties on electronic transmission. The Declaration stated that members would continue this practice until the Fifth Ministerial Conference (25).

But, the organization remains divided on the question of whether to treat electronic commerce transactions and digitally delivered products as goods or services. The issue is crucial for businesses engaging in e-commerce, since it determines which multilateral trade rules and market access obligations apply to these transactions. The United States, in particular, has urged that goods delivered in digital form be classified as goods rather than services to the maximum extent possible, thus automatically making such transactions subject to the mandatory basic market access provisions of the General Agreement on Tariffs and Trade ("GATT"). In contrast, the European Union has advocated a services classification, which would only require WTO members to commit to a market access liberalization over which they have significant discretion.

### **3.7 The Industry Perspective:**

While governments strive to develop appropriate methods for taxing e-commerce (likely based on the residence of the consumer), consumers and technology vendors largely take an opposite view – no new Internet taxes.

The Internet Tax Fairness Coalition (a U.S. organization whose members include; AeA (formerly the American Electronics Association, America Online, Inc., Apple Computer, Inc., Cisco Systems, Inc., Direct Marketing Association, First Data Corporation, Information Technology Industry Council, Information Technology Association of America, Microsoft Corporation, Novell, Inc., Oracle Corporation, Software Finance and Tax Executives Council, Software & Information Industry Association, Sun Microsystems) contends that imposing additional taxes on Internet sales could severely hamper existing small and midsize resellers and retailers, and could prevent others from entering the market. They feel that interstate commerce and the economy are burdened by multiple, confusing and inconsistent state tax rules. Therefore, development of a simple and uniform system is critical. They support the following objectives for reducing the tax burdens imposed on interstate commerce that thwart the development of a borderless marketplace:

- Establish simple and uniform sales and use tax rules that reduce compliance burdens for all taxpayers.
- Enact nexus standards for business activity taxes that eliminate uncertainty and the potential for double taxation.
- Promote availability of the Internet to all by prohibiting taxes on access fees.
- Prevent multiple and discriminatory taxation by extending the application of traditional tax rules to electronic commerce.

In their letter to the of September 6, 2001 to The Finance Committee, following testimony at the August 1, 2001 Finance Committee hearing on "Cybershopping and Sales Tax: Finding the Right Mix"; they urged the Committee to move forward on the single point of consensus that emerged from the witnesses' collective testimony—that the moratorium of the Internet Tax Freedom Act ought to be extended. They made an identical plea to the US Congress suggesting, "If the ITFA moratorium is permitted to expire it will cast a chill over interstate commerce by signaling to the more than 7600 state and local taxing jurisdictions that disparate tax treatment of transactions based on the medium used is acceptable. The Internet Tax Fairness Coalition (ITFC) believes that Congress must not delay. We urge you to extend the moratorium on the imposition of these new taxes before it is too late". Their proposed draft legislation provided to extend the moratorium enacted by the Internet Tax Freedom Act through 2007, and encouraged States to develop an Internet tax regime that is simple and uniform (17).

"We're opposed to any new taxes on the Internet," says George S. Isaacson, acting director of the Association for Interactive Media (reportedly the largest Internet trade association) (12). Isaacson explains "We're working for the Amazons of the future to make sure they have the ability to grow and gain market share". In his presentation to the commission, he argued, "Information technology and electronic commerce have been the most important factors fuelling the largest and longest economic boom of this century" and warned against the negative effects of inappropriate e-commerce taxation policies (4).

However, there are more moderate and even dissenting views. Mark Negergall, president of the Software Finance and Tax Executives Council, says his group, compiled of major software providers, is neutral on taxation as long as the tax is non-discriminatory. "Our view is that we should be treated no better or worse than any other medium, such as telephone, telegraph, telefax or direct mail."

In spite of a study released by Ernst & Young (funded by the e-commerce Coalition) which challenges the notion that Internet commerce threatens to drain the treasuries of state and local governments; leadership in Silicon Valley appears to be siding with state and local governments in favor of taxing the Internet. As with other advocates for taxation, they argued that state and local governments need the potential sales tax revenues offered by on-line commerce. They suggest that failing to apply sales taxes to on-line transactions is fundamentally unfair and is a disadvantage to traditional in-store buying.

## **4. What Happens Next?**

It is clear that if electronic commerce continues to grow (especially if the growth is at the expense of conventional commerce) the question of e-commerce taxation will have to be answered both at the domestic

and international levels. The current lack of neutrality and basic fairness in e-commerce taxation legislation will become more painfully obvious (at the heart of the debate is the principle that states and other local governments have the right to tax goods sold within their jurisdiction). Consequently any future discussion on e-commerce taxation must include the following key issues:

- The proper relationship between federal and the local governments on issues of taxation, and which levels of government ought to bear the responsibility for determining and financing the needs of their citizens and businesses;
- The necessity of keeping tax policy neutral so that neither traditional retailers nor remote sellers (catalog, Internet, or similar enterprises) are given an advantage based on tax policy;
- The need to stop erosion of essential revenue streams that support education and other key public services at the local level.

And, The technical issues on the table continue to be:

- What constitutes taxable presence from the use of the Internet?
- What is the tax classification of income from electronic activities (the main consequences being the application of withholding tax and indirect taxes)?
- How are taxpayers identified and their transactions audited?
- What are the implications for transfer pricing and the use of tax havens?

The U.S. is making an effort with its Streamlined Sales Tax System for the 21<sup>st</sup> Century Project. The European Union, growing more and more concerned about the potential loss of revenue adopted new rules with regards to VAT on electronic commerce which will come into effect in July 2003. But the new directive has drawn international criticism – the OECD, Japan and the U.S. have all voiced concerns. The Commission justified making its proposals without waiting for the outcome of the OECD negotiations, saying that under the Ottawa Framework, consumption taxes such as VAT should be levied in the jurisdiction where consumption takes place, and that for those purposes, a supply of digital products should not be treated as a supply of goods. It said the new proposals would ensure that the EU VAT system conformed to the framework's principles. Commissioners also assured the U.S. and Japan that they recognized the need for international collaboration on the taxation of e-commerce, but suggested that they were particularly concerned with simplifying European VAT rules to ensure that non-EU operations were brought within their scope as soon as possible. The is growing concern however that this unilateral move by the EU could open the floodgates for other nations to impose e-commerce taxes in an uncoordinated, cost-inflicting patchwork.

The OECD continues its work and is supported by the US in their efforts to create consensus around baseline taxation rules that could undergird the international

expansion of e-commerce. The WTO will present the latest developments in its efforts to address e-commerce taxation at the Fifth Ministerial Conference.

While the debate is far from with international “saber-rattling” continuing; the EU has definitely moved the discussion up a notch with its new electronic commerce directive. Only time will tell if their new “consumption-based” directive, and its inherent administrative cost burden, is taking the e-commerce taxation issue in the right direction. If accepted by the global community this shift in emphasis in allocating taxing authority, from the supply based residency concept to the consumption based residency concept, would provide an unprecedented opportunity for developing countries to increase their tax base – particularly for those developing countries, such as China, which are experiencing astronomical growth in internet usage.

## Abstract

This thesis systematically analyses the concept of e-business, its components, e-business technology environment and society environment. It especially lays emphasis on the importance of the combination of e-business and the internal informationization of enterprises and e-business society environment. Based on them, the thesis further makes systematic analysis on the main problems existing inside enterprises and the problems of its environment during the development of e-business. Next it points out that e-business has been prevented from developing mainly by inner informationization and society environment. At last the thesis proposes the countermeasures for the development of e-business.

## 1. Introduction

E-business (EB) embodies the close combination of the latest science and technology and production and management. It means not only their continual and wide combination, but also the market's return to technology and its impetus to it. As a result of it, the efficiency of production and management must be raised and resources must be distributed reasonably. E-business embodies many scientific new ideas, which represent the most advanced ideas of the human development.

What's more, the essential idea and value lie in its overcoming the limit to the freedom, to the district, to the time, to the communication and to the cooperation. In addition to these advantages, e-business is also the advanced form of business, which embodies the inevitable tendency of its development in that such characteristics as unlimited areas, low cost, personalized product and service, high efficiency, sufficient information, manpower and material resources distributing all over the world are just the requirements of e-business itself. Therefore, e-business is the business form with a broad prospect.

To china, e-business is only in the initial stage and there lies much difference whether in scale, management model, coverage and ideas compared with the developed countries. In addition, the special Chinese market environment also brings about the special e-business activities. Chinese economic system innovation is in the crucial period: the traditional means of planning is fading and the market mechanism is not yet sound. When enterprises enter market, they also must enter the market of e-business. E-business is a complicated systematic project, involving the systematic management of computer information, finance settlement and the enactment of law

regulations, etc.

It needs organizing and harmonizing by the powerful institution with cross-department and cross-district. And the thesis makes a systematic analysis on Chinese e-business in order to reach some beneficial conclusions, which presents the following sections. The second section discusses the concept of e-business. The third section analyzes e-business systematically. While the fourth one presents the problems and its reasons for them in the development of e-business. On the basis of the research, countermeasures make the fifth section. At last, the thesis draws some conclusions.

## 2. The Signification of E-business

### 2.1 The Process of E-business Development

So far e-business has experienced two stages. The first stage was during the late 1960s and the early 1980s, whose core was e-trade based on EDI. And we call this stage **traditional e-commerce**. However, the system of EDI was deficient in flexibility and the components of the system were expensive and its usage was only limited to customer-merchant, while the end-customer was exclusive from it.

When e-business was based on EDI, Intranet and web sites came into being; it was immediately widely identified and was performed with surprising speed. Thus it came into the second stage of e-business and we call it **modern e-business stage**. During this stage, e-business developed quickly with such characteristics it possesses as its openness, cheapness and globalization.

But recently the development of e-business has been covered by the shadow of a tendency of web-sites breaking down. So we think the present e-business is not perfect and needs to be further studied. The future e-business is a complete e-business with enterprises centered, containing all the management activities and we call it **mature e-business**. And then is the third stage of e-business.

### 2.2 The Concept of E-business

There are many concepts concerned e-business, such as e-commerce, Internet marketing and e-business, etc. All these concepts refer to the bargaining on the Internet. That is to say, the core of e-business is "business" and "electron" is the means of e-business. But at the same time, e-business not only simply refers to the transaction on Internet, but also contains internal informationization of enterprises. The informationization is the background

support of e-business and is also the very important part of e-business. Thus, e-business is not only the patent of such new Internet companies as Sohu and Sina. What is more, it is combined with traditional industries. Traditional industries have accumulated advantages of all aspects for a long time and it has laid a solid foundation for e-business and it is the main field where e-business is applied. Only all various industries involved in it will e-business have a broad prospect. To say exactly, e-business has two meanings from two aspects. In the narrow sense, e-business is business and transaction through Internet or what we call electronic commerce (EC). While in the wide sense, e-business refers to the whole business activities that have been electronized by the technology of IT. The latter will take advantage of various forms of network, among which there are Internet, Intranet and local area network and so on.. The comparison between e-business and e-commerce sees the following table 1.[1]

**Table 1 The comparison between EB and EC**

	EB	EC
<b>Technology</b>	Web	Web + IT
<b>E-business activities</b>	Internet trade	Internet trade + business

### 3. The Systematic Analysis of E-business

#### 3.1 The Structure of E-business System

E-business is a complicated system, having systematic traits. System that is made up of numerous interrelated elements is an organic entirety having special functions and it has many characteristics, such as collectiveness, stratification, relativity, entirety and environmental adaptability, etc. E-Business as a system also has such characteristics. So the research on e-business must be led by the systematic thought to study its factors and its interrelation. And according to it, we in the end establish the systematic model. See figure.1.

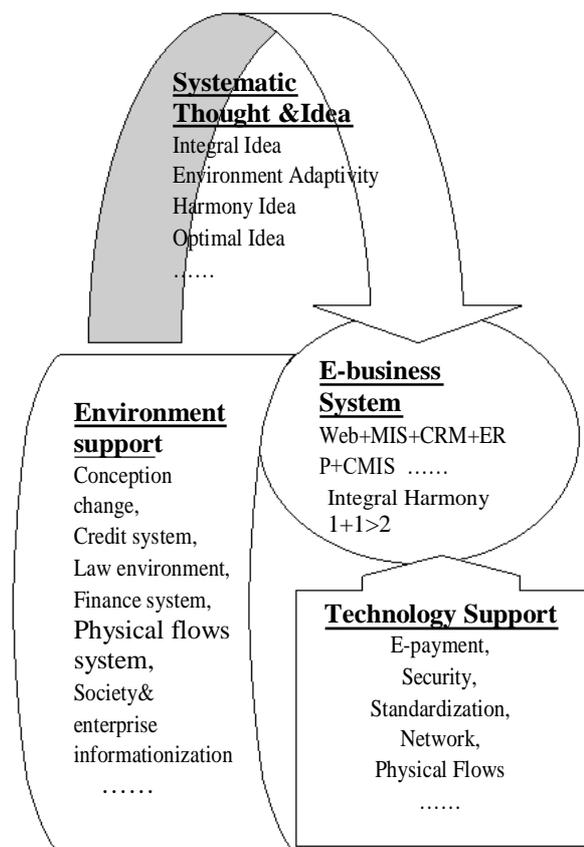

From the figure, we can see e-business, as a system, on one hand, contains downstage e-trade system for external, which we call e-shop. On the other hand, e-business, as a system, can't exist without the support of every department and every tache of enterprises, which we call background support system. The informationization and efficiency of all these departments and taches have direct influence on the normal course of e-shop. Among the background support system, there are MIS, CMIS, ERP, CAD, and CRM etc. Only under high degree of internal informationization of enterprises does high quality e-commerce exist.

Therefore, The e-business system is reasonably divided into three function modules: content management, collaboration, commerce service is reasonable.[1]

##### 3.1.1 Content Management

Content management means the management of issuing various information on Internet. It mainly contains managing and classifying the information of enterprises;

issuing and updating information on Web; providing with the information concerned products and service; helping

**Fig. 1 E-business system and its environment**

transmit internal information of enterprises. To say exactly, by Internet, the policies and notices of enterprises are transmitted to staff, customers and business partners. Thus by such management, information is used fully to increase the value of brand names and enlarge the influence of enterprises.

##### 3.1.2 Collaboration

Collaboration helps to cooperate departments and operation taches. By the automatically operated flow, the cost of operation is lowered and the period of product exploitation is shortened. Concretely it includes the collaboration of intranet and the collaboration of extranet. The latter refers to collaborating inner resources of enterprises, among which there are manpower resources, capital, equipment and material, etc. Intranet connects all departments and operation taches. Extranet connects providers and business partners and so on.

##### 3.1.3 Commerce Service

Commerce service is mainly used to perform

transaction on Internet and provide services of pretransaction, of during transaction and of posttransaction. It can mainly serve the following functions: provide products and service lists; deal with order form; sign transaction contract; perform e-payment and provide after service.

### 3. 2 The Harmony in E-business System

As a system, the coordination of inner elements is the key to producing the best effect on the whole. If the elements have good interrelations, the good system structure will be established and then the good function will be able to be performed. ERP, CRM etc are the most important parts of the informationization inside enterprises, which support e-business. It is hard to imagine that an enterprise with lagging manual management can perform e-business well. In the meanwhile, e-payment system, e-authentication system and safety guard system are also very important parts of e-business. The optimal integration of these subsystems is the key to making the best e-business operation.

#### 3.2.1 The Integration of ERP and EC

ERP mainly focuses on the internal flow of enterprises, while the focus of EC is external transaction. The management model of enterprises before their integration is as follows: receiving order form on website, but goods stocking and collocating and delivering are performed in a traditional way. What we call purchase online is a simple form of EC. The efficiency of its background function is still very low. The process of transaction on the whole is broken and out of joint. By virtue of the technology of Intranet, Extranet and Internet, enterprises fulfill the integration of ERP and EC. In addition, they realize the integration from customers to providers and that of internal flow of enterprises.

#### 3.2.2 The Integration of ERP and CRM Based on EC

CRM is a suit of management ideas and also a suit of practical ideas based on Internet. By recombining operation flow of enterprises, CRM integrates user information resources in order to manage client resources in the effective way and provide clients with more economic, shortcut and circumspect products and service and finally to maximize the profit of enterprises. On the base of modern information technology, CRM can furthest satisfy the individual needs of clients so as to retain old clients and attract new clients, which is enterprises' magic weapon to win. Now enterprises attach more and more importance to CRM.

In the competing environment of EC, enterprises, on one hand need quick and flexible production model and take advantage of ERP to fulfill it. On the other hand, they need to realize the market model of individuation service and CRM serves this purpose. CRM and ERP support each other and depend each other and their relationship is that of transmitting of data information. First of all, ERP

provides CRM with rich data. Next, CRM provides ERP with decision-making data by analyzing and forecasting market development. Only if ERP and CRM are integrated with EC is the transaction model on line realized. And it is the modern EC model. In this model, internal flow of enterprises integrates with external transaction. CRM makes a mutual marketing with clients and ERP makes the data flow on the supply chain fluent. CRM and ERP make enterprises powerful and gain more profit in different ways. The former is used to ease the relationship between customers and clients, while the latter is used to optimize the production flow of enterprises. EC is the reflection of the achievements of ERP and CRM. Consequently it is an integral "end to end" EC with "customer centered"

### 3. 3 The Environment Analysis of E-business

Environment consciousness or environment idea is also very important content of systematic thought. Environment analysis is an essential link in systematic analysis. And environment is also systematic, which we call environment super-system. Environment plays two reverse roles in system. On one hand, it supplies such favorable conditions with the space of survival and development, sustentation of resources and infrastructure and so on. On the other hand, it will exert a passive influence on system development, like exerting restriction, disturbance and pressure, etc. Thus environment plays an important part in e-business development.

From the figure, we can see that the environment of e-business mainly consists of two parts: **technology -support environment** and **social environment**. EB cannot develop without the support of technology. The development of related technology is the precondition and the safeguard of successful EC development. Only perfect technology can be the safeguard for transaction. The technology mainly concludes Internet technology, safety technology, payment technology, and standardization technology, physical flow technology, etc. These technologies provide technology support for e-business.

To say exactly, there is no e-business without corresponding technology safeguard. Among these technologies, we attach importance to the security of safeguard, authentication technology, e-payment technology and standardization technology, etc. Security technology is centered among them, concerning data signature technology, identity authentication technology and encryption techniques, etc. Payment technology relating to capital transfer and settlement, is also concerned by people. It means the problem of capital security and the convenience of payment. The standardization of the related technology of EC is a key problem. Criteria can make the products and service provided by manufacturers interchange and mutually operate. Furthermore, they can normalize market participants' behavior and encourage competition and decrease the risk. By the way, standardization involves the standardization of contract text, that of EC technology, that of e-payment and that of ECM, etc.

E-business is in a complicated social environment. And the environment concerns many aspects, such as law, the construction of credit system, the level of society informationization and that of enterprise informationization and the informationization of finance system and that of physical flows, etc. The appropriate social environment is an important support for EC success. Social environment is the soil on which e-business develops

#### **4. The Chinese Problems Existing in the Development of E-business**

The development of e-business exists great difference between China and developed countries. In contrast, Chinese e-business has its own specialties. Generally speaking, the following problems have to be solved in the development of e-business.

##### **4.1 The Inner Problems of Enterprises**

Inside enterprises, the degree of informationization is low. The degree of informationization of large enterprises on the whole is very low. According to the research on 638 key enterprises of our country, there are 48 and 7.5% enterprises that have completely realized the information system of basic management, containing OA, MIS systems and so on; there are a half and 59.9% enterprises that have partly realized it; there are 208 and 32.6% enterprises that have not realized it. While there are 30 and 4.7% enterprises that have completely realized the comprehensive information system of management, containing CIMS and ERP, etc; there are 30.7% enterprises that have partly realized it; there are 412 and 64.6% enterprises that haven't set about it. Besides, there are 8 and 1.2% enterprises that have basically used e-business; there are 482 and 75.5% enterprises that haven't started. Though there are 435 and 68.2% enterprises have established websites, only 117 (18.3%) enterprises change information per week and only 139 (21.8%) ones operate e-business and their total sales are 0.1%, which are the business income of 638 enterprises in the year of 2000. [2]

Such low informationization has greatly restrained e-business from developing. Next, because e-business has not been combined with the strategy of enterprise development and the strategy cannot adapt to the development of e-business well, traditional business model of enterprises cannot obviously adapt to e-business. These are the main factors that prevent e-business from developing. In addition, the factors that ideas hang behind, sincerity and credit widely lack, the means of management fall behind and the groundwork is weak have influenced the performance of e-business in some degree.

##### **4.2 The Social Environmental Problems**

First of all, the degree of informationization in the whole society is low and Internet doesn't widely spread.

Secondly, the credit system of socialization is not

perfect and the credit degree of society is low. At present, our credit institutions of enterprises have not yet established and that no credit exists in enterprises is in fashion. Thus the problem of enterprise credit has prevented e-business from developing.

The third is the problem of system. The present system of management is basically the offspring of planning economy period, which is stick-block division, the setup is not reasonable, the cooperation is not enough, the rate of work is low and the adaptability to the new economy is weak. To start with the finance system, the e-business needs such means of finance as payment and settlement to support. So e-business is in great need of the service of finance with hi-quality and hi-efficiency and the cooperation of its electronization. Next is the safe authentication system. Now the system is in disorder and it is hard for authentication to be uniform, which keeps e-business from developing.

Fourthly, the modern degree of physical flows is very low and there are short of commerce automatization, informationization, transfer of physical flows and supply chain system to match with. The development of Chinese physical flows starts late and its degree is very low. Thus the present physical flows system restricts e-business in large degree. For instance, our understanding of e-business is limited to the electronization of information flow, commerce flow and capital flow and we ignore the process of physical flows automatization; the infrastructure of physical flows is not perfect; the technology of physical flows management falls behind; the traditional storage and convey system and its means prevent modern physical flows from developing; the third-party service lags; the physical flows system adaptive to e-business has not been established.

The fifth is the problem of law. The legislation of e-business has a long way to go. Now the law environment cannot meet the needs of e-business. Especially, the legislation of electron signature, the protect of knowledge right and the construction of safe authentication system, etc. seriously falls behind, which keep e-business from developing.

#### **5. The countermeasures of Chinese EB Development**

E-business development is a systematic engineering. It cannot ensure e-business to develop soundly by solving only one aspect of problems. E-business system in all directions must be established, which is web-based, business-centered and is supported by good environment and reliable technology.

##### **5.1 Update the Concepts of Enterprises and Strengthen the Construction of Information System of Enterprises to Improve the Informationization of Enterprises**

Try to reinforce the policy-makers' sense of urgency and responsibility, to establish the information work system with the chief information officer (CIO)-centered,

to set up the integral project and technology scheme, and to make preparation for capital, technology and manpower. Besides, try to sort out the inner resources of enterprises and realize the informationization of basic management, research and exploitation according to the requirements of inner resources management of enterprises.

To connect the following links, such as research and exploitation, production, supply, marketing and service, etc. in virtue of ERP, CRM. And try to optimize the resources of manpower, financial resources, material resources and technology, etc. Try to set up the proper e-business model and to make strategies for the development of e-business actively according to different enterprises, in order to put e-business into enterprise system, to make the components of enterprises to collaborate and finally to exert the predominance of integrity.

## **5.2 Strengthen the Environmental Construction to Create the Feasible E-business Environment**

First of all, energetically raise the level of society informationization, quicken the construction of network infrastructure, extend the coverage of network and widen the capacity of e-business marketing.

Then, hasten the construction of credit system and law environment. Credit is the key to the development of e-business. It concerns three aspects: government credit, enterprise credit and personal credit, among which government credit is a guarantee and personal credit is base and enterprise credit is the emphasis. If we want to make the construction of credit better, we must make a medium agency play its role and make credit system perfect as fast as possible.[3][6] At last, perfect the corresponding standard system, security technology and payment technology to provide e-business with technology.[4]

In the meanwhile, the good law environment can ensure e-business to develop continuously and will make e-trade uniform and confirmative in law, no matter the trade is done in the same country or in the trans-nations. Try to issue law regulations that are explicit, collective and recognizable by local, country and international law authorities. At present, what is most important is to make early the rules of law involved the activities of e-business.

The law and rules of law contains the following items: the first is the law concerning time, place and signature of signing contracts and the contract original and the law position of e-bill and the acceptability as lawsuit.

The second is the effectiveness system of e-signature which refers to the applicable scope and the ascription of e-signature and also the usage and effectiveness of e-signature, etc.

The third is about the supervision system of e-business. The finance supervision department must strengthen the supervision of e-transaction to establish the branches of issuing e-money, to make certain of the limits of its power and responsibility and to make corresponding crackdown measures and to make law of preventing cybercrimes.

The fourth is to establish the uniform principle of taxation and the jurisdiction. In addition, the construction of Chinese legal system of EB attends actively International interlocution and tries to make Chinese code accepted by International. By applying the code, Chinese e-business will be provided with strong legal safeguard and be made to further develop. [5]

## **5.3 Actively Push the Construction of Physical Flows System**

Physical flow is the main bottleneck of EB. The problem can be solved in the following ways:

### **5.3.1 Socialize Physical Flows**

The socialization of physical flow can make the disperse physical flows uniform by distributing physical flows reasonably, which can make physical flows become industry and can produce the scale efficiency. The key to realizing the socialization of physical flows is to build physical flow center adaptive to e-business.

### **5.3.2 The Informationization of Physical Flows**

It means the informationization of collecting, processing, transferring and storing of physical flows information. Such technology as that of bar code, of database, of e-order system, and EDI, etc, will be applied widely in physical flows.

### **5.3.3 The Automatization of Physical Flows**

The automatization adopts such system of physical flow automatization as automatic identity system, automatic choice system and automatic storing and taking system and so on. It can save manpower, strengthen the capability of physical flow operation and enhance the efficiency of it.

### **5.3.4 The Network of Physical Flows**

It refers to the uniform layout of physical flow system. When making a plan designing the amount, the place and the scale of physical flow center in a certain field, we must consider the plan of transaction, the range of accommodating and its scale. Besides, we must actively adopt the advanced transportation means and tools, scientific dispatching technology of physical flow to reduce overstocking in transportation.

## **5.4 Hasten to Produce Talents of EB**

The operation of EB is a complicated system engineering, which involves all aspects of society. For instance, it concerns the construction of information infrastructure and that of standardization. In addition, it is concerned with trade, customers, bank, revenue, traffic and transportation, etc. Thus EB needs not only a great number of talents of technology, and talents with all kinds of application, but also talents of management in all layers.

Consequently, we should train the persons concerned in the respect of the consciousness of EB, the knowledge and theory of layout and decision-making. For the development of Chinese EB, we should cultivate numbers of the persons not only knowing the management, but also applying the technology of EB, who can engage in the building, applying and managing EB system.

### **5.5 Reform Finance System, Promote Finance Informationization to Solve the Bottleneck of E-payment**

Finance system is the key factor to e-payment. First of all, in order to create an appropriate finance environment, we must strive to hasten the finance system reform and strengthen the cooperation of banks. Secondly, we must take an active part in financial innovation, improve the financial service and produce continually financial products adaptive to e-payment. Thirdly, promote the informationization of finance system, solve the problems of security and payment and encourage to construct the network banks. At last, we must establish the financial credit system and improve the credit degree of banks, enterprises and persons to reduce the financial risk.

## **6. Conclusion**

With the globalization of economy and the quick development of information technology and information industry, e-business will become the most popular and most active information trade activities and will become the most focused field that every country and every department of industry will strive to be the first to develop.

Chinese e-business is still in the initial stage, faced with many problems from system, technology and management, etc. But China has moved the first delightful step. E-business is a complicated system. So the research on e-business must be led by the systematic thought and we must perform research on soft environment and inner informationization of enterprises. Try to get each element in line according to the principle of integral optimization and at the same time to improve the quality of each element to put e-business practically into enterprises' strategy.

In addition, we must regard environment as a systematic engineering in the construction of environment to create favorable environment support in all aspects for e-business development.

## Abstract

There are a lot of problems that make the business of electronic stores very difficult, especially for those firms that lack the required expertise and resources for running an electronic business. This study proposes a new business model of electronic commerce (EC), which aims to tackle those problems and help enterprises run electronic stores well. This model applies the franchise system of chain store, a very successful modern business model, to the management of electronic stores to take advantage of the chain's competitive power by integrating individual affiliate sites as a whole. There are eight components in the model. Implementation strategies of the model, which are quite different from those generic strategies commonly used in implementing business models, are also proposed. The feasibility of the model and its implementation strategies were validated using the Nominal Group Technique (NGT), the case study, and the questionnaire survey approaches. Finally, practical implications for applying the model are discussed, and directions for further study are also suggested.

**Keyword:** electronic commerce (EC), business model, strategy, electronic store, franchise.

## 1. Introduction

There have been many current organizations and new investors running electronic commerce in recent years. Various business models have been invented. However,

very rarely have successful cases been reported to date. "Direct-to-consumer" is one of the most popular EC models[20]. Dell computer is a very successful example of this model that has a positive return on its investment. Amazon.com, the largest Internet bookstore in the world, is another good example of the model. Its business model is very successful and has increased its sales very quickly. But it has not broken even yet even though its sales volume is expected to grow in the next few years. Electronic stores are very important applications of the model because they really benefit consumers and also give enterprises an additional channel to expand their business. Unfortunately, a great many electronic stores fail to survive.

There are many reasons for the failure of an electronic business. Huang and Dai[8] argued that enterprises couldn't generate a return quickly on their EC investments. As a result, a number of electronic businesses close because they cannot continue to sustain big losses over a long period. For many electronic stores, they cannot survive simply because they don't know how to manage the new business. However, most of the failures of electronic businesses are due to a lack of strategies that can fit their business models and thus can sustain a competitive advantage. The business model under the EC environment is quite different from traditional ones because of the unique characteristics of electronic businesses. It is therefore essential for

electronic businesses to have innovative strategies, which can be properly integrated with their EC models and help the models be successfully implemented, such that these businesses can gain a good stance in the drastically changing and severely competitive new market.

Business models and innovative strategies are very important EC issues. A good business model is the key to success for an electronic business. However, a good business model without proper strategies cannot assure its successful implementation. Although much research has been conducted on EC models and strategies, an important issue, the integration of innovative strategies with the EC model for its successful implementation, has been neglected. This study attempts to investigate the issue by reviewing current EC models and strategies and proposing a new EC model with innovative implementation strategies. The new model applies the franchise system, which has been successfully implemented in physical stores for several decades, to the management of electronic stores and is aimed at helping current electronic stores or those who are interested in running electronic stores to have greater competitive advantage in the industry.

## 2. Literature review

Many things need to be taken into consideration when running an electronic business. Kalakota and Whinston [10] proposed several of them: product/content, software interface, work flow, price, payment, and market penetration. Those are all essential issues that should be included in the business model of EC. EC models have to deal with the interactions between enterprises and consumers. Treese and Stewart[19] presented a framework of the businesses' value chain of EC regarding their interactions with customers. The framework includes four phases: attracting customers, interacting with customers, processing customers' orders, and responding to customers' questions. The idea of the value chain is like that of traditional management, but its execution needs an innovative method to adapt to the computer network, which is a new media for the business transaction.

EC will give rise to new kinds of business models, which can be categorized in different ways [16]. For instance, according to Weill and Vitale [20], there are models for direct to customer, full-service provider, whole of enterprise, portals, agents, auctions, aggregators, shared infrastructure, virtual community, value net integrator, and content provider situations. Yu[22] summarized current EC models and classified them into six categories in terms of transaction subjects, web services, electronic markets, economic benefits, selling contents, and specific applications. Deitel et al.[6] reviewed some practically important business models of EC. They are the storefront model, the auction model, the portal model, the dynamic-pricing model, the B2B model, and the click-and-mortar business.

The integration of EC models with implementation strategies is important to EC success. Some studies found that the high connectedness of information strategy and

business strategy is helpful to achieve better business performance [18][14]. Since the business model of an EC firm is inseparable from the firm's business strategy, and implementation strategies of the EC model are partly dependent on the firm's information strategy, it is therefore crucial to integrate the model with its implementation strategies when implementing the EC model. A good match of the EC model with the implementation strategy will align them toward the enterprise's business strategy and information strategy. As a result, this may lead to better performance.

Several factors are critical to the success of the electronic store. Cheng[4], and Lin and Chuang[15], proposed some of these factors: rich information content, plenty of products and services with the related information, good corporate image, sufficient bandwidth, secure transaction environment, reliable host computer with enough capacity, and comprehensive back-end management system. All these factors are important in running an electronic store. However, these are not enough. Actually, consumers usually demand more; they demand electronic stores to be complete and operative which provides high-quality services. Most of current electronic stores don't run well because they cannot meet the demand of customers. Accordingly, the establishment of an electronic store should be targeted to meet consumers' demand.

There are three approaches to constructing an electronic store: renting a virtual host machine from the Internet service providers, joining in an electronic mall, and developing a web site by internal staff [7]. No matter what approach is adopted, to run an electronic store effectively needs five main functions: the communication function, the product marketing function, the linkage function, the function of online ordering and payment fulfilling, and the customer relations function[17]. These functions together with the above-mentioned important factors will be integrated into the new model of franchise electronic store of this study.

The study will apply the franchise system, which has been successfully implemented in physical stores for several decades, to the management of electronic stores. A franchise is a special type of chain store or chain business in which the franchise offers affiliates the license and the brand to run a store or a business under the authorization of the franchise [9][13][5]. The franchise will give affiliates directions and support in activities of organization, training, purchasing, and management. Affiliates have to pay royalties to the franchise and run their chain businesses by following the management system of the franchise. In addition, Lee[12] argued that all affiliates in a chain should be consistent in business ideas, business identifications, products and services, and management system so that the chain can be successful.

The franchise system gives the advantages of large scale and reduces business risks for small enterprises [2]. Accordingly, they would like to join the franchise system as affiliates, even though they would lose some autonomy, in order to obtain assistance and support, and benefits of professional management and brand value. The

performance of the franchise certainly will affect the realization of the potential advantages of a franchise system. Good relationships between the franchise and its affiliates will have a positive effect on the marketing performance of the franchise[3]. The relationship is usually dependent on the content and the execution of franchising contract. In the contract, the primary issue is the economic interaction between the franchise and its affiliates. According to Woll [21], the initial sources of income for the franchise are franchise fee, royalty, rent, equipment lease, material supply, and product selling, and these items concerning money are also the key parts of the contract. Bacus et al[1] argued that factors of determining the royalty and other base fees that will be designated in the contract are characteristics of the industry and the franchise, which include the duration, the brand value, the market share, the number of employee, and the provision of services of the franchise. Lafontaine and Kaufmann[11] found that some franchises do not

charge their affiliates for initial fees of royalties and other fixed charges but collect royalties and other fees from them according to their sales volume. The above-mentioned issues of marketing and operations under the circumstance of the franchise electronic store will be further analyzed and their feasible strategies will be included in the new model of this study.

### 3. Methodology

The study developed a conceptual framework for a new EC model after reviewing the literature related to business models and innovative strategies for EC. To validate the appropriateness and the comprehensiveness of the new concept, three methods were used consecutively for enhancing it: the Nominal Group Technique (NGT), the case study, and the questionnaire survey. The research process is illustrated as Figure 1.

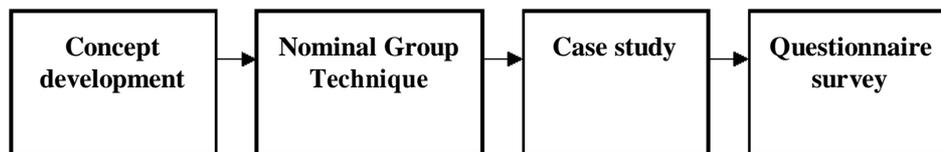

Figure 1 The research process of the study

In the stage of concept development, the study examined the related factors that need to be taken into consideration in building up a franchise system for electronic stores by analyzing the business models of the electronic store and the franchise, and then proposes a franchise model for electronic stores. After the stage of concept development, the NGT method was used to validate the proposed conceptual model. There were four persons in the study's NGT discussion group. Three were EC practitioners who are knowledgeable about the franchise system. The other one was a professor with EC as his main research and teaching interests. This group evaluated the feasibility of the conceptual model and selected the best alternative strategies for implementing the model by following the NGT's designated procedure.

After the validation by NGT, the case study method was used to enhance the model from the practical point of view. According to features of the franchise in the new model, chain stores, IT firms, and electronic malls are the most likely industries to establish the franchise system of electronic stores, so four famous electronic stores with such industry background were chosen as the study's subjects. Business models of these cases were studied and their managers were interviewed to validate the practical feasibility of the study's proposed model. Little adjustment was made to the model and its implementation strategies according to the results of case study. The model was then completed.

In the last stage, the study conducted a questionnaire survey in Taiwan for analyzing the feasibility of the new

model. Since, besides consumers, there are two main subjects related to the model: the franchise and affiliates, subjects of the questionnaire survey were potential franchisees and affiliates of the franchise electronic store. As mentioned before, potential franchises include chain stores, IT firms, and electronic malls. All enterprises in the name lists of these three industries were the population of the survey. In order to receive at least fifteen responses for the analysis at an anticipated response rate of about ten percent, one hundred and fifty questionnaires were mailed. These companies were selected by using purposive sampling method. On the other hand, the survey of affiliates was targeted at current electronic stores and those small manufacturing companies that possibly run electronic stores. Similarly, one hundred and fifty of these two types of companies were chosen by purposive sampling method as survey subjects. The questionnaires were sent to the managers of EC department, or information department if there was no EC department, of those subject companies. The questionnaire inquired about a respondent's perception of the feasibility of the franchise model of the electronic store and the appropriateness of alternative implementation strategies of this model. A five-point Likert scale was used to measure the respondent's perception except for some open questions about the respondent's basic information and comments, such as: his or her professional background and correspondence, and suggestions for the model and its implementation strategies.

## 4. A new EC model with innovative strategies

### 4.1 The new model

This study proposes a new model for electronic stores. The new model applies the franchise system to operations of electronic stores and can integrate all stores as a whole to take advantage of the effect of synergy. This new model includes a franchise website, affiliated websites, and the franchise system that support all the operations and management of the franchise electronic store. The framework can be illustrated as Figure 2. There are two main subjects, besides consumers, related to the model: the franchise and affiliates. The franchise must establish its website as a portal site for customers to enter the franchise electronic store. In addition to that, it has to help its affiliates to build up their own websites that can be linked to and integrated with the franchise website. Moreover, and which is also the most important, the franchise must have a franchise system specifying how operational and management activities of the franchise electronic store should be proceeded and assuring that affiliate stores can operate consistently and effectively. On the other hand, affiliates will join the franchise if they can gain sufficient support in those aspects they need. However, they need to run their electronic stores by following the regulations of the franchising contract so that the franchise electronic store can give a good and consistent image to customers.

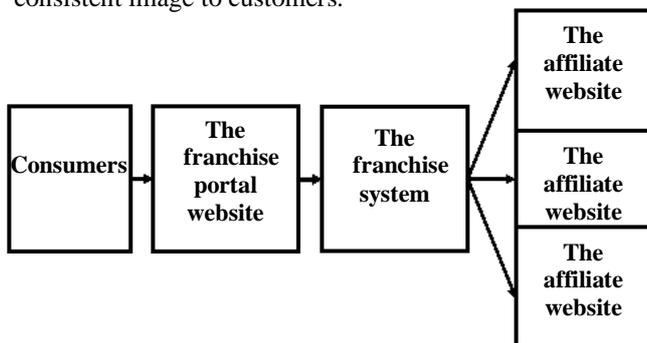

Figure 2 The framework of the new model

In the new model, a franchise system of electronic stores shall be established with respect to technology, operations, and marketing. From the dimension of technology, the model provides three components for the franchise system: the integrated portal website with the personalized technology, the technical support for affiliated websites, and the operations system of the franchise electronic store. First, the integrated portal website is very important in the new model. It is a customer portal built by the franchise, which is dynamically linked with affiliates' websites. By applying the personalized web technology and business identification system in its design, the portal site can meet the individual demand of customers and maintain a consistent image of the entire franchise electronic store. Next, the technical support for affiliated websites is also essential in the system because potential affiliates of the franchise are targeted to those firms that lack the professional staff of web technology. This component can

provide affiliates with necessary technical support and service for establishing their websites and maintaining operations of websites. Last, the operations system of the franchise electronic store is core component of the franchise system. It integrates all activities of transaction flow, material flow, payment flow, and information flow among the franchise, affiliates, and customers and offer efficient franchise operations.

From the dimension of operations, the model offers three components to the franchise system: the integrated management information system, the communication and control system, and the education and training system. First, the integrated management information system is developed to meet individual demand of the franchise and affiliates. It can help affiliates save the cost of developing and maintaining their own management information systems and take advantage of the integrated effect of information sharing. Next, the communication and control system can assist the routine operations between the franchise and its affiliates to be processed efficiently. As a result, it can also promote the utilization of resources of the franchise system. Third, the education and training system provides the necessary training to the employees of the franchise and affiliates. It can help the franchise system keep good quality of personnel. In addition to that, it can also assure that the requirement of consistent quality of operations in the franchise system is met.

From the dimension of marketing, the model provides two components for the franchise system: the integrated marketing and advertisement and the CRM system. The component of integrated marketing and advertisement plans and executes activities of marketing and advertising for the franchise system. It also support the marketing promotion of individual affiliate website. On the other hand, the CRM system is used to effectively understand and satisfy the demand of customers. It can help the franchise electronic store keep good relationships with customers and create new opportunities of selling.

### 4.2 Implementation strategies

Since the new model is an innovative idea to establish the franchise system for electronic stores, generic strategies for implementing EC models are not enough for the implementation of the new model. Innovative strategies should be adopted for the model to be successfully implemented. This study proposes implementation strategies of the model according to the unique characteristics of the franchise system. Since the appropriateness of subjects of the franchise electronic stores will have a significant effect on the success of the new model, first of all, the strategy of the selection of subjects shall be carefully developed. Current franchise physical stores, electronic malls, and the IT solution providers are appropriate subjects of the franchise of the new model. And a good strategy to establish a franchise for electronic stores is by an alliance of these three types of enterprises. As for the selection of affiliates, the strategy shall target at current electronic stores and small firms that are interested in the business of electronic store.

In addition to the strategy of selecting subjects, several strategies are important for the implementation of the new model. These strategies are illustrated below in terms of operations, technology, and marketing. From the dimension of operations, there are strategies of the mode of cooperation, the source of income, the physical distribution, and the payment. From the dimension of technology, there are two strategies: the development of website, and the technical support. From the dimension of marketing, three strategies should be taken into consideration. They are strategies of the participation of marketing, the marketing mix, and the brand.

### **4.3 The feasibility analysis and practical implications**

The practical feasibility of the new model was validated by the NGT group discussion, the case study, and the questionnaire survey. The results are analyzed here. First, in the NGT group discussion, the group agreed that the new model is practically feasible. Overall, they agreed that those proposed implementation strategies are important and appropriate. Particularly, they thought that current franchises of physical stores are more likely to be initiators of the franchise system of electronic stores than current electronic malls and IT solution providers, although they are appropriate initiators, too. In addition to that, the group also argued that a strong bond of the franchise with its affiliates may be a critical factor to the success of the franchise system, and the physical distribution is very important in the operations of the franchise system. Both factors should be valued while implementing the new model.

Second, four cases of electronic stores, which have the industry background of chain stores, IT firms, electronic malls, and bookstores respectively, were studied. We found that all of them have some problems with respect to the management, the technology, and the marketing. These problems with their solutions were taken into consideration in our proposed strategies. For instance, one of them had some technical problems because they lacked sufficient technical staff and another faced channel conflicts with its physical retailers. The former problem can be solved by the strategy of technical support, and the place strategy will deal with the latter problem. Managers of these stores were interviewed about the feasibility of the new model and implementation strategies, too. All of them felt that the model was feasible and the strategies were appropriate. Specifically, they thought that the most appropriate franchise of the new model was an alliance of three potential subjects of the franchise we proposed. This is a very good point because such an alliance will have all necessary capabilities to implement the model.

The results of questionnaire survey also validated the practical feasibility of the new model and its implementation strategies. We had thirty-two respondent companies (10.66%) from this survey. General speaking, almost all respondents confirmed the feasibility of the model and implementation strategies. Especially, respondents of potential affiliates have a higher average score of agreement on the feasibility than respondents of

potential franchises. This may be related to the fact that those potential affiliates need such model to help them enter the market of electronic stores or help them solve the difficulties they are encountering in their business now.

To implement the new model, the proposed strategies should be appropriately executed. These strategies are aimed to completely solve common problems of electronic stores in an integrated way within a franchise system of the new model, which is different from current EC models, such as electronic malls, electronic marketplace, and affiliate programs, that can solve only a specific part of those problems. The successful implementation of the new model is dependent on the effectiveness of eight components of the model and the appropriateness of implementation strategies, and the integration of the model and implementation strategies. Specifically, several issues are critical for the implementation of the model. First, sufficient capabilities of the franchise are very important to implement the new model successfully. Secondly, attracting appropriate affiliates to join the franchise system is crucial to the operation of the system since whether the franchise system reach the economic scale will have great impact on its profitability. Finally, the franchise system must specify how operational and management activities of the franchise electronic store should be proceeded and thus can assure that all affiliate stores operate effectively and provide consistent quality products and services to customers.

## **5. Conclusions**

It is not easy to operate an electronic store for an individual firm, especially the small enterprise that lack of the required expertise and resources for running the electronic business. This study proposes a new EC model to help enterprises run electronic stores. The new model applies the franchise system of chain store, a very successful modern business model, to the management of electronic stores to take advantage of the chain's competitive power by integrating individual affiliate sites. This model provides eight components for the franchise: the integrated portal website with the personalized technology, the technical support for affiliated websites, the operations system of the franchise electronic store, the integrated marketing and advertisement, the integrated management information system, the communication and control system, the education and training system, and the CRM system. Implementation strategies of the model, which are quite different from those generic strategies commonly used in implementing EC models, are also proposed. These innovative strategies are developed with respect to dimensions of operations, technology, and marketing, so that they can help the model be successfully implemented.

The proposed model is practically feasible and can be adopted to establish the franchise system of electronic stores. In addition, the results of this study can also be used as the basis for the future study on EC business models. There are some directions for further research.

Specifically, develop prototype systems for those eight components of the new model and examine the effectiveness of implementation strategies of the new model through experimental studies will be very important for the technical transfer of the model. This study is going to advance to the development of prototype systems, which can then be used to examine the effectiveness of those implementation strategies.

## Abstract

In this study we theoretically develop and empirically test a measurement model of consumer trust in Internet stores. In particular, we define the notion of trust based on what is commonly agreed on by scholars across disciplines. We treat trust as a second-order construct and measure it using four first-order components: perceived security, privacy, integrity, and transactional accuracy. We conducted controlled experiments using three Internet bookstores and 173 subjects. We applied confirmatory factor analysis to determine the measurement efficacies.

## 1. Introduction

There have been many discussions on what propels successful Internet commerce (IC). Based on value-focused thinking, Keeney [31] suggested that IC success might be more a function of customer's belief and perception of the net value of the benefits and costs of both a product and the processes of finding, ordering, and receiving it. The Federal Administration and the Better Business Bureau showed that consumer's trust is a critical factor in stimulating Internet purchase. Castelfranchi and Tan [8] showed that a lack of trust is one of the main reasons that consumers and companies do not engage in IC. Keen [30] argued that the most significant long-term barrier to Internet purchasing will be the lack of consumer trust, both in the company's honesty and in the company's competence to fill Internet orders. A recent survey by Information Technology Association of America also found that 62% of respondents believed that trust was the top overall obstruct.

Since trust is an important aspect of IC success, the understanding of its meaning and measurement is imperative. For academic research, this construct can be used as a dependent or independent variable in a nomological network that links IC with preceding and ensuring constructs. For management practice, metrics are a way of learning what works and what does not, what is reinforcing and what is disconfirming feedback [49]. Unfortunately, there is an alarming lack of effort in validating the instrument for trust. A few studies have examined the notion of trust [9, 21, 27, 33]. However, their definitions and instruments of trust are different. It makes it difficult to compare and accumulate findings and thereby to develop syntheses of what is known [14]. Javenpaa et al. [27] felt a need to reexamine

their instrument of trust adapted from marketing channels [17]. Lee and Turban [33] suggested that the construct should be reinvestigated in light of emerging technology, research and practice. They indicated that, if the construct is modeled incompletely and then integrated as part of a network of other constructs, the key aspects of variation among measures might be lost. The loss in explained variation can lead to errors in interpretation between dependent and independent variables within a system of path models [51]. The insufficiency of the metrics for IC trust corroborates with that of the metrics for information systems research in general and studies on net-enabled organizations in specific [53]. As Zmud and Boynton [58] noted, researchers have paid too little attention to measurement development issues and theoretical advancement has been constrained by the absence of reliable measures.

In this study we theoretically develop and empirically test a measurement model of consumer trust in Internet stores. In the parlance of latent variable statistics, we treat trust as a second-order construct and measure it using four first-order components: perceived security, perceived privacy, perceived integrity, and perceived transactional accuracy. The theoretical implication of higher-order models is that each first-order factor and the implied second-order factor are important in capturing the domain of the construct. Moreover, the second-order factor may be a more important mediator between a consequent and predictor variable than the first-order construct [51]. There is an additional consideration when choosing the current approach to the measurement of trust. Although it is prudent to borrow relevant scales from marketing to study IC, the unique feature of Internet technology warrants unique metrics for IC [52] and there is a danger associated with indiscriminate adoption [2]. In specific to the construct of trust in an Internet store, the unique feature of the Internet technology in terms of the conditions for trust to arise and the composition of trust [46] dictates that the notion of trust may be regarded as the synonym for security, privacy, or integrity; better cryptographic algorithms for data transmission and better authentication protocols for authenticity are considered equivalent to a higher level of trust. This consideration implies that trust in IC may be better reflected in multiple dimensions such as security, privacy, accuracy, and integrity.

## 2. A Theoretical Domain of Trust

To date, there is no universally accepted definition about what trust is. Economics define trust mainly as a phenomenon within and between institutions, and as the trust individuals put in those institutions [3]. Social psychology characterizes trust in terms of expectations and willingness of the trusting party in a transaction, the risks associated with acting on such expectations, and the contextual factors that either enhance or inhibit the development and maintenance of that trust [40]. Finance views trust as a level of subjective probability at which an agent will perform certain action [20].

Despite the differences in how trust is defined, scholars across disciplines seem to have two fundamental agreements. First, there is an agreement on what constitute trust: positive expectations of others [34] and willingness to be vulnerable [40]. Trust is a psychological state comprising the intention to accept vulnerability based on positive expectations of the behavior of another [46]. Second, why is someone willing to be vulnerable? There is an agreement on the necessary conditions for trust to arise: risk and interdependence. Risk is the perceived probability of loss [10, 35] and is an essential condition in psychological, sociological, and economic conceptualization of trust [16, 45, 57]. Trust would not be needed if actions could be undertaken without uncertainty and risk [35]. Uncertainty about what others intend to and will act appropriately is the source of risk [46]. Interdependence means the interests of one party cannot be achieved without reliance on another [46]. If one can achieve the interests without involving others, trust would not exist.

Table 1. Sample Trust Dimensions

Studies	Trust Dimensions
[4]	Information Security
[6]	Availability, Competence, Consistency, Discreetness, Fairness, Integrity, Loyalty, Openness, Promise Fulfillment, Receptivity
[15]	Ability, Trustworthy Intentions
[18]	Ability, Intention to delivery
[17]	Reputation, Size, Willingness to Customize
[22]	Ability, Intention, Trustee's Promises
[26]	Privacy, Security
[29]	Competence, Motives
[33]	Ability, Integrity, and Benevolence
[36]	Competence, Integrity
[44]	Moral, Integrity, Goodwill
[54]	Anonymity, Security, Transaction Size
[55]	Privacy

In the context of IC, both necessary conditions exist for consumers to trust Internet stores and online transactions. First, the perceived benefits of Internet shopping and/or established customer relations increase the interdependence between customers and online stores. IC is claimed to reduce prices, inventory levels, and the role of brokers [32]. It can reduce the advantages of scale of large retailers, lower the costs of entering international consumer markets,

reduce transaction cost, and are more convenient to make a purchase.

Second, Internet shopping involves more uncertainty and risks than traditional shopping. Internet consumers cannot physically check the quality and quantity of the products before receiving a purchase [35]. They cannot monitor the security of sending sensitive personal and financial information, like credit card numbers, through the Internet to a party whose behaviors and motives may be hard to predict [35]. Moreover, the free exchange of electronic information brings the threat of providing easy, and many times unwanted, access to personal information [51]. Consumers cannot control the use of their personal information after they release it to Internet stores during Internet shopping. In sum, the integrity of a store, the security of performing transactions, the accuracy of the transactions, and privacy are the four primary risk factors that cause trust issues to be a concern.

In addition to the analysis of the vulnerabilities that constitute trust, Churchill [14] suggested that extensive literature review and expert opinion provide a sound foundation on which a theoretical domain of trust can be found. Thus, we conducted an extensive review of the literature on trust. The review covered over 120 publications from academic journals, professional magazines, and textbooks, and identified over 40 repeating words that are characteristic of the trustworthiness of Internet stores. We also kept notes on various concerns and vulnerabilities that reflect each of these key words. We listed a sample of studies and their referenced attributes in Table 1. From the list we see that certain attributes like ability and competence are semantically identical or similar. Certain attributes like integrity, security, and privacy appear more frequently than others especially in the context of IC. Some attributes like consistency, atomicity, and discreetness reflect one fundamental concern about accuracy.

To verify the completeness of the list and consolidate conceptual redundancies, we formed a panel of "experts" and asked each member to add overlooked attributes, take away irrelevant ones, and identify similar or identical ones. The panel consisted of three professors respectively in the areas of MIS, Social Psychology, and Organization Studies, four Ph.D. students in Management and Information Systems, and 12 undergraduate students who had experience with Internet shopping. Through a session of brainstorming, we identified a shorter list of 9 items: security, privacy, integrity, accuracy, benevolence, fairness, motives, promise keeping, and capability. By definition, integrity is the perception that an Internet store is honest, ethical, and fair, and adheres to an acceptable set of principles [33]. Thus, integrity captures benevolence, fairness, motives, and promise keeping. Although many studies feel capability is an important dimension of trustworthiness, it is actually an enabler or formative (or causal) factor for other dimensions such as security, privacy, and accuracy. Therefore, the expert panel collectively judged that integrity along with

security, privacy, and accuracy covered the appropriate content domain of trust.

Based on the convergent views on the components of trust, we conceptualize trust as a psychological state comprising the intention to accept vulnerability when shopping in an Internet store. Then we conclude that such vulnerability is reflected in the four aspects: security, privacy, integrity, and accuracy.

**Perceived Security:** Web providers and users are now sharing the concerns on security that were once raised by environment control [26]. In the context of IC, communication can be intercepted, tampered, and falsified. Personal accounts can be accessed for illegal purposes. Personal properties can be damaged due to malicious attacks and viruses. Consequently, consumers are often unwilling to conduct online transactions for the fear of security breaches and potential damage to personal interests. As a matter of fact, the concern with security has become the top reason for not shopping online [26]. Therefore, to reflect the intention to accept the vulnerability in security, we conceptualize perceived security as the perception that making a transaction with an Internet store is safe. Such a notion of security signals the capability and responsibility of an Internet store in preventing unauthorized data access, illegal data interception, and illegal attacks on customer properties, and in protecting the interests of its customers. Of course, absolute security does not exist. We intend to operationalize the construct in terms of a comparison with traditional means of shopping and whether transmitted data could be intercepted, and accounts broken in.

**Perceived Privacy:** When associated with consumer activities that take place in the arena of electronic marketplace, the term privacy usually refers to personal information and the protection of its confidentiality. For example, when customers give out their identification numbers, they expect confidentiality that the numbers will only be known by the party who has a legitimate need to know them. Similarly, a customer who buys a bulk of marketing research data may not want his or her competitors to know it; a customer who buys a good of questionable value does not want to disclose his or her identity. The violation of privacy includes unauthorized collection, disclosure, or other misuse of personal information as a direct result of e-commerce transactions. Privacy has been identified as one of the most crucial issues in e-commerce. It is consumers' fear and distrust for potential loss of personal privacy that often makes them unwilling to conduct online transactions [55]. Therefore, to reflect their intention to accept the vulnerability in privacy, we conceptualize perceived privacy as the perception that their personal data with an Internet store are confidential. The concept signals the degree to which an Internet store is capable of and responsible for observing procedural fairness [26] and to exert control on its data collection, access, and secondary use [51]. It reflects a fundamental concern for the loss of proper control on personal data due to improper collection of private in-

formation, improper monitoring on Internet activities, and improper transfer of personal information.

**Perceived Integrity:** In physical commerce, customers often trust a business by its physical locations, facilities, and business licenses. However, they are not as much concerned with these characteristics per se as its integrity to conduct businesses honestly and professionally. The same concern becomes more serious when conducting online transactions. In e-commerce, it is virtually impossible to authenticate the identity of an Internet store through its physical characteristics. Thus, when making online transactions, customers deal with other parties whose true motives and absolute identity are uncertain [54]. Consequently, they are concerned about whether they will receive products or services even though they have paid for them. They are concerned about whether the store will take advantage of them and behave opportunistically. They are also concerned with whether the store has the capacity to offer products and services as it described. To reflect such concerns, we define perceived integrity to be the perception that an Internet store is honest and adheres to an acceptable set of principles [35]. As per the definition, integrity consists of two related aspects of semantics. First, it means that an Internet store does as what it said, i.e., it keeps promises and is procedurally fair. Second, it means that the store says as what it did, i.e., it is honest and credible. In prior studies, the term "reputation" is sometimes considered to be equivalent to perceived integrity. For example, Doney and Cannon [17] defined reputation as the extent to which customers in the industry believe that a company is honest and concerned about its customers. Based on such equivalence, perceived integrity signals the forbearance from opportunism [50] and reflects the capability and responsibility of a store to act professionally.

**Perceived Accuracy:** In Internet shopping, customers cannot physically touch, check or test a product. All they know about the product is from the descriptions or pictures provided by an Internet store. Besides opportunistic behaviors, customers are also concerned with potential transaction errors such as incorrect product brands, sizes, and quantities, as well as incorrect billing statements. Such errors can occur due to human mistakes. They can also occur due to computer system irregularities such as lack of transaction atomicity [54]. For example, when purchasing a document online, a power failure between sending in payment and obtaining a password to download the document can leave the transaction partially finished. Ideally, such a transaction should be rolled back so that the customer can re-start the process again. However, without atomicity control, the customer will end up with troubles and delays or paying for another transaction. In physical commerce, such errors can be easily corrected using a trip or phone call back to the store. However, making corrections with an online store typically means extra effort and time and sometimes even extra shipping and handling fees. Therefore, Javenpaa et al. [27] suggested that, in order to be able

to trust an Internet store, a customer must believe that the store has both the ability and the motivation to reliably deliver goods and services of the quality expected. Similarly, Butler [6] suggested the dimension of transaction accuracy by emphasizing the criteria such as consistency and discreetness. To capture such a dimension of trust, we conceptualize perceived accuracy as the extent to which a customer believes that transactions with an Internet store are error-free. This concept signals the capability and responsibility of an Internet store in performing its functions accurately.

### 3. Data Collection

Following the advice by Churchill [14], we utilized the expert panel and a class of undergraduate students to participate in a pre-test and a pilot test respectively. In the pretest, we provided a formal definition of each construct and then a list of measurement items (sentences), which we intend to use to measure the constructs. We asked each member to first read each definition carefully and then give a rating for each item in the 5-point scale to indicate how well the sentence matches the intended construct.

The pretest started with 48 items in total. After the pretest, we analyzed the ratings of each item individually. An item was retained if it was consistently scored 4 or 5 points across the experts. It is dropped if it was consistently rated as no match. For an item that had inconsistent ratings, we adopted alternatives, rephrased it, or dropped it entirely. The pretest substantially refined some of the items by eliminating their ambiguity. The number of items was also reduced to 33.

To further validate the items, we conducted a pilot test using 35 undergraduate students. We randomized the 33 items and created a survey that asked each participant to visit amazon.com and respond to each item by indicating how much he or she agreed with its statement. Then we used the responses and calculated the correlation between each pair of the items. Under each dimensional construct, we retained those items that were highly correlated. However, if an item seemed not to go along with others, we dropped or modified it depending on its content. Through the pilot test, we finally selected 17 items in total for the final test (see Table 2).

The final test involved 173 participants selected from graduate and undergraduate students in two large national universities. Nevertheless, if a subject is not aware of Internet technology and its potential problems, he or she may not make perfect sense of some of the statements in Table 2. Therefore, when identifying participants, we required them to have exposure to electronic commerce. To be representative of the population actually engaging in IC activities, we identified the subjects from students at various stages: 24% from graduate programs, 38% from juniors and seniors, and 38% from freshmen and sophomores. We also distributed the subjects roughly equally in two regions,

Midwest and Northeast, in the hope to capture the variation due to urban and rural settings. The subjects were primarily selected from 4 graduate and 8 undergraduate classes on the voluntary basis. Among the individuals who were qualified to participate, the response rate was 73%.

Table 2. Initial Measurement Items for Trust

<b>Perceived Security</b> (5-point Scale Anchored by "Strongly Disagree" and "Strongly Agree")	
PS1	I believe that shopping on this Internet store is just as safe as placing an order by phone
PS2	It is just as safe to make a credit card purchase at this Internet store as it is to make one in person
PS3	The data transmission between my computer and this Internet store is safe
PS4	This Internet store is capable of preventing illegal access
<b>Perceived Privacy</b>	
PP1	I trust that this Internet store will keep customer information confidential
PP2	I am afraid that this internet store might misuse my personal information (Reverse)
PP3	I think it's likely that this store would sell my personal data to others (Reverse)
PP4	This store can be trusted to keep the identities of its customers private
<b>Perceived Integrity</b>	
PI1	I have confidence in this store
PI2	I trust this store to keep my best interests in mind
PI3	I trust this store to act professionally
PI4	Something about this store strikes me as deceptive and misleading (Reverse)
<b>Perceived Accuracy</b>	
PA1	I would trust this store to deliver exactly what I order
PA2	The Internet store can be trusted to fulfill my order accurately
PA3	The store will not overcharge my credit/debit account
PA4	The online product and service information is accurate
PA5	This store will make corrections if my order is in error

In order to ensure the representativeness of our sample to the Internet user population, we collected general and technology demographic data using Gvu's WWW User Survey instrument. The participants had ages ranged from 20 to 46 and were on the average 24 years old. 92% of them were English speakers and other 8% spoke Spanish, Chinese, French, etc. More than 90% of the subjects had 2 to 17 years work experience. All except for a few subjects used Internet and web browsers once or several times a day. 72% had purchased goods and services on the Internet and 40% made a purchase for more than 100 dollars. 46% shopped on the Internet frequently. Most of these demographics match the corresponding sample statistics of thousands of Internet users recently surveyed by Georgia Institute of Technology.

Consistent with prior work [27], we used online bookstores to conduct the controlled experiment and to collect data. To avoid possible biases due to the familiarity [21] with a particular store, we searched all online bookstores and identified three at potentially various levels of familiarity to the subjects. We randomly assigned the subjects to the three stores with approximately equal number of subjects assigned to each. Among those assigned to the first

store, all had heard about it and more than half had visited it before. Among those assigned to the second store, 69% had heard about it and 19% had visited it. Among those assigned to the third store, only one had heard about it but none had visited it.

After the participant-store assignment, we provided each subject with a cover page that guides him or her to visit the store, search for a textbook to buy, create an account with the store, and proceed to finish the order. We also provided a credit card number, a billing address, and a social security number for them to create accounts and check out the books. The goal of the experiment was to simulate real Internet shopping experience. After the experiment, each subject was asked to respond to a survey regarding their attitudes to Internet shopping, their perceptions about the store, and their willingness to purchase from the store. For each question, we used a 5-point Likert scale anchored by “Strongly Disagree” and “Strongly Agree.” And we gave sufficient time for them to finish the survey.

#### 4. Hypothesized Models of Trust

According to the analysis of the content domain of trust, we see that a common theme of the dimensional constructs is the ability and responsibility of an Internet store. Ability and responsibility form the basis of trust and a lack of either characteristic will lead to no trust. One would not trust an Internet store if it were not capable even though it has good motives. Similarly, he or she would not trust it either if it were not responsible even though it may be capable. On the other hand, if a store is both capable and responsible, what else does one need to be able to trust it? There is possibly none. Therefore, we considered the trustworthiness to be the overall sum of perceived ability and responsibility. Many other authors also suggested the two overall and possibly uncorrelated dimensions of trust. [15, 18] proposed ability and trustworthy intentions as the two overall dimensions of trust. Kee and Knox [29] proposed competence and motives.

Then why do not we measure trust using the two larger dimensions: perceived ability and perceived responsibility? The reason is that they are formative rather than reflective factors of trust. In general, to measure trust using first-order factors, trust must be a common factor underlying the first-order factors rather than be a simple sum of them. The fundamental issue is consistency in directional change among the first-order constructs [11]. In particular, does a directional change in ability imply similar directional shift in responsibility? The answer is possibly negative; an organization is capable does not necessarily imply it is responsible.

On the other hand, ability and responsibility as a common core of trust underlie perceived security, perceived privacy, perceived integrity, and perceived accuracy. If a store is capable of and responsible for its business, it will act professionally to improve its perceived in-

tegrity. It will also take a strong measure to ensure security, customer privacy, and transaction accuracy. Therefore, perception in any of the four dimensions is manifested in perceptions in the other dimensions through a larger perception of ability and responsibility. For example, if a customer found that his account had been hacked and modified, he would naturally doubt the ability and/or responsibility of the store and infer that his privacy and expectation of accuracy would be in danger. His perception of its professionalism would be also reduced.

In sum, trust in an Internet store is reflected in the four specific dimensions such as perceived security, perceived privacy, perceived integrity, and perceived accuracy. The overall trustworthiness accounts for the interrelationships among these dimensional factors through the perception of the ability and responsibility of the store. Based on this hypothesis, let us propose and examine six measurement models that are plausible representation of our anticipation.

##### *First-Order Factor Models*

Model 1 hypothesizes that one first-order factor — trust in Internet stores — accounts for all the common variance among the 17 items. As we reviewed before, most existing studies have approached trust in Internet stores as a single-dimensional construct [13, 21, 27]. Typical survey questions to assess trust include “This store is trustworthy” [27] and “I trust this store” [21]. If this model is accepted, then it is appropriate to view trust as a single dimensional construct.

Model 2 hypothesizes that two first-order factors account for the variance of 17 items. In this model, perceived privacy and perceived security are combined into one factor, and perceived integrity and perceived accuracy into another. This model emphasizes perceptions in two primary areas: data and goods. The first combination is due to data and is plausible because both security and privacy have a common underpinning: personal information. If data are not secured in transmission and storage, privacy cannot be enforced even though a store does not violate it voluntarily. The second combination reflects that a customer is concerned with whether she will receive goods as expected and be charged correctly regardless whether a discrepancy is due to a mistake or due to a lack of integrity.

Model 3 hypothesizes that 17 items form two first-order factors. However, it combines perceived integrity and perceived privacy into one construct and perceived security and perceived accuracy into another. This model focuses on two overall dimensions: capability and motives. Integrity and privacy are more reflective of the motives of a store whereas security and accuracy are more reflective of its capabilities.

Model 4 hypothesizes still another two first-order factor structure, where perceived integrity is distinct whereas other three are combined into one first-order construct. The justification for this model is as follows. Perceived security, perceived privacy, and perceived accuracy are all

perceptions from the perspective of consumers' own interests such as their security, their privacy, and their orders. On the other hand, perceived integrity is more a perception of the characteristics of an Internet store.

Model 5 hypothesizes that four first-order factors account for the variance of all items. Prior theoretical analysis of content domain provides support for this model. Essentially, this model assumes that every pair of constructs correlate but the correlation is not strong enough to justify for a merger. In addition, this model will act as a benchmark for the test of a second-order model. According to Marsh and Hocevar [39], although a higher-order model is able to explain the covariance of first-order factors, the goodness-of-fit of the higher-order model can never be better than that of the corresponding first-order model. Thus, this model provides a target for testing a second-order model.

#### *A Second-Order Factor Model*

Model 6 hypothesizes that four first-order factors account for the variance of the 17 items whereas a second-order factor accounts for the covariance of these first-order factors. Statistically, if Model 5 demonstrates significant interdependence (covariation) among the first-order factors, a natural inference is that there might be a common factor that accounts for the interdependence [42]. If such a common factor exists, then trust will be more than the sum of the four first-order factors. It will consist of the first-order factors as well as the structure of interrelationships among them [51].

Theoretically, ability and responsibility form a common core of trust that underlies the four first-order factors. As we have argued, each first-order construct reflects the ability and responsibility of an Internet store in a specific dimension such as security, privacy, integrity, or accuracy. Therefore, the perceived ability and responsibility, i.e., the trustworthiness of the store, not only extract the variation of these first-order factors but also account for the interrelationships among the first-order factors. Thus, trust in an Internet store may be better measured as the second-order common factor.

## **5. Data Analysis**

To validate the hypothesized models, we employed confirmatory factor analysis using LISREL 8.3 [28]. In the current study, the observed covariance matrix for the 17 measurement items is listed in Appendix. The latent variables include the four first-order factors and one second-order factor. Different measurement models hypothesized in Section 5 underlie different joint distributions of all the variables involved, observed and latent as well. How much each model fits the data can be determined by the extent to which its implied covariance matrix matches the observed one.

As its rationale implies, an important assumption of confirmatory factor analysis is multivariate normality. However, a verification of this assumption is difficult. In-

stead, we conduct normality test for each observed variable using both normal plots and Kolmogorov-Smirnov statistic. All normal plots show straight lines and all test statistics are strongly significant at  $\alpha = 0.000$ . They indicate no departure from univariate normality. The test result signals that the multivariate normality holds.

Before conducting confirmatory test on the hypothesized models, we followed the procedure suggested by Segars [47] and tested each first-order factor in isolation first and then in pairs. The procedure can provide the fullest evidence of measurement efficacy and reduce the likelihood of confounds in full structural equation modeling [48]. In the initial phase of isolated model testing, we found that items PA4, PA5, and PS4 have loadings less than 0.6. By analyzing the correlation matrix, we realized that these items seem not to go along with other items under the same construct. Therefore, we deleted these three items to improve the reliability of corresponding constructs. All items under perceived integrity and perceived privacy had reasonably large loadings. However, the modification indices for the test of perceived privacy suggest adding an error covariance between PP2 and PP3. Being reluctant to delete additional items, we add other first-order constructs and conducted paired tests. All test results seem fine except that a similar modification index suggests the existence of error covariance between PP2 and PP3. By analyzing these items, we can see that they both are reversed and both suggest misuse of personal information. Thus, to remove the extraneous correlation that is not captured by the notion of perceived privacy, we deleted PP3. After removing PA4, PA5, PS4, and PP3, all isolated and paired tests went through well.

Finally, we used the remaining 13 items to test the six hypothesized models. Table 3 provides a summary of the model-fit indices and their thresholds recommended by previous studies. As shown, by all measures of fit Models 5 (four first-order factors) and 6 (the second-order factor model) are deemed excellent while alternative models being deemed unacceptable. Models 5 and 6 both had insignificant  $\chi^2$  statistics with p-values above 0.4, which is far higher than the threshold 0.05. They satisfied other cited criteria in terms of GFI, NFI, RMR, RMSEA, and the ratio of  $\chi^2$  to degree of freedom, as well as the more stringent criterion of AGFI [12, 23]. Most strikingly, their corresponding probabilities of close fit, i.e.,  $RMSEA < 0.05$ , are all higher than 0.95. It means that the type I error of rejecting a not-close fit hypothesis is less than 0.05 [5].

It is interesting to observe from Table 3 that, while all often-cited fit indices being able to tell a good model fit from a bad one, their powers of detection are not equal. According to the ratio of  $\chi^2$  to degree of freedom, Models 2 and 3 might be declared acceptable because their ratios are close to 2. Similarly, the NFI, GFI, and AGFI for Models 1-4 are all close to 0.8 and some values are even close to 0.9. The corresponding values of RMR are close to or less than 0.08. Using less stringent criteria, these models would

be judged acceptable. However, by using the  $\chi^2$  statistic and  $P(RMSEA < 0.05)$ , these models fall apart and a clear distinction from Models 5 and 6 can be identified.

Table 3: Measures of Model Fit: Alternative Models

Model	1	2	3	4	5	6	
$\chi^2$	228.61	142.19	146.20	196.40	57.24	63.13	
df	65	64	64	64	59	61	
$\chi^2/df$	3.517	2.222	2.284	3.069	0.970	1.035	<2.00
$\chi^2$ Sig.	0.000*	0.000*	0.000*	0.000*	0.541	0.401	>0.05
NFI	0.785	0.825	0.819	0.818	0.935	0.927	>0.90
CFI	0.841	0.896	0.890	0.876	0.998	0.992	
GFI	0.830	0.887	0.884	0.851	0.951	0.947	>0.90
AGFI	0.762	0.840	0.836	0.788	0.925	0.920	>0.90
NNFI	0.809	0.874	0.866	0.849	0.997	0.990	
RMR	0.080	0.068	0.075	0.074	0.041	0.046	<0.05

### Convergent Validity

Figure 1 illustrates the structure and estimated parameters of the four-construct, first-order factor model (Model 5). As shown, the indicator loadings of items to their respective constructs are all above 0.60, indicating that each measure is accounting for 50 percent or more of the variance of the underlying latent variable [11]. The t-values obtained for the coefficients range from 8.317 to 13.564, indicating that all factor loadings are significant at the level  $\alpha = 0.0001$ . The significance level is far in excess of the critical value 0.01 suggested by Hair et al. [23]. Both loadings and their significance levels provide strong evidence to support the convergent validity of the items [1].

The composite reliability indices of [19] are listed in Table 4. As shown, they are all in excess of 0.70, implying acceptable level of reliability for each of the constructs [28]. As a comparison, we also show the corresponding Cronbach  $\alpha$  coefficients, which are also higher than the accept-

able threshold 0.7 [41]. As a similar indicator of measurement reliability, average variance extracted (AVE) represents how much variance in each item on the average is explained by the corresponding construct [19]. It is conceptually similar to the total variance extracted (TVE) in principal factor analysis. The AVE values based on the formula of [19] are listed in Table 4. As shown, except for perceived accuracy, the AVE for each construct is above 0.5. It indicates that, on the per-item average basis, the amount of variance captured by the first-order construct is more than the amount of variance due to measurement error. The AVE of perceived accuracy is 0.45, which is a little bit lower than 0.50 (see Section 7 for a discussion). As a comparison, we computed the TVE value for each construct by using the eigenvalues of the correlation matrix of its scale items. As shown, all TVE values are higher than 0.6, indicating that more than 60% of total variance contained in all the items is captured by the corresponding factor. In sum, all indices suggest the first-order constructs exhibit strong properties of convergent validity.

### Discriminant Validity

Discriminant validity is the extent to which items measuring two distinct constructs are shown to be empirically distinct and not so highly related to each other [7]. To do the test, we made a series of comparisons between the original model, where two constructs are treated as distinct, and the alternative model, where they are united as one construct. Discriminant validity is implied if the  $\chi^2$  statistic of the original model is significantly lower than that for the alternative model; this suggests that the original model has a better model fit.

Table 5 shows the results in all six paired comparisons. All the  $\chi^2$  differences are highly significant at  $p < 0.001$ . Hence, each item seems to capture a construct that is significantly unique from other constructs, providing strong evidence of discriminant validity. Also importantly, the estimated correlation between each pair of constructs is below the suggested cutoff value 0.90 [19], indicating distinctness in construct content.

### Testing the Second-Order Model

Both convergent and discriminant validities indicate how well the first-order constructs are defined and measured. However, our eventual goal is to determine how well trust as a higher-order construct captures the variance and covariance of these first-order constructs. To formally test the validity of the second-order factor model (Model 6), we need to first compare its model fit with that of the baseline model (Model 5). Compared to the baseline model, the second-order factor model explains the covariance among first-order factors in a more parsimonious way. Thus, even when the higher-order model is able to explain the factor covariance, its goodness-of-fit can never be better than the corresponding first-order model. In this sense, the first-order model provides an optimum fit or target for the higher-order model [39]. It has been suggested that the

efficacy of a second-order model be assessed using the so-called target coefficient, i.e., the ratio of  $\chi^2$  (baseline model) to  $\chi^2$  (second-order model). This coefficient has an upper bound of 1.0 with higher values indicating the higher power of the second-order factor in capturing the covariance among first-order factors. Figure 2 shows the structure and estimated parameters of the second-order factor model of trust (Model 6). The overall  $\chi^2$  is 63.13 that is insignificant with a p-value = 0.40 (see Table 3). Adjusting the degree of freedom, the normed value of  $\chi^2$  is 1.04, indicating an excellent model fit and no evidence of over-fitting. The target coefficient is a very high value 0.91, indicating that the introduction of the second-order factor into the baseline model does not significantly increase  $\chi^2$ . Since the second-order model is more parsimonious, it should be accepted as a better representation of the “true” factor structure according to Occam’s razor [42].

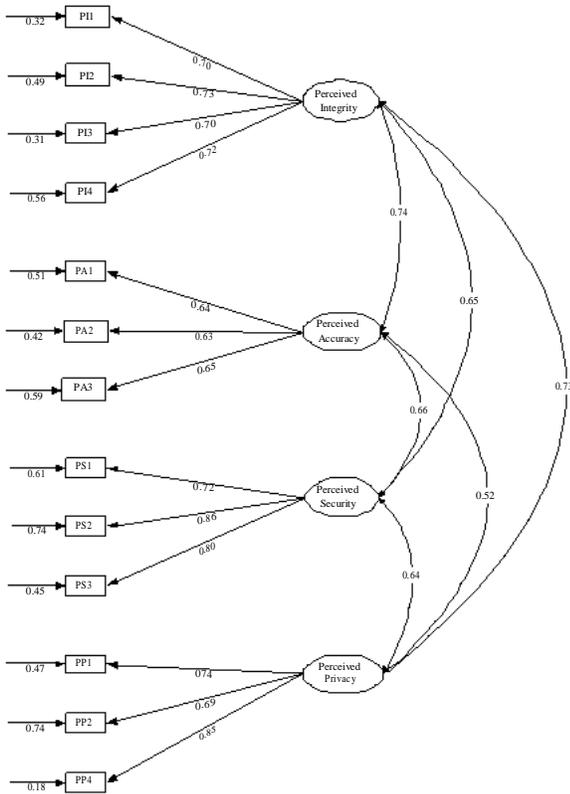

Figure 1. A First-Order Model of Trust

In addition to target coefficient, the power of the second-order factor in explaining the variance of the first-order factors provides another piece of evidence in support of the second-order factor structure. The path loadings to perceived security, perceived privacy, perceived integrity, and perceived accuracy are respectively 0.77, 0.78, 0.92, and 0.78 with t-values ranging from 7.03 to 9.9. The corresponding  $R^2$  values are respectively 0.59, 0.61, 0.85, and 0.61. Similar to the loadings from a first-order factor to its observed items, these loadings and their significance show

a strong convergent validity and reliability of the second-order factor [11]. To obtain overall validity indices, we can similarly compute the composite reliability and AVE of the second-order construct, which are respectively 0.89 and 0.66. Segars and Grover [48] noted that the most convincing evidence of the explanation power is the observed total coefficient of determination. This statistic is 0.94 for Model 6, indicating that a large amount of variance and covariance among the four first-order constructs is explained by the second-order factor and captured by the regression models.

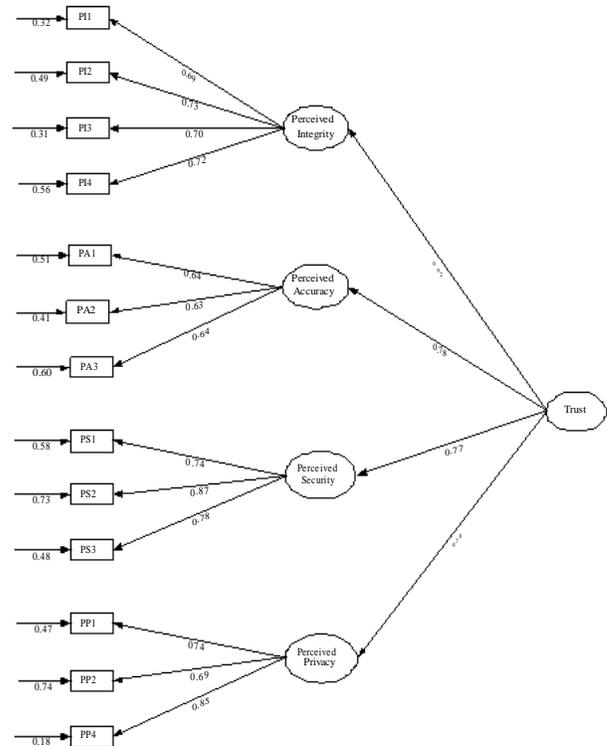

Figure 2. A Second-Order Factor Model of Trust

All evidence in support of the second-order model has been based on type I errors. Then, is it likely that we accept a wrong hypothesis of close fit but in fact the model has a bad or mediocre fit? To answer this question, we conducted power analysis for tests of fit using the technique proposed in [27, 37] and considered  $RMSEA < 0.08$  to be a good fit. Browne and Cudeck [5] suggested a more restrictive criterion:  $RMSEA < 0.05$  for close fit and  $RMSEA$  between 0.08 and 0.1 for mediocre fit. Based on the latter stringent criterion, we used the SAS program provided by MacCallum et al. [37] and computed the power indices with various  $RMSEA$  values in [0.08, 0.1] representing mediocre fit. We found that Model 6 has a power between 0.77 and 0.99, implying that more than 77% of time we can reject a hypothesis of close-fit if the model indeed has a mediocre fit. By using a more lenient criterion, such a power can increase to almost 100%. Therefore, based on Type II errors, the second-order model will be still considered to fit data well.

## 6. Conclusions and Discussions

From the perspective of potential risks and vulnerabilities involved in online shopping, we conceptualized the first-order constructs of perceived security, perceived privacy, perceived integrity, and perceived accuracy, and proposed measuring trust in an Internet store using these dimensions. Then, by conducting an extensive review of literature on trust, a pre-test, and a pilot test, we operationally defined the first-order constructs and developed scale items to measure them. We conducted a controlled experiment that provided a simulated online shopping experience to all participants before they responded to our survey.

To be consistent with a wide range of existing studies on trust, we believed ability and responsibility to be an overall dimension that governs how the trustworthiness of an Internet store is perceived. Therefore, we hypothesized the equation that trust = perceived ability + perceived responsibility. Then, based on this equation, we theoretically justified that the first-order factors—perceived security, perceived privacy, perceived integrity, and perceived accuracy—are the reflections of a single higher-order construct, trust. Each first-order factor is manifested in other first-order factors through trust. In addition to this second-order factor model, we proposed 5 alternative first-order factor models, with a four-factor model as the target for benchmarking the test of the second-order model.

We employed confirmatory factor analysis using LISREL. We used selected items and tested the six hypothesized models. We reported all model fit indices cited in the existing information systems research and additional ones such as the significance of  $\chi^2$  and the p-value for RMSEA < 0.05, which we felt are powerful in separating a good model from mediocre ones. All the indices and their corresponding criteria clearly indicate the superiority of the second-order factor model and the four first-order factor model while rejecting the acceptance of other alternative models. By using the statistics of the first-order model, we determined that the four first-order factors are empirically valid in terms of their convergent and discriminant validities. Finally, we determined that the second-order model is a better representation of the factor structure than the first-order counterpart based on its parsimony, the target coefficient, and the total coefficient of determination. We also empirically determined the power of such a test of the second-order model to be close or higher than 0.8.

Before we discuss the implications of this study, its limitations should be noted. First, the use of student subjects and Internet bookstores may limit the generalizability of the results. Although we carefully simulated and controlled many parameters so that our sample is representative of the Internet user population, a further replication using real online customers might be worthwhile. The second limitation is about the use of confirmatory factor analysis. As we noted, the technique essentially validates a joint distribution assumption using the conformance of its

marginal to observed data. There is a possibility that there exist equivalent models [24]. In this study, we build our models based on a conceptual foundation. We also explored alternative models. The chance of having equivalent models is slim. Third, our measurement model has an excellent model fit. In comparison, the reliability of perceived accuracy is a bit low. Its AVE is 0.45, which is below the recommended value 0.5 [19]. The problem is largely due to the early stage of research in the area. We found a similar problem in some existing studies.

All statistical evidence converges and is in support of our conceptualization that trust is a multi-dimensional construct and is well measured by perceived security, perceived privacy, perceived integrity, and perceived accuracy. We also found that the notion of trust, as a second-order construct, accounted for most of variance and covariance in the first-order factors. These results have several implications. First, they imply that trust is more complicated than previously thought. In general, consumers manifest their trust in an Internet store through their perceptions in security, privacy, integrity, and accuracy. In other words, customers reflect their trust in an Internet store through their perceptions that their shopping activities are safe, their privacy is protected, their transactions are error-free, and the store acts professionally. Furthermore, the results indicate that consumers have vulnerability concerns in all these aspects rather than in any particular dimension and that the interrelationships among these factors are an important component of accurately measuring trust. Second, the results imply that the measurement of trust in an Internet store, although complicated, can be done through an indirect measurement of the first-order factors. Such a measurement model will provide an important metric of the effectiveness of an Internet store for its managers and/or an important metric of vulnerability, perceived risk, as well as expectations of consumers when shopping online. Third, since each first-order construct is manifested in the others through perceived ability and responsibility, our results imply that a store can manipulate certain variables in order to improve consumer trust. For example, by providing accurate billing statements or filling customer orders accurately, a store can convey a sense of ability and responsibility. Such a sense will improve the customer perception in security and integrity that will otherwise be difficult to achieve.

## Abstract

This paper develops a taxonomy of product innovation methods for entering e-businesses. These product innovation strategies share two common features: 1) a goal of disrupting the competitive structure of an existing industry, and 2) the use of digital technology combined with e-commerce to enhance or transform products and services. By disruption, the authors denote the attempt to destabilize the profit structure of an industry such that the incumbent firms can no longer earn economic rents above the industry average. Under these conditions, incumbent firms make no more than new entrants, surrendering their economic advantages. Theoretical frameworks in strategic management and the management of innovation and technology suggest that radical innovations are more likely to lead to destabilized markets. While this paper suggests that the dominant incumbent's advantage can be toppled, the paper does not suggest that the firm destabilizing the market will become the eventual market leader. While one can readily conceptualize the potential of e-commerce to disrupt existing markets, in practice few e-businesses have replaced entrenched competitors. Some of the failures of e-businesses to disrupt markets can be laid at the feet of strategies that were inadequately radical.

## 1. Introduction

E-commerce product innovation strategies are often proposed as a means for new firms to unseat incumbent businesses in established markets. With e-commerce growing at more than twice the rate of the global economy-- more than \$2 trillion was spent worldwide on e-commerce in the year 2000 [21], we expect an increasing number of new entrants will flock into e-markets. These new entrants must more fully understand the e-commerce competitive environment and its corresponding innovation strategies.

This paper develops a taxonomy of product innovation methods for entering e-businesses. These product innovation strategies share two common features: 1) a goal of disrupting the competitive structure of an existing industry, and 2) the use of digital technology combined with e-commerce to enhance or transform products and services. By disruption, the authors denote the attempt to destabilize the profit structure of an industry such that the incumbent firms can no longer earn economic rents above the industry average. Under these conditions, incumbent firms make no more than new entrants, surrendering their economic advantages [18]. The paper does not suggest that the firm destabilizing the market will become the eventual market leader; it suggests only that the dominant incumbent's advantage can be toppled.

### 1.1 Advantages of incumbent firms

The strategic management literature provides a research basis for understanding the advantages and vulnerabilities of incumbent firms. These advantages can flow from a firm's unique resource position as described by the resource based view of the firm [2] [17] [23], or they can flow from the firm's market position as described the industrial/organizational model of firm and market behavior [6]. The advantages and weakness of incumbent firms are compared in the context of both the resource-based view of the firm and industrial organizational economics.

Under the resource based view of the firm, incumbents are posited to have resources superior to entrants, resources that are valuable, rare, and costly to imitate. Among those resources commonly cited are: reputation, preferred sources of supply, and exclusive distribution agreements [3] [12].

Incumbent reputation works against entering firms who possess what is referred to as the liability of newness. Particularly in technology markets, buyers need to have confidence that they will be able to receive spare parts, service, and technology upgrades over the life of the product. Established firms have reputations that act

as a proxy of experience and legitimacy. New entrants need to have technologies or other benefits that are sufficiently superior to offset the customer's perceived risk of the entrant failing and stranding the customer with unsupportable technology. Additional resources frequently possessed by incumbent firms are 1) strong relationships with key existing suppliers and 2) an established and often exclusive access to distribution channels. By controlling key suppliers, incumbents are often able to secure higher quality. By controlling distribution, incumbents preclude entrants from entering traditional marketing channels.

Industrial organizational economics also suggests incumbent firms will have significant advantages. First, incumbents will likely have established entry barriers making it more costly for new entrants. Commonly cited entry barriers included first mover advantages, market power, brand recognition, economies of scope, economies of scale, and economies independent of scope and scale. Market and technological leadership can also deter new entrants [11].

In an industrial organizational framework, incumbents can be overtaken if they are not sufficiently flexible. This is particularly true in e-commerce where speed and change are the norm. New entrants can capitalize on incumbents' inflexibility and inability to learn and innovate. They can also benchmark and sidestep the incumbents to identify niche markets.

Strategy entails a set of commitments [8], often to specialized resources that cannot be utilized for other strategic purposes. Further, the network of a firm's business relationships forms a type of social exit barrier locking a firm into a set of supplier or distributor resources, thus, making it difficult to exit from unattractive arrangements. Also, managers often have difficulty abandoning strategies that have been successful for them in the past, even when the environmental context has changed [10]. Such complacency and inertia tend to create pockets of opportunities for new entrants. Not only can new entrants free ride the smoother path paved by incumbents, they can also capitalize on incumbents' mistakes and make the right moves in the new markets—moves that were difficult for the first-mover to envision.

Taken together, factors identified in the resource based view and the industrial/organizational model indicate that new entrants have the potential to overtake incumbent market leaders. Given existing resource endowments and market positions, however, the margin of error for product developers is small. To achieve industry leadership positions, entering firms must destabilize existing markets; they must take away their opponents basis of competitive advantage.

### 1.2 Product-design responses to incumbent power

Traditional product design frameworks often focus on one of two development strategies: incremental differentiation, or targeting a specific market niche. In incremental differentiation, the innovator attempts to develop a product or service whose benefits offset the

liabilities of newness in a sufficiently strong manner as to allow the innovator to charge a premium price, thereby offsetting some of the margin losses faced by entrants operating at a smaller than efficient scale.

An alternative approach is found in the hypercompetition literature [7]. Under hyper competition, firms choose strategies specifically designed to disrupt the normal functioning of markets. One such method is the introduction of a radical innovation. By definition, radical innovations obsolete knowledge [22]. If an innovation is sufficiently radical as to fundamentally change the way a customer does business, then traditional entry barriers fail to protect incumbents. Such disruption is likely in e-commerce for two main reasons. First, e-commerce is technology-driven and rapid technological change is the norm. For instance, when Iomega developed zip drives and high-capacity disks to replace the 3.5 inch floppy diskettes, computer hard drive manufacturers suddenly decided to build read/write hard drives with greater capacity, making zip drives and disks less marketable. Second, the product life cycle in e-commerce has become very short. The product developed of today may become irrelevant tomorrow in marketplace. Technological obsolescence is a common feature of e-commerce [1].

The high-velocity e-environment, with its inherent turbulence and uncertainty makes it easier to find windows of opportunity in which to launch new product designs. The rapidly emerging product launch windows in e-markets are a marked contrast to the pace of change in many traditional industries. In the auto industry for example, steam, diesel and internal combustion engines competed directly with each other for only about two decades; the next eighty years have belonged to the internal combustion engine and the now giant firms that mastered its technology. It is only in this decade that fuel cell technology has created a window of opportunity for smaller firms to compete with the giant automakers.

While one can readily conceptualize the potential of e-commerce to disrupt existing markets, in practice few e-businesses have replaced entrenched competitors. Some of the failures of e-businesses to disrupt markets can be laid at the feet of strategies that were inadequately radical. Early industry analysts expected electronic commerce to be sufficiently radical an innovation so as to obsolete traditional methods of conducting business. This proved to be far from the case. In the early stages of e-commerce, new entrants often employed off-the-shelf technologies, technologies that could be easily purchased by any competitor. As a result, incumbents were often able to adopt the same technology as entrants negating the newcomer's technical advantage.

## 2. Taxonomy of e-commerce product innovation strategies

This paper proposes a taxonomy of product/service innovation strategies specifically designed to disrupt markets, stripping incumbents of their resource based, and positionally based sources of competitive advantage.

The authors define product transformation as the creation of a product or service that generates a technological discontinuity [19]. For this paper, enhancement refers to strategies to incrementally improve core or ancillary goods or services in the new product bundle through e-business technology.

Taxonomies provide parsimonious descriptions of phenomenon that are useful in discussion, research and pedagogy [15]. The development of a taxonomy is beneficial because it reduces influences of confounding factors so that relationships and patterns can be detected [13] [14]. Identifying product/service innovation strategies with common features can help us understand how new entrants can destabilize markets and potentially unseat incumbent firms in established markets. Thus a taxonomy is useful both to researchers attempting to test relationships and patterns and practitioners who wish to exploit them.

### 2.1 Product service bundles

Central to the discussion of product innovation is the concept of product-service bundles. These bundles include the core product or service as well as ancillary services and expected future services [9]. A network administrator for example, purchasing computer system acquires the primary product of hardware and software; and ancillary services like training, documentation, and expected future services like the ability to purchase spare parts or additional training at some future date.

Firms do not compete on just products or services but on bundles of products and services. Product development teams clearly include enhancements to ancillary elements of the product in their research agendas.

### 2.2 Creating disruptive strategies

New product development teams can develop disruptive strategies for either the core product/service or the ancillary products/services. The core product is the primary instrument of customer value-creation; it is the customer's principal reason for doing business with the company. When products within an industry are similar, firms attempt to differentiate based on ancillary services, e.g., training, warranty, documentation, diagnostics, compatibility with other products, upward compatibility, etc. Given limited development resources, firms typically choose whether they will enhance or transform a core product or ancillary service. These choices lead to the matrix described in figure 1: The product innovation/market disruption matrix.

The product innovation/market disruption matrix identifies four unique product bundle strategies. They are: core and ancillary enhancement; core enhancement with ancillary transformation; core transformation with ancillary enhancement; and core and ancillary transformation. The paper describes the four strategies in detail and provides concrete examples for current e-commerce practice. The empirical literature and preliminary practitioner evidence suggest that firms wishing to disrupt incumbent market positions will be

most successful if they pursue a product transformation strategy. By definition, transformations require a radical innovation, thereby obsolescing knowledge. This obsolescence and weakens resource-based barriers like reputation and can even offset large positional barriers like economies of scale.

	Core Products		
	Enhance	Transform	
Ancillary services	Enhance	1 Enhance core and ancillary products	3 Transform core products/ enhance ancillary service
	Transform	2 Enhance core product/ transform ancillary services	4 Transform core and ancillary products

Figure 1: Disruptive product innovation strategies

### 2.3 Product digitization

In his influential research on technological innovation, Sahal [20] posited that as devices are made larger or smaller (scaled) the relationship between their structure and function changes. To Sahal, technological progress can be characterized as "learning by scaling." Product or service digitization represents the ultimate "scaling" of technology, taking physical goods and scaling them for instantaneous virtual delivery.

Choi et al [5] conceptualized e-commerce along three dimensions: products, processes, and agents. Firms considering e-business opportunities could chose a physical or virtual product; a physical or virtual process; or a physical or virtual agent/intermediary. Traditional firms had all three dimensions in the physical world; pure e-businesses had all dimensions in the virtual world. Implicit in Choi's model is the emerging capability of firms to digitize traditional products.

Product digitization is a radical innovation in that it obsolesces the economics of distance. To the extent a product is physical, it incurs logistics costs: inventory, warehouse, shipping, and warranty returns. Firms that can digitize products can compete globally at a cost advantage over traditional businesses. Similarly, physical agents typically accompany physical distribution. In addition to the direct costs of this model, there is the cost of recruiting, training, and retaining culturally sensitive agents who can represent products and services across cultures.

Service and agent digitization converts variable costs into fixed ones. Given fixed costs, firms with high volumes will achieve economies of scale and above normal returns when competing directly against firms with high variable costs. The cost advantages of digital intermediaries is ravaging traditional distribution

philosophy, rendering many distribution channels obsolete [16].

#### 2.4 Enhancement strategies

Firms may choose to enhance either their core product or ancillary services in order to gain competitive advantage. Enhancements, being less radical innovations than transformations, are easier for competitors to imitate and therefore tend not to form the basis for sustainable advantage.

National and international newspapers used to deliver single edition products worldwide; through product digitization and delivery they evolved to create regional editions that were delivered electronically to distributed-production facilities. These publishers integrated local materials like advertising into the regional edition for physical distribution. The result was an enhanced product. These same publishers have added enhanced services in the form of on-line tools for subscribers to accompany the printed page. These tools may allow subscribers to search full text of back issues or view the full set of regional editions.

Software firms have long known that they can reduce the cost of product distribution by digitizing product documentation. For large firms like IBM and Hewlett Packard, the savings over printing and distribution costs is substantial. Further, customers can have the enhanced features of search engines and advanced indexing. Like most incremental innovations however, once it has been introduced into the market, it is easily imitated.

Credit card issuers have added a number of enhancements to their services to merchants including instantaneous credit screening and card issuance, electronic accumulation and transfer for frequent flyer miles and internet security provisions. None of these features transform the industry, but they tend to make the innovator more competitive for the short-run.

#### 2.5 Transformation strategies

Transformation strategies are so radical that they render obsolete the existing basis of competition within an industry. Consider the case of the global recording industry. Questions of copyright aside, point-to-point file transfers combined with disk copying technology has ravaged the industry's existing product development and distribution framework.

From the perspective of the resource-based view of the firm perspective, incumbents should have had such enormous advantages as to blunt the threat of any entrant, especially small ones like Napster or Kazaa. Independent producers were unable to imitate the industry's large distribution networks. As a result, many talented artists choose to work with large record labels, even when they had artistic disagreements with the company, for fear of losing access to captive markets.

Electronic commerce has created a significant disruption in the recording industry. Independent producers can now distribute product over the Internet in small volumes and still be economically viable. With electronic distribution, small labels argue that artists can

be more profitable selling 15,000 items with them than through signing with giant labels selling millions of copies. The supergroup Backstreet Boys recently bolstered this argument in a lawsuit against their record label; after their sale of multiple million CDs, their label argued that the company has not made sufficient profit to justify extra payments to the band. Even for a small artist, industry analysts suggest a major label needs to sell 500,000 units to reach the break-even point.

Further, the very source of success in the record industry has created a high level of strategic inflexibility; record companies seem unwilling or unable to abandon their traditional strategies in light of new technology. Industry analysts note they have relied instead on copyright infringement suits to protect rents. However, sales revenues indicate this strategy has been particularly ineffective.

Similar radical e-commerce technologies are emerging in health care finance. U.S. hospitals and physicians have struggled for decades with case flow problems. Patients are required to pay the balance of their accounts after insurance companies have paid their share. The insurance payment is very unpredictable. The patient's co-pay amount is determined by a complex set of rules governing covered procedures, reasonable and customary charges, and accumulated health costs. The patient waits for the insurance industry to pay their share in order to establish their true out of pocket expense. In practice, the medical community has expected payment from individuals three to four months after the service has been provided. An entire billing and claims processing industry has developed in the US to help the medical community managing the patient billing and financing process.

An emerging radical e-business technology in healthcare has the potential to destabilize the patient financing industry. New services are being developed that would allow the instantaneous calculation of the outstanding account balance of an individual after insurance payments. The patient would be required to settle on the spot using cash or credit cards. The first card company to perfect the system will likely destabilize the billing, claims processing and patient financing industry.

Radical innovations are not without major shortcomings. First, radical innovations have a more complicated development process. Identifying breakthrough technologies is speculative work at best. Second, firms may create a radical technology that is disruptive to the industry but does not become the industry's dominant design. Third, radical designs need to be sufficiently beneficial to consumers for them to overcome exit barriers and other forms of inertia. Just having a radical design is not then a guarantee of market success.

### 3. Implications for research and practice

If radical innovations obsolete knowledge, and product digitization is a radical innovation, then e-businesses have the potential to destabilize markets. In a destabilized market, incumbent firms possess no better advantage than

entrants. Through radical innovation, entering firms can level the strategic playing field. For practitioners, this raises several important implications. New entrants may wish to focus greater resources on both search and development [22] and research and development.

Incumbent firms need to identify areas where product digitization would fundamentally change the industry and develop an a-priori strategy for responding to this challenge. It may be particularly valuable for firms to identify intelligent second-mover or late mover strategies that would allow them to benefit from resources like reputation while still competing on the new playing field.

Market entrants need to consider the value in disrupting the existing market. Without a discontinuous change, incumbent advantages in mature industries may be too powerful to overcome. Entrants need to consider methods of altering the fundamental customer value proposition through radical innovations like core product/service digitization.

Researchers face several key questions. While for purposes of simplicity the paper proposes an enhanced versus transformed innovation dichotomy, in practice innovations form a continuum from incremental through radical. An important question for researchers to determine is the extent to which an e-commerce innovation must be radical in order to disrupt an existing industry. Similarly, while a single enhancement will unlikely lead to competitive advantage, it is conceivable that a set of enhancements may combine to form an industry-destabilizing package. Researchers may wish to examine the effect of multiple product/service enhancements.

Due to the business risks associated with radical innovations, it is important for researchers to understand the role of intelligent late mover strategies. Intelligent late mover strategies have played an important role in the emergence of several Asian high-tech firms. It is unknown whether late-mover strategies can lead to competitive advantage in e-markets.

Theoretical frameworks in the management of innovation and technology and strategic management suggest that innovations like product/service digitization have the potential to obsolete incumbent advantages, thereby destabilizing existing markets. Given the potential rewards from overcoming incumbent positions, we anticipate more radically innovate e-business concepts in the future.

## Abstract

Trust seals are business assurance service in e-commerce. Vendors apply for trust seals to increase their trustworthiness. In this paper, we classify trust seals in five different categories: (1) comprehensive certificate provider, (2) seller evaluation service, (3) market evaluator, (4) market assurance service, and (5) niche service. We derive the five categories through three steps: (1) reviewing literature, (2) examining e-commerce processes, and (3) reviewing seal providers' documents. Our framework and analytical process can help e-commerce consumer to differentiate different types of seals and inspire seal provider to develop new services. We also identify many research opportunities for academics.

## 1. Introduction

In this paper we intend to answer the following questions. First, what does trust mean in the context of e-commerce? Second, can we create a simple framework to help people to differentiate the various types of seals? Third, what kinds of seals are currently available to consumers in e-commerce?

To answer our research questions, we proceed as follows: (1) From literature review, we create a theoretical framework (a classification scheme) identifying the role of trust in both traditional markets and electronic commerce. (2) We identify a list of the seals currently available in the United States. (3) We use our framework as an analytical tool to evaluate the seals identified in step 2. (4) Finally, we summarize our findings as a foundation for future research.

The results of the study will benefit both merchants and consumers. The framework used in this paper will help merchants to determine the seals that will be most effective in increasing consumers' trust, thus increasing sales. Our framework will also benefit consumers by helping them to discriminate among available seals. For the seal providers, our framework identifies opportunities for both new seal development and seal policy improvement. This paper will contribute to academics by identifying opportunities and directions for future research.

## 3. A Process Model to Identify the Sub-dimensions of Trust

Trust is a personal, organizational or mechanical status. It is people's willingness (for human systems) or a contract (for non-human system) to take risks in a relationship. Recently, researchers have recognized that trust is a multi-dimensional construct [20] [21] [22]. One method used to identify the sub-dimensions of trust is to identify the different types of trust-relationship and different risks associated with each type of relationship. For example, Sheppard and Sherman [22] studied the sub-dimensions of trust and developed a model to classify relationships in terms of form and depth. They note that there are four types of relationships: shallow dependency, shallow interdependency, deep dependency and deep interdependency. They also note that there are three types of risks associated with each relationship: (1) the risk of unreliability, (2) the risk of indiscretion, and (3) the risk of poor coordination.

Adopting the same method, we determine that we could develop a classification scheme if we could identify (1) the type of relationship being studied, and (2) the types of risks involved in the relationships. However, there may be many different ways to define the types of relationships and risks. We choose to classify relationships and risk by studying the e-commerce processes.

After reviewing Sheppard and Sherman [22], we adopt their definitions of risks involved in relationships and modify them for the e-commerce setting. We determine that there are essentially two types of risk involved in every trusting relationship: "risk of information disclosure" and "risk of task reliability". The risk of information disclosure is the risk that the trustee will not disclose relevant information fully and accurately. For example, sellers may not fully disclose their privacy policy. The risk of task reliability is the risk that the trustee will not perform the agree-upon tasks. For example, sellers may not deliver quality products or they may not be discrete with the buyer's private information.

Based on the above discussion, we develop Table 1 identifying 16 sub-dimensions of trust. Instead of describing the six possible trust-relationships, we simplify the framework by describing the responsibilities of three trustees, the buyer, the seller, and the market. Furthermore, since the objective of this paper is to help consumers differentiate among various seals, we exclude buyers as one of the interested trustees resulting in two trustees, the seller and the market.

Table 1. The 16 trust sub-dimensions

	Seller	Market
Trustee's Information Disclosure	1. Evaluation Phase	9. Evaluation Phase
	2. Purchasing	10. Purchasing
	3. Order-Fulfillment	11. Order-Fulfillment
	4. After-Sale	12. After-Sale
Trustee's Task Reliability	5. Evaluation Phase	13. Evaluation Phase
	6. Purchasing	14. Purchasing
	7. Order-Fulfillment	15. Order-Fulfillment
	8. After-Sale	16. After-Sale

Column 1 of Table 1 presents the two types of risk involved in e-commerce relationships: risk of information disclosure and risk of task reliability. Column two and three present the buyers' information disclosure risk and task reliability risk for each phase of the market process from the seller and the market respectively.

#### 4. An Exploration Analysis of Current Web Seals

We used Table 1 to analyze the available seals. The unit of analysis in this study is each individual seal. Some companies offer many different seals to cover different interest groups. We treated each seal as an independent unit. We used two methods to identify currently available seals. First, we utilized two popular search engines, google.com and the Microsoft search engine, to find seals. We used two key words: "trust" and "seal", in the queries. All seals identified with country postfix in their URL were excluded. Second, the search results were given to 200 students (both accounting and MIS majors) in the Fall 2001 semester at a large state university. The students were given the opportunity to earn bonus points by identifying additional seals. Table 2 lists all seals identified through this process and will be used as our sample for analysis.

Table 2. A list of popular Web seals

Sponsor	Seal Program
ABAecom	SiteCertain Seal
AICPA	Web Trust
The Council of Better Business Bureaus	BBB online reliability seal
	BBB Online privacy seal
	BBB Online kid's privacy
Better Internet Bureau Association	Quality Assurance
BuzRate.com	BizRate.com seal
Digital Signature Trust (DST)	TrustID Certificate
EPublicEye.com	Web Watch Dog
Entertainment Software rating Board (ESRB)	ESRB Privacy online
GeoTrust	True Site
Internet Content Rating	ICRA Label

Association	
Invisible Hand Software	PrivacyBot
PriceWaterHouseCoopers	The Better Web Program
Privacy Secure, Inc.	Privacy Secure Seal
Quality Testing Lab	QTL Licensing Program
SafeSerf	SafeSurf Logo
Safe Shopping Network	Tested for Safety Program
The Netcheck Commerce Bureau	Netcheck Membership seal
TRUSTe	Trustee Privacy
	E-Health Program
	Children's Seal Program
	EU Safe Harbor Program
Trustsecure	ICSA Security Certificate
VeriSign	SSL Certificate

Next we used Table 1 as our coding instrument. The three listed authors are the coders. We choose to limit the number of coder involved in the process for validity reason. For coding of latent content, too many coders involved in an early stage research project may result in wrong interpretations of the coding instrument [3, p. 311]. The coders obtain information about each seal by visiting its corresponding Web site. We coded each seal based on its functionalities or features as described in its publicly available documentation, such as FAQ, disclaimers, principles and guidelines, and/or application requirements etc. We used a simple "Yes" or "No" to describe if a certain seal provides assurance of a particular cell in table 1. After each coder completed all his/her evaluations, we compared our notes and identified the differences. We also set certain "rules" to resolve differences in coding (Table 3 is omitted to fit the page limit of this version).

Table 4a Comprehensive Certification Provider

## 5. Some Preliminary Observations Toward Current Web Seals

A completed coding sheet is presented in available upon request. We classified Internet seals into five basic types (see table 4a to 4e).

We categorized the first type as "Comprehensive Certificate Provider." AICPA's WebTrust seal and PriceWaterhouseCooper's BetterWeb seal fall into this category. Both of these seals provide services similar to ISO9000 certificates that require trustees to document all their business practices and offer certificates after certain auditing procedures. We categorized the second type as "Seller Evaluation Services." Seals in this category include: BBBOnline's Reliability Program, ePublicEye seal, Privacy Secure Seal, Quality Testing Labs' QT Mark, and Netcheck.com evaluation service. This category represents the largest group in our study and provides assurance services about the seller but not the market. The third category includes SafeShoppingNetwork and BizRate.com. We labeled this group "Market Evaluator." This group differs from the previous group by providing certain assurances about market mechanism. Seals falling within this group evaluate task reliability but not

information disclosure. Unfortunately, the current two members of this group are themselves market builders, thus, rendering their assurances suspect.

The fourth category is the "Market Assurance Service" group. The group consists of Digital Signature Trust's Trust ID and VeriSign. Both companies sell either certification authority or Internet security software and services. Strictly speaking, they cannot be classified as Trust Seal since they do not act as third party evaluators. However, they do allow their customers to display their logos (this practice is very similar to the "Intel Inside" logo on many personal computers). This provides name recognition assurances to consumers by displaying the logo.

The last category is the "Niche Service" group. This group includes various privacy seals provided by TRUSTe, ESRB Privacy Seal, TruSecure Seal and ABAecom's SiteCertain Seal. Each of the seals in this group covers only one or two dimensions in our framework. Some of these seals provide even more narrow services targeting a particular industry or a particular interest group.

## 6. Conclusion

This research is exploratory in nature. The main purpose of this paper is to layout a foundation for future investigation on trust seals by creating a framework against which currently available seals may be evaluated. We identified currently available seals and used our framework to classify the seals into five categories. The categories are determined by the assurances they provide. The five categories are (1) comprehensive certificate provider, (2) seller evaluation service, (3) market evaluator, (4) Market assurance service, and (5) niche service.

Future research in this area could be aimed at answering the following questions. Do customers differentiate trust seals when they are conducting e-commerce activities? If they do, what underlying dimensions are they looking for? Can our framework raise the awareness and increase customers' capability in differentiating trust seals?

Our paper will extend the literature on trust in e-commerce. Currently this line of research is limited. However, the growing e-commerce market makes this line of research extremely valuable. We are sure that our efforts will inject energy to our research community and inspire new development in e-commerce.

## Abstract

The paper establishes the necessity for collaboration for effective supply chain management. We briefly explore some enablers and obstacles and propose the basic components of a strategy for enabling and overcoming these obstacles. Supporting technology for collaboration involves Supply Chain Management Software, Enterprise Resource Planning systems as well as the Internet for the communication platform. A brief discussion of the benefits that go beyond the bottom line, including customer demands and personalisation are noted.

Key words: Collaboration, Supply Chain Management, e-Supply.

## 1. Introduction

Many definitions of a supply chain exist, of particular relevance here because it illustrates the end-to-end processes within the supply chain, is (Granesan et al 1995) definition:

“A supply chain is a network of facilities and distribution options that performs the functions of procurement of materials, transformation of these materials into intermediate and finished products, and the distribution of these finished products to customers”

Traditionally, supply chains have existed in both service and manufacturing organisations and the processes within it are marketing, distribution, planning, manufacturing, and the purchasing, and they have operated independently having their own objectives which were often conflicting. For example, marketing’s objective could be based upon high customer service and maximum sales which could directly conflict with manufacturing operations/objectives, which are designed to maximise throughput and lower costs, with little consideration given to inventory levels and distribution capabilities. As a result of this, organisations have had no single integrated plan, creating a specific need for a mechanism through which different functions can be integrated together. The mechanism for this is supply chain management and this paper presents a case for collaboration as a necessary component for effective supply chain management.

## 2. The role of collaboration in supply chain management.

### 2.1 Supply Chain Management

The managing of the supply chain is nothing new, originating in the manufacturing and retailing sectors, with products like EDI being used for the sending of orders, production schedules and other information across private networks. In contrast the concept of “Supply Chain Management”, is indeed relatively new, and is applied to business in a much wider sense than that relating to the simple flow of goods used in the manufacturing process.

There is not a widely accepted definition of SCM, however, two suitable definitions are as follows:

“The management of materials, information and financial flows in a network consisting of suppliers, manufacturers, distributors and customers” (Youngman 2000a)

“Supply chain management is a collaborative-based strategy to link cross-enterprise business operations to achieve a shared vision of market opportunity”...“It is a comprehensive arrangement that can span from raw material sourcing to end consumer purchase” Quinn (1998)

These definitions underline two important points: firstly, the presence of a multi-party network of processes and secondly that it is a collaborative effort, which embraces all parties across the full length of the chain.

Keeme and Hafeez have explicitly noted the importance of co-ordination and collaboration: “Collaborative relationships have gained significant importance in recent years”, furthermore, “while engaged in a collaborative relationship organisations must be aware that they enter into a complex set of interdependencies..” Keeme and Hafeez [2001]

Therefore, our view of supply chain management embraces the various types of supply chains that lie between a fully vertically integrated firm, where it owns the entire material flow, and that where each channel member operates independently. As a consequence of this, coordination and collaboration between the various players in the chain is key to effective management of the supply chain (Warren 2001).

## 2.2 Collaboration: Enablers, Obstacles and Strategy

Following Uchneat [2001] collaboration in supply chain management means that all parties are working together toward common objectives; the process is characterised by the sharing of information, knowledge, risk, and profits, however before this can happen a culture change needs to take place, in order to redress the guiding philosophy from an "I win" to a "we win" approach.

Supply chain professionals have long suspected that true collaboration requires more than latest technology and that the key factors are people related. In order to expand on these factors that can deliver a host of competitive benefits we follow Anthony [2001] by considering the enablers that are required to be in place and how the obstacles, internally and externally, can be overcome.

Therefore not surprisingly, these enablers and obstacles have more to do with management style and interpersonal relationships than with technology. Indeed the enablers focus on collective co-operation whilst obstacles focus on the resistance to change. The difference is because people working within organisations reach a certain comfort level in their work and collaboration initiative disrupts that comfort level and requires a lot more effort (Quinn 2001). Examples of some key collaboration enablers and impediments are listed below.

Enablers:

- Common interest, clear expectations and good communications
- Mutual openness, trust and benefit sharing.
- Recognition of push and pull principles
- Leadership through co-operation, not punishment.

Obstacles:

- Limited view of the supply chain.
- Lack of Co-ordination in intra-organizational of resources
- Conventional accounting practices.
- Inconsistency of standards

Our Strategy builds on and enhances, Japuchi [3], the basic activities of a strategy for overcoming the obstacles and enabling the collaboration is as follows:

- Planning - the strategic portion of supply chain management. It requires a strategy for managing all the resources that go toward meeting customer demand for your product or service. A big piece of planning is developing a set of metrics to monitor the supply chain so that it is efficient, costs less and delivers high quality and value to customers.
- Choosing the best source of suppliers that will deliver the goods and services you need to create your product or service. This is achieved by developing a set of pricing, delivery and payment processes with suppliers and create metrics for monitoring and improving the relationships.

- Scheduling the activities necessary for production, testing, packaging and preparation for delivery. This is the most metric-intensive portion of the supply chain because it measures quality levels, production output and worker productivity.
- Logistics coordinating the receipt of orders from customers, develop a network of warehouses, pick carriers to get products to customers and set up an invoicing system to receive payments.
- Customer/Supplier Management Relationship The problem part of the supply chain. Create a network for receiving defective and excess products back from customers and supporting customers who have problems with delivered services.

## 2.3 Technology for enabling collaboration.

Without doubt, technology is a critical component of collaboration and the ability to exchange data among the supply chain partners and to gain visibility over product movement is fundamental to strategic supply chain management.

Many new technologies now exist to help companies in their collaborative efforts, with supply chain software solutions now able to promise trading partners instant connectivity and product availability across the pipeline (Cookson 2001). Recent advances in supply chain management software, coupled with the ease and cheapness associated with connecting to the Internet, now allow for streamlining of order management, manufacturing and logistics. These changes have been brought about as a result of three major issues of evolving supply chain management (Anthony 2000):

- The need to reduce the impact of time on supply chains.
- The creation of supply chain communities
- Cultivating customer and consumer intimacy (customer-centric supply chain)

Supply chain management solutions have become the logical extension from ERP, due to their increased flexibility and information flow on which to base critical decisions. According to a July 1997 study by the Gartner Group, key benefits stated include that, Whilst ERP systems provide a great deal of planning capabilities, the material, capacity, and demand constraints are all considered separately, in relative isolation of each other.

In contrast to this the more leading edge SCM products are able to consider all the relevant constraints simultaneously, and to perform real-time simulations of adjustments on them. It concludes that ERP systems have a harder time adding increased dynamic functionality because they are chiefly concerned with transaction processing, and have many more jobs to do than just SCM packages, whose leading products contain more enhancements such as visible maps of the entire supply chain, showing where problems are in contrast to ERP packages .

Despite considerable investments in ERP and supply chain planning systems, companies have realised that these systems are focused on internal processes, and that they now require solutions that are focused on inter-enterprise business processes. Today's SCM systems now encompass the entire production and sales cycle in a collaborative process with both customers and suppliers now incorporating such aspects as:

- f Match the demand to supply.
- f Allocate the supply to customers.
- f Commit the supply and promise orders.
- f Deliver to customers.
- f Collaborate with customers to forecast the next round of demand.
- f Collaborate with customers to focus demand.
- f Prepare a demand plan.

The communication platform for enabling collaboration is clearly the Internet which has had major implications on the way in which businesses now conduct business with one another and the consumer. Common terms such as e-commerce have arisen as a direct result of the innovation and change in supply chain management brought about by the latest technologies.

The Internet vastly changes the way in which businesses can procure products and services, in real-time and on a global basis. Riding on the back of the Internet we have seen the advent of 'hubs' or 'e-hubs', which are simply electronic market places. Technology provides a replacement for the middleman, becoming the mediator between the buyer and the seller, and it is these eMediators that will add tremendous value, particularly in the B2B marketplace (Fontanella 2001). The core benefits of hubs include cost savings through streamlining fax, phone and paper-based trade, and dynamic pricing as multiple suppliers negotiate cheaper prices, however many also incorporate supply chain management software providing transparency through the chain, allowing decisions to be made in real time (Anderson 2001).

### 3 Discussion

Therefore, we can see that this e-enabled Supply Chain Management now links all members of the supply chain to the information network, which improves effectiveness, reduces paperwork and pushes costs down (Fontanella 2001).

Whilst the biggest anticipated benefits will be financial, others will be achieved from the breaking down of functional barriers and less 'fire fighting', however for the benefits of collaboration to be achieved enablers must be implemented aggressively and obstacles should be addressed head on (Harreld 2001). The benefits of ESCM have been summarised by Quinn as shown in the Table 1 below. E-supply chain management enhances supply chain performance because tight coordination between business partners will result in all critical supply chain elements, such as information, transactions, and decisions becoming synchronized. The increased need for this change has been brought about due to the customers ever increasing

demands. They now look beyond cost as the sole arbiter of value, demanding innovation and personalisation of not only the products but also the associated services and delivery (Johnson 2001). By fully integrating your SCM functionality with your ERP systems this will provide three key benefits, quicker to market, cheaper and more flexible (Gossieux 2001).

Benefits	
Reduced inventory	Faster speed to market of new products
Improved customer service	Stronger focus on core competences
More efficient use of human resources	Enhanced public image
Better delivery through reduced cycle times	Greater trust and interdependence
Increased sharing of information and technology	Improved shareholder value
Stronger emphasis on supply chain whole	Competitive advantage over other supply chains

E-supply chain management provides companies with the unique ability to tap into performance and cost benefits and regardless of the type of marketplace, the benefits are many: lower product acquisition costs, lower procurement transaction costs, that ability to tap into almost unlimited supply sources to respond to changing market needs, and a means to profitably dispose of unused excess inventory (Anderson 2000).

The bottom line of the financial oriented benefits is expected to improve returns and increased shareholder value, whilst the non-financial benefits would be aspects such as increased trust, resulting in the sharing of information, ideas and technology. In short one benefit seems to compound another (Quinn 2001).

As for the future a recent report conducted by Jupiter Research predicts that 'e-supply chain management will continue to stay one of the hottest B2B technology fields'.

# The Impact of Internet-Based Technologies on the Procurement Strategy

Margaret L. Sheng  
Department of International Business Studies  
National Chi Nan University  
Nantou, Taiwan  
[msheng@ncnu.edu.tw](mailto:msheng@ncnu.edu.tw)

## Abstract

The big company may spend millions of dollars of expenditure on indirect goods and services. However, much of them may be carried out locally or divisionally, bypassing central guidelines. From a corporate perspective the fragmented procurement resulted in slow and expensive processes and excessive product costs due to poor leverage of buying power. The greater information processing capability achieved through the use of technology, especially Internet-based procurement systems, will enable significant cost improvements and leverage to be obtained through a more strategic approach to management of the typically routine and repetitive tasks with a low unit value, high variety of goods and services, but relatively high frequency. According to the researches, a 10 percent reduction in purchase costs can easily lead to a 50 percent rise in profit margin. This paper addresses the issue of how the Internet-based technologies will impact on the procurement strategy. I believe that the radical change in the Internet will give rise to new marketplaces, which may have the largest impact on procurement. The benefits to aware impacts come not only through direct cost savings but also through the improved efficiency of companies rethinking how they operate.

## 1. Introduction

Emerging technologies, such as the Internet and Web, are bringing the promises to change the picture of costly, time-consuming, and inefficient procurement processes by enabling major improvements in terms of lower administrative overhead, better service quality, timely location and receiving of products, and increased flexibility. With most organization spending at least one third of their overall budget to purchase goods and services, procurement holds significant business value (Zenz & Thompson, 1994; Killen & Kamauff, 1995). Meanwhile, growing pressures from increasingly competitive markets all around the world reinforce the need to reorganize and streamline inefficient procurement procedures.

IT-based tools have been introduced to support production procurement and supply chain operations. However, procurement activities in the non-production items have long under-estimated on an organizational level as well as with respect to the use of IT. Because of little process standardization and a majority of manual activities, the non-production procurement is often a poorly managed, uncoordinated, and non-valued activity (Croom, 2000; Gebauer & Zagler, 2000). Available IT

systems usually do not cover the full process or are very expensive to set up. Internet and Web-based applications promise alternatives that are cheaper and easier to set up. Consequently, procurement function is facing significant reengineering and change management challenges.

This paper addresses the issue of how the Internet-based technologies will impact on the procurement strategy. I believe that the radical change in IT will give rise to new marketplaces, which may have the largest impact on procurement. The benefits to aware impacts come not only through direct cost savings but also through the improved efficiency of companies rethinking how they operate. I will provide an overview of procurement processes and some of the activities that organizations had undertaken to improve performance, then taking a look at currently available Internet- and Web-based technologies, and the opportunities that they open. The impacts and obstacles are also discussed.

## 2. Research Background

The corporate procurement has traditionally been separated along two dimensions: the direct or production-oriented procurement and indirect or non-production-oriented procurement. Direct procurement generally refers to the purchasing of items that immediately enter a manufacturing process, such as the parts that are assembled into a car or computer. Indirect procurement includes everything that is not covered by direct procurement. In addition to so-called maintenance, repair, and operations (MRO) supplies that are consumed in the production process and required to keep up the manufacturing process, indirect procurement also includes items, as diverse as office supplies, computer equipment, promotional material, travel and other services (Segev, Gebauer, & Farber, 2000). Other researchers also include items in the indirect category such as training materials, accessories, temporary staff, public relationships, entertainment (Croom, 2000) and contract workers and consultants (Moozakis, 2001).

The direct procurement has been emphasized on and treated differently than indirect procurement. Compared to direct procurement, indirect procurement covers a wider range of products and services, typically involved a larger number of buyers (possibly every employee, for example, office supplies), and is much less predictable with respect to buying volume and frequency. Add the fact that it is often not regarded of strategic relevance but rather as a clerical function, and it comes at no surprise that the businesses processes are typically not well standardized, most manual, and as a result inefficient and non transparent (Gebauer & Segev, 2001).

Incidentally, the difference between direct and indirect procurement also shows in organizational charts: direct procurement often reports to a Vice President of Supply Chain Operations (or similar) while indirect procurement might fall into the responsibility of the finance function. The line of management for both areas only meet at the level of the Chief Executive Officer. In the literature, the indirect products and services, variously known as MRO (maintenance, repair, and operation) items, have received little attention, as by far the dominant focus of the purchasing literature has been the management of production item procurement. However, a big company may spend millions of dollars of expenditure on indirect goods and services. Much of them may be carried out locally or divisionally, bypassing central guidelines. For example, a large manufacturer bought office supplies from as many as three hundred suppliers, more or less regularly. Nobody was in control of the overall process and each business unit had its own procedures in place. From a corporate perspective the fragmented procurement resulted in slow and expensive processes and excessive product costs due to poor leverage of buying power (Nelson, Moody, & Stegner, 2001). According to PricewaterhouseCoopers, a 10% reduction in purchase costs can easily lead to a 50% rise in profit margin.

The greater information processing capability achieved through the use of technology, especially Internet-based procurement systems, will enable significant cost improvements and leverage to be obtained through a more strategic approach to management of the typically routine and repetitive tasks with a low unit value, high variety of goods and services that constitute the main category of MRO (maintenance, repair, and operation) items. However, most information processing and communication around procurement in the organizations is still based on paper and telephone (Segev, Gebauer, & Farber, 2000). The new procurement systems (i.e. E-procurement) allow employees to order goods directly from their PCs, either through an Intranet or a website. Orders are automatically channeled to suppliers, often via a hub that acts as a host for their online catalogues. The catalogues hold the companies negotiated prices, as well as authorization rules that ensure the right people buy only what they are allowed to. When employees put the job out to tender, it will come back with a list of three or four suppliers. Operators of procurement hubs will increasingly scour the world for new low-cost suppliers, to offer a better service for their purchasing customers. They will check out these suppliers for quality and integrity, if necessary build catalogues for them, and plug them into their systems.

E-procurement system allows employees to combine catalog from several suppliers, check the availability of items, place and track orders, and initiate payment over the Internet. It does not mean just putting purchasing decisions online, but also means linking suppliers into the purchasing network and broadening the range of employees who can carry out transactions. Therefore, e-

procurement is not an example of computerizing the old manual process, but of re-engineering the process itself.

How will the Internet-based technologies impact on procurement strategy? Does Internet mean just doing the same things faster and cheaper? This study attempts to answer those questions. There are also three goals in which this study intends to pursue:

1. Evolve from buying of simple indirect products to sourcing of complex direct products  
Most firms are currently stuck at the first stage of procurement, i.e. simple automation transaction. After starting with non-production related, indirect or MRO (maintenance, repair, and operation) purchases, companies will gradually transfer what they have learned to other parts of the business.
2. Extend from large companies to small or medium-size companies  
Similar to traditional EDI applications, early e-procurement projects have been undertaken by large organizations. In the future, the small companies will also benefit from these new technologies.
3. Increase automation and flexibility  
The companies often experience great difficulties to keep up with the rapidly advancing technological development. Not prepared for the changes, lots of people charged with procurement have little or no experience in buying online (Ramsdell 2000). A number of factors have prevented a shift from focusing on automation to focusing on flexible e-procurement solutions. New systems should be able to increase automation and flexibility to cope with exceptional demands and inexperienced workers.

### 3. Literature Review

The related literature will be reviewed in this section.

#### 3.1 Procurement vs. Purchasing

Procurement includes all activities involved in obtaining materials, transporting it, and moving it towards the production process (Segev, Gebauer, & Beam, 1998). Purchasing is the act of buying and services, represents a core element of procurement.

Procurement processes take on many different forms in reality. Considering the types, uses, and the value of the goods purchased, three categories of procurement have been distinguished (Hough & Ashley, 1992; Zenz & Thompson, 1994):

- n Procurement of raw material and production goods is usually characterized by large quantities, high frequencies, and important and unique specifications; just in time is often critical.
- n Procurement of maintenance, repair, and operation (MRO) supplies is characterized by low unit cost and high variety, but relatively high frequency; examples include office supplies.
- n Procurement of capital goods means dealing with goods of high value at low frequency (e.g. new factories) and/or procuring items outside the regular

purchasing process, often because of convenience or speed requirements.

Close supplier relationships are particularly relevant for direct procurement (raw materials or production goods) where the quality and availability of suppliers can be of critical importance (Lutz, 2001). Company typically spends several years to establish the relationship and to ensure the supplier meets the high quality standards. The unknown suppliers are unthinkable in this context. For indirect procurement (MRO and capital goods), efforts to consolidate the supply base and to establish relationships with preferred suppliers often consider cost rather than quality and availability (Cousins, 1999). Buying firms expect better product prices and less costs to manage the supplier base.

These three types of procurements also involve in three main categories of costs (Gebauer & Zagler, 2000). In the first category, the cost of procurement of raw materials is the product cost (and quality). To ensure consistent quality, the pre-selection of suppliers and active supplier management are critical activities of the sourcing cycle. The involvement of suppliers in target costing activities and collaborative design has proven useful to limit total project cost. In the second category, the cost of procurement of MRO items is the process cost. In this category, the process costs may equal or even exceed the product cost. Therefore, the price is critical. The third category is the technology cost for capital goods. Typically, the characteristics of capital goods are high complexity, innovation, and strategic relevance. Therefore, the range of available supplies is typically very limited (Brown, 2000).

### 3.2 Strategic vs. Transactional Tasks

Procurement activities can also be categorized: long-term-oriented strategic and short-term-oriented transactional activities (Segev, Gebauer, & Beam, 1998). Long-term-oriented, strategic tasks include sourcing activities, identifying vendors, and establishing and managing supplier relationships, as well as contract negotiation and management, but also the design and implementation of buying procedures, and financial and asset management. Activities are long-term oriented and the resulting supplier relationships often last for many years. Short-term-oriented transactional tasks are mostly clerical order-related activities.

### 3.3 Sourcing vs. Buying

Many purchasing organizations distinguish between activities of sourcing and buying tasks (Dobler & Burt, 1996). Sourcing processes cover more than just one or a few individual buying operations and include:

- n Market Intelligence
- n Demand forecast and planning
- n Identification of suppliers
- n Requests for quote and bidding
- n Negotiation of terms of contract
- n Selection of sources and finalizing of contract
- n Supplier management

Buying processes typically refer to single transactions only and include activities such as:

- n Selection of product and supplier, from catalog or other sources
- n Submission of internal requests and management approval
- n Submission of purchase orders to pre-approval supplies
- n Delivery, payment
- n After-sales support and customer service

## 4. Theoretical Foundations

The benefits to the firms deploying Internet technologies include: increased efficiency of order processing, reduced costs due to just-in-time inventory management, locked in trading partners because of the difficulties competitors faced once a network is in place, and greater ability to customize products and services based upon information arising from the transactions carried by the network (Cash & Konsynski, 1985; Johnston & Vitale, 1988). The internet will also increase the efficiency of supply chain by facilitating inter-organizational information sharing, reduce the length of the supply chain by making it easier to locate suppliers, and help handle situations of unforeseen demands better (Gebauer & Segev, 2001).

### 4.1 Supply Chain Management

Supply chain management (SCM) has been used to partner with suppliers and to integrate logistics functions and transportation providers to efficiently and effectively manage the value chain. Most of the recent literature on supply chain management focuses on manufacturers' attempts to integrate processes and form alliances with suppliers to more efficiently and effectively manage the purchasing and supply function.

The supply chain management philosophy expands the internally focused integrating activities of logistics by bringing multiple organizations along the supply chain together with the common goals of efficiency and end-consumer satisfaction (Harwick, 1997). SCM creates a virtual organization of independent entities to efficiently and effectively manage the movement and transformation of materials, components, products, and services along the supply chain until final delivery to the end user (Croom, 1998). Thus, SCM integrates a number of key functions, including purchasing, demand management, manufacturing planning, and materials management, throughout the supply chain.

The short-term objective of SCM is primarily to increase productivity and reduce inventory and cycle time. To realize this objective, all strategic partners must recognize that purchasing function is a crucial link between the sources of supply and the organization. Indeed, the origin of SCM can be traced back to efforts to better manage the transportation and logistics function. In this respect, SCM is synonymous with integrated logistics systems that control the movement of goods from the suppliers to end customers without waste (Ellram, 1991; Ellram & Billington, 2001).

Integrated logistics systems seek to manage inventories through close relationships with suppliers and transportation, distribution, and delivery services. A goal is to replace inventory with frequent communication and sophisticated information systems to provide visibility and coordination. In this way, merchandise can be replenished quickly in small lot size and arrive where and when it is needed (Handfield 1994).

#### 4.2 Strategic Networks

Strategic networks are defined as the long-range, deliberate, cooperative, and goal-oriented organizational forms among distinct but related organizations that enable such network member organizations to sustain competitive advantage vis-à-vis their competitors outside the network (Jarillo, 1993). Wingand, Picot and Reichward (1997) emphasized strategic networks as a distinct organizational form, that is, as being separate from hierarchy and market.

Networks optimize communication, and a more efficient exchange of information becomes possible. As Powell (1990) stated, information passed through networks is thicker than information obtained in the market (since the price mechanism tends to treat information as a commodity and thus tries to make it as scarce as possible) and freer than that communication in a hierarchy (since information is not filtered as clearly through power relationships). Therefore, network organizations combine the advantages of hierarchies, such as better control and coordination of actors, with the advantages of small, independent companies—who has more innovative abilities, tend to be in closer contact with the market, and more flexible, with smaller staffs, fewer intermediaries, and lower overhead.

Malone, Yates, and Benjamin (1987) believe that the development of inter-organizational electronic networks would increase the numbers of buyers and sellers. The use of open information systems may be seen to provide greater levels of information to buyers, thereby opening up greater competitiveness between providers. In addition, they argued that the use of electronic communication links between firms could reduce both the costs of coordinating economic transactions and the costs of coordinating production. As a result, the lowered coordination costs would encourage more outsourcing, enabling firms to buy goods and services less expensively than by producing them in house (Malone, 1987; Malone et al., 1987; Malone et al., 1989).

Existing evidence at the industry level indicates that increases in investment in information technology are associated with a decline in average firm size and a rise in the number of firms (Brynjolfsson, Malone, Gurbaxani, & Kambil, 1993). It may be expected that greater information availability will lead firms to increase their level of outsourcing. As a consequence, an increase in the proportion of bought-out goods and services will place an increased strategic emphasis on the purchasing process.

#### 4.3 Transaction Cost Theory

Economists have classified transaction among and within organizations as those that (a) support coordination between multiple buyers and sellers, that is, market transaction, and those (b) supporting coordination within the firm, as well as the industry value chain, i.e. hierarchical transactions (Wigand, 1997). Marketing hierarchy progressing from manufacturer to wholesaler, retailer, and consumer is associated with transaction costs. Transaction costs include the costs of searching, bargaining, coordinating, and monitoring that companies incur when they exchange goods, services, and ideas (Benjamin & Wigand, 1995; Wigand, Picot & Reichwald, 1997).

The major force driving electronic commerce is the ability of networks to reduce transaction costs (Auger & Gallagher, 1997; Garcia, 1997). Capitalism depends on information to allocate resources efficiently. When business can access the best available information at the most appropriate moment, they can reduce their costs and enhance their productivity. Similarly, when buyers and sellers can easily locate one another and have a good idea of what they can expect in terms of quality and prices, they are more likely to engage in trade. The ever-increasing and innovative use of the Internet or Web to conduct business is clear example of firms' desires to reduce transaction costs. Thanks to information technology, the evolution from separate databases within the firm to linked databases between firms to shared databases between firms, transaction costs are indeed falling rapidly (Wigand, 1997). Malone et al. (1987) also suggested that the communication effect via information technology and a tighter electronic linkage between buyers and sellers may lead to reduced transaction costs.

#### 4.4 Collaborative Commerce

Michael Hammer (2000) defined collaborative commerce as "it is multiple companies working together to achieve better results than they could together" (p.190). Clearly, the Internet is the key enabler of that. The corporate purchasing has been shaken by those collaborative activities. A new category of "buy-side" software from vendors like Ariba and CommerceOne appeared on the scene. This software allows companies to automate and streamline the purchase of indirect, everyday supplies that not used in products. Then came net markets, with their tantalizing promise of even greater cost saving in the purchase of direct products—the raw materials that actually go into a product.

Recently, several hundred independent exchange have opened for business and announced plans to build their own Web-based marketplaces. These online markets create new ways of doing business in traditional industries such as papers and chemicals, where the process of buying and selling commodity-like products. Buyers and sellers can meet on a virtual trading floor and transact as quickly and efficiently.

We see that the first wave of Internet-enabled collaboration focused on the supply chain, as companies collaborated with their customers, suppliers, and

intermediaries (Bowles, 2000). But the second wave is extending to enterprises with which a company previously had no relationship. Collaborative commerce is rapidly becoming the norm. Over the next years, increased business process integration will lead companies to a big payoff—a more synchronized supply chain, which yields better customer service, higher quality products, lower inventory and faster delivery.

## 5. The potential of Internet-based Procurement Systems

With procuring processes typically involving a large amount of information processing and communication, procurement is well suited for IT support and automation throughout all its steps.

Early initiatives to introduce Internet technologies to support procurement concentrated on the automation of highly structured processes. Desktop purchasing systems (DPS) extend traditional EDI systems with user friendly, browser-based interfaces, increased flexibility and automated workflow, well suited to facilitate end-user empowerment and self-service. Based on electronic catalogs as a central data repository, these systems are readily available and well suited to automate highly repetitive activities, as they prevail in the category of process cost oriented procurement (low unit value and high variety items purchased at high frequencies, such as MRO items). In many cases, the operational gains from reduced process costs and lead times allowed procurement departments to reduce their administrative workloads and free time and resources for strategic sourcing activities.

Recent developments are most prevalent in the area of Internet-based exchange, be they horizontal or industry specific (Kaplan & Sawhney, 2000; Phillips & Meeker, 2000). While horizontal exchanges connect market participants of the same function, such as automotive industry, exchanges provide information and services to all members of a particular industry. The other examples of trade exchange include MetalSite, e-STEEL, MetalSpectrum, GlobalNetExchange, WorldWideRetailExchange (retail), and E2Open (electronics). Although the boundaries are usually indistinct, exchanges tend to provide less automation than DPS but cover a wider area of products, typically procured at low frequency with a focus on product cost and quality. Also, solutions oftentimes support only a few aspects of the procurement process, such as supplier identification (supplier directories), or obtaining access to product information.

## 6. Research Methodology

The first and most important condition for differentiating among various research methodologies is to identify the type of research question being asked (Strauss & Corbin, 1990; Yin, 1994). The primary question of this research is, how will the Internet-based technologies impact on procurement strategy. According to Yin (1994), case studies are preferred when “why” and

“how” questions are being posed, when the investigator has little control over events, and when the focus is on contemporary as opposed to historical phenomena (p. 1). This research aims to answer the question of how, and because Internet technologies is a contemporary phenomenon and changes rapidly, the investigator cannot expect any control. Therefore, the case study methodology will be applied in this study.

### 6.1 Data Collection

The principle of data collection is to use multiple sources of evidences. Any finding or conclusion in a case study is likely to be much more convincing and accurate if it is based on several different sources of information, following a corroboratory mode (Yin, 1994). Evidences in this study will come from three sources: semi-structured interview, Website visits, and document review. Semi-structured interviews and web site visits were the primary vehicle for investigation. Documents, secondary data collection were also applied to support and complement the primary approach. The convergence of results between multiple data collection sources enhances confidence that the results are valid, and weaknesses in one method are compensated by the strengths of another.

Semi-structured interviews were carried out in the fall of 2000. More than one person per firm was interviewed to cross-check for any inconsistencies in interview responses and to strengthen the data reliability. The participants located in Minnesota came from companies' Chief Operation Officers, purchasing managers and e-procurement experts. The interviews employed open-ended questions.

Although on-site interviews can reduce the researcher's distance from the phenomena and provide insights, interviews are subject to problems of bias, poor recall, and poor or inaccurate articulation (Yin, 1994). A reasonable approach is to corroborate interview data with information from other sources. Website visit is the second resource of collecting the original data. It will be undertaken in an attempt to bring about greater understanding of the background and process of procurement. A review of the specialized industry magazines and conferences was also used. Several other sources were reviewed to safeguard the reliability and validity of the secondary data. I coded data from all interview responses using typical content analysis procedures (Lincoln & Guba, 1985; Strauss, 1987; Taylor & Bodgan, 1984).

## 7. Impacts

The impacts are examined as below.

### 7.1 Role Change in Purchasing Department

There are changes to business practices and organizational structures over the next years as e-commerce solution becomes more mature and more widespread. As a general development we see the role change between end users and purchasing department, i.e. new procurement system will continue to either automate purchasing operations or help push them down to the end

user, allowing the purchasing department to concentrate more on strategic and managerial tasks, such as partnership relationships, long-term supply contract. Since employees can purchase directly through their Web access, purchasers no longer need to process orders, invoices, or chase delivery. As a result, purchasing department will become composed of mostly managers, and less of clerks, secretarial staff, and administrative support. Additionally, the determining factor of geography will reduce, freeing organizations to obtain the best deal and the most appropriate products from anywhere on the globe.

### **7.2 Convergence between Direct and Indirect Goods**

The division between direct and indirect goods will be blurred. E-procurement encourages commoditisation (brand details are often stripped from the catalogues), which means they will be ideal for standard production items (nuts, bolts, paper clips, and so on), as well as non-production indirect goods. The real distinction will be between purchases that can be commoditised, and those that cannot.

### **7.3 Supply Base Reduction**

Small supplier bases could go into reverse. This will not happen for critical components, where the need for ever-closer collaboration will continue to shrink supplier numbers. But if you are buying paper clips, why not cast your search as wide as possible? Reverse auctions will allow you to spread the net far more widely, and the Internet is excellent at handling complexity. This is not to say that the end buyer will necessarily deal with more suppliers-but he will be dealing with a bigger supplier base. The consolidation of suppliers will appear.

### **7.4 Increased Procurement Control**

The variety of MRO items consider difficulty in terms of developing specialist knowledge regarding product and service technical characteristics, and supply market conditions. The ability to consolidate and categorize suppliers, services, and MRO goods is seen as an enabler in the move toward greater professional contribution to MRO procurement. In addition, the centralized purchasing function was able to exert greater control over sources of supply, purchase price, and inventory policy. Organizations will be able to manage their MRO low-value and high variety items in a more strategic manner through such action as the establishment of single-source arrangements, consolidation of commodities and services, and increased buying power over the supply base.

### **7.5 E-auction**

The new generation MRO, electronic auctions might start to play an important role. A prospective purchaser could dial in and see the spot price of paper, chairs, or office supplies and determine whether to purchase. In the future, next generation auctions will also feature more complex items and allow matching of supply and demand not only with respect to price, but also for features such as service, quality, or speed of delivery.

### **7.6 E-bidding**

Writing up an electronic Request for Quote and submitting it to the electronic marketplace will become easy for buying organizations. Suppliers would be able to electronic contact each other, negotiate a team-based approach, and automatically respond to the Request for Quote.

## **8. Obstacles**

The following obstacles are discussed.

### **8.1 Security Concerns**

The issue of security is a major concern, especially in the context of electronic payments. The capability of any system to provide secure data transfer was regarded as a major criterion for both existing and potential users of e-procurement systems.

### **8.2 Inefficiencies in Locating Information**

This lack of interoperability and the lack of standards make it difficult to pull all buyers and suppliers together into a single protocol or a few marketplaces for buying and selling. Despite its steady growth, the current use of Internet-based technologies has not yet reached critical mass.

### **8.3 Staff Resistance**

Sometimes, the purchasing staff will resist online solution because, not unreasonable, they detect a threat to their job security. In fact, their roles do change dramatically because they are freed from burdensome clerical labour which takes up 70 percents of their time in manual systems and allowed to put their real skills into practice by negotiating contracts and monitoring supplier performance. Also, organizations used to rely extensively on interpersonal communication (telephone, face-to-face negotiation, or fax, etc.). The habits are hard to change. The staff resistance will increase.

### **8.4 Lack of Top Management Support and Vision**

This is understandable, because not even researchers and market analysts are yet sure of the exact direction electronic purchasing will move. There is a long road from the friction-free e-procurement to the reality. However, the successful e-procurement is a top-down process that requires a champion and a visionary at the boardroom table who can grasp the strategic potential of the procurement issue.

## **Abstract**

In the new century, the concept of e-business (EB) has to be redefined. It covers more than e-commerce (EC) which simply handles with electronic ordering and/or on-line payment. EB covers all the managerial and operational functions of a business. So the concept of EB is to be more extensive. More and more people and business firms have recognized the fact that the application of Internet will cover both the outward functions (such as marketing, supplying, etc.) and the inward ones (such as manufacturing, R&D, etc.), go from the surface layers to the deeper layers, and arrive at the core of a firm's business and the center of the social economy. From the point of view of a business firm, more realistic EB refers to replacement of the physical activities with electronic processes and to establish new cooperative relations with the suppliers and customers, and among all internal sections of the firm. It can be shown from an investigation and the author's observations that the trend of EB is to integrate the information technology with the supply chain.

Once business firms have completed the ERP (enterprise resources planning) or other internal integrated information systems, the business firm could develop CRM (customer relation management) or SCM (supply chain management) and so on, to get an external optimization with the internal optimal process. So EB will come true when the bases are ready and sound.

By establishing communications between the upstream suppliers and the downstream cooperators, a business firm should extend its integrated information system and its operational conformity to the whole marketing management and to the whole supply chain.

In years, the downstream links of a supply chain (B to C) may exist in various forms for that the customers have their individualized needs. But among the upstream links of a supply chain (B to B), the traditional business modes among business firms will certainly be replaced by EB.

All the business firms have to face such a fact that from the basic application of Internet to the real-time business on Internet, there is a long way to go. At present, all business firms must face a complicated environment. Starting with the analysis of the environment of EB, this

paper discusses EB's trend and its influence on the business development, and brings forward that modern EB requires the participation of the suppliers, enterprise employees, cooperate partners, government and service institutes altogether.

## **1. Introduction**

Since most people recognized that e-business didn't mean the economy of web site, enterprises have begun to integrate their primary elements, such as products' R&D, manufacture, and marketing, with Internet. This trend has come into being since 2000 and assumed the following characteristics:

1. EB got developed with traditional enterprises as its core and the pattern of B to B as its mainstream. Recent studies by technology consulting groups show that more than one fourth of all B2B purchases will be transacted on the Internet by 2004—a dollar volume 10 times that of Internet consumer purchases[1]. International Date Corporation estimated that the total market turnover of the Internet in the whole world will exceed 425 billion dollars in 2002, more than 75% of which comes from B to B transactions.[2] Gartner Group further forecasted that in 2004 the volume of trade of B to B in the US will be more than 10 times of that of B to C at least.

2. EB is widely distributed not only into newly developed IT business but into traditional manufacturing industries and other service lines, such as circulation, securities and travel as well.

3. EB has got applied to a high degree. Many businesses have begun to make use of ERP, CRM and SCM, or even begun to conduct business integration both inside and outside the enterprise and established virtual firms.

In China, EB has experienced three stages or phases: the first phase (1997-1998): focused on IT manufacture and media; the second phase (1999-2000): focused on EB internet service; the third phase (2000-now): focused on traditional industries. In the third phase, enterprises are assuming the principle part of "e-transfer".

Such transformation is due to that (1) the consumption habits of consumers cause that it is impossible to expand B to C business in a large scale; (2)

commercial tension forced businesses to cooperate with their suppliers and clients more directly, and to make quicker response to any change. American Gartner Cooperation has predicted that any enterprise that still maintains the old style of mass production and keeps the control to marketing channels will become much less competitive in 2005. [3] The press originates from the below ten:

Table 1. The top ten business press enterprises face

More rapid commercialization of products	Relation-based competition (based on the quality of customer relationship, for instance)
Pressure from profits	Temporal-based competition (based on cycle of order, for example)
Increment of marketing channels	Special customers' requirements
More rapid launch of products	Globalized market
Web business requirements	Outsourcing relationship

SCM includes the optimizing of products, fund, and information transition between upstream suppliers and downstream cooperators. Therefore, it is a management of optimizing cost. On the other hand, the flow of various resources through the supply chains is an increment process. Hence, supply chains management can also be called incremental chain management.

By Internet, Extranet and Intranet, IT united all the business including upstream and downstream into supply chains of the whole manufacturing system, and formed a dynamic, virtual and global net of supply chains by combining with supply chains of other business and manufacture. Thus, purchasing cost and logistics activity cost are reduced, and every process of the whole net of supply chain are optimized. To the most important, enterprises' response to market and ultimate customers' requirements is made quicker, and the market competition of a business firm is promoted.

Supply chain management based on IT is an open

management pattern. Therefore, it is easier to achieve more personalized products and service with less production cost and quicker response.

As far as China is concerned, to achieve the more normative market environment and the more lucid information, IT-based SCM is a favorable choice for various enterprises involved in cooperation, which will make all enterprises, whether big or small, definitely benefit.

## 2. The Role of Information Technology (IT) in SCM

Enterprises' information technology includes three basic elements: Internet; Extranet and Intranet [4], which will make SCM adapt to e-business

Comparing with other communication means, Internet is the most resourceful and the cheapest. This facilitates enterprises to collocate their supply chains with lower cost within the whole world.

Extranets are dynamic wide area networks that link a company's employees, suppliers, customers and other key business partners in an electronic online environment for business communication. In manufacturing, setting up an Extranet linking business partners directly allows the handling of purchase order, receiving, invoicing to be done electronically over a secured network. The Extranet is a powerful form of infrastructure required for sophisticated SCM software that allows business partners to benefit from better response time, removal of non-value added inventories and reduction of overall inventory level in the chain by managing the information flow among business partners.

The Intranet allows the internal manufacturing operations to run smoothly and coherently by managing and providing information in a real-time manner to enhance resources planning process. Dispersed applications are linked together through client-server architecture [5].

Fig.1 illustrated how IT is permeated into supply chains and get used inside an enterprise and among enterprises.

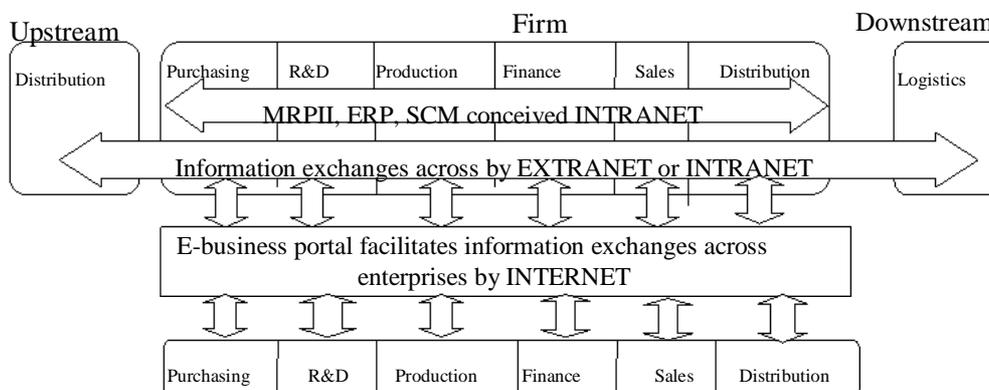

Fig.1. IT permeating into supply chain

Among the three streams in supply chains (that of material, information, and case), information stream is the most difficult to control. Information distortion is magnified gradually as it transmits from downstream to upstream of supply chains. This is so called 'the bullwhip effect'. [6] That is, orders given to upstream manufactures and supplier will fluctuate severely when there is only a tiny change in customer's requirements. IT improved SCM from three aspects.

1. Owing to IT, information transition and share among business partners within supply chains are changed from a linear structure to a network structure. This realized the direct relation between any two knots on the network and prevented information distortion caused by multi-layer prediction in the hierarchy structure. [7]

2. EDI provided criteria for global e-business. [8]

3. It is helpful to know the market instantly, and met ultimate personalized requirements.

As a kind of modern business management strategy, SCM owns a set of integrated strategic and tactical thinking, ECR, JIT, for instance. But only with the support of IT can the advantage of supply chains be fully taken.

### 3. Why the SCM Based on the IT will be the Trend of E-Business?

#### 3.1 Transformation of internal production organization patterns

In order to realize economies of scale, traditional industries usually adopt vertical solution production organization pattern. That is, the core enterprise united its raw-material suppliers into a cooperation organization by internal construction, merge and acquisition. This organization pattern confronted with three severe defects in 1990s when global economic environment changed a lot: (1) bulky business organizations couldn't make quick response to the complicated and ever-changing market requirements; (2) limited resource consumption in diverse field made it difficult to form conspicuous nuclear advantage; (3) the frequent economic fluctuation made it difficult for a company to receive the risk of investment and construction cycle resulted from internal construction, merge and acquisition. So the production organization patterns of many businesses have begun to transit from vertical solution to horizontal solution, a new production and management pattern.

Under the vertical solution pattern, supply chains within an enterprise are generally long. But for the management conformity within the enterprise, united information system and supply chain management system, it is comparatively easy to realize the best distribution of resources along the supply chains. And under the horizontal solution pattern, the supply chains to provide customers with integrated services are composed of many enterprises. Their connection doesn't take the form of 'chain' purely, but that of a complicated 'supply network' (virtual enterprises). As the interests conflicts among enterprises are prone to lead to the delayed transit and

distortion of information, the SCM becomes even more complicated. In this case, enterprises on the 'supply network' enter into a dynamic alliance or interests community, in which each enterprise only need to pay its attention to its own comparative competitive advantage in the value incremental chain. The new management pattern is not only capable of greatly promoting each enterprise's nuclear competitive competence, but also making it possible to reduce the investment and risk each enterprise undertakes, for they are dynamically organized. Therefore, supply chain management under horizontal solution has increasingly assumed the focus of both academic and industrial world. And the emergence of Internet and EB provided means to solve those issues. [9]

#### 3.2 The information-sharing management of exterior uncertain demand

At the age of e-business, thoroughly changes take place on the relationship between producer and consumer, which can attribute to the emergence of new markets. At the electronic space time beyond the tradition physics space time, the different demands of the customer gained further satisfied, which bring about even more complex and levity requirements. At the same time, since all sort of recourses become virtualized at the EB terrace, producers, to a greater extent, possess the throughput which can satisfied the increasingly changeful demands. So the result is that the relationship between producers and customers change from the push phase in which producers push their products to customers via 4Ps(Product, Price, Place, Promotion) to the pull phase in which producers are pulled by customers via 4Cs(Consumer, Cost, Convenience, Communication)

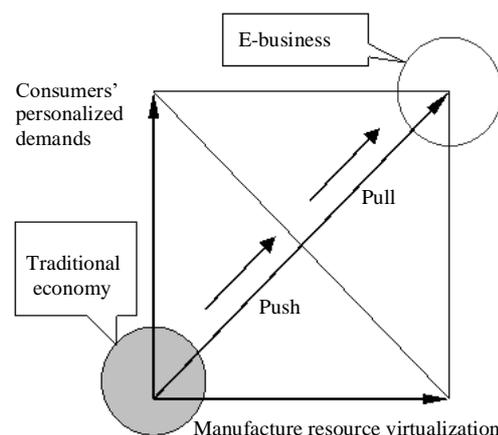

Fig.2 The change of relationship between producers and customers

Fig.2 shows the change. From the point of view of SCM, with the degree of produce recourses virtualization and the pull power of consumers enhancing, the headstream which supply power to the flow of logistics

and information changes from the producers to the consumers That's to say, at the traditional mode, the SCM is focused on how to make use of the producers' predominance in the production technique and management method. While at the age of e-business, it is centered on how to ensure the customers' driver status, how to make use of information by analyzing the uncertain demand, and how to create value by sharing the information on the whole supply chain.

#### 4. The E-Business Cases in China

Viewed from the fulfillment result, most enterprises that carried out e-business have get profits, such as Haier and Legend. Integrating the information technology with SCM in Chinese large business enterprises has become the main body EB's application.

##### 4.1 Haier Group

###### 4.1.1 Background

Haier Group is the biggest home appliances producer in China. Haier now produces a wide range of household electrical appliances in 86 categories and 13,000 specifications. Its products are exported to 160 countries. A total global sale of Haier in 2001 was 7.28 billion dollars. Haier's international promotion framework encompasses competitive globalize trading design, production, distribution and after-sales service networks. Haier now operates 18 design institutes, 10 industrial complexes (1 in USA, 1 in Pakistan, 8 in China), 58,800 sales agents and 11,976 after-sales services throughout the world.[10] Haier operation capital in one year has 12 billion dollars and average 33.4 million dollars a day. Haier receives 0.9 million order which involve 10,000 specifications around the world every mouth, and need to stock 0.26 million kinds of raw and processed materials. So if Haier did not carry out SCM and information technology management, it is difficult to maintain current operation, not to speak of development.

###### 4.1.2 The processes and the effects

1. Strategically adjusting the organizations is the basis of the realization of general information management.

Haier changes from former function management which junior was responsible for superior to the flow management which every department was responsible for markets. Haier's organization is also reformed from a pyramid pattern to a flat style, and converging every subsidiary's logistics, capital, information flow departments to headquarters. And it carries out purchase, physical distribution, storage and conveyance globally. All of these form the main procedure of operation of Haier.

Haier integrates its function management recurses to form 3R departments (R&D, HR, CR---customer recurses) which develop orders and form 3T departments (TCM, TPM, TQM) which ensure the

fulfillment of orders. 3T and 3R are function departments that had been registered as independently working service company.

Haier saves more than 13 million dollars every year from its interior recurses integration.

2. Carrying out the reconstruction of information SCM based on marketing chain

Haier e-business Company comes into existence in 2000, which carries out B to B for suppliers and B to C for customers. By e-business purchase and customization terraces, Haier establishes close relationships with suppliers and marketing terminals by Internet and thus strikes up dynamic business enterprise alliances. Haier's business process is shown in Fig.3

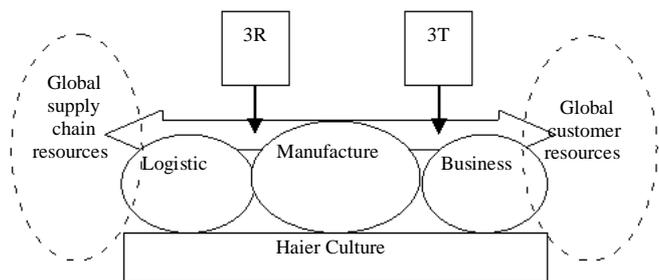

Fig.3 Haier's business process

On the basis of BPR, Haier's SCM has formed a closed loop system. Now, all of Haier's purchase order and 20% of the payment come from the Internet. The performance of inviting public bidding and competitions of price on the Internet makes the prices management more transparent.

The application of computer network cuts down the period of purchase from 10 days to 3 days and reduces the cost of SCM, the sluggish material by 73.8%, the area of warehouse by 50%, and the storage capital by 67%.

###### 3. Interior agile manufacturing

Haier's e-manufacturing adopts CAD and CAM to construct CIMS (Computer Integration Manufacture System). On the basis of DSS (decision support system), ERP, JIT, agile manufacturing system, and concurrent engineering which can correspond with the design and manufacture by network, Haier realized the change from volume-product to mass custom-made.

##### 4.2 Legend Group

###### 4.2.1 Success of China Legend Group

Legend Group is the largest computer manufacturer in China.

The successful establishment of EB terrace makes the producing, marketing and purchasing related each other, and saves capital 0.25 billion dollars only from shortening the stock cycle.[11] In 2000, Legend made profit of 0.1 billion dollars after the establishment of basic EB terrace.

Tables 2 and 3 are the aspects of its marketing and operation management.

Table 2. The aspects of marketing

Year	1998 (Before actualizing EB)	2000 (After actualizing EB)
Sale quantity (million sets)	0.791	2.618
Sale (billion dollars)	2.13	3.43
Market share in China (%)	10.7	30

Table 3. The aspects of operation management

Year	1995	2001
Stock cycle (days)	72	22
Turnover days of receivables	28	14

Legend only invested 3.63 million dollars in ERP and invested 18.2 million dollars to construct three EB terraces including date, process and decision-making.

#### 4.2.2 The developmental process of EB of China Legend group

Legend considers that the aim of B to B is to extend exchange. The integration of enterprises' interior and exterior recurses by ERP is the basis of B to B, and is the necessary guarantees of sustainable development of B to B.

Legend adheres to channel sale system and adopts B to B model from original telephone and fax to dynamic information issuance system. Now, Legend has realized the integration of B to B's former system with the ERP terrace, so the agents can learn the orders including the information such as the time of shipment, the warehouse of the consignment, the circumstance of goods on transportation, the railway and air parcel's indentures and conveyances. Its exchange volume from e-business broke through 1 billion dollars in 1999 and accounted for 50% of total exchange in 2001.

## 5. New Characters of IT and SCM

### 5.1 Shortened and virtualized supply chain

The essential characters of production in communication society are to shorten the intermediate link between manufacture and consuming and to create value by responding to targets quickly and directly. The digital network provides a realistic and reliable foundation for cutting the unnecessary inter-link processes. The supply chain on EB is no longer a complex multi-level network, which is shortened and virtualized. That is, for business reasons, a manufacturer and a supplier can form strategic fellowship, but once the exchanges finished, their fellowship ended. The exchanging costs are reduced and the products become individualized.

### 5.2 The flat and netlike inner-organization

On EB, the information communion is no longer subject to space-time restrictions. The communications among various departments within an enterprise, such as marketing, designing, manufacture and stocking become smooth. The management scope of the departments becomes blurred and the management span was extended. Therefore, the corporation groups' management system transforms from the multilayer pyramid style to an information-based flat and netlike style which takes the projects as longitude and takes the manufacture flat roof, the marketing flat roof, the administration flat roof as the latitude to administrate. As a result, the administration cost is descended and the market reaction to the customer needs is accelerated.

### 5.3 Information can create new value

In supply chain of EB, the information does no longer perform the assistant support function, but bring new value by aggregating, organizing, selecting, composing and distributing. The enterprises can utilize the information to enhance value on three phases: the first phase is visible management; the second phase is reflection ability; the third phase is constructing new customer relationship by IT. At the age of industrial economy, the value increment is manifested by substance increment, but at the age of information, it becomes more and more dependent on the information and knowledge.

### 5.4 The weakened predominance of economies of scale

In supply chain of new EB with agility manufacturing, economies of scale will not possess great predominance than ever. The extremely important thing is to give prominence to core competencies in the supply chain and the value chain. Together with the transparent information and opening supply chain connection, there are more opportunities to small and medium enterprises (SMEs).

Many of the e-business portals are developed by large corporations for free participation, there lie the opportunities for SMEs to access part of varieties of trading communities. For example the Legend Group has 2000 agents around China and the Haier Group has 1000 agents around the world. Fig.4 shows the opportunities of SMEs in participating in e-business portals.

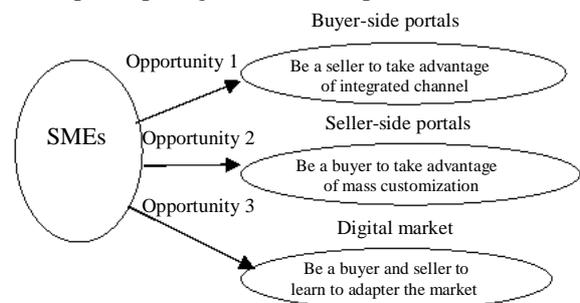

Fig.4 Opportunities for SMEs participating in EB

## 6. Conclusion

EB is changing the world economy drastically, and this alteration is more rapid than any other economy transform in history. Many experts have assumed that e-business in emerging markets will evolve along the same lines as it has in the US, North America, and to a great extent, in Western Europe. This assumption fails to take into account the differences that exist between the economic infrastructures of emerging markets and those of the developed markets of the West. China's economic infrastructure, which like the infrastructures of most emerging markets is much less highly developed than the industrial West's, will influence the development of e-business in China [12].

The network revolution and the EB revolution caused by network revolution are global. How to find a new development path that makes China enterprises linking with the world experiences is an urgent task to be solved.

As this paper has discussed, the construction of China e-business should start with the building of infrastructure facilities altogether with the participation of enterprises as the cells of economy. The timorously development of SCM based on the information technology is the preparatory work for massive introduction of EB. All the business firms have to face such a fact: from the basic application of Internet to the real-time business on Internet there is a long way to go. On the current stage, all business firms must face a complicated environment. Starting with the analysis of the environment of EB, this paper discusses EB's trend and its influence on the business development, and brings forward that modern EB requires the participation of the suppliers, enterprise employees, cooperate partners, government and service institutes altogether.

## Abstract

The need for information sharing has been increasing as a consequence of the globalization of production and sales, and the advancement of enabling technologies. Yet, beyond resolving the technical issues associated with information sharing and joint decision making, a greater challenge is for the supply chain partners to understand the “lost value” due to uncoordinated decision-making, and more importantly, to determine how the recovered value will be shared among the participating stakeholders. This paper presents some models for understanding the incentives for supply chain collaboration, and describes the enabling technologies for collaborative demand planning and replenishment.

## 1. Introduction

Synchronizing the supply chain from raw materials to the consumer offers the greatest opportunity to improve profitability and provide greater value to the consumer. It is quickly becoming the standard for competition.

### 1.1 The Bullwhip Effect

A well-balanced and well-practiced relay team is more competitive when each runner knows how to be positioned for the hand-off. The relationships are the strongest between players who directly pass the baton, but the entire team needs to make a coordinated effort to win the race [4]. Unfortunately, stakeholders along the supply chain have different and frequently conflicting objectives. Accordingly, the stakeholders often operated independently, resulting in a phenomenon called the bullwhip effect on demand and supply [14], [15], [3], [6]. As a result of the bullwhip effect, orders to the supplier tend to have larger variance than sales to the buyer (i.e. demand distortion), and the distortion propagates upstream in an amplified form.

### 1.2 Supply Chain Collaboration

Supply chain collaboration requires industry-wide process and data standards for information exchange. It requires a reliable and secure data exchange medium to facilitate collaborative decision making. Electronic data interchange (EDI) was an initial attempt towards facilitating communication between trading partners. With the advent of the Internet, business documents could now be quickly and securely exchanged. Organizations such as RosettaNet have developed

standards and guidelines for automatic system-to-system exchange of business information and transaction [7].

### 1.3 Incentives for Supply Chain Collaboration

Enabling collaborative supply chain goes beyond resolving the technical issues associated with information sharing and joint decision making. Perhaps a bigger challenge is for the supply chain partners to understand the “lost value” due to uncoordinated decision-making, and more importantly, to determine how the recovered value will be shared among the participating stakeholders.

For example, in collaborative forecasting, if there is no incentive to bind the customers to their forecasts, the customers may be motivated to over-forecast to raise the likelihood that the supplier will have sufficient stock should the customers require more. On the supplier side, if information provided to the customers about the supplier’s allocation is not binding, if the supplier’s situation changes, it could change the allocation at the last minute.

This paper presents some models for understanding the relationships between demand distortion and safety-stock level, and describes the enabling technologies for collaborative demand planning and replenishment.

## 2. B2B Means “Belly-To-Belly”

The need for information sharing has been increasing as a consequence of the globalization of production and sales, and the advancement of enabling technologies. Improving supply chain efficiencies means the companies should direct their focus outside of the four walls of their enterprises. E-business technology is beginning to restructure the ways businesses conduct business. Yet, no matter how much has changed in the new economy, business is still a function of the same reciprocal, collaborative process of decision-making that defined commerce centuries ago and still applies to today's multinational trade. Supply chain collaboration is not, and will never be conducted within the confines of the impersonal, anonymous environments of computer workstations. As Palmer aptly puts it, B2B may as well stand for “belly-to-belly” [11]!

### 2.1 Inter-Organizational Information Sharing

Collaborative demand planning begins with information sharing. Information sharing can occur within an organization (intra-organizational) as well as across organizations (inter-organizational).

A widely cited benefit of information sharing is that it can dampen the bullwhip phenomenon. The bullwhip effect often results in excess cost, such as inventory cost, transportation cost or excess raw materials cost due to unplanned and unbalanced production. Using simulation and analytical research, [8] shows that sharing “sell-through” data and inventory information from downstream stakeholder might reduce the bullwhip effect on upstream stakeholders.

Inter-organizational information sharing is at the core of today's most important business strategies, including Web enablement, supply chain management (SCM), customer relationship management (CRM), multichannel and mobile computing, and self-service applications. Inter-organizational information sharing employs collaboration techniques to create a multi-echelon supply chain involving the focal organization and additional suppliers and customers. At present, the most popular collaboration models include the Collaborative Planning, Forecasting and Replenishment (CPFR) model [5], and RosettaNet-based software solutions like WebLogic [2].

CPFR is a set of guidelines supported and published by the Voluntary Inter-industry Commerce Standards (VICS) Association. Trading partners share their plans for future events, and then use an exception-based process to deal with changes or deviations from plans. By working on issues before they occur, both partners have time to react.

A supplier can build inventory well in advance of receiving a promotional order and carry less safety stock at other times. A retailer can alter the product mix to reduce the impact of supply problems.

RosettaNet is an independent, self-funded, non-profit consortium founded in 1998. The consortium is dedicated to the development and deployment of standard electronic commerce interfaces to align the processes between IT supply chain partners on a global basis.

As of April 1999, the RosettaNet Managing Board consists of 34 CEOs, CIOs, and executives representing global members of the IT supply chain, including initial board member companies: American Express, CHS Electronics, Cisco Systems, CompUSA, Compaq, Computacenter, Deutsche Financial Services, EDS, Federal Express, GE Information Services, GSA, Hewlett-Packard Co., IBM, Ingram Micro Inc., Insight, Intel, Microage, Microsoft, Netscape, NEC Technologies, Oracle, pcOrder, SAP AG, Tech Data, Toshiba Information Systems and United Parcel Service (<http://xml.coverpages.org/rosettaNet.html>).

## 2.2 Intra-Organizational Information Sharing

Intra-organizational information sharing occurs at the data level and at the business-process level. These two levels of information sharing have been widely studied by SCOR [12] and RosettaNet ([www.rosettanet.org](http://www.rosettanet.org)). Solutions such as RosettaNet rely heavily on the definition of EDI-like standards for the exchange of data, process knowledge, messages, etc. [2].

Intra-organizational information sharing means creating or modifying the interactions among semi-autonomous but related application systems, encompassing purchased packages, legacy applications and new Web services. This is generally realized through ERP or middleware serving as an information backbone to transact and convert data among disparate systems.

Enterprise Application Integration (EAI) links together diverse systems and applications across the enterprise, allowing the organization to keep pace with and respond to market changes [9]. An enterprise resource planning (ERP) system, on the other hand, provides an integrated transaction processing fabric for an organization, which enhances organizational performance by reducing information inconsistency and by improving transaction-processing efficiency.

## 3. Incentives For Collaboration

In [13], Sharafali and Co showed that significant savings in inventory-related costs could be achieved if the buyer and the seller cooperate. In analyzing the buyers' and the sellers' replenishment decisions, the authors pointed out that only the supplier benefits from such cooperation. In order to motivate the buyer to cooperate, the authors considered some cooperative strategies. These include the analysis of the impact of (1) price changes, (2) discount policies, and (3) partial deliveries. The authors showed that the partial deliveries strategy is preferable. This is in tune with the benefits cited in the literature as a result of JIT-like relationship between the two parties concerned.

Due to the bullwhip effect, suppliers often have to deal with a demand patterns that are perceived to be erratic and cyclical. The variability of demand increases in moving up the supply chain from consumer to retailers to distribution center to central warehouse to factory. This section provides some models for understanding the advantages of cooperation between the supplier and the buyer: collaborative demand planning.

### 3.1 Optimal Safety-Stock

Uncertainties in lead time and demand exert considerable influence on the stability and credibility of inventory control systems. There are various strategies for coping with the many sources of uncertainties. Murthy and Ma [10] provide an excellent review along with the possible research directions for coping with uncertainties in Material requirements planning systems.

Let  $Y_t$  = replenishment quantity at period  $t$ , for  $t = 1, 2, \dots, n$ , where  $n$  is the length of the planning horizon. The current period is  $t = 1$ . If the lead time =  $L$ , then  $Y_t$ , for  $t = 1-L, 2-L, \dots, 0$ , represent the on-order quantities that are expected to arrive in periods  $1, 2, \dots, L-1, L$  respectively.

Let  $I_{t+L-1}$  = beginning inventory at period  $t+L$ . If the forecasted demand for period  $t+L$  is  $\mu_{t+L}$ , the replenishment quantity made  $L$  periods ago should at least be equal to  $\mu_{t+L} - I_{t+L-1}$  (Otherwise, there would be a

shortage). Supposed the desired safety stock for period  $t+L$  is  $s_{t+L}$ , then  $Y_t = [\mu_{t+L} + (s_{t+L} - I_{t+L})]^+$ . Let  $s_{t+L} = \beta_{t+L}\mu_{t+L}$ , i.e., the safety stock is a fraction of the forecasted demand. Then,

$Y_t = [(1 + \beta_{t+L})\mu_{t+L} - I_{t+L}]^+$ . In the literature, the  $\beta_{t+L}$  is often referred to as the overplanning factor.

The actual demand  $D_t$  is stochastic and non-stationary. Let  $G_t =$  demand distribution is with mean  $\mu_t$  and standard deviation  $\sigma_t$ . Assume the demand sequence  $\{D_t, t = 1, 2, \dots\}$  to be mutually independent. We assume that the forecast for each period  $t$  is unbiased and is equal to  $\mu_t$ . Since demand is non-stationary, the optimal production ordering quantities vary over the planning horizon. In practice, under such an environment, decisions are usually made on a rolling horizon basis. That is, each time a period has passed, it is dropped from the planning horizon, and the forecast demand for a new period is added at the end of the forecast window.

Suppose demand not met are backordered at a cost of  $p$  \$/unit; and the unit inventory holding cost is  $h$  \$/unit. If the ending inventory in period  $t$  is  $I_t$ , the total inventory cost for period  $t$  is  $h[I_t]^+ - p[I_t]^-$ , where  $[I_t]^+ = \max(0, I_t)$  and  $[I_t]^- = -\min(0, I_t)$ . The optimal replenishment problem is to determine  $Y_t$ , for  $t = 1, 2, \dots, n$ , such that:

$$\text{Min}_{\beta_{L+1}, \beta_{L+2}, \dots, \beta_{L+n}} E[TC] = \sum_{t=1}^n [hE[I_{t+L}^+] - pE[I_{t+L}^-]] \quad (1)$$

Subject to:

$$\begin{aligned} I_{t+L} &= I_{t+L-1} + Y_t - D_{t+L} \\ Y_t &= [(1 + \beta_{t+L})\mu_{t+L} - I_{t+L-1}]^+ \\ \beta_{t+L} &\geq 0, \text{ for } t = 1, 2, \dots, n. \end{aligned} \quad (2)$$

The objective function (1) is convex (see [1]). Solving

$$\frac{\partial}{\partial \beta_{t+L}} E[TC] = 0 \quad \text{leads to} \quad G_{t+L}((1 + \beta_{t+L})\mu_{t+L}) = \frac{p}{p+h}, \quad t = 1, 2, \dots, n \quad (3)$$

Note that (3) is true for any lead-time  $L$ , for simplicity we assume that  $L = 0$ . As we have a rolling schedule, we plan for the replenishment quantity for the current period, i.e., we consider  $t = 1$ . Equation (3) then

$$\text{becomes: } \beta_1 = \frac{1}{\mu_1} G_1^{-1} \left( \frac{p}{h+p} \right) - 1. \quad (4)$$

We note that the successive overplanning factors are constant if the sequence of demands are independent and identically distributed (i.i.d.).

### 3.2 Forecast Errors and Safety-Stock

Suppose  $D_n$  is exponentially distributed,

then  $G_n(x) = 1 - e^{-\mu_n^{-1}x}$ ,  $x > 0$

Then  $[1 - e^{-(1+\beta_1)\mu_1^{-1}}] = \frac{p}{h+p}$ , or  $e^{-(1+\beta_1)\mu_1^{-1}} = \frac{h}{h+p}$ .

Hence,  $\beta_1 = -\mu_1 \ln \frac{h}{h+p} - 1$

or  $\beta_1 \mu_1 = \mu_1^2 \ln \frac{h+p}{h} - \mu_1$ . The optimal safety stock

is a quadratic function of the sales forecast! Clearly, this can be seen as the worst-case scenario. If the demand distribution is exponentially distributed, the level of uncertainty as measured by the variance is as large as the forecast itself (the mean).

Suppose  $D_n$  is uniformly distributed over  $(a_n, b_n)$ , then

$$G_n(x) = \begin{cases} \frac{x - a_n}{b_n - a_n}, & a_n < x < b_n \\ 1, & x \geq b_n \\ 0, & \text{otherwise} \end{cases}$$

It can be shown that the optimal safety stock  $\beta_1 \mu_1 =$

$$\frac{(p-h)(b_1 - a_1)}{(p+h)(b_1 + a_1)} \mu_1$$

Apparently  $0 < \beta_1 < 1$ . This guarantees that the safety-stock level will never exceed 100% of forecasts.

Moreover, if the forecasts are unbiased, then  $(b_1 + a_1)/2 =$

$\mu_1$ , the optimal safety stock is  $2 \cdot \frac{(p-h)}{(p+h)} \cdot (b_1 - a_1)$ ,

i.e., the optimal safety-stock level is directly proportional to the forecast error  $=K \cdot (b_1 - a_1)$ . It is noteworthy that as inventory-holding cost approaches backordering cost, the need for safety stock diminishes.

### Abstract

An analysis of multiple criteria decision support systems and facilities management Web-based automation applications that were developed by researchers from various countries assisted the authors to create one of their own Multiple Criteria Decision Support Web-Based System for Facilities Management (DSS-FM). DSS-FM differs from others in its use of new multiple criteria analysis methods as were developed by the authors. The database of a facilities management was developed and provides a comprehensive assessment of alternative versions from the economic, technical, technological, infrastructure, qualitative, technological, legislative and other perspectives. Based on the above complex databases, the developed Multiple Criteria Decision Support Web-Based System for Facilities Management enables the user to analyze alternatives quantitatively and conceptually. Applying the DSS-FM may increase the efficiency of calculators, analyzers, software, neural networks, expert and decision support systems and e-commerce.

One of the major problems in e-business is to find what you want. The number of alternative products and services on the Internet are in the thousands. How can customers find the rational products and services on the Internet? Once product or service information is found, the customer usually wants to compare alternatives.

The major players in facilities management Web sites can find calculators, analyzers, software, neural networks, expert and decision support systems and e-commerce, etc. According to B.K. Forbes [1] [2], the top seven facilities management automation application areas follows: real property and lease management, strategic master planning, space management, furniture and equipment management,

telecommunications and cable management and building operations management.

A calculator is software application that is used for completing mathematical calculations. Facilities management Web sites sometimes contain calculators: CRESA Space Calculator [7] (calculates office space needs), Comfort calculator [8] (analyzes thermal comfort and estimates the optimal temperature), etc.

Web sites might also contain various purpose analyzers [9, etc.] that help customers to analyze various facilities management situations.

Information about facilities management software can be found on the following facilities management Web sites: ARCHIBUS/FM [10], FM Systems [11], etc. The above facilities management software offers various modules and tools: lease management, move management, strategic space planning, maintenance management, accounting charge-back, communication/cable management and personnel management.

Expert systems [12, etc.] today generally serve to relieve a 'human' professional of some of the difficult but clearly formulated tasks.

The major players in facilities management can use various purpose decision support systems [13, etc.]. The decision support system (DSS) provides a framework through which decision-makers can obtain the necessary assistance for decisions through an easy-to-use menu or command system.

The above calculators, analyzers, software, neural networks, decision support and expert systems, e-commerce, etc, are not connected. Therefore, in the future the above FM automation solutions to some extent must be integrated.

Based on the analysis of the multiple criteria decision support systems and facilities management Web-based automation applications and in order to determine the most efficient versions of real estate and facilities

management, a Multiple Criteria Real Estate E-Commerce System was developed. The Multiple Criteria Decision Support Web-Based System for Facilities Management (DSS-FM) consisting of a database, database management system, model-base, model-base management system and user interface is a part of the Multiple Criteria Real Estate E-Commerce system and was developed by the authors of this research. A short description of the DSS-FM follows.

Facilities management involves a number of interested parties who pursue various goals and have different potentialities, educational levels and experiences. This leads to various approaches of the above parties to decision-making in this field. In order to do a full analysis of the available alternatives and to obtain an efficient compromise solution, it is often necessary to analyse economic, qualitative, legal, social, technical, technological, space and other type of information. This information should be provided in a user-oriented way.

The presentation of information needed for decision-making in the DSS-FM may be in a conceptual form (i.e. digital/numerical, textual, graphical, diagrams, graphs and drawing, etc), photographic, sound, video and quantitative forms.

The presentation of quantitative information involves criteria systems and subsystems, units of measurement, values and initial weights that fully define the provided variants. Conceptual information means a conceptual description of the alternative solutions, the criteria and ways of determining their values and the weights, etc.

In this way, the DSS-FM enables the decision-maker to receive various conceptual and quantitative information on facilities management from a database and a model-base allowing him/her to analyse the above factors and to form an efficient solution.

The analysis of database structures in decision support systems according to the type of problem solved reveals their various utilities. There are three basic types of database structures: hierarchical, network and relational. DSS-FM has a relational database structure where the information is stored in the form of tables. These tables contain quantitative and conceptual information. Each table is given a name and is saved in the computer's external memory as a separate file. Logically linked parts of the table form a relational model.

To design the structure of a database and perform its completion, storage, editing, navigation, searching and browsing etc. a database management system was used in this research.

The user seeking for an efficient facilities management solution should provide, in the tables assessing facilities management solutions, the exact information about alternatives under consideration as to the client's financial situation. It should be noted that various users making a multiple criteria analysis of the same alternatives often get diverse results. This may be due to the diversity of the overall aims and financial positions of the users. Therefore, the initial data provided by various users for calculating the facilities management project differ and consequently lead to various final results.

The character of the objective's choice for the most efficient variant is largely dependent on all available information. It should also be noted that the quantitative information is objective. The actual facilities management services have real costs. The values of the qualitative criteria are usually rather subjective though the application of an expert's methods contributes to their objectivity.

The interested parties have their specific needs and financial situation. Therefore, every time when the party uses the DSS-FM they may make corrections to the database according to their aims and their financial situation.

The efficiency of a facilities management variant is often determined by taking into account many factors. These factors include an account of the economic, aesthetic, technical, technological, management, space, comfort, legal, social and other factors. The model-base of a decision support system should include models that enable a decision-maker to do a comprehensive analysis of the available variants and to make a proper choice. The following models of a model-base aim at performing the functions of: a model for the establishment of the criteria weights; a model for multiple criteria analysis and for setting the priorities; a model for the determination of a project's utility degree; a model for the determination of a project's market value.

According to the user's needs, various models may be provided by a model management system. When a certain model (i.e. search for facilities management alternatives) is used the results obtained become the initial data for some other models (i.e. a model for multiple criteria analysis and setting the priorities). The results of the latter, in turn, may be taken as the initial data for some other models.

The management system of the model base allows a person to modify the available models, eliminate those that are no longer needed and add some new models that are linked to the existing ones.

The following multiple criteria analysis methods and models as developed by the authors (Kaklauskas, A., Zavadskas E. [3] [4] [5] [6] are used by the DSS-FM in the analysis of the facilities management alternatives:

a new method and model of complex determination of the weight of the criteria taking into account their quantitative and qualitative characteristics was developed; a new method and model of multiple criteria complex proportional evaluation of projects enabling the user to obtain a reduced criterion determining the complex (overall) efficiency of the project was suggested.

In order to find what price will make a valued project competitive on the market a method and model for determining the utility degree and market value of projects based on the complex analysis of all their benefits and drawbacks was suggested; a new method and model of multiple criteria multi-variant design of a project's life cycle enabling the user to make computer-aided design of up to 100,000 alternative project versions was developed. Any project's life cycle variant obtained

in this way is based on quantitative and conceptual information.

Application of Multiple Criteria Decision Support Web-Based System for Facilities Management (DSS-FM) allows one to determine the strengths and weaknesses of each phase and its constituent parts. Calculations were made to find out by what degree one version is better than another and the reasons disclosed why it is namely so. Landmarks are set for an increase in the efficiency of facilities management versions. All this was done argumentatively, basing oneself on criteria under investigation and on their values and weights. This saved users' time considerably by allowing them to increase both the efficiency and quality of facilities management analysis.

Below is a list of typical facilities management problems that were solved by users: multiple criteria analysis of space management, administrative management, technical management and management of other services alternatives; analysis of complex facilities management alternatives; analysis of interested parties (competitors, suppliers, contractors, etc.); determination of efficient loans; analysis and selection of rational refurbishment versions (e.g. roof, walls, windows, etc.); multiple criteria analysis and determination of the market value of a real estate (e.g. residential houses, commercial, office, warehousing, manufacturing and agricultural buildings, etc.); analysis and selection of a rational market; determination of efficient investment versions, etc.

## Conclusions

Facilities management is an information business. Technological innovation mainly through changes in the availability of information and communication technology inclusive calculators, analysers, software, neural networks, decision support and expert systems, e-commerce that have been provided by a variety of new services developed by the facilities management sector. Most of all calculators, analysers, software, decision support and expert systems, neural networks seek to find out how to make the most economic facilities management decisions and most of all these decisions are intended only for economic objectives. Facilities management alternatives under evaluation have to be evaluated not only from the cost (design, construction, indirect expenses, operating and maintenance expenses, renovation costs, the interest paid on loan), but take into consideration qualitative, technical, technological, space and other characteristics as well. Therefore, applying multiple criteria analysis methods and decision support systems may increase the efficiency of facilities management calculators, analysers, software, neural networks, decision support and expert systems, e-commerce. Based on an analysis of multiple criteria decision support systems and facilities management Web-

based automation applications and in order to determine the most efficient versions of facilities management Multiple Criteria Decision Support Web-Based System for Facilities Management was developed by authors of paper. The related questions were analysed in this paper.

# The Design of a Web Snapshot Management System for Decision Support Applications

David Chao  
College of Business  
San Francisco State University  
San Francisco, CA  
dchao@sfsu.edu

## Abstract

Database snapshots that are defined and/or delivered via the Web are called web snapshots. This paper addresses the requirements for web snapshot management. A web snapshot management system is proposed; its architecture and functions of the major components are described; new commands are defined to perform web snapshot management activities.

## 1. Introduction

Providing information to support decision-making is a major database application on the World-Wide Web. Many web sites let external users query their databases. Frequently accessed queries can be predefined and retrieved on personalized pages. Internally, Intranets are being used as a platform within an organization for improving communication, information sharing, and for developing business applications to support managerial decision-making. Many companies develop Enterprise Information Portal (EIP) to integrate Intranet applications. Decision support databases and tools such as web-enabled Online Analytical Processing (OLAP) tools are major components of EIP [7]. With the development of decision support activities on Intranet, an easy access to the decision support databases via Intranet is essential to the success of such development.

Database snapshots are an effective way to support predefined and recurrent queries for decision support. They are read-only copies of a selected portion of the database representing the state of the database, and a user's view of the operational data at a fixed point in time (snaptime) [1]. A DEFINE SNAPSHOT statement that defines the snapshot contents initiates a snapshot. In Structure Query Language, SQL, this command might look like:

```
DEFINE SNAPSHOT <snapshot-name>  
AS <query>  
AS OF <snaptime>
```

where <query> can be any valid SQL SELECT command. Database records that satisfy the query are said to be relevant or qualified to the snapshot. Relevant records are materialized and stored under the snapshot-

name. A snapshot is read-only from the user's point of view to maintain its consistency with the database at the snaptime. As updates occur to the database, the snapshot will eventually become "stale" and its value for decision-making will diminish. To bring a snapshot to a new state consistent with the database, the user issues a REFRESH command. In SQL this command is:

```
REFRESH SNAPSHOT <snapshot-name>  
AS OF <new snaptime>
```

Thus, snapshots are similar to "materialized views", however, with the following major differences: 1. Materialized views are created to efficiently answer queries with real time data [4]. Unlike materialized views, snapshots are not designed to provide real time data. 2. User determines the snaptime of a snapshot. In decision support systems users may either prefer not to use, or should not be allowed to use real time data. Many such applications call for historical or end-of-period data. Thus, snapshots are created mainly for decision support applications. 3. Materialized views are updated automatically either by an immediate or deferred update scheme deemed optimal by the system. Snapshots are "refreshed" only when the user explicitly issues a refresh request.

A decision support database (DSDB), such as a data warehouse, is essentially a generalization of the snapshot concept. A DSDB contains data from various sources including internal and external data. Data from these sources are first extracted, cleaned, and then integrated before loaded to the DSDB [5]. A DSDB is read-only, and holds information that is consistent with the various data sources as of a specific point in time. Updates to the DSDB will be done according to a predefined schedule. Thus, a DSDB is a snapshot of the source databases. Its content remains static between two refreshes so that users involved in decision support and analysis activities can work with a relatively static copy of the database.

Database snapshots that are defined and/or delivered via the Web for decision support applications are called web snapshots. Figure 1 depicts the environment and major components involve with web snapshots. Web snapshots are defined on a DSDB. The DSDM maintenance algorithm takes updates from various data sources to

Table 1: Possible combinations of web snapshot materialization and delivery options

Materialization Options

Delivery Options	Materialization Options				
	Database File	HTML File	XML File	OtherFile Formats	Virtual Snapshot
HTMLFile	Conversion	Ready	Conversion	Conversion	Querying & Formatting
XML File	Conversion	Conversion	Ready	Conversion	Querying & Formatting
Other File Formats	Conversion	Conversion	Conversion	Ready/ Conversion	Querying & Formatting

update the DSDB and web snapshots. A web snapshot manager is in charge of the snapshot management activities, such as defining and refreshing snapshots, and delivering web snapshots to the web server. The management of web snapshots is quite different from that in a traditional database system. Some major differences and new requirements are discussed in the following.

**Virtual And Materialized Snapshots** Snapshots defined on a traditional database must be materialized to maintain the consistency at the snaptime. A DSDB is updated by a periodical maintenance schedule, and is static between two updates. Hence, it is consistent with its source databases at the time of the last maintenance. Therefore, snapshots that require the same consistent point as the DSDB do not have to be materialized to maintain their consistency. Hence it is possible to have virtual snapshots defined on a DSDB.

**Snapshot Location** A web snapshot can be easily downloaded to a user's computer as a client-site snapshot. A web page can be saved as a local page. File formats supported by browsers can be opened and/or saved as a local file. File formats not supported by browsers can be downloaded without opening. A client-site snapshot is locally available and saves communication costs if accessed frequently. In a wireless environment client-site snapshots can be implemented as a mobile data warehouse to support mobile agents [6].

**Materialization And Delivery Options** In a traditional database system, snapshots are typically materialized at a centralized location and are materialized as a regular database file. A web snapshot may be delivered as an HTML web page, an XML page, or other file formats such as a spreadsheet. Table 1 illustrates the possible combinations of snapshot materialization and delivery options. A materialized snapshot may be ready to be delivered, or requires conversion to the target format. Virtual snapshots need to be generated by querying the database, and format the results to the target format. In practice, a snapshot's delivery format may be different

from its materialization format. A user may view the snapshot in an HTML format with a browser and download it as a spreadsheet.

**Personalization** Web sites today typically provide personalized web pages to users. A snapshot may be embedded or appear as link in a personalized web page. A web snapshot manager must keep track of users and their snapshots in order to create personalized pages.

**Snapshot Refresh Options** A snapshot is usually refreshed in response to a user's refresh request. Such a refresh is called pull refresh [2]. Alternatively, a snapshot can be refreshed by a push refresh where the snapshot manager refreshes a snapshot automatically and still maintains the user's requirement for consistency. This can be done if a snapshot's snaptime is implicitly changing with time. For example, a user may require the snapshot to be one-day old; the server is able to update the snapshot even without the refresh request.

**Large Number of Users and Small Number of Snapshot Definitions** Web sites typically present forms with interface controls to users to define queries by clicking pre-entered values in the controls. This implies that web sites can predetermine the kind of snapshots that will be defined. The number of unique values in those controls is small when compared with the number of web site users. Consequently the number of unique snapshot definitions that can be constructed is small. Therefore, the ratio of the number of snapshot users to the number of unique snapshot definitions tends to be large. It is very likely that each snapshot may associate with many users. Hence a materialized snapshot may be used to support many users.

This paper proposes a web snapshot management system. This system implements new snapshot management commands that incorporate requirements discussed above. The architecture of the web snapshot manager and the functions of its components will be described. From a user's perspective, managing snapshots involves

defining, accessing, refreshing and deleting snapshots. These commands will be defined in the next section.

## 2. Defining Web Snapshot Management Commands

A web snapshot is the realization of the function  $S(SC(Q, T, D(T)), SM(O, N, L, \{F\}, R))$  where  $SC(Q, T, D(T))$  is a set of parameters specifying the contents of the snapshot, and  $SM(O, N, L, \{F\}, R)$  is a set of parameters specifying the management of the snapshot. The meaning of these parameters is explained below:

SC(Snapshot Contents)

Q: Query operations and logical conditions

T: Snaptime

D(T): Database state at T

SM(Snapshot Management)

O: Snapshot owner

N: Snapshot name

L: Snapshot location

{F}: Snapshot formats where {} indicates repetition

R: Snapshot refresh option

The following DEFINE SNAPSHOT command lets users to enter parameters:

```
DEFINE SNAPSHOT <snapshot-name>
AS <query>
[AS OF snaptime ]
[OWNER IS system | username]
[MATERIALIZE AT client-site| server-site]
[{DELIVER AS file format}]
[REFRESH BY push | pull]
```

In the syntax, clauses enclosed in the brackets are optional; clauses enclosed in the braces may be repeated; words in italic separated by the vertical bars are possible choices for the parameters.

The AS OF clause lets users specify the snaptime. Since the DSDB is basically a snapshot of the source databases, the DSDB is consistent with the source databases at the time the DSDB was last updated in a scheduled maintenance. Without the AS OF clause, the DSDB's consistent point is assumed.

The OWNER IS clause specifies the user of the snapshot. Without it, the snapshot is system-owned. Only registered users can issue DEFINE SNAPSHOT command.

The MATERIALIZE AT client-site clause specifies user's intention to download the snapshot to local site. Note that the snapshot may still be materialized at the server. Without it, the server-site is assumed.

The DELIVER AS lets users specify the format of delivery such as an HTML or XML page. Although users may specify a delivery format, the actual materialization may be different. A snapshot manager may consider other factors (discussed in the next section) in choosing a format for materialization. This clause may be repeated which indicates users may request multiple delivery formats. Hence, it is possible to enter the following clauses in a DEFINE SNAPSHOT command:

```
DELIVER AS xml
DELIVER AS spreadsheet
```

The REFRESH BY clause specifies the snapshot to be refreshed by a push or pull refresh. Without it, the pull refresh is assumed.

Refreshing Snapshots: The REFRESH command refreshes the snapshot to the new snaptime specified in the AS OF clause.

```
REFRESH <snapshot-name>
[AS OF snaptime]
```

A forward refresh is performed when the new snaptime is later than the old snaptime; otherwise a backward refresh is performed. Without the AS OF clause, the DSDB's consistent point is assumed. Note that the REFRESH command applies only to snapshots on the server. To refresh a client-site snapshot, the following RETRIEVE command is proposed.

Retrieving Snapshots The RETRIEVE command delivers a snapshot with the specified format which may be different from its original materialized format.

```
RETRIEVE <snapshot-name>
[{AS file format}]
```

The AS clause may be repeated. Without it, the web page is assumed. Hence, it is possible to enter the following clauses in a RETRIEVE command:

```
AS xml
AS spreadsheet
```

Deleting Snapshots: The delete command is simply:

```
DELETE <snapshot-name>
```

## 3. Components of a Web Snapshot Manager

This section describes the architecture of the web snapshot manager. Figure 2 depicts the major components of the web snapshot manager and the interface among them. It takes snapshot management commands as inputs and delivers requested snapshots as outputs to the web server. The functions of these components are discussed in the following.

**Authorization Control and User Registry** This module maintains user directory and checks that the user has the authorization to issue commands. Only registered users can issue snapshot management commands. Validated commands are passed to the Command Processor.

**Command Processor** This module analyzes the commands, determines their action, and passes them to appropriate components for execution.

**Snapshot Catalog** This module maintains information about web snapshots found in the DEFINE SNAPSHOT command including parameters Q, T, O, N, L, and F, R described earlier. It also maintains a link to the snapshot once it is materialized. This information is needed to support the RETRIEVE and REFRESH SNAPSHOT commands. It updates a snapshot's snaptime once it is refreshed. Information of the deleted snapshots will be removed from the catalog.

**Materialization Optimizer** This module takes snapshot definitions from the catalog and determines the optimal materialization plan. Managing snapshots incurs the cost of generating, refreshing, and delivering snapshots. Generating a snapshot may incur the cost of querying the database and formatting the results to a target format. Refreshing a snapshot may be done by performing a differential refresh or by regenerating the snapshot. Delivering a snapshot may involve the cost of reading and formatting the snapshot to a target format. Without describing the optimizer in details major issues involved in deciding an optimal plan are discussed in the following.

. Choosing a criterion for optimization: A typical criterion in selecting an optimal snapshot materialization is to minimize the total snapshot management costs. For web snapshots, however, reducing the response time of delivery is important in maintaining the quality of web site service.

. Choosing between materialization and virtual implementation: Not all web snapshots require materialization. The frequency of accessing a snapshot is an important parameter in making this decision. A frequently accessed snapshot typically requires materialization.

. Choosing between one materialized format and multiple formats: The DEFINE SNAPSHOT and the RETRIEVE SNAPSHOT commands let users specify multiple delivery formats. Materializing in multiple formats will reduce the response time but may require more refresh costs and vice versa.

. Choosing between using one materialized copy to support one snapshot and multiple snapshots: Snapshots with identical (or significantly overlapping) definitions and with the same consistency requirement can be supported more efficiently with a single materialization.

**Refresh Optimizer** This module processes the REFRESH commands. The major functions of this module are:

. Choosing an optimal refresh method: A snapshot can be refreshed by a full regeneration or by a differential refresh. Typically, a frequently refreshed snapshot or a snapshot with only a few updates can be refreshed more efficiently with a differential refresh.

. Maintaining update log: The REFRESH command lets users to specify a new snaptime, which may be before or after the current snaptime. In order to support this refresh capability, the optimizer must maintain a log of updates. Updates to a base table are either deletions or insertions if modifications are treated as the deletion of the before-image followed by the insertion of the after-image. A typical log design is: (TimeStamp, UpdateFlag, UpdatedRecord) where the TimeStamp records the update time and the UpdateFlag is a flag indicating deletion or insertion [3]. This type of log keeps updates in chronological order. Since snapshots are defined on a DSDB, the updates gathered by the DSDB maintenance algorithm can be used to refresh snapshots.

. Generating refresh messages: Updates between the old snaptime and the new snaptime can be generated from the log. These refresh messages are sent to the materialization optimizer to refresh the materialized copy.

Once the refresh is done, the refresh optimizer will notify the snapshot catalog to update the snaptime.

**Retrieve and Delivery Module** This module processes the RETRIEVE commands. It retrieves the snapshot from the materialization optimizer, converts it to the format requested by the user, and delivers it to the web server.

## 4. Summary

This paper addresses issues and requirements for the management of web snapshots. Database snapshots that are defined and/or delivered via the Web are called web snapshots. They are used mainly for decision support applications in a Web environment. New commands are defined to perform web snapshot management activities. A web snapshot management system is proposed; the functions of the major components in this system are described.

## Abstract

Information techniques have brought us tremendous benefit, whereas people are increasingly depended on lots of information systems. Therefore, how to establish an assessment model to choose a better software quality suitable for end-users is an important issue. This study is to present an algorithm of the group decision makers with crisp or fuzzy weights to tackle the integrated software quality for evaluating user satisfaction using fuzzy set theory, where the grades of quality and the grade of importance of quality items are assessed by linguistic values represented by triangular fuzzy numbers. The proposed algorithm is more flexible and useful than the ones that have presented before, since the weights against decision makers are considered.

## 1. Introduction

During the past decades, information industries have been flourishing in Taiwan. Compared to hardware information technologies, software engineering needs to improve more because more efforts are put into the development process than the control of software quality. Software products are powerful but hard to revise, modify, expand or transfer. Therefore, how to promote the quality of software is important.

Software quality was assessed with software attributes but its complexity and unpredictable nature cannot be easily processed. Therefore, how to build an effective software quality measure model becomes an important issue. In the early 1990s, the software engineering community attempted to consolidate the many views of quantity into one model that could act as a worldwide standard for measuring software quantity. The result was ISO 9126, a hierarchical model with six major attributes contributing to quality [7]. Since ISO 9000 is already widely used in industry and also corresponds with Satty's Analytical Hierarchy Process (AHP) [8], as shown in Table 1, we denote the attribute to be  $X_i$  and the items as  $X_{ij}$  [4-5, 7, 9].

Based on the algorithm developed in [4], Wang and Chiang [9] presented a software quality assessment model to evaluate user satisfaction. In [2], Fey et al. presented

the simplified algorithm to tackle the user satisfaction. In [2, 9], they assumed the relative important weights of each evaluator to be the same. But, in general, the relative importance of each decision maker or expert probably may be widely different. Sometimes there are important experts in the group decision making, the final decision is influenced by the different importance of each expert. Therefore, the best method of aggregating experts' assessing data must consider the degree of importance of each expert in the aggregation procedure.

We reviewed the Wang and Chiang method [9], Fey et al. method [2] in Section 2, 3, respectively. In Section 4, we proposed the fuzzy group decision making for evaluating the user satisfaction.

## 2. A review of Wang and Chiang's method [9]

Based on Lee [4], when evaluating each item of software quality, we assign its grade of quality, and grade of importance [4, 9]. Then we range both of them into 11 ranks, as shown in Table 2 [4, 9].

We made the linguistic values 1, 2, ..., 11 into corresponding reasonable fuzzy numbers with triangular membership functions as listed in Table 3 [4, 9].

By the multiplication of fuzzy number of grade of quality and fuzzy number of grade of importance, and the defuzzification  $g(a, i)$  by the centroid method, Lee derived the values of  $g(a, i)$  as shown in [4]. Based on [4], Wang and Chiang [9] constructed the ISO 9126 model into the structure model as shown in Table 4. The weight of quality attribute  $X_i$  is represented as  $W_i$ , while  $W_{ij}$  denotes the weight of item  $X_{ij}$ .

The criteria ratings are linguistic variables with values  $V_1, V_2, V_3, V_4, V_5, V_6, V_7$  (as shown the figure in [4]), where  $V_1 =$  extra low,  $V_2 =$  very low,  $V_3 =$  low,  $V_4 =$  middle,  $V_5 =$  high,  $V_6 =$  very high,  $V_7 =$  extra high. These linguistic values are treated as fuzzy numbers with triangular membership functions [4]. Let

$V = \{V_1, V_2, V_3, V_4, V_5, V_6, V_7\}$  be the set of the criteria rating of quality for each item. By fuzzy relation on  $X_i \times V$ , we can form a fuzzy assessment matrix  $M(X_i)$  for  $X_i \times V$ . Thus, fuzzy assessment matrix  $M(X_2)$  for  $X_2$  is formed as the following [4]:

$$M(X_2) = \begin{bmatrix} V(a_{21}, i_{21}, 1) & V(a_{21}, i_{21}, 2) & \dots & V(a_{21}, i_{21}, 7) \\ V(a_{22}, i_{22}, 1) & V(a_{22}, i_{22}, 2) & \dots & V(a_{22}, i_{22}, 7) \\ V(a_{23}, i_{23}, 1) & V(a_{23}, i_{23}, 2) & \dots & V(a_{23}, i_{23}, 7) \end{bmatrix}$$

By using the same way, fuzzy assessment matrices  $M(X_1), M(X_3), \dots, M(X_6)$  can be formed respectively. Then the first-stage aggregated assessment quality  $R_2 = (W_{21}, W_{22}, W_{23}) \times M(X_2)$  for attribute  $X_2$ .  $R_1, R_3, \dots, R_6$  can be derived respectively.

The rate of aggregated quality of software quality for user satisfaction is calculated by using the second-stage assessment as the following formula:

$$(fW_1, fW_2, fW_3, fW_4, fW_5, fW_6, fW_7) \times \begin{bmatrix} R_1 \\ R_2 \\ R_3 \\ R_4 \\ R_5 \\ R_6 \end{bmatrix}$$

The final rate of aggregated quality of software quality for user satisfaction is then defuzzified by centroid method and becomes:

$$FW = \frac{\sum_{i=1}^7 VG(i) \times fW_i}{\sum_{k=1}^7 fW_k} = \sum_{i=1}^7 VG(i) \times fW_i$$

where  $\sum_{k=1}^7 fW_k = 1$ ,  $VG(i), i = 1 \dots 7$ , which are the centroids of  $V_1, V_2, \dots, V_7$  [4] and  $VG(1)=0.0556$ ,  $VG(2)=0.1667$ ,  $VG(3)=0.3333$ ,  $VG(4)=0.5$ ,  $VG(5)=0.6667$ ,  $VG(6)=0.8333$ ,  $VG(7)=0.9444$ .

### 3. A review of Fey et al. method [2]

Step 1. Let

$$R2(k) = \frac{\sum_{j=1}^{n(k)} W_{(k,j)} * g(r_{kj}, i_{kj})}{\sum_{j=1}^{n(k)} W_{(k,j)}}$$

$$= \sum_{j=1}^{n(k)} W_{(k,j)} * g(r_{kj}, i_{kj})$$

(since  $\sum_{j=1}^{n(k)} W_{(k,j)} = 1$ ),  $k=1, 2, \dots, 6$ , where  $n(k)$  is

the number of quality item for attribute  $X_k$ , then we have  $n(1)=4, n(2)=3, n(3)=3, n(4)=4, n(5)=4, n(6)=2$ ;  $g(r_{kj}, i_{kj})$  is the rate of quality item  $X_{kj}$  appeared in [4];  $W_{(k,j)}$  is the weight of quality item  $X_{kj}$ .

Step 2. The final rate of aggregative quality of the software quality for the user satisfaction is by the centroid method as follows:

$$\text{Let } R1 = \frac{\sum_{k=1}^6 W_{(k)} * R2(k)}{\sum_{k=1}^6 W_{(k)}} = \sum_{k=1}^6 W_{(k)} * R2(k)$$

(since  $\sum_{k=1}^6 W_{(k)} = 1$ ), where  $W_{(k)}$  is the weight of

attribute of  $X_k$ , for  $k=1, 2, \dots, 6$ . Then, the value of  $R1$  is the rate of aggregative quality of the software system for the user satisfaction.

### 4. A fuzzy group decision makers with crisp or fuzzy weights to evaluate the user satisfaction

In [5], Lee proposed an algorithm of the group decision makers with crisp or fuzzy weights to tackle the rate of aggregative risk in software development in fuzzy circumstances by fuzzy set theory during any phase of the life cycle. We applied this algorithm to this Section as follows:

Step 1: Let  $SAT(k)$  be the rate of aggregative quality of the software system for the user satisfaction for the evaluator  $D_k$ 's assessing data, i.e., let  $SAT(k)$  be  $FW(k)$  in Section 2, or  $R1(k)$  in Section 3.

Step 2:

(A) Corresponding to the crisp relative importance of each decision maker or evaluator:

We assign  $d_1, d_2, \dots, d_n$  to be the relative weight of each evaluator  $D_1, D_2, \dots, D_n$ . Then, we define

$$w(j) = \frac{d_j}{\sum_{k=1}^n d_k}, \text{ for } j=1, 2, \dots, n$$

to be the normalization of  $d_1, d_2, \dots, d_n$ .

(B) Corresponding to the fuzzy relative importance of each decision maker or evaluator:

We assign the relative fuzzy weight  $\tilde{w}_j = (w_{j1}, w_{j2}, w_{j3})$  to be the triangular fuzzy number in  $[0, 1]$  for the evaluator  $D_j$  for  $j=1, 2, \dots, n$ .

Defuzzified  $\tilde{w}_j = (w_{j1}, w_{j2}, w_{j3})$  by the classical centroid method, we obtain

$$w_j = \frac{1}{3}(w_{j1} + w_{j2} + w_{j3})$$

Normalize  $w_j$ , we obtain the degree of importance

$w(j)$  for the evaluator  $D_j$  as follows:

$$w(j) = \frac{w_j}{\sum_{k=1}^n w_k}, \text{ for } j=1, 2, \dots, n.$$

Step 3: By Step 1 and Step 2, we have that the rate of aggregative quality of the software system for the user satisfaction for the evaluators with weights  $w(1), w(2), \dots, w(n)$  is

$$SAT\_User = \sum_{j=1}^n SAT(j) \cdot w(j)$$

The value of  $SAT\_User$  is the rate of aggregative quality of the software system for the user satisfaction for the evaluators' assessing data. If there is only one evaluator to evaluate then we have the same formula as in [2] and [9].

## 5. Conclusion

The proposed algorithm of the group decision makers or evaluators with crisp or fuzzy weights for

evaluating rate of aggregative quality of the software system for the user satisfaction is more useful and flexible than Wang and Chiang in [9] and Fey et al. in [2], since the weights against evaluators /decision makers are considered.

## Abstract

An algorithm is constructed in this study to estimate the market sizes of daily commodity in Taiwan based on the sampled sales information provided by retailer chains. Though retailer chains provide sampled sales information from only small portions of their retailing stores, they expect to receive more valuable processed information from that. As result of this research, a DSS is proposed to compute value-added information from this joint sales information database, namely the estimation information. Through certain public accessible data such number of stores by each chain and retailers' financial reports, the sampled sales information can be transferred to the market size information of each item in Taiwan. Two similar algorithms are constructed for convenient stores and supermarkets/hypermarkets separately. A simple integration method is used to combine these results. Finally, a DSS is built based on these estimation algorithms and is implemented successfully.

## 1. Introduction

Sales information is always the important fundamental information that the decisions of the future sales and inventory policies were based on. However, not all the retailers have the ability to utilize information technology. Some retailers are unable to process and analyze the sales information further due to the lack of investment in capacity, capital, and people. Therefore, Department of Commerce in Ministry of Economic Affairs in Taiwan support a project initialized by Computer and Communications Research Laboratories (CCL) of Industrial Technology Research Institute (ITRI) to analyze and integrate the demands from all the retailers regarding to the sales information for the retailing industry in Taiwan. After analyzing the demands, CCL/ITRI setup Distribution Information Service Center, or DISC, to study and fulfill information requirement of retailers in Taiwan in May 2000. DISC collected sampled sales information from the retailers and constructed a joint sales information database, called "Retailing Sales Information Sharing System" or RSISS. There are currently more than 100,000 retailing items with Universal Product Code (UPC) in this database and all of them have been classified with three levels of classification codes.

As more and more retailers agree to cooperate in this project, the joint sales information database of RSISS is growing with more and more data. The retailers who joint

this project is expecting to receive more value-added information such as estimation, prediction, etc in the future. In light of this expectation, DISC endows a project to construct a DSS that estimates the sales of retailing industry in Taiwan based on the sample sales data. This DSS is constructed and implemented successfully through the cooperation and efforts of DISC, Department of Information Management and Department of Business Administration in National Taiwan University.

## 2. Literature Review

As mentioned in Andreasen [1] and Rapp etc [12], the research in Marketing in the past usually concentrated on certain subject and solved specific problem from scenario analysis, to problem formulation, to data collection, to result finding. However, this type of research ignores the supply-demand environment issues and the relationship of marketing activities among different chain stores. The study in Marketing Research Systems (MRS) [4] or Marketing Information Systems (MKIS) [2] arises for this reason. Through collecting customer and sales information, a sales and marketing related database can be constructed to provide continuous and relevant sales/marketing reports. Morris etc [11] surveyed the views of 101 marketing managers toward MRS and found that they think positive of MRS though these managers don't exactly know what computer technology would affect them. Li [8] tracks the development of MKIS among the Fortune 500 companies in 10 years. He concludes that the usage of MKIS is getting more and more complicated and matured but the marketing managers are still unsatisfied with the reports and information provided by MKIS. Talvinen etc [15] also survey the senior marketing managers of 156 wholesalers in Finland and find that MKIS plays a crucial role in marketing policy making.

Constructing a complete MRS or MKIS needs consistent and long-term efforts as well as computerized capability to clean, integrate, classify, and transform data. Talvinen [14] suggests a specific system architecture of a MKIS with important processing subsystems such as decision support, planning, and internal/external control. Amaravadi etc [2] think the future trend of MKIS is Intelligent Knowledge System with marketing/sales knowledge base and decision support function. With a complete sales/marketing database, more and more researchers focus their efforts on the decision support functions that could be added on the system. Higby etc [6]

found that information after cleaning, classification, and computation is much more valuable to marketing managers in terms of decision making. Li etc [7] analyzes the utilization of MKIS in Fortune 500 companies and finds that marketing managers commonly use MKIS/Decision Support System/Expert System in their decision making and are more interested in value-added information such as sales forecast and market share estimation. Li [9] surveys the conditions of using MKIS in 1000 small US companies and finds a relationship between sales and probability of MKIS utilization. In other words, the larger the sales of a company, the more possible the company has a MKIS. As to how the company applies MKIS to marketing policies, 67.7% are for pricing strategy, 65.8% for new product evaluation, 61.8% for advertisement media selection, 52.6% for product out-of-market, 46.1% for budget, and 43.4% for salesperson allocation. Li etc [10] found that the support of MKIS to management is in 4 aspects: planning (44%), control (19%), organization (15%), direction (14%), and personnel (8%). They also think that more and more IT specialists joint the sales/marketing department to help salesperson or marketing personnel obtaining more value-added information without relying too much on MIS/IT department.

Adopting mathematical modeling and statistics method is also a future trend of MKIS to provide more valuable decision support functions. Among all the value-added information, sales estimation and forecast is the most important and common one provided by MKIS [7, 16, 17]. Marketing managers from all types of industries are all eager to know the sales estimation of a single product or the whole company, or the estimation of future market shares. Higby etc [6] also find that 66% of MKISs provide support on sales estimation/forecasting. The conclusion can also be found in Li etc [7]. Current research on data mining also showed the same result. Berry etc [3] think that one of the important functions provided by data mining is estimation followed by prediction. Concluded from the above reviews, estimation is a very important value-added information provided by MRS or MKIS. Therefore, this research proposes to build a DSS upon a joint MKIS, namely RSISS, to estimate the retailing market size of each individual item in Taiwan.

### 3. Problem Description

The problem faced by DISC is to estimate the market size of every individual product with UPC based on the sampling sales information provided by the retailer chain stores. There are three major types of retailing stores in Taiwan: convenient stores, supermarkets, and hypermarkets. Old-fashioned grocery stores now exist only in the remote areas and take up only a very small part of the total sales of the retailing industry in Taiwan. They are usually not equipped with IT capability and thus, are not able to provide digital sales information to DISC. Six major chains of convenient stores capture about 95% of the

convenient store market in Taiwan and joint the project of Retailing Sales Information Sharing System (RSISS) founded by DISC in May 2000. As to the supermarket chains, major players capture more than 50% of the supermarket sales in Taiwan and joint the project of RSISS a year later than the convenient-store chains in May 2001. More supermarkets under negotiation are interested in joining the project. It is estimated that 85% of the supermarkets will be included in this project in the end of 2002. The negotiation of hypermarkets' cooperation in the project is currently under way. A full-scale cooperation from the major hypermarkets is expected to begin in July 2003.

With so many partners in the project, it is impossible to process all the sales information from all the stores. As to the end of May 2001, there are more than 6,250 convenient stores, 570 supermarkets, and 100 hypermarkets in Taiwan. On the average, each convenient store carries more than 4000 items with UPC while each supermarket carries more than ten thousand UPC items and each hypermarket carries forty thousand UPC items. Not only is it impossible to process such large scale of sales information, it is also unrealistic to ask retailer chains to submit all the sales information of all stores. To balance the information-sharing scale, each chain of convenient stores samples sales information of 100 stores. As to supermarkets, most of the supermarket chains have less than 40 stores except Wellcome. Therefore, Wellcome provides sales information of 40 stores out of its 105 stores while others provide sales information of all their stores. From the geographic point of view, the scattering of the stores around Taiwan is not balanced. DISC has divided Taiwan into three geographic areas: North, Center, and South. More than 60% of the retailing stores are located in Northern Taiwan. As result of negotiation, each convenient store chain provides sales information of 40 stores from north, 20 from center, and 20 from south if there are enough stores in each area. For supermarkets, Wellcome provides sales information of 20 stores from north, 10 from center, and 10 from south while others provide sales information of all their stores based on the locations. Random sampling is not applicable here since the scales of the convenient store chains vary significantly. To balance the differences among sampling stores, DISC requires the samples to be taken from the top 50% list for all the convenient store chains and Wellcome supermarkets. From the above sampling process, the problem of estimating sales faced by DISC can be depicted as Figure 1. In other words, the sales estimation of each individual item with UPC in Taiwan is computed based on the sampled sales data collected each month by DISC. The sales estimation can be seen as a summarized figure or be analyzed from different points of views.

### 4. Estimation Algorithm

Two separate but similar heuristic algorithms are constructed to estimate the market size of convenient

stores and supermarkets/hypermarkets. A simple computation module is then used to combine these two results and provides the final estimation of the entire retailing market as seen in Figure 2. These two heuristic algorithms are very similar in terms of estimating the market sizes but different in the analysis dimensions. Two types of analysis dimensions are applied: item and store characteristics. From item point of view, some items are seasonal or regional while others are not. In order to aggregate the similar effect, items are grouped into three levels of categories: first-layer, second-layer, and third-layer. Through the years, DISC has developed a standard classification mechanism to the items in RSISS. In this study, the same classification method is adopted. For the store characteristics, geographic areas, living zones of convenient stores, and sizes of supermarkets and hypermarkets are all the related analysis dimensions.

Six steps are involved in the algorithm of estimating the market size of convenient stores for each item as seen in Figure 3 and are elaborated below.

- **Step 1:** Compute the average sales at each store of each chain: The reason to compute this average is that some chains might not be able to provide sales information for the stores in all areas. However, those sales will have to be included in the estimation. Therefore, other chain K will be used as the reference to help estimating sales in those areas without any sales information. However, the scale of reference chain is different from the chain to be estimated in terms of sales. To adjust the difference in scales of different chains, average sales at each store of each chain will have to be calculated first.
- **Step 2:** Compute the average sampling sales of each first-layer category of each chain in each area: The reason to compute this average is due to the customer's behavior differences among different areas. However, to compute the average for each individual item is an impossible task due to the enormous amount of item information. In order to reduce the amount of calculation efforts, first-layer category is used instead of individual item. To obtain the average, compute the total sales of sampling stores for each first-layer category of the reference chain of Chain R in reference area of area A first. Then compute the ratio of average store sales of Chain R in area A over the average store sales of its reference chain and area and adjusting the ratio by number of stores sampled by chain R and its reference chain.
- **Step 3:** Compute the percentage of the total sales for each first-layer category of each chain occurs in each area after normalization: The percentage of total sales at chain R occurred in area A of chain R can be collected from retailers. However, it is for the summary of all items instead of individual items. However, to calculate the

percentages for individual items is a difficult job due to the same reason mentioned above. Since products in the same first-level category possess similar characteristics, this percentage is computed for each first-level category. To get the percentage, compute the total sales of each first-layer category at sampling stores of each chain in each area. Sum up the total sales of every first-layer category for each chain next. Then, calculate the percentage by dividing the above two figures. However, the sum of all percentages for each first-layer category in each area of each chain might not be 1. Thus, the percentages need to be normalized to make the sum of percentages equal to 1.

- **Step 4:** Compute the adjustment factor of the total sales for each first-layer category of each chain occurs in each zone after normalization: The purpose of this step is similar to step 3 but from different angle, namely living zones. To attain this adjustment factor, compute the total sales of sampling stores for each first-layer category of each chain in each living zone first. Sum up the total sales of the first-layer category J for chain R next. Then, compute the percentage for first-layer category J of chain R adjusted by the scattering of stores.
- **Step 5:** Compute the estimated total sales amount of each item in each living zone and each area: Compute the total sampling sales of each item in every zone Z of every chain first. Then, divide it by the percentage of the total sales at chain R occurred in the sampling stores and multiply the result by the adjustment factor computed in step 4 to obtain the total sales of each item in each zone of each chain. Multiply the percentage obtained in step 3 to the above result to get the sales of each item in each zone and each area of each chain. Finally, sum up the total from each chain to be the total sales amount of each item in every zone and every area.
- **Step 6:** Compute the estimated total sales amount of each first-, second-, and third-layer category in every zone and every area: To do this, simply add up the result from step 5 for all items belong to each first-, second-, and third-layer category in every zone and every area.

Certain assumptions have to be made in order to finish this algorithm and are elaborated as follows:

1. The sales pattern of each item in the same first-layer category is similar. Under this assumption, each item can apply the same percentage of the total sales for each first-layer category of each chain occurs in each area after normalization.
2. The sales pattern of each store in the same area of the same chain is similar, which implies that the

average sales amount of each store in the same area of the same chain is also very similar.

3. The sales pattern of each store in the same living zone of the same chain is similar, which implies that the average sales amount of each store in the same living area of the same chain is similar, too.

Six steps are also involved in the algorithm of estimating the market size of supermarkets or hypermarkets for each item as seen in Figure 4. As comparing with the algorithm for convenient stores, the differences lie in the analysis dimensions. In the algorithm for convenient stores, living zone is a very important analysis dimension, while size of store is used in the algorithm for supermarkets. Two different sizes are adopted in the algorithm: large and small. Stores with spaces larger than 661 square meters (7200 square feet or 200 pings) are defined as large while else are small.

After the previous two algorithms are run, the results are imported and combined by the following steps:

- **Step 1:** Compute the total sales amount of each item in each area
- **Step 2:** Sum up the total sales of each item in each area by  $\sum_i \alpha_i \cdot (\text{sales estimated for retailer type } i \text{ for each area})$  where  $\alpha_i$  is the percentage of the sales of retailer type  $i$  included in RSISS.
- **Step 3:** Compute the estimated total sales of each first-, second-, and third-layer category in each area.

In the above algorithm, several parameters are assumed known and constant. However, difficulties arise when started to collect these needed parameters. The total number of stores of each chain in each area is public data and can be collected from government reports each month. The percentage of the total sales at chain  $R$  occurring in the sampling stores of chain  $R$  or  $P(R)$  is the most important ratio that needs to be gathered but all the retailing chains refuse to provide this information because of ferocious market competition. The percentage of total sales at chain  $R$  happened in area  $A$  of chain  $R$  or  $W(R, A)$  should be provided by all the retailing chains but is also rejected for the same reason. Therefore, an evaluation process is proposed in this section to compute the two important ratios,  $P(R)$  and  $W(R, A)$ .

- **Evaluation of  $P(R)$ :** By definition,  $P(R)$  is the percentage of the sales at the sampled stores in the total sales at all stores of chain  $R$  each month. Sales information at the sampled stores of chain  $R$  is collected every month. Therefore, the total sales amount at the sampled stores of chain  $R$  can be easily computed every month. The total revenue of chain  $R$  can also be obtained from the

companies' monthly financial reports. However, several items such as prepared food, fee-collecting services, etc in revenues should not be included because they are not sales of UPC items. About 15 to 20 percent of the revenue should be excluded from the total sales in the financial reports used to compute  $P(R)$ . For each chain,  $P(R)$  is equal to the total sales amount at the sampled stores divided by 85% or 80% of the total revenue found in the financial reports.

- **Evaluation of  $W(R, A)$ :** To estimate  $W(R, A)$ , which is the percentage of total sales at chain  $R$  happened in area  $A$  of chain  $R$ , numbers of stores in each area for each chain is collected every month. By interviewing the chain managers, it is known that on average, the sales of a store located in the south or central area is about  $q\%$  less than the sales of a store located in the north where  $q$  is usually between 10 to 15. Therefore,  $W(R, A)$  can be computed on this base.

## 5. System Structure and Implementation

The position of this Estimating DSS in the RSISS is shown as the gray-fill box in Figure 5. The system is built on MS Server 2000 environment with MS SQL as database server and JDE as the development tool. The architecture of servers used in this DSS is shown in Figure 6. The system is built and tested on a PC server with Pentium IV 1.7GB CPU and 1GB memory. The testing data is from convenient stores and contains more than 2.4 million records. The computer computation time each month is less than 30 minutes because of efficient algorithm but the storage space requirement is enormous. The estimation of 2-year sales history occupies 40 GB of hard disk space. The estimating DSS is finished and implemented in December 2001. It started the estimation process since March 2002. Totally, 24 months of history sales data of convenience stores has been imported to the system. The estimation has been made for each item each month. Drilling down and summing up OLAP functions are also added to the DSS so users can query the estimation from item, classification, area, or living-zone point of views. The DSS is also built with web enabling capability so users can easily access the results through internet browsers as seen in Figure 7.

Although verification procedure has been carried out carefully to make sure the execution of the algorithm accurately, no public data exists to validate the result of estimation. The estimation result has been shown to the participants of the project including the convenient chain stores, supermarket chains, and hypermarket chains. In June 2002, a meeting is held among DISC, retailers and the manufacturers to show some estimation results from this system. The purpose of this meeting is also to validate the estimation results through manufacturers. The manufacturers all showed great interests in obtaining this estimation result mainly

because there is no other source to provide such census retailing information. It is the first time that the manufacturers have the opportunity to be able to gain some insight of the local market for each individual product. To show some impact, the sales of a famous tea drink (200 ml) reaches 200 millions of NT dollars (more than 6 millions US\$) alone last year in convenient stores market. To everyone's surprise, its biggest group of consumers is student since it showed the biggest sales in school zone. The estimation also shows that the market of tea drink is fierce competed among several large local manufacturers. With such valuable information, the manufacturers are willing to pay for this information but the scales and levels of services are still under negotiation.

The DSS for supermarkets and hypermarkets are also finished and implemented at the same time. However, the import of the sales information from these two types of retailers has not been completed until July 2002. The system is under testing and is expected to be on line at the end of this year. Because of the sensitivity and confidentiality of the sales data, it is prohibited to show the user interfaces and results of this estimation DSS here.

## 6. Conclusion

This study proposed an algorithm to estimate the market size of product with UPC in Taiwan based on the sampled sales information provided by retailer chains. By sampled sales information, it means that each retailer chain provides sales information from only a small portion of its retailing stores. Through certain public accessible data such number of stores by each chain etc, the sampled sales information can be transferred to the market size information of each item in Taiwan. A DSS is built based on this estimation algorithm and is implemented successfully. In the future, the estimation information can be further processed to provide more value-added information. One of the extensions will be to adopt some forecast models such as time series analysis and economic/environmental variables. From current estimation results, it is clear that zones, areas, and classifications of items all have impacts on sales. For example, sales of tea drink in school zone show very significant seasonal effect while sales of coffee on the other hand demonstrate no seasonal effect at all. In the future, different prediction models can be used for items in different classifications, zones, and areas.

## Abstract

Errors or inaccuracy always occurs when we use the Analytic Hierarchy Process to aid decision making. This paper shows the errors can be divided into two parts. One is called System Error and another is called Judgment Error. System Error is caused by the judgment ratio of pairwise compare matrix which must be taken from set of  $\{1/9, 1/8, \dots, 1, 2, \dots, 9\}$ . The Judgment Error is caused by human wrong judgment. The computational results in this paper demonstrate that the System Error may cause the confusable priority of the alternatives and a proposed method which increase the ratio accuracy can clear the priority of the alternatives.

Key Word: Decision Support, Analytic Hierarchy Process (AHP), Reversal Rank, System Error

## 1. Introduction

The Analytic Hierarchy Process (AHP) is a powerful decision support tools which aid decision makers in solving complex decision problems. It decomposes the real complex decision problems into several levels of hierarchies. The first level of the hierarchy is the goal of decision problem, the second and the lower levels are placed by many relevant criteria, subcriteria, and/or alternatives. Usually, the alternatives occupy the last level of the hierarchy and represent the goal to be accomplished. The decision maker assesses a pairwise comparison judgment matrix (PCJM(n)) for each level of hierarchy to establish local vectors of priorities for n criteria, subcriteria, and alternatives. The composite vector of priorities for decision alternatives is obtained by combining the local priority vectors associated with the criteria or subcriteria of all levels of the hierarchy.

How to get accurate priority of alternatives from the judgments given by decision maker is a important problem in decision making science [3]. In the Analytic Hierarchy Process (AHP), this problem is solved by getting the information of redundant judgments of a decision maker. According to the AHP theory, the decision maker is required to give  $n(n-1)/2$  pairwise judgments ratio for an n alternatives decision problem and only (n-1) judgments is necessary. The AHP method modifies the accuracy of judgments by using the  $n(n-1)/2$

- (n-1) redundant judgments [1]. But using the AHP makes at least two kinds of errors. One is called System Error (SE) and another is called Judgment Error (JE). SE is caused by the judgments ratio must be taken from the set  $= \{1/9, 1/8, \dots, 1, 2, \dots, 9\}$ . The JE is caused by human wrong judgment. Now we focus on the SE problems and propose how to clear the confusable priority which caused by SE.

When we use the AHP to aid in our decision making, the System Error is always caused since the judgment ratio must be taken from the set  $S1 = \{1/9, 1/8, \dots, 1, 2, \dots, 9\}$ . Therefore, the ratio is approximate to the real value. Here the real value of weight of alternatives is continuous, which is true in more application problems. The priority we obtain by using the AHP is also an approximation of the true priority. In our research, we try to find the difference between the computational priority and the real priority.

Triantaphyllou and Mann gave some relative research in this problem. He concluded that it is possible for some alternatives to have the same rank while in reality they are distinct [4]. In additionally, he demonstrated that it is possible alternatives which in reality are less important than others to appear to be more important after the AHP are used. In our present simulation, we confirm the Triantaphyllou and Mann's results and suggest a method to avoid reversal problem caused by SE.

## 2. Our Simulation Analysis

As assumption that the real weights of alternatives are continuity, the  $w_1, w_2, \dots, w_n$  are the real weight values of the n alternatives. We suppose that the decision maker knew the above real values and he would be able to construct a matrix with the real pairwise comparisons. This matrix is called Real Continuous Pairwise matrix (RCP). In RCP, each element,  $a_{ij}$  is obtained by the ratio  $w_i/w_j$ . Also, the judge would be able to determine the entry  $a_{ij}$  as close as possible  $w_i/w_j$  value taken from the set  $S1 = \{1/9, 1/8, \dots, 1, 2, \dots, 9\}$  when the AHP is used. Notice that this determination has a little bit difference with Triantaphyllou and Mann's. It is because the matrix is a reciprocal matrix. The minimal of  $|a_{ij} - w_i/w_j|$  is not same as that of  $|1/a_{ij} - w_j/w_i|$  when the  $w_i/w_j < 1$ . This matrix is called Closed Discrete Pairwise matrix (CDP).

Our simulation includes that randomly generate the real vector of the alternatives, construct the RCP and CDP, calculate the eigenvectors of RCP and CDP, then

compare the eigenvectors with the real vector. In generating the real vector, the ratio of largest against smallest value is less than 9 since the comparable axiom limited [1]. The eigenvectors of RCP and CDP are calculated by Power Method because it is suit for the simulation [2]. The comparison of the vectors just compare the rank of the vectors. That is, if the eigenvector of the CDP has the same rank with real vector, the Correct Sign (CS) is given. If the eigenvector of the CDP has rank changed for real vector rank, the Rank changed Sign (RS) is given. If some elements of eigenvector of the CDP have the same rank while in real vector they are distinct, the causing Equal elements Sign (ES) is given. Here is a number example which given in the Trantaphyllou and Mann's paper, but the result is not exact same as theirs because their calculation has some mistake.

Real vector : (0.1325 0.0890 0.5251 0.2533)

$$RCP = \begin{bmatrix} 1.0000 & 1.4888 & 0.2523 & 0.5231 \\ 0.6717 & 1.0000 & 0.1695 & 0.3514 \\ 3.9603 & 5.9000 & 1.0000 & 2.0730 \\ 1.9117 & 2.8461 & 0.4824 & 1.0000 \end{bmatrix}$$

Eigenvector of RCP : (0.1325 0.0890 0.5252 0.2533)

$$CDP = \begin{bmatrix} 1.0000 & 1.0000 & 0.2500 & 0.5000 \\ 1.0000 & 1.0000 & 0.1667 & 0.3333 \\ 4.0000 & 6.0000 & 1.0000 & 2.0000 \\ 2.0000 & 3.0000 & 0.5000 & 1.0000 \end{bmatrix}$$

Eigenvector of CDP: (0.1187 0.0970 0.5229 0.2614)

In this example, for CDP, the CS = 1, RS = 0 and ES =0.

Let us show another example:

Real vector : (0.0486 0.3551 0.2558 0.3406)

$$RCP = \begin{bmatrix} 1.0000 & 0.1368 & 0.1899 & 0.1426 \\ 7.3111 & 1.0000 & 1.3881 & 1.0426 \\ 5.2671 & 0.7204 & 1.0000 & 0.7511 \\ 7.0126 & 0.9592 & 1.3314 & 1.0000 \end{bmatrix}$$

Eigenvector of RCP : (0.0486 0.3551 0.2558 0.3406)

$$CDP = \begin{bmatrix} 1.0000 & 0.1429 & 0.2000 & 0.1429 \\ 7.0000 & 1.0000 & 1.0000 & 1.0000 \\ 5.0000 & 1.0000 & 1.0000 & 1.0000 \\ 7.0000 & 1.0000 & 1.0000 & 1.0000 \end{bmatrix}$$

Eigenvector of CDP : (0.0507 0.3249 0.2996 0.3249)

In this example, for CDP, the CS = 0, RS = 0 and ES =1.

From later example, we find the ES is caused by the approximation of ratio especially the ratio which equal to

1. That is, these alternatives have very close weight values. If we increase the accuracy of ratio of these weight values to 0.1, the eigenvector of CDP should present the correct rank. The following is the eigenvector of revised CDP:

$$CDP1 = \begin{bmatrix} 1.0000 & 0.1370 & 0.1887 & 0.1429 \\ 7.3000 & 1.0000 & 1.4000 & 1.0000 \\ 5.3000 & 0.7143 & 1.0000 & 0.7692 \\ 7.0000 & 1.0000 & 1.3000 & 1.0000 \end{bmatrix}$$

Eigenvector of CDP : (0.0485 0.3521 0.2573 0.3421)

In this example, for CDP1, the CS1 = 1, RS1 = 0 and ES1 =0. This revision which increase the accuracy is reasonable because we must increase the accuracy of measurement to determine the priority of the alternatives when present accuracy cannot identify difference between some alternatives.

Table 1 shows the results of our simulation for 1000 times and comparison results between real vector rank and eigenvector rank of CDP, CDP1, CDP2, CDP3 and CDP4 while eigenvector rank of RCP always same as the real vector rank.

Table 1. The Comparison Between Real Vector and eigenvector of CDP

Dimensio n	RS	ES	ES1	ES2	ES 3	ES4
15	0	928	287	23	2	0
14	0	920	271	20	2	0
13	0	922	243	16	1	0

### 3. Conclusions and discussions

In this paper, we do a preliminary simulation on the System Error which caused by the require the ratio taken from the set  $S1 = \{1/9, 1/8, \dots, 1, 2, \dots, 9\}$ . From the simulation, we find the System Error may make the rank of the CDP confusable especially when the number of the alternatives increased, but it doesn't make the reverse rank in the rank of the CDP. In order to clear the confusable of the rank of the alternatives, we propose a method which increases the accuracy of the pairwise ratio of those close alternatives. By using the revised method, the number of the confusable rank decrease very fast. Therefore, we can conclude that the revised method is an

effective method to solve the confusable rank of alternatives.

There are other problems relative to the System Error. In Triantaphyllou and Mann's paper, they found for the two level of a problem, the System Error causes the reversal problem. Therefore, the further research needed to do on this topic. These research include:

1. Can the revised method be used to solve the reversal problem which mentioned in Triantaphyllou and Mann's paper.
2. How to detect the Judgment Error? First, the model of judge has to be established. The model is decide by the probability of making wrong judgment when the real is  $r$ . Suppose the wrong ratio will be given in AHP is  $r, r \pm 1, r \pm 2, \dots, r \pm 9$ . As judge intent to get the correct ratio, the first corresponding probabilities are  $9P_{r \pm 9}, 8P_{r \pm 9}, \dots, 1P_{r \pm 9}$ . The  $P_{r \pm 9}$  is the probability which judge give the  $r \pm 9$  value. Then  $P_{r \pm 9} = 1/45$ .  $9P_{r \pm 9} = 20\%$ . That means judge will give correct ratio rat probability 20%. The second corresponding probabilities are  $2^8P_{r \pm 9}, 2^7P_{r \pm 9}, \dots, 2^0P_{r \pm 9}$ . Then  $P_{r \pm 9} = 1/511$ ,  $2^8P_{r \pm 9} = 256/511 = 50.098\%$ .
3. How to measure the System Error when we do not know the real weight of the alternatives?
4. The inconsistency of the PCJM is partly caused by system error and the judgment error. Which one causes the inconsistency more? It should be true that Judgment Error more than the System Error?
5. Can the System Error and the Judgment Error be used as another method to determine the consistency ratio?

## Abstract

It is quite reasonable to presuppose that information systems provide various benefits to manufacturers. But we don't have much evidence on the benefits especially in Japanese manufacturing. In this paper we investigated the hypotheses presented by Matsui and Sato [6] [7] concerning the effects of information technologies and information systems upon manufacturing benefits with slightly different analytical approach and samples. We introduced more precise measure for implementation of information technologies and information systems, and divided the sample consisting of forty-six Japanese manufacturing companies into two sub-sample, world-class and random. The result of our analysis endorsed some of the propositions proved by Matsui and Sato [7], and provided new evidence to the hypotheses that utilization of statistical process control software improves product quality, implementation of computer-based production equipment control increases product-mix flexibility, and utilization of database for quality information and an increase in the percentage of external units electronically linked with the plant improve customer service. It also suggested additional hypotheses. Further, we discovered different relationships of information systems implementation with manufacturing benefits between world-class and randomly sampled companies.

## 1. Introduction

Market competition in manufacturing sectors is becoming fierce in these days. The globalization of economy expands market for manufacturing goods, but at the same time it enlarges the area of competition among manufacturers. One of the most important weapons for manufacturing firms is information technologies and information systems, which are hereafter abbreviated as IS. IS potentially gives many benefits and competitive advantages to manufacturers, if it is appropriately used. These benefits include reduction in manufacturing cost, decrease in inventories, overall lead-time reduction, improvement in on-time deliveries, increased product-mix flexibility, increased production-volume flexibility, reduced new product introduction time, improved customer service, increased level of cooperation with customers and suppliers, improved product differentiation, and improved product quality. These benefits become

critically dependent on the implementation of IS, although they are certainly affected by various factors except IS.

In this paper we intend to focus effects of IS upon these benefits in Japanese manufacturing plants. According to Matsui and Sato [7], appropriate implementation of production IS had strong impact upon these benefits in Japanese manufacturing companies. It also shows that the effect varied among IS employed. For example, implementation of computer-based production equipment control (CPEC) has strong impact on reduction of manufacturing cost (RMFC), but implementation of automated retrieval/storage systems (ATRS) has little impact on RMFC. Because the study used only one sample for Japanese manufacturers, and because there are few relevant studies, we investigate more about those propositions and extend above empirical research further to answer the following questions in this paper:

1. Did the implementation and experience of production IS contribute to a set of manufacturing benefits in Japan?
2. What kind of IS has more impact on each benefit in the Japanese manufacturing plants?
3. Did world-class companies enjoy IS benefit more than others in Japan?
4. Are propositions that Matsui and Sato [6] [7] presented robust enough?

## 2. Research Background

One of the most important weapons to compete against rivals in global manufacturing markets is application of IS. As Heizer and Render [2, p.272] described, "firms that know how to use technology find it an excellent vehicle for obtaining competitive advantage." Knowing how to apply and use IS to gain maximum benefit has been, therefore, a critical subject for most manufacturing companies for last decades.

However, we cannot find much research concerning IS benefits for Japanese manufacturing companies. Matsui and Sato [4] [5] [6] [7] proposed an analytical framework and research hypotheses concerning benefits of production information systems for manufacturing companies. Matsui and Sato [7] did an empirical research about IS benefits for Japanese manufacturing plants. It revealed that implementation of computer aided design (CAD), computer aided processes planning (CAPP), machine tools with computer or direct numerical control,

material requirements planning II (closed-loop MRP), computer-based production equipment control, utilization of statistical process control software, purchase orders sent to suppliers by electronic data interchange, and high percentage of external units (including suppliers, distributors, company plants, banks, etc.) that were electronically linked with the plant have contributed to Japanese manufacturing firms.

The results endorsed some of their hypotheses about benefits of each information technology (IT), but failed to prove others. The hypotheses are summarized in Table 9 below, where P's and S's in the cells stand for primary and secondary effects of each IT, respectively. The merits of their research were the relatively high fitness of the model to their data, and the potential for international comparison partly made in Matsui and Sato [4] [6] among others. On the other, it has certain limitations that were the paucity of samples available, and some incongruence to their hypotheses.

### 3. Hypotheses

As discussed in the above research as well as others including Hammer and Champy [1], Schroeder and Flynn [8] etc., IS is supposed to have positive impact on manufacturing performance. For example, CAD is supposed to contribute shortening design phase of new product development, improve design quality and help automation of production process. These reduce cost for new product introduction. CAE seems to improve reliability of parts and finished goods as well as hasten the new product development process. CAPP has a main effect on the reduction in cycle time, which in turn reduces manufacturing cost. The effect of LAN could be widespread from the automatic control of machine tools and robotics through various flows of production information to attain CIM.

However, the level or degree of IS impact may be differing among plants, companies, industries, and countries. One reason that Matsui and Sato [7] failed to endorse their hypotheses completely might come from the difference among sub-samples. For example, high performance companies may employ IT wiser than other companies. As a result, if we divide the Japanese sample into world-class plants and others, world-class plants may reveal stronger relationships between IT implementation and the benefits. If we employ more samples to investigate the difference, we may be able to find different or stronger relationships between IS and manufacturing benefits. Therefore, our research hypotheses will be expressed as follows:

H1: World-class manufacturers (WCM) show stronger relationships between implementation of IT and the benefits on manufacturing than other firms.

H2: More hypotheses suggested by Matsui and Sato [6] [7] are proved if we limit samples to WCM.

We shall study these hypotheses, resting on our empirical data for the Japanese manufacturing companies.

## 4. Data

### 4.1 Data Collection Procedure

We have conducted a set of questionnaire surveys on Japanese manufacturing plants. We selected plants from machinery, electrical & electronics, and automobile manufacturers located in Japan, visited those plants and asked their cooperation to collect data. We left a set of questionnaires in the plants and recovered them back later.

Table 1  
Abbreviations of IS used in this study

Abbreviation	Explanation
CAD	Implementation of computer aided design
CAE	Implementation of computer aided engineering
CAPP	Implementation of computer aided processes planning
LAN	Introduction of local area networks linking design and engineering stations
CDNC	Implementation of machine tools with computer or direct numerical control
FMS	Implementation of flexible manufacturing systems
ATRS	Implementation of automated retrieval/storage systems
MRP1	Implementation of material requirements planning I (type one MRP)
MRP2	Implementation of material requirements planning II (closed-loop MRP)
JITS	Utilization of just-in-time software
SIMT	Utilization of simulation tools
SPCS	Utilization of statistical process control software

Our Japanese sample accounts for forty-six plants. Among them, thirty-two plants are subjectively judged to be world-class and the rest are randomly sampled from machinery, electrical & electronics, and automobile manufacturers. In any plant, twenty-six individuals across levels responded to fifteen types of questionnaires that partly share the same questions. The respondents included plant manager, plant superintendent, plant research coordinator, plant accountant, human resource manager, inventory/purchasing manager, information systems manager, production control manager, process engineer, quality manager, supervisors and direct labor. Plant-level data were calculated as an average value of all the valid responses at the plant for each measurement scale.

### 4.2 Measures of IS Implementation

This study deals with eighteen information technology variables concerning CAD, CAE, CAPP, NC machine tools, FMS, computer-based production equipment

control, automated retrieval/storage, MRP I and II, simulation tools, JIT software, SPC software, database for quality information, LAN, and EDI. Twelve independent variables measure implementation of these IS. They are listed in Table 1 with abbreviations. In order to identify which IS had been utilized in the plant, the IS manager was asked the year when the plant had implemented each IS listed in Table 1. We calculated the usage length from implementation or experience of each IS by subtracting the year from 2000, and regarded it as a measure of IS implementation. If a plant had not implemented certain IS, we assigned a zero to the variable. These measures have more information on the implementation of IS than the dummy variables employed in Matsui and Sato [4] [5] [6] [7].

Table 2  
Additional Scales of IS Implementation

Abbreviation	Explanation
PCOR	Percentage of customer orders received via electronic data interchange (%)
PPOS	Percentage of purchase orders sent to suppliers by electronic data interchange (%)
PSPL	Percentage of suppliers linked to the plant via electronic data interchange (%)
PELL	Percentage of external units electronically linked with the plant (%)
CPEC	Implementation of computer-based production equipment control
DBQI	Utilization of database for quality information

We appended six more measures of IS implementation in Table 2. Four variables, customer orders received via EDI (PCOR), purchase orders sent to suppliers by EDI (PPOS), suppliers linked to the plant via EDI (PSPL), and external units (including suppliers, distributors, company plants, banks, etc.) electronically linked with the plant (PELL), were measured in percentage. PSPL and PELL were directly asked to the IS manager. The inventory/purchasing manager also answered PCOR and PPOS. These variables range from 0 to 100 as percentage. The other two variables, implementation of computer-based production equipment control (CPEC) and utilization of database for quality information (DBQI), are dummy variables and take only two values, either 1 if implemented or 0 otherwise.

As a result, we have three types of data, i.e., year, dummy, and percentage. Because the range and distribution are different among variables, we normalize those variables, which can delete the size effect and make easy direct comparisons of the data. We will use the normalized variables as scales of IS implementation in the subsequent analysis.

#### 4.3 Measures of Benefits

Manufacturing benefits of IS implementation are listed in Table 3. They are designed as five-point Likert scales (1=Strongly disagree, 2=Disagree, 3=Neither agree nor disagree, 4=Agree, 5=Strongly agree), and added to our questionnaire. These questions are asked to an IS manager, a production manager, and a plant superintendent of each plant. They assessed subjectively whether the benefits could be directly attributed to the implementation of particular information system in the plant on a five-point Likert scale. We calculated average values of the responses from these three persons to construct manufacturing benefit measures at the plant level.

Table 3  
Abbreviations of IS Benefits Measured

Abbreviation	Explanation
RMFC	Reduction in manufacturing cost
DINV	Decrease in inventories
OLTR	Overall lead time reduction
IOTD	Improvement in on-time deliveries
IPMF	Increased product-mix flexibility
IPVF	Increased production-volume flexibility
RNPI	flexibility
ICSV	Reduced new product introduction time
ILCC	Improved customer service
ILCS	Increased level of cooperation with customers
IPDF	Increased level of cooperation with suppliers
IPQL	Improved product differentiation
	Improved product quality

#### 5. Research Method

We investigate our hypotheses about the effect of implementation of IS on manufacturing benefits by correlation analysis, using the above data. Because all data are real measures, Pearson's true product-moment correlation is appropriate for this analysis. We consider manufacturing benefits as dependent variables, and IS implementation as independent variables. We compare results of correlation analysis among the following cases:

1. Use data for all forty-six plants
2. Use data for thirty-two world-class plants
3. Use data for fourteen randomly sampled plants

Generally speaking, the smaller the sample size is, the higher the correlation coefficient becomes to attain certain significance level of rejecting the null hypothesis that the correlation is zero. Therefore, we compare the levels of significance as well as the absolute values of the coefficients.

We did not employ regression analysis that tried to explain variation of manufacturing benefits with a set of IS implementation variables because of high correlation among independent variables.

Table 4  
Comparison of Correlation Coefficients (1)

Benefits IS	RMFC			DINV	OLTR

## 6. Results of Analysis

### 6.1 Interpretation of Negative Coefficients

Tables 4 to 7 compare the results of correlation analysis. They show only significant results. We find that some of IS have significant negative effects on manufacturing benefits, although we did not originally assumed significant and negative correlation coefficients. Hence, we need to discuss about them first of all. Implementation of MRP II significantly correlates with the increase in manufacturing cost in non-WCM plants, shown in Table 4. We may be able to interpret this finding as MRP II is so expensive and complex for non-WCM plants to use that the introduction could complicate their processes and increase their costs for production. The

correlation coefficient between DBQI (database for quality information) and OLTR (overall lead time reduction) is also significantly negative for the whole sample. We can interpret the result as the existence of tradeoff between utilization of quality information database and delivery performance.

Table 6  
Comparison of Correlation Coefficients (3)

Benefits IS	RNPI			ICSV		ILCC	
	ALL	WCM	OTHER	ALL	WCM	ALL	WCM
CAD	0.376*						
CAE	0.362*		0.699+				
CAPP							0.433*
LAN	0.368*						
FMS	0.321*			0.320*			
ATRS	0.329*	0.438*		0.297*	0.375*		
MRP2	0.363*	0.405*					
JITS	0.448+	0.485+					
SIMT	0.340*

DBQI				0.423+	0.468+	0.325*	0.373*
PELL				-0.332*	-0.373*	-0.406+	-0.462+

+ significant at the 1% level by one-tailed test  
\* significant at the 5% level by one-tailed test

Table 7  
Comparison of Correlation Coefficients (4)

Benefits IS	ILCS			IPDF		IPQL	
	ALL	WCM	OTHER	ALL	WCM	ALL	WCM
CAE			0.647*				
ATRS	0.354*	0.365*		0.301*	0.383*		
SIMT	0.294*						
SPCS							0.376*
CPEC	0.477+	0.431*					
DBQI						0.301*	

+ significant at the 1% level by one-tailed test  
\* significant at the 5% level by one-tailed test

We also find significant negative correlation coefficients of PELL (percentage of external units that were electronically linked with the plant) with ICSV (improved customer service) and ILCC (increased level of cooperation with customers) for the whole sample and WCM sample. The results reveal that the usage of electronic link to external units decreases customer service and cooperation with customers. Most customers for the plants are not consumers but wholesalers or other manufacturing companies. Usually the number of customers is considerably limited, and both customers and plants prefer face-to-face contacts rather than electronic linkages.

We tend to presuppose that introduction of IS *always*

provide benefits in *all aspects* in a plant. But our results imply that this is not true. External links may be good in many cases, but they are not necessarily for customer service and cooperation with customers.

## 6.2 Do the relationships become stronger if we limit samples?

After we calculate correlation coefficients and compare the significance, we can identify five patterns of significance in correlations for three samples. They are summarized in Table 8. In Table 8, “significant only when ...” means that a significant coefficient appears only one of three columns (corresponding to samples) for each dependent variable. “More significant when ...” represents significant coefficients appear two of three columns for each dependent variable. We actually compared the whole sample with WCM sample or non-WCM sample. The last pattern, “Significant regardless sample limitation,” means significant coefficients appear in all columns for each dependent variable. We counted the number of these cases in Table 4 through Table 7.

Generally speaking, the larger sample size becomes, the easier it is to get significant coefficients. Therefore, the number of significant cases tends to be large for the

whole sample than for the WCM sample, and in turn for the WCM sample than for the non-WCM sample. The distribution of the number of significant cases in Table 8 is intuitively reasonable.

If a case is in pattern 1, then the relationship is consistent but not so robust. If a case is in pattern 2, then it means it is specific to WCM plants only. It may be the

Table 8  
Patterns of Significance

	Pattern	Sample size	Number of significance
1	Significant only when we use all data	46	19
2	Significant only when we limit to WCM data	32	8
3	Significant only when we exclude WCM data	14	6
4	More significant when we limit to WCM data	32, 46	18
5	More significant when we exclude WCM data	14, 46	2
6	Significant regardless sample limitation	46, 32, 14	0

Table 9  
Matching hypotheses and two empirical results

2. \* Significant results by Matsui and Sato [7]
3. Significant Relationship in this paper 2: pattern 2 4: pattern 4

secret source of excellence in the WCM plants. Or, it might represent a kind of hurdle a manufacturing plant must overcome to be world class. This pattern supports our hypothesis H1. If a case is in pattern 3, it is a strong relationship we find for non-WCM plants only. It may be a false application of IS to the manufacturers. If a case is in pattern 4, then the relationship is consistent but it appear more explicitly in WCM plants. These are cases that our hypothesis H2 implies. If a case is in pattern 5, we cannot find the correlation coefficient is not high for the WCM sample, and there is certainly significant relationship for non-WCM plants, as compared to the whole sample. It would be specific to non-WCM plants. If a case is in pattern 6, the relationship is consistent and robust regardless of plant type (either WCM or not). Unfortunately we cannot find this pattern from Table 4 through Table 7.

Now we go for the examination of our hypotheses, H1 and H2. We compare the cases in pattern 2 and pattern 4 with hypothesized effects presented in Matsui and Sato [6] [7] in Table 9. “P” stands for a hypothesized relationship as a primary effect. “S” means the relationship is hypothesized as a secondary effect. “\*” indicates that the relationship was significant at 5% level in Matsui and Sato [7]. “2” and “4” mean the relationship is classified into pattern 2 and pattern 4, respectively, in Table 8.

Table 10 counts the number of cases according to the combination of marks (\*, 2, 4, P and S) in Table 9. The combination takes seven different forms or types. For instance, the hypothesized relationships that were not proved by Matsui and Sato [7] but acknowledged by this correlation analysis are to be categorized into type 3. These relationships potentially include four different combinations of marks in Table 9 as follows: 2P, 4P, 2S, and 4S. Actually the table includes the entries of 2P and 4S only.

According to these tables, we can induce some important results concerning the hypotheses, H1 and H2. Firstly, CPEC contributes IPMF, that is, implementation of computer-based production equipment control increase product-mix flexibility. This sounds natural, but the point is that this relationship is applicable only to WCM plants. In fact, we find a reverse relationship for non-WCM plants, although it is not significant. Implementation of computer-based production equipment control might decrease product-mix flexibility for non-WCM plants. This associates the old CIM model, which was punctuated by a series of failures and results that fell below expectations.

Secondly, DBQI contributes ICSV, that is, utilization of database for quality information improved customer service. This also sounds natural and associates quality assurance activities by WCM plants. This relationship is labeled “4S” in table 9. Matsui and Sato [7] hypothesized the relationship as secondary, and Table 6 shows it is significant for the whole sample and highly significant for the WCM sample (p-value is 0.007). On the other hand, the non-WCM sample shows negative relationship between DBQI and ICSV, but the correlation coefficient is

almost zero.

Thirdly, PELL effects ICSV. But the relationship is negative, as we have already discussed in the previous section.

Finally, SPCS contributes to IPQL, i.e., utilization of statistical process control software improved product quality. This is marked as “2P” in Table 9. Matsui and Sato [6] [7] hypothesized the relationship as primary, and this relationship is strongly supported for the WCM sample only. Certainly, the relationship is negative for the non-WCM sample, although not significant. At least utilization of statistical process control software doesn’t seem to improve product quality of non-WCM plants. Unless they use statistical process control software appropriately, it won’t contribute to quality performance. This could be the case for non-WCM plants.

Table 10  
Summary of Congruence Between Hypotheses and Results

	Type	Mark	Number
1	Proved by Matsui and Sato [7]	*P or *S	6
2	Proved by this analysis	2P or 4S	4
3	Proved by both empirical studies	*2P, *4P, or *4S	5
4	Not hypothesized but both empirical studies agree	*2 or *4	4
5	Hypothesized but unproved	P or S	40
6	Appear only in Matsui and Sato [7]	*	21
7	Appear only in this analysis	2 or 4	7

The marks appear in table 9.

## 7. Conclusions

In this paper we investigated hypotheses set by Matsui and Sato [6] [7], and conducted an additional empirical analysis with different approach and samples. We can answer to the questions that we addressed in the introductory section of this paper as follows:

1. Did the implementation and experience of production IS contribute to a set of manufacturing benefits in Japan?  
Our analysis gives additional support for the proposition.
2. What kind of IS has more impact on each benefit in Japanese manufacturing plants?  
Table 4 through Table 7 summarize significant relationships between IS implementation and manufacturing benefits.
3. Did world-class plants enjoy IS benefit more than others in Japan?  
As table 8 shows, world-class companies proclaim more significant relationships between certain IS implementation and benefits than others.
4. Are propositions that Matsui and Sato [6] [7] presented

robust enough?

Some of them are endorsed by our analysis as shown in table 9 and they seem robust to us. There are still, however, others which remain unproved.

We took up a set of hypotheses that Matsui and Sato [6] [7] had raised, and verified them through different analytical approach and different samples. Human beings don't know the truth of the universe. In order to approach the truth, we need to accumulate empirical research hopefully from different points of view along with different analytical tools and different samples to verify our hypotheses, and then refine our hypotheses if accumulated empirical results are not consistent with them. Straub [9] recommended multi trait multi method (MTMM) as an empirical research approach, and Mahmood and Soon [3] applied the method to IS. Although this research is not MTMM, precisely speaking, it investigates a set of hypotheses presented by Matsui and Sato [6] [7] from a different method. Regression results by Matsui and Sato [4] [5] [6] [7] tend to be inconsistent depending on samples employed in the analysis. This is especially true if we don't have enough sample size, as was the case of Matsui and Sato [7]. As a result, true hypotheses might be rejected with the analysis, or false hypotheses might be accepted. We tried to verify the findings of Matsui and Sato [7].

In fact, our analysis supports five hypotheses proved by Matsui and Sato [7], but fails to endorse six hypotheses proved by the paper according to Table 10. We successfully find evidences for four additional hypotheses that Matsui and Sato [7] hypothesized but failed to support. The most important finding is that WCM sample insisted the significance of some relationships, but non-WCM sample implied reverse relationships. These suggest critical differences between WCM plants and others. Besides, we can support four more relationships that Matsui and Sato [7] revealed but had not hypothesized. Because these relationships seem robust, we may be able to establish them as new hypotheses.

We need to repeat more empirical analyses to confirm the robustness of these hypotheses, verify and refine them hopefully from different points of view with different analytical approaches, and establish new set of hypotheses. There are also some weaknesses in our study.

Firstly, samples used are not large enough (see Table 8). Secondly, many samples are the same as those of Matsui and Sato [7]. Thirdly, the method we employ to establish our measures needs to be examined more. Empirical results might be affected by what kind of measures we used in the study, and this caveat is also applicable to our study. At last we need to examine the relationships that non-WCM plants enjoy but WCM plants do not. These are pattern 3 and pattern 5 in Table 8. We need to investigate why WCM plants fail to enjoy these benefits from IS. These will be next research topics for us.

## Abstract

This study examines the association of corporate strategy with multiply criteria of financial performance across national boundaries. Using data over a four-year period from Korea, the United States, and Japan, the study presents a multidimensional definition of corporate strategy. These dimensions are then modeled as predictors of three corporate performance criteria. The results show that corporate strategy explains a significant portion of financial performance. In addition, corporate strategy relates differently to different performance criteria within and across the three countries.

## 1. Introduction

This paper examines the association of corporate strategy with financial performance across national boundaries. Throughout the paper corporate strategy is viewed as the plan a firm follows in pursuit of its long-term goals. A viable corporate strategy defines the scope of a company's business and the portfolio of products it must offer. In turn, this definition guides a company's allocation of resources, with the aim of building and maintaining a competitive advantage by developing or acquiring essential skills. These capabilities are functionally-based and emerge from a firm's expertise and excellence in different areas. When the firm possesses such skills, it can build a strong market position.

Evidence suggests that corporate strategy is a major predictor of financial performance within an industry or across economic sectors in one country and across borders. Yet, despite the ever growing interest in comparative corporate practices, only few empirical studies have been conducted to date on the relationship of corporate strategy and financial performance. A possible reason for this paucity of empirical research is the difficulty in collecting data on corporate strategy across countries because of the differences in accounting systems and variations in reporting practices. Not surprisingly, then, the bulk of past research in the area has emphasized such industrialized countries as the United States, Canada, England, West Germany, France, and Italy. While insightful, these studies' findings may not apply to other non-western countries that are at different stages of economic growth or espouse non-western cultural value systems. Moreover, as other regions of the world gain economic power, there is a need to test existing theories of corporate strategy in these new contexts. Findings from

such comparative studies can be used to revise or construct theories that guide corporate strategic choices under different national economic structures.

## 2. Objective

This study examines the association between corporate strategy and financial performance in three countries: Japan, Korea and the United States. To achieve this goal, the study advances a multidimensional definition of corporate strategy and outlines the predicted relationships between the components of corporate strategy and financial performance. We will follow this by presenting the sample, methods, and results of a comparative empirical that uses data from 150 manufacturing companies from each of the three countries, for four years. Finally, the nature and implications of our findings for managerial action and future research are discussed in the last section of the paper.

## 3. Corporate Strategy

A strategy is best viewed as a stream of decisions made by a company over a finite time horizon. In formulating corporate strategy, executives must define the scope of the firm's business and sources of its competencies and capabilities.

A starting point in mapping corporate strategy is the delineation of the breadth of the firm's domain. The issue revolves around deciding the extent to which a firm will specialize in one industry or compete in multiple industries. This decision is based on the firm's track record, resources, forecast of industry trends, and preferences of its senior executives.

Once the breadth of the domain (scope) of business has been determined, the next step involves developing the sources of a firm's competitive competence. This is achieved by examining potential sources of excellence in functional areas such as marketing, finance, and production/operations. Other functions can also provide a basis for building a competitive advantage that enables the firm to position itself in its chosen markets.

There are many sources within each functional area that can be used to build and sustain a competitive advantage. As suggested in literature, different components of corporate strategy can determine corporate financial performance. The magnitude and direction of these effects depend on the performance criterion used. These effects vary from one country to another.

### 3.1 Breadth and Performance

The breadth of a company's concept of business is usually clarified in the extent of its diversification; i.e., the degree to which a firm pursues different lines of business. Some companies are committed to one, core business while others actively pursue different businesses in related or unrelated fields.

The relationship between corporate diversification and financial performance has been the subject of considerable discussion in the literature. However, the results of past empirical research have been contradictory. Some studies suggest that diversification does not always result in improved financial performance. Benefits - such as improved performance - will result only from the effective implementation of diversification activities and by integrating acquired firms within the business portfolio. Without this integration, diversification may result in poor financial performance.

In this comparative study we expect diversification to be associated with high corporate financial performance for several reasons. Diversification enhances a firm's market power, thus enabling it to control its suppliers, buyers, and resources. Diversification also enables companies to use excess cash and reduce business risk. Diversification helps a firm to shield itself against business and economic adversity by maintaining a balance portfolio. Moreover, when carefully carried out, diversification can take the firm into lucrative fields and high growth industries, thus improving its performance. These observations lead to the study's first hypotheses (H1): H1: Diversification is positively associated with corporate financial performance.

Of the three countries examined in this study, Korea remains the least diversified in its manufacturing sector. It was observed that Korean manufacturing firms stress "business groups," a collection of vertically and horizontally related enterprises that support one another. A business group, then, reduces the need for extensive diversification activities among its members since many of them function as both suppliers and buyers of each other's goods. Not surprisingly, the statistical results reported in the literature suggest that group-affiliated firms show superior economic performance than those firms that do not belong to a "business group."

The above discussion suggests that significant differences exist in the level of diversification among American, Japanese and Korean companies. This suggests that the association between diversification and company performance (postulated in H1) will vary from one country to another.

### 3.2 Marketing Activities and Performance

Marketing strategies and practices can enhance a firm's ability to serve its markets or penetrate new segments. There is a growing body of literature centered on the role of strategic marketing in determining company performance. The literature suggests that a firm possess-

ing expertise in marketing is well-poised to make important inroads into its domestic and foreign markets.

Two variables are of interest in this study because they determine a firm's ability to reach its customers: advertising intensity and export levels. Both variables are predicted to be positively associated with corporate financial performance. The rationale for these predicted associations is discussed below.

#### 3.2.1 Advertising Intensity

Research suggests that a firm must be close to its customers while differentiating itself from its rivals to achieve effective financial performance. Advertising enables a firm to attract new customers or increase penetration of existing segments, in domestic and international markets. This means that a corporation must invest heavily in its advertising activities to create a substantial competitive advantage. This advantage is reflected in a strong, positive corporate reputation in the minds of customers, thus creating loyalty to products and brands. A strong, positive reputation also encourages potential customers to "switch," from using competitors' products to using the company's own brands. For these reasons, advertising can be the source of barriers (thus protecting a company's market position) and income by attracting new customers. Consequently, advertising is expected to be associated with high corporate financial performance. For companies whose products are diverse (as is true of the corporations studied here), investment in advertising can be highly profitable. An increase in advertising intensity, defined as the level of that activity's expenditure divided by company sales, leads to higher profits.

It appears American, Japanese and Korean companies view advertising spending as crucial to financial success in their own home markets and overseas as well. This leads to the following hypothesis: H2a: Advertising intensity is associated positively with corporate financial performance.

#### 3.2.2 Export Activities

Engaging in exporting provides a firm with several benefits beyond serving solely a domestic market. Exporting is expected to bring more profits when the foreign market is growing or has very few substitutes, or when a company's capacity exceeds the needs of its local market. And, during a domestic business downturn, exports generally tend to help steady financial performance and sometimes can even increase profits during a domestic recession. Selling abroad also helps to gain economy in production at home-economies which can improve a firm's competitive position. For many companies, export business frequently provides the difference between a profit and a loss.

Because of the many benefits of exporting, countries are increasingly active in promoting this strategy. For instance, Japan, Korea, and the United States have adopted several measures to promote their exports. However, the success of the strategies adopted by these coun-

tries varies considerably. These very startling differences reflect currency fluctuations and different levels of competence among companies in the two countries in producing and marketing in international markets. Statistics and case studies also suggest that Japanese and Korean firms continue to succeed far more frequently in their export efforts than American companies, significantly raising the deficit in the US balance of trade. No matter the sources of success and failure in exporting, companies in the three countries are increasingly active in pursuing new international markets while strengthening their hold on existing niches in those markets. This emphasis stems from a belief that exporting is a major source of growth in revenue and profitability. Thus: H2b: A higher level of export activities is positively associated with company financial performance.

### 3.3 Financial Structure and Performance

Traditionally, financial structure is an important dimension of corporate strategy. Its importance stems from the fact that the ability of a firm to acquire financial resources plays a crucial role in determining its success in the marketplace. Two variables, in particular, are emphasized in this study as indicators of corporate success in developing appropriate financial strategies: leverage position and credit efficiency.

#### 3.3.1 Leverage

This variable refers to the portion of a firm's capital secured through long-term debts; it is operationalized as the debt-to-equity ratio. Several studies have reported a negative association between debt leverage and firm profitability. Higher corporate debt loads tend to depress profits because they increase the burden of servicing the debt. In addition, financial risk increases as this ratio rises because of the increased cost of servicing debt. Moreover, it has been compellingly argued that increased leverage frequently reduces risk-taking by the firm's senior executives. This line of reasoning suggests that benefits from leverage (access to financial resources from external sources) may be far lower than the risks associated with it (conservatism and slowness in corporate activities) which, ultimately, leads to lower profits. Therefore, H3a: Increased leverage is negatively associated with corporate financial performance.

#### 3.3.2 Credit Activities

This variable refers to the ability of a firm to collect its accounts receivables efficiently. Failure to manage credit activities dilutes a firm's financial resources and reduces its cash position. The ability of a firm to collect its accounts is usually measured by the average period it takes the company to accomplish this task. The shorter the period, the more efficient the firm and the higher its performance. Efficient management of credit activities reduces reliance on leverage for financing corporate activities. This helps to counteract the negative side effects of

high leverage, discussed above. Thus: H3b: Efficiency of credit is associated positively with corporate financial performance.

### 3.4 Operations Activities

The value of manufacturing is becoming increasingly recognized as a competitive tool in global markets. Simply stated, manufacturing can make or break an organization. If well managed, manufacturing can be a potent source of competitive advantage and superior corporate performance. A comprehensive review of the literature on operations strategy suggests that three variables are particularly crucial: capital intensity, inventory efficiency, and employee efficiency.

#### 3.4.1 Capital Intensity

As a component of corporate strategy, this variable represents a firm's long-term commitment to building its technological base and upgrading its productive capacity. Capital intensity is defined as total corporate assets divided by sales. Such investments lead to improved production processes that reduce cost or eliminate waste, thus enhancing company performance.

Capital intensity has been the subject of much research in industrial economics and international business. Interest in this variable stems from the recognition of possible substitution of labor and capital in manufacturing. Typically, the question centers on the optimal combination of these two variables (labor and capital), with other factors of production, that lead to an optimal cost structure.

We expect a positive association between capital expenditure and corporate financial resources. This prediction is based on the assumption that capital expenditure, which may dilute short-term resources, will pay off over time. This positive view of the relationship between capital intensity and corporate performance is supported by several classic empirical studies. Past studies and this discussion suggest the following hypothesis: H4a: Capital intensity is positively associated with corporate financial profitability.

#### 3.4.2 Inventory Efficiency

The literature highlights the importance of effectively managing inventory to reduce waste and ensure sufficient supplies for corporate operations. Efficient inventory control is an integral component of an effective operations strategy. As a result, new approaches ensure efficient inventory management. Just-in-time (JIT) techniques and other methods make it possible to plan logistics prudently to improve corporate performance. The popularity of these and similar innovative techniques attests to a growing appreciation by American, Japanese and Korean companies of the implications of inventory management for their profitability and smooth process of manufacturing. Thus: H4b: Inventory efficiency is positively associated with corporate financial performance.

### 3.4.3 Labor Productivity

It has been suggested that labor productivity, measured as the per capita, value added or sales contribution, provides an important indicator of the success of operations strategy. Labor productivity is a major source of corporate performance; the higher this productivity, the higher the corporate performance. This argument rests on a valid assumption: for productivity improvements to occur, successful systems of managing the manufacturing process should exist. Toward this end, American companies have initiated several efforts to reform their managerial practices with the goal of improving labor productivity, as a means of improving their corporate performance. Thus: H4c: Labor productivity is associated positively with corporate financial performance.

## 4. The Moderating Effect of National Boundaries

The literature suggests that the impact of strategy variables on performance varies from one country to another, and even within the same country at different points in time. Therefore, the preceding hypotheses (H1 through H4) should be viewed as contingent (dependent) on country membership.

There are several reasons for expecting the associations to vary by country. First, as argued earlier, the countries vary in their reliance on diversification, use of leverage, capital structure, extent of their export activities, and investment in marketing efforts (e.g., advertising intensity). These differences are expected reflected in different coefficients between individual components of corporate strategy as "predictors" of company performance. Second, companies in the three countries compete in markets that differ significantly in their structure. Japanese and Korean companies are well protected from any massive foreign entry in many segments of their home manufacturing sectors. Such protection enhances the profitability of these firms. American companies do not necessarily enjoy such protected "home base" advantage. Third, the literature suggests that American companies are managed quite differently from Japanese and Korean companies. While differences in the strategic process among companies in different countries are not the focus of this study, we cannot help but wonder if these differences translate into specific sources of competence across countries. Fourth, as mentioned, there are important differences among firms in the three countries in the levels of labor productivity. These differences can be the source of significant cost and price differences in international markets, thus affecting levels of company performance in the three countries differently. These differences, as well as those suggested above in discussing individual hypotheses (H1 through H4), lead to a final hypothesis. H5: Corporate strategy-financial performance associations will vary from one country to another.

## 5. Method

### 5.1 Samples and Data Collection

The samples used in this study consisted of the leading 150 publicly listed manufacturing corporations from the United States, Japan and Korea. These countries were selected because of the different stages of their economic development and the variations in the structure of their national economies. Another reason for their selection is the wide recognition of the important role of the three countries in world trade.

To ensure as valid comparisons as feasible, firms were matched by their sales volume, measured in US\$ million. They were chosen from among the leading 500 companies in each country. The data covered the four-year period of 1996-1999.

Data for American companies were collected from COMPU-STAT, annual reports and 10-K Reports. For Japanese corporations, data were gathered from annual reports of listed companies by the Japanese Chamber of Commerce. Finally, annual reports of listed companies by the Korean Chamber of Commerce were the primary sources of data for South Korean corporations.

### 5.2 Measures

#### 5.2.1 Financial Performance

Corporate performance is multifaceted and, thus, no single measure can fully capture its domain. In addition, preferences for financial performance criteria may vary from one country to another. For example, some Korean firms have opted to forego making significant profits for years to ensure international expansion and growth. Consequently, to gain accurate results and safeguard against the problems associated with any single performance measure, this study employed three indices of major financial performance measures for the 1996-1999 period: return on sales (ROS), return on investment (ROI), and return on assets (ROA), as follows:

∅ Return on Sales = Operating Profit/Sales

∅ Return on Investment = Operating Profit/Investment

∅ Return on Assets = Operating Profit/Assets

#### 5.2.2 Breadth

This study was concerned with the diversification of organization; i.e., reliance on development and specialization of product. Therefore, diversification was operationalized in terms of product specialization. This measure followed the widely-acknowledged entropy measure which emphasized three key elements of a firm's diversification operations: the number of product segments in which the firm operated; the distribution of the firm's total revenues across the product segments; and the degree of relatedness among the various product segments. Accordingly, diversification was operationalized

Accordingly, diversification was operationalized in terms of the ratio of the sales of the major product to the total sales of the firm, as follows:

Diversification =  $1 - (SP_i/TS_i)$  where:  $SP_i$  is the sales volume of the major product and  $TS_i$  is the total sales of the firm in a given year. While this measure is widely used in the literature, it must be noted that it is difficult to identify Korean and Japanese companies' major product lines because of the business groups that dominate those two countries' economies. To safeguard against this problem, multiple secondary sources were consulted to cross-validate the data.

### 5.2.3 Marketing Activities

Two ratios were constructed, using the formula below.

1. Advertising Intensity = Corporate Advertising Expenditure/Corporate Sales Volume
2. Export Level = Export Volume/Corporate Sales Volume

### 5.2.4 Financial Structure

Leverage and credit efficiency were measured as follows:

1. Leverage = Long-term Debt/Equity
2. Credit = (Account Receivables/Total Sales Volume) X 365

### 5.2.5 Operations Strategy

Three formulae were used to gauge operations strategy, as follows:

1. Capital intensity = Fixed Assets/Total Assets
2. Inventory efficiency = Inventory (book value)/Sales
3. Labor productivity = Corporate Sales Volume/Number of Full-Time Employees

All measures were calculated using the four-year averages. This 4-year average allows us to eliminate extremes in the data and year-to-year variations that might obscure trends. Further, we believe that this time frame is necessary to observe the results of corporate international activities. Shorter time frames do not afford us such an opportunity.

## 6. Analysis and Results

### 6.1 Overview

Data for each country were analyzed separately to avoid problems associated with translating currencies using volatile exchange rates. Separate analyses also controlled for variations in accounting conventions among Japanese, Korean and American companies.

As a first step, Pearson's simple correlations among the independent variable set (i.e., components of corporate strategy) for each country were examined to determine lack of multi-collinearity. In the Japanese sample,

correlations ranged between -.44 to .23. For the Korean sample, correlations ranged between .02 and .37. For the American corporations, intercorrelations ranged between -.01 and .34. These ranges suggested the independence of predictor variables. Further, we tested for multicollinearity using the procedures outlined in Neter et al. (1989). These analyses suggested that multicollinearity was not a serious issue in the current data.

Multiple regression analysis served as the primary technique for testing hypotheses 1 through 4.

To test the study's fifth and final hypothesis, the Chow test was employed to find whether the results of regression analyses (9 runs = 3 regressions X 3 dependent variables each) were statistically different.

### 6.2 Japanese Companies

Table 1 shows that the three regression analyses for the Japanese sample were statistically significant (all at  $p < .05$ ). The explanatory power ( $R^2$ ) of the regression models varied:  $R^2$  was .19 for ROS, .31 for ROA, and .41 for ROI. These results supported the importance of corporate strategy variables as correlates of corporate financial performance.

	Performance Criteria		
	ROS	ROA	ROI
<u>Domain Breadth</u>			
Diversification	-.02	-.11	.04
<u>Marketing Strategy</u>			
Advertising Intensity	.16*	-.12	-.12**
Export Level	-.08	-.03	-.08
<u>Financial Strategy</u>			
Leverage	-.02	-.02	-.06
Credit Policy	.09	-.23**	-.39***
<u>Operational Strategy</u>			
Inventory Efficiency	-.01	-.46***	.68***
Employee Productivity	-.32***	-.06	.07
Capital Intensity	-.09	-.36***	-.16**
Constant	.91	.42	.19
$R^2$	.19	.31	.41
F	4.15***	8.21***	40.51***

\*  $p < .05$   
 \*\*  $p < .01$   
 \*\*\*  $p < .001$

Table 1 also showed that different dimensions of corporate strategy exhibited different associations with financial performance. This supported the literature suggestion to use multiple performance indicators. For instance, Table 1 shows that advertising intensity was related to ROS positively but employee productivity was negatively associated with this measure. Note that inventory efficiency was associated positively with ROA and ROI whereas a high credit policy and capital intensity

were associated with lower ROA and ROI. Finally, advertising intensity was significantly associated with ROI.

### 6.3 Korean Companies

The Korean sample exhibited different patterns of associations between corporate strategy and financial performance criteria from those observed earlier in the Japanese sample, at least in three aspects (see Table 2). First, Korean firms with higher levels of diversification had higher returns compared to other companies selected for this study. The beta value of the diversification ratio had a strong positive association with the three company financial performance measures: ROS, ROA and ROI.

	Performance Criteria		
	ROS	ROA	ROI
<u>Domain Breadth</u>			
Diversification	1.13***	.53***	.99***
<u>Marketing Strategy</u>			
Advertising Intensity	-.66***	-.28**	-.58***
Export Level	-.06	.02	-.02
<u>Financial Strategy</u>			
Leverage	.02	.03	-.10
Credit Policy	.04	-.11	.03
<u>Operational Strategy</u>			
Inventory Efficiency	-.05	.11	-.16
Employee Productivity	.06	-.13	.27
Capital Intensity	.09	.04	.14
Constant	-.01	1.15	.00
R <sup>2</sup>	.69	.14	.47
F	39.72***	3.12**	15.91***

\* p < .05  
\*\* p < .01  
\*\*\* p < .001

Second, the intensity of advertising expenses was negatively related to the three corporate financial performance criteria. In other words, the more money that Korean companies spent on advertising relative to their sales volume, the less return on sales, assets, and investment.

Finally, these dimensions of corporate strategy were fairly powerful in explaining ROS and ROI ( $R^2 = .69$  and  $.47$ ). ROA was primarily affected by other factors beyond those included in this study since the  $R^2$  is equal to  $.14$ . Such low  $R^2$  is quite common in many studies of competitive strategy even when the number of predictor variables is very large. Clearly, corporate strategy is one of many factors that influence financial performance.

### 6.4 US Companies

The three regression models for the American sample were significant (all at  $p < .05$ ), with  $R^2$  ranging from  $.21$  to  $.41$ , as shown in Table 3. These  $R^2$  were smaller than

those observed in the Japanese and Korean samples. The results for the American sample are presented in Table 3. ROS, ROA, and ROI were associated positively with two variables: advertising intensity and inventory efficiency. ROS was also associated positively with credit policy and capital intensity. Clearly, the pattern of relationships in the American sample was different from the preceding results of both the Japanese and Korean corporations.

	Performance Criteria		
	ROS	ROA	ROI
<u>Domain Breadth</u>			
Diversification	.05	.03	-.01
<u>Marketing Strategy</u>			
Advertising Intensity	.16*	.14*	.13*
Export Level	.07	.11	.09
<u>Financial Strategy</u>			
Leverage	-.02	-.12	.05
Credit Policy	.17*	.02	.00
<u>Operational Strategy</u>			
Inventory Efficiency	.37***	.53***	.62***
Employee Productivity	.07	.10	.01
Capital Intensity	.02*	.05	-.00
Constant	-.03	-.01	-2.21
R <sup>2</sup>	.21	.35	.41
F	4.94***	10.05***	12.89***

\* p < .05  
\*\* p < .01  
\*\*\* p < .001

### 6.5 Comparisons of the Results Across Three Nations

This section will compare and contrast the results of the study's first four hypotheses (H1 through H4). Clearly, the results vary from one country to the next, as summarized in Table 4, which presents a comparison of the three samples.

#### 6.5.1 Breadth (H1)

Diversification strategy is not associated with higher corporate performance for Japanese or American companies, but is significant in Korean firms. Therefore, the general hypothesis of the positive relationship between diversification and corporate performance is not fully supported in this study. A possible explanation for the lack of success of the diversification strategy of Japanese and American firms is that the companies in this sample are, for the most part, multinational enterprises - their product lines are broad. This raises the possibility that diversification in these firms might have taken them away from their core businesses. If this situation is true, diversification is tantamount to wasted resources.

Another possible reason for lack of significant association between diversification and company financial performance

formance emerges from the literature: most diversification efforts fail to enhance company performance and productivity. This failure stems from lack of experience by senior managers in new lines of business, lack of synergy between new and existing units, and differences in organizational cultures among new and old units in the portfolio. Finally, there is the possibility that some diversification efforts pay off handsomely but it takes a considerably longer period (than the period examined here) to do.

Table 4  
The relationship between corporate strategy and performance: Regression of three samples

	Performance Criteria *		
	Japan	Korea	US
<u>Domain Breadth</u>			
Diversification	NS	S (+)	NS
<u>Marketing Strategy</u>			
Advertising Intensity	XD	S (+)	S (+)
Export Level	NS	NS	NS
<u>Financial Strategy</u>			
Leverage	NS	NS	NS
Credit Policy	M (-)	NS	M (-)
<u>Operational Strategy</u>			
Inventory Efficiency	M (+)	NS	M (-)
Employee Productivity	L (-)	NS	L (-)
Capital Intensity	M (-)	NS	M (-)

\*For each sample

- S = Consistently significant using the three performance criteria
- M = Significant on two performance criteria
- L = Significant on only one criterion
- XD = Mixed support
- NS = Not significant
- + = Positive relationship
- = Negative relationship

### 6.5.2 Marketing Strategy (H2)

Surprisingly, expansion via exporting does not seem to bring a higher return for firms in the three nations examined here. This may be the result of the similar size of the firms in this study and their international experience. Exporting is the first step in entering the global market. Once they have established their export business, companies tend to take advantage of other international activities such as sourcing, offshore production, and direct investment.

The above explanation gains credence as evidence on the export behavior of American, Japanese and Korean firms is reviewed. It appears that Japanese, Korean and Pacific Rim countries have gained prominence in international trade by encouraging their small companies to be active in exporting. So, the benefits for larger companies may be limited whereas smaller firms gain considerably from international commerce.

In contrast to exporting, increasing advertising expenditure brings different financial results depending on

where the firm is located. For American firms, a higher advertising expenditure relative to sales is associated with better financial performance. On the other hand, if Korean firms spend more on advertising, their payoff is negative. For the Japanese firms, an increase in advertising expenditure brings mixed results, either improving or decreasing corporate financial performance. These results may reflect the level of the stage of economic development. Developed countries tend to spend more on advertising than developing and newly industrialized nations. While developed countries employ advertising to stimulate consumer demand, in other nations - where supplies of consumer goods are limited - advertising is an important selling tool to diversify demand from supply-constrained products to those which are plentiful. This is why an increase in advertising intensity has led to negative financial returns in Korea in the current study. For Japanese firms, the impact of advertising on financial performance is inconclusive, although Japan has reached the developed country status. A possible reason for such a mixed signal is that the Japanese market structure is based on imperfect competition between networks of controlled or closed channels of distribution. Consumers have limited choices of what is available in stores.

### 6.5.3 Financial Strategy (H3)

The results show that financial leverage is not associated with high corporate financial performance. An explanation is that companies (especially in the United States) are sometimes leveraged beyond their optimal level. Therefore, the cost of capital may offset any benefits from their leverage position. Interestingly, the more efficient an American or Japanese firm is in managing the credit it provides, the poorer is its financial performance. An explanation is that the impact of efficiency in managing credit may vary from one line of business to another. This means that the total efficiency index should be "decomposed" to examine the effect of its different components on financial performance. Another, and perhaps, more compelling explanation is that most companies offer credit terms and are generally efficient in managing their accounts receivables; this means that in today's competitive markets the efficient management of credit is required to do business but insufficient on its own merit to improve corporate performance.

### 6.5.4 Operational Strategy (H4)

For Korean firms, none of the measures under the operations strategy correlate significantly with the three financial performance criteria. For Japanese and American firms, the results are different. Inventory efficiency is positively related to the measures of financial performance; employee productivity is negatively associated with the financial performance; and capital intensity is negatively associated with the financial performance. Japanese firms have mastered the craft of operating inventory efficiently while American firms have imitated Japanese practices to increase their competitiveness. The

achievements of firms in these two countries have led to a lower level of inventory in relation to their sales volume. For Korean firms, inventory efficiency has been a less crucial factor to their competitiveness because of their low labor costs, reliance on small enterprise, and their use of many Japanese manufacturing practices.

On the surface, the negative relationship between employee productivity and corporate financial performance for Japanese and American firms is perplexing. Increasing sales per employee does not lead to better financial performance. This result can be explained by using the Leontief paradox. It suggests that developed countries' competitiveness depends on their production using skilled labor which causes exports to have a high labor intensity. Growth opportunities in the global market for firms in developed countries such as Japan and the United States require the use of high-skilled labor. This causes the employee productivity measure (sales volume divided by the number of employees) to be inversely associated with corporate financial performance.

Conversely, firms in newly-industrialized nations like Korea are facing a process of transition to move away from producing less low-tech to more high-tech items. That is probably why the relationship between employee productivity and financial performance is not significant.

One possible reason for a negative relationship between capital intensity and corporate financial performance is that Japanese and American firms rival each other for the position of the global economic leader. Investing in fixed assets to increase future productivity is one way to achieve a leadership status at the expense of short-term financial performance. Therefore, hypotheses H4a-c are partially supported.

#### 6.5.5 Moderating Influence of National Boundaries (H5)

The above discussion of cross-country differences and the statistical results support the fifth hypothesis (H5); the relationship between corporate strategy and financial performance differs in strength and magnitude from one country to another. This was confirmed using the Chow test, where seven of the nine regression runs (3 countries X 3 dependent variables) were statistically significant at  $p < .05$ . This suggested that the regression equations reflected very different situations and exhibited different structures.

The different results for each country suggest that theories of corporate strategic behavior need to be grounded in a thorough understanding of the national economy and culture. That is, universalistic assertions should be replaced with a well-crafted contingency model of organizational strategy. This message is consistent with the thrust of Michael E. Porter's (1990) work, as well as the conclusions reached by Alfred Chandler (1990). Using very different research designs and methods, both Chandler and Porter reach essentially the same conclusion: countries employ very different strategies to establish their lead in particular industries. These strategies build on the unique features of the domestic econ-

omy, national character and resource advantage. This implies that American, Japanese and Korean firms would employ very different strategies in asserting their competitive lead in international markets. Companies in these countries have expanded internationally at very different points in time, taking advantage of the distinct skills and competencies they developed in their home base or acquired through international trade. The point is: a theory of international competitiveness would benefit greatly from reviewing existing evidence and then postulating specific country-by-country hypotheses depending on the nature of the national economy and its stage of evolution.

## 7. Conclusions and Suggestions

This study has examined the relationship between corporate strategy and financial performance in three countries. As we expected, components of corporate strategy are correlated differently with different financial performance criteria within and across the three countries. That is, the relative significance and magnitude of the component of strategy have varied according to the criteria used and the country under consideration. Diversification emerges as the key strategy for Korean corporations in their effort to increase financial performance. For American firms, and to a certain extent Japanese firms, advertising is the major correlate of financial performance.

Future research on the topic would benefit from using different measures of corporate strategy variables. For instance, an alternative or more detailed measure of the diversification, financial, marketing and operations components may yield very different results from those found in this study.

Another useful study would be to look at the complete life-cycle of overseas corporate strategy. Although most of our hypotheses were partially supported by the results, the data provided only a snapshot of the corporate strategies under consideration. Strategy is drawn from a series of decision making. Better parallels can be drawn if comparisons are made at similar points in the corporate histories under examination. It would be unrealistic to expect the companies of different nations to employ the same strategies at the same time. Therefore, longitudinal research designs would allow a thorough evaluation of the effect of corporate strategy on performance.

A third possibility for future studies is to examine the impact of strategy on corporate performance by industry types. Although insignificant in this study, other studies suggest that different industries exhibit distinct characteristics in Korea, Japan, and the United States. These characteristics can explain possible differences in corporate performance.

This study highlights the importance of corporate strategy for understanding financial performance. The nine regression performance equations are statistically significant ( $p < .05$ ). Moreover, the results show that the efficacy of different strategy dimensions varies across countries. While the findings for particular dimensions are not consistent with theory-based predictions, they

only highlight the need for more theory building in this area and for large scale empirical studies to gain a better appreciation of the full ramifications of corporate strategy for company performance. We hope that this paper and its results encourage other researchers to test its findings or provide alternative frameworks that will enrich the field.

## Abstract

This study examines the association of corporate strategy with multiply criteria of financial performance across national boundaries. Using data over a four-year period from Korea, the United States, and Japan, the study presents a multidimensional definition of corporate strategy. These dimensions are then modeled as predictors of three corporate performance criteria. The results show that corporate strategy explains a significant portion of financial performance. In addition, corporate strategy relates differently to different performance criteria within and across the three countries.

## 1. Introduction

This paper examines the association of corporate strategy with financial performance across national boundaries. Throughout the paper corporate strategy is viewed as the plan a firm follows in pursuit of its long-term goals. A viable corporate strategy defines the scope of a company's business and the portfolio of products it must offer. In turn, this definition guides a company's allocation of resources, with the aim of building and maintaining a competitive advantage by developing or acquiring essential skills. These capabilities are functionally-based and emerge from a firm's expertise and excellence in different areas. When the firm possesses such skills, it can build a strong market position.

Evidence suggests that corporate strategy is a major predictor of financial performance within an industry or across economic sectors in one country and across borders. Yet, despite the ever growing interest in comparative corporate practices, only few empirical studies have been conducted to date on the relationship of corporate strategy and financial performance. A possible reason for this paucity of empirical research is the difficulty in collecting data on corporate strategy across countries because of the differences in accounting systems and variations in reporting practices. Not surprisingly, then, the bulk of past research in the area has emphasized such industrialized countries as the United States, Canada, England, West Germany, France, and Italy. While insightful, these studies' findings may not apply to other non-western countries that are at different stages of economic growth or espouse non-western cultural value systems. Moreover, as other regions of the world gain economic power, there is a need to test existing theories of corporate strategy in these new contexts. Findings from

such comparative studies can be used to revise or construct theories that guide corporate strategic choices under different national economic structures.

## 2. Objective

This study examines the association between corporate strategy and financial performance in three countries: Japan, Korea and the United States. To achieve this goal, the study advances a multidimensional definition of corporate strategy and outlines the predicted relationships between the components of corporate strategy and financial performance. We will follow this by presenting the sample, methods, and results of a comparative empirical that uses data from 150 manufacturing companies from each of the three countries, for four years. Finally, the nature and implications of our findings for managerial action and future research are discussed in the last section of the paper.

## 3. Corporate Strategy

A strategy is best viewed as a stream of decisions made by a company over a finite time horizon. In formulating corporate strategy, executives must define the scope of the firm's business and sources of its competencies and capabilities.

A starting point in mapping corporate strategy is the delineation of the breadth of the firm's domain. The issue revolves around deciding the extent to which a firm will specialize in one industry or compete in multiple industries. This decision is based on the firm's track record, resources, forecast of industry trends, and preferences of its senior executives.

Once the breadth of the domain (scope) of business has been determined, the next step involves developing the sources of a firm's competitive competence. This is achieved by examining potential sources of excellence in functional areas such as marketing, finance, and production/operations. Other functions can also provide a basis for building a competitive advantage that enables the firm to position itself in its chosen markets.

There are many sources within each functional area that can be used to build and sustain a competitive advantage. As suggested in literature, different components of corporate strategy can determine corporate financial performance. The magnitude and direction of these effects depend on the performance criterion used. These effects vary from one country to another.

### 3.1 Breadth and Performance

The breadth of a company's concept of business is usually clarified in the extent of its diversification; i.e., the degree to which a firm pursues different lines of business. Some companies are committed to one, core business while others actively pursue different businesses in related or unrelated fields.

The relationship between corporate diversification and financial performance has been the subject of considerable discussion in the literature. However, the results of past empirical research have been contradictory. Some studies suggest that diversification does not always result in improved financial performance. Benefits - such as improved performance - will result only from the effective implementation of diversification activities and by integrating acquired firms within the business portfolio. Without this integration, diversification may result in poor financial performance.

In this comparative study we expect diversification to be associated with high corporate financial performance for several reasons. Diversification enhances a firm's market power, thus enabling it to control its suppliers, buyers, and resources. Diversification also enables companies to use excess cash and reduce business risk. Diversification helps a firm to shield itself against business and economic adversity by maintaining a balance portfolio. Moreover, when carefully carried out, diversification can take the firm into lucrative fields and high growth industries, thus improving its performance. These observations lead to the study's first hypotheses (H1): H1: Diversification is positively associated with corporate financial performance.

Of the three countries examined in this study, Korea remains the least diversified in its manufacturing sector. It was observed that Korean manufacturing firms stress "business groups," a collection of vertically and horizontally related enterprises that support one another. A business group, then, reduces the need for extensive diversification activities among its members since many of them function as both suppliers and buyers of each other's goods. Not surprisingly, the statistical results reported in the literature suggest that group-affiliated firms show superior economic performance than those firms that do not belong to a "business group."

The above discussion suggests that significant differences exist in the level of diversification among American, Japanese and Korean companies. This suggests that the association between diversification and company performance (postulated in H1) will vary from one country to another.

### 3.2 Marketing Activities and Performance

Marketing strategies and practices can enhance a firm's ability to serve its markets or penetrate new segments. There is a growing body of literature centered on the role of strategic marketing in determining company performance. The literature suggests that a firm possess-

ing expertise in marketing is well-poised to make important inroads into its domestic and foreign markets.

Two variables are of interest in this study because they determine a firm's ability to reach its customers: advertising intensity and export levels. Both variables are predicted to be positively associated with corporate financial performance. The rationale for these predicted associations is discussed below.

#### 3.2.1 Advertising Intensity

Research suggests that a firm must be close to its customers while differentiating itself from its rivals to achieve effective financial performance. Advertising enables a firm to attract new customers or increase penetration of existing segments, in domestic and international markets. This means that a corporation must invest heavily in its advertising activities to create a substantial competitive advantage. This advantage is reflected in a strong, positive corporate reputation in the minds of customers, thus creating loyalty to products and brands. A strong, positive reputation also encourages potential customers to "switch," from using competitors' products to using the company's own brands. For these reasons, advertising can be the source of barriers (thus protecting a company's market position) and income by attracting new customers. Consequently, advertising is expected to be associated with high corporate financial performance. For companies whose products are diverse (as is true of the corporations studied here), investment in advertising can be highly profitable. An increase in advertising intensity, defined as the level of that activity's expenditure divided by company sales, leads to higher profits.

It appears American, Japanese and Korean companies view advertising spending as crucial to financial success in their own home markets and overseas as well. This leads to the following hypothesis: H2a: Advertising intensity is associated positively with corporate financial performance.

#### 3.2.2 Export Activities

Engaging in exporting provides a firm with several benefits beyond serving solely a domestic market. Exporting is expected to bring more profits when the foreign market is growing or has very few substitutes, or when a company's capacity exceeds the needs of its local market. And, during a domestic business downturn, exports generally tend to help steady financial performance and sometimes can even increase profits during a domestic recession. Selling abroad also helps to gain economy in production at home-economies which can improve a firm's competitive position. For many companies, export business frequently provides the difference between a profit and a loss.

Because of the many benefits of exporting, countries are increasingly active in promoting this strategy. For instance, Japan, Korea, and the United States have adopted several measures to promote their exports. However, the success of the strategies adopted by these coun-

tries varies considerably. These very startling differences reflect currency fluctuations and different levels of competence among companies in the two countries in producing and marketing in international markets. Statistics and case studies also suggest that Japanese and Korean firms continue to succeed far more frequently in their export efforts than American companies, significantly raising the deficit in the US balance of trade. No matter the sources of success and failure in exporting, companies in the three countries are increasingly active in pursuing new international markets while strengthening their hold on existing niches in those markets. This emphasis stems from a belief that exporting is a major source of growth in revenue and profitability. Thus: H2b: A higher level of export activities is positively associated with company financial performance.

### 3.3 Financial Structure and Performance

Traditionally, financial structure is an important dimension of corporate strategy. Its importance stems from the fact that the ability of a firm to acquire financial resources plays a crucial role in determining its success in the marketplace. Two variables, in particular, are emphasized in this study as indicators of corporate success in developing appropriate financial strategies: leverage position and credit efficiency.

#### 3.3.1 Leverage

This variable refers to the portion of a firm's capital secured through long-term debts; it is operationalized as the debt-to-equity ratio. Several studies have reported a negative association between debt leverage and firm profitability. Higher corporate debt loads tend to depress profits because they increase the burden of servicing the debt. In addition, financial risk increases as this ratio rises because of the increased cost of servicing debt. Moreover, it has been compellingly argued that increased leverage frequently reduces risk-taking by the firm's senior executives. This line of reasoning suggests that benefits from leverage (access to financial resources from external sources) may be far lower than the risks associated with it (conservatism and slowness in corporate activities) which, ultimately, leads to lower profits. Therefore, H3a: Increased leverage is negatively associated with corporate financial performance.

#### 3.3.2 Credit Activities

This variable refers to the ability of a firm to collect its accounts receivables efficiently. Failure to manage credit activities dilutes a firm's financial resources and reduces its cash position. The ability of a firm to collect its accounts is usually measured by the average period it takes the company to accomplish this task. The shorter the period, the more efficient the firm and the higher its performance. Efficient management of credit activities reduces reliance on leverage for financing corporate activities. This helps to counteract the negative side effects of

high leverage, discussed above. Thus: H3b: Efficiency of credit is associated positively with corporate financial performance.

### 3.4 Operations Activities

The value of manufacturing is becoming increasingly recognized as a competitive tool in global markets. Simply stated, manufacturing can make or break an organization. If well managed, manufacturing can be a potent source of competitive advantage and superior corporate performance. A comprehensive review of the literature on operations strategy suggests that three variables are particularly crucial: capital intensity, inventory efficiency, and employee efficiency.

#### 3.4.1 Capital Intensity

As a component of corporate strategy, this variable represents a firm's long-term commitment to building its technological base and upgrading its productive capacity. Capital intensity is defined as total corporate assets divided by sales. Such investments lead to improved production processes that reduce cost or eliminate waste, thus enhancing company performance.

Capital intensity has been the subject of much research in industrial economics and international business. Interest in this variable stems from the recognition of possible substitution of labor and capital in manufacturing. Typically, the question centers on the optimal combination of these two variables (labor and capital), with other factors of production, that lead to an optimal cost structure.

We expect a positive association between capital expenditure and corporate financial resources. This prediction is based on the assumption that capital expenditure, which may dilute short-term resources, will pay off over time. This positive view of the relationship between capital intensity and corporate performance is supported by several classic empirical studies. Past studies and this discussion suggest the following hypothesis: H4a: Capital intensity is positively associated with corporate financial profitability.

#### 3.4.2 Inventory Efficiency

The literature highlights the importance of effectively managing inventory to reduce waste and ensure sufficient supplies for corporate operations. Efficient inventory control is an integral component of an effective operations strategy. As a result, new approaches ensure efficient inventory management. Just-in-time (JIT) techniques and other methods make it possible to plan logistics prudently to improve corporate performance. The popularity of these and similar innovative techniques attests to a growing appreciation by American, Japanese and Korean companies of the implications of inventory management for their profitability and smooth process of manufacturing. Thus: H4b: Inventory efficiency is positively associated with corporate financial performance.

### 3.4.3 Labor Productivity

It has been suggested that labor productivity, measured as the per capita, value added or sales contribution, provides an important indicator of the success of operations strategy. Labor productivity is a major source of corporate performance; the higher this productivity, the higher the corporate performance. This argument rests on a valid assumption: for productivity improvements to occur, successful systems of managing the manufacturing process should exist. Toward this end, American companies have initiated several efforts to reform their managerial practices with the goal of improving labor productivity, as a means of improving their corporate performance. Thus: H4c: Labor productivity is associated positively with corporate financial performance.

## 4. The Moderating Effect of National Boundaries

The literature suggests that the impact of strategy variables on performance varies from one country to another, and even within the same country at different points in time. Therefore, the preceding hypotheses (H1 through H4) should be viewed as contingent (dependent) on country membership.

There are several reasons for expecting the associations to vary by country. First, as argued earlier, the countries vary in their reliance on diversification, use of leverage, capital structure, extent of their export activities, and investment in marketing efforts (e.g., advertising intensity). These differences are expected reflected in different coefficients between individual components of corporate strategy as "predictors" of company performance. Second, companies in the three countries compete in markets that differ significantly in their structure. Japanese and Korean companies are well protected from any massive foreign entry in many segments of their home manufacturing sectors. Such protection enhances the profitability of these firms. American companies do not necessarily enjoy such protected "home base" advantage. Third, the literature suggests that American companies are managed quite differently from Japanese and Korean companies. While differences in the strategic process among companies in different countries are not the focus of this study, we cannot help but wonder if these differences translate into specific sources of competence across countries. Fourth, as mentioned, there are important differences among firms in the three countries in the levels of labor productivity. These differences can be the source of significant cost and price differences in international markets, thus affecting levels of company performance in the three countries differently. These differences, as well as those suggested above in discussing individual hypotheses (H1 through H4), lead to a final hypothesis. H5: Corporate strategy-financial performance associations will vary from one country to another.

## 5. Method

### 5.1 Samples and Data Collection

The samples used in this study consisted of the leading 150 publicly listed manufacturing corporations from the United States, Japan and Korea. These countries were selected because of the different stages of their economic development and the variations in the structure of their national economies. Another reason for their selection is the wide recognition of the important role of the three countries in world trade.

To ensure as valid comparisons as feasible, firms were matched by their sales volume, measured in US\$ million. They were chosen from among the leading 500 companies in each country. The data covered the four-year period of 1996-1999.

Data for American companies were collected from COMPU-STAT, annual reports and 10-K Reports. For Japanese corporations, data were gathered from annual reports of listed companies by the Japanese Chamber of Commerce. Finally, annual reports of listed companies by the Korean Chamber of Commerce were the primary sources of data for South Korean corporations.

### 5.2 Measures

#### 5.2.1 Financial Performance

Corporate performance is multifaceted and, thus, no single measure can fully capture its domain. In addition, preferences for financial performance criteria may vary from one country to another. For example, some Korean firms have opted to forego making significant profits for years to ensure international expansion and growth. Consequently, to gain accurate results and safeguard against the problems associated with any single performance measure, this study employed three indices of major financial performance measures for the 1996-1999 period: return on sales (ROS), return on investment (ROI), and return on assets (ROA), as follows:

∅ Return on Sales = Operating Profit/Sales

∅ Return on Investment = Operating Profit/Investment

∅ Return on Assets = Operating Profit/Assets

#### 5.2.2 Breadth

This study was concerned with the diversification of organization; i.e., reliance on development and specialization of product. Therefore, diversification was operationalized in terms of product specialization. This measure followed the widely-acknowledged entropy measure which emphasized three key elements of a firm's diversification operations: the number of product segments in which the firm operated; the distribution of the firm's total revenues across the product segments; and the degree of relatedness among the various product segments. Accordingly, diversification was operationalized

Accordingly, diversification was operationalized in terms of the ratio of the sales of the major product to the total sales of the firm, as follows:

Diversification =  $1 - (SP_i/TS_i)$  where:  $SP_i$  is the sales volume of the major product and  $TS_i$  is the total sales of the firm in a given year. While this measure is widely used in the literature, it must be noted that it is difficult to identify Korean and Japanese companies' major product lines because of the business groups that dominate those two countries' economies. To safeguard against this problem, multiple secondary sources were consulted to cross-validate the data.

### 5.2.3 Marketing Activities

Two ratios were constructed, using the formula below.

1. Advertising Intensity = Corporate Advertising Expenditure/Corporate Sales Volume
2. Export Level = Export Volume/Corporate Sales Volume

### 5.2.4 Financial Structure

Leverage and credit efficiency were measured as follows:

1. Leverage = Long-term Debt/Equity
2. Credit = (Account Receivables/Total Sales Volume) X 365

### 5.2.5 Operations Strategy

Three formulae were used to gauge operations strategy, as follows:

1. Capital intensity = Fixed Assets/Total Assets
2. Inventory efficiency = Inventory (book value)/Sales
3. Labor productivity = Corporate Sales Volume/Number of Full-Time Employees

All measures were calculated using the four-year averages. This 4-year average allows us to eliminate extremes in the data and year-to-year variations that might obscure trends. Further, we believe that this time frame is necessary to observe the results of corporate international activities. Shorter time frames do not afford us such an opportunity.

## 6. Analysis and Results

### 6.1 Overview

Data for each country were analyzed separately to avoid problems associated with translating currencies using volatile exchange rates. Separate analyses also controlled for variations in accounting conventions among Japanese, Korean and American companies.

As a first step, Pearson's simple correlations among the independent variable set (i.e., components of corporate strategy) for each country were examined to determine lack of multi-collinearity. In the Japanese sample,

correlations ranged between -.44 to .23. For the Korean sample, correlations ranged between .02 and .37. For the American corporations, intercorrelations ranged between -.01 and .34. These ranges suggested the independence of predictor variables. Further, we tested for multicollinearity using the procedures outlined in Neter et al. (1989). These analyses suggested that multicollinearity was not a serious issue in the current data.

Multiple regression analysis served as the primary technique for testing hypotheses 1 through 4.

To test the study's fifth and final hypothesis, the Chow test was employed to find whether the results of regression analyses (9 runs = 3 regressions X 3 dependent variables each) were statistically different.

### 6.2 Japanese Companies

Table 1 shows that the three regression analyses for the Japanese sample were statistically significant (all at  $p < .05$ ). The explanatory power ( $R^2$ ) of the regression models varied:  $R^2$  was .19 for ROS, .31 for ROA, and .41 for ROI. These results supported the importance of corporate strategy variables as correlates of corporate financial performance.

	Performance Criteria		
	ROS	ROA	ROI
<u>Domain Breadth</u>			
Diversification	-.02	-.11	.04
<u>Marketing Strategy</u>			
Advertising Intensity	.16*	-.12	-.12**
Export Level	-.08	-.03	-.08
<u>Financial Strategy</u>			
Leverage	-.02	-.02	-.06
Credit Policy	.09	-.23**	-.39***
<u>Operational Strategy</u>			
Inventory Efficiency	-.01	-.46***	.68***
Employee Productivity	-.32***	-.06	.07
Capital Intensity	-.09	-.36***	-.16**
Constant	.91	.42	.19
$R^2$	.19	.31	.41
F	4.15***	8.21***	40.51***

\*  $p < .05$   
 \*\*  $p < .01$   
 \*\*\*  $p < .001$

Table 1 also showed that different dimensions of corporate strategy exhibited different associations with financial performance. This supported the literature suggestion to use multiple performance indicators. For instance, Table 1 shows that advertising intensity was related to ROS positively but employee productivity was negatively associated with this measure. Note that inventory efficiency was associated positively with ROA and ROI whereas a high credit policy and capital intensity

were associated with lower ROA and ROI. Finally, advertising intensity was significantly associated with ROI.

### 6.3 Korean Companies

The Korean sample exhibited different patterns of associations between corporate strategy and financial performance criteria from those observed earlier in the Japanese sample, at least in three aspects (see Table 2). First, Korean firms with higher levels of diversification had higher returns compared to other companies selected for this study. The beta value of the diversification ratio had a strong positive association with the three company financial performance measures: ROS, ROA and ROI.

	Performance Criteria		
	ROS	ROA	ROI
<u>Domain Breadth</u>			
Diversification	1.13***	.53***	.99***
<u>Marketing Strategy</u>			
Advertising Intensity	-.66***	-.28**	-.58***
Export Level	-.06	.02	-.02
<u>Financial Strategy</u>			
Leverage	.02	.03	-.10
Credit Policy	.04	-.11	.03
<u>Operational Strategy</u>			
Inventory Efficiency	-.05	.11	-.16
Employee Productivity	.06	-.13	.27
Capital Intensity	.09	.04	.14
Constant	-.01	1.15	.00
R <sup>2</sup>	.69	.14	.47
F	39.72***	3.12**	15.91***

\* p < .05  
\*\* p < .01  
\*\*\* p < .001

Second, the intensity of advertising expenses was negatively related to the three corporate financial performance criteria. In other words, the more money that Korean companies spent on advertising relative to their sales volume, the less return on sales, assets, and investment.

Finally, these dimensions of corporate strategy were fairly powerful in explaining ROS and ROI (R<sup>2</sup> = .69 and .47). ROA was primarily affected by other factors beyond those included in this study since the R<sup>2</sup> is equal to .14. Such low R<sup>2</sup> is quite common in many studies of competitive strategy even when the number of predictor variables is very large. Clearly, corporate strategy is one of many factors that influence financial performance.

### 6.4 US Companies

The three regression models for the American sample were significant (all at p < .05), with R<sup>2</sup> ranging from .21 to .41, as shown in Table 3. These R<sup>2</sup> were smaller than

those observed in the Japanese and Korean samples. The results for the American sample are presented in Table 3. ROS, ROA, and ROI were associated positively with two variables: advertising intensity and inventory efficiency. ROS was also associated positively with credit policy and capital intensity. Clearly, the pattern of relationships in the American sample was different from the preceding results of both the Japanese and Korean corporations.

	Performance Criteria		
	ROS	ROA	ROI
<u>Domain Breadth</u>			
Diversification	.05	.03	-.01
<u>Marketing Strategy</u>			
Advertising Intensity	.16*	.14*	.13*
Export Level	.07	.11	.09
<u>Financial Strategy</u>			
Leverage	-.02	-.12	.05
Credit Policy	.17*	.02	.00
<u>Operational Strategy</u>			
Inventory Efficiency	.37***	.53***	.62***
Employee Productivity	.07	.10	.01
Capital Intensity	.02*	.05	-.00
Constant	-.03	-.01	-2.21
R <sup>2</sup>	.21	.35	.41
F	4.94***	10.05***	12.89***

\* p < .05  
\*\* p < .01  
\*\*\* p < .001

### 6.5 Comparisons of the Results Across Three Nations

This section will compare and contrast the results of the study's first four hypotheses (H1 through H4). Clearly, the results vary from one country to the next, as summarized in Table 4, which presents a comparison of the three samples.

#### 6.5.1 Breadth (H1)

Diversification strategy is not associated with higher corporate performance for Japanese or American companies, but is significant in Korean firms. Therefore, the general hypothesis of the positive relationship between diversification and corporate performance is not fully supported in this study. A possible explanation for the lack of success of the diversification strategy of Japanese and American firms is that the companies in this sample are, for the most part, multinational enterprises - their product lines are broad. This raises the possibility that diversification in these firms might have taken them away from their core businesses. If this situation is true, diversification is tantamount to wasted resources.

Another possible reason for lack of significant association between diversification and company financial performance

formance emerges from the literature: most diversification efforts fail to enhance company performance and productivity. This failure stems from lack of experience by senior managers in new lines of business, lack of synergy between new and existing units, and differences in organizational cultures among new and old units in the portfolio. Finally, there is the possibility that some diversification efforts pay off handsomely but it takes a considerably longer period (than the period examined here) to do.

Table 4  
The relationship between corporate strategy and performance: Regression of three samples

	Performance Criteria *		
	Japan	Korea	US
<u>Domain Breadth</u>			
Diversification	NS	S (+)	NS
<u>Marketing Strategy</u>			
Advertising Intensity	XD	S (+)	S (+)
Export Level	NS	NS	NS
<u>Financial Strategy</u>			
Leverage	NS	NS	NS
Credit Policy	M (-)	NS	M (-)
<u>Operational Strategy</u>			
Inventory Efficiency	M (+)	NS	M (-)
Employee Productivity	L (-)	NS	L (-)
Capital Intensity	M (-)	NS	M (-)

\*For each sample

- S = Consistently significant using the three performance criteria
- M = Significant on two performance criteria
- L = Significant on only one criterion
- XD = Mixed support
- NS = Not significant
- + = Positive relationship
- = Negative relationship

### 6.5.2 Marketing Strategy (H2)

Surprisingly, expansion via exporting does not seem to bring a higher return for firms in the three nations examined here. This may be the result of the similar size of the firms in this study and their international experience. Exporting is the first step in entering the global market. Once they have established their export business, companies tend to take advantage of other international activities such as sourcing, offshore production, and direct investment.

The above explanation gains credence as evidence on the export behavior of American, Japanese and Korean firms is reviewed. It appears that Japanese, Korean and Pacific Rim countries have gained prominence in international trade by encouraging their small companies to be active in exporting. So, the benefits for larger companies may be limited whereas smaller firms gain considerably from international commerce.

In contrast to exporting, increasing advertising expenditure brings different financial results depending on

where the firm is located. For American firms, a higher advertising expenditure relative to sales is associated with better financial performance. On the other hand, if Korean firms spend more on advertising, their payoff is negative. For the Japanese firms, an increase in advertising expenditure brings mixed results, either improving or decreasing corporate financial performance. These results may reflect the level of the stage of economic development. Developed countries tend to spend more on advertising than developing and newly industrialized nations. While developed countries employ advertising to stimulate consumer demand, in other nations - where supplies of consumer goods are limited - advertising is an important selling tool to diversify demand from supply-constrained products to those which are plentiful. This is why an increase in advertising intensity has led to negative financial returns in Korea in the current study. For Japanese firms, the impact of advertising on financial performance is inconclusive, although Japan has reached the developed country status. A possible reason for such a mixed signal is that the Japanese market structure is based on imperfect competition between networks of controlled or closed channels of distribution. Consumers have limited choices of what is available in stores.

### 6.5.3 Financial Strategy (H3)

The results show that financial leverage is not associated with high corporate financial performance. An explanation is that companies (especially in the United States) are sometimes leveraged beyond their optimal level. Therefore, the cost of capital may offset any benefits from their leverage position. Interestingly, the more efficient an American or Japanese firm is in managing the credit it provides, the poorer is its financial performance. An explanation is that the impact of efficiency in managing credit may vary from one line of business to another. This means that the total efficiency index should be "decomposed" to examine the effect of its different components on financial performance. Another, and perhaps, more compelling explanation is that most companies offer credit terms and are generally efficient in managing their accounts receivables; this means that in today's competitive markets the efficient management of credit is required to do business but insufficient on its own merit to improve corporate performance.

### 6.5.4 Operational Strategy (H4)

For Korean firms, none of the measures under the operations strategy correlate significantly with the three financial performance criteria. For Japanese and American firms, the results are different. Inventory efficiency is positively related to the measures of financial performance; employee productivity is negatively associated with the financial performance; and capital intensity is negatively associated with the financial performance. Japanese firms have mastered the craft of operating inventory efficiently while American firms have imitated Japanese practices to increase their competitiveness. The

achievements of firms in these two countries have led to a lower level of inventory in relation to their sales volume. For Korean firms, inventory efficiency has been a less crucial factor to their competitiveness because of their low labor costs, reliance on small enterprise, and their use of many Japanese manufacturing practices.

On the surface, the negative relationship between employee productivity and corporate financial performance for Japanese and American firms is perplexing. Increasing sales per employee does not lead to better financial performance. This result can be explained by using the Leontief paradox. It suggests that developed countries' competitiveness depends on their production using skilled labor which causes exports to have a high labor intensity. Growth opportunities in the global market for firms in developed countries such as Japan and the United States require the use of high-skilled labor. This causes the employee productivity measure (sales volume divided by the number of employees) to be inversely associated with corporate financial performance.

Conversely, firms in newly-industrialized nations like Korea are facing a process of transition to move away from producing less low-tech to more high-tech items. That is probably why the relationship between employee productivity and financial performance is not significant.

One possible reason for a negative relationship between capital intensity and corporate financial performance is that Japanese and American firms rival each other for the position of the global economic leader. Investing in fixed assets to increase future productivity is one way to achieve a leadership status at the expense of short-term financial performance. Therefore, hypotheses H4a-c are partially supported.

#### 6.5.5 Moderating Influence of National Boundaries (H5)

The above discussion of cross-country differences and the statistical results support the fifth hypothesis (H5); the relationship between corporate strategy and financial performance differs in strength and magnitude from one country to another. This was confirmed using the Chow test, where seven of the nine regression runs (3 countries X 3 dependent variables) were statistically significant at  $p < .05$ . This suggested that the regression equations reflected very different situations and exhibited different structures.

The different results for each country suggest that theories of corporate strategic behavior need to be grounded in a thorough understanding of the national economy and culture. That is, universalistic assertions should be replaced with a well-crafted contingency model of organizational strategy. This message is consistent with the thrust of Michael E. Porter's (1990) work, as well as the conclusions reached by Alfred Chandler (1990). Using very different research designs and methods, both Chandler and Porter reach essentially the same conclusion: countries employ very different strategies to establish their lead in particular industries. These strategies build on the unique features of the domestic econ-

omy, national character and resource advantage. This implies that American, Japanese and Korean firms would employ very different strategies in asserting their competitive lead in international markets. Companies in these countries have expanded internationally at very different points in time, taking advantage of the distinct skills and competencies they developed in their home base or acquired through international trade. The point is: a theory of international competitiveness would benefit greatly from reviewing existing evidence and then postulating specific country-by-country hypotheses depending on the nature of the national economy and its stage of evolution.

## 7. Conclusions and Suggestions

This study has examined the relationship between corporate strategy and financial performance in three countries. As we expected, components of corporate strategy are correlated differently with different financial performance criteria within and across the three countries. That is, the relative significance and magnitude of the component of strategy have varied according to the criteria used and the country under consideration. Diversification emerges as the key strategy for Korean corporations in their effort to increase financial performance. For American firms, and to a certain extent Japanese firms, advertising is the major correlate of financial performance.

Future research on the topic would benefit from using different measures of corporate strategy variables. For instance, an alternative or more detailed measure of the diversification, financial, marketing and operations components may yield very different results from those found in this study.

Another useful study would be to look at the complete life-cycle of overseas corporate strategy. Although most of our hypotheses were partially supported by the results, the data provided only a snapshot of the corporate strategies under consideration. Strategy is drawn from a series of decision making. Better parallels can be drawn if comparisons are made at similar points in the corporate histories under examination. It would be unrealistic to expect the companies of different nations to employ the same strategies at the same time. Therefore, longitudinal research designs would allow a thorough evaluation of the effect of corporate strategy on performance.

A third possibility for future studies is to examine the impact of strategy on corporate performance by industry types. Although insignificant in this study, other studies suggest that different industries exhibit distinct characteristics in Korea, Japan, and the United States. These characteristics can explain possible differences in corporate performance.

This study highlights the importance of corporate strategy for understanding financial performance. The nine regression performance equations are statistically significant ( $p < .05$ ). Moreover, the results show that the efficacy of different strategy dimensions varies across countries. While the findings for particular dimensions are not consistent with theory-based predictions, they

only highlight the need for more theory building in this area and for large scale empirical studies to gain a better appreciation of the full ramifications of corporate strategy for company performance. We hope that this paper and its results encourage other researchers to test its findings or provide alternative frameworks that will enrich the field.

## Abstract

Classic diffusion theory is effective and useful at describing adoption of technologies or certain behaviors. However, innovation adoption is not the only kind of adoptive behavior. Communication specialists encourage the adoption of brands, fads, political positions and behaviors that may not necessarily be innovative. This paper discusses an alternative model for the adoption called resonance that is less sensitive to past assumptions. Resonance replaces prior models to describe adoption such as diffusion, critical mass and collective action. Resonance proposes two forces at work a motivating force and a receptive mass. The two work together to create the adoption event. The motivating force provokes the event and the receptive mass supplies the energy. The model is applied to a communication systems forum to make it more useful to telecommunication systems.

## 1. Introduction

Classic diffusion theory is effective and useful at describing adoption of technologies. However, innovation adoption is not the only kind of adoptive behavior. Communication specialists encourage the adoption of brands, fads, political positions and behaviors that may not necessarily be innovative. At the same time, the economics of communications has changed dramatically as industries deregulate and converge. Online communication systems continually lower the cost of adoption leading to changes in adoptive behavior not anticipated by current models.

It becomes more difficult to effectively apply traditional diffusion theory as key elements are removed. First, success can be defined as "enough" adoption rather than universal adoption -- even within a group. Second, critical mass of adoption need not occur within a specified time frame. Third, easy and perceptively cheap adoption opportunities lessen the importance of product characteristics.

This paper will reconsider the adoption process within a framework more in tune with current market trends. The goal is not to abandon current adoption studies but rather to enliven them by mixing alternative theoretical foundations. This paper will discuss an alternative model for the adoption that is less sensitive to past assumptions. The goal is to create a model that can be ap-

plied to more behaviors and technologies. Specifically, the model should be useful in information systems.

## 2. Classic Diffusion of Innovations

Diffusion of innovations and its sub-theories, dominate adoption literature for very good reasons. The model achieves an effective parsimony in design. At the same time, diffusion is rich enough in scope to permit multiple testing areas. The long tradition of research in this area makes diffusion one of the most thoroughly applied models in existence today.

Rogers [13] proposed a "diffusion of innovation" model most effectively with his seminal book *Diffusion of Innovations*, first published in 1962. The emphasis of diffusion was to describe the process by which innovations are adopted by a population. Key concepts, most often studied by others, include (a) attributes of the innovation, (b) adopter classes/ innovation life cycle, and (c) the innovation-decision process.

Attributes of the innovation include relative advantage, compatibility, complexity, trialability, and observability [15, p. 210-234]. Successful manipulation of these attributes should result in a greater chance of innovation success. For example, America Online offers 700 hours of its service free to enhance trialability. These attributes are useful for predicting which innovation or marketing plan would be most successful.

The innovation would go through an adoption life cycle complete with heterogeneous groups adopting at different times in the life cycle. The stages include innovator, early adopter (sometimes called early adapter), early majority, late majority and laggard [15, p. 247-251]. Most of the study in this area concentrates on the first two or three stages. The farther along an innovation is in the diffusion life cycle, the more likely it will succeed. This life cycle process tends to take on a normative, pro-innovation stance. For example, the first to adopt are innovators and the last are laggards. Later theorists developed the description of the innovator/early adopter process to enhance the model (see Critical mass section below).

Finally, a too often overlooked area of diffusion studies considers the diffusion process of individual decision makers. The individual might go through five stages in the process including (a) knowledge, (b) persuasion, (c) decision, (d) implementation and (e) confirmation [15, p. 163-195]. At each stage, an effective researcher or

marketer could find the factors to increase the likelihood of innovation adoption. Through these stages, Rogers effectively describes the opportunity for adopter class interaction. However, the model concentrates on information seeking behavior or opinion leadership.

### 2.1. Critical Mass

Markus [6] modified the traditional diffusion curve to allow for the possibility that non-adopters could affect adopters. Under this model, current adopters will not continue to use an innovation if others do not also adopt. After a finite period of time, if the medium is not adopted by a certain percentage of the community then current users will revert to another technology.

Critical mass is not a single theory so much as a general concept upon which theoretical models have been built. In many cases, it fails to rise to the "theory" level and is really simply an analogy. The original analogy refers to the term's proper use in physics -- the minimum amount of a nuclear fuel necessary for an explosive chain reaction. In practical use, "critical mass" can be defined as the minimum amount of some resource (people, money, etc.) needed before another condition or product explodes into existence. For example, Hiltz [4] suggested that there was a critical mass of participants needed for the success of a computer discussion forum. The physics analogy also acknowledges the idea that the mass is unstable and in a constant state of decay. If the minimum mass is not collected in time, that which has been collected is lost.

Critical mass enhanced diffusion by allowing for some critical changes. It allowed for reciprocal interdependence of heterogeneous adopter classes. It also left open the possibility of an adopter replacing one innovation (or service) for another. While these options were not excluded from diffusion, they were not as formalized. While adopter classes are theorized heterogeneous, most research focused on differences rather than interaction. At the same time, most work involved adopter classes interacting with society rather than with each other.

### 3. Collective Action

While diffusion studies dominated mass communications and business research, a second line of adoption studies developed in sociology and political science. Collective action research concentrated on the motivations of the individuals. While there is significant overlap, collective action took a relatively microeconomic perspective compared to diffusion.

The watershed book for collective action was Olsen's *The Logic of Collective Action* [12]. It considered what motivates an individual to participate in a group effort. Collective action involves situations where a group of previously unorganized individuals must work together to achieve some mutually desirable goal. One popular example is where a group of residents must work together to prevent the closing of a nearby school [8]. Another classic study was on the development of riots. Granovetter [3] attempts to predict the development of riots as a collective action. While riots may seem removed from

information systems, the same forces are at work. Collective action studies assume that:

- 1 Participation requires cost or risk.
- 2 Non-participation will not require cost.
- 3 A common good may be produced without participation.

In collective action individuals must choose to invest in a common good. If successful, everyone will benefit from his or her effort. If not successful, only those that invested effort will lose. Essentially, collective action theorists look at situations where individuals must invest in an activity where they may never benefit. In addition, others that do not participate may benefit from the action. Non-participants who enjoy the common good are called "free riders" on the collective action.

For example, suppose a local radio disk jockey has been offending the community. A growing group may wish to get rid of him but how do they start? The effort will be time consuming and require a risk to one's personal reputation. It is also possible that the situation could resolve itself if left alone. A local minister is particularly interested and decides to lead the fight. Others choose to adopt the cause as well when their personal interest level is met. If the effort is successful, all interested will enjoy the departure of the disk jockey. If it is unsuccessful, those that participated will have wasted their time and damaged their reputation.

Collective action theorists assume that potential groups are made up of people that have different levels of the desire to participate [7] [9] and who elect to participate either through rational decisions [6] [11] or based on learned behavior [6]. Decisions to participate are based on a combination of perceived cost, anticipated value and personal interest [9]. Most collective actions are caused by action that originates with one person or a few people who plan a campaign and purposely draw others into it [10]. Participants become a part of an interest group desire a collective action, [7]. A collective campaign includes the activities oriented toward that goal while social movements are actions by people who can and do change their responses over time.

What is interesting about a collective action is how fragile or powerful it can be. Collective action describes events that can quite literally change the direction of a society. At the same time, the collective action can fail for the want of a single person. Since inclination to participate is dependant (in part) on a likelihood of success, Dick [2] observed that the lack of a single individual may doom a small collective action. The collective action could also be self-limiting. Oliver [11] effectively described a scenario where potential participants realize that they will not make a significant contribution to a collective action. As such, their motivation to contribute would decline.

Collective action studies do not consider alternatives to the CA. While opportunity costs are considered a part of the costs of a CA, these costs are simply considered the cost of doing "something else." Surely there is no discussion of joining riot A or riot B. Therefore; attributes of the adopted behavior are not well developed.

#### 4. Linking it Together

What are the common elements between the two foundations?

Heterogeneous participation: Both foundations allow for heterogeneous levels of participation. In diffusion, adopter classes are described as distinct subgroups of the larger population -- complete with demographic and psychographic differences. Collective action theorists go further to postulate an individualize "inclination to participate." Some even use a formula to describe a rather mechanical decision making process based on an individual's perception of the potential adoption [9].

Adoption at a cost: Whether it is personal embarrassment or financial loss, both traditions recognize perceived costs as an inhibiting factor for adoption. For example, the main difference between innovators and early adopters in diffusion is the willingness to risk adopting an unsuccessful innovation. Collective action assumes people assess cost, benefits, and likelihood of success before adopting the group behavior.

Critical Mass: Critical mass is a term that comes most from diffusion literature. However, both traditions assume there is a threshold. In diffusion, that threshold happens to be societal. In collective action, each person has a threshold. Once a personal threshold is met, the individual adopts the behavior.

Levels of interaction: Diffusion allows for the possibility of information seeking behavior. This implies that an opinion leader could have a direct influence on the adoption decision of a later participant. Collective action tends to suggest a more passive level of interaction. In effect, the individual will look at other individuals who may or may not be participating in the collective action to see if their personal threshold has been met. This does not imply direct interaction but, at least, an awareness of others.

Time line: A required time line is implicit in collective action. There is, after all, a fine line between a riot and one rebel with a brick. If the brick is thrown and others join in, the rebel becomes a leader. If others do not join, the rebel is arrested. Still, establishing a time line is not center of collective action research. Diffusion has a rather strict timeline. Critical mass theorists formalize the deadline. Establishing the time line is explicitly researched.

Free rider: The free rider comes from collective action models. The free rider is the person that can enjoy the collective good without participating in the production. Diffusion researchers tend to believe that the free rider can be excluded from the innovation. Still, diffusion researchers' normative approach to adopter classes suggests resentment toward the laggard.

Many of these elements still hold true in practical applications. Despite earlier criticisms, these elements are all useful and should be retained in a new model. A single model that can unify all the above elements should be even more powerful.

#### 5. Resonance

The goal of this study is to suggest a new framework for analysis. This new framework should take the best from diffusion, critical mass and collective action research.

Goals for the new model include:

- 1 A more flexible timeline.
- 2 A greater sensitivity to the interaction between adopters.
- 3 An ability to consider smaller scale adoptions.

Since two of the previous models used an analogy to a process borrowed from the hard sciences, this model will as well. A more apt analogy for collective action is that of resonance. Academic American Encyclopedia Letcher [5] describes resonance as:

... the large absorption of energy and the resultant large amplitude of motion that occurs when a vibrating system is driven by an external force at its natural frequency of vibration.

Resonance is a generalized concept used in many fields of study, including physics, electronics, quantum mechanics and chemistry. While individual readers may understand the term from the point of view of one discipline or another, for parsimony, it must be discussed in more generalized terms. In general terms, resonance is used to describe many systems that are dependent on waves of energy in a moving system.

The principles of resonance are at work when a person pushes a child in a swing; the greatest effect will be achieved for the least effort if the force is applied at the natural frequency of the swing and in phase with the motion. Two opposing forces - inertia and restoring force determine the resonance frequency. Inertia causes objects in motion to want to continue to be in motion. Restoring force causes the object to want to return to its resting state. Using a swing as an example, input energy drives the swing beyond its resting state. Inertia would cause the swing to continue away from its original position if it were not for the restoring force (i.e., gravity and a good sturdy rope). When the restoring force overcomes inertia, the swing moves back to its resting position but is carried by inertia beyond. In this way, the input energy activates a chain of forces - each reacting to one another. At resonance frequency, input energy only needs to overcome the mechanical friction of the system. Below resonance frequency, input energy must overcome mechanical friction and the restoring force. Above resonance frequency, input energy must overcome mechanical friction and inertia.

In another example, resonance can be used to describe the relative ability of a musical instrument to produce sound. The instrument is a vibrating system and any such system would have at least one resonance frequency. Energy is applied to the instrument through air movement or vibrating strings. When energy is applied at the proper frequency and time (in phase with the output), the greatest output is produced for the expended effort. At resonance, output power reaches a peak for a consistent effort.

At resonance there should be qualitative changes as well as a quantitative. In a musical instrument, resonance

produces overtones as harmonic frequencies are excited. The entire tonal output becomes more complex and thereby changing the quality of that output. In a practical application, the successful adoption activity may seem to lose focus in resonance as used start to adapt the behavior.

## 6. The Resonance Model

The resonance model assumes that any successful adoption is comprised of two groups. First, a motivating force of people interested enough to lead. Second, a receptive mass that is ready to adopt something – not necessarily this adoption. If the motivating force successfully excites the receptive mass to action, the adoption activity is successful. The keys are the availability of receptive mass and the ability of the motivators to excite the mass.

The relationship between these two groups is more interactive than the normal opinion leader/follower relationship. The resonance model assumes an interaction between current and future adopters. The strength of the model should lie in the ability accommodate adoption. The interaction between adopters and non-adopters can accommodate adoption in two ways. First, on the individual level, those encouraging the innovative behavior must push adoption when the non-adopters are ready. There is an implicit assumption of a social negotiation that would demand adaptation. For example, the American cable channel MTV works very hard to be source of new fads. Still, it does not declare something cool and leave it at that. MTV's research department finds trends with an innate appeal to its demographic group [15]

Second, an interrelationship between past and future successes (or failures) suggests a continuous trial and error process. When Dick [2] studied online forum activity as a collective action, he found that almost all discussion areas had little to no activity. In this study, fifty-six percent of the discussion groups accounted for all of the activity. However, Further, Dick's results indicate a dramatic slope in the distribution where most of the real activity was concentrated in very few areas. If this pattern exists in general adoption behavior, most adoption research concentrates only on relatively rare instances where innovations approach success. For every innovation that gets studied, one thousand may have already been discarded. Adoption occurs by survival of the fittest. We can see this kind of adoption today in the various short messaging/instant messaging services -- each one upgrading to optimum quality. The goal should be to expect adaptation as a normal part of adoption.

### 6.1. Resonance and New Media

A key to the success of a new telecommunication service is a valid estimate of the potential market. Too often, universal adoption is the assumed standard for success [1]. There are good reasons. After all, a communication system cannot be effective unless there is someone with whom to communicate. The natural logic would be that a system is most efficient when everyone is using it. However, the pace of change is such that we cannot depend on universal adoption before obsolescence. Rather

than striving for 100 percent market penetration, new communication systems should change their definition for success to be more realistic. There are several communications activities where even large-scale adoption is undesirable. The tattooed, body-pierced teenager might be horrified to find her parents joining in. In the same way, a citizen band channel is useless if everyone is using it.

Online discussion groups, or forums, provide the framework for our remaining discussion of adoption behavior. These discussion areas are popular on many services, and are seen as an important method for system owners to communicate with their audiences. At the same time, the forum requires the same forces of any adoption behavior. The forum requires shared adoption. There is uncertainty that adoption will yield benefits while it wastes time. As such, they are a reasonable starting point.

Online forums may be studied for a critical mass where the forum fluctuates around a specific level of traffic. A forum provides represents both a communication medium and a collection of individuals that must make a joint investment for a common good. The forum participant must adopt more than just the medium. They must also invest in a project that is only successful if others act in a similar way through replying to the messages. Collective action theory has been extensively developed but has suffered in field trials due to the inability to accurately record the collective action. Since forums records and archives from creation to degeneration, forums offer the researcher more choices in field trials of adoption behavior. What this means to the forum is: Forum leaders (motivating force) drive a previously non-involved group of individuals (receptive mass). The group produces its maximum output at or near a certain frequency.

If the driving force is removed or reduced, the group as a whole can lose its natural frequency and thereby the positive effects of resonance. The quality of the conversation is dependent on the frequency of the conversation (activity level).

Even though a simultaneous force is necessary, this force can be achieved, lost, re-achieved and even become too powerful. Forum leaders are in the position of tuning that force to the proper frequency.

Although the resonance model is used to replace critical mass, it augments the base established in collective action research. The model can be used to better describe the collective action process by dividing it into stages. Individual participation decisions still drive the growth of the collective action. Heterogeneity of participants is emphasized by the categorization of participants into separate classes.

### 6.2. Developing Adoption

In a study of forum activity [2], two critical break points were described. First, critical mass was described as the point at which there was a dramatic increase in the amount of activity. Second, critical saturation was used to describe the point at which activity was so heavy that there was a dramatic decrease in activity. Resonance can be defined as the period of time between these two criti-

cal break points. In the resonance model, these two points become two parts of a single condition. Critical mass becomes the lowest possible frequency of resonance. Critical saturation then becomes the point where the frequency of activity becomes detrimental to future activity going beyond resonance. While some simultaneous force is necessary, this force is not as dependent on a time period from an artificial starting point - such as the building of the swing. Resonance can be achieved as soon as the forces are marshaled. From this point on, the terms "critical mass" and "critical saturation" will not be used. The forum is either in a state of resonance or not.

#### 6.2.1. The Motivating Force

Forum leaders become the motivating force, though not the only force in creating the successful adoption. Not only do they define the forum's environment, they supply the initial energy that activates the mass of potential participants (receptive mass). In this way they give the forum its direction and the mass of participants supplies a reactive energy that gives the forum its real activity. One of these two groups is not enough. The forum leaders reacting without the aid of the mass is similar to the musician attempting to perform without an instrument. The reverse might naturally be true except that leaders might naturally emerge from the mass and become the needed motivating force.

For a forum to become active, it is necessary to have a group of willing participants. Sheer quantity of participants is necessary but not sufficient to start the active forum. Assuming that there is a normal distribution of inclination to participate, the true success relies on the presence of those individuals with an unusually high inclination. A successful forum requires not just a number of people but the actual people willing to participate first. If even one of these people is missing, an otherwise active forum may languish. The group may be willing to participate, if only someone else would start. The leaders provide that initial energy necessary to activate the resulting mass. In this way, the actions of others are, to a great extent, dependent on them.

#### 6.2.2. The Resonance Curve

In the resonance model, qualitative changes and quantitative changes happen together. The result is more of a life cycle model and can be broken up into several stages. Each stage will have its own unique characteristics and will be discussed below.

It should be noted however, that the model represent possible stages of the forum's life cycle not necessary stages. A forum may never leave the "quiet stage." The forum, in this model, must pass from quiet, to definition, to resonance but it may never achieve super-resonance. It is also possible that after recession, it can return to resonance. To emphasize the optional nature of these stages, super-resonance will be discussed after recession.

#### 6.2.3. Quiet

The quiet stage of the life cycle can be viewed in one of two ways. First, it could be at a time in the forum

before the driving force is applied. Second, quiet areas could simply uninteresting topics. Forum leaders do not often know what topics will be of interest to participants. Since resonance requires both leaders and a mass of participants, leaders do not wish to cut off an area that could be potentially active. These areas are trials that have not yet succeeded.

#### 6.2.4. Definition

At some point prior to resonance, the forum should define itself and its market. Like the swing that is trying to overcome the restoring force, the forum is trying to become something other than inactive. To accomplish this, the forum must establish a direction. The definition stage is one where activity and interest level interact. The forum cannot be all things to all people any more than the swing can move in all directions at the same time. The forum will become more interesting to some and less interesting to others. The activity level of past participant affects the qualitative interest level of the forum.

If you assume incoming messages are valuable, then a mass of messages should increase everyone's inclination to participate. But that assumption does not consider a basic premise of resonance -- heterogeneity among participants. If users are truly different, then the values of certain messages are equally different. Messages should cause an increase in the inclination to participate for some users while a decrease for others. As messages increase, a conversation becomes more specific in both topic and level (intellectual, maturity, etc.). The activity will cause the forum to be more interesting but to a smaller group of potential participants. In effect, the collective action is defining its market. This market definition is similar to an instrument being tuned to produce the strongest output (harmonic frequencies).

This portion of the life cycle is probably most similar the original critical mass model. Each system user is making individual participation decisions based on what they believe to be the potential rewards. Loyalty to the group has not yet been established so the restoring force continues to have its greatest effect.

#### 6.2.5. Resonance

During the time of resonance, forum managers have successfully excited the group into action. The leaders' participation should become more enjoyable. The leaders may actually increase their activity (in relation to the rest of the group) at this point simply because it takes less effort and because their experience with the forum lets them know "where the action is." The friendship of the mass of participants should increase as well because information is being exchanged freely and the participants are benefiting from the public good that has been created. At this point, loyalty should develop among participants. This loyalty allows the forum to continue even if there is a momentarily lose of resonance.

#### 6.2.6. Recession

Oberschall [9] suggested that the successful collective action could be reversed by the loss of a minor percent-

age of the group. This idea can be included in this resonance model. For example, assume that summer starts and a forum leader leaves for other activities. Even if most participants are not affected by the change in season, all participants receive less interaction and the value of the forum drops. Since everyone's inclination to participate is equally reduced, other current users withhold participation and the probability of reward diminishes further. An active forum dies due to the introduction of a variable that may not even be important to even a majority of the participants.

Recession is the point when the forum loses its resonance frequency and drops to a level of relative inactivity. Since forum leaders are the driving force, they should be the first to leave at times of recession. Recession may, in fact be caused by their driving force running out of energy. This may be due to a loss of interest in the current topic and a desire to move on to other areas. Using the swing analogy again, recession would occur when the child grows tired or bored and moves on to other toys.

The mass of participants may experience an entirely different effect at the time of recession. Loyalty has been created in the group. Also, since leaders are most likely to be the first to send messages, the mass of participants is more likely to try to continue the topic (not yet bored). The energy originally invested by the leaders will remain for some time after resonance. Inertial energy provided by the receptive mass may push the forum back into resonance.

#### 6.2.7. Super-resonance

Super-resonance occurs when activity exceeds resonance. At this point, management of the interaction should become more difficult because there is much more activity. Conversations should lose their focus and multiple topics should be present. Like the swing that wants to fly off away from the tree, the forum flies away from its center of interest.

Super-resonance may not be enough to kill forum activity but it may motivate participants to limit their contributions. Two separate effects may cause super-resonance. First, participants may simply be unwilling or unable to process too many messages at one time. Participants may find ways to limit their commitment to the group (e.g., put off responding for another time). Second, as Oliver [11] suggested, the forum may reach a point where participants feel they have little to add. In either case, forum activity should not be expected to exceed some maximum level - at least not for long.

## 7. Conclusion

We have already seen communication systems (e.g., citizen band radio, audio cassettes, and microfilm) that are successful on their own terms but will never be universally adopted. It is time to consider these scenarios as we consider adoption.

New opportunities to look at adoptive behavior are available today. This study presents the first attempt to develop this new model for adoptive behavior. The author believes it is time to start the discussion in a fresh

direction. The first step is to lay a theoretical foundation rich enough for further study. The next step is to test past assumptions and those included in this model in light of the demands of current technology.

The model outlined above provides a rich basis for innovative study. First, adoption research needs to look at a greater variety of adoption behaviors. Second, researchers need to look the entire adoption lifecycle including the relationship between one adoption event and the next. Finally, greater attention needs to be paid to the dynamics of the adoption decision.

# Taiwan Internet Diffusion: An Empirical Study of Internet Interactive Effects

Hsiang-Chi Huang  
FIND-ECRC  
Institute for Information Industry  
Taipei, Taiwan  
illusion@iii.org.tw

## Abstract

The primary objects of this research were applying the innovation diffusion model to internet hosts and internet subscribers. The results of this study may be a useful reference to the further concept building of the relationship of innovative and adopters.

## 1. Introduction

During the last decade, there has been a lot of optimism regarding Internet Development. Reports and news showed that Internet growing at an exponential pace with no predictable upper bound or saturation limit. However, in March 2000, with NASDAQ Internet stocks falling, no one thought about it but rather than returned to the reality. [4][6]

Internet hosts' and Internet subscribers' growth at an exponential pace happened in early stage of Internet development. Common customer frustrations are concluded because of slow response time, inaccessible online service...etc. These problems can follow inadequate capacity planning caused by ignorance of the Internet growth pattern. [2]

After a six-year growth boom, Internet growth rate slow down. Analysts are claiming that Internet adoption by consumers has essentially saturated. Since Internet stock fell, stockholders are eager to see the real profit than gold in the heaven.

Thus for Internet companies accessing Internet subscribers and hosts accurately is a daunting but increasing important task. The purpose of this study is to understand Taiwan internet diffusion models of internet subscribers and internet hosts and the relation between internet subscribers and internet hosts.

## 2. Internet Diffusion

### 2.1. Internet Diffusion Model

The diffusion model is one classical model used to study the impact of a specific technology. The model is informed by the diffusion of innovation and various

economics theories and assumes that non-adopters of an innovation are increasingly likely to imitate adopters.

In other words, one person adopted because he or she observes the success of another person who has already adopted.

However, the number of adopters in a social system has its upper limit. Thus growth rates increases first and then decreases over time to achieve a finite saturation level. We call the point at the maximum growth rate of the growth models "the inflection point". Some growth curves are called "S-Curve" because of its shape.

Empirical studies shows the model have been used in many disparate fields such as social study ,public health ,management, sociology, marketing, communication networks to model diffusion through a population of adopters or subscribers.[7]

### 2.2. Mathematics form of growth model

There are three common growth models –the exponential model, the logistic model and the Gompertz model. [3]

#### 2.2.1. The exponential model

The exponential model assumes a constant rate of growth and thus does not involve either an inflection point in the growth rate or a definite saturation limit. Some studies shows in the early stages of its diffusion, the exponential model is suitable for understanding the growth. And the form of the exponential model

$$Y=A*\exp( B*T) \quad (1)$$

In equation (1), Y is the cumulative number of existing adopters. A、 B are constants. T is the period.

#### 2.2.2. The Logistic model

Unlike the exponential model, the logistic model assume variable growth rate whereby the growth rate first increase and then decrease over time. The form of the Logistic model (also known as Pearl model)

$$Y=A/(1+B*\exp(-C*T)) \quad (2)$$

In equation (2) , Y is the cumulative number of existing adopters. B、 C are constants. T is the period. A is the upper limit of Y.

### 2.2.3. The Gompertz model

In this model, the rate of diffusion is a function of existing adopters and the difference between the logarithms of the number of adopters at the saturation level and the existing number of adopters. The form of the Gompertz model

$$Y=A*\exp(B*\exp(C*T)) \quad (3)$$

In equation (3),Y is the cumulative number of existing adopters. B、 C are constants. T is the period. A is the upper limit of Y.

### 2.3. Interactive Process of innovations and adopters

The Internet is a communication mesh of networked computers with their associated resources, including but not limited to email, ftp, gopher and the web. Organizations and individuals may adopt and use varying subsets of the Internet. [5]

In other words, Internet users could communicate with each other through “Internet” such as email, news groups...etc and interact with internet resources (webs, mail servers, ftp servers).

This interactive process first studied in the 1980s by diffusion researchers. Researchers found that interactive innovations (telephone, fax, email) possess different characteristics from innovations spread in the normal diffusion networks (mass media, interpersonal networks).

The main feature of the interactive process of innovations and adopters is its two-way communication process. In the case of non-interactive innovations, the earlier adopters have a sequential interdependence effect on later adopters. But in the case of interactive innovations, not only earlier adopters influence later adopters but later adopters also influence earlier adopters.[9]

Based on interactive innovations, one researcher showed internet client-server architecture may cause a new many-to-many communication model. .

In dual acceptance theory, diffusion of internet adopters depends upon internet servers whereas the diffusion of the web server depends upon internet users.

Chen’s study indicated that if there are only a few web servers, using the web is of little value to users. Similarly, if there are only a few web users on the internet,

creating a web server is of little value to organizations or business. That is the rate of adoption of web servers depends upon the number of users, not the number of web servers.[1]

## 3. Research Method

This study attempts to use diffusion model to access diffusion models of Taiwan internet users and internet hosts ,but also to fit the dual acceptance model.

The data of Taiwan internet hosts comes from Internet Software Consortium. The number of Taiwan Internet hosts equals to the sum of the number of .tw domain name and the number of hinet.net domain name. Hinet is the largest ISP in Taiwan and other ISP domain name is including in .tw domain name. The data of Taiwan internet users comes from Taiwan Directorate of Telecommunications.[8]

At the beginning this study, we use the data of internet users and hosts in Taiwan to fit the diffusion model . Secondly, we apply Taiwan Internet diffusion model for dual acceptance model.

#### 4. Analysis and Discussions

##### 4.1. Analysis of Taiwan Internet Hosts

We use the data regarding the number of Taiwan Internet hosts from Jan-95-Jul-00 at half-year intervals, based on reports publish by Internet Software Consortium to fit three growth models. Which model is the best? For  $R^2$ , these three growth models are acceptable. (Table3)

Table.3 Regression Models of Taiwan Internet hosts

Model	$R^2$	Model
Logistic	0.981 3	$Y=6794521/(1+844.38*\exp(-0.4339*t))$
Gompertz	0.976 0	$Y=65693134*\exp(-10.70*\exp(-0.0826*t))$
Exponentia	0.973 1	$Y=33328*\exp(0.2976*t)$

##### 4.2. Analysis of Taiwan Internet Users

We use the data regarding the number of Taiwan Internet hosts from Jan-95-Jul-00 at half-year intervals, based on reports publish by Internet Software Consortium to fit three growth models. Which model is the best?

For  $R^2$ , these three growth models are acceptable. (Table 4) But if we look at the trend of the three model, the exponential model seems not unacceptable.

Table.4 Regression Models of Taiwan Internet Users

Model	$R^2$	Model
Logistic	0.998 2	$Y=9044.2858/(1+80.38*\exp(-0.4089*t))$
Gompertz	0.998 2	$Y=11366.30*\exp(-7.7977*\exp(-0.1997*t))$
Exponentia	0.937 1	$Y=701.3346*\exp(0.1607*t)$

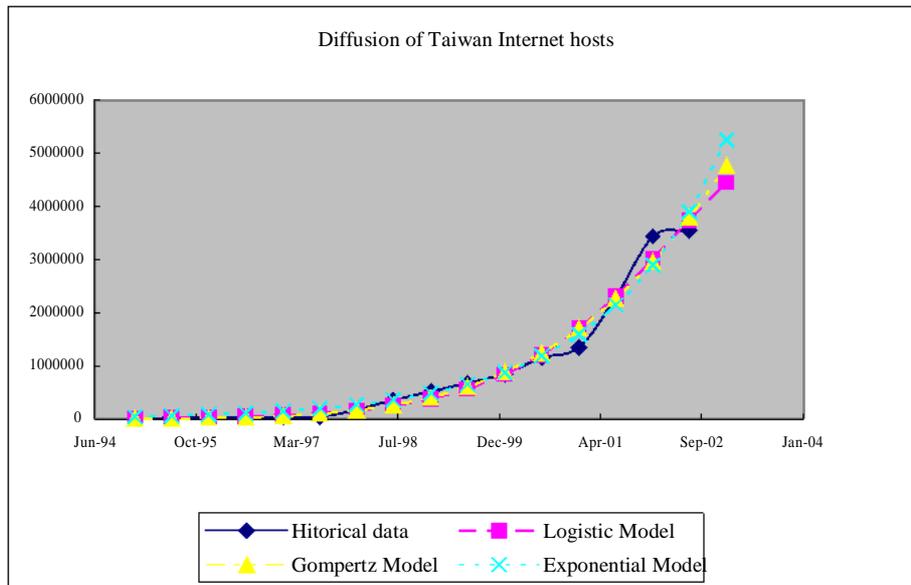

Figure 1 .Diffusion of Taiwan Internet hosts

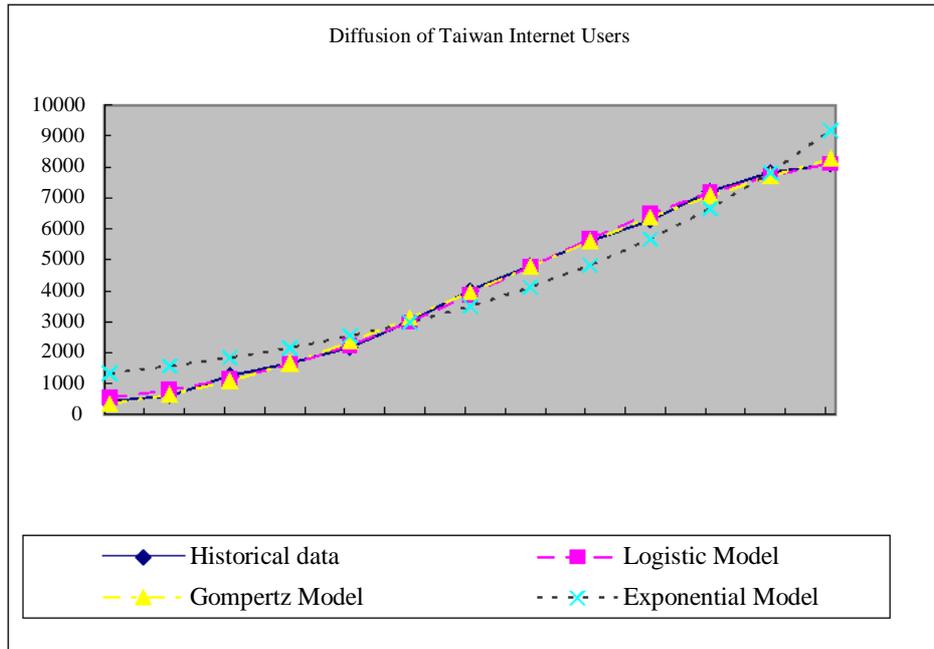

Figure 2 .Diffusion of Taiwan Internet Users

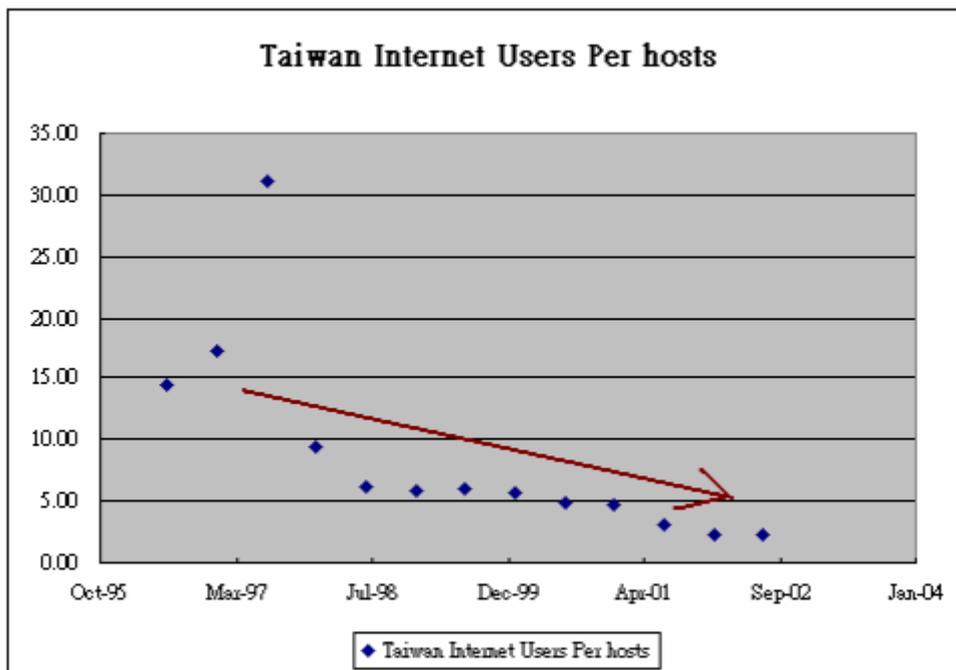

Figure 3.Taiwan Internet Users Per hosts

#### 4.3. Analysis of Dual Acceptance Model

Dual acceptance model implied that internet hosts is related to internet users and the relation of internet hosts and internet users follows a linear relationship.

Though the Correlation coefficient of Taiwan internet users and Taiwan Internet hosts appears to be a high relationship ( $r=0.9193$ ), the total number of internet hosts doesn't follow a stable linear relationship with the

total number of internet users, but follows a decreasing relationship.(Table 5, Figure 3).

Dual acceptance theory indicated the rate of adoption of web servers depends upon the number of users, not the number of internet hosts, which means more internet users, more internet hosts. But the growth rates of Taiwan internet hosts and internet users changes every period and don't follow the dual acceptance theory.

In short ,the data of Taiwan Internet users and hosts doesn't support. dual acceptance theory.

Table 5.Taiwan Internet Users per host

Time	Internet Users Per host
Jul-96	14.36
Jan-97	17.32
Jul-97	31.09
Jan-98	9.39
Jul-98	6.14
Jan-99	5.79
Jul-99	5.94
Jan-00	5.65
Jul-00	4.84
Jan-01	4.65
Jul-01	3.15
Jan-02	2.28
Jul-02	2.28

## 5. Conclusion

Although the Internet is still developing now, we couldn't get the whole picture how Taiwan internet users interact with Taiwan internet hosts. However the results of this study still prove some useful finding to the concept of the diffusion process of innovative and adopters. They are summarized as following:

### 5.1.Models of diffusion of innovations

Developing models that explain the growth process is critical for policy formulation, capacity planning and introduction new network hardware and software. Growth projection informs providers of Internet products and service of the potential consumer base.

This paper has presented that Gompertz and Logistic models could be used for forecasting regional Internet diffusion. The exponential model is only useful at early stage of diffusion of innovations. For a long-term planning, the general S curve regression model could be better fitting models.

### 5.2.Dual acceptance theory in Taiwan

In dual acceptance theory, diffusion of internet adopters depends upon internet servers whereas the diffusion of the web server depends upon internet users. The rate of adoption of web servers depends upon the number of users, not the number of internet hosts.

The Correlation coefficient of Taiwan internet users and Taiwan Internet hosts supports the relationship of Internet hosts and Internet Users.

However , the total number of internet hosts follows a decreasing relationship with the total number of internet users. The data indicated the rate of adoption of internet hosts increased faster than the rate of adoption of internet users. And this doesn't follow the study of Chen's research.

This finding implied that dual acceptance model should be modified. The dual acceptance model is a new concept which has not been sufficiently explored. Further research on the dual acceptance model is needed to expand the knowledge about on the relationship of innovative and adopters and the consequence of innovative.

# Allying BPR with Strategy: A New Perspective for BPR

Xiao-Xia Huang

Shao-Zu Mei

School of Management  
University of Science and Technology Beijing  
Beijing, China  
Huang824@vip.sina.com    mei\_sz@yahoo.com

## Abstract

Since early 1990's, Business Process Reengineering (BPR) has become a buzzword around the world. Of the BPR methods and models suggested, the majority has put much attention on redesigning processes at operational levels. Those who stress the importance of strategic process reengineering tend to emphasize that redesigning should be embarked and implemented at a broader scope (cross-functional) in order to obtain greater pay offs, whereas the impact of BPR on strategies is less studied. In this paper, we propose that BPR ally with strategies and, consequently, emphasize the importance of BPR relevant to strategies and the significant role of strategic directions in light of BPR. Thus, we develop a conceptual BPR model that links a firm's strategy, with a real world example. The main purpose of this paper is to demonstrate the inter-relationship between BPR and strategy and to help provide guidelines for better BPR implementation to enterprises.

Keywords: BPR, strategy, ally

## 1. Introduction

Since early 1990's, Business Process Reengineering (BPR) has become a buzzword around the world. Though success reports are accompanied by a list of failures, firms are still moving ahead with BPR. For example, a survey of 1,000 U.S. Chief Financial Officers expressed their enthusiasm for radical changes: over 90% of the respondents indicated that their companies would embark on new re-engineering efforts in the future<sup>[14]</sup>. In response to firms' appeal for better implementation methods, some methods and models of BPR have been suggested. By studying these methods and models we find that many of them are focused on redesigning processes at operational levels<sup>[1][4][6][8][9][11][12][15][16]</sup>. For those who stress the importance of strategic process reengineering tend to emphasize that redesigning should be embarked and implemented at a broader scope (cross-functional) in order to obtain greater pay offs<sup>[14]</sup>. Less studied are the important contributions of BPR to strategies and how strategic directions can better guide reengineering. Motivated by these shortcomings, in this paper, we investigate the importance of BPR relevant to strategies and the significant role of strategic directions in light of BPR. The main purpose of this research is to demonstrate a close relationship between BPR and strategy and to help provide guidelines for better BPR implementation to enterprises in China.

Section 2 discusses the literature review on the strategic importance of BPR. Section 3 presents a conceptual model of allying BPR with strategy. Section 4 illustrates the role of strategic directions in light of BPR. Section 5 builds the linkages between BPR and strategy. Section 6 shows a real world example. Section 7 concludes the paper.

## 2. Literature Review

Along with its great successes, BPR also has a disappointing track record. One of the BPR implementation problems is that firms do not have a proper method supporting a systematic redesign<sup>[10][13]</sup>. Many methods and models were presented to help firms redesign processes successfully. Yoon Ho Cho, Jae Kyeong Kim, and Soung Hie Kim<sup>[6]</sup> focused their attention on process simulation modeling and analysis of the simulation result (ie. process) based on a role-based concept. They believe that a business process can be defined as a combination of roles that are defined as a set of people and their accountabilities, and the interactions among them, or that a process can be defined as a series of customer-supplier relationships with desirable results at specific points in time. They introduced an object-oriented queuing model and developed a simulator, which tried to find bottlenecks of a process and to reengineer the process. The bottlenecks are regarded as roles that have higher utilization, lower process time/elapsed time ratio, and higher work allocation ratio. Ren-qian Zhang, Fa-jie Wei, Guo-ping Xia, and Si-ping Shan<sup>[11]</sup>, and Feng Zhang and Yu-liu Zhang<sup>[4]</sup> studied how to use activity-based cost (ABC) method to provide useful information in helping understand and reengineer existing business processes, in order to reduce costs. Aalst<sup>[15]</sup>, and Jian-zhong Li and Liang-qiu Chen<sup>[6]</sup> worked on a process technique: EPC (Event Process Chain) or EEPC (Extended Event Process Chain) in implementing BPR. Aalst researched on the improvement of EPC, who defined syntax and semantics of EPC by mapping EPCs (without connectors of type v) onto petri nets. Among many analysis techniques for EPCs, Jian-zhong Li and Liang-qiu Chen<sup>[6]</sup> established EEPC model to help identify problems of the exist processes and reengineer them. To adopt EPC models, K-H Kim and Y-G Kim<sup>[8]</sup> developed EPRE (enterprise process reverse engineering) process modeling and redesign method, which consists of the following three stages: 1) to analyze form: to define forms and form fields, and to identify field set operations with field type; 2) to generate process model: to generate EPC diagram; and 3) to redesign process: to redesign intra-FSO (Field Set

Operation defined as a set of activities which processes one or more form fields and is performed at a single location during a single session for a specific customer service) and to redesign inter-FSO. Their process redesign support is restricted to information handling activities. Soung-Hie Kim, Ki-Jin Jang<sup>[12]</sup>, and Brane Kalpic and Peter Bernus<sup>[1]</sup> worked on another process technique: IDEF0. Soung-Hie Kim and Ki-Jin Jang discussed the application of IDEF0 tools to implement the process modeling and performance capabilities. They presented a framework to support analysis of activities and information flows within the scope of manufacturing application. Their effort was to coordinate information flow for activities, to enhance requirement reconfiguration, and to minimize errors and the unplanned evolution of activities in BPR project executions. Brane Kalpic and Peter Bernus utilized the functional modeling language IDEF0 to reengineer the processes of new products development. They followed a simple three-step method of BPR: 1) description phase of a business process, 2) analysis phase that focused on the investigation of facts and characteristics of existing process, and 3) redesign phase where the process model was redesigned based on the findings of the analysis phase and predefined objectives. They stressed the important role of modeling and analysis of functional structure in process reengineering. M. Abdomerovic, and G. Blakemore<sup>[9]</sup> focused attention on analyzing process variables in order to discover project process interactions. They argued that understanding project process interactions would help define what influences project results, and discovering factors that influence project results would lead to improvement of the existing processes. For this reason, they believed that the design of project process interaction can serve as a project process reengineering tool. There are other models and methods for BPR implementation: S. Guha's Life Cycle methodology, T. Davenport's framework of process reengineering, R.b. Kaplan's core process redesign, Gateway Company's Rapid Re Method<sup>[7]</sup> and method provided by Richard J. Mayer in KBSL (Knowledge Based Systems Inc.) incorporation<sup>[17]</sup>.

By studying these models and methods, we see that their methods or models do not deviate the theme that consists of: first understanding the existing process, and then identifying and eliminating the problems of the existing process. William J. Kettinger and James T. C. Teng<sup>[14]</sup>, who stressed the importance of strategy in process reengineering, emphasized much on the idea that embarking of BPR should be at a higher level (cross-functional) instead of a lower level (intra-functional) in order to obtain higher pay offs. Most of them had same hypothesis that the existing strategy is appropriate and need not be examined. They emphasized their study more at the operational level than at the strategic level. But the fundamental question is: when we reengineer processes, does strategy really matter?

### 3. The Strategic Place of BPR

BPR is defined by Doctor Hammer and Champy as "the fundamental rethinking and radical redesign of business

processes to achieve dramatic improvements in critical, contemporary measures of performance such as cost, quality, service and speed."<sup>[5]</sup> In their terms, BPR is characterized as a "clean sheet" approach that starts from fundamental rethinking. As time passes, redesign from clean sheet is improved and modified. Some scholars feel that the clean sheet redesign is not feasible in reality. Process improvement and process innovation are presented. But one core of BPR: "fundamental rethinking" presented by Hammer and Champy was universally accepted by scholars and entrepreneurs. Fundamental rethinking requires that people rethink about such fundamental questions as to why an enterprise should do what it is now doing, what resources it owns, what it is going to achieve in the future and how to achieve the goal effectively and efficiently. BPR tries to change an enterprise through process changes to let the enterprise fit the business environment. Therefore, BPR in fact requires that an enterprise stand at the height of the strategic level to re-examine its processes: what it is doing, what resources it owns, what changes it makes to the environment, and why it should do what it is doing to help either create a new value source or to enhance the existing competence. For example, Wiltel<sup>[3]</sup> is traditionally a natural gas pipe company. When they were faced with such basic questions as "What do we actually own?" they found that they actually owned utility rights of pipes and nation wide roads. After rethinking how they can make most effective use of these resources and what are the benchmarks in the industry, they made an innovation by providing new optical fiber cables in order to full making use of the existing establishment. Consequently, they are able to compete with such major telecom companies as MCI and AT&T. Their rethinking at the strategic level created a new value source. Reebok and Compaq are other examples of enhancing competence through re-thinking on their fundamental issues. Reebok raised the basic question "Why should we make shoes?" This rethinking helped Reebok realize that making shoes is not pivotal to company. As a result, they shifted their attention from production processes to design and marketing<sup>[3]</sup>. Likewise, Compaq decreased their production of terminal products by 30% and concentrated on marketing and R&D<sup>[3]</sup>. Re-thinking on a company's core business ensures that the company does the right things, which is considered the corner stone of BPR.

BPR must start from rethinking a firm's basic business model is obliged by customer needs and ever-changing business environment. Customers care more on service results than on production processes although service results are the product of production processes. In fact, production processes determine the service results, and the service results in turn guide the directions in improving the production processes. An enterprise must change its business processes for better service results required by its customers, through such BPR as enlarging, shrinking, or abandoning its production processes. According to the Economist Intelligence Unit, 57% of the companies surveyed claim that they have experienced profound innovation in the past five years, and 79% of the subjects anticipate that they would

launch a profound innovation by year 2010<sup>[3]</sup>. Companies that do not change to enhance competitiveness will fail and competence increases should not be limited within the industry. An enterprise must increase competence not only to survive, but also to thrive in the global marketplace. Having the right direction to implement BPR is by far the most important thing for any company to ensure. Otherwise, the enterprise will fail the competition even if it has excellent processes. Therefore, that a firm should re-think why it should do what it is doing and what it should do is the first priority of business process reengineering.

Before entering into real estate industry in Hong Kong, a well-known entrepreneur, Jia-cheng Li, was successful in plastic flower production with the nickname “king of plastic flower.” Li was good at asking himself what he should do. Re-thinking the basic question made him change his business directions at the right timing. Instead of continuously increasing the competence in the industry he shrank his plastic flower production business and began investing in real estate, which proved to be a correct strategic change<sup>[18]</sup>. Similarly, Wen-han Liu, another famous entrepreneur in Hong Kong, was once called “Father of Hairpiece.” He also changed his business orientation from hairpiece production to a new industry at the right time by asking himself what he should do. Rethinking the strategy prevented him from a possible failure when customers’ enthusiasm in hairpiece decreased<sup>[18]</sup>.

#### 4. The Role of Strategy in BPR

To embark process reengineering, a BPR project must be guided by strategy. There are three most important roles of strategy in business process reengineering.

First, BPR under strategy will ensure that process reengineering increases the company’s competence, and avoid the possibility of performance increase in part but hurt in the whole. For example, one big American insurance company transfers human and technology resources from an investment management process to a new insurance policy issuing process. Though the latter has been improved, the reengineering hurts the performance of the estate investment, which contributes to its bankruptcy<sup>[3]</sup>.

Second, business strategies guide the dimensions of the reengineering with four possible options: value creation, cost reduction, quality improvement, and cycle time reduction. In the past, BPR was often linked only with cost reduction and staff reduction. However BPR can do more. For example, when high-risk drivers were rejected by other insurance companies, Progressive Insurance<sup>[1]</sup>, the ninth-largest auto insurer in the USA decided to create a new value source. They re-generated the underwriting process to make it more detailed and more precise than that of their competitors, which led to a very precise price decision. When their competitors began imitating, they changed their

reengineering focus to quality improvement. It reengineered their claim process by exploiting a technique called “immediate response.” Now, Progressive can dispatch an adjuster to examine a claimant’s car on the day of the accident - in many cases, going to the accident site themselves. Guided under a strategic rethinking, its BPR helped Progressive poach on new territory and increased customer satisfaction and, as a result, increased competitiveness. Example of cycle time reduction can be found with Kodak, where it reduced its research cycle time of 35mm focus camera from 70 weeks to 38 weeks<sup>[5]</sup>.

Third, strategies can help define the reengineering scope and select processes by means of three different levels: company strategy, business unit strategy, and function strategy. The company level strategy guides the business unit strategy and the business unit strategy, in turn, guides the function strategy. The company strategy includes vision or mission statements as well as goals and objectives. Vision or mission statements delineate the directions an organization wants to pursue or avoid. Goals and objectives can cascade down from mission statements, which are usually more specific and quantitative. There are a wide range of strategic tools, including mission statement, competitive intelligence, environmental scanning, technology assessment, portfolio matrices, SWOT, core competence, value chain, scenario analysis, stakeholder mapping, market value addition (MVA), and economic value addition (EVA). Different levels of strategies and various strategic tools can help determine the reengineering scope, select the reengineering processes, and help set definite and clear reengineering goals that are essential for BPR. For example, when Belgium Communication<sup>[3]</sup> found that improving the company’s image is vital for the future development, it selected two critical processes for reengineering – the supply process and the maintenance process, which had close connection with its customers.

#### 5. Allying BPR with Strategy

Figure 2 shows a conceptual model for reengineering, as opposed to traditional models summarized in Figure 1. Table 1 compares the traditional and the conceptual new models to highlight the differences and commonalities. It is seen from Table 1 that the traditional models focus more on the selection of the processes and tools for reengineering under the guidance of strategies, whereas the conceptual new model emphasizes on the re-examination of organizational strategies on the basis of understanding their business environment and value-added processes. In other words, the more a firm understands the existing processes, the more it helps understand its potential resources relevant to the global business environment.

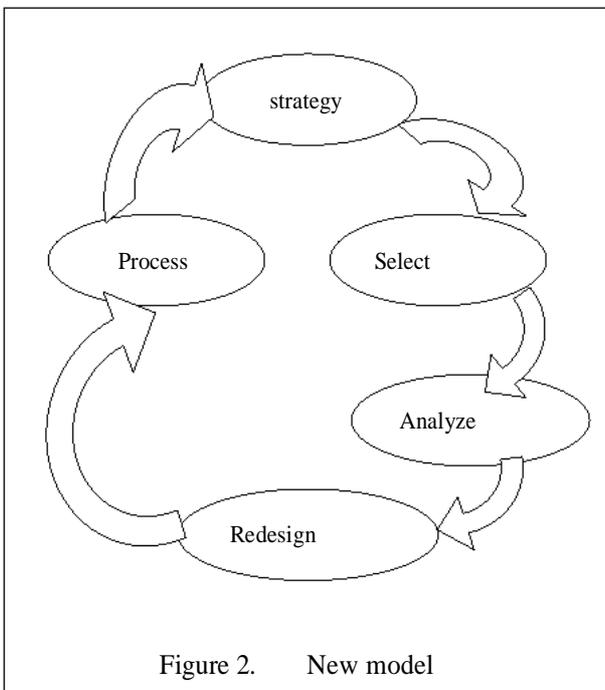

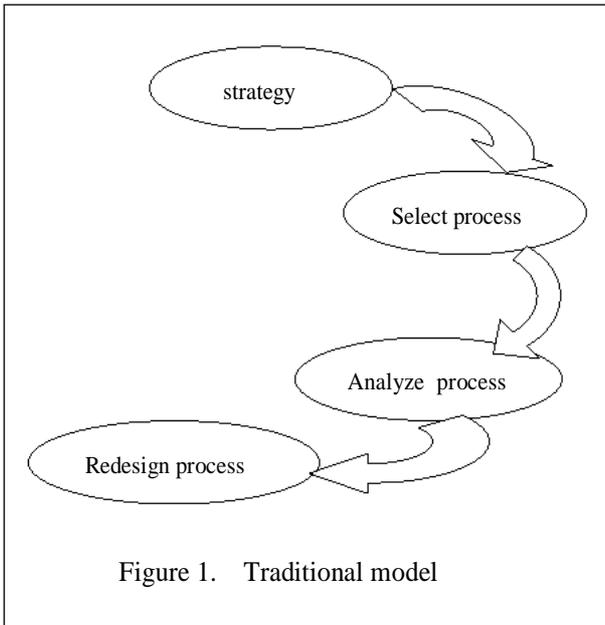

Table 1. Difference between the Traditional and the New Models

	Traditional Model (Figure 1)	New Model (Figure 2)
Hypothesis	The existing strategy need not be re-examined.	The existing strategy need be re-examined.
Start Point	Understand existing strategy.	Rethink about the basic question of the company.
Basic Question	How can process be better implemented?	Why process should exist? Then how can

to Answer		process be better implemented?
Focus	Establish various models to help identify problems of existing process and redesign new process.	Not only concern establishing various models but also concern how to cascade strategy to definite and clear goals to guide BPR.

## 6. An Example

Without loss of generality, let us consider XYZ, a subsidiary of a big American IT company, as an example. This company was established in China in 1999 with its headquarters in Hong Kong. It has staff over 600 and has established branch offices in 24 major cities in China. When they decided to embark reengineering, they did the following:

First, XYZ analyzed its six business lines: 1) system product, 2) net product, 3) product component, 4) consumption product, 5) engineering solution, and 6) electronic commerce. XYZ divided its products and services into two types: low value-added products and high technology, high value-added services.

Second, XYZ classified its customers into three groups - retailers, distributors, and service suppliers who provide the system with high value-added services - including such companies as Haier, Changhong, Nokia, First Department Store of Shanghai, Beijing Modern Shopping Center, China Software, Tide.

In doing so, XYZ found that their business lines were long and diversified. Further analysis showed that long and diverse business lines resulted in high level of inventory stock. Sometimes monthly turnover was only ¥ 30,000,000, but stock occupied capital over ¥ 130,000,000.

Third, XYZ identified its main competitors and finished SWOT analysis. Through benchmarking, it realized the gap between XYZ and its main competitors: it sold a big portion of low value-added commodities, whereas the proportion of high technology, high value added services were low. Moreover, XYZ felt that it needed to pay much more attention in establishing its brand name.

Fourth, XYZ analyzed the internal production capability and facilities.

Thus, the company re-aligned its mission statements and differentiated itself as the best supplier of scientific and technological products in the world. Consequently, it delivered the biggest benefits to its stakeholders and, at the same time, modified its goals and objectives in accordance with its mission. For future development, they decided that they should establish its brand name recognition, and that they should raise the turnover ratio of high value added services and products and change their marketing from sales promotion to customer satisfaction. In light of its mission and objectives, XYZ chose the marketing process as its reengineering focus. They set the reengineering target as integrating marketing oriented capital resources and

strengthening macro-control ability to help achieve this objective. Sub-targets were determined through further analysis and six sub-processes were redesigned. As of today, XYZ is one of the most successful companies in the industry in Hong Kong, as well as in the world.

## 7. Conclusion

BPR is an essential and effective endeavor for enterprises to increase their competitiveness and to thrive in the global marketplace. Since speed of change is faster and faster nowadays, BPR must ally with strategies. First, BPR must start with rethinking on an enterprise's strategic issues. That is, it should start BPR at the strategic level by asking such fundamental questions as what are we doing, what do we have, and why should we do what we are doing. Starting at such a strategic level will ensure that the enterprise is advancing in the right directions. Second, BPR must be guided by strategies, which will ensure that BPR increases the enterprise's competence as a whole, instead of increasing performance in one part but hurting as a whole. In order for strategies to better guide BPR, they must be cascaded into definite, clear, and specific objectives and sub-objectives. Since strategy management can be classified into the category of management research, the interfaces between strategy management and BPR is a direction for future research, which may help answer such questions as how to depose higher level of strategies into more specific and clearer goals and objectives of BPR implementation.

# Optimal Online Interactive Service Policy and Pricing Decision with Negative Network Externalities

David C. Teng David M. Chiang  
Graduate Institute of Business Administration  
National Taiwan University  
chingit@ms22.hinet.net cmh@ccms.ntu.edu.tw

## Abstract

In online interactive service industries, customers' utility is mainly from the service received but it is also affected by other customers' annoying behavior. Annoying behavior is configured to increase the utility of externality-loving customers who do it but on the contrary reduce the utility of externality-hating customers.

This paper proposes the optimal online interactive service policy and pricing decision in three sections. First, "forbiddance" policy is the norm. Second, "allowance" policy is the norm. Third, "forbiddance" policy is partially expected.

The results contradict to some intuitions. First, intuition may tell us that negative externality is harmful to customers' utility and service provider's revenues. Thus, it is favorable to eliminate the externality. In this paper, "forbiddance" policy that eliminates the annoying behavior is not always optimal. When the externality-loving segment is large enough, it's optimal to adopt "allowance" policy to delight this segment.

Second, intuition may tell us meeting the preference of the majority of customers brings the most revenues. In this paper, the intuition may guide to the wrong way especially when "forbiddance" policy is the norm. Besides, we propose three simple decision support figures for service providers.

(Keywords : Internet Marketing; Electronic Commerce Management; Service Operations on the Web; Network Externality)

## 1. Introduction

### 1.1 Externalities in Online Interactive Service Industries

Online interactive services include at least online games, online auctions, and online chat rooms. In these industries, the customers' utility is mainly from the online interactive service received but the presence or behavior of other customers in the same system will affect it [8] [12]. In online games, chatting answers of quests may reduce other players' fun in quest solving. In online auctions, exaggerate overpricing may waste potential buyers' time. In online chat rooms, commercially personal selling may waste users' time if they are not interested. The utility change due to other customers' presence or behavior is called "externality" other customers bring.

Customers may bring positive [9] [12] or negative [8] [12] [14] [16] externalities into the system through various ways. For example, signals of quality, utility of communication [9], congestion [16], competition for resources [14], presence of different social classes [8], or intergroup utility piracy [4]. All means above could alter customers' utility and decision by presence of another individual or another group of customers.

### 1.2 Literature Review

The term "network externality" is generally recognized after the works of [4] and [9]. Network externality in nature is the externality result from equivalent adoption decisions by other customers [4] [9].

The literature of network externality could be categorized into three parts. Economists firstly focus on the positive and direct network externality. Second, the positive and indirect network externality also attracts some attention [1] [2]. Third, the literature [8] that discussed about negative network externality is rather little. In sum, the literature in Economics largely focused on social welfare and less emphasizes the managerial implications than the literature in Management Sciences.

Literature in Management Sciences focuses on negative network externalities. If the service provider ignores the congestion externality, the problem of unexpected congestion may emerge. The utilization rate may deviate from optimality [16].

Besides, Metcalfe's Law should be modified, because the utility of each link between customers may not always be symmetric, positive, and even existing. One trial shows that the monopolistic system owner may overprice, overestimate revenues, and wrongly focuses on too more customers with negative network externality ignored [4]. Generally speaking, network externalities are far less studied in Management Sciences.

### 1.3 The Purpose of This Paper

This paper aims to find the optimal online interactive service policy (to forbid or to allow) and pricing decision with the existence of forbidable annoying behavior in three sections (Section 3, 4, and 5). First, "forbiddance" policy is the norm. Second, "allowance" policy is the norm. Third, "forbiddance" policy is partially expected.

This paper also examines two intuitions. First, intuition may tell us that negative externality is harmful to customers' utility and service provider's revenues. Thus, it is favorable to eliminate the externality. Second, intuition may tell us meeting the preference of the majority of customers brings the most revenues.

The first intuition obviously undervalues the externality-loving customers. When externality-loving customers are willing to pay a higher price, it's possibly more favorable to accommodate externality-loving customers only.

The second intuition neglects the alternative only serving a smaller group of customers. The alternative may generate more revenues when the group alone can fill the capacity completely and pay a higher price for preferred policy (forbiddance to externality-hating customers and allowance to externality-loving customers).

#### 1.4 The Importance of The Topic

The topic is rather important in industries such as online games, online auctions, and online chat rooms, because various behaviors may create externality in customers' interactions. For example, exaggerate overpricing in online auctions may waste potential buyers' time and greatly reduce their utility and then affect their choices among similar service providers. Furthermore, should the online interactive service provider allow the occurrence of annoying behavior or forbid that? It's an interesting problem not solved yet but contributes a lot to practitioners' decision making.

#### 1.5 Comparison with Past Literature

Compared with past literature, the paper configures that there are two groups of customers having different quality recognition and that is different from only one group of customers having same quality recognition [10]. Models including different tastes may describe the reality more precisely.

The externality-loving customers may cause no externality (to externality-hating customers) if they are forbidden to do the annoying behavior. That is different from externality due to other customers' presence [14] [16]. The configuration in this paper is proper to describe marketing situations.

The externality-loving customers were once treated as "pests" and they generate rather few revenues to service provider [4]. In this paper, the externality-loving customers were treated as normal customers generating the same revenues as externality-hating customers if no annoying behavior real takes place.

The paper points out a new source of negative externality among customers: annoying behavior. That is, the externality is accompanied with the annoying behavior of the externality-loving customers. In online games, the answer-chatting customers may reduce other quest-solving customers' fun. The externality does not come from the presence of the answer-chatting customers, but from the annoying behavior "chatting the answer" they do.

The issue of optimal policy and pricing decision is rarely addressed in the past literature.

#### 1.6 The Organization of the Paper

The remainder of the article is organized in five sections. Section 2 describes the model. Section 3 analyzes the optimal policy and pricing decision when

forbiddance is the norm. Section 4 analyzes the optimal policy and pricing decision when allowance is the norm. Section 5 is the generalization of Section 3 and 4. Then conclusion and future research opportunities are drawn.

## 2. Model

### 2.1 Online interactive service System and Customer Segmentations

The online interactive service provider is configured as a monopolist. This paper segments the customers into two groups. One group is composed of externality-hating customers who are represented as A-group customers and the other group is composed of externality-loving customers who are represented as B-group customers.

### 2.2 Price and Utility

The online interactive service provider only can set a single price toward two groups of customers and simultaneously set the policy (to forbid or to allow). Every customer's utility is zero if he (she) chooses not to join in the online interactive service system. Implying that every customer would join in the system if and only if his (her) utility could be nonnegative in the online interactive service system. Every customer joining in the system obtains utility (represented by  $S$  in the model) and pays the price (represented by  $P$  in the model).

Many factors may be considered and expected by customers [11] but the paper addresses utility change due to forbiddance or allowance of annoying behavior. "Desired" and "adequate" are two service levels [17]. The former is the satisfactory level and the latter is not-dissatisfactory level. Based on the two concepts, three sections and corresponding configurations are described:

In Section 3, "forbiddance" is the norm. B-group customers treat "forbiddance" as adequate and treat "allowance" as desired. Therefore, B-group customers obtain additional utility (denoted by  $E$ ) doing annoying behavior under the "allowance" policy. Analysis is done in Section 3.

In Section 4, "allowance" is the norm. B-group customers take "allowance" as adequate. Therefore, no additional utility would be received since annoying behavior is not a privilege but taken for granted. On the contrary, B-group customers would lose some utility (denoted by  $E$ ) if the annoying behavior were forbidden. Analysis is done in Section 4.

In Section 5, "forbiddance" policy is adopted by only a part of the industry and the remaining part set "allowance" policy. B-group customers may set a reference point between "forbiddance" and "allowance" policies. To be more specific, B-group customers obtain additional utility (denoted by  $e_1$ ) facing "allowance" policy and lose utility (denoted by  $e_2$ ) facing "forbiddance" policy. Analysis is done in Section 5.

Here,  $(e_1 + e_2)$  is assumed to be equal to  $E$  because the same behavior offers the same utility (denoted by  $E$ ) to B-group customers regardless of the norms of the industries. The configurations of three sections are showed in Table I.

**Table 1 : Configuration of three sections**

Utility Policy Section	B-group customers' utility		A-group customers' utility	
	Forbiddance	Allowance	Annoying behavior takes place	Otherwise
Section 3	S	S+E	$S - N * N_n$	S
Section 4	$S - E$	S	$S - N * N_n$	S
Section 5	$S - e_2$	$S + e_1$	$S - N * N_n$	S

For example, there are 3 B-group customers doing annoying behavior in the system and every A-group customer's utility is  $S - P - 3N_n$  and every B-group customer's utility is  $S - P + E$  (under the setting of Section 3). The utilities from different sources are additive and that is common in model configurations [7] [13].

**2.3 Notations and Variables**

- Notations used in the model are as follows:
- S: every customer's utility from the online interactive service system
- E: the utility difference between to do and not to do annoying behavior for any B-group customer
- $N_n$ : the utility reduction for any A-group customer facing per B-group customer doing annoying behavior
- M: the number of A-group customers
- N: the number of B-group customers
- P: the single price charged to every customer
- C: the capacity of the online interactive service provider
- FO: the policy "forbiddance"
- AL: the policy "allowance"

Section 3, 4, 5 manipulate the utility addition and subtraction those due to forbiddance or allowance of can/cannot doing annoying behavior for B-group customers. The policy and price set by the online interactive service provider are decision variables and the "join-or-not" decisions made by customers are endogenous variables. The revenue received by the online interactive service provider is the main dependent variable.

S, E,  $N_n$  are given positive numbers and M, N, C are given positive integers. Furthermore, P is restricted to be positive.

If the customers choose in sequence, then  $A_i$  is denoted to the  $i^{th}$  customer choosing in A-group customers and  $B_j$  is denoted to the  $j^{th}$  customer choosing in B-group customers.

**2.4 Procedure of the Events**

The scenarios to be discussed all follow the same procedure of the events:

First, the online interactive service provider sets the behavior policy as "forbiddance" or "allowance" and meanwhile sets a single price to every customer.

Second, all B-group customers as a whole choose whether to join the service system or not. (This could be relaxed at 2.5)

Third, all A-group customers as a whole choose whether to join the service system or not. (This could be relaxed at 2.5)

Fourth, all customers obtain the utility they perfectly expect and the service provider collects the revenues.

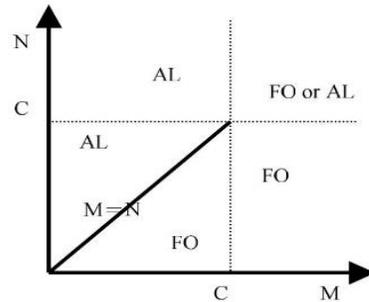

**2.5 The Irrelevance of Choice Sequence among Customers**

In 2.4, B-group customers are assumed to choose simultaneously and make the same decision. After B-group customers' choices, A-group customers are assumed to choose simultaneously and make the same decision.

In 2.5, we prove that same-group customers all make the same decision (to join or not) under any choice sequence in Appendix.

**2.6 Intuition to be Examined**

In intuitions, the online interactive service provider should meet the preference of the majority. When each segment alone can fill the capacity completely, meeting preference of either one segment is equally optimal. Figure 1 illustrates the thinking.

**Figure 1 : The optimal policy in intuition**

In Figure 1, 2, 3, and 4, "AL" is assigned when the optimal policy is "allowance" and "FO" is assigned when the optimal policy is "forbiddance". "FO or AL" is assigned when both policies are equally optimal.

**3. "Forbiddance" Policy is the Norm**

In online games, online auctions, and online chat rooms, most service providers forbid cheating and threatening. Every customer knows the norm and takes "forbiddance" policy as granted.

B-group customers thus obtain "normal" utility (denoted by S) without doing the behavior they love, but B-group customers' utility may increase (denoted by E) if they are permitted to do the behavior.

In this setting, every B-group customer's utility is always no less than every A-group customer's utility. This is tabularized in Table 2.

**Table 2 : The utility settings in Section 3**

Utility Policy Group	Forbiddance	Allowance	
		With B-group	Without B-group
A	S	$S - N * N_n$	S
<b>B</b>	<b>S</b>	<b>S + E</b>	

Since every B-group customer's utility is always no less than every A-group customer's utility, it's impossible

only to attract A-group customers through behavior policy and pricing decision. This is proved in Lemma 3.

*Lemma 3 :*

When “forbiddance” is the norm, the online interactive service provider cannot only attract A-group customers only through behavior policy and pricing decision.

**Proof:**

According to Table 2, it’s obvious that under any policy the reservation price of B-group customers is always no smaller than the reservation price of A-group customers. Thus, no price exceeds the reservation price of B-group customers but at the same time not exceeds the reservation price of A-group customers. Lemma 3 is proved.

With Lemma 3 proved, the online interactive service provider should treat B-group customers as the main segment and try to serve them in the first priority.

Because the sizes (denoted by M, N) of two groups of customers and the capacity (denoted by C) of the online interactive service provider are relevant factors in decision-making, three scenarios incorporating the factors are presented in Table 3 and guide the following analysis.

**Table 3 : The parameter settings in Section 3**

Scenario 1	$N \geq C$ and $M + N \geq C$
Scenario 2	$N < C$ and $M + N \geq C$
Scenario 3	$N < C$ and $M + N < C$

### 3.1 Scenario 1 : $N \geq C, M + N \geq C$

In scenario 1, the capacity could be filled completely only by B-group customers. Thus, the online interactive service provider should adopt “allowance” policy to meet B-group customers’ preference and charge them a higher price.

*Theorem 1 :*

When “forbiddance” is the norm and  $N \geq C$ , the optimal policy is “allowance” and the optimal price is  $P = S + E$ .

**Proof:**

When “allowance” policy is adopted, the price can be set at  $P = S + E$ , which is the reservation price of B-group customers. The system could only attract B-group customers to completely fill the capacity. Thus, the revenues would be  $C*(S + E)$ .

When “forbiddance” policy is adopted, the price can be set at  $P = S$ , which is the minimum of the reservation prices of both groups of customers. The system could attract both groups of customers to completely fill the capacity. Thus, the revenues would be  $C*S$ .

For  $C*(S + E) > C*S$ , the optimal policy is “allowance” and the optimal price is  $P = S + E$ . Theorem 1 is proved.

The managerial implication of Theorem 1 is further discussed. When B-group customers alone can

completely fill the capacity, the online interactive service provider should only meet B-group customers’ preference and charges them a higher price for the policy they prefer.

### 3.2 Scenario 2 : $N < C, M + N \geq C$

In scenario 2, the capacity could *not* be filled completely by only B-group customers, but could be filled completely by two groups of customers. Thus, the online interactive service provider should set the price to balance the additional revenues from attracting A-group customers and the additional loss from lowering price to attract A-group customers.

*Theorem 2.1*

Under the setting “forbiddance” is the norm and  $N < C$  and  $M + N \geq C$ . When  $N > \frac{CS}{S + E}$ , the optimal policy is “allowance” and the optimal price is  $P = S + E$ .

*Theorem 2.2*

Under the setting “forbiddance” is the norm and  $N < C$  and  $M + N \geq C$ . When  $N < \frac{CS}{S + E}$ , the optimal policy is “forbiddance” and the optimal price is  $S$ .

**Proof:**

When “allowance” policy is adopted, the price can be set at  $P = S + E$ , which is the reservation price of B-group customers. The system could only attract B-group customers to fill part of the capacity. Thus, the revenues would be  $N*(S + E)$ .

When “allowance” policy is adopted, the price can be set at  $P = S - N*N_n$ , which is the minimum of the reservation prices of both groups of customers. The system could attract both groups of customers to completely fill the capacity. Thus, the revenues would be  $C*(S - N*N_n)$ .

When “forbiddance” policy is adopted, the price can be set at  $P = S$ , which is the minimum of the reservation prices of both groups of customers. The system could attract both groups of customers to completely fill the capacity. Thus, the revenues would be  $C*S$ .

For  $C*S > C*(S - N*N_n)$ , the optimal policy and pricing decision only depends on whether  $C*S$  is larger than  $N*(S + E)$ .

If  $N > \frac{CS}{S + E}$ , the optimal policy is “allowance” and the optimal price is  $P = S + E$ . Theorem 2.1 is proved.

If  $N < \frac{CS}{S + E}$ , the optimal policy is “forbiddance” and the optimal price is  $P = S$ . Theorem 2.2 is proved.

When the size (denoted by N) of B-group customers is smaller than the capacity (denoted by C), Theorem 2 may apply. The optimal policy and pricing decision could be judged by comparing the gain from attracting more customers (M of A-group customers) and the loss from

lowering price to attract the additional customers. When the gain is larger than the loss, it's optimal to set policy as "forbiddance" and set the price  $P = S$  to attract both groups of customers. Otherwise, it's optimal to set policy as "allowance" and set the price  $P = S + E$  only to attract B-group customers even the capacity is only partially filled.

### 3.3 Scenario 3 : $M < C, N < C, M + N < C$

In scenario 3, the size of the whole market is below the capacity. As a result, each group of customers cannot completely fill the capacity.

#### Theorem 3.1

Under the setting "forbiddance" is the norm and  $M + N < C$ . When  $M * S < N * E$ , the optimal policy is "allowance" and the optimal price is  $P = S + E$ .

#### Theorem 3.2

Under the setting "forbiddance" is the norm and  $M + N < C$ . When  $M * S > N * E$ , the optimal policy is "forbiddance" and the optimal price is  $P = S$ .

Proof:

When "allowance" policy is adopted, the price can be set at  $P = S + E$ , which is the reservation price of B-group customers. The system could only attract B-group customers to fill part of the capacity. Thus, the revenues would be  $N * (S + E)$ .

When "allowance" policy is adopted, the price can be set at  $P = S - N * N_n$ , which is the minimum of the reservation prices of both groups of customers. The system could attract both groups of customers to fill still only part of the capacity. Thus, the revenues would be  $(M + N) * (S - N * N_n)$ .

When "forbiddance" policy is adopted, the price can be set at  $P = S$ , which is the minimum of the reservation prices of both groups of customers, to attract both groups of customers to fill still only part of the capacity. Thus, the revenues would be  $(M + N) * S$ .

For  $(M + N) * S > (M + N) * (S - N * N_n)$ , the optimal policy and pricing decision only depends on whether  $(M + N) * S$  is larger than  $N * (S + E)$ .

When  $M * S < N * E$ , the optimal policy is "allowance" and the optimal price is  $P = S + E$ . Theorem 3.1 is proved.

When  $M * S > N * E$ , the optimal policy is "forbiddance" and the optimal price is  $P = S$ . Theorem 3.2 is proved.

Theorems 3.1 and 3.2 have their managerial meaning. If the gain were larger than the loss, "allowance" policy would be optimal. Otherwise, "forbiddance" policy would be optimal.

The analytical result of Theorem 1~3.2 are combined to form Figure 2.

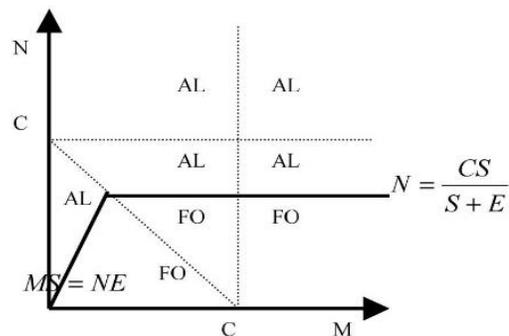

Figure 2 : The optimal policy when "forbiddance" policy is the norm

Comparing Figure 2 with Figure 1, it's surprising that the policy and pricing decision made by intuition could deviate from optimality when  $M > C$  or  $N < C$ .

## 4. "Allowance" Policy is the Norm

In online games, online auctions, and online chat rooms, most service provider allow customers idle and not respond to others' inquiry. Every customer knows the norm and takes "allowance" policy as granted.

Now B-group customers treat "allowance" policy as the baseline and the right they own. Therefore, B-group customers' utility drops to  $S - E$  facing "forbiddance" policy. Thus, B-group customers' utility is no less than A-group customers' utility facing "allowance" policy, but B-group customers' utility is less than A-group customers' utility facing "forbiddance" policy. The utility setting is tabularized as Table 4.

Table 4 : The utility settings in Section 4

Utility Policy Group	"Forbiddance" policy	"Allowance" policy	
		With B-group customers	Without B-group customers
A	S	$S - N * N_n$	S
B	$S - E$	S	

Five scenarios, which regard the relative sizes of  $M$  and  $N$  and  $C$ , are analyzed to find the optimal policy and pricing decision. Table 5 could illustrate the settings of five scenarios.

Table 5 : The parameter settings in Section 4

Scenario	Parameter Settings
Scenario 1	$M \geq C, N \geq C, \text{ and } M + N \geq C$
Scenario 2	$M \geq C, N < C, \text{ and } M + N \geq C$
Scenario 3	$M < C, N \geq C, \text{ and } M + N \geq C$
Scenario 4	$M < C, N < C, \text{ and } M + N \geq C$
Scenario 5	$M < C, N < C, \text{ and } M + N < C$

### 4.1 Scenario 1 : $M \geq C, N \geq C, M + N \geq C$

In scenario 1, each group of customers alone can fill the capacity completely. Both "forbiddance" and "allowance" policy are optimal.

#### Theorem 4

When “allowance” policy is the norm and  $M \geq C$  and  $N \geq C$ , both “allowance” and “forbiddance” policies are optimal and the optimal price is  $P = S$ .

Proof:

The proof of Theorem 4 is similar to the proofs in Section 3.

According to Theorem 4, targeting on each group of customers could reach the optimality when each group alone can completely fill the capacity.

#### 4.2 Scenario 2 : $M \geq C, N < C, M + N \geq C$

In scenario 2, A-group customers alone can completely fill the capacity. The optimal policy is “forbiddance” and the optimal price is  $P = S$ .

Theorem 5

When “allowance” policy is the norm and  $M \geq C$  and  $N < C$ , the optimal policy is “forbiddance” and the optimal price is  $P = S$ .

The proof of Theorem 5 is similar to the proofs in Section 3.

Further, the implication of Theorem 5 is discussed. When A-group customers alone can completely fill the capacity, it’s optimal to adopt “forbiddance” policy and set the price  $P = S$ . That is, focusing on A-group customers could generate the maximal revenues.

#### 4.3 Scenario 3 : $M < C, N \geq C, M + N \geq C$

In scenario 3, B-group customers alone can completely fill the capacity. The optimal policy is “allowance” and the optimal price is  $P = S$ . The argument is proved in Theorem 6.

Theorem 6

When “allowance” policy is the norm and  $M < C$  and  $N \geq C$ , the optimal policy is “allowance” and the optimal price is  $P = S$ .

The proof of Theorem 6 is similar to the proofs in Section 3.

According to Theorem 6, it’s optimal to set policy as “allowance” and set price as  $P = S$  to focus on B-group customers when only B-group customers can completely fill the capacity.

#### 4.4 Scenario 4 : $M < C, N < C, M + N \geq C$

In scenario 4, each group of customers can only fill part of the capacity. Both groups of customer can completely fill the capacity. Now, the policy and pricing decisions and their corresponding revenues are as Table 6.

**Table 6 : The policy and pricing decisions and their corresponding revenues in scenario 4 in Section 4**

Decision Combination			
Number	Policy	Pricing	Revenues
1	Allowance	$P = S$	$N * S$
2	Allowance	$P = S - N * N_n$	$C * (S - N * N_n)$

3	Forbiddance	$P = S$	$M * S$
4	Forbiddance	$P = (S - E)$	$C * (S - E)$

The optimal policy and pricing decision combination is the one leading to the maximal revenues.

#### 4.5 Scenario 5 : $M < C, N < C, M + N < C$

In scenario 5, each group of customers can only fill part of the capacity. Even both groups of customers cannot completely fill the capacity. Now, the policy and pricing decisions and their corresponding revenues are as Table 7.

**Table 7 : The policy and pricing decisions and their corresponding revenues in scenario 5 in Section 4**

Decision Combination			
Number	Policy	Pricing	Revenues
1	Allowance	$P = S$	$N * S$
2	Allowance	$P = S - N * N_n$	$(M + N) * (S - N * N_n)$
3	Forbiddance	$P = S$	$M * S$
4	Forbiddance	$P = (S - E)$	$(M + N) * (S - E)$

The optimal policy and pricing decision combination is the one leading to the maximal revenues.

Theorem 7.1

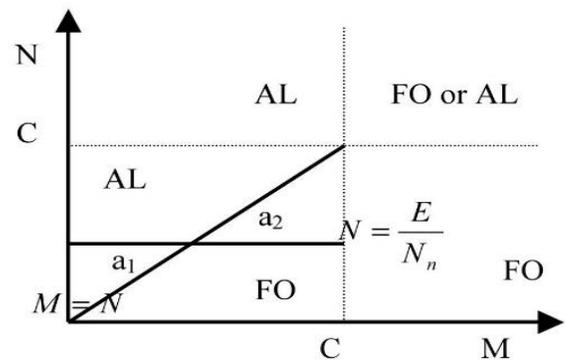

Under the setting allowance is the norm and  $M < C$  and  $N < C$ . When  $N > M$  and  $N < \frac{E}{N_n}$ , the optimal policy is “allowance”.

Theorem 7.2

Under the setting allowance is the norm and  $M < C$  and  $N < C$ . When  $N < M$  and  $N > \frac{E}{N_n}$ , the optimal policy is “forbiddance”.

The proofs of Theorems 7.1 and 7.2 are similar to the proofs in Section 3.

The analytical result of Theorem 4~7.2 are combined to form Figure 3.

**Figure 3 : The optimal policy when “allowance” policy is the norm**

It's interesting that intuition applies well in most cases except the two areas:  $a_1$  and  $a_2$  in Figure 3; e.g. in area  $a_1$ , "forbiddance" policy is optimal when  $(M+N)*(S-E) > N*S$ . The case is contradictory to intuition.

When "allowance" policy is the norm, the intuition (see Figure 1) applies well in most cases. However, the possibility of misjudgment of policy and pricing decision still exists when  $M < C$  and  $N < C$ .

### 5. "Forbiddance" Policy is Partially Expected (Generalization of 3. and 4.)

Some customers may seek others' personal data in their interest. In online games, online auctions, and online chat rooms, some service providers forbid the behavior and others allow that. Thus, customers take neither "forbiddance" nor "allowance" policy as granted. This reality in practice is called "partially expected" in this paper.

B-group customers facing "allowance" policy would feel better to be allowed to do the behavior they love. In the model, B-group customers' utility would raise (denoted by  $e_1$ ) when B-group customers face "allowance" policy.

On the other hand, B-group customers facing "forbiddance" policy would feel somehow disappointed to be forbidden to do the behavior they love. In the model, B-group customers' utility would drop (denoted by  $e_2$ ) when B-group customers face "forbiddance" policy.

The value of  $e_1+e_2$  is assumed to be equal to  $E$  for the same utility due to the same behavior.

Section 3 is a special case of Section 5 by setting  $e_1 = E$  and  $e_2 = 0$ . Also, the Section 4 is another special case of Section 5 by setting  $e_1 = 0$  and  $e_2 = E$ . Thus, Section 5 is the generalization of Section 3 and 4. Those are shown in Table 8.

**Table 8 : The utility settings in Section 5.**

Utility Group	Policy	"Forbiddance" policy	"Allowance" policy	
			With B-group customers	Without B-group customers
A		S	$S - N*N_n$	S
B		$S - e_2$	$S + e_1$	

Five scenarios, which regard the relative sizes of  $M$  and  $N$  and  $C$ , are analyzed to find the optimal policy and pricing decision. Table 9 could illustrate the settings of five scenarios.

**Table 9 : The parameter settings in Section 5**

Scenario 1	$M \geq C, N \geq C, \text{ and } M + N \geq C$
Scenario 2	$M \geq C, N < C, \text{ and } M + N \geq C$
Scenario 3	$M < C, N \geq C, \text{ and } M + N \geq C$
Scenario 4	$M < C, N < C, \text{ and } M + N \geq C$
Scenario 5	$M < C, N < C, \text{ and } M + N < C$

#### 5.1 Scenario 1 : $M \geq C, N \geq C, M + N \geq C$

In scenario 1, each group of customers alone can completely fill the capacity. It's optimal to adopt "allowance" policy to attract B-group customers and set price at  $P = S + e_1$ .

#### Theorem 8

When "forbiddance" is partially expected and  $M \geq C$  and  $N \geq C$ , the optimal policy is "allowance" and the optimal price is  $P = S + e_1$ .

The proof of Theorem 8 is similar to the proofs in Section 3.

Further, the implication of Theorem 8 is discussed. Although meeting preference of either group of customers could completely fill the capacity, it's optimal to meet B-group customers' preference for their high utility perceived ( $S + e_1 > S$ ).

#### 5.2 Scenario 2 : $M \geq C, N < C, M + N \geq C$

In scenario 2, A-group customers alone can completely fill the capacity.

##### Theorem 9.1

Under the setting "forbiddance" is partially expected and  $M \geq C$  and  $N < C$ . When  $N > \frac{CS}{S + e_1}$ , the optimal policy is "allowance" and the optimal price is  $P = S + e_1$ .

##### Theorem 9.2

Under the setting "forbiddance" is partially expected and  $M \geq C$  and  $N < C$ . When  $N < \frac{CS}{S + e_1}$ , the optimal policy is "forbiddance" and the optimal price is  $P = S$ .

The proofs of Theorems 9.1 and 9.2 are similar to the proofs in Section 3.

Theorems 9.1 and 9.2 could be applied in situations that market is divided into a high-end segment with fewer customers and a low-end segment with more customers. In such situations, only attracting one group of the two groups of customers is optimal by serving the high-end segment and charging them a higher price or serving the low-end segment and charging them a lower price. It's worthy to pay attention that the model applies most when the high-end customers would do some annoying behavior to reduce low-end customers' utility.

#### 5.3 Scenario 3 : $M < C, N \geq C, M + N \geq C$

In scenario 3, B-group customers alone can completely fill the capacity.

##### Theorem 10

When "forbiddance" is partially expected and  $M < C$  and  $N \geq C$ , the optimal policy is "allowance" and the optimal price is  $P = S + e_1$ .

The proof of Theorem 10 is similar to the proofs in Section 3.

#### 5.4 Scenario 4 : $M < C, N < C, M + N \geq C$

In scenario 4, each group of customers alone can only fill part of the capacity. Both groups of customers can completely fill the capacity. Now, the policy and pricing decisions and their corresponding revenues are as Table 10.

**Table 10 : The policy and pricing decisions and their corresponding revenues in scenario 4 in Section 5**

Decision Combination			
Number	Policy	Pricing	Revenues
1	Allowance	$P = S + e_1$	$N^*(S + e_1)$
2	Allowance	$P = S - N^*N_n$	$C^*(S - N^*N_n)$
3	Forbiddance	$P = S$	$M^*S$
4	Forbiddance	$P = S - e_2$	$C^*(S - e_2)$

The optimal policy and pricing decision combination is the one leading to the maximal revenues.

### 5.5 Scenario 5 : $M < C, N < C, M + N < C$

In scenario 5, each group of customers alone can only fill part of the capacity. Even both groups of customers cannot completely fill the capacity. Now, the policy and pricing decisions and their corresponding revenues are as Table 11.

**Table 11 : The policy and pricing decisions and their corresponding revenues in scenario 5 in Section 5**

Decision Combination			
Number	Policy	Pricing	Revenues
1	Allowance	$P = S + e_1$	$N^*(S + e_1)$
2	Allowance	$P = S - N^*N_n$	$(M + N)^*(S - N^*N_n)$
3	Forbiddance	$P = S$	$M^*S$
4	Forbiddance	$P = S - e_2$	$(M + N)^*(S - e_2)$

The optimal policy and pricing decision combination is the one leading to the maximal revenues.

#### Theorem 11.1

Under the setting forbiddance is partially expected and  $M < C$  and  $N < C$ . When  $N > \frac{MS}{S + e_1}$  and

$$N < \frac{e_2}{N_n}, \text{ the optimal policy is "allowance".}$$

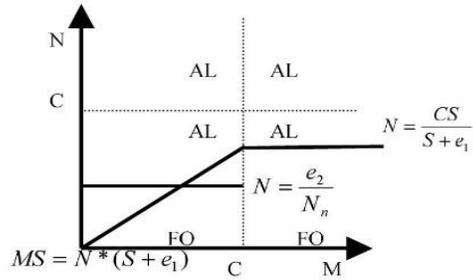

#### Theorem 11.2

Under the setting forbiddance is partially expected and  $M < C$  and  $N < C$ . When  $N < \frac{MS}{S + e_1}$  and

$$N > \frac{e_2}{N_n}, \text{ the optimal policy is "forbiddance".}$$

The proofs of Theorems 11.1 and 11.2 are similar to the proofs in Section 3.

The analytical result of Theorem 8~11.2 are combined to form Figure 4.

**Figure 4 : The optimal policy when forbiddance policy is partially expected**

It's surprising that the policy and pricing decision made by intuition (Figure 1) could deviate from optimality when  $M > C$  and  $N < C$ . Besides, "allowance" policy could be optimal even when the externality-hating segment (denoted by M) is larger than the externality-loving segment (denoted by N) and the capacity (denoted by C).

## 6. Conclusion

When customers in reality are of two distinct groups with opposite preferences, following the intuition (Figure 1) to accommodate the majority may not guide the decision toward optimality. By comparing Figure 1 with Figure 2, 3,4 we know that intuition applies well only in limited situations.

This paper improves policy and pricing decisions and presents three decision support figures (Figure 2, 3, 4). It's convenient to judge the optimal policy (to allow or to forbid) and corresponding optimal price with the three figures when parameters' values are known.

The results contradict to some intuitions. First, intuition may tell us that negative externality is harmful to customers' utility and service provider's revenues. Thus, it is favorable to eliminate the externality. In this paper, "forbiddance" policy that eliminates the annoying behavior is not always optimal. When the externality-loving segment is large enough, it's optimal to adopt "allowance" policy to delight this segment.

Second, intuition may tell us meeting the preference of the majority of customers brings the most revenues. In this paper, the intuition may guide to the wrong way especially when "forbiddance" policy is the norm.

This paper conforms to recent empirical researches and also manifests its uniqueness. [12] pointed out that externality caused by customers' behavior is related with situation context ("allowance" policy or "forbiddance" policy). The paper is a trial to incorporate Martin's opinion into model analysis. This paper bases on "customer-centric" concept [15] to analyze the influence of service policy on customers' utility. The presented model includes conflicting attributes (opposite preferences) as [3] and addresses the importance to understand customers' characteristics and needs as [6].

There are some future research possibilities. First, the model can be extended to the two online interactive service providers' case and the game theory would apply to offer more insights of the issue in competitions.

Second, the assumption that A-group customers all know the choice behavior of B-group customers can be relaxed to see the effects of imperfect information.

# Use of Graphic Images and Text Characters in Internet Banners as an Effective Marketing Tool

Eric Kin Wai Lau

Faculty of Business

City University of Hong Kong

Hong Kong, China

mgeric@cityu.edu.hk

## Abstract

Participants were presented with a list of Internet banners and asked to perform a series of matching tasks to test the effectiveness of using graphic images as compared with verbal characters in web-site banners for e-marketing purposes. Participants studied ten different web pages. The web banners consisted of image or characters that had some degree of linkage to the corresponding web contents. Results show that: (a) participants have a greater ability to match web contents if banners are relevant to the web page contents; (b) contextual cues can be enriched by the context of the images used in the web banners; (c) frequent web surfers are less likely to recall web banners than normal web users. These findings are discussed in light of research on the effect of “picture superiority” and “semantic coding” on memory of pictures and words. This study concluded that the selection of graphic elements in web banners is important to an effective e-marketing strategy.

## 1. Introduction

The Internet has provided many opportunities for marketers, and a countless number of different online advertisements can be found on web sites. Companies have experimented with the use of various graphic-oriented web components, such as banners and animated images, to capture the attention of busy web visitors. Previous research efforts have focused primarily on the importance of the Internet as a marketing tool. Only a few studies have been undertaken to identify the effectiveness of different graphic-oriented web components— that is, the graphics and characters used in advertisements. This study therefore attempts to address the importance of memory for pictures, as developed in earlier research, and examines how tracking online consumer behavior allows companies to design their web pages such that can they capture the attention of web users in more effective ways.

## 2. Cues from pictures and characters

Studies have found that people can recall pictures much better than words [1][5][7]. The most influential contribution to the discussion about the effectiveness of people’s pictorial memory was presented by Bower, Karlin, & Dueck (1975) [1]. They found that participants recalled pictures better if they achieved a meaningful interpretation of the picture used in the experiment. In their first experiment, a group of 18 undergraduates was divided into two groups— designated ‘label’ and ‘no-label’ groups. All participants were asked to study a series of 28 simple doodled pictures. Appropriate interpretation was given by the experimenter to the ‘label’ group, whereas no interpretation was given to the ‘no-label’ group. The results of the experiment indicated that the ‘label’ group did better in recalling the pictures than the ‘no-label’ group. In the second experiment, Bower, Karlin, & Dueck (1975) [1] tried to test the participants’ ability for associative matching. Doodle pairs were shown to the participants once, and the experimenter then asked the participants to match the corresponding pairs. Again, the ‘label’ group did better than the ‘no-label’ group in the matching exercise.

Similarly, Rafnel & Klatzky (1978) [6] found that semantic encoding of a picture can be facilitated by a meaningful label. Three separate experiments were conducted to test the effect of meaningful interpretation on participants’ memory for nonsense pictures. In each test, the participants’ retention was assessed by a recognition test with certain distractors. It was found that the physical appearance of the pictures shown to participants did not help them in recalling meaningless pictures. However, the experimenters found that participants did recall meaningful pictures better. The findings indicated that the semantic interpretation of a picture enhances semantic coding, rather than the physical coding.

From the more recent experiments conducted by Dewhurst & Conway (1994) [2], it was suggested that encoding conditions in sensory-perceptual and semantic

processing affect recall ability. Five experiments were conducted to investigate whether pictures can provide rich information for sensory-perceptual coding, rather than the conceptual representation of texts. Findings were consistent with the previous studies— that is, that picture superiority effect was found in meaningful pictures as compared with nonsense pictures.

Several factors affect picture superiority. From the sensory-semantic model proposed by Nelson, Reed, & McEvoy (1977) [4], picture superiority takes place only in certain conditions. These conditions are: (a) pictures that pose more distinctive sensory codes than words; and (b) pictures that are more likely to undergo semantic processing than verbal labels. As noted by Durso & Johnson (1980) [3], some studies in the past have failed to yield a picture superiority effect because of a lack of meaningful representation. Therefore, it would seem that people try to assign meaning to what they have seen in order to facilitate recall.

Durso & Johnson (1980) [3] have conducted two experiments to test the validity of the model of Nelson, Reed, & McEvoy (1977) [4]. The first experiment tried to identify the effect of different orienting tasks on the subsequent recognition of concepts presented in either graphic or verbal form. Participants were presented with a list of pictures and words, and were then required to perform certain tasks which tested for an association between the pictures and words, with or without defined concepts. The findings were compatible with the sensory-semantic model, in which the sensory distinctiveness of pictures and the ability to perform semantic processing were enhanced by pictures with a greater picture superiority effect.

### 3. Research objectives

The research presented in this paper investigated the ability to recall graphic and verbal elements used in web pages. Two general research questions emerged from the literature review of the previous section. These were:

1. Does the picture superiority effect extend to Internet web pages?
2. Do the participant's characteristics (such as the level of web usage and gender) affect the assertiveness of graphic elements used in web pages?

Regarding the first question, it was hypothesized that meaningful graphic contexts used in web pages can capture a participant's attention on a given web page better than can verbal elements. For the second research question, it was hypothesized that a participant's characteristics (such as the level of web usage, age, and gender) do not influence the memory structures (that is, the schemata) that are accessed during the initial perception and encoding of a message received from a shown web page.

## 4. Method

### 4.1 Participants

Participants were 136 part-time MBA students from two universities in Hong Kong. They included 58 participants studying the interactive MBA program, in which much of the course materials are provided on the world wide web. All participants were volunteers for this study. They were assumed to have a similar cultural pattern, but different individual levels of usage of the Internet. However, all were asked to undertake a short Internet 'basic knowledge' test. This established that all participants were fully capable of using the Internet. The mean age of participants was 36.11. A total of 136 participants (89 male, 47 female) were tested.

### 4.2 Stimulus materials

The stimuli consisted of thirty web banners downloaded from various local and international web sites (for example, amazon.com; 30.com; ebay.com; and so on). The major business conducted by these web sites included online shopping, electronic banking, online auction, online newspapers, and search engines. Based on the web banner used in the web sites, they were divided into three categories of stimuli— (i) a purely verbal banner; (ii) a nonsense graphic banner; and (iii) a graphic banner with direct linkage to the particular web site's contents.

### 4.3 Procedure

The study was based on the research designs developed by Bower, Karlin, & Dueck (1975) [1], with some modification for the application of the two research questions noted above. All participants were given a brief introduction regarding the objectives of this study. The experimenter then presented a set of web pages with corresponding web banners. Participants had 30 seconds to look at each web page. After looking at the web pages, all participants continued their regular lesson. In the next class— that is, a week after the initial stage of the experiment— they were asked to recall each of the web banners presented to them, and were asked to match the recalled pages with the corresponding web contents by a paper-and-pencil matching exercise. Additional web banners were included in the matching exercise— that is, web banners and web pages that had not been previously presented to the participants. On the first page of the matching exercise was a statement instructing participants on how to complete the matching exercise. They were given 15 minutes to complete the matching. No discussion among participants was allowed.

## 5. Results

The simple student's *t*-statistic (*t*-test) was used to compare the differences in the mean scores for the two research questions. Results for the first research question were dramatic. Table 1 shows that participants were far less likely to recall and match nonsense graphic web banners with the corresponding web pages than meaningful graphic web banners and verbal web banners. On average, each participant correctly matched 4.56 pieces of nonsense graphic web banners, compared with 9.10 pieces of meaningful graphic web banners ( $t = 49.89$ ; d.f. = 135,  $p < 0.001$ ) and 8.01 pieces of verbal web banners ( $t = 35.26$ ; d.f. = 135,  $p < 0.001$ ). Table 1 shows that participants did better in the matching exercise for meaningful graphic web banner than for verbal web banners ( $t = 15.30$ , d.f. = 135,  $p < 0.001$ ).

**Table 1. Means and standard deviations of the scores in the matching exercise for different kinds of web banner**

Category of web banner	N	Mean score	S.D.
Meaningful graphic web banner	136	9.10	1.21
Nonsense graphic web banner	136	4.57	1.30
Verbal web banner	136	8.01	1.26

Not surprisingly, gender did not affect the power of picture superiority. The results showed an insignificant difference between males and females in the matching exercise for meaningful graphic web banners ( $t = -0.172$ ; d.f. 134,  $p > 0.05$ ). Similar results were found for the nonsense graphic banners and the verbal graphic banners (Table 2).

**Table 2. Means and standard deviations of the scores in the matching exercise for different gender group**

Category of web banner	Male			Female		
	N	Mean score	S.D.	N	Mean score	S.D.
Meaningful graphic web banner	89	9.09	1.28	47	9.13	1.10
Nonsense graphic web banner	89	4.65	1.30	47	4.40	1.30
Verbal web banner	89	7.94	1.25	47	8.15	1.30

Note: Means in the same row do not share mean differ at  $p < 0.05$ .

However, the level of web usage did affect recall. It was found that frequent web surfers were most likely to have forgotten what they had seen than were normal web users (Table 3). It was found that frequent web surfers recalled 8.61 pieces of meaningful graphic web banners in the matching exercise, whereas normal users recalled 9.54 pieces of a total of 12 pieces of meaningful graphic web banners ( $t = -4.83$ ; d.f. 134,  $p < 0.001$ ). Similar findings were found for nonsense graphic web banners and verbal web banners (Table 3).

**Table 3. Means and standard deviations of the scores in the matching exercise for different group of web surfers**

Category of web banner	Frequent web surfers			Normal web users		
	N	Mean score	S.D.	N	Mean score	S.D.
Meaningful graphic web banner	64	8.61	1.11	72	9.54	1.14
Nonsense graphic web banner	64	4.11	1.29	72	4.97	1.17
Verbal web banner	64	7.38	1.16	72	8.58	1.07

Note: Means in the same row show mean difference at  $p < 0.001$ .

## 6. Discussion

Two questions guided this study. The first was whether the picture superiority suggested by Bower, Karlin, & Dueck (1975) [1] also applied to web elements. The answer seems to be that it does. The present findings demonstrate that memory of the materials seen by participants depends upon the construction of meaningful interpretations of the web banners as they are viewed. Results from the matching exercise demonstrated that semantic interpretation is a major determinant of how well a person can remember a web banner. Consistent with previous studies for picture superiority, people having meaningful illustrations for the web elements reported a greater successful recall rate.

Secondly, the study asked whether the participant's characteristics (that is, the level of web usage and gender) affect recall of the graphic web elements used. The answer seems to be variable. Frequent web surfers did poorly in the matching exercise for both kinds of web banners they had previously seen. However, the gender variable did not interact with recall on any kinds of the web banner. The latter finding was not in accordance with the body of research which has repeatedly demonstrated differences in recall for female and male.

The online population is growing, and it is clear that the Internet is a multi-segment market channel. It is an increasingly important channel for the deployment of marketing strategies. An effective web element in such strategies is one that creates an attractive presence to its targeted segment. Creating an effective web presence can be critical for firms operating on the web. The findings of this study suggest that e-marketers should take more care in the design of their web pages. People are not pleased with web pages that are purely word-based. As technology develops, more computer animations are

likely to be put on the web. These distinctive web elements should be closely related to the nature and contents of the corresponding web page. This is especially so for web pages that target frequent web surfers. More interactive web elements should be used to capture this market.

## Abstract

The issue of electronic mail (e-mail) communication has attracted much academic attention over the last two decades. Yet, little is known about why people forward emails to others. Through a review of the literature, this paper aims to investigate reasons why people forward emails and proposes several variables related to one's intention of doing so. More specifically, we hypothesize that the higher degree the four possible variables are (the recipient's trust in the email content, the recipient's trust in the senders, intention to staying in touch with friends, and the receivers' altruism trait), the more likely people will forward emails. On the other hand, we hypothesize that the lower degree the two possible variables are (the size of email file, and the cost of forwarding e-mail), the less likely people will forward emails.

Keywords: email communications, trust, trait, Internet marketing

## 1. Introduction

Nowadays, more and more people are using e-mail for their daily communications. According to a recent Nielsen/NetRatings report of 12 countries over the past five months, more than 531 million people are using Internet worldwide and email ranked first among the all the Internet usage. Furthermore, a Net Value survey showed that, the popularity rate of email usage is 69.1% for Taiwanese netusers, ranked first among the four little dragons in Asia, Hong Kong, South Korea and Singapore. In addition to a MCI report, email communication ranked first among all the purposes of Taiwanese's using Internet [8]. This can be attributed to e-mail's characteristics, such as simplicity, low cost, fast, convenience and so on [8] [12][14]. However, while people receive numerous emails each day, many of which are unsolicited and quickly deleted [8]. Still, many others are kept in personal files or forwarded to family, friends, colleagues, etc.

Over the past two decades, the issue of email communication has received much of researcher's attention [9][10][13]. However, not much has been done regarding e-mail forwarding behavior intention. As a result, we know very little about why people forward emails to others. Therefore, the purposes of this paper are to review literature and propose several variables influenced the intention of one's forwarding emails to others.

## 2. Literature review

Email is a way of communication between people or organizations via Internet system. Files or letters can be transferred between the two parties through email, on condition that each one has its own email box [9]. In other words, email enables people to communicate, to exchange data, and to increase interactions [2].

Previous research of email has been focused on issues like usage rate and purposes [9][10][13]. In recent years the track has shifted to attitude towards email usage [2]. Also, marketing impact of email has attracted much attention these days.

More and more messages are transferred through emails, as a result, it has become an important issue to investigate the reasons why people forward emails. This topic is crucial from a theory perspective as it can be of help in constructing a model for better understanding email usage behavior. From a practical viewpoint, it can assist marketers in developing advertising strategies in the web world.

Forwarding e-mail is a popular way of communication these days. According to communication theory, its effectiveness is affected by source credibility, message content and personal trait of the user [4]. This research is based on source credibility, message content and user's trait, three factors that have much influence on communication effects, and to try to explore the reason why people forward emails in more detail.

Therefore, the research will then base on the above literature reviewed to develop the following hypotheses.

## 3. Research Hypotheses

Extending current research, we present the following people perceptions of source credibility, the content of email, and the user's trait as major determinants of the intention to forward email to others.

### 3.1 The recipient's trust in the email content

Past research showed that message credibility is one of the factors influencing communication effect. That is, people are more inclined to forward a message if the message is considered to be reliable, regardless of the attribute of it [4]. In essence, forwarding email is a way of communication. The research, hence, hypothesize that the higher the content credibility the more likely that one will forward an email.

*Hypothesis 1:* the more the trust of the recipients in the email content, the higher the intention of forwarding emails to others;

### **3.2 Source credibility**

Another factor believed to have impact on communication effect is source credibility. That is, one is more inclined to forward an email received from a trustworthy person [4]. Reviewing of other related literature indicated that there are three dimensions affecting the reliability of source credibility: the source being having related knowledge and experience, the feeling of sincerity of the source, and the charisma of the source itself [11]. The arguments with personal experience or viewpoints from authoritative people tend to be more reliable and convincing [11]. The research, hence, hypothesize that the higher the source credibility the more likely that one will forward an email. That is, one is more inclined to forward an email received from a trustworthy person.

*Hypothesis 2:* the more the trust of the recipients in the senders, the higher the intention of forwarding emails to others;

### **3.3 The receivers' altruism trait**

A review of the literature related to communication revealed that personal trait plays an important role in message transmission [4] and the way one communicates with others [6]. For instance, one who fears of speaking in public will choose a way of communication not having to face much audience. Some researchers, therefore, argued that one's communication style could be predicted by his personal trait [6].

That is, the receivers have more altruism trait, the higher the intention of forwarding emails to others. Thus, the following hypothesis was proposed:

*Hypothesis 3:* the more the altruism the recipients have, the higher the intention of forwarding emails to others; and

### **3.4 Staying in touch with friends**

According to social exchange theory [1], the interaction between people is in fact a mutually beneficial kind of behavior. People will engage in message exchange for rational reasons as well as for gaining some rewards. Apart from receiving some forms of external rewards, one may also get some internal benefits from message exchange, such as friendship, love and social interdependence. One can sustain his social relationship through forwarding of emails. From the angle of social exchange theory, the convenience and speed of email enable it to become a most effective way of increasing interaction and social relationship between people [5]. Evidence from some empirical research [15] showed that the main purposes for 61% of the respondents using emails at home are to keep contact with friends and relatives. Furthermore, another research found that people tend to forward emails as a way of staying in

touch with their friends [2]. Furthermore, interpersonal relationships can be built through email as well as they are in face to face to interactions [17]. The research, therefore, propose that the higher one intends to maintain a stable relationship with others the more likely that one will forward emails.

*Hypothesis 4:* the more intention to staying in touch with friends, the higher intention in forwarding emails to others.

### **3.5 The size of email file**

The size of an email file will affect the speed required to transfer it. The larger the file is the longer it will take to transfer it. Hence, we proposed that the smaller the file the more likely that one will forward it to others.

*Hypothesis 5:* the less size of e-mail file, the higher intention in forwarding emails to others.

### **3.6 The cost of forwarding e-mail**

Most human behavior has its root in increasing one's benefits and decreasing costs at the same time [3] [16]. Researchers of social exchange theory assumed that it is human nature to pursue benefits [1]. Hence, people will rationally assess the costs and benefits of message exchange. That is, the less cost for forwarding and emails the more likely that people will do it.

*Hypothesis 6:* the lower cost of forwarding e-mail, the higher intention in forwarding emails to others.

## **4. Conclusion and suggestions for future research**

The final section draws conclusions and makes suggestions for future research on forwarding e-mail should address.

### **4.1 Conclusion**

We hypothesize that the higher degree the four possible variables are (the recipient's trust in the email content, the recipient's trust in the senders, intention to staying in touch with friends, and the receivers' altruism trait), the more likely people will forward emails. On the other hand, we hypothesize that the lower degree the two possible variables are (the size of email file, and the cost of forwarding e-mail), the less likely people will forward emails.

### **4.2 Suggestions for future research**

It is suggested that further research can adopt qualitative or quantitative approach to empirically test the six hypotheses proposed in this research so as to get a deeper understanding of the reasons why people forward emails to others.

In quantitative approach, a questionnaire will be developed to identify frequent email users and forwarders, and the reasons why people forward emails. In

qualitative approach, face-to-face interviews will be undertaken to ask frequent email users the reasons why they forward emails.

In sum, this study is proposed to get the hypotheses that the several variables investigated, the content of emails, the trust of the recipient's in the senders, the receivers' altruism trait, and the recipient's intention of keeping in touch with others will all positively related to the intention of forwarding emails to others.

# Motivation and Consumer Knowledge on Processing Online Advertisement

Alex Wang  
Department of Marketing and Health Communication  
Emerson College  
Boston, MA 02116 USA  
Alex\_Wang@emerson.edu

## Abstract

This study investigated how consumers use their motivation and objective knowledge to process online advertisement. The laboratory experiment tested several hypotheses on the determinants of consumers' process measures toward the ad. The findings suggested that involved subjects tended to process the ad more to a certain point until subjects reached the highest involvement level and did not feel the need to processing the ad anymore. In addition, when objective knowledge remained an accessible source to evaluate the ad, it hindered the persuasion effects of the ad. Implications for advertisers and the direction of future research are also presented.

## 1. Introduction

The increasing number of people accessing the Internet is fueling the increase of online sales. "Even though this amount could change due to the economic slowdown, eCommerce still won't shrink. Conversely, if the current economic storm passes early, eCommerce will experience substantial growth in 2002" (URL: <http://www.forrester.com/ER/Press/Release/0,1769,651,00.html>) [12]. New communication technologies are creating new challenges for the advertising industry. While the Internet represents new possibilities for advertisers, there is little information available regarding how to take advantage of the Internet.

The Internet makes it possible to create ads or information that are more targeted, accessible, and more personal. Thus, seeing an online banner ad can be an experience in which the consumer participates and is engaged. How engaged they are may depend on how motivated and knowledgeable they are. While separating the effects of involvement and domain knowledge "remains problematic because they are related" [6, p.213], several studies and untested propositions do suggest they can independently influence information processing [30; 1; 16; 4]. This is especially true when knowledge is usually distinguished among three types: objective knowledge, subjective (self-assessed) knowledge, and product-related experience (familiarity). By studying these factors, this study can answer or test how these factors independently influence consumer's information processing toward online advertisement. Moreover, the results might suggest a better strategy to target different

types of consumers to influence their processing towards online advertisement.

## 2. Literature Review and Study Model

Advertising has been defined traditionally as "a form of controlled communication that attempts to persuade consumers, through use of a variety of strategies and appeals, to buy or use a particular product or service" [10, p.564]. It is also the "paid communication from an identified sponsor using mass media to persuade or influence an audience" [31, p.13]. Clearly, the central goal of advertising is to persuade consumers to purchase a product or service. Today, many new channels of mass communication are developed, exposing the public to an increasing number of mediated messages [11; 28]. Consumers are exposed to hundreds of advertising appeals delivered via television, magazines, newspapers, billboards, direct mail solicitation, e-mail, Internet banner ads and more. As a result, consumers have developed a more sophisticated understanding of the mass media and of advertising [5]. All of the above reasons create a greater challenge for advertisers to attract attention, especially thoughtful attention, to their messages either in traditional media environment or online environment.

Interactive advertising (IA) often means simply advertising on the Internet or online advertising [18]. Leckenby and Li defined IA as the paid and unpaid presentation and promotion of products or services by an identified sponsor through mediated means involving mutual action between consumers and producers [20]. IA technologies will be used to gather important consumer information, which will be accomplished through increased interactive means of asking questions (e.g., online surveys) and through more advanced forms of setting cookies and analyzing log files, keeping a record of interactive media experiences.

The ability, motivation, and opportunity (AMO) model in the consumer psychology literature suggests that ability, motivation, and opportunity provide frameworks theoretically to address strategies for effective communication with consumers [22; 15]. These three factors moderate or serve as antecedents to information processing by consumers and suggest that consumers engage in progressive levels of processing, ranging from superficial to deep processing [22; 15; 2; 3]. Motivation refers to "heightening arousal so that audiences are ready, willing, interested, or desire to process a message" and "represents a predisposition or preparedness to allocate

precious cognitive resources to processing information” [15, p.466]. Motivation can moderate the linkage between exposure, cognitive processing, and consequence of cognitive responses and attitude formation [22]. Ability refers to “the need to maximize an individual’s skills or proficiencies in interpreting a message” [15, p.466]. High-ability consumers who are knowledgeable about a topic can process information more efficiently and schematically than can novices [1; 15].

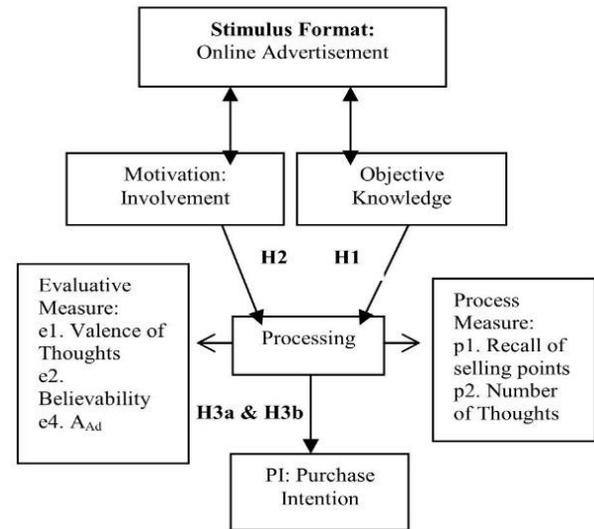

MacInnis and Jaworski offered a six-stage model that began with the feature analysis of message, followed by basic categorization of the message and topic, meaning analysis, information integration with personal experience, mental rehearsal, and mental construction of product attributes and benefits [22]. Certainly, the conceptual origin of emphasizing ability, motivation, and opportunity can be traced to the development of dual processing models in the social psychology literature including the Elaboration Likelihood Model (ELM) and the Heuristic-Systematic Model (HSM) [26; 8]. Both proposed that relevant message played a motivational role in the strategies consumers used to process advertising information.

Consumer knowledge can be defined as information that is learned, organized, represented, and stored in memory so it can be retrieved, used, and updated to create inherent, meaningful and useful property of the knowledge itself and make analogy, inference, reasoning, and elaboration regarding product messages [1; 16]. Consumer knowledge has two major components: familiarity and expertise. While familiarity accumulates from product-related experiences, expertise is defined relative to a performance criterion and implies increased ability to perform the product-related tasks successfully [1].

While definitions of consumer knowledge vary in the literature, the study uses the most common distinction that defined three types of knowledge, objective knowledge, subjective (self-assessed) knowledge, and product-related experience (familiarity). While three types of knowledge are usually correlated, the study uses subjective knowledge and objective knowledge as two different types of knowledge. “Subjective knowledge can be thought of as including an individual’s degree of confidence in his/her knowledge, while objective knowledge refers only to what an individual actually knows” [4, p.2]. The knowledge that consumers possess and the way it is organized lies at the heart of the understanding of consumer cognition. An understanding of what consumers know about products underpins what marketers and scholars of consumer behavior know about the processes, such as product preferences, attitudes toward brands, and purchase decisions.

An integrated model is illustrated in Figure 1. The model demonstrates that PI depends on consumers’ evaluative dimensions of processing information. The rationale for the conceptual framework is to separate the different influences from knowledge and involvement (motivation). In this case, the study can test how they independently influence information processing toward

consistent or inconsistent messages across the content types. The hypotheses with rationales are described in the following section.

**Figure 1: Conceptual Model**

Highly motivated consumers process information effortfully or systematically, whereas consumers with low motivation rely on cognitive shortcuts such as peripheral cues or heuristics. Central route or systematic processing is more enduring than persuasion that relies on peripheral route or heuristic processing [14; 21; 22; 26; 7; 8]. MacInnis, Moorman, and Jaworski suggested in-depth processing is desirable for two reasons: first, attention is likely to be modest as a result of too much information and distractions in the typical communication setting [21]. Second, enhancing levels of processing evokes more enduring memory and attitude change. It is possible that reading about high-involvement products led to lower recall and cognitive response scores because readers felt confident and saw no need to process the information more thoroughly. In this case, the study hypothesizes:

**H1: Medium-involved subjects are likely to have a better process measures toward the ads than low-involved subject.**

Ability refers to “the need to maximize an individual’s skills or proficiencies in interpreting a message” [15, p.466]. High-ability consumers who are knowledgeable about a topic can process information more efficiently and schematically than can novices [1; 15]. Objective knowledge is activated when the consumers feel the needs to [1; 16; 6]. When consumers are not motivated to process information, objective knowledge may not come into work since further processing is not desirable. In other words, the usage of objective knowledge should be evident when the expert not novice is motivated to process the information.

Even though it might be possible that low involved consumers have very high objective knowledge, they might

not be motivated to active the objective knowledge from long-term memory to comprehend and elaborate on the information. Brucks found that efficiency in information search could occur in attribute evaluation among knowledgeable consumers who only search useful information [4]. In this case, there is a negative relationship between knowledge and the possible number of message examined. On the other hand, “knowledge facilitation explanation” [4, p.4] could happen when the positive relationship between knowledge and the possible number of message examined. In this case, the inverted-U shaped relationship may result. Since there is possibility that both explanations could happen, it is hypothesized that:

**H2: Objective knowledge is related to evaluative and process measures of the ad. The relationship may be negative or positive.**

The proposed framework hypothesizes that purchase intention depends on positive evaluative measure responses, a function of valence of product-related thoughts, and attitude toward the ad. These evaluative measures and attitude mainly are affected by how subjects process the information. Given adequate ability, highly motivated consumers process information effortfully or systematically, whereas consumers with low motivation rely on cognitive shortcuts such as peripheral cues or heuristics. According to MacInnis and Jaworski [22], deep processing often accompanied communication exchanges in which the parties were fully engaged. However, because of consumers’ low objective knowledge about and low involvement in a topic, they were unlikely to engage in any more than superficial processing. Their processing of messages was likely to be limited to feature analysis, categorization, and elementary meaning analysis. In other words, subjects with low motivation and ability to process might be the group that is easier to be persuaded. In this case, the study hypothesizes:

**H3a: Purchase intention is increased by positive evaluative measure responses, a function of valence of product-related thoughts, and attitude toward the ad;**

**H3b: Among subjects who have high objective knowledge, purchase intention should be lower since they are more difficult to be persuaded.**

### 3. Methodology

Several sections of laboratory experiment were conducted to test the hypotheses, identified in the previous section. This section describes the sample, the experimental design, task, manipulations, and the constructs used to measure and test the hypotheses. To investigate the hypotheses, a 4 by 4 factorial design was employed. The 4 × 4 factorial design manipulated four levels of product involvement and four levels of objective knowledge. The product chosen for the study was a

tennis racquet. Tennis was selected because it was a product category that previous research studies used and proved to be a good product category for studying [6; 13]. Banner ad was selected as the advertising format because it is the most common usage and has proved to be successful and relatively easy to implement [9]. The power banner ad designed to communicate evidence of relative superiority claimed that the Head i.S6 has superb power for shots.

The size of online ad (550 by 240 pixels) was measured to be located at the central part of viewing range of the monitors. Since 24 computers at the lab were all the same type with exactly the same monitors, this nullified the possibility that subjects would have performed the experimental task differently due to different computers they used. With 19-inch monitor at the computer lab, the ad was shown to be in the center when subjects went to the homepage. Two hundreds and twenty one students were recruited from different levels of tennis class, beginning, intermediate beginning, intermediate, and advanced intermediate classes, taught at a large U.S. university. As an incentive for their participation, the subjects received credit points when they participated in the study.

The questionnaires were developed from the literature and using literature as guides to adapt, when necessary, to the specific focus of the study. Subjects first answered the first stage of recruiting questionnaire including measures of product involvement and objective knowledge. Measures of objective knowledge employed Moreau et al. [24] and Celsi and Olson’s [6] approaches including three questions, previously used by Celsi and Olson [6, p.217]. These questions can reflect subjects’ expertise regarding playing tennis. In addition, 12-item true-false questions were used to access subjects’ objective knowledge about selecting a tennis racquet (see Table 1). The highest score was 14 while the lowest score was 2 based on a possible range from 1-15.

**Table 1: Objective Knowledge Scores (4 Groups)**

	N	%	Mean	SD
Low Objective Knowledge	57	25.8	6.07 <sub>a</sub> ***	1.24
Low-medium Objective Knowledge	45	20.4	8 <sub>b</sub> ***	.00
Medium-high Objective Knowledge	77	34.8	9.51 <sub>c</sub> ***	.5
High Objective Knowledge	42	19	11.76 <sub>d</sub> ***	.88
Total	221	100	8.74	2.13

Note: Means that do not share a common subscript significantly differ. \*\*\* p < .000; F=455.291, df=3,217, p=.000

To measure the constructs of interest, the study also employed several multiple-item scales, used by other researchers and proved to have adequate reliability and validity. Subjects’ product enduring involvement scores were measured by Zaichkowsky’s [32] Personal Involvement Inventory (PII). Table 2 showed the possible three or four different levels of average involvement scores. The lowest average involvement score was 1 while the highest was 7.

**Table 2: Involvement Score (4 Groups)**

	N	%	Mean	SD	ANOVA
Low Involvement	55	24.9	2.84 <sub>a</sub> ***	.85	F=396.412 df=3, 217 P=.000
Low-medium Involvement	54	24.4	4.19 <sub>b</sub> ***	.19	
Medium-high Involvement	57	25.8	4.92 <sub>c</sub> ***	.20	
High Involvement	55	24.9	5.99 <sub>d</sub> ***	.43	
Total	221	100	4.49	1.25	

Note: Means that do not share a common subscript significantly differ.  
\*\*\* p < .000

Purchase intention was measured by a 7-point semantic differential scale from the lowest to the highest. Quality of information was measured by asking subjects whether the overall information presented in the ad was “accurate,” “truthful,” and “factual.” Believability and persuasion of the ad were measured by asking subjects whether the ad was “convincing” and “believable.” The study also used the measures of Advertising Message Involvement (AMI), proposed by Laczniak, Kempf, and Muehling [19] to form message involvement measures toward the ad. The items with 1-7 scaling included four components: (1) self-reported attention to the message claims, (2) perceived relevance of messages, (3) perceived engagement of messages, and (4) overall attention paid to the messages.

The numbers of selling points recalled from the messages were measured by the free-recall task. Each successfully recalled point was given a value of one and the sum of all points was the final score of recalled selling points for each subject. To qualify as recall of selling point, an examination of the recall data had to demonstrate memory of the key messages in the ad.

Product-related thoughts were measured by thought elicitation task in 3-minute period. After the thoughts elicitation task, a few questions were asked to determine whether the appeals in the ad were perceived to provide the best evidence of performance superiority (i.e., “Did the ad make you believe that tennis racquets provide increased power?”). Also, subjects were asked whether the appeals provided the information for making a better purchase decision (i.e., “Without considering specific message information, did the ad make you feel better about your decision?”). These questions were used as the general attitude toward the ad.

Control variables included attitude toward online shopping, credibility of Tennis Magazine and the questions regarding asking subjects’ past experiences of purchasing a racquet and playing tennis. Bipolar, 7-point semantic differential scales were used to measure all trust, believability, persuasion, and attitudinal measures ranging from 1 (low) to 7 (high) except the recall of selling points, number of the product-related thoughts, valance of the product-related thoughts. Subjects were asked to use their own words in 3 minutes to elaborate what are the messages they perceive from the ad regarding the i.S6. The recall of selling points were counted as how many selling points they mentioned. The product-related thoughts were numbered, counted, and evaluated by their valances. For example, if a subject had

three positive thoughts and one negative thought, his or her valance of thoughts would be 2 (3-1=2).

## 4. Data Analysis and Results

### 4.1 Manipulation Checks

The manipulation checks for reading the stimuli showed that subjects reviewed the ad without skipping under any condition. The manipulation checks for the ad showed all subjects in all conditions read them completely (100%).

### 4.2 Validity and Reliability of Measures

To assess the validity of measures, factor analysis with a Varimax rotation was conducted to verify that the items included in each construct loaded as expected without strong cross loading [29]. Table 3 contained the summary of the main constructs in the study, including descriptive statistics and the measure of reliability, Cronbach’s alpha. The results confirmed that all measures formed only one construct, which verified that the items loaded as expected without strong cross loading. All Cronbach alphas were larger than 0.82, indicating that all measures were reliable. The values of the constructs were computed as the mean of the ratings of the items, associated with each construct. No confounds were detected based on several demographic measures and control variables incorporated in the study including gender, major, education level, how much tennis subjects played, or whether subjects have purchased something online before. In this case, the data analysis focused on testing hypotheses by proposed experimental groups regardless of respondents’ gender, education level, and shopping experiences.

**Table 3: Summary of Descriptive Statistics for the Main Constructs**

Construct	Mean	SD	Reliability
<b>Independent Variable</b>			
Involvement score	4.49	1.25	0.97
Objective knowledge score	8.74	2.13	N/A
<b>Dependent Variable</b>			
Purchase intention	5.22	1.31	N/A
Message involvement	4.70	1.14	0.88
Recall of selling points	2.57	2.07	N/A
Number of thoughts	4.33	2.12	N/A
Product-related thoughts	3.37	2.30	N/A
Valence of Product-related thoughts	3.22	2.46	N/A
Quality of information	4.69	1.19	0.93
Believability	4.94	1.37	0.90
Attitude	4.77	1.28	0.82

### 4.3 The Effects of Enduring Product Involvement on Processing Online Advertisement

It was hypothesized in the study that medium involved subjects are likely to have higher process measures than low involved subjects. Support was found that more involved subjects did demonstrate the higher process measures to certain degree. The main effects of product involvement in Table 4 found main effects on the number of thoughts,  $F(1, 219)=5.017, p=.002$ , the number of product-related thoughts,  $F(1, 219)=4.802, p=.003$ , and valence of product-related thoughts,  $F(1, 219)=4.923, p=.003$ , generated by the ad. Results in Table 4 showed that subjects with medium-high involvement consistently had higher process measures toward the ad than the subjects with low-medium or low involvement. Highly involved subjects scored equal but not better process measures than subjects with medium-high involvement since highly involved subjects might not need the information or they considered that they already knew a lot. Subjects with medium-high but high involvement became the group that mostly engaged in the processing. The finding seemed to suggest that more involved subjects tended to engage in processing more until the need of information was demolished, which supported the hypothesis 1.

#### **4.4 The Effects of Objective Knowledge on Processing Online Advertisement**

It was hypothesized that when subjects are motivated to process information, objective knowledge is related to evaluative and process measures of the ad. The relationship may be negative or positive. The results found support for this proposition. The main effects of objective knowledge in Table 5 found no main effects evaluative measures, and post-hoc analyses found differences among means regarding the message involvement and the quality of information toward the ad. Subjects with high objective knowledge had lower evaluation of the ad than the subjects with medium-high objective knowledge. In other words, when the objective knowledge was low to medium, subjects were easier to be persuaded. When subjects' objective knowledge became the highest, they tended to evaluate the ad lower. In addition, subjects with high objective knowledge had lower message involvement toward the ad than the subjects with low-medium objective knowledge. This may mean subjects with highest objective might not think they need more information. In this case, the relationship is negative when the subjects have the highest objective knowledge regarding processing and evaluating the ad while the relationship is positive when the subjects have the low, medium or medium-high objective knowledge regarding processing and evaluating the ad.

On one hand, subjects with high objective knowledge might not need more information while subjects with low objective knowledge might not have the ability to process all the messages, explaining why the process and evaluative measures between subjects with high and low objective knowledge were not statistically different. On the other hand, subjects with high objective knowledge might not be easily persuaded since they have better

knowledge to evaluate the messages, supported by the evidence that subjects with high objective knowledge had the lowest purchase intention than other subjects (see Table 5).

#### **4.5 The Effects of Involvement and Knowledge on Purchase Intention**

As the study framework suggested, purchase intention would depend on several evaluative measures such as evaluation of the ad, believability of the ad, valence of product-related thoughts from the ad, and attitude toward the ad. The hypothesis 3a was supported as Table 6 revealed that subjects tended to use evaluation of the ad, the valence of the product-related thoughts perceived from the ad, and the attitude toward the ad to make their decisions.

The three components contributed significantly to the regression model ( $p=.000$ ) and suggested that when valence of the product-related thoughts perceived from the ad was positive ( $p=.021$ ) and the evaluation of the ad ( $p=.000$ ) and the attitude toward the ad ( $p=.018$ ) were high, subjects were inclined to have higher purchase intention. However, subjects with high objective knowledge might have low purchase intention. A negative valence ( $-2.406$ ) was placed on the coefficient of objective knowledge, which contributed significantly to the regression model ( $p=.017$ ). This suggested that when objective knowledge was high, the purchase intention was reduced, which supported the hypothesis 3b.

### **5. Discussion, Implication and Limitations**

There are companies that have created Web site and advertisements on the Internet today. They have done so simply because the competition has done so. Many think a poorly constructed Web site is better than no Web site at all. This mistake can cost the company missed business and disappointed customers. Just like a billboard or a magazine ad, consumers will bypass the digital advertising unless there is something available that is really useful and convincing to them. The AMO model is useful because it provides a theoretical umbrella for integrating a variety of otherwise disjointed communications tactics. Consumer research has shown that attitudes toward communications messages moderate attitudes about the products or services in promotional messages [22]. In this case, messages that strike affective responses generate more attention, greater interest, more cognitive responses, higher message recognition, and greater topic recall [25]. AMO model offers a potentially useful framework for conceptualizing and unifying otherwise seemingly disjointed message tactics that can be undertaken to communicate better with consumers. The results in the study provide advertisers with many opportunities of manipulating strategies in forming information based on the levels of consumers' product involvement and objective knowledge. With the significant customers in mind, key questions need to be answered are: will the consumers be motivated to process

the message? Is this issue relevant to the consumers? Are the consumers able to process the message? The answers to these questions will help decide whether a central or peripheral route would be more effective for message persuasion.

One limitation of this study is that the subjects did not actually purchase from the store: they advised a hypothetical friend about purchasing it. It is not clear whether conclusions reached by this study would apply to their own purchasing behavior. It might be that individuals with more at stake (i.e., their own money) would work harder at evaluating not just information but the whole site. The amount of time spent inspecting the message claims and the enthusiasm demonstrated by some of the subjects suggested however that this might not be a major threat to validity. Nonetheless, a study that tests subjects' real purchase behavior will be much more desirable.

Another technique to increase motivation, not studied here, evolves around enhancing the relevance of the message to individuals is the use of value-expressive appeals vs. utilitarian appeals. This technique has been shown to increase attention and message elaboration [17]. MacInnis and Jaworski [22] proposed several propositions regarding  $A_{Ad}$  and  $A_B$  based on utilitarian needs versus expressive needs. They proposed when the needs are utilitarian, negative feelings will be elicited by salient ad cues, utilitarian appeals, but need not have a negative impact on brand attitudes. However, there will be a negative effect on attitude toward the ad. When the needs are expressive, few negative feelings will be elicited by salient ad cues, expressive appeals. On the contrary, positive feelings will affect both brand attitudes and attitude toward the ad. In addition, they also proposed the "mediational effect of  $A_{Ad}$  on  $A_B$  will be weaker when the ad stimulates utilitarian versus expressive needs" [22, p.12]. Finally, MacInnis and Jaworski suggested "when needs are utilitarian (expressive) and the consumer is engaged in meaning analysis, salient cues that communicate the brand's ability to solve functional problems (that communicate emotional, symbolic, or ego-related meanings) will serve as heuristic indicators of brand benefits" [22, p.12]. The future study could incorporate all these factors to test the processing of advertisement.

## 6. Conclusion

The importance of the Internet is its interactive platform that introduces a new way of doing business to the world. The term "interactivity" is best defined as simply two-way communication, rather than merely a delivery mechanism [27]. The concept of interactive media has been developed through the idea of a hypertext medium that opens a new way of communication when, "hypermedia is multimedia with links among the components and a mechanism for moving along the links" [27, p.205]. This platform manipulates links between discrete pieces of information from one channel and synchronizes other information from other channels,

which helps advertisers to integrate information from different sources in real time, compared to traditional media. This advantage not only provides many promotional opportunities but also helps online shoppers exercise a certain degree of involvement with what consumers intend to purchase.

The change is so rapid that 1 year on the Internet is like 7 years in any other medium [23]. Now the concept of business communications has multiple and complex dimensions. As communication technologies evolve and browsing information becomes more interactive, personal, and sophisticated, advertising is being forced to evolve and integrated with other forms of communication as well. Due to advances in technology and production, it is very possible there will be no product advantages, no price advantages, no distribution advantages, and no location advantages. Competition will be based on customer information, customer service, and customer preference.

The Internet provides the technology to tailor shopping experience to the needs of the consumer. Advertising specialists are involved in the flow of online information where their consumers are looking for information. Today businesses find it necessary to concentrate on building long-lasting relationships with its consumers. The ability for two-way communication and the near instantaneous nature of the Web make the Internet the medium of choice for relationship marketing. Through carefully designed and coordinated programmatic studies, studies can help better understand how advertising messages generate a consumer's perception of a product or a service. Studies can also help better understand how factors such as motivation and knowledge can provide the basis for effective persuasion.

Aiqun Yao  
Agriculture University of China, Beijing

## Abstract

In recent years, similar to what has happened in other parts of the world, electronic commerce (EC) in Mainland China has come through the great developing and changing. E-business is not only a tool for purchasing or buying, but also a marketing media for business. People combine the on-line marketing with off-line sales to develop their business. Cyber-Marketing will become the mainstream of EC development in future.

This paper reviews the development of China's EC, points out the impediments that impact EC developing in China, presents some surveys and statistics of EC in China, and analyses EC development's trends in future.

**Key Words:** Marketing; Electronic Commerce; Cyber-Marketing; Electronic Marketing; Electronic Business.

## 1. Introduction

As the fastest economic Development State in the world, China's EC and Network Economy develop very quickly in recent years. Similar to what has happened in other parts of the world, the EC development in China has experienced the following three phases.

First phase is the concepts importing and technologies developing stage from 1994 to 1997. In this phase, 1G mobile telecommunication system (mobile phone) and EC's concepts officially entered Mainland China. China's network economy began. National information infrastructure construct very quickly. The digital fibre cable and microwave network increased from 400000 km to 820000 km at the end of 1997, its geographic span from large cities to the whole country. The number of telephone users has reached 83.5 million, the number of mobile phone users has reached 13.23 million, the population of using Internet has reached 0.67 million.

Second phase is the quantity development taking off stage from 1997 to 2000. In this phase, China's digital

fibre cable and microwave network increased by 145%, from 820000 km to 1250000 km. The number of telephone users increased by 174%, from 83.5 million to 145.121 million. The ratio of Internet using population increased by 3359%, reached 22.5 million in the end of 2000. And the number of mobile phone users exceeded the United States, China become the largest mobile telecommunication market in the world.

Third phase is the China's EC booming stage since 2001. Although many pure "dot com" companies have closed down, many traditional enterprises begin to develop their on-line business. Business executives have understood the importance of cyber-marketing (on-line marketing). They combine the on-line marketing with off-line sales to develop the substantial business.

## 2. Review of EC in China

According to surveys conducted by some governmental, semi-governmental and non-profit Internet management and service organisation, such as Ministry Information Industry of China, Institute of Telecommunication Science Research, Internet Network Information Centre (CNNIC), there has been great increase in both aspects of the information infrastructure and application market.

### 2.1 NII Constructs and Applications

Table 1: China's NII Constructs from 1996-2000

	2000	1999	1998	1997	1996

## 3. Surveys and Analysis of EC Development

As time goes on, China's E-Commerce development has experienced drastic change since 2001. With the development of E-business, China's business executives understand that E-business is the business, IT must be combined with the traditional business. Substance industry enterprises understand the potentialities of EC, and become the mainstream of EC development, instead of pure "dot com" companies.

## 3.1 The Number of On-line Buyers isn't Increase

According to a survey conducted by CNNIC in July 2001, although the both number of Internet user and B2C web site have huge increase, the number of on-line buyer is nearly not on the increase.

Table 5: The Rate of people browser EC website (%)

	2000. 6	2000. 12	2001. 6
Always	72. 46	69. 07	73. 9
Sometimes	27. 54	30. 93	26. 1

## 3.2 Primary Obstacles

The primary obstacles impacting business to consumer (B2C) EC development in China are following 4 aspects. First is that the number of both people and stores are very great, B2C on-line sale can't show its advantages. Second is that both credit system and on-line payment system have been not established. Third is that the third part distribution (or physical distribution, logistics, supply chain) system is undeveloped. At last, there are not proper laws to protect it.

### 3.3 Enterprise Users and Scope are Increasing

According to the survey conducted by Information Centre of State Economy and Trade Committee (SETC) in 2001, the ratio that enterprise can access Internet is nearly 100%, and most large enterprises have business web sites and used the web sites to display their products and marketing strategies. [6]

According to another survey conducted by CCID Consulting, the EC scopes have reached 95.5 billion RMB in China in 2001. Thereof, 1% is from B2C and 99% from business to business (B2B). And there are much more enterprises using business web site to promote their products, provide the before or after sale services, create the customer relationship management system, and show enterprise's marketing strategies. [5]

### 3.4 E-Marketing

According to a questionnaire conducted by (SETC) in 2001, most of the managers are fairly optimistically thinking that E-marketing will develop very quickly in China. Nearly two-third of them predict that E-marketing would take off in China in the next two years and that combination of the on-line marketing and off-line sales will be the most promising one. These managers also feel that E-marketing is more suitable for China's business situations versus on-line sales. EC's major impacts on business seem to change idea, promoting products, on-line service, marketing expansion. [6].

### 3.5 The Driving Forces

The driving forces of recent EC market growth are expected to be the competitive compressive stress. Due to China acceding to World Trade Organization (WTO) and the trends of economy globalization, traditional enterprises have to use the Internet to develop their markets and business.

### 3.6 Current Advertising and Communication Media

The Respondents were asked about their firms' current advertising and communication channels and how satisfied they are with those channels in order to assess the potential of the Internet as a new medium for advertising and communication. About the thirty-nine firms reported their advertising mediums. Printed media is the most popular advertising media. Thereof, magazines are used by 23 firms and newspapers are used by 21 firms; billboards and TVs are used by 12 and 10 firms respectively. Most of the firms have not been very

satisfied with their advertisements because of a lack of promotion effectiveness (11), followed by high cost of advertisement (10) and limited contents of advertisements. Most of them think that Internet should have great potential to promote products and marketing strategies in the future. [9]

## 4. Conclusion

Based on survey results, some recent reports and the analysis in this paper, the summary of the e-commerce development in China are following:

### 4.1 China's B2C Market Can't Have Large Growth in Recent Years

Because the restrictive conditions that were depicted above can not be changed in recent years, the B2C market in China will not have large growth in recent years.

### 4.2 On-line Marketing Will Become the Mainstream of EC Development in China

With the growth of Internet population, more and more enterprises will use business web sites to show the marketing strategies, extend their market scope, provide their service and promote their products. The Enterprises will combine Internet and traditional trade way and create the most suitable way of developing China's EC.

Using Internet, mobile telecommunication and relative technologies to develop marketing will become the Mainstream of EC Development in Mainland China.

## Abstract

E-business has been rapidly growing in the retailing and service industries. As an innovative mode for selling and delivering products/services, e-business model involves both technological and strategic changes. It has been observed that firms in the same industry may adopt e-business model at different paces. Questions remain why some firms tend to actively implement e-business while others take cautious attitudes toward it. Scholars from different research fields have approached the innovation adoption issue from various theoretical perspectives. Drawing upon the innovation adoption literature as well as institutional theory, market orientation theory, and strategic choice perspective, this study proposes a multi-level explanatory model about e-business adoption in the travel industry. We identified some important environmental, organizational, and managerial variables that may affect e-business investment. Using survey data from a sample of travel agencies in Taiwan, we found that external competitive pressure, the firm's innovation orientation, its IT human resource base, the CEO's perception of e-business advantage, and CEO openness to experience were associated to e-business investment.

## 1. Introduction

In this study we define e-business broadly as an innovative business mode involving delivery of products / services, exchange of data / information, and financial payments through the Internet between the focal firm and its customers, suppliers, and other business partners. Using a sample of travel agencies, we intended to investigate the effects of some important environmental, organizational, and managerial factors on a service firm's involvement in e-business. Why some organizations adopt innovations while others do not has been an often-researched issue [7]. Previous researchers have approached to this issue from different theoretical perspectives, e.g., the innovation adoption / diffusion theory [8][9] and institutional theory [3][10][11]. A

significant suggestion of these research streams is that the variances among firms' adoption decisions could be fully captured only if the influential factors at multiple levels are taken into consideration [12]. There have been a large number of empirical studies on the adoption of such advanced IT systems as EDI [13][14][15], BITNET [16], integrated services digital network (ISDN) [17], and customer-based inter-organizational systems (CIOS) [18]. However, literature discussing the implementation of e-business model has been limited except for some case studies (e.g., [19]). This paper identified some critical factors that may influence a service firm's decision to implement e-business. We were especially interested in the so-called "traditional" firms' responses to the trend of e-commerce. Instead of trying to conceptualize a complete explanatory model, we identified specific antecedents of e-business implementation based on both theoretical literature and field interviews. Our purpose was to address the specific contextual factors with respect to the travel industry. Our pilot field work revealed that travel agency managers had different understandings of the prospect of e-commerce. It is interesting to explore three questions in this context: (1) Is the adoption of e-business model a symbolic / institutional action or an efficiency-driven decision? (2) Which type of market orientation is more closely related to e-business? and (3) How does the CEO's personal characteristics affect the firm's tendency toward e-business?

To answer the above questions, we developed hypotheses based on multiple theoretical perspectives and conducted a mail questionnaire survey in a sample of Taiwan-based travel agencies. We chose the travel industry as the research setting because this industry has seen probably the most striking impact of e-commerce. Travel agents have a long history of utilizing IS technologies and were among the first online retail businesses [1]. According to a Forrester Research survey, travel products sale accounted for 38 percent of the total online sales in 1999, which made the travel industry the largest online seller [20]. In Taiwan, an increasing number of Internet users and a thriving travel industry have pushed e-commerce to the central stage.

These trends make the travel industry of Taiwan an ideal setting to study e-commerce adoption.

## 2. Hypotheses

This study addresses the issue of e-business investment among travel agencies. A multi-level explanatory model is illustrated in Figure 1. Previous research has shown that organizational tendency for innovation adoption is influenced by a variety of factors [9][21]. One stream of research focuses on the characteristics of particular individuals within an organization (“champions” of innovation) and their influence on the development and adoption of innovative ideas. The other studies emphasize the effect of organizational factors such as organizational structure and business strategy [18][22] and environmental/institutional factors [3]. It is argued that the adoption of e-business model is a complex issue for the firms to handle because e-business involves significant investment in computer and networking technologies as well as human resources. As mentioned above, we did semi-structured interviews with a small sample of travel agency CEOs before the mail survey. Several themes repeatedly emerge from our interviewees’ descriptions about their own understanding of the determinants of e-business adoption. We organized these themes into three categories: environmental, organizational, and managerial factors. The research framework illustrated in Figure 1 reflects the pilot findings.

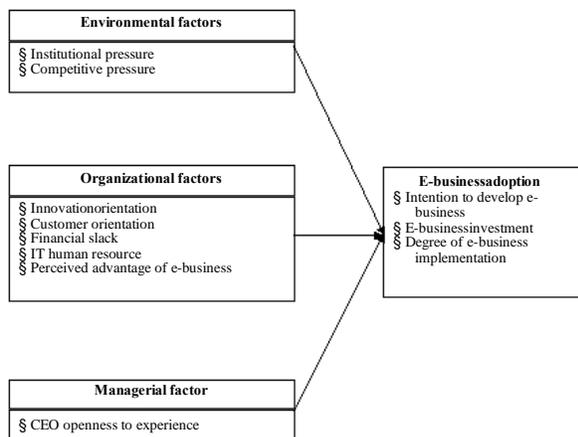

Figure 1. A multi-level model for e-business adoption

**Hypothesis 1:** The CEO’s perceived institutional pressure is positively related to the firm’s adoption of e-business.

**Hypothesis 2:** The CEO’s perceived competitive pressure is positively related to the firm’s adoption of e-business.

**Hypothesis 3:** Firms with a high level of innovation orientation are more likely to adopt e-business.

**Hypothesis 4:** Perceived advantage of e-business is positively related to the firm’s adoption of e-business.

**Hypothesis 5:** The more financial slack resource a firm

owns, the more likely that it will adopt e-business.

**Hypothesis 6:** IT human resources have positive effect on the firm’s adoption of e-business.

**Hypothesis 7:** A firm managed by a CEO with strong openness to experience is more likely to adopt e-business.

## 3. Research Method

### Research Setting

We chose Taiwan-based travel agencies as the research subjects. The travel industry has been regarded as having the biggest potential to do e-commerce. It is appropriate to test our theoretical model in the context of a single industry because single-industry studies would provide better control over inter-industrial differences and more precise identification of intra-industrial variances [61]. A single industry approach also avoids problems in variable definition and consequent comparability question of peer firms [62]. This is especially important for testing new ideas and identifying specific organizational and institutional factors.

### Pilot Study

We collected data through a large-scale questionnaire survey. Before the mass mailing of questionnaires, we conducted pilot interviews with travel agency CEOs for the purpose of obtaining in-depth understanding of the business environment and management practices of the travel agencies upon which we might improve the theoretical relevance of our study. The most important issue was to probe to what extent e-commerce had been introduced into the travel industry. Moreover, we asked the interviewees to describe the key factors related to the implementation of e-commerce.

We developed the initial questionnaire based on the pilot findings and a literature review. The factors mentioned by the interviewees were categorized and linked to similar theoretical concepts appearing in the theoretical literature.

### Data Collection

Our sampling frame was the member list of the Taipei Association of Travel Agents of 2000. Since it is a legal requirement that all registered travel agencies must join the above-mentioned trade association, the member list provides an ideal sampling framework. We randomly selected 500 travel agencies from the 961 member firms of the Association. The 10 firms we had interviewed in the pilot study were not included in the sample for questionnaire survey. Then we mailed questionnaires to the selected travel agencies. In order to increase response rate, the first author delivered some of questionnaires personally to the CEOs during a field trip to Taiwan.

We received completed questionnaires from 137 travel agencies. The response rate was 27.4%, which could be seen as acceptable for the large-sample, organization-level surveys [31][65]. We compared the responding firms and the non-responding firms on firm size (operationalized as

total capital) and did not find significant difference. So we felt it safe to say that no non-response bias was observed in our final sample of 137 travel agencies.

**Measurement**

The final survey instrument was a multi-item, Likert-type (5-point) questionnaire. We used subjective measures because our theoretical focus was on the manager’s perception of environmental and organizational contexts. Previous researchers have suggested that managerial subjective judgment about organizational contexts would accurately reflect the true situation in the organization. Moreover, top managers are well qualified to assess environmental and organizational factors related to innovation adoptions [12]. To measure the travel agent’s investment in e-business in terms of both human resource and financial resource commitments. The CEO was asked to answer two questions: (1) percentage of the employees whose jobs are related to e-business, and (2) investment in e-business as a percentage of the firm’s total assets. Considering that it may be difficult for the CEO to give exact numbers, we used a five-point scale to measure these two variables. A higher score represents a higher percentage. The average of the two items was used as the dependent variable -- *e-business investment*.

**4. Results**

The average history of the sample firms was 14.81 years (standard deviation = 10.04). The average employment size of the sample firms was 82 employees, with the largest firm hiring 600 people while the smallest firm hiring only 4 people. There were 94 Type A agencies and 43 general agencies.

Hierarchical regression analyses were performed to test the hypotheses. The results are showed in Table 1. We had tested two models; Model 1 includes only control variables and Model 2 includes both control and independent variables.

The results of hypotheses testing are displayed in the full model (Model 2). We did not find multicollinearity problem among IVs after examining the variance inflation factor (VIF) value corresponding to each independent variable (IV). All the VIF values were much lower than the threshold value of 10 [67]. Firm age does not have significant effect on the dependent variable (DV). Additionally, the general travel agencies appear to have moved further than the type A agencies in implementing online booking and payment systems.

As for the results of hypothesis testing, it is first noted that there is no significant relationship between institutional pressure and e-business investment. Thus H1 was not supported. It seems that innovation orientation has little to do with the firm’s “real” involvement in e-business measured as investment.

A positive relationship is found between perceived advantage of e-business and investment, providing strong support for H4. However, H5 is not support. The last organizational factor – IT human resource shows positive effect on the DV. These results support H6. Finally, H7 obtains partial support for CEO openness to experience is positively related e-business investment. Overall, the variance of each DV explained by the full model is significantly higher than explained by the control variables.

Table 1. Results of regression analysis

\*\* *p* < .05

\*\*\* *p* < .05

**5. Discussion**

In this study we proposed a multi-level model about the factors influencing a service firm’s adoption of e-business. We measured e-business adoption as the level of investment in e-business a firm has committed. Our research framework is rooted in innovation adoption literature. Institutional theory, market orientation theory, and managerial strategic choice perspective were applied to explain how e-business adoption is influenced by different contextual factors. The hypotheses were tested in a sample of 137 travel agencies in Taiwan. The empirical findings are mixed. Two variables that consistently predict e-business adoption are the firm’s strength of IT human resources and the CEO’s perception of advantage of e-business. Finally, there is a positive linkage between the CEO’s personality trait (openness to experience) and the firm’s investment in e-business measured as both human resource and financial commitments.

## Abstract

This paper attempts to integrate concepts of e-marketplace and inter-organizational relationship to build a framework for influencing factors of e-business partnership and empirically explore it. The importance for five dimensions of the Research Model based on four top representatives of interviewed Taiwanese companies engaged in e-marketplaces is summarized. Fuzzy Delphi Method is used to decide which factors are vital for the success in three phases of partnership in e-marketplace. Data are collected through a survey of organizations that are actively involved in the planning or operation of e-marketplaces. Except exploiting of new market, the result has been shown the influencing factors are not the same in three phases of partnership in e-marketplace. It implies that to manage an e-marketplace must have different strategies to select, develop, and maintain participants.

## 1. Introduction

In the past years, many organizations have tried to expand or broaden their supply chains in e-marketplaces. However, successful e-marketplaces are rare until now, it maybe partly dues to the Internet stock slump making financing much more difficult for e-marketplaces, but organization behavioral adjustments should be also considered. Transitioning from traditional transaction approaches to an e-business model and adopting new technology present many organizational challenges. Building an Internet infrastructure and attracting more participants initially may not ensure the longevity of an e-marketplace.

Therefore, this research tries to cover the findings of studies on e-marketplaces and organization behaviors. The research methodology is comprised of three approaches:

1. Literature review for building a Research Model.

2. Interviews with top-level executives in leading Taiwanese companies engaged in e-marketplaces to validate and justify the Research Model.
3. Questionnaire Survey based on the Research Model and Fuzzy Delphi Method to explore the critical influencing factors of e-business partnership.

Goal of this research is hence to present the Research Model for influencing factors of partnership in e-marketplace. These factors may create valuable information for e-marketplace administrators to build appropriate strategies for their businesses.

## 2. Literature Review

Within the literatures, it is shown that appropriation of information technology such as e-marketplaces justifies organization behaviors[5]. As to the relationship styles of business partners, scholars propose many types such as arm's length, joint venture, supply chain and so on[2,4,8,9,10,12,17].

Two major schools of thought have pursued the study of information technology and organizational changes. The decision-making school[14] emphasizes the cognitive processes associated with rational decision making and adopts a psychological approach to the study of technology and change. Institutional school[11,13] emphasizes the role of ongoing discourse in generating social constructions of technology, with a consequent emphasis on human interaction in studies of technology effects. Several theoretical views synthesize these competing schools to form the social technology perspective. Adaptive Structuration Theory (AST) proposed by DeSanctis and Poole[5] in 1994 provides a model that describes the interplay between Advanced Information Technology (AIT), social structures, and human interactions. AST focuses on social structures, rules and resources provided by technology and institutions as

the basis for human activities.

The constructs of AST[5] are (1) structure of AIT including structural features and spirit, (2) other source of structure including task and organization environment, (3) group's internal system including styles of interacting, knowledge and experience with structures, perceptions of others' knowledge and agreement on appropriation, (4) emergent sources of structure including AIT outputs, task outputs and organization environment outputs, (5) new social structures including rules and resources, (6) social interaction including two subsets: (a) appropriation of structures including appropriation moves, faithfulness of appropriation, instrumental uses, and persistent attitudes toward appropriation, and (b) decision processes including idea generation, participation, conflict management, influence behavior and task management, and (7) decision outcomes including efficiency, quality, consensus and commitment.

AIT brings social structures which enable and constrain interaction to the workplace. E-marketplace is one type of AIT for the modern organizational market; it combines computing, communication, and business trading decision support capabilities to aid in buyer-seller groups idea generation, planning, problem solving and choice making. Within the e-marketplace literatures, technology designs put computer systems to support business tasks, such as billing, inventory management, financial analysis, report preparation, coordination among people and provide procedures for accomplishing interpersonal exchange.

Structural features are the specific types of rules and resources, or capabilities offered by the system. Features within e-marketplaces might include anonymous recording of business transactions, periodic data collecting and analyzing, and negotiation within business groups. Those features govern exactly how information can be gathered, manipulated, and managed by members in e-marketplaces. Features of e-marketplaces bring meaning and control to group interaction. There currently is burgeoning interest in e-marketplaces and their potential role in facilitating organizational and social changes. Once e-marketplaces are applied, the technology should bring productivity, efficiency, and satisfaction to individuals and organizations, but the social evolution of structure within industrial and human institutions are also changing. Social technology perspective as AST can be an analytic principle to explore the influencing factors for e-marketplaces. Based on the meaning of each construct in AST, initial dimensions for the Research Model are listed as Table 1.

### 3. Research Model

Researches related to e-marketplaces focus on finding characteristics and functions. The findings in literatures

Table 1. Initial Research Dimensions inspired from AST

Major Constructs of AST	Initial Dimensions for the Research
Structure of AIT	Characteristics of e-marketplaces
Other Source of Structure	Administration of e-marketplaces
Group's Internal System	Members of e-marketplaces
Emergent Source of Structure	Market Environment
New Social Structure	Derivative Problems of e-marketplaces
Appropriation of Structure	Functions of e-marketplaces
Decision Process	Phases of Partnership in e-marketplaces

include information gathering, buyers-sellers matching, transaction efficient, supply chain integration, cost reduction, etc[1,3,7,15,16]. The influencing factors of each dimension are summarized in Table 2.

The relationship styles of buyers-sellers in organizational markets proposed as five relationship styles of partnership in e-marketplaces are also defined. They are (1) arm's length, (2) buyer-seller relationship, (3) trusted partnership, (4) joint venture and (5) value chain. Expert depth interview is employed to validate the Research Model. Then a primary questionnaire survey is conducted to analyze which influencing factors are vital for the success in three phases of partnership in e-marketplaces, including a question about the relationship styles of partnership in e-marketplace in order to exploit participants' perspectives.

Four top representatives of Taiwanese companies related to e-marketplaces are selected for expert depth interview to validate the Research Model. The companies interviewed are DRAMeXchange, Liet-On eCommerce, Universal Exchange, and Oracle Taiwan. The actors of these four companies in e-marketplaces are neutral, buyer-oriented, seller-oriented, and technology provider, respectively. The importance of each research dimension based on opinions of four executives of the interviewed companies is summarized in Table 3. The importance of five out of six research dimensions are bigger than 75% that is set to be significant (i.e. significant dimensions

Table 2. Influencing Factors of Research Dimension

Research Dimension	Influencing Factors
Characteristics of e-marketplaces	(1)buyer-seller gathers (2)information gathering (3)information transparency (4)efficiency
Administration of e-marketplaces	(1)professional knowledge (2)credibility (3)capacity of information integration (4)providing of service integration (5)providing characters of commodity for transactions
Market Environment	(1)characters of industry (2)degree of computerization (3)promotion of pioneers
Derivative Problems of e-marketplaces	(1)reform of business procedures (2)reform of organization structure (3)degree of information transparency (4)security of online payment (5)standards of commodity
Functions of e-marketplaces	(1)styles of e-marketplaces (2)mechanism of matching (3)cost reduction (4)expansion of new channels (5)risk control (6)inventory control (7)integration of supply chain *(8)Information obtaining *(9)exploiting of new market
Phases of Partnership in e-marketplaces	(1)selecting of partners (2)developing of partnership (3)maintenance of partnership

\* proposed by four interviewed representatives.

Table 3. Importance of Research Dimension

Research Dimension	Number of factors mentioned by experts	Sum of importance among factors	Importance of dimension
Characteristics of e-marketplaces	15	16	94%
Administration of e-marketplaces	19	20	95%
Market Environment	11	12	92%
Derivative Problems of e-marketplaces	19	20	95%
Functions of e-marketplaces	27	36	75%
Phases of Partnership in e-marketplaces	6	12	50%

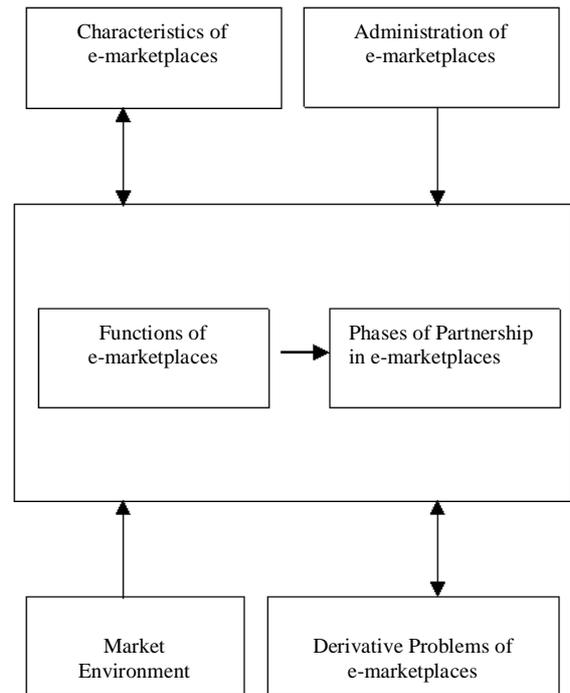

Figure 1. Research Model

must have three out of four interviewees mention at least). Based on the importance recommended by four executives, the Research Model is proposed as Figure 1. Information obtaining and exploiting of new market are two additional factors proposed by four interviewed representatives.

#### 4. Primary Questionnaire Survey and Research Findings

Since the Research Model is justified and validated, the questionnaire survey is deployed next. In the questionnaire, fifty questions are developed for twenty-six influencing factors of five dimensions in the Research Model. Items appearing in the question are measured in five-point Likert-type scales. Data are collected through a survey of organizations that are actively involved in the planning or operation of e-marketplaces. Twenty-five questionnaires are delivered. Eighteen are recycled and considered effective after examination. For avoiding bias from extreme values, Fuzzy Delphi Method uses geometric means instead of average means to evaluate answer values of questionnaire surveys. This research is hence to use Fuzzy Delphi Method to decide which factors are vital for the success in three phases of partnership in e-marketplace.

The geometric mean of answer values to each question is converted into percentage form. Questions with the percentage bigger than 75% are considered significant in this research. Influencing factors related to those significant questions are the crucial factors this research aims to find. According to the primary analysis, the crucial influencing factors of three phases of partnership in e-marketplace are summarized in Table 4.

Table 4. Crucial Influencing Factors of Partnership in E-marketplace

Phase	Selecting Of Partners	Developing of partnership	Maintenance of partnership
Factor	Cost Reduction	Characters of industry	Expansion of new channels
	Credibility	Exploiting of new market	Exploiting of new market
	Information gathering	Efficiency	Credibility
	Information obtaining	Information gathering	Standards of commodity
	Exploiting Of new market	Buyer-seller gathers	Characters Of industry

## 5. Conclusion

The research findings have been shown the influencing factors are not the same in three phases of partnership in e-marketplace, except exploiting of new market. These factors are dispersed in different dimensions (as shown in Figure 1). The research findings imply that to manage an e-marketplace must have different strategies to select, develop, and maintain participants.

As to the prospective relationship style of partnership in e-marketplaces, experts involved in the questionnaire survey regard e-marketplace transactions as the traditional ones. organizations involved in e-marketplaces only put their supply chains on Internet to make transactions more efficient.

Small sample size is one of the limitations of this research. A larger-scale questionnaire survey is expected to be conducted in the future to verify and enrich the primary research findings. Also factor analysis is going to be used for finding the vital research dimensions.

## Abstract

Even in best of the times, big companies find it difficult to sustain in the market with the same line of products. There is always a threat from the competitors and the new entrants of the market, engaged in creating new businesses and products. With the coming of digital age & fierce competition, breathing space of company is reduced to minimum. Managers of old industrial companies are sending SOS calls and looking forward for new business models. The need of the time is to listen to the survival calls for the 'clicks-and-bricks' business model that blends the traditional off-line assets with digital initiatives. The Internet is encouraging a shift from industrial age "brick and mortar" strategic thinking to a greater emphasis on the use of alliances.

### 1. E-enabled enterprise.

"NCR is a 117 year old company. We learned that new-economy people did business in other ways. They forced us to think out of the box, and that was a good thing. It's healthy for an old company to think that way. It's one of the biggest challenges in keeping an old company vibrant..."

- Lars Nyberg, Chairman & CEO, NCR Corp.

Value net as, Michael Porter puts are Customers, Competitors, Suppliers and Complementors with your firm in the center. The question is how to leverage our value net to create and capture value. The only way to create and capture value is to strategically transform the old economy traditions to new economy applications. The new e-enabled enterprises abide by e-transformation issues of Customer Relationship Management (CRM), Supply Chain Management (SCM), E-Commerce and Knowledge Management (KM). These new e-transformation themes offer different value propositions.

Customer Relationship Management (CRM) draws emphasis on to identify, select, acquire, develop and retain our most profitable customers. Digital economy companies strongly believe in buyers market. CRM not only addresses personal preferences, value and need of the customers but also builds customer loyalty through acquisition, development and retention.

The essence of the SCM is to deliver the right product, to the right place at the right time at the lowest cost. Implementing the principals of SCM provides end-to-end seamless capability in the supply chain, which in turn, results in improved customer relations and lower inventory levels. E-commerce is more than just trading on net. Internet acts as medium to deliver a more higher quality interaction to suppliers, distributors and customers. E-commerce facilitate in expanding business opportunities by reaching new markets, reducing cost via order processing efficiencies, maintaining fills rate while reducing inventory expenses and lowering cost of sales.

Knowledge Management (KM) is defined as "Management of organizational knowledge for creating business value and generating a competitive advantage". KM is the process of delivering the right knowledge to the right people at the right time to leverage expertise and information to improve the organizational performance. The main focus of KM is to acquire, analyze, store, disseminate and enrich knowledge throughout the enterprise.

In addition the e-marketplaces establish new trading models in vertical and horizontal markets. Online catalog digitalized product information in paper-based catalogs of multiple vendors and provide one stop shopping over the net and also allows buyers to search for products more efficiently. E-Auctions provides venues for the purchase and sale of new items where pricing is dynamic. E-Exchanges allows buyers and sellers to trade anonymously and provide a spot market for commodities, often with high price volatility. E-Communities bring together potential buyers and sellers, usually professionals with common interests, through web sites that feature industry specific content and community aspects. They typically provide industry specific news, editorials, market information, job listings, chat, message board etc. So the importance is to build an enterprise e-business framework that encompasses all touch point of the organization i.e. customers, vendors, people, alliances, stockholders etc.

Currently, five e-business themes are driving business strategies and initiatives.

1. Enhance operational efficiency.
2. Improve customer access, service, delivery and intimacy.
3. Redesign product and service offerings.
4. Reinforce brand image and company image in the marketplace.
5. Reinvent services, product and/or business.

## 2. Moving up in Value Chain.

“My favorite misread was the idea that business fundamentals had changed – that the traditional ways of doing business didn’t matter anymore: If you sold enough product or enough items at a loss, eventually you’d make a profit...”

- Warren Holtsberg, VP, Motorola Inc.

Every organization can move up in the value chain by reducing cost, improving process, redefining processes, redefining business models and creating new markets. Cost reduction can be done by introducing intranet for employee self-service and providing online support to the sales force rather than calling them to the office again and again.

Processes can be improved by providing online customer support and procuring via net (e-procurement). Vendor management inventory, strategic sourcing initiatives and selling products through e-channels can be some processes, which can be redefined.

It’s prominent to give services free with sale of product. In Networked economy, the business models need to be redefined. Customer should learn to pay for service like wise manufacture rather than producing itself everything should outsource production.

Creation of new market is another aspect, which is most important in value chain. Companies should identify opportunities and become market maker. They should invent new markets through e-channels and leverage their intangible assets.

An organization can adopt e-business strategies at any point in business cycle.

Stages of Business Life Cycle	E-Business strategies
Introduction	e-presence <ul style="list-style-type: none"> <li>• Use the Internet internally.</li> <li>• Establish a website.</li> </ul>
Growth	e-transaction <ul style="list-style-type: none"> <li>• Allow access to core systems.</li> <li>• Allow transactions on core systems.</li> </ul>
Maturity	e-business <ul style="list-style-type: none"> <li>• Improve core business processes.</li> <li>• Redefine core</li> </ul>

	business.
Decline	e-transformation <ul style="list-style-type: none"> <li>• Reinvent Business models.</li> <li>• Redefine products/services, add value.</li> </ul>

Readiness and integration are two important issues that must be considered when pursuing an overall e-business transformation. Managers should first find out that their business is robust enough and sufficiently ready to take advantage of e-business. Second issue is of integration of business processes to maximize investment in e-business initiatives.

## 3. From E to E.

There is a wonderful Chinese saying, “Journey of 1000 miles began with a small step”. Succeeding in digital economy calls for a different resolve. Create Energy that drives the organization, Energize the team, Empower your colleagues, create Edge in market with new product innovation, Execute your plans with simplicity and speed, follow Ethical business practice, give Equity to stockholders, Encourage mistake and learning, Examine ones mental model, Experiment for continuous improvement, Educate others like top management on technology and inside of organization on customers and have Environmental concerns.

### 9P FORMULA for winners

1. Knowledge is the key.
2. New Business hrs. 24x7x365
3. Everyone and everything will be networked.
4. Everything will be smart.
5. The customer is in charge.
6. Time is the scarcest resource.
7. Barriers to competitive entry are lower then ever.
8. Constant innovation is an ingenious tactic.
9. Follow rule 1 to 9 or become extinct.

# 'Do It Yourself (DIY)' E-Business Solutions for Small and Medium Enterprises

George Q. Huang, JB Zhao

Department of Industrial and Manufacturing Systems Engineering, University of Hong Kong,

[gqhuang@hku.hk](mailto:gqhuang@hku.hk)

## Abstract

The potential benefits and cost of adopting and implementing e-business solutions are both high. They are major attraction and concern for Small and Medium sized Enterprises (SMEs) respectively. If a right tradeoff point is not balanced between the two, a breakthrough progress is unlikely to become true. This paper addresses this very issue by proposing and developing a new approach based on the concept of "portalets" that are used as building blocks to develop e-business solutions with no or varying degree of customization efforts. Portalets are designed following the platform for deriving the software product lines. This "Do It Yourself (DI)" approach significantly reduces the time and effort to an affordable level while capturing the unique business logics into the solutions. In this paper, the necessity, feasibility, and the challenging issues of the proposed DIY e-business approach will be discussed. Case studies will be presented to demonstrate the approach and directions for further work.

**Keywords:** Enterprise portal, e-business, Do It Yourself (DIY), Digital enterprises, Small Medium Enterprise (SME).

## 1. Introduction

In recent years, the importance of Internet and World Wide Web (WWW) technologies in manufacturing industries has been rising very rapidly in a global context, the impact of which is deemed most profound ever since the Industrial Revolution (Manufacturing Foresight 2020). The waning interests in the electronic commerce and electronic business (e-commerce / e-business) have spread, from the heartland (product development) to the battlefield (shop floor), of manufacturing enterprises. The technology gradually transforms traditional manufacturing to what can be referred to as Digital Manufacturing (or e-Manufacturing), with more companies using the Internet to get into new markets, increase supply chain efficiency, create new value chains, and increase the efficiency of internal planning and operations.

The number of web applications is ever on the rise, and many practitioners are keen on trying these remote systems through web browsers to support their decision-making activities. Indeed, product design and manufacture professionals will soon be able to benefit from such remote services and supports commercially available on the Internet. The practice and performance of product development and realization are expected to make immense progress. Web applications in product design and manufacture signals the beginning of a new era of the digital manufacturing enterprise.

Although the Internet technology has the potential of enhancing a company's competitiveness, it has also created a new challenge for the manufacturing industry. Manufacturing companies have just been persuaded to invest in Information Technology (IT) and Information Systems (IS), and have made appropriate changes to accommodate and adapt to these technologies. Now these information systems are becoming legacies even before their capabilities have been fully exploited. Now their roles have to be performed under the Internet and web environment. Hence, manufacturing companies have difficulties in formulating the most appropriate investment strategy in IT and IS under such rapidly changing environment.

In addition, the adoption of the web-based manufacturing approach is not only the decision of the manufacturers. If the customers, suppliers, and the commercial and financial sectors prefer to adopt the web approach, the IT industry will provide various web applications to meet their requirements. Eventually, most decision-support systems (DDS) for the manufacturing industry will also become web-based. They will then have to incorporate some or many of their business activities, decisions, and operations into web applications.

The potential benefits and cost of adopting and implementing e-business solutions are both high. They are major attraction and concern for Small and Medium sized Enterprises (SMEs) respectively. However, SMEs are generally unclear about which approach should be adopted to introducing the e-business solutions (EBS). This paper is in favour of the so-called DIY (Do It Yourself) approach, meaning that SMEs designing, developing, deploying and maintaining their own EBS. The rationale behind this DIY approach is only valid on the assumed emergence of the concept of "portalets" which are ready made constructs to facilitate the EBS design, development, deployment and maintenance. This paper will discuss the necessity and feasibility of the portalet-based DIY approach to EBS.

The remainder of the paper is arranged as follows. Section 2 presents a typical scenario that motivates this research, highlighting the major issues. Section 3 articulates the concept of Digital Enterprises in general and Digital Manufacturing (Enterprises) in particular. Typical approaches to EBS are discussed in Section 4 to highlight the necessity of the proposed approach. Section 5 demonstrates the feasibility of the proposed approach from a number of aspects. The concept of "portalets" is briefly introduced in Section 6. Section 7 focuses on the case study on the "TreeTable" portalets which have been widely in a variety of EBS.

## 2. Motivating Scenario

Let us first imagine a typical manufacturing enterprise that has enjoyed a rapid business expansion from a much smaller scale two decades ago to the present medium-sized scale. The company was created in Hong Kong as a family business in early 1960s and enjoyed a steady development by serving the US and European markets during 1970s.

The company took advantage of the Mainland China' open door policy since early 1980s and moved most of its manufacturing facilities to the Peal River Delta while keeping its headquarter in Hong Kong to accommodate production-related logistic activities such as purchasing, marketing, product development. Because of much cheaper labour and raw materials in Mainland China, relatively fewer competitors and growing US and European markets, the business had enjoyed a rapid development during 1980s and 1990s.

Like most of the other manufacturing enterprises, the company invested in Information Technology and Information Systems (IT/IS) mainly to support operations of routine business processes. The Computer Aided Design and Manufacturing systems have been routinely applied. The company also invested in MRP (Materials Requirements Planning) and a number of hiccups occurred during the implementation and introduction process. Eventually, the company was able to manage a partial success.

These IT solutions were able to support the company to cope with the busy routine business activities until the company recently encountered enormous challenges. Firstly, more competitors have entered even contracting markets. Some of these newcomers have even been better equipped with sophisticated IT solutions and are likely to take competitive advantage in terms of responsiveness. Secondly, the customers are becoming more demanding in terms of quality, price, delivery times, and after-sales supports. Finally, the costs of labour and raw materials are no longer a distinctive advantage because they have increased considerably and other competitors are equally enjoying the same benefits anyway.

The external pressure has changed the way in which the operations were internally managed. In the past, although the schedules were busy, operations were generally executed smoothly with very few major hiccups. However, the current situation can be described as "fire-fighting". Some of the problems become apparent. Firstly, the communications between the Mainland manufacturing plants, the Hong Kong headquarter, and customers/suppliers became a major source of a variety of problems. Although managers and engineers from the headquarter visited the manufacturing plants regularly, the effectiveness and efficiency were not impressive because of long journey. Telephone calls, faxes and email messages have been used to compensate the face-to-face communications. The problem of effectiveness and efficiency of these communication methods was even more serious. Very often, data sent through faxes and sometimes

email messages have to be processed again before sensible analyses can be conducted.

Secondly, the new product designs developed at the Hong Kong headquarter tend to have more errors related to downstream business processes. For example, manufacturing difficulties and quality defects exist in many new designs and were not identified promptly. This was because the manufacturing expertise and test labs are located in Mainland China and not readily available and accessible by the Hong Kong development team.

Thirdly, it was evident that the Purchasing and Sales departments spend significantly more time and efforts in clarifying purchase and sales orders with the suppliers and customers respectively. This problem has significantly affected the new product development team because they have to modify their new designs too often to cope with order changes.

Fourthly, there have been increasing complaints from engineers about the increasing number of requests for making changes to the product designs and manufacturing plans. This has not only affected the lead time but also the total costs.

Finally, the product range has increased significantly from a limited few in 1960s to several hundreds at present. Every product is a different product but all the products look similar. The increased product variety has further stretched the increasingly more expensive resources.

The company was determined to solve the problem. During the tide of e-commerce around the turn of the century, the company was naturally advised to look into the potentials of the latest web and Internet solutions. The top management was very open-minded, supportive but skeptical/cautious. As long as IT/e-Business solutions truly deliver their promises in improving the competitive and efficiency significantly, they were prepared to invest in such solutions.

The company was seriously considering getting a suite of sophisticated e-business solutions from a reputable vendor. Consultants from this major vendor were invited to give an overview of its e-business solutions. During the talk, the aggressive promotion by the consultants actually scared the engineers involved in the project. Firstly, the consultants talked about the evolving history of their e-business solutions over one and half decade. This period may be long enough to the IT vendor but short to an IT user. Their systems evolved from early standalone system through networked client-server to fat-client web-based systems. They also indicated that they will launch a fully web-based thin-client system shortly.

Secondly, the consultants pledged that their e-business solutions would contribute to the reengineering and rationalization of the business processes and operations if they were fully implemented. This was in fact imposed by their solutions: whether willing or unwilling, changes must be made to suit the methodologies embedded in the solutions.

Thirdly, the consultants offered intensive training for the company staff members of the project team. The basic training was included in the initial acquisition price of the

suite. However, extra charges would be made to advanced training for features such as customization after the installation and implementation.

Fourthly, the consultants mentioned their joint venture with a service provider for an opportunity for the company to subscribe to their EBS with the Application Service Provider without purchasing the solutions to reduce the acquisition and maintenance costs.

Finally, the consultants proudly announce that they provide a suite of solutions encompass the entire business operations and these solutions can be introduced in different phases according to individual needs.

After the consultants' promotion talk, the company decided not to continue along this direction for the following reasons:

- The solutions themselves have been evolving too fast to follow as an IT user. The fundamental question is can we keep up with the changes made by this vendor? A free upgrading would be attractive. But any fundamental major changes to the user interfaces and underlying methodologies might cause significant problems.
- The business and operation models incorporated in the solutions were not readily compatible with the existing ones of the company and significant changes must be made in order to implement the solutions. This may potentially lead to more fundamental traps, operational chaos, and significant resistance from the engineers and workers.
- The customization of the solutions to suit the company's unique features might take too long and too much specialist skills may be required to customize and maintain the customized systems. Chaos might occur in case of personnel turnovers.
- Training and maintenance costs might be unpredictable and thus unmanageable after a few years with uncertain commitment and benefits.
- The opportunity of subscribing to an Application Service Provider was attractive in some sense. But the above concerns were basically addressed. In addition, this approach introduces a third-party whose commitment is yet a major concern.

For the above reasons, the company decided to abandon the previous approach. Instead, they decided to conduct an exercise of business process reengineering (BPR) for the sake of improving the business operational performance, instead of jumping into EBS directly. Following this "IE (Industrial Engineering) before IT (Information Technology)" approach, Key business processes were identified and then analysed one after another. Problems with each business process were examined and then determined what IT solutions were appropriate. Suitable IT solutions would then be acquired and implemented. The company, however, experienced the following dilemma:

- Very few IT solutions that suit the company's requirements were readily available in the commercial

market. Most such vendors were small IT firms. Long-term customer services become a major concern.

- Those suitable IT solutions were from completely different third-parties. Their interfaces were completely different. They had different user management. After all, they were separate systems.
- If the company really wanted a solution that best suits its requirements, the best approach was to develop it on its own. Several questions arise immediately: Do we have the necessary IT expertise and skills? Can we afford the time and efforts? Is this a commercially viable approach?

The above company and its story is purposefully created to illustrate concerns that typically represent those of many SMEs. The long-term implication is however significant. The DIY approach seems to be most appropriate for SMEs and EBS vendors may have to transform themselves from total EBS vendors to the so-called "Portalets" vendors in the future. The rest of this paper is to explain and justify the belief that the Portalets-based DIY approach is not only a suitable approach to SMEs, but also a commercially viable and technically sound approach.

### **3. Vision towards Digital Enterprises**

#### **3.1. EBS: Electronic Business Solutions**

A web application is defined as any software application that depends on the World Wide Web, or simply web, for its correct execution (Gellersen and Gaedke, 1999). Hence, software systems that are explicitly designed for delivery over the web, for example web sites, and that use the web infrastructure for their execution, are web applications. For example, many information systems that were designed and built prior to the web are now wrapped and made available as web applications through the use of web browsers.

Electronic Business Solutions (EBS) are web and Internet applications or solutions that are used to facilitate the business decision making and executing activities. The imaginary company in the motivating story is interested in gradually introducing a spectrum of web applications throughout the product development and realization process, focusing on topics ranging from market research to the supplies of tools/equipment and raw materials. In other words, one or more EBS are needed for each of its business processes.

#### **3.2. Enterprise Portals**

If a manufacturing enterprise uses only one web application for the purpose of product design, the users access the relevant web pages and components after the successful login session. Because they belong to the same web application, all the web pages are arranged in such a way that they are efficiently and effectively used.

If the enterprise uses multiple web applications, the above method of accessing them can still be used on an

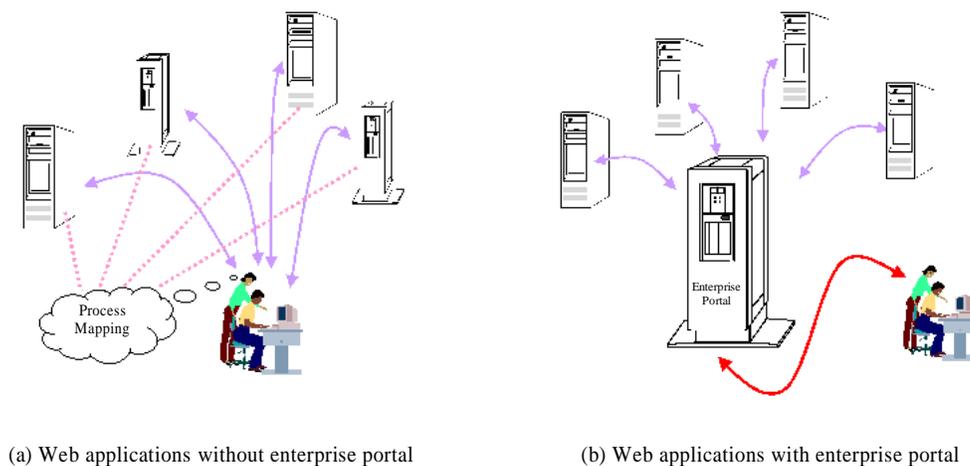

individual basis. That is, the access to each web application is controlled by itself separately. If the number of the multiple web applications is limited to the manageable level, say  $7 \pm 2$ , the users are able to work effectively and efficiently with these web applications. However, if this number increases dramatically and these web applications are left scattered on the Internet without a central hub, it will be very difficult for the designers and team members to locate the appropriate web applications at the right time for the right tasks. This situation is shown in Figure 1(a). The engineers should have an overall picture of the organization's business processes and functions. At the same time, they should also be conscious in the relevant documents, information flow and applications over the Internet. However, the situation will quickly become problematic when the number of information sources increases and the complexity of the business changes dynamically. The situation will be worse by the adoption of standalone and isolated applications, each with different working procedures, different interfaces which are non-self explanatory, and different installation and maintenance requirements.

The concept of enterprise portals is introduced as a central hub for accessing web applications to overcome the above problems, as shown in Figure 1(b). Enterprise portals gather and organise the huge amounts of unconnected data scattered across the enterprise, and then present the information in the forms of window areas, where each containing a view of the enterprise. Enterprise Portals provide a secure, personalized view of the enterprise for each individual user or class of users, based

on job functions, roles or other relevant criteria. An Enterprise Portal integrates disparate sources of information and business logic, and provides a single point of access to the knowledge and processes of the organisation through a simple and intuitive interface to users of the extended enterprise, including customers, employees, suppliers, and business partners alike, with a single point of access to the knowledge and processes of the organization through a simple, intuitive interface. The technicalities of the back-end applications, documents or databases remain in the background and are invisible to users. Using an enterprise portal, these constituencies (customers, partners, employees) can conduct business via the Intranet, Extranet or Internet from wherever and whenever convenient for them.

In the most simplistic sense, an enterprise portal can be simply a web page that has been created to collate the hyperlinks to all the web applications which are basically separate applications with differing functions and user interfaces. A user with multiple responsibilities, each of which requires the access to a web application, still needs to login and access a relevant web application for each responsibility.

Sophisticated enterprise portals are expected to accomplish much more than a web page hyperlinked to web applications. The accesses are usually highly personalized, depending on the roles and responsibilities of the users in the organization. Rapid deployment is achieved while high consistency is maintained. Searching within the portal is facilitated and better teamwork and collaboration is enabled.

**Figure 1** An enterprise portal as a central hub for accessing web applications.

### 3.3. Digital Enterprises

An enterprise is called a “digital enterprise” if its web portal plays an important role in its business activities and decisions. Some digital enterprises conduct their businesses mainly by providing online contents (which are

relatively simple form of web applications) and more sophisticated web applications. Their business processes are entirely accomplished on the Internet.

However, traditional businesses such as manufacturing and even software development extensively employ web applications (and consequently digital

enterprises) across the entire business processes to improve their operational efficiency and quality thus competitiveness. For example, a manufacturer becomes a digital manufacturing enterprise or simply an e-Manufacturing enterprise if it uses the web applications extensively in its business and engineering operations.

Indeed, a digital enterprise has the following characteristics. Firstly, the access to a digital enterprise is logically dimensionless in terms of time and geographical location, although it may be physically distributed (deployed) at different locations. To the user, it is a central web site. The geographical boundaries of the physical enterprise vanish with the emergence of the digital enterprise.

Secondly, a digital enterprise builds up the inter-connections between and among enterprises and intra-connections between and among units within a member enterprise via various levels of access control and authorities. The term "Virtual Enterprise" is often used to describe such a digital enterprise.

Thirdly, the lifecycle activities in the product development and realization processes are no longer arranged sequentially. The corresponding web applications are deployed in parallel across the entire the digital enterprise.

Finally, there is no longer difference between front- and back- offices in the digital enterprise.

#### **4. Approaches to E-Business Solutions**

The motivating story in Section 2 indicated three general approaches to the implementation and adoption of EBS. The first approach is for the enterprises to purchase/license, deploy and maintain the off-the-shelf e-business solutions commercially available in the market. Leading vendors have been developing comprehensive suite of sophisticated e-business solutions that are generally produced for large corporations because of the high costs, built-in business models, oriented towards the western culture, and level of customization and thus training. These are significant difficulties for SMEs (Small and Medium sized Enterprises) to take advantages of the recent developments in the technology.

In order to resolve these problems, efforts have been made by both application solution providers and application service providers to provide online services especially for SMEs. This second ASP approach reduces the cost and minimizes the technical skills required for implementing the technology to an affordable and acceptable level. However, other limitations still exist, prohibiting the widespread use of the technology in SMEs. For example, business models and business processes vary widely from one SME to another. It is extremely difficult to accommodate them into one e-business solution. This can only be achieved through customization which adds significant sophistication to the system and its operation. Advanced training is usually required. In addition to these limitations that are shared by the first approach as well, the ASP approach imposes serious dependency of the

enterprises on the technical and business decisions of the service providers. If a service provider determines to terminate one service, the enterprise users who subscribed for the service will be unable to continue the service, leading to unacceptable interruptions.

The third approach is the "Do It Yourself (DIY)" approach. It is generally perceived that it takes significantly long time and enormous efforts to develop e-business solutions by enterprise users themselves because of technical sophistication and special programming skills even if they are fully familiar with their own business processes and operations. Therefore, it is not usually considered a viable approach to developing an e-business solution for a specific application by an SME.

The research discussed in this paper is mainly concerned with the fourth approach to deal with the above dilemma. This new approach is an extension to the third "Do It Yourself (DIY)" approach to e-business solutions. This DIY approach is however enhanced by the concept of "portalets" that emerge from the software product line management. This portalet-based DIY approach is expected to reduce the total adoption cost dramatically by at least 50~70% to a level affordable by SMEs. Such reduction is achieved by eliminating costs involved in the comparison and acquisition of the e-business solutions while keeping the development time and efforts to a level equivalent to those involved in the training and customization of commercial e-business solutions. In addition to the cost reductions, the DIY approach allows the SMEs to incorporate their own business models and business operations into the e-business solutions, instead of being rigidly imposed and prescribed by commercial systems. By so doing, SMEs are able to truly exploit the technology to support their daily decisions and operations thus really improve their competitiveness.

#### **5. Portalets-Based DIY Approach**

Let us now focus on examining its feasibility from the following aspects:

- Nature of the Internet and web technology
- Maturity of the Internet and web technology
- Readiness of technological developments
- Efforts of business process reengineering
- Awareness and enthusiasm of MIS
- Software product line / platform management

##### **5.1. Nature of Internet and Web Applications**

An EBS basically follows the so-called 3-tiered architecture. It normally includes three parts: the application client, server and database. One of the advantages of this architecture is its modularity for changing one component without or with little impacts on the other two. For example, the enterprise business logics are usually captured in the middleware server components. The client components can be added according to individual user requirements. The business data and the business logics are relatively independent of each other.

## 5.2. Technology Maturity

The Information Infrastructure Technology, both hardware and software, are evolving very rapidly. However, several aspects have reached a mature stage that justifies the DIY approach. For example, relational databases are now more or less standardized with a few limited dialects. SQL (Structured Query Language) is used in conjunction with JavaScript and/or VBScript on the server side to deal with the data between the database and the clients. These scripting methods are also relatively standard, widely taught with other standard web programming skills. Any graduates are expected to have reasonable understanding and skills in these aspects after completing courses like Information Technology, Information Systems, Computing and Programming, etc.

On the hardware and system side, setting up a web server and web site has been made as easy as creating a file for word processing by following simple instructions. This is expected to be improved even further in the near future.

## 5.3. Efforts of business process reengineering

Companies have been increasingly engaged in rationalizing and streamlining their business processes. Through these efforts, the workflow and information within the organizations are better structured to an extent that is difficult to change again to suit the requirement of a particular IT solution but ready for specifying a custom system that suits itself most.

- Simplify the business operations
- Streamline the business process
- Rationalize the flow of work
- Reveal the potential bottleneck issues
- Outline the fundamental logic and method

## 5.4. Software Product Line / Family

Advanced theories and methodologies for designing manufactured products have been a major area for research. One of such approaches is the so-called Platform Product Development (Robertson and Ulrich 1998). Similar approaches are emerging for designing, developing, deploying and maintaining software products. For example, Parnas (1976) and Meyer and Lehnerd (1997, Last few chapters) are dedicated to Software Product Line and Software Platform approaches respectively. The greater reusability and modularity will not only speed up the development process but also improve the interchangeability and exchangeability among EBS with the same enterprise.

## 5.5 Insights from Past Case Studies

Over the last 5 years, the first author has led a group of researchers at the University of Hong Kong on a variety of research projects involved in developing prototype web applications in product design and manufacturing with the financial supports from Hong Kong Government Research Grants Council and the University of Hong Kong Research Committee. Recent developments have been documented in Huang and Mak (2002). Some examples are listed:

- Engineering change management

- FMEA (Failure Mode and Effect Analysis)
- QFD (Quality Function Deployment)
- Design for X
- Collaborative Product Design Review
- Early supplier involvement in new product development
- Morphological chart analysis for concept generation and evaluation
- Market testing with conjoint analysis

Our direct experience from these projects shows that the Internet and web technology lend itself a strength of rapid development and deployment of applications components if certain templates are provided for key issues such as database connection, user interface formatting, etc. The time and efforts of developing a “new” application by this ‘Do It Yourself’ approach is no more than that involved in customizing a comprehensive commercial suite and participating in training courses. Customizing a system requires in-depth knowledge about the system, and therefore requiring intensive training. Our experience shows that 1-3 months of efforts are generally sufficient for two persons to develop one simple EBS, assuming that they have the necessary skills and background knowledge about the application. The “necessary programming skills” that we are referring here are not specialist skills, but common programming techniques such as SQL, Java scripts, and HTML scripts. These have been widely taught in undergraduate courses of not only computer and software engineering but also other engineering disciplines such as industrial engineering. If the source codes of some templates are available, this time and effort level can be further reduced below 2 months. This is the level that is usually required to learn how to use and customize a commercial e-business solution. By so doing, the high acquisition costs of the commercial systems are avoided, while company-specific business and operation models are easily accommodated.

## 6. DIY Portalets as Product Family Platform

“Applets” and “Servlets” are well-known Java constructs for building up client and server components of web applications, respectively. ActiveX components and Enterprise Java Beans (EJB) are two more recent concepts of competition. One of their main purposes is to standardize the techniques and constructs to facilitate the design, development and deployment of the web solution components at different levels (tiers).

### 6.1. Portalets

By following the similar conventions such as Applets and Servlets, the term “Portalets” is introduced to represent powerful constructs for developing enterprise portals. This introduction is necessary when more and more web applications are put into practice to support business operations, leading to the emergence of digital enterprise. The scope of this paper is limited to the manufacturing context, especially product design and manufacture.

There are at least three approaches to building enterprise portals and their features are summarized in Table 3. In a recent enterprise portal market study, Meta Group found that 75% of enterprise portal development efforts were still being accomplished using labor-intensive traditional web development environments. Their research concluded that companies should use portal frameworks or portalets, rather than conventional web tools to build their enterprise portals.

Portalets themselves are web applications for managing other domain-specific web applications. As a matter of fact, some utility web applications such as calendar, email, online chatting, bulletin board, whiteboard, etc. are delivered as constituent components of some commercial enterprise portalets.

Enterprise portalets range from simple Intranet indexing and search tools to enterprise-level database-driven information storage and retrieval products. Table 3 summarizes, without prejudice or preference, some of the typical enterprise portalets commercially available on the market. Although they offer competing features and unique facilities, they serve the similar purpose of facilitating the deployment of web applications to form enterprise portals. Figure 5 shows the architecture of the appssolut Enterprise Portal Suite (<http://www.appssolut.com>).

An enterprise portalet differs from general-purpose website development environments such as Microsoft Frontpage while sharing numerous common functions. A website development environment is generally considered as an environment for developing and deploying individual web applications ranging from simple HTML contents to web pages with sophisticated computational components embedded or attached.

In contrast, an enterprise portalet provides an environment for deploying various individual web applications into a central website called an enterprise portal. There is no doubt that environments like MS Frontpage have been used for this purpose in practice. However, this approach is unlikely to meet the requirements set out for many commercial enterprise portalets (see for example White Papers of portalets listed in Table 2).

### 6.2. Portalet Architecture

Because portalets themselves are web applications, they also share the 3-tiered architecture, as shown in Figure 2. This point is the major difference between the portalets and applets/servlets (ActiveX components and Enterprise Java Beans as well). Therefore, a portalet may include an applet at the client tier, a servlet at the web server tier, and of course a database at the data tier. Some of the alternative combinations are given in Table 1.

Another point worth pointing out is that different portalets can be obtained through different configurations of the same set of components at the 3 tiers. For example, "TreeTable portalet 1" is formed by combining the "HTML Table" client with the Server-side scripting and SQL recordset. "TreeTable portalet 2" is formed by

combining the "TreeTable Java Applet" client with the Server-side scripting and XML data.

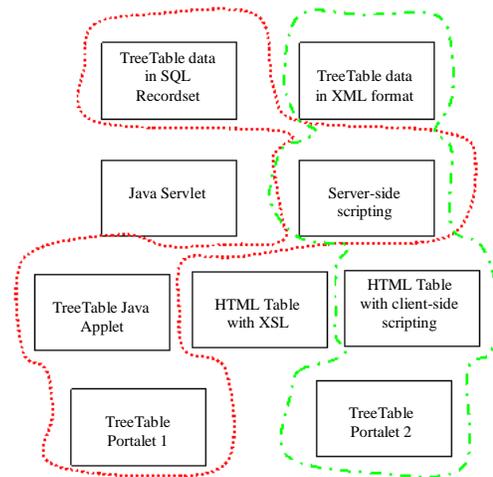

Figure 2 3-Tiered Portalet architecture.

Table 1 Alternative combinations of portalets

	Client Tier	Server Tier	Data Tier
1	Applet	Servlet	RDBM SQL
2	Applet	Server-side scripts	
3	HTML with scripts	Servlet	
4	HTML with scripts	Server-side scripts	

### 6.3. Portalets-Based EBS

The concepts of ActiveX components and Java Applets/Servlets/Beans have been devised by various IT vendors as basic constructs for building up web applications. The aim is to improve the reusability and rapid development/deployment. However, the technical complexity is still high and often not suitable for the DIY approach because the level of technical skills required is high. For this reason, these components should usually be designed and developed by highly skilled IT professionals and programmers. After they are purposefully configured into portalets, it becomes straightforward to design (configure) and develop a new EBS. For example, Figure 3 shows how to use the same set of portalets (general-purpose) to develop two completely different web applications, one for presenting the Bills of Materials (BOM) in product development in Figure 3 (a), and the other for archiving Design Objects (usually documents) submitted for review. Because they are based on the same portalets, the configuration and customization are extremely easy to accomplish.

#### 6.4. Towards EBS Family Portalets Platform

Because of our primary interests in web-based collaborative product design and manufacturing, a set of portalets specialized in Collaborative Product Commerce (CPC) will be developed to demonstrate our proposed portalet-based DIY approach to EBS, in addition to some general-purpose portalets. These portalets become common features shared by all the resulting EBS. This will lead us to develop further along the direction of Software Product Line or Family management.

#### 7. “TreeTable” Portalet Example

The lower part of Figure 4 shows an example of a TreeTable. The first column is an indented tree structure and the rest is actually a table. The tree branches can be extended to show and collapsed to hide details. Therefore, only the useful information is displayed at a time while giving the necessary overview. This combination of a tree and a table has been widely used in building the user interfaces of e-business solutions because many items of the enterprise information including engineering, business

and market information are logically represented in this treetable format. It has also been widely used in most of our own prototype systems mentioned in the preceding section. As a result, TreeTable should be constructed as a “portalet” in our DIY e-business framework.

As shown in Figure 4, this TreeTable portalet includes three components that are ready for inclusion in the components corresponding to the 3 tiers of the web application. Source codes have been omitted from the paper because of limited space of 10 pages allowed for the proceedings of this conference.

#### 7.1. Database Structure for “TreeTable”

The top of Figure 4 shows database tables used to construct a TreeTable for representing the Bills of Materials (BOM). The “Parts” Table is used to store the items of the BOM tree. The hierarchical relationship between the items is of the “many to many” type. The “BomStructure” Table is used to store these relationships. The “ParentID” and “ChildID” correspond to the two items in the “Parts” table, indicating the item with “ChildID” is a branch of the item with “ParentID”. The 3<sup>rd</sup> table, actually a group of tables, provides additional information for describing the BOM items and their relationships.

The customization at the database level (tier) becomes very simple exercise of copying and then renaming the “Parts” and “BomStructure” tables to form new tables. There is even no need to change the naming scheme of the fields of the new tables for the “Tree” area. For the Table area of the TreeTable, additional data tables can be easily created to suit specific applications.

#### 7.2. “TreeTable” Middleware Data Structure

The TreeTable portalet middleware that is used by the application server includes a few lines of scripts (either JavaScript or VBScript) to be embedded in the application server. First of all, the database must be connected. In Microsoft Active Server Pages, a few lines of short codes are needed to connect the application server to the database and then remember the connection as a session variable for future references. These connection codes are extremely simple and modular, independent of any other codes. Therefore, customization is straightforward.

The TreeTable data are retrieved using the SQL (Structured Query Language) together with the Java/VB scripts. The retrieved data can be represented in the native form of recordset or resultset of the particular Relational Database Management (RDBM) system.

Once again, the customization of the SQL string is straightforward. If the naming scheme for the fields are not changed, only the names of the tables need to be modified in the SQL string, and no other changes are necessary.

Alternatively, the retrieved data can be represented in the XML data structure, either directly from SQL if it support such conversion or through an XSL template to convert the SQL recordset into hierarchical XML data structure. XSL templates normally need not be changed for different applications.

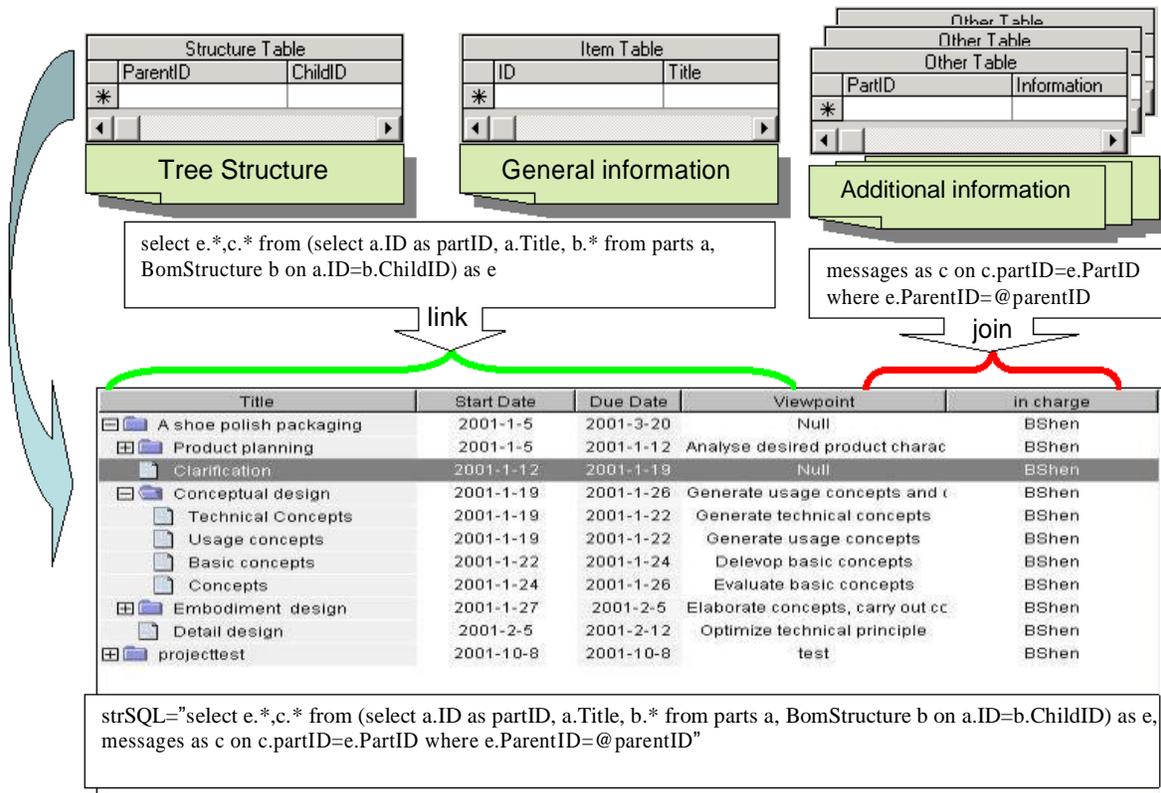

Figure 4 TreeTable Portalet and its components at the 3 tiers.

### 7.3. "TreeTable" Clients

Several methods exist for building TreeTable clients:

- Using a commercial Java Applet with SQL recordset
- Using standard HTML table with SQL recordset
- Using standard HTML table with XML without XSL
- Using standard HTML table with XML and XSL

#### 7.3.1. "TreeTable" Java Applet with SQL Recordset

One method is to take advantage of ready-made TreeTable Java Applet, several versions of which are commercially available on the market. In MS Frontpage, server-side scripts are used to populate the data in the TreeTable Applet. The populating action takes place on the server side while the contents of the TreeTable are displayed on the client side.

The server-side codes include a few sections to greatly improve their modularity to facilitate the customization. For example, an independent procedure is prepared for populating the column headings of the TreeTable from the names of the columns of the recordset. Another independent procedure is prepared for populating the menu items for the right-click events of mouse buttons over the TreeTable items (rows). Finally, a procedure is developed for building up the tree branches and their associated information items.

The above three sub-procedures are used to form an overall procedure for building up the TreeTable. It takes an SQL as its input variable. Therefore, for different applications, it is only necessary to change the SQL string without changing the TreeTable procedure at all.

#### 7.3.2. TreeTable with HTML Table from XML and XSL

If the retrieved data are represented in a nested XML format where nesting indicates the hierarchy in the TreeTable, then there are two ways of populating the XML formatted data into a HTML table. One is to use the script and the other is to use XSL. The latter is demonstrated here for its better modularity. The XSL template is designed and developed such that it converts any nested XML data into a TreeTable regardless of their contents. As a result, only the SQL string is needed for different applications and no further changes are necessary.

## 8. Conclusions

This paper has argued for the necessity and demonstrated the feasibility of developing e-business solutions by the SME manufacturing companies. This DIY approach is only practically viable with the support of the concept of "portalets". Portalets are built upon standard web and Internet technologies. They are basic constructs commonly used in web applications. They are highly modular,

implying that no or little customization is required to adapt to a particular application. Portalets are logically configured to form what is called a “platform” of a software product lines/family. As a result, the portalet-based DIY approach to e-business solutions offers several advantages:

- The requirements for specialist IT skills are dramatically reduced to a level attainable by engineering graduates with certain on-site training.
- Developing and maintaining web applications (web pages) become as simple and easy as create, revise and maintain a word document.
- The time and efforts of developing e-business solutions are dramatically reduced to a level competitive to out-sourcing commercial e-business solutions.
- DIY e-business solutions are able to accommodate the unique business models and operation models of a particular company demanding minimum changes to the current good practice.
- The upgrading and extensions can be made freely without any external constraints at any time whenever necessary.

Further work will be conducted to substantiate the portalet-based DIY approach to e-business solutions in three directions. One is to create a number of widely used portalets such as TreeTable, Menu, Table, Charts, FillForm, etc. Another direction is to create a framework for configuring portalets within a web application according to certain requirements. Finally, case studies will be conducted to demonstrate how the proposed approach can be used to develop CPC (Collaborative Product Commerce solutions).

The impact of the portalet-based DIY e-business approach is enormous and fundamental. One has to change the traditional perception that e-business solutions require mythical specialist skills to develop and therefore have to be acquired (purchased or licensed) at high cost with intensive training. The technology has now evolved to a stage and provided an opportunity that one is now able to take full advantage to maximize one’s competitiveness in one’s own way and pace.

## Acknowledgements

The authors are grateful to the University of Hong Kong Committee on Research and Conference Grants, the HKSAR Research Grant Council, and the Graduate School for the financial supports. A great deal has been learnt in the past few years from previous researchers who are now alumni of the research group.

## Abstract

A micropayment scheme is proposed to enable transactions of different denominations and to eliminate possibilities that either the vendor or the user in a payment system misbehaves to get illegal profit. The proposed offers a solution while keeping transactions efficient.

## 1. Introduction

The Internet is, nowadays, a source for information seekers to have a variety of services such as stock quotes, news reports, video streams, etc. These multimedia services in essence may include text, audio, and/or video information that have different values for information providers. As the cost of each kind of service differs from one another, every service may need different numbers of tokens if single-denomination tokens, such as payword, the payment token of PayWord [1] protocol, is chosen as the information seeker's payment tool. PayWord uses a one-way hash function to produce successive tokens, and it is frequently referred to among other schemes in literature, such as Millicent [2], iKP [3], and MicroMint [1]. With the irreversible characteristic of one-way hash function, this scheme prohibits receivers of a payword token from guessing subsequent tokens while keeping the process of transactions efficient. If a service costs more than a single token, the nature of payword token leaves the potential risk to the token holder that he or she may lose some or all tokens given to the service provider without receiving anything. When the span of Internet services consistently grows, the flexibility of payment tools should be noticed.

In addition to flexibility, the issue of fairness is generally important for most on-line payments. In the environment of micropayment transactions, this issue is usually left intact. When a payword token is passed to the vendor, it is the user's potential loss that the vendor might redeem that token without sending the target information good to the user. Namely, the vendor may gain improper advantage over the user in PayWord protocol if he or she accumulates and redeems tokens without offering services.

We hereby propose a solution to prevent misconducts of both the user and the vendor while retaining its payment flexibility in transaction value. It is particularly suitable for web sites providing multimedia services that have payments of different values.

## 2. Literature Review

In this paper, discussion and analysis are focused on PayWord and other protocols based on the successive release of elements in a chain of cryptographic hash values. There are three participants in PayWord: the user  $U$ , the vendor  $V$  and the broker  $B$ . Each user has to register with information such as the broker's name, the user's name and the user's public key, with at least one broker, which offers a PayWord certificate. This relationship is represented by a PayWord certificate signed and issued by the broker, which binds the broker's name, the user's name and the user's public key together.

Before  $U$  requests a service from  $V$ , a fresh chain of hash values  $w_n, w_{n-1}, \dots, w_1, w_0$  is generated by randomly picking  $w_i$  in formula (1).

$$w_{i-1} = h(w_i), \text{ for } i = n, n-1, \dots, 1. \quad (1)$$

Notably,  $h$  is a one-way hash function, which is publicly known and cryptographically strong. Furthermore,  $w_0$  represents a root of the hash chain, and is delivered to  $V$  at the beginning of a service session. Root  $w_0$  authorizes  $B$  to pay  $V$  for any of the tokens in this chain that  $V$  redeems thereafter.

$U$ 's  $i$ th micropayment to  $V$  consists of the pair  $(w_i, i)$ . The validity of this token can be verified by  $V$  using  $w_{i-1}$  which is known from the previous payment or from the commitment in case of  $i = 1$ .

If no dispute occurs,  $V$  presents  $w_0$  and the final token received to  $B$ .  $B$  verifies their legitimacy and if successful, pays  $V$  the amount that corresponds to the tokens and charges the same amount to  $U$ 's account. When  $V$  misbehaves,  $U$  will lose at least the last token already sent to  $V$ . Even though the value of a payword token is not high enough to cause serious loss for the user, a persistently cheating vendor can collect a substantial amount of money by sending an unexpected service or nothing at all.

## 3. Revised scheme

The proposed micropayment scheme is a variation of PayWord, and it is also inspired by Asokan *et al.*'s proposal, an approach that achieves a complete and fair exchange [6]. The main idea of our scheme is to make a valid token a combination of two hash values from two independent hash chains. These two hash values can be regarded as two half-tokens. The first is forwarded to the vendor before service provision and the second is not sent until the service is provided. That is, unless the

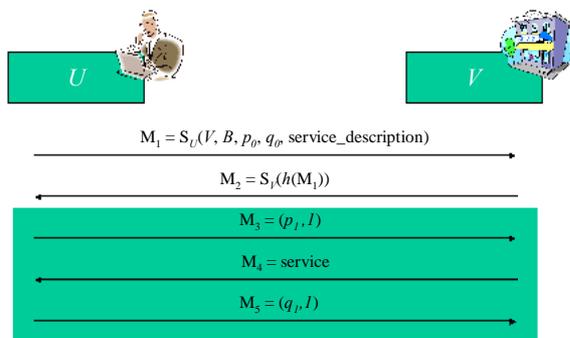

vendor offers the requested service, a complete token cannot be collected and redeemed. This feature secures the user from the vendor's malicious redemption without offering the requested service.

Before transactions begin,  $U$  must register with  $B$  and obtain a signed certificate. Information recorded on this certificate includes  $U$ 's id,  $B$ 's id, and  $U$ 's public key. Thus,  $U$  generates fresh hash values;  $p_n$ , and  $q_n$  are randomly chosen, and  $n$  is decided based on his or her own need. Via the same secure one-way hash function  $h(\cdot)$ ,  $U$  computes two hash chains  $p_n, p_{n-1}, \dots, p_0$  and  $q_n, q_{n-1}, \dots, q_0$  as shown in formulae (2) and (3).

$$p_{i-1} = h(p_i), i = n, n-1, \dots, 1. \quad (2)$$

$$q_{i-1} = h(q_i), i = n, n-1, \dots, 1. \quad (3)$$

The roots of the chains are  $p_0$  and  $q_0$ , and  $U$  sends these values to  $V$  at the beginning of the service session. Thus, every legitimate token is composed of two hash values; i.e., the token used in the  $i$ th transaction is  $(p_i, q, i)$ .

**Fig. 1. The initialization steps and the first transaction of the proposed protocol**

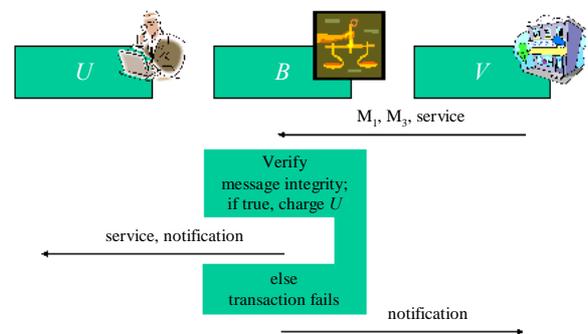

$U$  begins a new transaction session by passing  $p_0, q, n$ , user certificate, as well as a general description of the requested service to  $V$  as a session commitment. A transaction session may have one or more transactions that  $U$  pays by the same token chain.  $V$  uses this commitment for token verification when tokens from  $U$  have been received. Then  $V$  signs and returns this message as his service provision commitment to offer the requested service. The initialization procedure of a transaction session is completed when the service provision commitment ( $M_2$  in Figure 1) is transmitted to  $U$ . This procedure is shown as the first two messages transmitted in Figure 1.

When a transaction session begins,  $U$  sends  $(p_i, i)$  to  $V$  as the first half-token of the  $i$ th micropayment. As a half-token,  $p_i$  also represents  $U$ 's payment commitment for that transaction.  $V$  validates  $p$  by comparing  $p$  and the result of hashing  $p_i$   $i$  times. The root  $p_0$  is retrieved from  $U$ 's session commitment. If the validity of  $p_i$  is confirmed,  $V$  may transmit the requested service to  $U$ .  $U$  must provide the second half-token  $(q_i, i)$  after receiving

the service. The vendor examines this half-token in the same manner exactly as the first half was.

In an ideal case,  $V$  sends  $B$  the session commitment of  $U$  and the last token collected, requesting payment redemption.  $B$  pays  $V$  and charges  $U$  the value of  $i$  tokens.

Because the proposed enables payments that cost multiple tokens, the issue of dispute handling should be more carefully examined. If disputes occur between  $U$  and  $V$ , they can be either one of the following two cases. If  $V$  refuses to offer the service  $U$  requested after receiving the first half-token  $(p_i, i)$ ,  $U$  has no loss as long as  $U$  does not send  $(q_i, i)$ . Even  $V$  receives other first half-tokens such as  $(p_{i+1}, i+1)$  for successive transactions, he or she can only verify the validity of first half-tokens. Without receiving requested services,  $U$  will not send the second half-tokens. In this case,  $V$  cannot get any illegal profit by redeeming only half-tokens.

**Fig. 2. Dispute handling**

The other case is shown in Figure 2, which occurs when  $U$  refuses to pay the second half-token after receiving the requested service.  $V$  in this case may show  $B$  the information collected from  $U$ 's session and payment commitments previously received. The target service of this transaction also has to be sent to  $B$ . Being a trusted third party,  $B$  justifies the dispute based on the information offered by  $V$ . If it is  $U$ 's malicious behavior to refuse to pay,  $B$  will pay  $V$  from  $U$ 's registered account directly, and pass the target service to  $U$ . Hence neither  $U$  nor  $V$  benefits from misbehaving in this case.

If true fairness is not absolutely necessary or the dispute handling efficiency is a serious concern, the idea proposed by Buttyán can also be applied in this proposed scheme.  $U$  is charged once the first half-token is sent; regardless of whether the second half-token is paid for or not. When  $V$  attempts to redeem with only a half-token, he or she will not be given the value of the incomplete token. Revenues from such disputes are donated to charity.

#### 4. Analysis

The proposed scheme makes the user free from possible losses caused by payments that cost more than

one token. And it is applicable to most practical Internet micropayment environment. When a user  $U$  intends to receive some information services from an on-line news web site  $V$ , for example, objects including text files, voice streams or even video clips satisfying the keyword are available. If these types of information objects are charged at different rates, the user of PayWord or other related extensions has to prepare token chains representing different denominations, otherwise he or she will have possible loss if paying multiple tokens of the same hash chain to a misbehaved web site. The user therefore has to prepare tokens of all denominations he or she needs before the transaction session begins. In case the user requests for a video clip that costs six tokens, either this user generates a new hash chain and tells the vendor that each token of this new chain represents exactly six units, or he has possible loss when giving all six tokens from the same hash chain. In other words, if malicious  $V$  is given  $w_6$  in PayWord, all six tokens from  $w_1$  to  $w_6$  can be verified and redeemed directly. Similarly, if  $V$  is given  $w_6$  in Buttyán's scheme, three tokens  $(w_1, w_2, 1)$ ,  $(w_3, w_4, 2)$  and  $(w_5, w_6, 3)$  will be regarded as valid and redeemed. Another way to avoid such loss is to make every payment a combination of tokens from chains that represent different denominations. Both situations would not be convenient enough for the web surfers and would cause restriction to micropayment applications.

In addition, the PayWord user might lose all  $i$  tokens if he or she pays  $w$  for some service that costs  $i$  tokens. Similar situations occur in other PayWord-like micropayment schemes. In this proposed scheme, the two half-tokens,  $(p_i, i)$  and  $(q_i, i)$ , are chosen from two independent hash chains. Hence even a service costs  $i$  tokens,  $V$  can only verify the received  $p_i$ . There is no means to compute a complete token unless  $U$  reveals the second half-token  $q$ . Taking the situation stated in the previous paragraph as an example, when  $U$  has paid  $p_i$  and the requested news report has yet to be received,  $U$  is free from any loss as long as he or she does not send  $q$  to  $V$ . It is easy for the on-line news web site to verify  $p_i$  via  $p_0$ , but mathematically difficult to compute or guess  $q_i$ . Hence, the web site  $V$  collects a full token  $(p_i, q)$  only if  $U$  receives the report and sends  $q$ .

In terms of efficiency, our scheme is roughly the same as Buttyán's. PayWord, Buttyán and the proposed all have the same number of public key cryptographic operations, including digital signature generation and verification. Although the proposed scheme requires twice the number of hash computation as PayWord does, it is still affordable due to the computation efficiency of hash function. Regarding transmission payload, this protocol sends 2 hash values for every consecutive transaction step, which is 1 hash value more than Buttyán's scheme. It would not cause serious network loading considering the size of a single hash value.

In comparison to Buttyán's and other PayWord-like schemes, the proposed offers better protection for both the user and the vendor. PayWord cannot justify the

malicious denial of service when  $V$  redeems the received paywords.  $U$  can only minimize his or her loss by refusing to make further transactions with  $V$  passively, after losing some tokens for incomplete services. In other words, by accumulating tokens from numerous users, the malicious vendor still gets a fortune of illegal profit. As to Buttyán's protocol, although neither  $U$  nor  $V$  takes improper advantage over the other party,  $V$  still bears potential losses when  $U$  refuses to pay after receiving the requested service.  $U$  in this scenario will be charged, but the revenue will be donated to charity instead of distributing to  $V$ . Our scheme does not cause such losses. As long as the second half-tokens are kept by  $U$ ,  $V$  cannot make any illegal profit by redeeming the incomplete first half-tokens. If  $U$  refuses to pay the second half-token after receiving the target service,  $B$  will be the trusted third party to justify whether  $V$  should be paid. Hence the proposed protocol causes no losses in the scenarios mentioned above.

## 5. Conclusion

A variation of the PayWord protocol was proposed to enable payments of different values without much loss in efficiency while the rights of both the user and the vendor are well protected. It solves the problem to pay varieties of multimedia services of different costs. Comparing to PayWord, it although requires twice as many on-line hash computations by the vendor, the complexity of hash computation should not be a real burden. Thus the advantages of this scheme lead micropayment to greater flexibility in real-world applications.

## Abstract

A modern business organization is increasingly dependent on smooth and reliable flows of data and information, both laterally and vertically, and both within and across its boundaries. Therefore, managing data should be viewed as an element of a fundamental corporate process. Information systems investments aim at enabling and supporting these processes. Investment decisions, again, originate from organizational strategies that need to be aligned with IT strategies, for systems to enable and support business processes. The topic of our enquiry is the planning and decision-making of those systems that qualify as strategic.

We have created an extended framework to cover strategic, tactical and operational levels of planning and decision-making, also focusing on related control, communication, benefits management, and follow-up activities. Our research approach is a single case study method using a multinational financial services company. The investment is a Web Content Management (WCM) system that the company wishes to deploy in a unified, centralized manner throughout the business and geographical areas with the intention of reaping synergy effects. In the paper we enumerate our observations on the strategic planning process, decision-making, control and communication.

This research has been supported by the Academy of Finland project no. 674917.

## 1. Introduction

A modern business organization is increasingly dependent on smooth and reliable flows of data and information, both laterally and vertically, and both within and across its boundaries. (The term “data” is used interchangeably with information.) Data is also increasingly considered as a corporate resource, having in

certain contexts a critical effect on day-to-day operations. Therefore, creation, accrual, manipulation, storage, distribution and use of data can, and should be viewed as elements of a fundamental corporate process. The constantly growing share of investments allocated to the area of information systems is evident from the constant growth of supplier industries, be they hardware, software or data communication vendors or consultants.

Any single benefit aimed at, may alone represent the sole purpose of an information systems investment. Alternatively, organizations may seek benefits in various combinations. An all-encompassing combination, i.e. a set of desired systems falls under the concept of strategic information systems plan (“SISP”) [1]. The systems are commonly categorized as compulsory – like ones enforced by a public authority, financial benefit accruing – such as revenue increasing or cost reducing, new business enablers – such as new product or service, and strategic – usually overarching systems linked to the organization’s strategic goal setting. Systems development may take place singly or as part of a major program. Currently, especially strategic systems investments are very often a part of a larger strategic development program. They allow for streamlining operations and business processes both inside an organization, and between an organization and its partners in business. These development programs are guided by the decisions made upon the business and IT strategies on corporate level. The business and IT strategies are intended to be in line with each other, i.e., aligned. Our conceptual framework for strategic business and IT planning is illustrated in Figure 1.

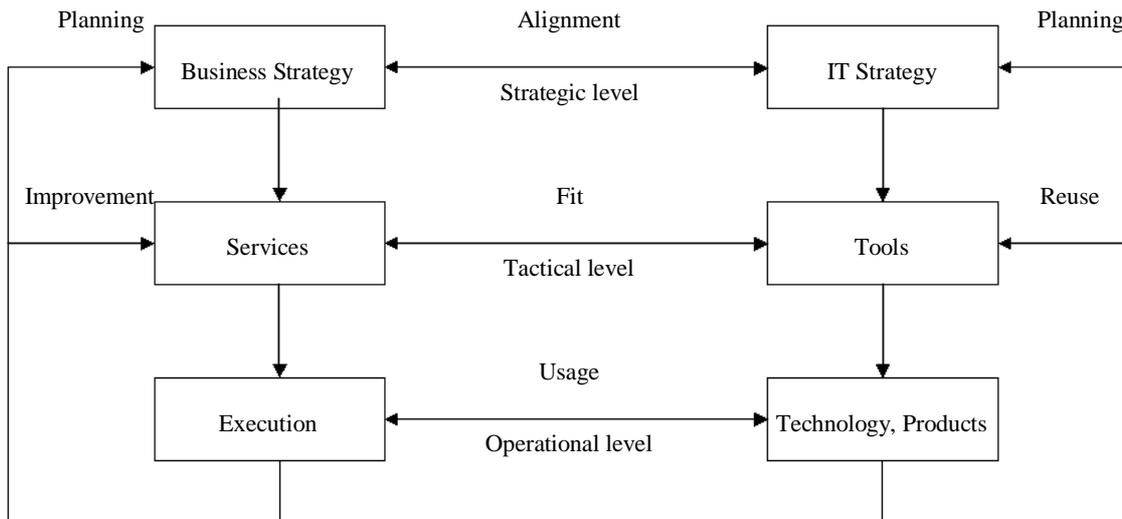

Figure 1 Strategic Planning Framework

The business strategy guides the development and implementation of services to customers, as well as the development and implementation of the internal business processes in an organization. The IT strategy guides the acquisition, implementation and service delivery of IT tools to support the organizational functions. The business and IT functions need to be aligned on the strategic level. Additionally, a fit is needed on the tactical level of business services and IT tools [2] [5]. Furthermore, the alignment and fit is actually tested on the operational level during the use process of information technology and individual IT products.

The turbulent business environment of contemporary organizations and changing customer needs require continuous feedback on and improvement of both services and the IT tools supporting them. Feedback arrows in Figure 1 illustrate this. The existing services are, of course, the basis for creating improved services, and on the IT side the existing systems and system documentation can be re-used when improving the IT tools supporting the business services and functions. The experience gained from implementing a company's services and the experience of using the supporting IT tools provide information, or they may sometimes even create the incentive for reconsidering the business and IT strategies.

## 2. Research Objectives

In this study we analyze the decision making and strategic investment planning process focusing on the following dimensions: strategic planning process, decision making and control, communication, benefits management, and follow-up. We relate the case experiences to our strategic planning framework in order to verify its descriptive power. We also pursue to explain the dynamics of the framework, i.e., to establish the forces that are indispensable to keep the feedback flows running.

The research questions include how the system development gets initiated at the strategy level and how it proceeds down to the operational level. Particularly we are interested in the communication that takes place along the arrows in our framework across different levels, as well as horizontally. Decision-making takes place on both formally and informally. In the present study we investigate the formal decision-making process in order to find out how decision-making power is allocated to different organizational levels and between IT and business. Furthermore, we explore the process of control of the planning and implementation of investment objectives and the communication.

## 3. Methodology

Our research approach relies on a single case study method. We have had an access to key company representatives that we have interviewed using thematic interviews. These were audiotaped. We selected a system development case that is strategic by its nature and also encompasses the whole group of companies with presence in several countries. We have also had the possibility to cover all pertinent, documented instruction material relating to strategic planning, system development work, as well as measurement and review forms. For a comparable, interpretive case study using one company in the financial services industry, see for instance Peffers and Tuunainen [3].

## 4. The Case Organization

The case organization selected for this research is a multinational portfolio type of company in the financial services field. The company has experienced many structural changes over the last decade. The number of employees has recently grown to well over 30 000. Being a member of the top tier as to the market share, and possessing several cutting edge technology financial products, the demands of integrating the corporate members are increasing. These demands stem from

customers, who would rather see the corporation as one single supplier across borders. They also stem from within, mainly articulated in terms of increased synergies. One vehicle conceived as an enabling, integrating strategic factor is the company's WWW-based network environment.

Whereas the company was previously faced with a wide selection of related software and solutions in creating intranet and extranet content, the overall strategic aim was integration. In more precise terms, the company pursued to reduce the number of content creation environments, separate (partly custom developed) content management systems, and the number of production sites. In this pursuit, the key issues were as follows.

Firstly, the company aimed at setting up one central, packaged WCM (Web Content Management) system, available for all portfolio members. Secondly, the company wished to strengthen its identity by providing a unified set of preprogrammed artifacts in the form of symbols, labels, logotypes and layout structures, which would be easily replicated and reused. The third key issue was making the content creation and publication directly available to individual business units. In the previous system environment a business unit, at the outset, typically drafted a content document. This effort was multiplied if counter-party units in other countries also wished to draft a version of their own. There followed perhaps several rounds of reviews (times the number of content producers). Eventually one version was selected in an approval process, which again may have taken several rounds. Finally, the document was ready for publishing, and it was delivered to the chief editor – sometimes called the WEB Master. The remaining source of anxiety was the timing of publication, if there was a backlog of material queuing up. A centralized WCM was the contemporary answer for streamlining such a process. Previously, creation, approval, testing and publication procedure was judged to be cumbersome, as illustrated above. In particular, the testing and publication phases relied on a few technically oriented persons stationed apart from each other in the portfolio countries. This naturally led to coordination costs that could be eliminated with a centralized WCM system. The last issue was considered to be of utmost importance and far reaching as to its consequences. Thus, the centralized, single system was regarded as having strategic level benefits in terms of integrating business processes and streamlining the web-publication process.

## 5. Preliminary Observations

### 5.1 Strategic Planning Process

All new system development initiatives in the case company originate from business strategies, which contain strategic focus areas and targets that are, to an extent, jointly with IT converted into a development program. This is called a consolidated information systems strategy and it paves way to the system portfolio

development that is to be launched over the annual planning horizon.

The tactical level planning brings together the issues of what is the service that business wants to offer and the tools made available by information technology. This fitting task launches the actual project planning work. At this stage, IT has already nominated a responsible project manager, who acts as the coordinator and head-figure, and who also collects the evolving documentation. All procurement related decision-making is founded on both business and IT strategies.

### 5.2 Decision-making

Participants in decision-making represent all interest groups, i.e., top corporate business management, participating business units' management and IT management, either according to organizational hierarchy or in various decision-making organs. Additional participants in decision-making are specialists that possess expert knowledge in the areas under discussion. Decisions concerning project work proper are made in the project management group. Other decisions, such as the one on procurement, are made either centrally or in a distributed fashion, depending on the decision object. The decision-making authority of different organs has been defined in monetary terms. The power balance between different interest groups in decision-making organs varies by development stages. In the project planning phase business units tend to have a relatively large representation, whereas implementation phase witnesses IT's relatively dominant representation.

Project proposal requires the approval of all user organizations that shall carry the costs involved, and the top executive organ in those cases, where the proposal is classified either as strategic or financially significant, i.e., investment exceeds a preset limit. All parties to the chain of approval have access to the same set of decision documentation. In the case at hand, two business units and IT approved WCM proposal. In addition – without strict necessity – the proposal was taken to the top executive organ due to its strategic nature in overarching the whole corporate group.

There is no formal procedure to decide upon the future ownership of a system to be developed. However, in practice and also in the case of WCM it was negotiated among the future user organizations during the drafting of the project proposal. The one in charge of the preparation of the proposal coordinates the negotiations of the ownership, since invariably one owner has to be identified and explicated in the final project proposal. The guiding principle underlying the negotiations is to vest the ownership on the organizational entity to the one to draw most benefit of the future system. In a likely fashion, it is the owner that usually will carry the largest share of the financial burden post implementation.

The allocation keys to split the license fees were also under negotiations in the planning phase. At the end, due to the threat of a notable delay, allocation mechanism was decided by an executive order, where after each country

organization made a parallel approval decision on allocation keys accepting the overall allocation principle.

In order to speed up the planning phase, the persons participating as responsables made decisions concerning their individual task areas with an explicit authority of the management group. Management group was then regularly notified of these decisions in its meetings, gave feedback and guidance if deemed necessary, but in essence approved them formally.

Coming down to the operational level of the framework we observed two sets of processes. One relates on the left side of Figure 1 to the business processes. The experience proved that business participants perceived process definitions as difficult due to inexperience. In addition to having to learn a new tool (a packaged program), the users found it difficult to draft processes from a clean sheet. We could not, however, establish the relative degrees of change resistance on one hand, and professional incapability, on the other. The second set of processes took place on the right side of the framework. This related to program engineering, configurations, hardware installation settings, all of which were more straightforward than work done on the opposite side. The decisions made on IT side were more technical by their nature and their impact more forcing towards business and users.

In addition to the traditional roles of business-, IT-, and project management, the case company has also designed and adopted a role of business chief information officer ("BCIO"). The hierarchical status of a BCIO is that of a first vice president, and they number some 15. They belong to the IT organization and act by and large as account officers towards business areas. In the decision-making process their role is to see that all documentation is in place and negotiate the development issues with the customers, i.e., the business areas or their units.

### 5.3 Control

The ultimate control of project activities lies always within the investing organization, even though external consultants and experts were used. It is also commonplace to have the project manager nominated from within IT, as in the case of WCM.

Each project management group meeting follows up on accrued costs and the project's progress that are reported on a monthly basis. The project manager, assisted by IT's administrative project office organization, reports on the figures and progress using a project review form. Business units, on the other hand, are responsible for monitoring of the accrual of the stated post-implementation benefits. All system work, IT production and IT services costs are also reviewed regularly on a summary level with business unit management, - controller representatives and the relevant business chief information officer in attendance.

### 5.4 Communication

There exists a formal procedure for intra-project communication and feedback, but it is scarcely deployed. The deployment is largely dependent on the individual project managers' work habits, but additionally general haste shadowing scheduled project work may cause a degree of indifference. In the WCM project, communication and feedback have worked exceptionally well, this is seen to be a consequence of several positive factors, such as exceptional staff motivation, extrovert nature of those involved and also due to communications professionals being involved. Additionally, one of the user organizations was the group communications, which added positively to the propensity to distribute information above and in excess of strict stipulated minimum.

A common cross-country document management system was available to cater for the internal communication and collection of feedback in the WCM project. This is a common project databank, where all documentation of cross-border projects is deposited. Read-only rights to browse WCM documentation were granted to each and everyone willing to have access. This was exceptional, since such authorities are normally sparsely granted due to the repository containing documents in progress that might be interpreted as finished and approved.

Internal feedback was perceived as very useful, and it was actively collected beyond the compulsory opinions and technical statements, also on ad hoc basis. Regular statements on systems descriptions were received at points that required a quality inspection based on the systems development work model. These statements ensured that the work and the resultant documentation complied with the appropriate work instructions correctly and adequately. Expert opinions were sought in abundance, but their delivery was often random. Additional feedback was received from the project management group. In the group participating in the project work there are individuals, mainly on management level, that are regularly informed of the progress. Their commitment was perceived somewhat loose, which was also seen to lead to a very low volume of feedback from them.

After the project has been finished, a final evaluation of the work is drafted. This contains issues that have been unexpectedly successful or negative experiences. This procedure, however, is still in its early introduction phase, and therefore there is not much experience of utilizing the evaluations. It is also uncertain, to which extent these final project work evaluations will be utilized in future projects.

Production stage communication is channeled through nominated individuals. IT has appointed one person – and a substitute – towards both internal and external interest groups. In a similar fashion the application supplier and the consultant company have also a nominated first point of contact.

## 6. Initial Conclusions and Discussion

Our tentative conclusion of the descriptive power of the framework used is positive. In the WCM case used, we have been able to witness the linkages, the roles and the levels depicted, with the provision of the far sided recursive arrows that will materialize only by lapse of time. However, the procedures, (feedback mechanisms), organs, (change management meetings) and administration routines, (change prospect databank) are all in place.

We have been able to establish the three levels of decision-making, namely strategic, tactical and operational, and the role-play involved. We would like to call these levels management, architecture and engineering levels. Our main conclusion in relation to the framework is the direction of decision flow that starts from top left, moves laterally to right, returns, steps down, moves right again, returns, steps down, and finally moves right to technology and products.

Some of our observations also support a view that the dominant decision-making – and bargaining power move diagonally from top left to down right, i.e., from business to IT. This view, however, requires more extensive substantiating, although this notion of widening role of business in planning, building and running information systems has been explicated for a considerable period of time, see for example Zmud et al. [6] and Pinker et al. [4].

Another, strongly emerged phenomenon was the key role played by the relevant BCIO. Our observations indicate that he/she plays a role of a catalyst. His/hers is a domain that covers ubiquitously all development projects, planning levels and interest groups. In summary, the BCIO enables the interplay between business and IT on all lateral arrow levels. The BCIO is the chief negotiator with business, planning coordinator of the business' system architecture, and a shop-floor steward on operational level activities.

We could further witness a remarkable requirement for feedback and communication that originates from introducing a centralized system to a setting of a complex of existing systems and country specific system environments. In the case project communication worked exceptionally well, since people were motivated and the company's communications professionals participated actively in the project. The internal feedback was

facilitated through the use of a common cross-country document management system. Basically everyone willing to have access to browse the WCM documentation was granted the rights. This was perceived very useful. The linkage between the complexity of the development task (technology included) and the required volume and management of feedback and communication needs, however, to be further elaborated before anything definite can be posited.

Reengineering literature emphasizes the need to start planning from a clean sheet. A less emphasized need is the preparedness and expertise of those business representatives involved in the task. In the WCM case this appeared to be one of the trickiest tasks. It is one thing to improve gradually and fine tune existing processes than design a completely new one that is based on a predetermined logic cemented in a packaged program application.

Our aim, as the next stage, is to crosscheck further our observations through revisiting the interviewees on the basis of our documented case material. We shall also re-confirm our observations against written material, like expert opinions, decision protocols, and job descriptions. If the descriptive power of our framework still remains on at least the present level, we intend to engage in further confirmatory research through a wider survey.

## Abstract

Anhui Tobacco Corporation (ATC) is a large state-owned group corporation. After a long period of planned economy system, ATC is not suit for marketing economy. With rigid management method, bad service and high trade cost, ATC is weak in competition. Shortly after 1-year's construction, ATC built up an E-commerce platform which has the largest bargain and perfectly combines the traditional industry with modern information technology. The information system is based on a network connecting all the subordinate factories, branches and wholesale center. It is centered by e-business, including e-commerce platform, centralized fund management system, and ERP for manufacturing factories and MIS for sales firms will be applied later. Since the platform went into operation in Oct.,2001,an average of thousand boxes of cigarette has been dealt. Up to March,2002, the trading fund amounts to 400 million yuan. This figure is forecasted to be one billion in 2002. At the same time, income grows rapidly. The allot income increases 24% compared with the same period last year; wholesale increases 14%, profit increases 21%. Information system must service the strategy target, and be driven by management innovation. The success is due to idea renewing, leadership, organization and Training from beginning to end.

## 1. Introduction

By the end of 2000, Anhui Tobacco Corporation (ATC) was still backward in information system, far behind such advanced provinces as Shanghai, Yunnan and Hunan. Shortly after 1-year's construction, ATC built up an E-commerce platform which has the largest bargain and perfectly combines the traditional industry with modern information technology. The success is due to idea renewing, leadership and organization. All enterprises preparing to construct e-commerce can learn much from this case.

## 2. Background of E-commerce construction

ATC has 23 subordinate organizations, including 8 factories, 17branches, with a totaling staff of 20000. It has 7000 wholesale net terminals, 27 retail shops. After a long period of planned economy system, ATC is not suit for marketing economy. With rigid management method, bad service and high trade cost, ATC is weak in competition.

In order to survive and grow rapidly in the new era of knowledge economy and information, ATC must solve two main problems. First, inside the corporation, it must

standardize production, strengthen management, re-organize management structure. Second, outside the corporation, it must setup a strict rule for tobacco market, blow away imitate and forge product. ATC undertook the above work before, but no better effect was achieved because of heavy job, bad organization and weak method. In the new era, this can be achieved by information system to guarantee the growth target.

## 3. Procedure of E-commerce system construction

### 3.1 Re-construction of marketing net up to sky and down on earth

According to administration region, geographic environment and economic region, ATC redesigned its business flow, logistic flow and inspection flow, and built up a network covering all the cities, counties and towns throughout the province. This net has 7156 sales routes, 6361 distribution routes and 7386 inspection routes. With an effort of standard service, sending goods directly to customers etc., the net is more complete, more unblocked and more effective. It is also a ready platform for the e-commerce platform to be constructed later.

### 3.2 Weaving a network up to sky and down on earth

The first step in constructing ATC tobacco information system is to build a computer network connecting all the subordinate factories, branches and wholesale center. By the end of 2000, ATC begin to invest several million yuan to construct the industrial private net that is 'up to sky and down on earth' with the principle of 'International standard, Chinese characteristic and suitable for Anhui'. In the sky, ATC links with China Tobacco Corporation through satellite; on the earth, ATC connects its subordinates, wholesale centers, inspection branches and banks through DDN,PSDN. The net will be further connects to workshops, machines and customers in the future.

The private net is used not only for data transmission, but also for other applications. The internal IP-phone system is used by all users throughout the province with a charge of zero. The video meeting system is normally in use for tobacco industrial meeting and training. Everyone can discuss business and learn new technology in his own office, saving a large amount of money that is needed for traveling. The inter- and extra- web sites are open to visitors inside and outside ATC.

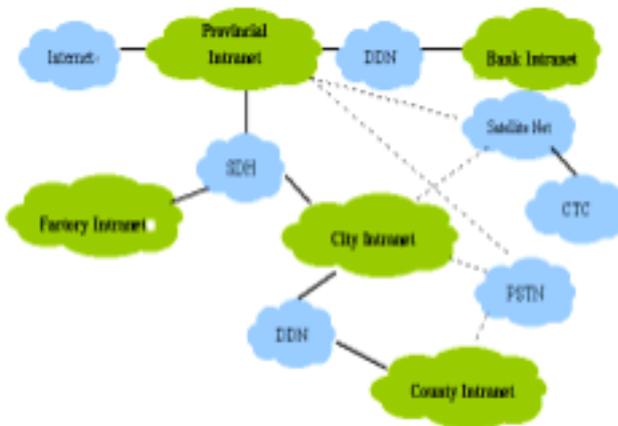

Fig.1 The Top Structure of ATC Intranet/Extranet

### 3.3 Innovation drives information system

Information system must service the strategy target, and be driven by management innovation. During the construction of information system, ATC invented many innovative methods.

The first is innovation of marketing network.. ATC built up a multi-dimensional marketing system covering information flow, currency flow and goods flow. The most significant innovation is centralized logistics, centralized customer visiting and centralized inspection. With specialization and division, such phenomenon as practicing fraud and secret bribery is eliminated completely, which ensures the purity of business.

The second is the innovation of managing idea. In 2000, ATC stated that 'Retail shops are our parents of living'; in 2001, ATC further raised the idea to 'Service is of outmost important; Customers should be respected everywhere'. With the application of methods in Customer Relationship Management, ATC setup a system of customer management, which focuses on improving customer's satisfaction, contribution and loyalty. This system tried hard to achieve a state that the co-operation between ATC and customer is distance-zero, customer's cost of purchase is zero, and customer's complain on service is zero. In this state, customer's resource and value can be fully mined.

Thirdly is the innovation of management system. ATC pays yearly salary for the main leaders of its subordinate organizations according to their work achievement. The application of yearly salary stimulated these leaders as were as provide a standard of assignment for them.

The fourth is the innovation of work examination. In the past 2 years, ATC did not assign such quota as profit, tax or selling. It assigned a new examination quota system mainly concerning the quality of operation. For subordinate organization, the quota is increase of growth; for salesmen, it's income and gross profit; for monopoly staff, it's quantity and purity of the market; and for all leaders, the main examination quota is the quality of their

work. This new examination system is more rational. It released all the people from traditional quota, enabling them to do more important work.

## 4. Application of software centered on e-commerce

### 4.1 The strategy of software application

In 1993, ATC began to build its information system, but the application goes slowly. Later, ATC developed a set of software named 'ATC Business Information System', which was appraised by China Tobacco Corporation in 1996. There were only four users by the end of 1998.

Entering 2000, the information system and their blocks still remained isolated from each other, forming many 'information islands'. The network equipments were out of fashion, only connecting cities. In such environment, ATC was hesitated to start e-commerce. Will the e-commerce platform become a mirage in this loose base of information system? Should we start from the very beginning in a traditional way? By that time, there was no complete e-commerce platform in our nation. Should we wait until other company builds a model?

It is risky to invest a large amount of money and build an information system. Such system may look vast, but it can't run smoothly. Therefore, ATC determined a strategy of planning totally and implementing progressively. First of all, ATC plans to build a e-commerce platform with the function of cigarette dispatching, transporting and accounting, ignoring the demand of factories and retails. After the platform operates in good condition, the logistic management is completed, and the market environment is improved, ATC will prolong the platform to B-C, and finally B-B including firms both inside and outside. At that time, online purchasing and selling will be achieved.

The basic idea of constructing ATC's e-commerce system is to achieve standardization through information system and build up a scientific management system. The system is centered by e-business, including e-commerce platform, centralized fund management system, ERP for manufacturing factories and MIS for sales firms. The

Fig.2 Framework of ATC information System

main frame of the system is shown in Fig 2.

#### **4.2 E-commerce trade platform**

E-commerce platform is a trade and managing tie connecting producers, agents, customers and banks. In order to be easily operated, ATC first built a B-B e-commerce platform which has a vast amount of trade. The platform is open to tobacco 8 factories, 17 branches, all the wholesale centers and 2 banks. The procedure includes web ordering, electric approval, online payment and logistics. It takes only 10-20 minutes to process an order.

As known to all, e-business has three difficult problems in China: safety, payment and material flow. Many e-business companies lost a lot in these problems. But with the superiority in tobacco industry, ATC ingeniously solved the problems.

First, the ATC's network is a sealed network in tobacco industry, not opened to outside yet. Therefore, enterprises outside tobacco industry can't trade in the e-commerce platform. On the surface, it seems to contrast the rule of opening advocated by e-business. But actually, it is this sealed network that ensures the safety in the not matured social environment. With all the traders being brothers inside the industry and strict control, no business cheat can appear.

Secondly, the rule of paying first and delivering second also avoids the debt crisis often appeared in such inside-industrial trading. Therefore, if relative enterprises are all involved in the e-commerce platform, the real time accounting can be achieved and the main problems become only technology and skill.

Thirdly, ATC connect the e-commerce platform with information systems in Industrial and Business Bank and Agriculture Bank by special lines. A machine located between information systems transmits data and ensures the safety. In this method, cigarette factories open bank accounts in both banks, and the sales companies in cities and counties open only one account in either bank. The purpose of cooperation with two banks is to avoid the difficulty of financial accounting between banks. At the same time, this structure can guarantee the platform running in good condition. If one bank has any problem, the other can be a 'backup'. The result of competition between two banks is better service.

Finally, the logistics network constructed by ATC itself ensures the material flow. A high-lever centralized dispatching center is built in each city. There are 6,159 delivery lines, 2,974 delivery cars in ATC. In cities and towns, the delivery occurs at least one time in 2 days to each retails, and in countryside, it occurs at least one time in 3-4 days.

Since the platform went into operation in Oct., 2001, an average of thousand boxes of cigarette has been dealt.

Up to March, 2002, the trading fund amounts to 400 million Yuan. This figure is forecasted to be one billion in 2002. Anhui tobacco industry has preliminarily realized internet ordering, trading, and payment. The platform can also trace the whole procedure of any business, display trading status simultaneously, and provide reports automatically for managers throughout the province. The application of e-commerce re-constructed the marketing system as were as the model of management, which ensures the policies such as 'payment first, delivery second' to be strictly carried out. By now, the platform is the largest B-B electronic commerce platform in China.

#### **4.3 Fund management centralization and account system**

It's important to centrally manage fund for groups as ATC. With Fund management centralization, flexible operation, safety and accuracy can be ensured, and the operation cost can be reduced. Several years ago, ATC began to centrally manage its fund. But with weak means of management, the target could not be achieved. After the operation of e-commerce platform, the fund management centralization and account system is also ignited, which connect tightly to the platform.

Now, all the 66 members are using this system. Every member has an independent account number and has the right of determining its own fund. The department of financial affairs can inspect the fund flow through network. It can also regulate the requirement and surplus of fund between two or more subordinate members. One member can lend its fund to another without the help of banks. From inner load applying to plan balancing, financial approving and lender's approving, it takes only minutes. The result is that the efficiency is improved, the total loan of ATC decreases rapidly and financial cost reduced greatly. Restricting only to financial cost, a total saving of about 50,000,000 Yuan is predicted.

The e-commerce system is not isolated. The supplement software such as Office Automation, Sales and Service come into operation last year. ATC plans to apply CRM, SCM in 2002 after the stable operation of e-commerce platform. It also plans to apply ERP to manufacturing factories in the near future. These systems will makeup a complete information system, centralized on e-commerce, connecting both inside and outside Anhui Tobacco Industry.

#### **5. Benefit of e-commerce application**

The following figure best shows the benefit of e-commerce application in Anhui Tobacco Industry.

Income grows rapidly. The allot income increases 24% compared with the same period last year; wholesale increases 14%, profit increases 21%. The wholesale gross profit ratio of cigarette product achieves 18.65% with an increase of 4.9%. The ratio of profit plus tax vs capital

increases 14 percentage. The ratio of capital income increases 12%. The storage of cigarette remains 200,000 boxes, a 110,800 boxes' below the control lever of assigned by China Tobacco Corporation. The total profit plus tax increases 34%. The productivity increases 28.7%.

The efficiency of fund utilization increases greatly. The total loan of Anhui Tobacco Industry decreases from 330 million Yuan in 1999 to 160 million Yuan in 2001. It will become zero by the end of March, 2002. This has an interest saving of about 10 million Yuan. At the same time, the harmful capital decreases. Through resource reconstruction, the total capital of ATC decreases from 1130 million in 1999 to 960 million now. The total debt decreases from 730 million to 532 million. The existing stock decreases from 300 million to 220 million.

With re-organization, department decreases 46%, management staff decreases 34%, financial cost decreases 54%, sales income increases 17%, total profit increases 242%.

The brand begins to centralize. The number of Brands of ATC decreases from 70 to 52. The number of brand which has a sales income over 100 thousand boxes increase from one to four.

## **6. Realization in e-commerce construction**

### **6.1 The renewing of idea is the fundamental requirement in information system construction**

Compared to first-rate tobacco companies in the world, ATC is far behind in production, management, technology etc.. The backward of management is extremely obvious, which mainly appeared in management idea. The practice of ATC e-commerce construction shows that, the most difficult problem lying in information system construction is neither technology nor fund, but the renewing of management ideas.

Shortly in one year of 2001, ATC completed over 10 important projects of system construction including computer network, e-commerce, fund centralization, office automation, bank accounting, group IP phone, video meeting and so on. If we followed the prescribed order, it's impossible to finish so many projects. Only when we take an idea of standing in a high lever, constructing simultaneously and arousing all the staff can we make the significant achievements.

For example, in the construction of computer network, ATC took the potential resource of the network in the future as its bargain weight. With the result of visit bids, the investment of the net became zero, and the yearly rent of was settled in 2 million. Besides, the bank provided the interface equipment valued over 4 million. This result is far bellow the budget of 20-30 million fund investment and nearly 10 million yearly rent.

### **6.2 Overall arrangement is the necessary prerequisite**

E-commerce system must be constructed to meet the practical requirement of enterprise. It must have an overall plan with obvious key points, sufficient fund and manpower. Meanwhile, the system must solve the most difficult problem. The procedure of construction must be focused on raising the competence of enterprise. With the principal of advanced in technology, practical, we must act according to our ability in order to invest little and harvest much.

### **6.3 Top leader's project**

To describe the importance of e-commerce construction, we often use the words of 'top leader's project'. It doesn't merely mean people and fund investment. First of all, the top leader must be confident. The construction is a process of standardization, reformation and innovation accompanied by the re-allocation of right and benefit. It's a new challenge to both the leader and the staff. Therefore, the leader must be confident himself and transfer this confidence to all the staff. Otherwise, the information systems are impossible to be constructed.

Secondly, the top leader must control the direction. He must be participated in distributing limited resource, inspecting the rate of progress, undertaking supplementary reform, coordinating departments and grasping the best chance. Finally, he must provide a priority of both fund and manpower to the system. The top leader of ATC takes the information system as an important part of ATC's strategy, and he has done much to guarantee the smooth construction of the system.

### **6.4 E-commerce requires many compound talents**

Talents are essential to e-commerce. Talent shortage is normal to most enterprises. There are two ways to solve the problem. One is to train own talents, and the other is to import from the outside. But the most important to the enterprise is to setup a system of talent usage. An environment of 'respect knowledge, respect talent' is highly needed to solve the problem of 'talents is difficult to be imported and hard to be kept'. The compound talents, who have the knowledge of both information technology and management, must be promoted to important position.

### **6.5 Training from beginning to end**

With the progress of e-commerce construction, ATC undertook training engineering from beginning to end. The training center which is responsible to training, launched 40 training classes. Over 5,000 people were trained there. ATC also raised classes of EMBA and Master of Engineering with universities. About 50 people study in the class in their spare time. ATC set the target of its rank construction as 'Intelligent workers, thinking cadres and researching leaders'. It is trying to build the corporation into a learning organization. With the overall quality improvement of both staff and the enterprise, the

competence of ATC is improving everyday.

## Abstract

The World Wide Web is a perfect medium for electronic retailers who specialize in cutthroat price competition (Coyle, 2002; Shulman, 1999; Wingfield, 2002). Amazon.com, for instance, has been taking a leading role in an on-line bestseller price war. In May of 1999 when Amazon.com cut its list price for bestsellers in half, Barnesandnoble.com and Borders.com quickly followed. Again, in 2002, a second price war started when Amazon lowered the minimum order size of \$49 from \$99 to qualify its customers for free shipping on most items - its fourth price cut in the past 11 months. The battle for the lowest prices among e-retailers has left most Internet shoppers little incentive to go bargain hunting at other sites (Mossberg, 2000).

E-retailers must monitor and collect competitors' price information in order to win the raging price war and increase e-commerce sales. In order to do this, office personnel are usually assigned to manually search and read price changes from competitors' Web sites. However, such a process is arduous, costly and inefficient. In an attempt to reduce cost and improve efficiency in price gathering process, inquiry is being made into ways of automation and computerization. This paper describes the design and development of an Internet application system, code named "ePrice Comparator," that automates the monitoring and collecting of prices from Web sites of targeted competitors on an hourly basis.

Users of this system will be able to access the program from an Intranet. After setting up the targeted retailers and particular products to search for, the user will trigger the comparator to get price information from those retailers' websites. Once the comparison is done, the prices will be listed along with retailers' names in a database for future analysis. By analyzing the data, the user will be able to figure out the current market situation for a particular product and adjust his price position. Note that the process of searching and reading prices from the targeted Web sites is automated by setting up time scheduling service of the operating system where the comparator is being hosted.

The system was developed in Visual Basic 6 with the use of a Microsoft SQL database server. The code modules of the system include a HTTP COM object that downloads targeted HTML pages, a HTML parser that

extracts desired pricing information, and a network of business object components that provide the data retrieval process and provide reporting services.

The system is also designed to have an easy-to-use interface with customizable functions and an open system available for future add-ons. The interface is basically comprised of three different administration panels. Within each panel, there are tabs to group different functionalities to allow for smooth operations. The three panels are database administration panel, parser administration panel, and the search engine panel. The database administration panel allows the user to set up targeted retailers' demographical data, URLs, and targeted HTML pages where the price information is stored. The parser administration panel enables the user to find the right position of price information in the targeted HTML page through analyzing the table tab structure of the page. The result of the parsing and the HTML page analysis is a template containing a set of positioning numbers for the targeted pages. The template is then stored in the database for run-time downloading and parsing when the search engine is activated. Finally, the search engine panel provides facilities for the user to configure when and how the engine is run once the system is activated from the hosting operating system.

ePrice Comparator can be scheduled to run at any interval as needed. The result of each run is stored in the database for analysis. One of the key features of the system is its capability to publish the analysis report in HTML format, which enables corporate managers to view the report from anywhere at anytime and makes price monitoring a ready-to-employ management practice.

In this newly-emerged and highly-interdisciplinary ecommerce domain, systems development is a key research methodology that interacts with other methodologies, such as theory building, experimentation, and observation. The advancement of ecommerce research and practice often comes from new system concepts, but systems must be developed first to test and measure the underlying concepts. ePrice Comparator is a result of such a proof-of-concept approach.

## Abstract

An example of supply chain coordination is early order commitment, wherein a retailer commits to purchase a fixed-order quantity and delivery time from a manufacturer before the real need takes place. In this paper, an analytical model is developed that quantifies the impact of early order commitment on the performance of a simple two-level supply chain consisting of a single manufacturer and a single retailer. The model reveals that the effect of early order commitment depends on a lot of factors such as the cost structure of the supply chain, the lengths of manufacturing and delivery lead times, and the correlation of the demand over time. This model can be used to evaluate the benefit of early order commitment, to determine the optimal early commitment periods of the supply chain, and to estimate the maximum incentives the manufacturer can provide to encourage the retailer to commit its orders in advance.

*Keywords: Supply Chain Coordination, Early Order Commitment, Inventory Control*

## 1. Introduction

Effective supply chain management requires coordination among the various members in a supply chain. Through coordinating activities across the boundaries of firms in a supply chain, it is believed that significant benefits can be achieved for the partners and the entire supply chain. Previous research has recognized different approaches for supply chain coordination, including information sharing -- sharing real-time demand data collected at the point-of-sales with upstream suppliers ([1],[6], [7]). A further-developed method concerning the effective use of such information suggests a centralized forecasting mechanism that accesses the final demand ([2], [3], [8]). These investigations reveal that information sharing can significantly enhance the performance of the supply chain by reducing the bullwhip effect, a negative phenomenon of demand variability amplification along a supply chain from downstream members to their suppliers.

Recently, as another alternative form of supply chain coordination, early order commitment has drawn attention from the researchers and practitioners. Early order

commitment means that a retailer commits to purchase a fixed-order quantity and delivery time from a manufacturer before the real need takes place. [5] presented an analysis for a steel distribution supply chain, and quantified the benefits for the consumers who commit orders in advance. [9-11] conducted extensive simulation studies on the effect of early order commitment on supply chain performance under various operational conditions. These researches show that under some cases, practicing early order commitment can generate significant cost savings in the supply chain. [4] examined the tradeoff between strategic early order commitment and postponement. Generally speaking, the impact of early order commitment on the supply chain performance is intuitively clear. On one hand, early order commitment increases a retailer's risks of over-estimating the demand; On the other hand, it helps the manufacturer reduce planning and executing costs. In order to accept early order commitment to achieve best performance for the entire supply chain, the members at different levels of the supply chain should make optimal tradeoff based on careful evaluation of both the negative effect for the retailer and the positive effect for the manufacturer. Unfortunately, up to now, no general analytical model is available to quantify the integrated effect of early order commitment and to guide such kind of tradeoff decisions. Besides, a fundamental question about early order commitment is why should a retailer make commitment (with penalty charge) if information sharing (without cost penalty for order commitment) can provide equal or close enough benefits!

This paper aims at proposing an analytical model to quantify the impact of early order commitment on the performance of a simple two-level supply chain consisting of a single manufacturer and a single retailer. The model reveals the effect of early order commitment depends on a lot of factors such as the cost structure of the supply chain, the length of manufacturing and delivery lead time, and the correlation of the demand over time. Furthermore, under some cases, significant benefit can be achieved for the supply chain even under the environment with information sharing. This model can be used to evaluate the benefit of early order commitment, to determine the optimal early commitment periods of the supply chain, and to estimate

the maximum incentives the manufacturer can provide to encourage the retailer to commit its orders in advance.

## 2. Supply Chain Model

### 2.1 Basic Assumptions

The basic assumptions underlying the model in this paper is similar to the one proposed by LST. The supply chain is assumed to be a simple one consists of a single manufacturer and a single retailer. Only the retailer faces external demand for a single product, and the demand is assumed to be a simple autocorrelated AR(1) process, i.e., the demand in period  $t$  is

$$D_t = d + \rho D_{t-1} + \varepsilon_t, \quad (1)$$

where  $d > 0$ ,  $-1 < \rho < 1$ , and  $\varepsilon_t$  is *i.i.d.* normally distributed with mean zero and variance  $\sigma^2$ . We also assume that  $\sigma$  is significantly smaller than  $d$ , so that the probability of negative demand is negligible. Furthermore, the demand process and its characteristic parameters are common knowledge, i.e., both the retailer and the manufacturer know the demand distribution in (1) and the values of the parameters  $d, \rho$ , and  $\sigma$ . LST gave some evidences to show that the assumption of AR(1) demand process with known characteristic parameters is reasonable in real world supply chain management when demand information is shared from the retailer to the supplier.

The manufacturing leadtime for the manufacturer (including the leadtime for the replenishment of raw materials from the external suppliers) is a constant  $L$ , and the delivery leadtime from the manufacturer to the retailer is a constant  $l$ . The most important feature of the current paper is that we incorporate an early order commitment period ( $A$ ) to the system. Early order commitment period is the number of the time periods that the retailer places her order in advance.

Both the retailer and the manufacturer use the order-up-to policy, a periodic reviewing policy which is optimal for the stochastic inventory system without fixed ordering cost, to make their ordering (or manufacturing) decisions with the review interval being one period (i.e., daily review). The events occur in sequence as follows. Before the end of period  $t$ , after demand  $D_t$  has been realized, the retailer places her order of size  $O_t$  based on her inventory level. Please note that, because of the early order commitment, this order is scheduled for the period  $t+l+A+1$ , not for the period  $t+l+1$ . That's to say, because of the early order commitment period  $A$  and delivery leadtime  $l$ , this order will arrive the retailer at the beginning of period  $t+l+A+1$ . If the retailer does not hold enough stock to satisfy the demand, the excess demand is backordered. When the manufacturer receives this order from the retailer, she does not need to ship the order  $Q$  to the retailer immediately. In fact, the quantity the manufacturer must ship to the retailer is the order placed by the retailer  $A$  periods ago, i.e. the order of size  $Q_{t-A}$ . We assume that this order must always be completely filled by the manufacturer. This means that if the manufacturer does not

hold enough stock to fill the order, she can obtain any quantity of the product from an external source with a penalty cost, where the same quantity of the product must be provided by the manufacturer to resupply the external source later. Finally, the manufacturer places his manufacturing order of size  $Q$  based on his inventory level. This order will arrive at the beginning of period  $t+l+1$ .

### 2.2 Retailer's Ordering Decision

Let  $S_t$  be the retailer's order-up-to level in period  $t$ , minimizing the total expected holding and shortage costs in period  $t+l+A+1$ . Comparing our case with the case in LST, we found that the only difference is that in LST's case, the retailer's order must cover the demand uncertainty up to  $t+l+1$ , while in our case the retailer's order must cover more periods' demand uncertainty, i.e., the uncertainty up to  $t+l+A+1$ . In fact, if we take the value  $l+A$  as the leadtime periods, then all the behavior of the retailer will be the same as in LST.

Denote  $X_t$  as the total demand during periods  $[t+1, t+l+A+1]$ , then using (1) we have

$$\begin{aligned} X_t &= \sum_{j=1}^{l+A+1} D_{t+j} \\ &= \frac{1}{1-\rho} d \sum_{j=1}^{l+A+1} (1-\rho^j) + \rho(1-\rho^{l+A+1})D_t \\ &\quad + \sum_{j=1}^{l+A+1} \sum_{i=0}^{l+A-j+1} \rho^i \varepsilon_{t+j} \end{aligned} \quad (2)$$

From (2),  $X_t$  is a normal distributed variable with the mean value

$$\begin{aligned} m_t = E(X_t) &= \frac{d}{1-\rho} (l+A+1) - \sum_{j=1}^{l+A+1} \rho^j \\ &\quad + \frac{\rho(1-\rho^{l+A+1})}{1-\rho} D_t \end{aligned} \quad (3)$$

and the variance

$$v_t = Var(X_t) = \frac{\sigma^2}{(1-\rho)^2} \sum_{j=1}^{l+A+1} (1-\rho^j)^2. \quad (4)$$

Thus the order-up-to level

$$S_t = m_t + k\sqrt{v_t}, \quad (5)$$

where  $k$  is the safety stock factor depending on the unit holding cost  $h$  and unit shortage penalty cost  $p$ . In fact, if  $\Phi$  is the standard normal distribution function, then

$$k = \Phi^{-1}\left(\frac{p}{h+p}\right). \quad (6)$$

Therefore the retailer's order quantity at period  $t$  is

$$\begin{aligned} O_t &= D_t + (S_t - S_{t-1}) \\ &= D_t + \frac{\rho(1-\rho^{l+A+1})}{1-\rho} (D_t - D_{t-1}). \end{aligned} \quad (7)$$

### 2.3 Manufacturer's Ordering Decision

Throughout this paper, we assume that the early order commitment period  $A$  is no more than the manufacturing leadtime  $L$ , i.e.,  $0 \leq A \leq L$ , since committing the orders even earlier is harmful to the retailer and not beneficial to

the manufacturer. Please note that  $A=0$  corresponds to the case that the supplier does not commit orders to the manufacturer in advance. As we have pointed out in Section 2.1, the quantity the manufacturer must ship to the retailer in period  $t$  is the order placed by the retailer  $A$  periods ago, i.e. the order of size  $Q_t$ . From (1) and (7), we have

$$O_{t+1} = d + \rho O_t + \frac{1 - \rho^{L+A+2}}{1 - \rho} \varepsilon_{t+1} - \frac{\rho(1 - \rho^{L+A+1})}{1 - \rho} \varepsilon_t. \quad (8)$$

Repeating to use (8) gives

$$O_{t+i} = \frac{1 - \rho^i}{1 - \rho} d + \rho^i O_t + \frac{1 - \rho^{L+A+2}}{1 - \rho} \varepsilon_{t+i} + \sum_{k=1}^{i-1} \rho^{L+A+1+k} \varepsilon_{t+i-k} - \frac{\rho^i(1 - \rho^{L+A+1})}{1 - \rho} \varepsilon_t. \quad (9)$$

Denote  $Y$  as the total orders that must ship by the manufacturer during periods  $[t+1, t+L+1]$ , then

$$\begin{aligned} Y_t &= \sum_{j=1}^{L+1} O_{t-A+j} = \sum_{j=1}^A O_{t-A+j} + \sum_{j=1}^{L-A+1} O_{t+j} \\ &= \sum_{j=1}^A O_{t-A+j} + \frac{d}{1 - \rho} \left[ (L - A + 1) - \frac{\rho(1 - \rho^{L-A+1})}{1 - \rho} \right] \\ &\quad + \frac{\rho(1 - \rho^{L-A+1})}{1 - \rho} O_t + \frac{1}{1 - \rho} \sum_{j=1}^{L-A+1} (1 - \rho^{L+1+3-j}) \varepsilon_{t+j} \\ &\quad - \frac{\rho(1 - \rho^{L-A+1})(1 - \rho^{L+A+1})}{(1 - \rho)^2} \varepsilon_t. \end{aligned} \quad (10)$$

Let  $T_t$  be the manufacturer's order-up-to level at the end of period  $t$ . We assume that the retailer shares her demand information to the manufacturer, thus the manufacturer knows both the retailer's order quantity and demand error  $\varepsilon_t$  up to period  $t$ . Raghunathan (2001) showed that the cases with information sharing and without information sharing do not make a great difference.

From (10),  $Y_t$  is a normal distributed variable with the mean value

$$\begin{aligned} M_t = E(Y_t) &= \sum_{j=1}^A O_{t-A+j} + \frac{d}{1 - \rho} \left[ (L - A + 1) - \frac{\rho(1 - \rho^{L-A+1})}{1 - \rho} \right] \\ &\quad + \frac{\rho(1 - \rho^{L-A+1})}{1 - \rho} O_t - \frac{\rho(1 - \rho^{L-A+1})(1 - \rho^{L+A+1})}{(1 - \rho)^2} \varepsilon_t. \end{aligned} \quad (11)$$

and the variance

$$V_t = Var(Y_t) = \frac{\sigma^2}{(1 - \rho)^2} \sum_{j=1}^{L-A+1} (1 - \rho^{L+1+3-j})^2. \quad (12)$$

Thus the order-up-to level

$$T_t = M_t + K \sqrt{V_t}, \quad (13)$$

where  $K$  is the safety stock factor depending on the unit holding cost  $H$  and unit shortage penalty cost  $P$ . In fact, if  $\Phi$  is the standard normal distribution function, then

$$K = \Phi^{-1}\left(\frac{P}{H+P}\right). \quad (14)$$

Therefore the manufacturer's order quantity at period  $t$  is

$$\begin{aligned} Q_t &= O_t + (T_t - T_{t-1}) \\ &= O_t + \frac{\rho(1 - \rho^{L-A+1})}{1 - \rho} (O_t - O_{t-1}) \\ &\quad - \frac{\rho(1 - \rho^{L-A+1})(1 - \rho^{L+A+1})}{(1 - \rho)^2} (\varepsilon_t - \varepsilon_{t-1}). \end{aligned} \quad (15)$$

### 3. Supply Chain Performance

In this section we evaluate the performance of the supply chain in terms of inventory holding and shortage cost.

#### 3.1 Supply Chain Cost

According to LST (2000), the retailer's and manufacturer's expected inventory holding and shortage costs in a period can be expressed, respectively, as

$$c = \sqrt{v_t} [(h + p)F(k) + hk], \quad (16)$$

$$C = \sqrt{V_t} [(H + P)F(K) + HK], \quad (17)$$

where  $F(\bullet)$  is the right loss function for the standard normal distribution, i.e.,

$$F(x) = \int_x^\infty (z - x) d\Phi(z). \quad (18)$$

Thus the percentage of the retailer's cost increasing in a period due to early order commitment is

$$\begin{aligned} \Delta c &= (\sqrt{v_t} - \sqrt{v_t}|_{A=0}) / \sqrt{v_t}|_{A=0} = \sqrt{v_t} / \sqrt{v_t}|_{A=0} - 1 \\ &= \sqrt{\frac{\sum_{j=1}^{L+A+1} (1 - \rho^j)^2}{\sum_{j=1}^{L+1} (1 - \rho^j)^2}} - 1 \\ &= \sqrt{1 + \frac{\sum_{j=1}^{L+A+1} (1 - \rho^j)^2}{\sum_{j=1}^{L+1} (1 - \rho^j)^2}} - 1 \end{aligned} \quad (19)$$

and the percentage of the manufacturer's cost saving in a period due to early order commitment is

$$\begin{aligned} \Delta C &= (\sqrt{V_t}|_{A=0} - \sqrt{V_t}) / \sqrt{V_t}|_{A=0} = 1 - \sqrt{V_t} / \sqrt{V_t}|_{A=0} \\ &= 1 - \sqrt{\frac{\sum_{j=1}^{L-A+1} (1 - \rho^{L+1+3-j})^2}{\sum_{j=1}^{L+1} (1 - \rho^{L+1+3-j})^2}} \\ &= 1 - \sqrt{1 - \frac{\sum_{j=L-A+2}^{L+1} (1 - \rho^{L+1+3-j})^2}{\sum_{j=1}^{L+1} (1 - \rho^{L+1+3-j})^2}} \end{aligned} \quad (20)$$

According to (16) and (17), the total cost of the supply chain is

$$\begin{aligned} SC &= c + C \\ &= \sqrt{v_t} [(h + p)F(k) + hk] + \sqrt{V_t} [(H + P)F(K) + HK]. \end{aligned} \quad (21)$$

In order to simplify the expression, we introduce a cost structure ratio ( $r$ ) to represent the cost structure of the supply chain. Specifically, we define

$$r = [(h + p)F(k) + hk] / [(H + P)F(K) + HK]. \quad (22)$$

Then the percentage of the entire supply chain's cost saving in a period due to early order commitment is

$$\begin{aligned} \Delta SC &= [(c + C)|_{A=0} - (c + C)] / (c + C)|_{A=0} \\ &= 1 - \frac{r\sqrt{v_t} + \sqrt{V_t}}{(r\sqrt{v_t} + \sqrt{V_t})|_{A=0}} \\ &= 1 - \frac{r\sqrt{\sum_{j=1}^{l+A+1} (1-\rho^j)^2} + \sqrt{\sum_{j=1}^{L-A+1} (1-\rho^{L+l+3-j})^2}}{r\sqrt{\sum_{j=1}^{l+1} (1-\rho^j)^2} + \sqrt{\sum_{j=1}^{L+1} (1-\rho^{L+l+3-j})^2}}. \end{aligned} \quad (23)$$

Obviously,  $\Delta c > 0$  and  $\Delta C > 0$  are both increasing function with respect to the early order commitment period  $A$ . Formula (19) shows that the retailer's relative cost increase due to early order commitment depends on the correlation of the demand process, the delivery leadtime from the manufacturer to the retailer, and the early order commitment period. Besides these three factors, formula (20) shows that another factor, the manufacturer's replenishment leadtime, affects the manufacturer's relative cost saving. Furthermore, formula (23) shows that the cost structure ratio also affects the integrated performance of the whole supply chain due to early order commitment. However, these results reveal that although the variance of the error item in the demand process (1) amplifies the absolute values for the costs, it does not have any impact on the relative cost increase or decrease for the retailer, the manufacturer, and the whole supply chain, unless there is no demand uncertainty (i.e., the variance of the error item is zero).

From (23), we can easily obtain the following condition where the early order commitment is beneficial to the whole supply chain:  $\Delta SC > 0$ , or equivalently

$$\begin{aligned} & r\sqrt{\sum_{j=1}^{l+A+1} (1-\rho^j)^2} - \sqrt{\sum_{j=1}^{l+1} (1-\rho^j)^2} \\ & < \sqrt{\sum_{j=1}^{L+1} (1-\rho^{L+l+3-j})^2} - \sqrt{\sum_{j=1}^{L-A+1} (1-\rho^{L+l+3-j})^2}. \end{aligned} \quad (24)$$

This is the critical condition that guides us to determine whether we should use the early order commitment or not in a supply chain. The smaller the cost structure ratio  $r$ , the more that early order commitment can benefit the whole supply chain.

In order to get more insights about the interaction between early order commitment and the parameters of the supply chain, we conduct some numerical results in the following Subsections.

### 3.2 Performance of Early Order Commitment

In this Subsection, we fix the parameters  $r=1$ ,  $L=l=10$ ,  $\rho=0.5$ , and vary  $A$  from 0 to  $L$  and calculate the corresponding relative cost increase or decrease for the retailer, the manufacturer, and the whole supply chain according to (19), (20) and (23). The corresponding relative cost increase or decrease are plotted in Figure 1. From this example, we can see that the earlier the retailer commit orders with the manufacturer, the more benefits can be achieved for the total supply chain. When  $A$  reaches the largest value (10 periods), the retailer's cost is increased by 43.92%, the manufacturer's cost is reduced by 69.85%, and the whole supply chain's cost is reduced by 15.30%.

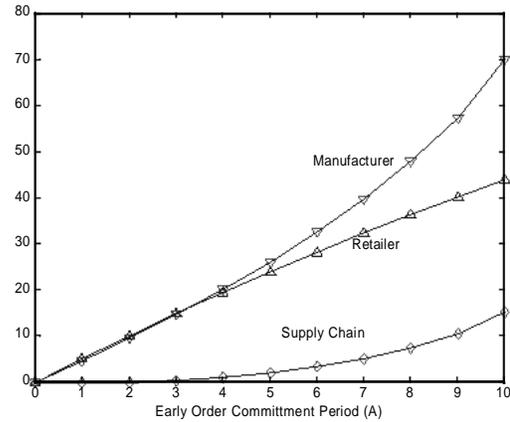

Figure 1. Performance of early order commitment period ( $r=1$ ,  $L=l=10$ ,  $\rho=0.5$ )

### 3.3 Impact of Demand Process Characteristics

In this Subsection, we first fix the parameters  $r=1$ ,  $L=l=10$  and vary  $\rho$  from  $-0.9$  to  $+0.9$  with increment 0.1. For each value of  $\rho$ , we vary  $A$  from 0 to  $L$  and calculate the corresponding relative cost increase or decrease for the retailer, the manufacturer, and the whole supply chain according to (19), (20) and (23). Then the value of  $A$  that results in the largest cost saving for the whole supply chain according to (23) is recorded as  $A^*$ , the optimal early order commitment period. We find that the optimal value of  $A^* = L=10$  periods under all the values of  $\rho$  for this setting. The corresponding relative cost increase or decrease are plotted in Figure 2. From the figure, we can see that the retailer's cost increases quickly as  $\rho$  increases to 0.5 or above. However, it shows that the cost savings for the manufacturer and the whole supply chain is about 70% and 15% respectively, and the results are relatively stable under different values of  $\rho$ .

However, there are interactions between  $A$ ,  $\rho$  and the leadtimes  $L$ ,  $l$ . Figure 3 represents the results for fixed parameters  $r=1$ ,  $L=10$ ,  $l=3$ . Similarly, we vary  $\rho$  from  $-0.9$  to  $+0.9$  with increment 0.1, and for each value of  $\rho$ , we vary  $A$  from 0 to  $L$  to find  $A^*$  the optimal early order commitment period. We find that the optimal value of  $A^*$  equals ten periods ( $A=L=10$ ) when  $\rho$  is not over 0.7, and  $A^*$

$=0$  periods when  $\rho$  is larger than 0.8. From the figure, we can see that the retailer's cost increase due to early order commitment climbs to extremely higher value as  $\rho$  increases, and finally exceeds the cost savings of the manufacturer. Under the cases where  $\rho$  is smaller than 0.5, the cost savings of the manufacturer and of the whole supply chain are about 70% and 10%, respectively.

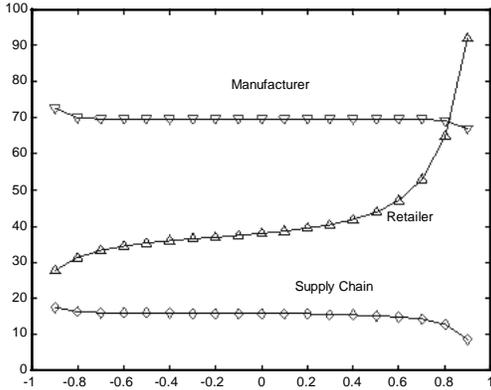

Figure 2. The impact of demand correlation ( $r=1, L=l=10$ )

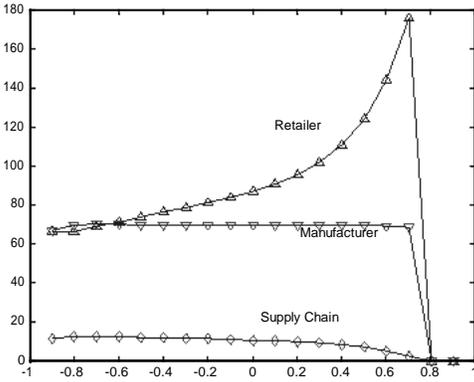

Figure 3. The impact of demand correlation ( $r=1, L=10, l=3$ )

### 3.4 Impact of Leadtimes

In this Subsection, we first fix the parameters  $r=1, \rho=0.5, L=10$  and vary  $l$  from 0 to 20. For each value of  $l$ , we vary  $A$  from 0 to  $L$  to find  $A^*$ , the optimal early order commitment period. We find that  $A^*=L=10$  periods when  $l$  is greater than or equals to 2, and  $A^*=0$  when  $l$  is very small (0 or 1). The corresponding relative cost increase or cost decrease is plotted in Figure 4.

Now we fix the parameters  $r=1, \rho=0.5, l=10$  and vary  $L$  from 0 to 20. For each value of  $L$ , we vary  $A$  from 0 to  $L$  to find  $A^*$ , the optimal early order commitment period. We find that  $A^*=L$  periods for all values of  $L$ . The corresponding relative cost increase or cost decrease is plotted in Figure 5.

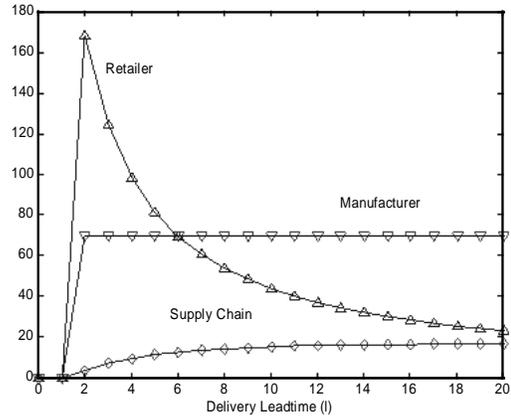

Figure 4. The impact of Delivery Leadtime ( $r=1, \rho=0.5, L=10$ )

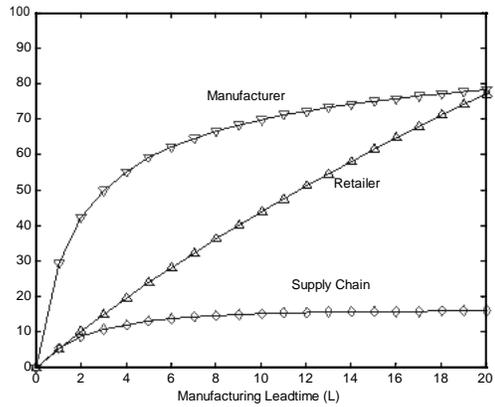

Figure 5. The impact of Manufacturing Leadtime ( $r=1, \rho=0.5, l=10$ )

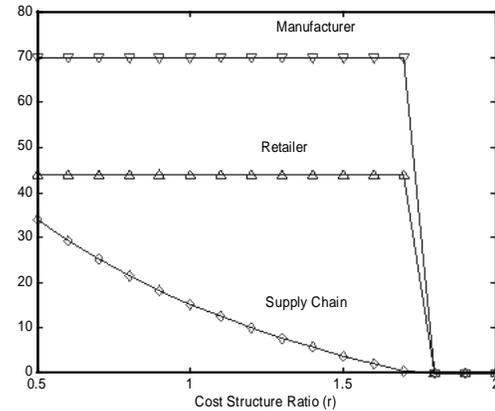

Figure 6. The impact of Cost Structure Ratio ( $\rho=0.5, L=l=10$ )

### 3.5 Impact of Cost Structures Ratio

In this Subsection, we fix the parameters  $\rho=0.5, L=l=10$  and vary  $r$  from 0.5 to 2.0 with increment 0.1. For each value of  $r$ , we vary  $A$  from 0 to  $L$  to find  $A^*$ , the optimal

early order commitment period. We find that  $A^*=L=10$  periods when  $r$  is smaller than or equals to 1.7, and  $A^*=0$  when  $r$  is relatively large (over 1.8). The corresponding relative cost increase or decrease are plotted in Figure 6. Obviously, the cost savings decrease as  $r$  increases.

#### 4. Conclusions

In this paper, an analytical model is developed that quantifies the impact of early order commitment on the performance of a simple two-level supply chain consisting of a single manufacturer and a single retailer. The model reveals that the effect of early order commitment depends on some key factors such as the cost structure of the supply chain, the lengths of manufacturing and delivery lead times, and the correlation of the demand over time. This model can be used to evaluate the benefit of early order commitment, to determine the optimal early commitment periods of the supply chain, and to estimate the maximum incentives the manufacturer can provide to encourage the retailer to commit its orders in advance.

## Abstract

Under increasing globalization, enterprises view supply chains (SC) as an integration of process control and management. The bicycle industry is one of the competitive industries in Taiwan, for which there is a complete supply chain system. To internationalize and improve the competitive advantage of this industry, it is necessary for it to improve the capacity of global production and distribution. In this paper, we consider both the maximum profit of enterprises and the maximum quality of customer service, using five programming methods to construct multi-objective production and distribution models. These five methods are: compromise programming, fuzzy multi-objective programming, weighted multi-objective programming, weighted fuzzy multi-objective programming and two-phase fuzzy multi-objective programming. The results reveal that the weighted multi-objective model was better for considering the maximum profit of enterprises and the maximum quality of customer service. Finally, we use the weighted multi-objective model for sensitivity analysis. These results show that after raising the per-unit production cost in production processes, the total profit would decrease. In addition, if the unit inventory cost increases due to improving the customer service level, then the total profit might increase, but not significantly. Furthermore, the shortage cost seems have interactive behavior on the enterprises, in which an increase of inventory cost will lower shortage cost.

Keywords: supply chain, bicycle industry, fuzzy multi-objective programming

## 1. Introduction

Due to the trend of globalization, the supply chain is increasingly important for many enterprises as one of the flow process controls and levels of management to be integrated. Ranging from the supply of raw materials, production, distribution, retail sales, and after-sales service to consumers, the primary objectives are to lower the total costs of production along the supply chain, and to increase production efficiency. With positive efforts from both government and industry, Taiwan has been admitted into the World Trade Organization (WTO) on January 1, 2001. Within the context of WTO, manufacturers are confronted with global competition, the need to accelerate the flow of materials and information. As a result, the development of an effective supply chain is essential for an industry to become successful.

an effective supply chain is essential for an industry to become successful.

The bicycle industry, generally considered as conventional industry, demands massive labor capital investment. With its development over the last fifty years, the industry supply chain has complete up-, middle-, and down-stream manufacturers, making Taiwan one of the significant bicycle manufacturing centers of the world. In 1980, the amount of bicycles sold overseas ranked first world-wide, surpassing that of Japan. Nevertheless, although bicycles are not a high-tech product they do follow trends of fashion, creativity and diversity of product, go speed of supply has become critical to compete in the face of saturated markets, supply greater than demand, and the diversified demands of consumers. Therefore, this study aims to strengthen the capabilities of global management, to expand the core system of this industry into a global supply and demand chain, to provide timely production and high service quality, enhancing the competitiveness of these on the international market.

As Taiwan's bicycle industry is exposed to international competition, bicycle manufacturers must develop global management abilities to confront this new situation. As a result, this study considers multiple objective production and distribution, focusing on Taiwan's conventional bicycle manufacturing industry, considering enterprise profit and customer service level for multi-objective programming to develop a production and distribution model for bicycle manufacturers in Taiwan.

Here, five multi-objective programming methods have been adopted for comparison: multi-objective compromise programming, fuzzy multi-objective programming, weighted multi-objective programming, weighted fuzzy multi-objective programming, and two-phase fuzzy multi-objective programming. These five methods have used to compare in resolution for this model. Finally, weighted multi-objective programming has been used to conduct sensitivity analysis in order to obtain outcomes that manufacturers can use for reference in developing their supply chains. The results show that when increasing the per unit production cost in production processes, the total profit would decrease. If the unit inventory cost increase for improving the service level of customer, the total profit might increase, but not significantly. Furthermore, shortage cost seems have an

interactive behavior on the enterprises, and increased inventory cost will lower the shortage cost.

The remainder of this paper is organized as follows. In Section 2 previous literature is presented. In Section 3 a model for the bicycle supply chain is established. In Section 4 an example for applying this model to the bicycle supply chain is presented. Finally conclusions and recommendations are provided.

## 2. Previous Literature on Supply Chain and Multi-objective Programming for Production and Distribution

Since this study explores the issues of production and distribution of bicycle manufacturing, which is related to management operation and industrial supply chain, we first review previous literature on supply chain management. Then, we present studies on multi-objective programming, compromise programming, fuzzy multi-objective programming, weighted multi-objective programming, and two-phase fuzzy multi-objective programming, since they are issues of production and distribution of bicycle manufacturing.

### 2.1 Relevant literatures of supply chain

Chandra and Fisher (1994) dealt with the production and delivery of a single factory with single production in multiple periods. Comparing the separation and integration models of production and transportation problems, they found that the integration model of production and delivery can help to lower total costs. Nagata et al. (1995) examined the production and transportation problems of multiple products and multiple factories in multiple periods, using multi-objective and fuzzy multi-objective model for programming. There the programming problem for multiple periods included obtaining uncertain information when considering a management plan so as to construct a reasonable multi-objective production and transportation model. Tzeng et al. (1996) addressed the needs of practical issues, using fuzzy bi-criteria multi-index linear programming to deal with uncertain supply and demand environments in face of the coal procurement and delivery schedule for the Taiwan Power Company (TPC). This kind of problem has multiple destinations, multiple kinds of goals, and multiple kinds of shipping vessels. Petrovic et al (1998, 1999), used fuzzy models and simulation for the supply chain, and developed a decision-making system for an uncertain environment. Thus, they determined the inventory level and the order amounts with the supply chain model to simulate operation control with limited time and reasonable cost. Van Der Vorst et al. (1998) considered that supply chain management should include lowering or limiting uncertainty, so that the integral benefits of the supply chain could be improved. Sources of uncertainty include the following: vertical order prediction, information input, administration management, decision-making procedures, and innate uncertainty. This study used the food chain as example to improve the structure of allocation and operation management.

Although many factors of uncertainty were eliminated in that illustration, results indicated that the reasonable benefit of supply chain management has also been determined. Dhaenens-Flipo (2000) proposed clustering problems of production and transportation of multiple products from multiple factories for integrated programming. To deal with sophisticated problems with spatial decomposition he changed them into sub-problems, and employed the resolution method for vehicle routing problem (VRP), which also helped simplify the problem and lower total costs.

To sum up, when this current study considers the maximization of both enterprise profit and customer service level, the resolution can also be obtained from developing a multi-objective programming model in view of global supply chain system. The proposed model is described in the following section.

### 2.2 Multi-objective and fuzzy multi-objective programming

Zeleny (1982) pointed out that there is nothing about decision making in programming when there is only one single objective, as decision making is already endowed in the estimation of the objective function value coefficient. Thus, when the objective function coefficient is determined the decision maker can only accept or discard the outcome resolved by the model, and no other information can ever be obtained from the model by the decision maker. As can be seen, the development of "multi-objective programming" was brought about by the incomplete consideration taking account of only one single objective, as well as the fact that the decision maker can either accept or discard the optimal solution presented. In contrast, the objective of multi-objective programming is mainly to find a feasible non-inferior solution set or compromise solution so that the decision maker can effectively focus on the trade-offs when several objectives are in conflict. This is generally indicated as follows:

$$\begin{aligned} \max/\min f &= [f_1(x), f_2(x), \dots, f_k(x)] \\ \text{s.t. } Ax &\leq b \\ x &\geq 0 \end{aligned} \quad (1)$$

where,  $b = [b_1, b_2, \dots, b_m]$ ;  $x = [x_1, x_2, \dots, x_n]$ ;  $A = A_{m \times n}$

#### (1) Multi-Objective Compromise Programming

First, the ideal solution is defined as indicating the optimal value  $f_i^*(x) = \sup\{C^k x | x \in X\}$ ;  $i = 1, \dots, k$  in the feasible solution domain  $X$  of every single objective,  $f_k(x)$ . Of them, Then, based upon the spirit of compromise programming, and according to the aforementioned definition of distance scale, we have to locate a point so that it has the shortest distance to the ideal solution from the non-inferior solution set, which can be written as:

$$\begin{aligned} \min d_p \\ \text{s.t. } x \in X \end{aligned} \quad (2)$$

where

$$d_p = \sum_{i=1}^k \left( |f_i^*(x) - f_i(x)| \right)^{\frac{1}{p}}; 1 \leq p < \infty$$

In the above mentioned equation, the distance scale  $d_p$  varies with different values of  $p$  and has diverse meanings (Yu 1985, and as seen in Appendix I).

Hwang and Yoon (1981) claimed that it is necessary to consider the closest positive ideal solution (PIS) and the farthest negative ideal solution (NIS), so that the greatest profit can be obtained and the greatest risk avoided during decision making (see Appendix (II)).

### (2) Weighted Multi-Objective Programming

According to the multi-objective linear programming problem, as put forward by Martinson (1993), the two separate models of fuzzy multi-objective and multi-objective compromise programming can be used. The easiest way to deal with this issue is to settle the weight values of each objective by the preferences of the decision makers.

If the weighted value of each objective  $w_i$ , then the resolution for the compromise programming of the multi-objective programming can be found as follows:

$$\begin{aligned} \min d \\ \text{s.t. } \frac{w_i}{w_i} \frac{f_i^*(x) - f_i(x)}{f_i^*(x) - f_i^-(x)} \leq d, i = 1, \dots, k \\ Ax \geq b \\ x \geq 0 \end{aligned} \quad (3)$$

### (3) Fuzzy Multi-Objective Programming

Bellman and Zadeh (1970) applied the notion of fuzzy sets for decision making theory, considering conflicts between constraint equation and objective equation of the general programming, and proposed the max-min operation method in order to determine the optimal decision of the two solutions. Furthermore, Tanaka et al. (1974) advanced fuzzy mathematics programming (FMP), which resulted in the widespread application of fuzzy mathematical programming on several practical levels.

Zimmermann first introduced fuzzy set theory into the conventional linear programming problem in 1976, and combined the fuzzy linear programming model with multi-objective programming into fuzzy multi-objective linear programming (Zimmermann, 1978). The fuzzy linear programming employed in this study uses the max-min-operation method, which turns multiple objectives into a single one. The procedures of the operation are as follows: initially, the upper bound and lower bound limits of each objective and constraint equation are determined; then membership function are

constructed and membership function of the decision making is set; and finally, multiple objectives are turned into one single objective for resolution (details as found in Appendix (III)).

### (4) Weighted Fuzzy Multi-Objective Programming

The membership function of the weighted fuzzy linear programming can be indicated as follows:

$$\mu_D(x^*) = \max \min \{w_i \mu_{G_i}(x^*), i = 1, \dots, k\} \quad (4)$$

Making multiple objectives into a single objective for resolution, this problem can finally be transformed into the following exact LP problem for resolution:

$$\begin{aligned} \max \lambda \\ \text{s.t. } \frac{1}{w_i} \frac{f_i(x) - f_i^-(x)}{f_i^*(x) - f_i^-(x)} \geq \lambda, i = 1, \dots, k \\ Ax \geq b \\ x \geq 0 \end{aligned} \quad (5)$$

### (5) Two-Phase Fuzzy Multi-Objective Programming

Lee and Li (1993) put forward two-phase fuzzy multi-objective programming in order to deal with the defects of non-compensatory solutions in the linear fuzzy objective programming by Zimmermann. In their two-phase fuzzy multi-objective programming, the fuzzy linear programming by Zimmermann was used to determine the non-compensatory solution (Phase I), and then the greatest average fuzzy membership function (Phase II) of an individual objective among objectives is employed once the non-compensatory solution is found. It has also been substantiated that the multi-objective solution obtained from the two-phase fuzzy multi-objective programming is a compensatory solution for raising the achieved level, and the steps of resolution are as follows:

#### (1) Phase I

Locate the non-compensatory solution  $(x^{(1)})$  of Zimmermann's fuzzy linear programming.

#### (2) Phase II

$$\begin{aligned} \max \bar{\lambda} = \frac{1}{k} \sum_{i=1}^k \lambda_i \\ \text{s.t. } \frac{f_i(x) - f_i^-(x)}{f_i^*(x) - f_i^-(x)} \geq \lambda_i \geq \lambda^{(1)}, i = 1, 2, \dots, k \\ Ax \geq b \\ x \geq 0 \end{aligned} \quad (6)$$

This study uses the five kinds of multi-objective programming methods mentioned above to resolve and compare the supply chain model construct below. It also compares and analyzes these results, and conducts sensitivity analysis using one of the models for a real case.

### 3. Model Establishment For the Bicycle Supply Chain

The research on supply chains in this study mainly investigates the production and distribution problems confronted by the bicycle manufacturer. Based on a review of previous research, the production and distribution of bicycles are explored to establish two objective models for manufacturers profit and service level.

#### 3.1 The establishment and basic assumption of model

Generally, the goal of enterprise management is to obtain maximum profit. However, both manufacturing and service industries have gradually turned to an orientation of consumer service to develop stability, and because consumer service can provide a competitive advantage for enterprises in the market. As a result, this paper furthermore incorporated the idea of improved consumer service into its design. This helps provide space for flexible adjustment in order to consolidate sources of clientele, while enterprises can produce to respond to demand, rather than simply following rigid production schedules. Ultimately, favorable consumer service for stable clientele can be provided with such a design.

This study, based on the characteristics of bicycle industry, used the following assumptions (see Figure 1):

1. Concrete material flow processes of bicycle are simplified as: input of raw material – inventory of raw material --- product – inventory of product --- distribution; and this study focuses only on the model structure of production – inventory of product – distribution;
2. For bicycle manufacturers, this study considers the problems of production and distribution for multiple periods and multiple products as demands vary because of factors such as the international economy, weather, etc;
3. Since demand for this product will vary due to factors such as weather, the season, or holidays; a one year time period within the research period is marked as the planning period, and this planning period is divided into four separate parts, conforming to the annual seasons.
4. The industrial strategy of the industry has already employed BTO once an order is received; therefore, it is assumed that product demand is already known;
5. Only a single transportation system 'land-sea' is considered.

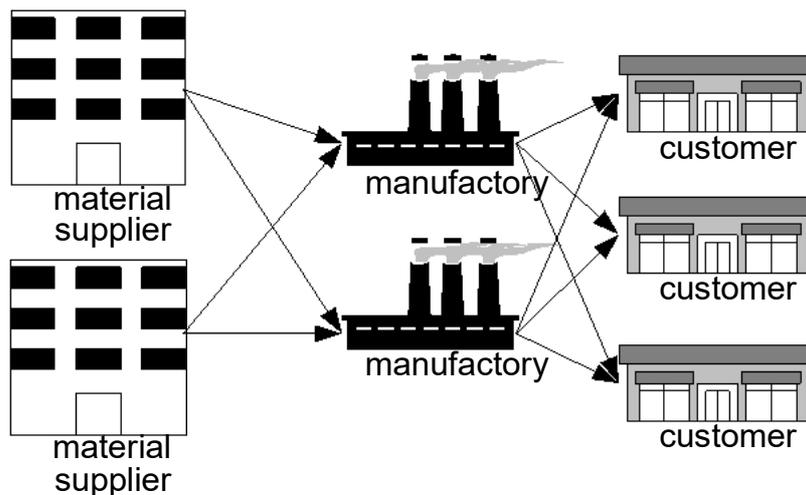

Figure 1 Research Domain

#### 3.2 Designation of Parameters and Variables

- $p_{kt}$  : Selling price of product k at period t;
- $d_{jkt}$  : Estimated demand of product k at period t in the locality j;
- $\alpha_{ijkt}$  : Unit delivering cost of product k at period t from manufacturer i to the point of demand j;
- $\beta_{ikt}$  : Unit production cost of product k at period t in manufacturer i during ordinary working hours;
- $\gamma_{ikt}$  : Unit production cost of product k at period t in manufacturer i during overtime working hours;

- $\delta_{ikt}$  : Unit inventory cost of product k at period t in manufacturer i;
- $\delta_{jkt}$  : Unit shortage cost of product k during period t at the locality of demand j;
- $a_{ikt}$  : The consumption amount of the needed material r for producing per product k at period t in manufacturer i;
- $f_{irt}$  : The upper bound value of the useable material r at period t in manufacturer i;
- $b_{kt}$  : The production time needed for producing per product k at period t in manufacturer i;
- $\eta_{it}$  : The upper bound value of ordinary working hours at period t in manufacturer i;

- $c_{it}$  : The upper bound value of overtime working hours at period  $t$  in manufactory  $i$ ;
- $h_{ikt}$  : The minimal safety inventory for product  $k$  at period  $t$  in manufactory  $i$ ;
- $\theta_{it}$  : The upper bound value of safety inventory at period  $t$  in manufactory  $i$ ;
- $x_{ikt}$  : The production amount of product  $k$  at period  $t$  in manufactory  $i$  during ordinary working hours;
- $\omega_{ikt}$  : The production amount during overtime working hours for product  $k$  at period  $t$  in manufactory  $i$ ;
- $y_{ijkt}$  : The amount of product  $k$  delivered at period  $t$  in manufactory  $i$  to the locality of demand  $j$ ;
- $e_{ikt}$  : The inventory of product  $k$  at period  $t$  in manufactory  $i$ ;
- $s_{jkt}$  : The shortage amount of product  $k$  during period  $t$  at the locality of demand  $j$ .

### 3.3 Model objective

#### (1) Maximize total profit

To pursue the maximum profit is one of the business objectives and equation (7) helps maximizing the total profits. Profit itself includes items such as revenue and cost, while cost embraces production cost (including both ordinary and overtime working hours), transportation cost, inventory cost, and shortage cost.

Max total profit = (revenue – production cost during ordinary working hours – production cost during overtime working hours – transportation cost for product – inventory cost of product – shortage cost of product)

$$\begin{aligned} \text{Max } z_0 = & \sum_{i=1}^T \sum_{k=1}^K \sum_{j=1}^m \alpha_{ijkt} y_{ijkt} - \sum_{i=1}^m \beta_{ikt} x_{ikt} + \sum_{i=1}^m \gamma_{ikt} \omega_{ikt} \\ & + \sum_{i=1}^m \sum_{j=1}^n \alpha_{ijkt} y_{ijkt} + \sum_{i=1}^m \epsilon_{ikt} e_{ikt} + \sum_{j=1}^n \delta_{jkt} s_{jkt} \end{aligned} \quad (7)$$

#### (2) Maximize the level of service in each period

Under the assumed state that both the production time and transportation time of per unit product are fixed, a portion of the production time is used as the flexible time-space for adjusting to demand changes in order to satisfy the customers' service needs. With this flexible period of time (spare production time in every period/total amount of time available for production in every period) as the crucial factor affecting the level of service, the assumption of relationship between the two can be indicated by the following formula.

Level of service  $l = f(\text{spare production time in every period/total amount of time available for production in every period})$

$$\begin{aligned} \text{Max } \zeta = & f(W_t), \quad t = 1, 2, \dots, T \\ \text{s.t. } & W_t = 1 - \frac{\sum_{i=1}^m \sum_{k=1}^K b_{ikt} x_{ikt} + \sum_{i=1}^m \sum_{k=1}^K b_{ikt} \omega_{ikt}}{(\eta_{it} + c_{it})} \end{aligned} \quad (8)$$

If the manufacturer is confronted with defects such as

instability of demand and supply or mismanagement, it could provide delayed product delivery. And if the value of  $W_t$  is high, that indicates that there are many facilities idle inside the factory to meet the urgent needs of customers: although a quality product could be generated there would be a low turnover. As a result, a trade-off relationship is created between the two objective equations, (13) and (14), in this study.

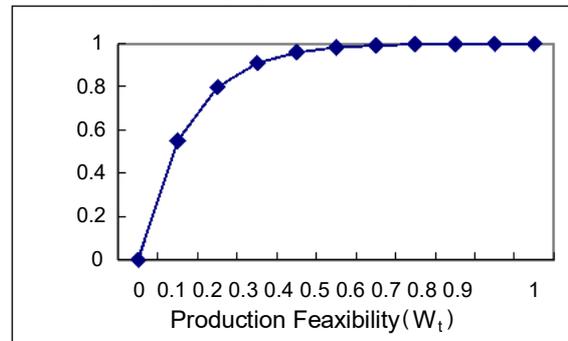

Figure 2 Relationship between Service Level of Manufacturer and Production Feasibility in  $t$  period

### 3.4 Model constraints

#### (1) Raw material Constraint

Raw material needed for production < amount of raw material provided

$$\sum_{k=1}^K a_{krt} (x_{ikt} + \omega_{ikt}) \leq f_{irt} \quad (9)$$

$$i = 1, \dots, m; r = 1, \dots, R; t = 1, \dots, T$$

#### (2) Productivity Constraint

Since a manufacturer is constrained by plant and equipment, it is limited to a certain maximum production capability. And this study uses the bases production time as its unit.

Normal working hours X time needed for production with per unit normal working hours < maximal productivity during normal working hours

Overtime working hours X time needed for production with per unit overtime working hours < maximal productivity during overtime working hours

$$\sum_{k=1}^K b_{ikt} x_{ikt} \leq \eta_{it}; \quad i = 1, \dots, m; t = 1, \dots, T \quad (10)$$

$$\sum_{k=1}^K b_{ikt} \omega_{ikt} \leq c_{it}; \quad i = 1, \dots, m; t = 1, \dots, T \quad (11)$$

#### (3) Inventory constraint

Due to the constraint of space for inventory, it is essential that the total amount of product inventory in every period must be smaller than the limit of maximal inventory capacity. Furthermore, the product inventory this period should be equal to the total amount of inventory for the last period and amount for this period, subtracted by the amount distributed.

Amount of inventory product < maximal capacity of inventory

Amount of inventory this period = inventory capacity of the last period + production amount this period – amount of product distributed.

$$\sum_{k=1}^K e_{ikt} \leq \theta_{it}; i = 1, \dots, m; t = 1, \dots, T \quad (12)$$

$$e_{ikt} = e_{ik(t-1)} + (x_{ikt} + \omega_{ikt}) - \sum_{j=1}^n y_{ijkt} \quad (13)$$

$$i = 1, \dots, m; k = 1, \dots, K; t = 1, \dots, T$$

#### (4) Relationship between the amount of product distribution and demand

The actual amount of product distributed has to be smaller or equivalent to the demands, as predicted in each locality, while the difference between the amount of distribution and demand will be the amount of shortage.

Amount of product distributed ≤ Estimated amount of demand

Shortage product = Amount of Product needed – Amount of Product distributed

$$\sum_{j=1}^n y_{ijkt} \leq d_{jkt}; j = 1, \dots, n; k = 1, \dots, K; t = 1, \dots, T \quad (14)$$

$$s_{jkt} = d_{jkt} - \sum_{i=1}^m y_{ijkt}; j = 1, \dots, n; k = 1, \dots, K; t = 1, \dots, T \quad (15)$$

#### (5) Non-negative constraint

$$x_{ikt} \geq 0; i = 1, \dots, m; k = 1, \dots, K; t = 1, \dots, T \quad (16)$$

$$\omega_{ikt} \geq 0; i = 1, \dots, m; k = 1, \dots, K; t = 1, \dots, T \quad (17)$$

$$y_{ijkt} \geq 0; j = 1, \dots, n; k = 1, \dots, K; t = 1, \dots, T \quad (18)$$

$$e_{ikt} \geq 0; i = 1, \dots, m; k = 1, \dots, K; t = 1, \dots, T \quad (19)$$

### 4. Illustrative Example: Bicycle Manufacturer

In this section the real case of a bicycle manufacturer in Taiwan is examined to demonstrate that this model can be effectively well planned for providing good idea and thinking to treat supply-chain problems. The latest data for the management scenarios were obtained and that manufacturer data was put into this model, whereas each of the information is obtained as modified from the actual data. Section 4.1 provides the problem description and designation for the model; Section 4.2 shows the results and analysis of the operation; and Section 4.3 is sensitivity analysis and discussion.

#### 4.1 Problem description and definitions

The operation problem of this practical example is designed to have three points of supply and seven points of demand, and the period of production programming is divided into four periods in each year. As learned from the case interviews, the demand for bicycle products varies seasonally, furthermore, bicycle has employed season as its different departments as different view-points from other high-tech products having high time cost and depreciation cost. As a result, in this study the first to the

fourth seasons are, respectively, July to September, October to December, January to March of the next year, and April to June. Since this study concerns only bicycles without power, the seven types of products used for product programming are mountain bikes, aluminum alloy bikes, light-weight bikes, children's bikes, sport bikes, racing bikes, and carbon fiber bikes. The working hours of the manufacturing plant are designated as the six ordinary working days per week with twenty-four hours per day. Based upon the already known productivity of the three points of supply, it takes an average of thirty to forty hours to assemble a bicycle, and productivity constraint is rendered during the ordinary working hours in every season. The overtime working hours of the plant is the working hours in holidays.

#### 4.2 Results and analysis

The operation in this part includes: (1) multi-objective compromise programming solution (MOCP), (2) weighted multi-objective programming solution (WMOP), (3) fuzzy multi-objective programming solution (FMOP), (4) weighted fuzzy multi-objective programming solution (WFMOP), (5) two-phase fuzzy multi-objective programming solution (TPFMOP). The results obtained are indicated in Tables 2 and 3.

Table 2 Multi-objective Programming Solution

Model	MOCP	WMOP*	FMOP	WFMOP*	TPFMOP
Total profit (N.T.\$*1000)	31038	456411	31133	493296	310925
1 <sup>st</sup> period	0.93	0.92	0.93	0.89	0.93
2 <sup>st</sup> period	0.95	0.93	0.95	0.89	0.95
3 <sup>st</sup> period	0.79	0.68	0.79	0.58	0.79
4 <sup>st</sup> period	0.88	0.87	0.88	0.76	0.88

\*weights:4:1:1:1:1

As can be seen from Table 2, the value of the total profit by the weighted multi-objective model is far larger than the profit from the multi-objective compromise model, and it is the same for the service level for all periods. The magnitude of value change of the service level in the fourth period as programmed in the fifth model is rather limited, indicating there is more stable service quality, it is thus understood that the multi-objective weight obtained depends largely on the importance with which decision maker endows objectives. Furthermore, the size of the weighted value will have to be adjusted according the nature of the particular problem.

Comparing the results of fuzzy multi-objective, weighted fuzzy multi-objective, and two-phase fuzzy multi-objective programming, the maximum of the total profit value is from weighted multi-objective programming; and comparing this to a single objective, the maximization of the profit will be about the same. The objective value of the service level in each of the programming periods in the weighted fuzzy multi-objective model are similar to the programmed results of the profit maximization of a single objective. It

can thus be said that the model has almost lost its multiphase analyzed, the objective of the two-phase fuzzy objective significance. Since the programmed results of multi-objective programming – its resultant value – would be somewhat smaller than that of fuzzy multi-objective programming, while the achievement of the service level of total achievement in the two-phase multi-objective programming is larger by 0.001, with an insignificant level of improvement.

Table 3 Cost Analyses of the Multi-objective Programming Model

Model		MOCP		WMOCP*		FMOP		WFMOP*		TPFMOP	
Outcome**		Cost-Profit	%								
Total profit		2571618	-	2662507	-	2570337	-	2720545	-	2570034	-
Total cost		2261231	-	2237054	-	2259001	-	2227248	-	2259109	-
Production cost (ordinary)	Material cost	1568831	0.69	1655888	0.74	1610677	0.71	1684356	0.76	1610528	0.71
	Manufacturing cost	221504	0.10	227610	0.10	231246	0.10	229880	0.10	231149	0.10
Production cost (overtime)	Material cost	42474	0.02	0	0	0	0.00	0	0.00	0	0.00
	Manufacturing cost	12565	0.01	0	0	0	0.00	0	0.00	0	0.00
Transportation cost	Tax cost	212911	0.09	234169	0.10	212999	0.09	245300	0.11	213110	0.09
	Ocean shipping cost	53630	0.02	61130	0.03	53535	0.02	67288	0.03	53471	0.02
Inventory cost		388	0.00	220	0	336	0.00	424	0.00	339	0.00
Stoket cost		148927	0.07	58038	0.03	150208	0.07	0	0.00	150511	0.07

\*weights: 4:1:1:1:1; \*\*Unit: hundreds N.

Comparing the results of the above-mentioned models in Table 3, it can be seen that material cost is the highest item of manufacturing cost for bicycles in terms of the total production cost, amounting to almost 70%; next is, the manufacturing cost, which amounts to 11% of the production cost. Thus, the production cost of this industry comprises 81% of the total cost, which shows that this industry is labor-intensive with high material cost. Despite the fact that the bicycle production has already been internationalized, and that its manufacturing, distribution, and selling behaviors are also multi-national, however, analysis of its costs indicates that it is not a high-tech product with high timing cost. Therefore, it is usually distributed by sea freight since that is inexpensive and the ratio of its cost to the total cost is almost negligible. However, the cost of custom can reach 10% of the total cost, amounting to the third highest cost item. As a result, the most important factor for the product sales of bicycle is the in-plant manufacturing cost and material cost of bicycle production, followed by export costs from the country of the manufacturing plant and the import taxes at the locality of demand. Of these three cost items, material cost is beyond the control of the bicycle manufacturer, so manufacturing cost and import and export taxes affect where the manufacturing plant is located.

After having compared multi-objective compromise model to two-phase fuzzy multi-objective programming, the difference of objectives between multi-objective compromise model and weighted multi-objective model programming are rather large, although, the objective

value of profit in multi-objective compromise is low. Even though the service level in each period of the weighted multi-objective model is not as high as that of the multi-objective compromise model, the programmed results of service level from 1<sup>st</sup> to 4<sup>th</sup> period of the weighted multi-objective model, with the exception of 3<sup>rd</sup> period (the service level of the 3<sup>rd</sup> period is about 0.7), are all well over 0.8. In addition, the programmed results of fuzzy multi-objective model and two-phase fuzzy multi-objective model are much the same. However, the outcome of the weighted fuzzy multi-objective programmed model differs insignificantly from the programmed resolution of a single objective. Consequently, if the decision makers, having analyzed the results of each model, wish to achieve the programmed results of multi-objective production and distribution with maximum profit and highest quality service, using the weighted multi-objective model would be more compatible with these results.

#### 4.3 Sensitivity analysis

Based on the conclusions above, the weighted multi-objective programming model is used to conduct the sensitivity analysis for the following policy. This policy is designed in three separate parts: (1) changes of unit production cost (manufacturing cost is increased by 20%, 40%, 60%, 80%, 100%); (2) changes of unit inventory cost (inventory cost is increased by 20%, 40%, 60%); (3) changes of unit shortage cost (shortage cost is lowered by 20%, increased by 20%, 40%).

Table 4 Results of Changes to Unit Manufacturing Cost

- (1) Changes of production cost: As can be seen from Table 4, the increase of production cost can impact the objective value of each objective in this study. With every increment of 20% to the manufacturing cost, the total profit would be lowered by approximately 9%. However, production cost has much less impact on the service level of each period.
- (2) Changes of inventory cost: As indicated from Table 5, after inventory cost is increased by 20%, 40%, and 60% it will, on the contrary, increase both the total profits and the service levels in the 3<sup>rd</sup> and 4<sup>th</sup> periods.
- (3) Changes of shortage cost: As seen in Table 6, the changes to shortage cost will have insignificant impacts on the five objectives studied in this research

because we have considered the feasible time-space unit production cost, unit inventory cost, unit shortage cost for adjusting the demand change. cost are increased. However, an increase of inventory cost

To sum up the analyses above, it is found that if the will increase the total profit, while shortage costs have an insignificant impact on the total profit. If all three of these unit production cost increases, total profit will be reduced. In contrast, an increase of unit inventory cost will cause unit cost items are increased, that will lead to a decrease in total profit to rise, although unit shortage cost has no the shortage cost and increase in the partial inventory cost, impact on total profit. On the other hand, the increase of indicating that shortage quantity will be lowered because these three unit cost items will lead to the decrease of cost, so inventory quantity should be increased to meet shortage cost and the increase of partial inventory cost, demand. Results of the kind show that inventory cost and indicating that shortage cost will be reduced as of cost, so shortage cost seem have interactive behavior on that inventory will be increased to meet the demand. This enterprises, in which the increase of inventory cost will result shows that the inventory cost and shortage cost lower shortage cost. seem to have interactive behavior on the enterprise, whereas the enhancement of inventory cost will reduce shortage cost.

## 5 Conclusions and recommendations

### 5.1 Conclusions

Currently, most of the Taiwan bicycle manufacturers are OEM plants, so enhancement of service level has been one of their goals. In addition, both manufacturing and service industries are gradually induced to be customer service-oriented since stable customer service helps enterprise survival. As a result, this study uses the notion that production elasticity as partial spared productivity is more favorable than full production. This allows for demand space for adjustment to customer elasticity, and it increases the quality of customer service. Although such practice would lower enterprise profit because there is a trade-off relationship between these two objectives, this study uses multi-objective programming to meat this system.

This study uses five kinds of multi-objective programming methods for resolutions: multi-objective compromise programming, fuzzy multi-objective programming, weighted multi-objective programming, weighted multi-objective fuzzy programming, and two-phase fuzzy multi-objective programming. Comparing these five kinds of programming, it is found that the result from weighted multi-objective programming could be well received by the decision maker. The results of this are as follows:

Production cost is the highest of all the total cost items for bicycle production, amounting to 81%, which indicates that bicycle production is a labor-intensive and high material cost manufacturing industry. Besides, although bicycle manufacturing has multi-national production, distribution, and sales; its cost of time is relatively unimportant compared to that of high-tech industries. Thus its distribution is done by sea freight, whose cost is almost insignificant in terms of the total cost. However, expert and import taxes are the third highest cost item. Therefore, the greatest factor that affects the production and distribution of this industry would be the material cost of the product and manufacturing cost of the plant, followed by the export tax of the country where the manufacturing plant is located and the import tax at the locality of demand.

It is found that the total profit will be lowered when

### 5.2 Recommendations

Recommendations offered in this study for subsequent research:

- (1) Although this study has considered the service level of the manufacturer, assumptions were used for the function relationship between service level and production elasticity factor. Nevertheless, there are too many factors that affect the service level of manufacturer, so subsequent studies could focus on them for further investigation.
- (2) In the planning model of this study, it is necessary to appreciate the weight relationship among each of the objectives; thus the preferences of the decision maker are extremely important.
- (3) For practical management, the transaction price and manufacturing cost are not linear; transaction behavior allows discount and differential pricing, whereas manufacturing cost requires a factor as economic scale, in order to make the model realistic. In this study, there is further investigation on the problem of import and export, whose factors of influence are rather widespread and which is also one of the important issues in enterprise management.
- (4) The fuzzy multi-objective programming employed in this study is simply a fuzzy objective equation, and fuzzy constraint equations can be added in subsequent studies.
- (5) This model has only considered the issues of production and distribution, while upper-stream part supply is considered to be already known. Thus, relevant variables of changes from the upper-stream manufacturing supplier are been considered; if these could be considered, the model would be even more comprehensive.

## Appendix

- (1) According to the explanation in Yu (1985),<sup>20</sup> should be used when the decision maker is focused on a certain objective. However,  $d_1$  is recommended when a balance of the objectives is required. The distance scale  $d_p$  found in the above-mentioned equation can also be standardized as follows:

$$d_{p=1} = \max_i \left| \sum_{i=1}^k \frac{f_i^*(x) - f_i(x)}{f_i^*(x)} \right|; i = 1, 2, \dots, k$$

M

$$d_{p=\infty} = \max_i \left| \frac{f_i^*(x) - f_i(x)}{f_i^*(x)} \right|; i = 1, 2, \dots, k$$

(II)

Considering the shortest distance to the positive ideal solution (PIS) and the farthest distance from the negative ideal solution (NIS),  $d_p$  can be indicated as follows:

$$d_p = \left| \sum_{i=1}^k \left| \frac{f_i^*(x) - f_i(x)}{f_i^*(x) - f_i^-(x)} \right|^p \right|^{\frac{1}{p}}$$

where,  $f_i^-(x) = \min_{x \in X} \{f_i(x)\}$ , while  $x^i$  is the solution relative to  $f_i^*(x)$ . Generally speaking,  $f_i^-(x)$  is a negative ideal solution.

(III)

(a) Determination of the ceiling and bottom limit of each of the objectives and constraint equations.

If it is assumed that the decision maker has the most satisfactory and ideal ceiling limit value  $f_i^*(x)$  and the bottom limit value  $f_i^-(x)$  toward the  $i$ th objective  $f_i^-(x)$ , then the decision maker can decide the values of the ceiling and bottom limit according to individual preference. Or the decision maker can take such objective as the function of the feasible solution space and find out the values through calculation, which is as shown in the payoff table.

(b) Establishment of membership function

The membership function toward the  $i$ th fuzzy objective is as follows:

$$\mu_G(x) = \begin{cases} 0 & f_i(x) \leq f_i^-(x) \\ \frac{f_i(x) - f_i^-(x)}{f_i^*(x) - f_i^-(x)} & f_i^-(x) \leq f_i(x) \leq f_i^*(x) \\ 1 & f_i(x) \geq f_i^*(x) \end{cases}$$

as shown in Figure A.

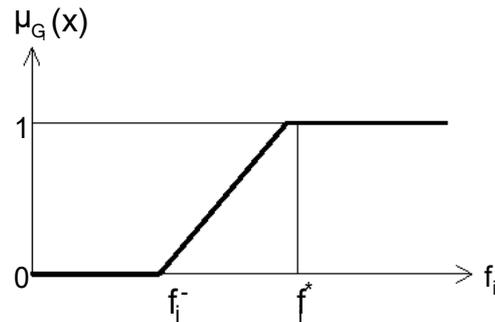

Figure A Membership Function of the Objective

(c) Set up the membership function for the decision making set  $\mu_D(x)$

$$\mu_D(x^*) = \min_{i,j} \{ \mu_{G_i}(x), i = 1, \dots, k \}$$

From the max-min operation equation, the feasible fuzzy set can be found at the intersection of the objective and constraint equation. Since the decision maker needs precise decision-making recommendations, the maximum value of the membership in this decision making set is required. As a result, the maximum is utilized, and the corresponding membership function is thus obtained.

$$\mu_D(x^*) = \max \{ \min \{ \mu_{G_i}(x^*), i = 1, \dots, k \} \}$$

$$\geq \max \{ \min \{ \mu_{G_i}(x), i = 1, \dots, k \} \}$$

(d) Turn the multiple objectives into a single objective for resolution

Finally, this problem can be transformed into precise LP problem for resolution:

$$\begin{aligned} & \max \lambda \\ & \text{s.t. } \frac{f_i(x) - f_i^-(x)}{f_i^*(x) - f_i^-(x)} \geq \lambda, i = 1, \dots, k \\ & Ax \leq b \\ & x \geq 0 \end{aligned}$$

Thus, general linear programming can be used for resolution.

# E-Supply Chain Integration for Inter-Enterprise Business Practices

Chian-Hsueng Chao<sup>†</sup>

<sup>†</sup> Department of Information Management, National University of Kaohsiung  
Kaohsiung, Taiwan  
<sup>†</sup> cchao@nuk.edu.tw

## Abstract

Traditional business partnerships are changing in response to technology advancements and business innovations. Many companies have already reengineered their internal processes, and now the focus has shifted to their trading partners. With network connectivity, supply chain integration is the core strategic competence that enables many companies to act as one. A supply chain represents the cross-functional integration of activities that cross the borders of individual companies. This feature is very important in many industries, because many firms must collaborate intensively throughout a project lifecycle. The issues involved in selecting e-supply chain partners extend beyond choosing a trading partner or a contractor and must include configuring the business-to-business inter-enterprise processes among partners. In the future, supply chains, rather than enterprises will compete with each other. There will be no isolated islands of automation, and the future of business applications will support inter-enterprise collaborative commerce (C-Commerce). The c-commerce e-supply chain scheme enables a dynamic “virtual team” to fulfill many mission-critical business processes throughout a project lifecycle will undoubtedly be the best business solution for the new millennium.

## 1. The Emerging Strategic Alliance

Increasing global competitiveness and the advancement of information technology are potent drivers for organizations to alter their business strategies. Companies need to adapt a new type of agile and responsive organizational structure to fit into the global spectrum of business. New market players in today's e-economy gain diverse skills of workers through alliances, and a flat managerial hierarchy enables them to collaborate on a virtual basis that produces flexible products to meet customers' needs. This places the global economy as a whole in a continual restructuring mode, putting pressure on every industry. The situation is intensified by rapid advances in Information Technology (IT), which have drastically shortened the adaptation periods for organizational changes that used to be comparatively long. Hammer (1990) suggested that enterprises use IT to reengineer their existing business processes to achieve strategic outcomes and improve competitiveness [1], and many companies have “reengineered” changes in their organizational structures, business functions, and business processes to achieve more agility, flexibility, and responsiveness in their operations. Reengineering is critical to an organization's

survival during certain periods when there are major economic upheavals that threaten the organization's existence, and many organizations that do not reinvent themselves are doomed to become part of business history. With the maturity of Internet technologies, organizations can readily perform certain business functions which go beyond organizational boundaries. E-commerce practices today have demonstrated the power of this “virtual organization”, which integrates business processes from the front office to the back office through the Internet.

Due to these paradigm shifts, the traditional business partnership scheme has changed, and the focus has now shifted to their business partners. Today, companies can achieve a business advantage by leveraging networking technology and the principles of supply chain integration. With network connectivity, supply chain integration is now the core strategic competence that enables many companies to act as one. This feature is very important for every industry, because many firms need to cooperate/collaborate intensively throughout a project lifecycle. Today, every industry is an information-intensive industry. Information and communication have always played a major role in their competitiveness and growth. In the future, the supply chains, rather than the enterprises (designer, manufacturer, and supplier) themselves, will compete with each other. An increase in horizontal integration synchronizes the output of the entire supply chain. There will be no isolated islands of automation [2], and those who best define and reengineer their business processes in the e-supply chain partnership will likely be the most successful in this industry.

## 2. The Fusion of E-Business

Although e-business is sometimes confused with e-commerce, it is widely accepted that e-commerce is the buying or selling of products, goods, information, and services over the Internet, whereas e-business is a complex fusion of business processes, enterprise applications, and organizational structure necessary to create a new high performance business model. The topic of e-business often includes business-to-business process automation. Some examples are procurement (bidding, and outsourcing), selling (production and supply chain management), ordering (shipping and logistics), billing, and payment. These processes, by definition, almost always go beyond enterprise boundaries, and there are many other e-business service environments where Internet technologies are being utilized by end users, enterprises, and other parties that wish to do business over the net. Structures changes caused by these shift

impacted the boundaries of the enterprises. Indeed, without transition to an e-business foundation, e-commerce cannot be executed effectively, and no e-business will be truly effective without interacting with all of its supply chain partners in an automated fashion.

### 2.1 The Customer-Centric Supply Chain Management

While technology is at the heart of the change that is revolutionizing our economic life, successful e-business is concerned with building new kinds of relationships with customers, employees, business partners, and all other participants in business life. These relationships are termed the supply chain. Supply Chain Management (SCM) evolved several decades ago from a set of logistics performance tools to an inter-enterprise, and even channel-wide, operating philosophy. The growing dependence on the supply chain has been emphasized by the following changes to traditional business practices: (a) the growth of information sharing between vendors and customers, (b) the paradigm shift in the marketplace from the mass-production of standardized products to flexible operations providing customized/personalized products that customers are demanding solutions designed to meet their specific needs, (c) the rise of process-oriented team efforts replacing traditional departmental functions, and (d) increased trend on inter-enterprise processing and outsourcing. All of these features are very important to today's industries, because many firms need to collaborate intensively throughout a project life cycle and the project team needs continuous access to business plans as the project proceeds.

### 2.2 Supply Chain Collaboration and Integration

The supply chain involves procurement, enterprise resource planning (ERP), EAI (Enterprise Application Integration), inter-enterprise processing, schedule sharing, logistics, inventory management, feedbacks, quality management, and so forth. However, to be successful the members of the supply chain need to collaborate to help the organizations reduce cost, utilize resources more effectively, and improve relationships with their clients. The fundamental benefit of SCM is cooperation and collaboration among different stakeholders. The objectives and scope of work must be clearly stated and faithfully executed (Figure 1). Cooperation and collaboration are especially critical in the management of today's supply chain; these depend on the organizations' willingness to link their strategic objectives and fundamental business processes to create unique, seamless, enterprise-wide portal that are ready to serve their customers. These companies are also capable of quickly consolidating critical competencies and physical processes to gain competitive advantages.

Therefore, issues related to e-supply chain integration include the internal and external core business processes,

the development of close linkages between channel partners, and the management of production and information as they move across organizational boundaries. For example, the manufacturing process for materials or the production and distribution of equipment are transparent to all members in the supply chain. A supply chain is integrated in terms of people focused on processes that ultimately respond to customer demand, but its success requires technology that can integrate and support every exchange of information across the entire supply chain. Issues involved in selecting e-supply chain partners extend beyond choosing a trading partner or a contractor and must include configuring the business-to-business inter-enterprise processes among partners. The selection of processes and cooperation with supply chain partners are critical to the success of business.

### 3. Designing an e-Business Supply Chain Strategic Framework

In today's e-supply chain practices, all business data are transmitted over a variety of communication networks, and the essence of e-business is the communication of business data between organizations under a collaborative scheme in an entire supply chain. Data communication is critical for streamlining the entire supply chain business processes. However, the difficulty is that management has not yet examined these issues from any perspective other than the one dedicated by the paradigm of the field, nor is there much effort to target the issue of transforming e-business practices into an inter-enterprise collaboration supply chain scheme.

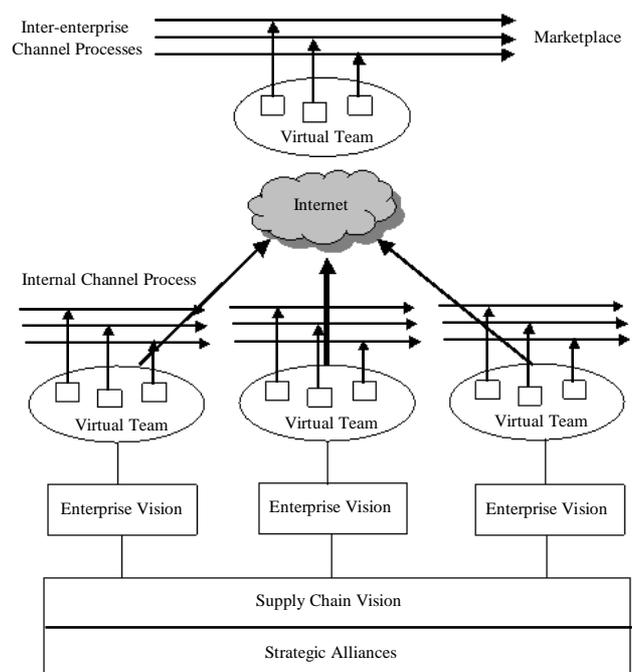

Figure 1. The Virtual Team in a Supply Chain Scheme

A typical project involves the coordination of multi-disciplinary work efforts by different organizations. Although participants may share a common goal of completing a project satisfactorily, their specific objectives are different and their degree of participation depends on their organizational strategies. Thus, the need for integration of trading partners—especially integration of the supply chain and managerial functions—becomes a strategic vision for the future of business practices in the e-business era, and the major parts of the supply chain inter-enterprise processing concepts are presented here.

### 3.1 The Value Chain

To design a supply chain solution, one must start by examining the basic framework of an enterprise's major business activities, which are considered competitive factors that are derived from Porter's value chain [3]. The value chain divides the organization into a set of generic functional areas, which can be further divided into a series of value activities. In the value chain, there are two distinct types of functional area: primary and support (Figure 2). Primary activities are concerned with the direct flow of production (such as inbound logistics, operations, outbound logistics, marketing, sales, and service), whereas support activities (firm infrastructure, human resource management, technology, and procurement) support the primary activities and each other. Starting with its generic value chain categories, a firm can subdivide into discrete activities, categorizing those activities that contribute best to its competitive advantage. Porter's version of supply chain management

is called a value chain because it focuses on value. The value is measured by the amount customers are willing to pay for an organization's product or service. Primary and support activities are called value activities, and an enterprise will be profitable as long as it creates more value than the cost of performing its value activities [4]. In this way, a value chain is defined and a better organizational structure and business process can be created around those value activities that can most improve an organization's competitive advantage [5].

Porter also recognized linkages outside the enterprise, as they relate to the customer's perception of value. This provides the possibility that one value chain could be linked to another value chain, because one business partner could be the other's customer. This interconnected value chain system can act as a supply chain that encompasses the modern business world, and participating organizations can readily extend their technologies to their partners. The "extended enterprise" aspect enables supply chain integration, more effective outsourcing, and self-service solutions for both internal and external stakeholders [5]. This extended enterprise allows for the sophisticated interweaving of online business processes across trading partners and with other internal and external information sources. The following section will illustrate a typical integrated e-supply chain solution for the inter-enterprise business practices.

### 3.2 The General Business Service

Based on a value chain analysis, several general base business activities are identified, and a series of

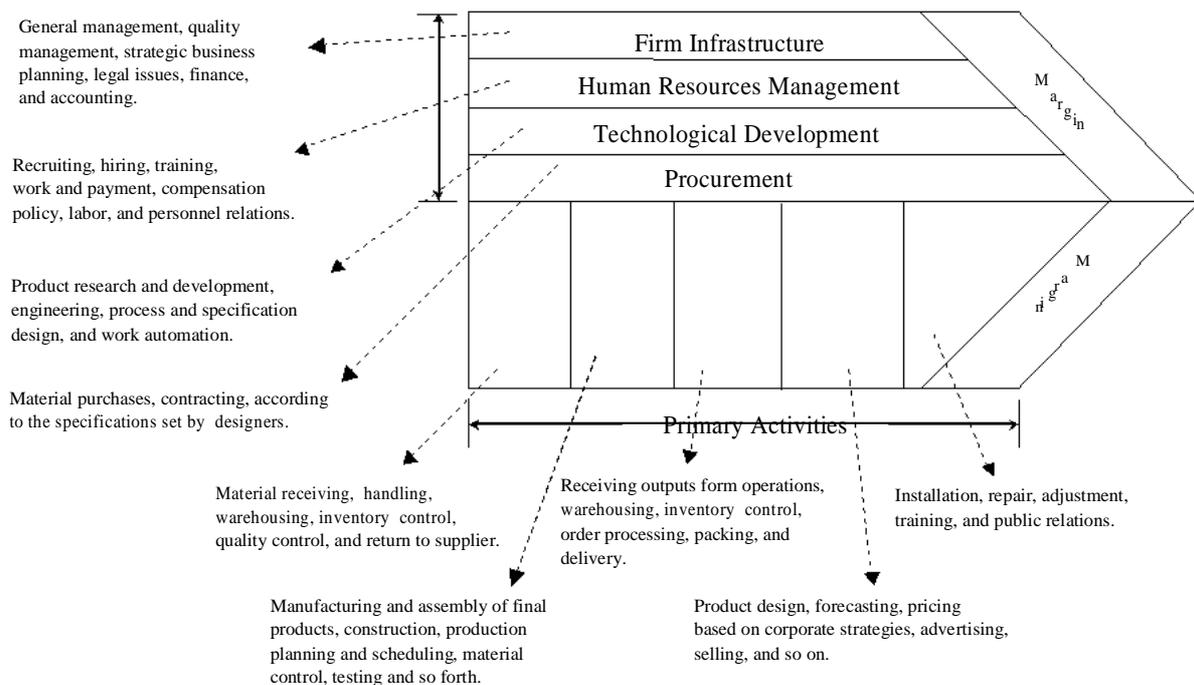

Figure 2 Porter's Value Chain and Value Activities

decomposing efforts will render more detailed sub-processes by using the object-oriented approach. On the other hand, effective management involves many managerial functions, such as scheduling, budgeting, quality control, resource management, and so forth. The ultimate purpose of these management functions is to allocate resources (manpower, equipment, material, etc.) and then monitor, control, and keep all processes on track during every stage of the project cycle. Many business management share many of the same business activities as derived from the value chain, because Porter's value chain activity is the backbone of every type of organization in every type of industry. In here, the Object-Oriented modeling of the transformation process for inter-enterprise processing is summarized in Figure 3.

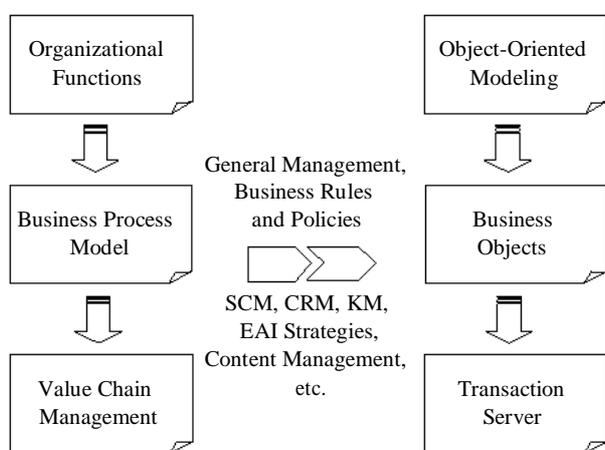

Figure 3 Transformation Process for Inter-enterprise Processing

### 3.3 The Object Orientation

In this study, an object-oriented approach is used to map the corporate business process with the information system in terms of a series of reusable business objects, which encapsulate complex business rules. Accordingly, (a) the tedious redesign efforts of information systems can be circumvented and the corporate information system can become very adaptive, (b) the applications can run on different platforms through network connectivity, and (c) this schematic business blueprint not only fits a given enterprise, but it can also be viewed as an open architecture that links to trading partners. From a process-oriented point of view, this blueprint allows many organizations to share the same business components (or database) in a network and to participate in the business practices of the strategic alliance supply chain. In contrast to an isolated IT system, this approach allows the organization business process to permeate different organizations, and communication in this system becomes process-to-process oriented.

The Unified Modeling Language (UML) is an object-oriented modeling technique that provides a

comprehensive methodology for designing object-oriented applications in a logical, structured manner, and it is available for the development of three-tier client/server distributed applications. A basic core set of diagrams (use case [6] models, interaction diagrams, class diagrams, and activity diagrams) is used in the development processes to refine the design and ultimately define the business objects, after which the class diagrams are coded and mapped into the organizational information system. By applying the object modeling methodology, these business component relationships can be transformed into object-based interactions.

### 3.4 Wielding the Solution

These tools and theories can now be combined to provide an inter-enterprise processing scheme for e-supply chain practices. The first step is to transform a functional organizational structure into a process-based structure based on the value chain model and business process reengineering. The second step is to use the UML to build an object view (Class Diagrams) of business operations that follows the organizational business rules, policies, and business process scenario (Figure 4). The third step is to translate the object-oriented blueprint of the enterprise processes model into machine recognizable codes that can be compiled into a series of reusable business objects.

Several programming languages (such as C++, Java, and Visual Basic) can be used in this transformation. The fourth step is to migrate these business objects into a transaction-processing system that has Internet/Intranet capability (for example, Microsoft Transaction server or the SAP R/3 Enterprise Resource Planning Transaction Server). The business objects can reside on the project team's information system and "talk" to each other using the Common Object Request Broker Architecture (CORBA) scheme to perform over the Internet certain business functions which go beyond organizational boundaries. Regardless of location, users can participate in team coordination/collaboration and share their "collective intelligence" within a virtual corporation. Figure 5 is a schematic diagram of a three-tier information system that stores business objects to perform certain tasks for the organization. This global information networking and inter-enterprise process offers enormous benefits to the many industries.

The business objects presented thus far depict business services, in that each represents an artifact that is encountered or produced in the daily business routine. Each module in the user services part of the model actually relates to a single use case statement, which, in code terms, would actually have to be divided into a number of distinct routines. These routines deal with the methods and properties of the business objects in the business services tier, and the user interface uses these objects to display needed information and feed user input into the system. The business objects, in turn, use objects in the data services layer to get their data. In this

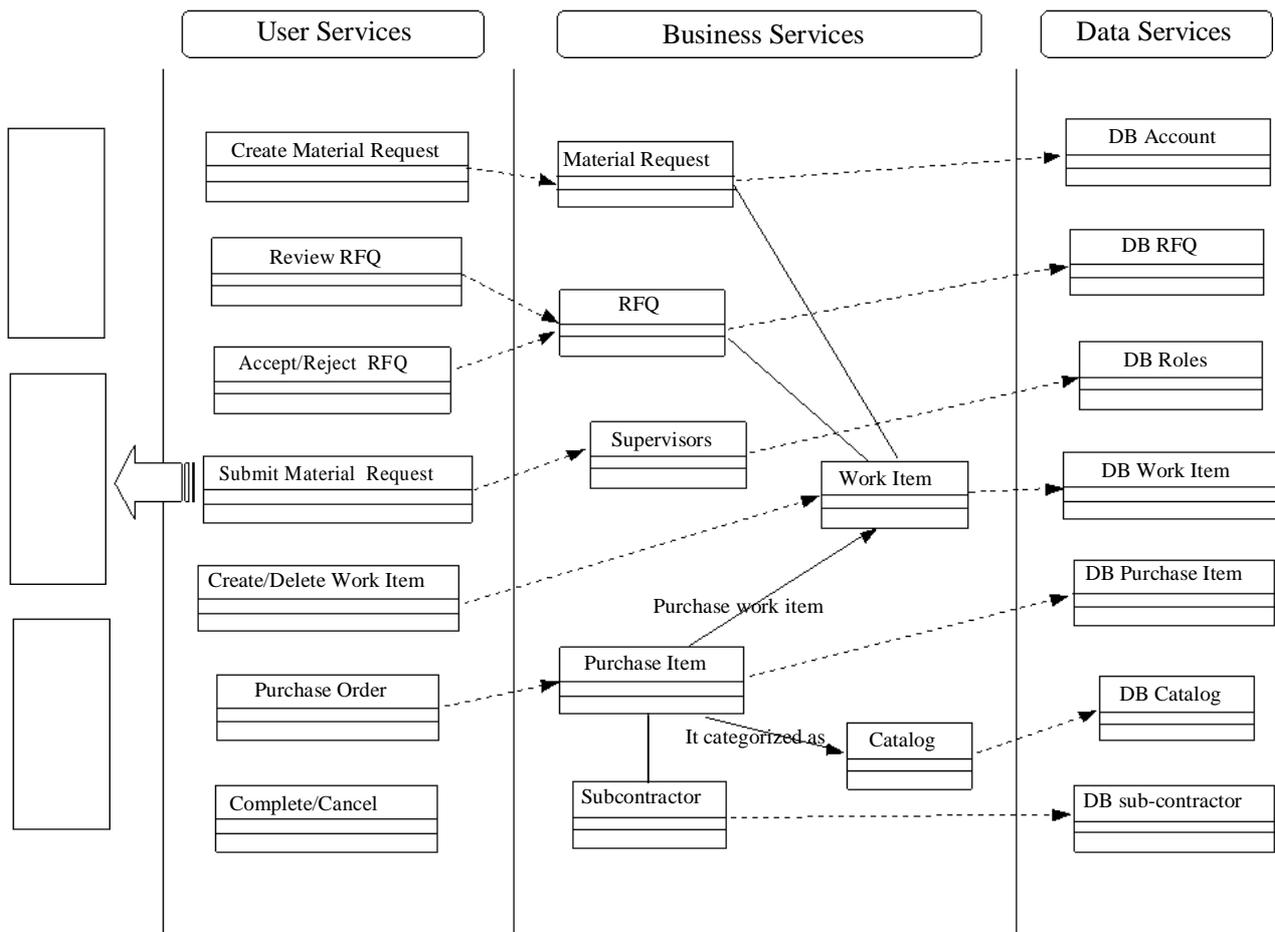

Figure 4 Object-Oriented of Typical Progress Payment in Three-Tier Service Approach

way the user interface could change without impacting the underlying way in which the application dealt with the business, and the database could be replaced with a new database without affecting the rest of the system. As long as the interface to the data service objects remains intact, the rest of the code will compile and run properly.

### 3.5 The E-Supply Chain Inter-Enterprise Application Integration

As mentioned previously, most business plans are unique, complex, extensive, expensive, and subject to tight schedules and budgets. The teams for any given project includes some combination of engineers, contractors, subcontractors, materials suppliers, equipment providers, and even inspectors, and thus the team will normally be different for each project. All of the complexities inherent to different project situations are an inherent part of business practices. As a consequence, managing a business project may require extensive interdisciplinary professional skills to achieve optimum performance. From the supply chain point of view, project members must collaborate to synchronize the output of the entire supply chain to fulfill a particular job. The project partnership in the supply chain becomes

a strategic alliance wherein contractors must align their business processes and information systems to support inter-enterprise processes and decision-making. Configuring business-to-business operations among trading partners is very important, because the supply chain represents the cross-functional integration of all activities that cross the borders of the participating organizations. The issues involved in selecting e-supply chain partners extend beyond choosing a trading partner or a contractor and must include the technological capability to configure the business-to-business collaboration among the partners. Using the value chain concept to identify an organization's competitive advantages and then reengineering its core business processes accordingly is the best way to make a company more process-aware, and that is the beginning of inter-enterprise processes.

E-business solutions should be built on an Internet computing architecture that leverages standard Internet communication protocols and company intranets, extranets, and the global Internet to provide low-cost and universal access to all members of the e-business supply chain. With new web technologies, such as XML, Internet-based systems can offer functionality and information to users through a standard Web browser,

thereby eliminating requirements for traditional Electronic Data Interchange (EDI) or client-based software and reducing IT implementation and maintenance costs, cycles, and burdens. The winners in the Internet economy will be those companies that can respond most rapidly and efficiently to the customer's demands. As a result, an e-business supply chain solution must provide support for the capture and communication of customer demand, as well as enable this demand to automatically trigger business events and initiate process workflow (such as launching manufacturing runs, starting business tasks, and issuing purchase requests within the enterprise and across the supply chain). This supply chain also needs a common data model, because to be effective an e-business supply chain solution will need to deliver an accurate and common view of customer demand data -- as well as any subsequent events, plans, or other business data. This new "e-supply chain" offers virtually unlimited business opportunities in the alignment of processes and technologies. A well-designed and well-integrated supply chain will improve upon existing cost-responsive processes and have organizational agility in the event of change.

#### 4. Conclusion

The challenges of the global marketplace are increasingly forcing today's process-centered organizations to utilize more fully the skills, knowledge, competencies, and resources found in their integrated supply chain networks. Parallel, rather than serial optimization is the key to supply chain management, and companies must acknowledge that adaptivity is increasing becoming a measure upon which its productivity will be evaluated. This adaptivity requires enhancing communication among all team members and aligning their actions toward a common project goal, and IT will be a key "enabler" for this transformation effort.

The explosion of strategic alliances and partnerships on a global scale has brought about the formation of inter-enterprise virtual organizations capable of leveraging the skills, physical resources, and innovative knowledge that reside at different locations in a supply chain network (Figure 6). This paper provides a broad discussion on the possible development of EAI scheme for inter-enterprise processes that embraces all aspect of business practices, and creates multi-channel and multi-technology solutions such as CRM, PRM in a fast-moving and technologically indefinite environment. In today's customer relation management, or selling chain management practices, the customer is in control, and a business must realign its value chain around the customer to eliminate

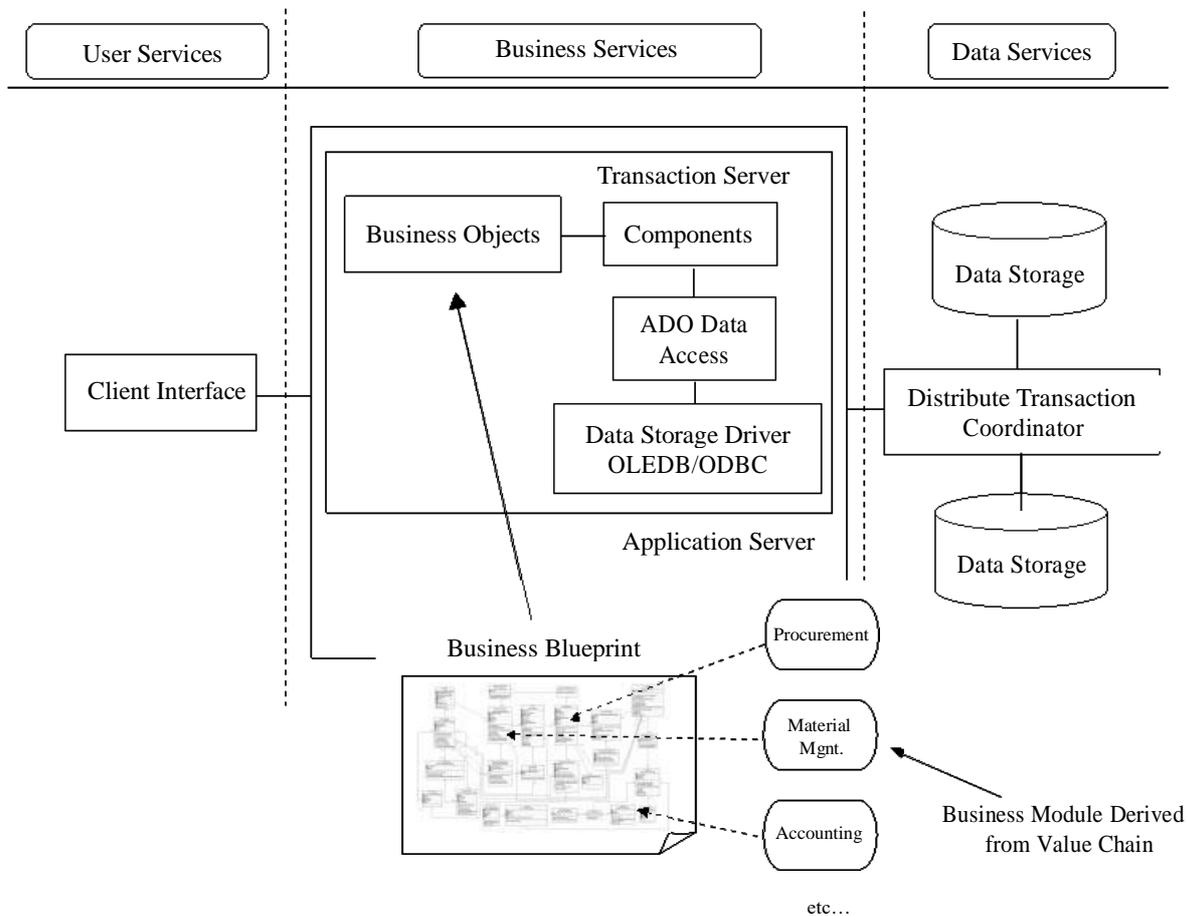

Figure 5 The Adaptive Business Information System

inefficiencies, and custom information, products, and services. Communication in the supply chain must be process-to-process oriented, and collaboration is the best way that trading partners can interact. Process integration across the supply chain becomes a new challenge for today's industries. Enterprises will need to learn that content communication is as important as technological infrastructure to the enterprise software application architecture. For example, the future mobile business will rely more heavily on content management than software application. Opportunity opens doors, but success requires walking through them. With a new focus on process and supply chain management, traditional business partnerships will have to redesign their business strategies. The Collaborative Commerce (CC) e-supply chain scheme that enables a dynamic "virtual team" to fulfill many mission-critical business processes throughout a project lifecycle will undoubtedly be the best business solution for the new millennium.

# **The Integration of the Third Party Information Resources: The Informationalization Breakthrough for Enterprises Based on the Star Supply Chain Management**

Bo Jiang, Nan He, Na Zhao, Zhao Zhao, Xin-Lu Yang

School of Economics and Management

Northern Jiaotong University

Beijing, China

chinabobo1980@yahoo.com

## **Abstract**

With the development and application of the technology of computer, network and telecom, the informationalization has become the significant guarantee for enterprises to realize the continuous development and strengthen the marketing competitive power. Now, how to make full use of information remains a hot issue for the enterprises. A new idea of the third party external resources integration is brought up here. Setting up a star-supply chain with the core of the third party information resources integration enterprise helps to solve the problem of sharing information resources among enterprises, and promote economic globalization.

## **1. Introduction**

With the development of the quick steps for the global economics and the fast popularity of the network, a lot of changes have taken place in the circumstance of global trade and fierce competition. In the next round of the economic competition, we could see that, developed countries will strengthen the enterprise competitive power by applying information technology as a main lever and weapon, constantly cut the cost of products on the value chain, reduce the period, improve the efficiency and the product additional value, thus strengthening the economic energy and the developing power. On the increment chain which helps to create the value chain, the relationships between the supplier, producer, distributor, customer and the interrelated benefit groups are strengthened; and the social value trend which keeps changing influences the decision-making and operation of enterprises.

Under such kind of background, the traditional pattern is broken, and it is impossible for the enterprises to gain long-term profits through single batch manufacturing or on a large scale. The interaction and influences between enterprise and enterprise, enterprise and supplier, enterprise and customer, and enterprise and other groups is much more stronger. And the times of great change, from isolated manufacture to collaboration operation, from independent development to cooperation, has arrived. And it results in the direction and evolvement of informationalization.

## **2. The connotation of informationalization**

The informationalization means that the enterprises utilize information technology in every tache of production and management, explore and take advantage of the internal and external information resources and human resources sufficiently, and set up a corresponding organizational pattern, in order to realize the automation of production, the network of the management and intelligence of the decision-making support, improving the efficiency, level and benefits of the production, management and decision-making, and strengthen the competitive power of enterprises.

In the market economy, informationalization mainly lies in the fact that in pursuit of fastness, novelty, endurance, low costs and efficiency, the enterprises, as the principal part of marketing competition, employ the information of modern technology and communications technology in the process of daily operation and management. The advantage of it is that it can span over the boundaries of the information gathering and sharing sections, fields and industries, break through the restraints of time and space, promote the transformation of enterprise management and the innovation of technology and knowledge, integrate and optimize the resources of the enterprises, including human resources, materials, capital, etc, and as a result, make the enterprises' competitive advantage more prominent.

The informationalization of an enterprise is a complex course, covering a wide field. It may be divided into two parts—the internal informationalization and the external informationalization of an enterprise.

### **2.1 The integration of the intranet and the home information for an enterprise**

The integration of internal information means to realize the informationalization of basic management, research, and development. The foremost task for the integration of internal information is to realize the management computerization, share of the information, rational decision-making and wholeness of management. In another word, realizing linking such taches as management, research, development, production, equipment, supply, sales, transportation and service, realizing the resource optimization of human, capital, materials, and technology by means of computer management software under advanced management idea,

such as MRP, MRP II, ERP, etc, thus helping the decision-making more rational for each department on the basis of the internal shared information, and lowering the marketing risk.

## 2.2 The exploitation and analysis of the extranet and the external information for an enterprise

The external informationalization means that through the exploitation and analysis of the external information, the enterprises make use of the information resources to guide and influence the internal activities of the enterprises. In the days of fierce competition, how to utilize the external resource is a very important issue for enterprises. By the enforcement of supply chain management and client resource management among enterprises, strengthen the relationship of enterprises, suppliers and distributors; take great advantage of the information resource of great quantity and quality from home and abroad, keeping track of the product technology and market trend, and ensuring the superiority of knowing the market changes timely, and of strengthening the ability against risk.

The internal informationalization is the basis of the external informationalization, and only by combining these two parts can we create an integration of the clients and their partners, therefore benefiting from the external informationalization, operating the enterprise systematically, helping the enterprise cut down the operation cost, exploring the market and attract the clients, and supplying the clients with satisfactory service. The exploitation of the external information is the prerequisite of the supply chain integration from the internal to external, and only on the basis of a sufficient exploitation of external resources can an enterprise truly make use of the advanced idea of supply chain management(SCM).

## 3. The actuality of enterprises' informationalization

With the arrival of new economy, the enterprises are trying hard on the informationalization, and have made outstanding progress, which represents in the following two ways:

### 3.1 The internal resource integration develops rapidly

In view of software resource, most enterprises have set up modernized system of production management and working, and the software resource they have mainly focuses on some fundamental software, such as operation system, system maintenance software, office automation software and finance software. On one side, enterprises select useful information from various information sources through modern technology, and set up large-scaled database of high density in order to store a large amount of original information and useful information; on the other hand, enterprises promote the management and operation by robots and computers in production, assembly and storage, which helps the products be yielded according to the right time and right quantity, and be delivered to the

clients in time. At the same time, automation is realized on office system by combining computer and modern telecom technology, and terminal equipment is set up on every position, which strengthens the efficiency and accuracy of information. Nowadays, many large-scaled and medium-scaled enterprises have elementarily realized the internal informationalization, which means they have purchased a certain amount of ERP software, made the internal resources integrated to some degree, and realized the internal management computerization, etc.

In the part of network construction, as the internal and external information of an enterprise piles up and up and competition information ranks especially high in the enterprise activities, more and more enterprises are beginning to set up such departments as information center, which help to make the internal information service more professional and scientific, in order to manage the information resource synthetically. At the present, most enterprises have had LAN(Local Area Net), and many of them are connected to internet.

### 3.2 The exploitation of external resources remains a low level

Although the integration of internal resource has improved a lot gradually, the integration of external resource remains a low level. The external informationalization construction of most enterprises stays as an internet platform which issues news or an E-business platform, and most enterprises lack the information source of themselves.

In order to overcome the fixed shortcomings of multiple production, it is necessary for enterprises to find a breakthrough of right decision-making, and only on the basis of complete information can they make wise decision. No matter whether the scale of the enterprise is large or small, the content of management is almost the same. However, different information is needed according to different levels of management. What the senior leaders of an enterprise need is strategy information, the middle-class leaders favor tactics information, and the profession and task information is for the basic managers. The complete degree of information for an enterprise determines the wise degree of decision-making, and as a result determines the operation risk. Therefore, there are three kinds of information that are necessary for an enterprise: macroscopic economy policy of the country, market information, and the information of the enterprise itself and its competitors. The general channel for information is rather simple, such as some publications, technology communication materials, and some materials gained on business. The patent information and some modern means and equipments such as online search are of such small number, and the materials got in these ways are not complete. The contents of some publications which are compiled and issued by the enterprises themselves are picked up from many sources with low quality, lacking the necessary technology analysis. This results in information contamination, and makes the enterprises lack fixed

information source of themselves. And on the other hand, due to the lack of management of information resource among enterprises, there are a great number of overlaps, dispersion, waste and deficiency. So, the exploitation of external resources is an imperative issue.

#### 4. The background of the external resources integration for an enterprise

Since the 1980's, there has been a great trend worthy of being noticed—the integration trend in circulation industry. Resource integration means that in the specified field, space and time, under the direction of market system, optimizing the investment environment, taking good advantage of various resources, and strengthening the relationship between them, making them regulated in the marketing competition, compensate for each other and influence each other, in order to reach the status of optimization.

The information resource of an enterprise not only includes the internal information arisen from the course of production and operation, but also includes the external information, such as macroscopic social information, market information, finance information, production resource distribution information, relevant scientific and technological information and the information of the competitors, and this information has become the basis of operation decision-making and long-term strategy for an enterprise. So, the velocity, quality and ability for an enterprise to handle, integrate and utilize information have become one of the important symbols of enterprise competitive power.

##### 4.1 the favorite condition for external resource integration—the economy globalization

The application of modern telecom technology and network technology, together with the development of E-business, has promoted the procedure of informationalization of an enterprise; the trend of globalization, informationalization, and integration of the world economy have brought the production elements into circulation at an unimaginable speed, so that broaden the visual field of the enterprise, provide new market opportunities, new external information and new partners, and also represent a larger scale competition and challenge. From the information expressway plan and enterprise "Digital Nervous System" of the USA, to the enterprise informationalization strategy of Japan, the European Union, and many developing countries, a global informationalization revolution has taken place on a large scale. All of these have become the favorite condition for external resource integration.

##### 4.2 the internal reason for external resource integration—the competition of circulation industry

The integration of circulation industry has provided the third profits source, a new way to cut cost, improve

efficiency and gain more profits. In our traditional opinion, the first way to cut cost, is to reduce the variable cost of operation, such as reducing the number of staff, cutting down the material and management consumption. The second way is to reduce the fixed cost, such as running a shop in a marginal region of city with convenient transportation. In nowadays, it has turned to cutting down the operation and logistics cost of the whole circulation procedure by integration of the internal and external information resources, and try to improve the service simultaneously.

##### 4.3 The technology support of the external information resource integration—the development of modern information and network technology

The rapid development of information technology has reduced the cost of information research, information storage, information transfer, and information analysis greatly. In the circulation field, the developed technologies are: POS, CAO, EOS, ASN, EFT, GPS, RF, AI, DSS, and EDI, etc. Besides, there are intranet, extranet and internet. As regard to software, there are MRP, MRPII, ERP, and CRM, which are developing with great potential in Europe and America. Modern information and network technology have provided a potent technology support for the external information resource integration.

##### 4.4 the concept basis of external resource integration ---supply chain management

The supply chain management has become a main subject for the enterprise competition. The supply chain is an integral net-chain function pattern which links the supplier, manufacturer, logistics enterprise and the terminal consumer. Focused on the core enterprise, it begins with purchasing materials, manufactures the unfinished and finished products, and delivers them to the consumers through internet, by control of information stream, material stream, and capital stream.

The supply chain is made up of all the member enterprises, among which there's a core enterprise generally. Spurred on by the demanding information and by media of capital stream, material stream and information, the node enterprises realize the incessant incrementing of the whole supply chain through division of labour and cooperation. The supply chain is a net-chain structure, which has the character of complexity, mobility, customer orientation and intersection.

All of the enterprises on the supply chain share the common information, especially the terminal consumption information of the common mobile change. Try to make the information exact, timely, and visible, eliminate the unnecessary commodity transfer, overstock, by promoting the information sufficient circulation among the enterprises. The information management with accuracy and specification, can weaken the uncertainty between the supply and demand, realize the fact of "replacing the

storage with information”,reduce the storage of products, cut down the possession of flowing capital ,and reduce the economic loss caused by the invalidity and damage in the storage, in order to make the material stream on supply chain flow rationally and optimally, and shorten the production cycle and lower the production cost.

### 5. The settlement plan of external resources integration for an enterprise

The external resources represent to be very multiple and unordered, in another word, the demands of every enterprise for the external resources are so different. Meantime, an enterprise should meet different needs of others, too. Therefore, enterprises should build up several supply chains. In this way, a multiple-to-multiple relationship of resource utilization among enterprises is set up. So, how to deal with this kind of relationship? A third party enterprise is required. By disposing and integrating a great amount of external resources, the Third Party Information Resources Integration(3PIRI) enterprises will surely meet the individual demand for external resources, set up a corresponding external resource platform, and help to run a truly global supply chain management.

3PIRI enterprises can provide services as follows:

#### 5.1 Establish an information database through the membership-system

The establishment of 3PIRI enterprises will lead to the formation of a Star Supply Chain Management(SSCM) system( Figure1), of which 3PIRI enterprise will be the core. Resources can be shared among different enterprises who are the members of the alliance. In this way, each enterprise acts as a member of 3PIRI enterprise, so it

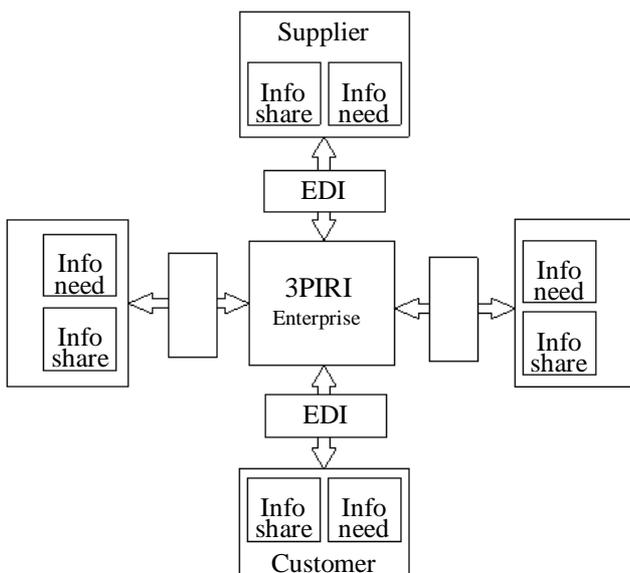

Figure 1: Star Supply Chain Management

should announce its own inner information to 3PIRI enterprise, so as to meet the needs of the other members in it.

#### 5.2 Dispose, integrate and allocate the enterprise’s resources

With their ascendant technology, the third party enterprises can dispose and integrate various information resources collected and fulfill individual needs of the members.

#### 5.3 Provide the enterprises with individual external resources

According to the demands of its members, and with the permission of the resource owner, 3PIRI enterprise can provide useful resources to the demanders with a certain kind of recompense. Thus, an enterprise’s individual need for the external resources is perfectly met, and an external resource platform is precisely built.

#### 5.4 Set up a synthesized electronic commerce platform of enterprise information

On the basis of a great deal of information, 3PIRI can steadily set up a synthesized electronic commerce platform. For one thing ,it can precisely and transparently combine the information of different members through the platform; and for another, this platform can become a synthesized electronic commerce web site, which can proclaim supplying and demanding information to the members.

The establishment of the electronic commerce platform is the foremost mission of 3PIRI enterprise. And This will be a tache which ties the inner and outer information resources of the SSCM system. Consequently, the safety of the platform, the integrality of the data and the management of the interface, will all become vital problems to be solved for 3PIRI enterprise.

### 6. The significance of setting up 3PIRI Enterprise

3PIRI enterprises will become the core of the SSCM system. And it is of great importance to the course of enterprises’ information construction and supply chain management.

#### 6.1 Integrate enterprises’ external resources to make them efficient members of the SSCM system

With 3PIRI enterprise’s entry into the system, a new structure of the supply chain will be created. In this case, there’s no need for a common enterprise to spend so much time, money and energy integrating the external resources. What they do is just to think over “ what do I need and what should I supply?” Therefore, it is much easier for a common enterprise to join in the global system of the supply chain management. Also, it results in realizing the integration of provision, production and marketing, lowering the business cost and decreasing the risk of administration.

#### 6.2 Meet the enterprises’ individual needs for external resources

Different types of enterprises require different kinds of external resources. 3PIRI enterprises can provide transparent interface according to various needs to achieve the goal of realizing individual service. Consequently, only by introducing the third party enterprises can we satisfy the individual needs perfectly.

### 6.3 Establish synthesized electronic commerce platform

Making full use of its information resources, 3PIRI enterprise helps to establish a synthesized electronic commerce platform. In this way, enterprise may operate with E-commerce, and on the other hand, it can be service platform for customers. With this synthesized platform, enterprises can advertise their corporation images and products, and proclaim their demanding information. And customers can enjoy a kind of synthesized service, such as acquiring large amounts of information of different products, services and so on.

### 6.4 The affiliation of 3PIRI enterprises will make the information resources integration more professional

3PIRI enterprises will become the main subject of the information integration. They can make full use of their professional personnel, technology and management so as to professionalize the work of integration. Meanwhile the data redundancy and the incompatibility in data coding can be efficiently reduced or avoided, and the safety of the data can be well ensured. As the information resources are integrated by 3PIRI enterprises, a common enterprise need not reintegrate its own inner resources when several supply chains are set up, and all the external resources it get can be utilized directly as well, which makes the construction of the supply chains much easier than before.

## 7. The Third Party Information Resources Integration enterprises

The business of integrating external resources can be undertaken by the following two types of enterprises.

### 7.1 The Third Party Logistics(3PL) Enterprise

3PL enterprise is a kind of enterprise which can realize the integration of its external logistics. Accordingly, it has a great advantage in the external resources integration management. Moreover, this will grow into a new increasing point of profit in 3PL enterprise.

The membership-system of 3PL provides a prerequisite for the external resources integration. The member corporation is not only the provider of all kinds of information resources, but also the user of the resource. This can make the information supply, demand and acquisition far more simple. At the same time, 3PL enterprise has advanced technology and management, so that it can bring various information resources into the supply chain management.

There are various members in the 3PL enterprises, such as material-supply enterprises, manufacturers, distributors, customers and other benefit interrelated entities. They are all nodes in the supply chain, which makes the Star Supply Chain set up more easily.

### 7.2 Application Service Provider(ASP) enterprises

For a small-scaled enterprise, obviously, it can not afford to take part in the SSCM system with its own limited resources. When ASP first appeared in the USA, it inaugurated a vast space in traditional enterprises using the internet and realizing information construction. Also, ASP has the ability to integrate the external resources in moderate enterprises.

An ASP enterprise owns all or most of the information resources of its member enterprises, which is a most important factor for an ASP enterprise's becoming the core of the external resource integration. ASP sets up supply chains for various enterprises of small scale and medium scale, and helps them realize SSCM with few human resources and little money.

An ASP enterprise has a great advantage in resources and meanwhile in technology. An ASP enterprise holds a set of advanced hardware and software, which will be the technical condition in the resources integration. Accordingly, an ASP enterprise will build up an integration system to deal with all kinds of information more operationally.

## 8. Conclusion

The affiliation of 3PIRI enterprises and the establishment of the SSCM will inevitably result in a new revolution in the enterprise's supply chain management. In this new revolution, external resource integration is an imperative request in a enterprise's management of its information construction. To gain the advantage in competition, a modern enterprise must combine its core ability and technology with other useful resources appropriately, for there comes a new era of cooperative competition, where benefit can be shared in a certain scope.

# Modeling Decision Systems via Uncertain Programming

Baoding Liu

Uncertainty Theory Laboratory, Department of Mathematical Sciences

Tsinghua University, Beijing 100084, China

<http://orsc.edu.cn/~liu>

*Abstract*—By uncertain programming we mean the optimization theory in generally uncertain (random, fuzzy, rough, fuzzy random, etc.) environments. The main purpose of this paper is to present a brief review on uncertain programming models, and classify them into three broad classes: expected value model, chance-constrained programming and dependent-chance programming. This presentation is based on the book: B. Liu, *Theory and Practice of Uncertain Programming*, Phisica-Verlag, Heidelberg, 2002.

*Keywords*—stochastic programming, fuzzy programming, uncertain programming, hybrid intelligent algorithm

## I. INTRODUCTION

Real-life decisions are usually made in the state of uncertainty. How do we model optimization problems in uncertain environments? How do we solve these models? Uncertain programming theory attempts to answer these questions.

By uncertain programming we mean the optimization theory in uncertain environments. The main topics of uncertain programming are stochastic programming, fuzzy programming, rough programming, fuzzy random programming, random fuzzy programming, random rough programming, rough random programming, fuzzy rough programming, rough fuzzy programming, birandom programming, bifuzzy programming, birough programming, and multifold uncertain programming.

With the requirement of considering randomness, appropriate formulations of stochastic programming have been developed to suit the different purposes of management. The first type of stochastic programming is the *expected value model* (EVM), which optimizes the expected objective functions subject to some expected constraints. The second, *chance-constrained programming* (CCP), was pioneered by Charnes and Cooper [8] as a means of handling uncertainty by specifying a confidence level at which it is desired that the stochastic constraint holds. In practice, there usually are multiple events in a complex stochastic decision system. Sometimes the decision-maker wishes to maximize the chance functions of satisfying these events. In order to model this type of problem, Liu [39] provided a theoretical framework of the third type of stochastic programming, called *dependent-chance programming* (DCP).

Fuzzy programming offers a powerful means of handling optimization problems with fuzzy parameters. Fuzzy programming has been used in different ways in the past. Liu and Liu [57] presented a concept of expected value operator of fuzzy variable and provided a spectrum of fuzzy EVM. Following the idea of stochastic CCP, in a fuzzy decision system we assume that the fuzzy constraints will hold with a possibility level. Thus we have a fuzzy CCP theory. Analogously, following the idea of stochastic DCP, Liu [46] provided the fuzzy DCP theory.

Rough set theory, initialized by Pawlak [71], has been proved to be an excellent mathematical tool dealing with vague description of objects. A fundamental assumption in rough set theory is that any object from a universe is perceived through available information, and such information may not be sufficient to characterize the object exactly. Liu [56] presented a concept of rough space, and defined a rough variable as a measurable function from a rough space to the real line. Expected value operator of rough variable and trust measure of rough event are also suggested. Rough programming is thus proposed.

More generally, Liu [48][56] laid a foundation for optimization theory in uncertain environments, and called such a theory *uncertain programming*.

Fuzzy random variable was developed by Kwakernaak [31][32], and defined as a measurable function from a probability space to a collection of fuzzy variables. Fuzzy random programming is the theory dealing with optimization problems in fuzzy random environments, and has been made in several ways. We will introduce the theoretical framework of fuzzy random EVM (Liu and Liu [61]), fuzzy random CCP (Liu [54]), and fuzzy random DCP (Liu [55]).

Random fuzzy variable was initialized by Liu [56], and defined as a function from a possibility space to a collection of random variables. That is, a random fuzzy variable is a fuzzy variable defined on the universal set of random variables. As a tool of handling random fuzzy decision problems, random fuzzy programming includes random fuzzy EVM (Liu and Liu [60]), random fuzzy CCP (Liu [56]), and random fuzzy DCP (Liu [58]).

In addition to fuzzy random variable and random fuzzy variable, we have also other types of multifold uncertain variables: random rough variable, rough random variable, fuzzy rough variable, rough fuzzy variable, birandom variable, bifuzzy variable, and birough variable. Thus we have random rough programming, rough random programming, fuzzy rough programming, rough fuzzy programming, birandom programming, bifuzzy programming, birough programming, and multifold (three-fold, four-fold, etc.) uncertain programming (Liu [56]).

## II. VARIOUS TYPES OF UNCERTAINTY

Fuzzy variable  $\xi$  is defined as a function from a possibility space  $(\Theta, \mathcal{P}(\Theta), \text{Pos})$  to the real line  $\mathfrak{R}$ . Let  $\tilde{a}_1, \tilde{a}_2, \dots, \tilde{a}_n$  be fuzzy variables, and  $f_j : \mathfrak{R}^n \rightarrow \mathfrak{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the *possibility* of the fuzzy event characterized by  $f_j(\tilde{a}_1, \tilde{a}_2, \dots, \tilde{a}_n) \leq 0$ ,  $j = 1, 2, \dots, m$  is defined by

$$\begin{aligned} & \text{Pos} \{f_j(\tilde{a}_1, \tilde{a}_2, \dots, \tilde{a}_n) \leq 0, j = 1, 2, \dots, m\} \\ &= \sup_{x_1, x_2, \dots, x_n \in \mathfrak{R}} \left\{ \min_{1 \leq i \leq n} \mu_{\tilde{a}_i}(x_i) \mid \begin{array}{l} f_j(x_1, x_2, \dots, x_n) \leq 0 \\ j = 1, 2, \dots, m \end{array} \right\}. \end{aligned}$$

The *necessity* of a fuzzy event is defined as the impossibility of the opposite event. Thus a necessity measure is the dual of possibility measure. The *credibility* of a fuzzy event is defined as the average of its possibility and necessity, i.e.,  $\text{Cr}\{\cdot\} = \frac{1}{2}(\text{Pos}\{\cdot\} + \text{Nec}\{\cdot\})$ .

Liu and Liu [57] presented an *expected value operator* of fuzzy variable. The expected value of  $\xi$  is defined by

$$E[\xi] = \int_0^{+\infty} \text{Cr}\{\xi \geq r\} dr - \int_{-\infty}^0 \text{Cr}\{\xi \leq r\} dr. \quad (1)$$

Fuzzy random variables are mathematical descriptions for fuzzy stochastic phenomena, and are defined in several ways. Kwakernaak [31][32] first introduced the notion of fuzzy random variable. This concept was then developed by Puri and Ralescu [75], Kruse and Meyer [30], and Liu and Liu [59]. Liu and Liu [59] presented a definition of scalar expected value operator and several types of law of large numbers for fuzzy random variables. Liu [54][55] provided a concept of primitive chance measure of fuzzy random event.

Liu [56] initialized the concept of random fuzzy variable which is a function from a possibility space to a collection of random variables. The primitive chance measure of random fuzzy event was defined by Liu [56] as a function from  $[0,1]$  to  $[0,1]$ . The expected value operator of random fuzzy variable was given by Liu and Liu [60].

Let  $\Lambda$  be a nonempty set,  $\mathcal{A}$  be a  $\sigma$ -algebra of subsets of  $\Lambda$ ,  $\Delta$  be an element in  $\mathcal{A}$ , and  $\pi$  be a nonnegative, real-valued, additive set function. Then  $(\Lambda, \Delta, \mathcal{A}, \pi)$  is called a rough space. A rough variable  $\xi$  is defined by Liu [56] as a measurable function from the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$  to the real line  $\mathfrak{R}$ . The lower and the upper approximations of the rough variable  $\xi$  are then defined as follows,

$$\underline{\xi} = \{\xi(\lambda) \mid \lambda \in \Delta\}, \quad \bar{\xi} = \{\xi(\lambda) \mid \lambda \in \Lambda\}. \quad (2)$$

Let  $\xi$  be a rough vector on the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$ , and  $f_j : \mathfrak{R}^n \rightarrow \mathfrak{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the upper trust of the rough event characterized by  $f_j(\xi) \leq 0, j = 1, 2, \dots, m$  is defined by

$$\text{Tr} \left\{ \left. \begin{matrix} f_j(\xi) \leq 0 \\ j = 1, 2, \dots, m \end{matrix} \right\} = \frac{\pi \{\lambda \in \Lambda \mid f_j(\xi(\lambda)) \leq 0, j = 1, 2, \dots, m\}}{\pi \{\Lambda\}}.$$

Let  $\xi$  be a rough vector on the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$ , and  $f_j : \mathfrak{R}^n \rightarrow \mathfrak{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the lower trust of the rough event characterized by  $f_j(\xi) \leq 0, j = 1, 2, \dots, m$  is defined by

$$\text{Tr} \left\{ \left. \begin{matrix} f_j(\xi) \leq 0 \\ j = 1, 2, \dots, m \end{matrix} \right\} = \frac{\pi \{\lambda \in \Delta \mid f_j(\xi(\lambda)) \leq 0, j = 1, 2, \dots, m\}}{\pi \{\Delta\}}.$$

If  $\pi\{\Delta\} = 0$ , then we define

$$\text{Tr} \{f_j(\xi) \leq 0, j = 1, 2, \dots, m\} \equiv \text{Tr} \{f_j(\xi) \leq 0, j = 1, 2, \dots, m\}.$$

Let  $\xi$  be a rough vector on the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$ , and  $f_j : \mathfrak{R}^n \rightarrow \mathfrak{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the trust of the rough event is defined as the average value of the lower and upper trusts.

Let  $\xi$  be a rough variable on the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$ . The expected value of  $\xi$  is defined by

$$E[\xi] = \int_0^{+\infty} \text{Tr}\{\xi \geq r\} dr - \int_{-\infty}^0 \text{Tr}\{\xi \leq r\} dr. \quad (3)$$

A random rough variable is defined by Liu [56] as a function  $\xi$  from a rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$  to a collection of random variables such that for any Borel set  $B$  of  $\mathfrak{R}$ ,

$$\xi^*(B)(\lambda) = \text{Pr}\{\xi(\lambda) \in B\} \quad (4)$$

is a measurable function of  $\lambda$ . Let  $\xi$  be a random rough variable defined on the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$ . Then its expected value  $E[\xi]$  is defined by

$$\int_0^{+\infty} \text{Tr}\{\lambda \in \Lambda \mid E[\xi(\lambda)] \geq r\} dr - \int_{-\infty}^0 \text{Pr}\{\lambda \in \Lambda \mid E[\xi(\lambda)] \leq r\} dr.$$

Let  $\xi = (\xi_1, \xi_2, \dots, \xi_n)$  be a random rough vector on the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$ , and  $f_j : \mathfrak{R}^n \rightarrow \mathfrak{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the primitive chance of random rough event characterized by  $f_j(\xi) \leq 0, j = 1, 2, \dots, m$  is a function from  $[0, 1]$  to  $[0, 1]$ , defined as

$$\begin{aligned} \text{Ch} \{f_j(\xi) \leq 0, j = 1, 2, \dots, m\}(\alpha) \\ = \sup \left\{ \beta \mid \text{Tr} \left\{ \lambda \in \Lambda \mid \text{Pr} \left\{ \left. \begin{matrix} f_j(\xi(\lambda)) \leq 0 \\ j = 1, 2, \dots, m \end{matrix} \right\} \geq \beta \right\} \geq \alpha \right\}. \end{aligned} \quad (5)$$

A rough random variable is defined by Liu [56] as a function  $\xi$  from a probability space  $(\Omega, \mathcal{A}, \text{Pr})$  to a collection of rough variables such that for any Borel set  $B$  of  $\mathfrak{R}$ ,

$$\xi^*(B)(\omega) = \text{Tr}\{\xi(\omega) \in B\} \quad (6)$$

is a measurable function of  $\omega$ . Let  $\xi$  be a rough random variable defined on the probability space  $(\Omega, \mathcal{A}, \text{Pr})$ . Then its expected value  $E[\xi]$  is defined by

$$\int_0^{+\infty} \text{Pr}\{\omega \in \Omega \mid E[\xi(\omega)] \geq r\} dr - \int_{-\infty}^0 \text{Pr}\{\omega \in \Omega \mid E[\xi(\omega)] \leq r\} dr.$$

Let  $\xi = (\xi_1, \xi_2, \dots, \xi_n)$  be a rough random vector on the probability space  $(\Omega, \mathcal{A}, \text{Pr})$ , and  $f_j : \mathfrak{R}^n \rightarrow \mathfrak{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the primitive chance of rough random event characterized by  $f_j(\xi) \leq 0, j = 1, 2, \dots, m$  is a function from  $[0, 1]$  to  $[0, 1]$ , defined as

$$\begin{aligned} \text{Ch} \{f_j(\xi) \leq 0, j = 1, 2, \dots, m\}(\alpha) \\ = \sup \left\{ \beta \mid \text{Pr} \left\{ \omega \in \Omega \mid \text{Tr} \left\{ \left. \begin{matrix} f_j(\xi(\omega)) \leq 0 \\ j = 1, 2, \dots, m \end{matrix} \right\} \geq \beta \right\} \geq \alpha \right\}. \end{aligned}$$

A fuzzy rough variable is defined by Liu [56] as a function  $\xi$  from a rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$  to a collection of fuzzy variables such that for any Borel set  $B$  of  $\mathfrak{R}$ ,

$$\xi^*(B)(\lambda) = \text{Pos}\{\xi(\lambda) \in B\} \quad (7)$$

is a measurable function of  $\lambda$ . Let  $\xi$  be a fuzzy rough variable defined on the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$ . Then its expected value  $E[\xi]$  is defined by

$$\int_0^{+\infty} \text{Tr}\{\lambda \in \Lambda \mid E[\xi(\lambda)] \geq r\} dr - \int_{-\infty}^0 \text{Tr}\{\lambda \in \Lambda \mid E[\xi(\lambda)] \leq r\} dr.$$

Let  $\xi = (\xi_1, \xi_2, \dots, \xi_n)$  be a fuzzy rough vector on the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$ , and  $f_j : \mathfrak{R}^n \rightarrow \mathfrak{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the primitive chance of fuzzy rough event characterized by  $f_j(\xi) \leq 0, j = 1, 2, \dots, m$  is a function from  $[0, 1]$  to  $[0, 1]$ , defined as

$$\begin{aligned} \text{Ch} \{f_j(\xi) \leq 0, j = 1, 2, \dots, m\}(\alpha) \\ = \sup \left\{ \beta \mid \text{Tr} \left\{ \lambda \in \Lambda \mid \text{Pos} \left\{ \left. \begin{matrix} f_j(\xi(\lambda)) \leq 0 \\ j = 1, 2, \dots, m \end{matrix} \right\} \geq \beta \right\} \geq \alpha \right\}. \end{aligned}$$

A rough fuzzy variable is defined by Liu [56] as a function from a possibility space  $(\Theta, \mathcal{P}(\Theta), \text{Pos})$  to a collection of rough variables. Let  $\xi$  be a rough fuzzy variable defined on the possibility space  $(\Theta, \mathcal{P}(\Theta), \text{Pos})$ . The expected value  $E[\xi]$  is defined by

$$\int_0^\infty \text{Cr}\{\theta \in \Theta | E[\xi(\theta)] \geq r\} dr - \int_{-\infty}^0 \text{Cr}\{\theta \in \Theta | E[\xi(\theta)] \leq r\} dr.$$

Let  $\xi = (\xi_1, \xi_2, \dots, \xi_n)$  be a rough fuzzy vector on the possibility space  $(\Theta, \mathcal{P}(\Theta), \text{Pos})$ , and  $f_j : \mathbb{R}^n \rightarrow \mathbb{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the primitive chance of rough fuzzy event characterized by  $f_j(\xi) \leq 0, j = 1, 2, \dots, m$  is a function from  $[0, 1]$  to  $[0, 1]$ , defined as

$$\begin{aligned} & \text{Ch}\{f_j(\xi) \leq 0, j = 1, 2, \dots, m\}(\alpha) \\ &= \sup \left\{ \beta \mid \text{Pos} \left\{ \theta \in \Theta \mid \text{Tr} \left\{ \begin{array}{l} f_j(\xi(\theta)) \leq 0 \\ j = 1, 2, \dots, m \end{array} \right\} \geq \beta \right\} \geq \alpha \right\}. \end{aligned}$$

A birandom variable is a function  $\xi$  from a probability space  $(\Omega, \mathcal{A}, \text{Pr})$  to a collection of random variables such that for any Borel set  $B$  of  $\mathbb{R}$ ,

$$\xi^*(B)(\omega) = \text{Pr}\{\xi(\omega) \in B\} \quad (8)$$

is a measurable function of  $\omega$ . Let  $\xi$  be a birandom variable defined on the probability space  $(\Omega, \mathcal{A}, \text{Pr})$ . Then its expected value  $E[\xi]$  is defined by

$$\int_0^\infty \text{Pr}\{\omega \in \Omega | E[\xi(\omega)] \geq r\} dr - \int_{-\infty}^0 \text{Pr}\{\omega \in \Omega | E[\xi(\omega)] \leq r\} dr.$$

Let  $\xi = (\xi_1, \xi_2, \dots, \xi_n)$  be a birandom vector on the probability space  $(\Omega, \mathcal{A}, \text{Pr})$ , and  $f_j : \mathbb{R}^n \rightarrow \mathbb{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the primitive chance of birandom event characterized by  $f_j(\xi) \leq 0, j = 1, 2, \dots, m$  is a function from  $[0, 1]$  to  $[0, 1]$ , defined as

$$\begin{aligned} & \text{Ch}\{f_j(\xi) \leq 0, j = 1, 2, \dots, m\}(\alpha) \\ &= \sup \left\{ \beta \mid \text{Pr} \left\{ \omega \in \Omega \mid \text{Pr} \left\{ \begin{array}{l} f_j(\xi(\omega)) \leq 0 \\ j = 1, 2, \dots, m \end{array} \right\} \geq \beta \right\} \geq \alpha \right\}. \end{aligned}$$

A bifuzzy variable is defined by Liu [53] as a function from a possibility space to a collection of fuzzy variables. Let  $\xi$  be a bifuzzy variable defined on the possibility space  $(\Theta, \mathcal{P}(\Theta), \text{Pos})$ . The expected value  $E[\xi]$  is defined by Liu [53] as

$$\int_0^\infty \text{Cr}\{\theta \in \Theta | E[\xi(\theta)] \geq r\} dr - \int_{-\infty}^0 \text{Cr}\{\theta \in \Theta | E[\xi(\theta)] \leq r\} dr.$$

Let  $\xi = (\xi_1, \xi_2, \dots, \xi_n)$  be a bifuzzy vector on the possibility space  $(\Theta, \mathcal{P}(\Theta), \text{Pos})$ , and  $f_j : \mathbb{R}^n \rightarrow \mathbb{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the primitive chance of bifuzzy event characterized by  $f_j(\xi) \leq 0, j = 1, 2, \dots, m$  is a function from  $[0, 1]$  to  $[0, 1]$ , defined by Liu [53] as

$$\begin{aligned} & \text{Ch}\{f_j(\xi) \leq 0, j = 1, 2, \dots, m\}(\alpha) \\ &= \sup \left\{ \beta \mid \text{Pos} \left\{ \theta \in \Theta \mid \text{Pos} \left\{ \begin{array}{l} f_j(\xi(\theta)) \leq 0 \\ j = 1, 2, \dots, m \end{array} \right\} \geq \beta \right\} \geq \alpha \right\}. \end{aligned}$$

A birough variable is defined by Liu [56] as a function  $\xi$  from a rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$  to a collection of rough variables such that for any Borel set  $B$  of  $\mathbb{R}$ ,

$$\xi^*(B)(\lambda) = \text{Tr}\{\xi(\lambda) \in B\} \quad (9)$$

is a measurable function of  $\lambda$ . Let  $\xi$  be a birough variable on the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$ . Then its expected value  $E[\xi]$  is defined by

$$\int_0^\infty \text{Tr}\{\lambda \in \Lambda | E[\xi(\lambda)] \geq r\} dr - \int_{-\infty}^0 \text{Tr}\{\lambda \in \Lambda | E[\xi(\lambda)] \leq r\} dr.$$

Let  $\xi = (\xi_1, \xi_2, \dots, \xi_n)$  be a birough vector on the rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$ , and  $f_j : \mathbb{R}^n \rightarrow \mathbb{R}$  be continuous functions,  $j = 1, 2, \dots, m$ . Then the primitive chance of birough event characterized by  $f_j(\xi) \leq 0, j = 1, 2, \dots, m$  is a function from  $[0, 1]$  to  $[0, 1]$ , defined as

$$\begin{aligned} & \text{Ch}\{f_j(\xi) \leq 0, j = 1, 2, \dots, m\}(\alpha) \\ &= \sup \left\{ \beta \mid \text{Tr} \left\{ \lambda \in \Lambda \mid \text{Tr} \left\{ \begin{array}{l} f_j(\xi(\lambda)) \leq 0 \\ j = 1, 2, \dots, m \end{array} \right\} \geq \beta \right\} \geq \alpha \right\}. \end{aligned}$$

A trirandom variable is a function  $\xi$  from a probability space  $(\Omega, \mathcal{A}, \text{Pr})$  to a collection of birandom variables such that for any Borel set  $B$  of  $\mathbb{R}$ ,

$$\xi^*(B)(\omega) = \text{Ch}\{\xi(\omega) \in B\} \quad (10)$$

is a measurable function of  $\omega$ .

A trifuzzy variable is a function from a possibility space to a collection of bifuzzy variables.

A ttrough variable is a function  $\xi$  from a rough space  $(\Lambda, \Delta, \mathcal{A}, \pi)$  to a collection of birough variables such that for any Borel set  $B$  of  $\mathbb{R}$ ,

$$\xi^*(B)(\lambda) = \text{Ch}\{\xi(\lambda) \in B\} \quad (11)$$

is a measurable function of  $\lambda$ .

We may also define other three-fold uncertainty. For example, a fuzzy random rough variable is a function from a rough space to a collection of fuzzy random variables such that for any Borel set  $B$  of  $\mathbb{R}$ ,  $\xi^*(B)(\lambda) = \text{Ch}\{\xi(\lambda) \in B\}$  is a measurable function of  $\lambda$ .

### III. RANKING UNCERTAIN VARIABLES

Let  $\xi$  and  $\eta$  be two uncertain variables. Different from the situation of real numbers, there does not exist a natural ordership in an uncertain world. Thus an important problem appearing in uncertain systems is how to rank uncertain variables. The following ranking methods are suggested.

(i) We say  $\xi > \eta$  if and only if  $E[\xi] > E[\eta]$ , where  $E$  is the expected value operator of uncertain variables. This criterion leads to expected value models.

(ii) We say  $\xi > \eta$  if and only if, for some predetermined confidence level  $\alpha \in (0, 1]$ , we have  $\xi_{\text{sup}}(\alpha) > \eta_{\text{sup}}(\alpha)$ , where  $\xi_{\text{sup}}(\alpha)$  and  $\eta_{\text{sup}}(\alpha)$  are the  $\alpha$ -optimistic values of  $\xi$  and  $\eta$ , respectively. This criterion leads to maximax chance-constrained programming.

(iii) We say  $\xi > \eta$  if and only if, for some predetermined confidence level  $\alpha \in (0, 1]$ , we have  $\xi_{\text{inf}}(\alpha) > \eta_{\text{inf}}(\alpha)$ , where  $\xi_{\text{inf}}(\alpha)$  and  $\eta_{\text{inf}}(\alpha)$  are the  $\alpha$ -pessimistic values of  $\xi$  and  $\eta$ , respectively. This criterion leads to minimax chance-constrained programming.

(iv) We say  $\xi > \eta$  if and only if  $\text{Ch}\{\xi \geq \bar{\tau}\} > \text{Ch}\{\eta \geq \bar{\tau}\}$  for some predetermined level  $\bar{\tau}$ . This criterion leads to dependent-chance programming.

### IV. EXPECTED VALUE MODELS

The first type of uncertain programming is the expected value model (EVM) in which the underlying philosophy is based on selecting the decisions with maximum expected value of return.

We have stochastic, fuzzy, rough, fuzzy random, random fuzzy, fuzzy rough, rough fuzzy, random rough,

rough random, birandom, bifuzzy, and birough EVM. The general form of EVM is formulated as follows,

$$\begin{cases} \max E[f(\mathbf{x}, \boldsymbol{\xi})] \\ \text{subject to:} \\ E[g_j(\mathbf{x}, \boldsymbol{\xi})] \leq 0, \quad j = 1, 2, \dots, p \end{cases} \quad (12)$$

where  $\mathbf{x}$  is a decision vector,  $\boldsymbol{\xi}$  is an uncertain vector,  $f(\mathbf{x}, \boldsymbol{\xi})$  is the return function,  $g_j(\mathbf{x}, \boldsymbol{\xi})$  are uncertain constraint functions for  $j = 1, 2, \dots, p$ , and  $E$  denotes the expected value operator.

The expected value multiobjective programming (EV-MOP) model has the following form,

$$\begin{cases} \max [E[f_1(\mathbf{x}, \boldsymbol{\xi})], E[f_2(\mathbf{x}, \boldsymbol{\xi})], \dots, E[f_m(\mathbf{x}, \boldsymbol{\xi})]] \\ \text{subject to:} \\ E[g_j(\mathbf{x}, \boldsymbol{\xi})] \leq 0, \quad j = 1, 2, \dots, p \end{cases} \quad (13)$$

where  $f_i(\mathbf{x}, \boldsymbol{\xi})$  are return functions for  $i = 1, 2, \dots, m$ .

We can also formulate an uncertain decision system as an expected value goal programming (EVGP) model according to the priority structure and target levels set by the decision-maker,

$$\begin{cases} \min \sum_{j=1}^l P_j \sum_{i=1}^m (u_{ij}d_i^+ + v_{ij}d_i^-) \\ \text{subject to:} \\ E[f_i(\mathbf{x}, \boldsymbol{\xi})] + d_i^- - d_i^+ = b_i, \quad i = 1, 2, \dots, m \\ E[g_j(\mathbf{x}, \boldsymbol{\xi})] \leq 0, \quad j = 1, 2, \dots, p \\ d_i^+, d_i^- \geq 0, \quad i = 1, 2, \dots, m \end{cases} \quad (14)$$

where  $P_j$  is the preemptive priority factor which expresses the relative importance of various goals,  $P_j \gg P_{j+1}$ , for all  $j$ ,  $u_{ij}$  is the weighting factor corresponding to positive deviation for goal  $i$  with priority  $j$  assigned,  $v_{ij}$  is the weighting factor corresponding to negative deviation for goal  $i$  with priority  $j$  assigned,  $d_i^+$  is the positive deviation from the target of goal  $i$ ,  $d_i^-$  is the negative deviation from the target of goal  $i$ ,  $f_i$  is a function in goal constraints,  $b_i$  is the target value according to goal  $i$ ,  $l$  is the number of priorities,  $m$  is the number of goal constraints, and  $p$  is the number of real constraints.

#### V. MAXIMAX CHANCE-CONSTRAINED PROGRAMMING

In this section, we provide a spectrum of maximax chance-constrained programming (CCP) models in which the underlying philosophy is based on selecting the alternative that provides the best optimistic return with a given confidence level. In order to do so, we may measure the uncertain return by its optimistic value.

We have stochastic, fuzzy, rough, fuzzy random, random fuzzy, fuzzy rough, rough fuzzy, random rough, rough random, birandom, bifuzzy, and birough CCP. A single-objective maximax CCP model may be written as follows,

$$\begin{cases} \max \bar{f} \\ \text{subject to:} \\ \text{Ch} \{f(\mathbf{x}, \boldsymbol{\xi}) \geq \bar{f}\} \geq \beta \\ \text{Ch} \{g_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0, j = 1, 2, \dots, p\} \geq \alpha \end{cases} \quad (15)$$

where  $\alpha$  and  $\beta$  are predetermined confidence levels, and  $\max \bar{f}$  will be the  $\beta$ -optimistic return.

Maximax chance-constrained multiobjective programming (CCMOP) may be written as follows,

$$\begin{cases} \max [\bar{f}_1, \bar{f}_2, \dots, \bar{f}_m] \\ \text{subject to:} \\ \text{Ch} \{f_i(\mathbf{x}, \boldsymbol{\xi}) \geq \bar{f}_i\} \geq \beta_i, \quad i = 1, 2, \dots, m \\ \text{Ch} \{g_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0\} \geq \alpha_j, \quad j = 1, 2, \dots, p \end{cases} \quad (16)$$

We can also formulate an uncertain decision system as a minimin chance-constrained goal programming (CCGP) according to the priority structure and target levels set by the decision-maker:

$$\begin{cases} \min \sum_{j=1}^l P_j \sum_{i=1}^m (u_{ij}d_i^+ + v_{ij}d_i^-) \\ \text{subject to:} \\ \text{Ch} \{f_i(\mathbf{x}, \boldsymbol{\xi}) - b_i \leq d_i^+\} \geq \beta_i^+, \quad i = 1, 2, \dots, m \\ \text{Ch} \{b_i - f_i(\mathbf{x}, \boldsymbol{\xi}) \leq d_i^-\} \geq \beta_i^-, \quad i = 1, 2, \dots, m \\ \text{Ch} \{g_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0\} \geq \alpha_j, \quad j = 1, 2, \dots, p \\ d_i^+, d_i^- \geq 0, \quad i = 1, 2, \dots, m \end{cases} \quad (17)$$

where  $P_j$  is the preemptive priority factor which expresses the relative importance of various goals,  $P_j \gg P_{j+1}$ , for all  $j$ ,  $u_{ij}$  is the weighting factor corresponding to positive deviation for goal  $i$  with priority  $j$  assigned,  $v_{ij}$  is the weighting factor corresponding to negative deviation for goal  $i$  with priority  $j$  assigned,  $d_i^+$  is the  $\beta_i^+$ -optimistic positive deviation from the target of goal  $i$ ,  $d_i^-$  is the  $\beta_i^-$ -optimistic negative deviation from the target of goal  $i$ ,  $f_i$  is a function in goal constraints,  $g_j$  is a function in real constraints,  $b_i$  is the target value according to goal  $i$ ,  $l$  is the number of priorities,  $m$  is the number of goal constraints, and  $p$  is the number of real constraints.

#### VI. MINIMAX CHANCE-CONSTRAINED PROGRAMMING

Murphy's law states that "if anything can go wrong, it will". If you believe it, you may select the decision with the best of these worst returns. In order to do so, we may measure the uncertain return by its pessimistic value.

As opposed to optimistic models, we have a spectrum of minimax CCP models in which the underlying philosophy is based on selecting the alternative with the best pessimistic return with a given confidence level. A single-objective minimax CCP model may be written as follows,

$$\begin{cases} \max \min_{\boldsymbol{\xi}} \bar{f} \\ \text{subject to:} \\ \text{Ch} \{f(\mathbf{x}, \boldsymbol{\xi}) \leq \bar{f}\} \geq \beta \\ \text{Ch} \{g_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0, j = 1, 2, \dots, p\} \geq \alpha \end{cases} \quad (18)$$

where  $\min_{\boldsymbol{\xi}} \bar{f}$  is the  $\beta$ -pessimistic return.

When there are multiple objectives, we may employ the minimax CCMOP model,

$$\begin{cases} \max_{\boldsymbol{x}} \left[ \min_{\bar{f}_1} \bar{f}_1, \min_{\bar{f}_2} \bar{f}_2, \dots, \min_{\bar{f}_m} \bar{f}_m \right] \\ \text{subject to:} \\ \text{Ch} \{f_i(\mathbf{x}, \boldsymbol{\xi}) \leq \bar{f}_i\} \geq \beta_i, \quad i = 1, 2, \dots, m \\ \text{Ch} \{g_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0\} \geq \alpha_j, \quad j = 1, 2, \dots, p \end{cases} \quad (19)$$

According to the priority structure and target levels, the minimax CCGP model is written as follows,

$$\begin{cases} \min_{\boldsymbol{x}} \sum_{j=1}^l P_j \sum_{i=1}^m \left[ u_{ij} \left( \max_{d_i^+} d_i^+ \vee 0 \right) + v_{ij} \left( \max_{d_i^-} d_i^- \vee 0 \right) \right] \\ \text{subject to:} \\ \text{Ch} \{f_i(\mathbf{x}, \boldsymbol{\xi}) - b_i \geq d_i^+\} \geq \beta_i^+, \quad i = 1, 2, \dots, m \\ \text{Ch} \{b_i - f_i(\mathbf{x}, \boldsymbol{\xi}) \geq d_i^-\} \geq \beta_i^-, \quad i = 1, 2, \dots, m \\ \text{Ch} \{g_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0\} \geq \alpha_j, \quad j = 1, 2, \dots, p \end{cases}$$

where  $d_i^+ \vee 0$  is the  $\beta_i^+$ -pessimistic positive deviation from the target of goal  $i$ , and  $d_i^- \vee 0$  is the  $\beta_i^-$ -pessimistic negative deviation from the target of goal  $i$ .

## VII. DEPENDENT-CHANCE PROGRAMMING

In order to model uncertain decision problems, we may employ dependent-chance programming (DCP) in which the underlying philosophy is based on selecting the decisions with maximum chance to meet the events. We thus have stochastic, fuzzy, rough, fuzzy random, random fuzzy, fuzzy rough, rough fuzzy, random rough, rough random, birandom, bifuzzy, and birough DCP.

A typical DCP in an uncertain environment is given as follows:

$$\begin{cases} \max \text{Ch}\{h_k(\mathbf{x}, \boldsymbol{\xi}) \leq 0, k = 1, 2, \dots, q\} \\ \text{subject to:} \\ g_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0, \quad j = 1, 2, \dots, p \end{cases} \quad (20)$$

where  $\mathbf{x}$  is a decision vector,  $\boldsymbol{\xi}$  is an uncertain vector, then event is characterized by  $h_k(\mathbf{x}, \boldsymbol{\xi}) \leq 0, k = 1, 2, \dots, q$ , and the uncertain environment is constrained as  $g_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0, j = 1, 2, \dots, p$ .

Since a complex decision system usually undertakes multiple tasks, there undoubtedly exist multiple potential objectives in the decision process. A dependent-chance multiobjective programming (DCMOP) in an uncertain environment has the following form,

$$\begin{cases} \max \begin{bmatrix} \text{Ch}\{h_{1k}(\mathbf{x}, \boldsymbol{\xi}) \leq 0, k = 1, 2, \dots, q_1\} \\ \text{Ch}\{h_{2k}(\mathbf{x}, \boldsymbol{\xi}) \leq 0, k = 1, 2, \dots, q_2\} \\ \dots \\ \text{Ch}\{h_{mk}(\mathbf{x}, \boldsymbol{\xi}) \leq 0, k = 1, 2, \dots, q_m\} \end{bmatrix} \\ \text{subject to:} \\ g_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0, \quad j = 1, 2, \dots, p. \end{cases} \quad (21)$$

We can also formulate an uncertain decision system as a dependent-chance goal programming (DCGP) according to the priority structure and target levels,

$$\begin{cases} \min \sum_{j=1}^l P_j \sum_{i=1}^m (u_{ij} d_i^+ + v_{ij} d_i^-) \\ \text{subject to:} \\ \text{Ch}\left\{ \begin{matrix} h_{ik}(\mathbf{x}, \boldsymbol{\xi}) \leq 0 \\ k = 1, 2, \dots, q_i \end{matrix} \right\} + d_i^- - d_i^+ = b_i, \quad i = 1, 2, \dots, m \\ g_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0, \quad j = 1, 2, \dots, p \\ d_i^+, d_i^- \geq 0, \quad i = 1, 2, \dots, m \end{cases}$$

where  $P_j$  is the preemptive priority factor which expresses the relative importance of various goals,  $P_j \gg P_{j+1}$ , for all  $j$ ,  $u_{ij}$  is the weighting factor corresponding to positive deviation for goal  $i$  with priority  $j$  assigned,  $v_{ij}$  is the weighting factor corresponding to negative deviation for goal  $i$  with priority  $j$  assigned,  $d_i^+$  is the positive deviation from the target of goal  $i$ ,  $d_i^-$  is the negative deviation from the target of goal  $i$ ,  $b_i$  is the target value according to goal  $i$ ,  $l$  is the number of priorities, and  $m$  is the number of goal constraints.

## VIII. UNCERTAIN DYNAMIC PROGRAMMING

Let us consider an  $N$ -stage decision system in which  $\hat{\mathbf{a}} = (a_1, a_2, \dots, a_N)$  represents the state vector,  $\hat{\mathbf{x}} = (x_1, x_2, \dots, x_N)$  the decision vector,  $(\boldsymbol{\xi}_1, \boldsymbol{\xi}_2, \dots, \boldsymbol{\xi}_N)$  the uncertain vector. We also assume that the state transition function is

$$\mathbf{a}_{i+1} = T(\mathbf{a}_i, \mathbf{x}_i, \boldsymbol{\xi}_i), \quad i = 1, 2, \dots, N-1. \quad (22)$$

## Expected Value Dynamic Programming

In order to maximize the discount expected return over the horizon, we may use the following expected value dynamic programming,

$$\begin{cases} f_N(\mathbf{a}) = \max_{E[g(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_N)] \leq 0} E[r_N(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_N)] \\ f_n(\mathbf{a}) = \max_{E[g(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_n)] \leq 0} E[r_n(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_n) + \theta f_{n+1}(T(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_n))] \\ n \leq N-1 \end{cases}$$

where  $r_i$  are the return functions at the  $i$ th stages,  $i = 1, 2, \dots, N$ , respectively,  $\theta$  is a discount rate,  $0 \leq \theta \leq 1$ , and  $E$  denotes the expected value operator. This type of uncertain (especially stochastic) dynamic programming has been applied to a wide variety of problems, for example, inventory systems.

## Chance-Constrained Dynamic Programming

In order to maximize the discount optimistic return over the horizon, we may use the following chance-constrained dynamic programming,

$$\begin{cases} f_N(\mathbf{a}) = \max_{\text{Ch}\{g(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_N) \leq 0\} \geq \alpha} \bar{r}_N(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_N) \\ f_n(\mathbf{a}) = \max_{\text{Ch}\{g(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_n) \leq 0\} \geq \alpha} \{\bar{r}_n(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_n) + \theta f_{n+1}(T(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_n))\} \\ n \leq N-1 \end{cases}$$

where the functions  $\bar{r}_i$  are defined by

$$\bar{r}_i(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_i) = \sup_{\bar{r}} \{ \bar{r} \mid \text{Ch}\{r_i(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_i) \geq \bar{r}\} \geq \beta \} \quad (23)$$

for  $i = 1, 2, \dots, N$ . If we want to maximize the discount pessimistic return over the horizon, then we must define the functions  $\bar{r}_i$  as

$$\bar{r}_i(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_i) = \inf_{\bar{r}} \{ \bar{r} \mid \text{Ch}\{r_i(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_i) \leq \bar{r}\} \geq \beta \} \quad (24)$$

for  $i = 1, 2, \dots, N$ .

## Dependent-Chance Dynamic Programming

In order to maximize the discount chance over the horizon, we may employ the following dependent-chance dynamic programming,

$$\begin{cases} f_N(\mathbf{a}) = \max_{g(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_N) \leq 0} \text{Ch}\{h_N(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_N) \leq 0\} \\ f_n(\mathbf{a}) = \max_{g(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_n) \leq 0} \{ \text{Ch}\{h_n(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_n) \leq 0\} + \theta f_{n+1}(T(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_n)) \} \\ n \leq N-1 \end{cases}$$

where  $h_i(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_i) \leq 0$  are the events, and  $g(\mathbf{a}, \mathbf{x}, \boldsymbol{\xi}_i) \leq 0$  are the uncertain environments at the  $i$ th stages,  $i = 1, 2, \dots, N$ , respectively.

## IX. UNCERTAIN MULTILEVEL PROGRAMMING

Assume that in a decentralized two-level decision system there is one leader and  $m$  followers. Let  $\mathbf{x}$  and  $\mathbf{y}_i$  be the control vectors of the leader and the  $i$ th followers,  $i = 1, 2, \dots, m$ , respectively. We also assume that the objective functions of the leader and  $i$ th followers are  $F(\mathbf{x}, \mathbf{y}_1, \dots, \mathbf{y}_m, \boldsymbol{\xi})$  and  $f_i(\mathbf{x}, \mathbf{y}_1, \dots, \mathbf{y}_m, \boldsymbol{\xi})$ ,  $i = 1, 2, \dots, m$ , respectively, where  $\boldsymbol{\xi}$  is an uncertain vector.

## Expected Value Multilevel Programming

Let the feasible set of control vector  $\mathbf{x}$  of the leader be defined by the expected constraint

$$E[G(\mathbf{x}, \boldsymbol{\xi})] \leq 0 \quad (25)$$

where  $G$  is a vector-valued function and  $0$  is a vector with zero components. Then for each decision  $\mathbf{x}$  chosen by the leader, the feasibility of control array  $(\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m)$  of followers should be dependent on  $\mathbf{x}$ , and generally represented by the expected constraint,

$$E[g(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi})] \leq 0 \quad (26)$$

where  $g$  is a vector-valued function.

Assume that the leader first chooses his control vector  $\mathbf{x}$ , and the followers determine their control array  $(\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m)$  after that. In order to maximize the expected return of the leader, we have the following expected value bilevel programming,

$$\left\{ \begin{array}{l} \max_{\mathbf{x}} E[F(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi})] \\ \text{subject to:} \\ E[G(\mathbf{x}, \boldsymbol{\xi})] \leq 0 \\ \text{where each } \mathbf{y}_i (i = 1, 2, \dots, m) \text{ solves} \\ \left\{ \begin{array}{l} \max_{\mathbf{y}_i} E[f_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi})] \\ \text{subject to:} \\ E[g(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi})] \leq 0. \end{array} \right. \end{array} \right. \quad (27)$$

A Nash equilibrium of followers is the feasible array  $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$  with respect to  $\mathbf{x}$  if

$$\begin{aligned} E[f_i(\mathbf{x}, \mathbf{y}_1^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi})] \\ \leq E[f_i(\mathbf{x}, \mathbf{y}_1^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i^*, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi})] \end{aligned} \quad (28)$$

for any feasible  $(\mathbf{y}_1^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*)$  and  $i = 1, 2, \dots, m$ . Let  $\mathbf{x}^*$  be a feasible control vector of the leader and  $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$  be a Nash equilibrium of followers with respect to  $\mathbf{x}^*$ . We call the array  $(\mathbf{x}^*, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$  a Stackelberg-Nash equilibrium to the expected value bilevel programming (27) if and only if,

$$E[F(\bar{\mathbf{x}}, \bar{\mathbf{y}}_1, \bar{\mathbf{y}}_2, \dots, \bar{\mathbf{y}}_m, \boldsymbol{\xi})] \leq E[F(\mathbf{x}^*, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi})] \quad (29)$$

for any feasible  $\bar{\mathbf{x}}$  and the Nash equilibrium  $(\bar{\mathbf{y}}_1, \bar{\mathbf{y}}_2, \dots, \bar{\mathbf{y}}_m)$  with respect to  $\bar{\mathbf{x}}$ .

#### Chance-Constrained Multilevel Programming

In order to maximize the optimistic return subject to the chance constraint, we may use the following chance-constrained bilevel programming,

$$\left\{ \begin{array}{l} \max_{\mathbf{x}} \bar{F} \\ \text{subject to:} \\ \text{Ch}\{F(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \geq \bar{F}\} \geq \beta \\ \text{Ch}\{G(\mathbf{x}, \boldsymbol{\xi}) \leq 0\} \geq \alpha \\ \text{where each } \mathbf{y}_i (i = 1, 2, \dots, m) \text{ solves} \\ \left\{ \begin{array}{l} \max_{\mathbf{y}_i} \bar{f}_i \\ \text{subject to:} \\ \text{Ch}\{f_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \geq \bar{f}_i\} \geq \beta_i \\ \text{Ch}\{g(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq 0\} \geq \alpha_i \end{array} \right. \end{array} \right. \quad (30)$$

where  $\alpha, \beta, \alpha_i, \beta_i, i = 1, 2, \dots, m$  are predetermined confidence levels.

A Nash equilibrium of followers is the feasible array  $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$  with respect to  $\mathbf{x}$  if

$$\begin{aligned} \bar{f}_i(\mathbf{x}, \mathbf{y}_1^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*) \\ \leq \bar{f}_i(\mathbf{x}, \mathbf{y}_1^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i^*, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*) \end{aligned} \quad (31)$$

for any feasible array  $(\mathbf{y}_1^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*)$  and  $i = 1, 2, \dots, m$ . Let  $\mathbf{x}^*$  be a feasible control vector of the

leader and  $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$  be a Nash equilibrium of followers with respect to  $\mathbf{x}^*$ . The array  $(\mathbf{x}^*, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$  is called a Stackelberg-Nash equilibrium to the chance-constrained bilevel programming (30) if and only if,

$$\bar{F}(\bar{\mathbf{x}}, \bar{\mathbf{y}}_1, \bar{\mathbf{y}}_2, \dots, \bar{\mathbf{y}}_m) \leq \bar{F}(\mathbf{x}^*, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*) \quad (32)$$

for any feasible control vector  $\bar{\mathbf{x}}$  and the Nash equilibrium  $(\bar{\mathbf{y}}_1, \bar{\mathbf{y}}_2, \dots, \bar{\mathbf{y}}_m)$  with respect to  $\bar{\mathbf{x}}$ .

In order to maximize the pessimistic return, we have the following minimax chance-constrained bilevel programming,

$$\left\{ \begin{array}{l} \max_{\mathbf{x}} \min_{\bar{F}} \bar{F} \\ \text{subject to:} \\ \text{Ch}\{F(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq \bar{F}\} \geq \beta \\ \text{Ch}\{G(\mathbf{x}, \boldsymbol{\xi}) \leq 0\} \geq \alpha \\ \text{where each } \mathbf{y}_i (i = 1, 2, \dots, m) \text{ solves} \\ \left\{ \begin{array}{l} \max_{\mathbf{y}_i} \min_{\bar{f}_i} \bar{f}_i \\ \text{subject to:} \\ \text{Ch}\{f_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq \bar{f}_i\} \geq \beta_i \\ \text{Ch}\{g(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq 0\} \geq \alpha_i. \end{array} \right. \end{array} \right. \quad (33)$$

#### Dependent-Chance Multilevel Programming

Let  $H(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq 0$  and  $h_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq 0$  be the events of the leader and  $i$ th followers,  $i = 1, 2, \dots, m$ , respectively. In order to maximize the chance function of the leader, we have the following dependent-chance bilevel programming,

$$\left\{ \begin{array}{l} \max_{\mathbf{x}} \text{Ch}\{H(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq 0\} \\ \text{subject to:} \\ G(\mathbf{x}, \boldsymbol{\xi}) \leq 0 \\ \text{where each } \mathbf{y}_i (i = 1, 2, \dots, m) \text{ solves} \\ \left\{ \begin{array}{l} \max_{\mathbf{y}_i} \text{Ch}\{h_i(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq 0\} \\ \text{subject to:} \\ g(\mathbf{x}, \mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_m, \boldsymbol{\xi}) \leq 0. \end{array} \right. \end{array} \right. \quad (34)$$

The feasible array  $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$  is called a Nash equilibrium of followers with respect to  $\mathbf{x}$  if

$$\begin{aligned} \text{Ch}\{h_i(\mathbf{x}, \mathbf{y}_1^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi}) \leq 0\} \\ \leq \text{Ch}\{h_i(\mathbf{x}, \mathbf{y}_1^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i^*, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi}) \leq 0\} \end{aligned} \quad (35)$$

for any feasible array  $(\mathbf{y}_1^*, \dots, \mathbf{y}_{i-1}^*, \mathbf{y}_i, \mathbf{y}_{i+1}^*, \dots, \mathbf{y}_m^*)$  and  $i = 1, 2, \dots, m$ . Let  $\mathbf{x}^*$  be a feasible control vector of the leader and  $(\mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$  be a Nash equilibrium of followers with respect to  $\mathbf{x}^*$ . We call the array  $(\mathbf{x}^*, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*)$  a Stackelberg-Nash equilibrium to the dependent-chance bilevel programming (34) if and only if,

$$\begin{aligned} \text{Ch}\{H(\bar{\mathbf{x}}, \bar{\mathbf{y}}_1, \bar{\mathbf{y}}_2, \dots, \bar{\mathbf{y}}_m, \boldsymbol{\xi}) \leq 0\} \\ \leq \text{Ch}\{H(\mathbf{x}^*, \mathbf{y}_1^*, \mathbf{y}_2^*, \dots, \mathbf{y}_m^*, \boldsymbol{\xi}) \leq 0\} \end{aligned}$$

for any feasible control vector  $\bar{\mathbf{x}}$  and the Nash equilibrium  $(\bar{\mathbf{y}}_1, \bar{\mathbf{y}}_2, \dots, \bar{\mathbf{y}}_m)$  with respect to  $\bar{\mathbf{x}}$ .

#### X. HYBRID INTELLIGENT ALGORITHMS

This section will introduce the general principle of designing hybrid intelligent algorithms. Essentially, there are three types of uncertain function arising in the area of fuzzy programming:

$$\begin{aligned} U_1 : \mathbf{x} &\rightarrow E[f(\mathbf{x}, \boldsymbol{\xi})], \\ U_2 : \mathbf{x} &\rightarrow \text{Pos/Cr/Nec}\{f_j(\mathbf{x}, \boldsymbol{\xi}) \leq 0, j = 1, 2, \dots, p\}, \\ U_3 : \mathbf{x} &\rightarrow \max\{\bar{f} \mid \text{Pos/Cr/Nec}\{f(\mathbf{x}, \boldsymbol{\xi}) \geq \bar{f}\} \geq \alpha\}. \end{aligned}$$

We may compute the uncertain functions by simulations. However, fuzzy simulation is obviously a time-consuming process. In order to speed up the process, we may generate input-output data for each type of uncertain function. Then we train a feedforward NN to approximate the uncertain function using the generated training data. For solving general fuzzy programming models, we may embed the trained NN into GA, thus producing a hybrid intelligent algorithm. The general procedure of hybrid intelligent algorithm is listed as follows,

*Step 1: Generate training input-output data for uncertain functions by fuzzy simulations.*

*Step 2: Train a neural network to approximate the uncertain functions according to the generated training data.*

*Step 3: Initialize pop\_size chromosomes whose feasibility may be checked by the trained neural network.*

*Step 4: Update the chromosomes by crossover and mutation operations in which the feasibility of offspring may be checked by the trained neural networks.*

*Step 5: Calculate the objective values for all chromosomes by the trained neural networks.*

*Step 6: Compute the fitness of each chromosome according to the objective values.*

*Step 7: Select the chromosomes by spinning the roulette wheel.*

*Step 8: Repeat the fourth to seventh steps for a given number of cycles.*

*Step 9: Report the best chromosome as the optimal solution.*

## Abstract

Parallel Genetic Algorithms (PGAs) were used to simultaneously optimize the structure and weights for feedforward neural networks. Aiming at its large-scale application in common distributed network system, a concentrative coarse-grained model for parallel evolutionary neural networks is designed and realized in a laboratorial distributed computation environment, and the initial results of experiments indicate that the parallel model can quicken the searching process and improve the evolutionary efficiency. For the parallel characteristics, this method can analyze massive information during the process of e-business. Several application scopes of this method in e-business are discussed also in this paper .

**Key words** Parallel Evolutionary Neural Networks; Distributed computation; E-business

## 1. Introduction

The application of Artificial Neural Networks (ANNs) has been extended to many areas in recent years. Common practices are usually involved with using back propagation (BP) algorithms on structure-predefined full-connected feed-forward neural networks for connection weights adjustment. Unfortunately such training is often time-consuming, especially for large-scale problem, and user-dependent for ANNs' architecture definition, which is crucial to the training process, while still a difficult decision, without optimum rules to follow.

Evolutionary Neural Networks (ENNs) provide a prominent alternative neural-network training method. They take advantage of evolutionary algorithms' (EAs) global searching ability, not only automatically optimize ANNs' architecture according to particular tasks, but also dynamically improve ANNs' generalization performance. However, when encountered with large-scale problem, ENNs also suffer from considerable computation expense due to complex network architecture.

Parallel Evolutionary Neural Networks (PENNs) have the potential to find fittest ANNs in significantly less time than serial ENNs. Aiming at PENNs' extensive application in common distributed computer network, we have been devoted to the analysis, design and implementation of parallel algorithms in distributed

computation environments, compared to numerous studies in multi-processor workstations.

In this paper, we introduce a kind of parallel model specially designed for PENN in distributed system, on the basis of which a parallel evolutionary algorithm is realized to optimize the architecture and weights of feed-forward neural networks simultaneously.

As we know, the most popular evolutionary algorithm used in ENNs is Genetic Algorithms (GAs). There are generally three kinds of evolution in GA-based ENN, i.e., the evolution of connection weights, of architectures and of learning rules, according to the level to which evolutionary search procedures come into ANNs<sup>[1]</sup>. If the learning rules are pre-defined and fixed, the main procedures of the two kinds of evolution are so similar that we can combine them into one evolutionary algorithm, which will be described later.

A successful design of ENN requires careful consideration about several crucial aspects<sup>[2]</sup>:

### 1) Encoding Scheme

How to map the ENNs' structure (connection weights and architecture) into one-dimension chromosomes? Using binary strings or real numbers to represent the connection weights? How to arrange the sequence of connection weights to reflect the network architecture?

### 2) Fitness Function

How to construct the fitness function? Need additional items besides training error? If necessary, how to decide their weights?

### 3) Genetic Operators

Which types of genetic operators are involved in the ENN? What specific operations do they execute respectively?

All these designing details have great influence on evolutionary process and final result, and need paying enough attention to. When discussing about our PENN later, we will describe these aspects thoroughly.

The parallelization of ENN is based on the parallelism of GA, and has been performed in four following ways:

### 1) The parallelization of single individual fitness evaluation

The work of fitness evaluation is most time-consuming in ENN, which is involved with decoding, training iteration and encoding. Using parallel computation technology on single individual fitness

evaluation will hopefully improve evaluation efficiency.

- 2) The parallelization of individual fitness evaluation in population

In a population, different individual's fitness evaluation is independent and can be performed on different processors simultaneously and independently.

- 3) The parallelization of individual-generating

The genetic operations involved in child-generation, i.e., reproduce, crossover, mutation etc, can be implemented on different individuals simultaneously and independently.

- 4) The parallelization based on population grouping

The evolutionary process of one or a group of individuals in the population is independent of each other, so this provides another way of parallel ENN based on population grouping: divide the population into several groups, assign each group a processor, evolve these population groups simultaneously, and exchange some individual information among groups at proper times to speed up global evolution progress.

The former three parallel methods haven't change ENN's overall frame, while the fourth, by breaking the population into groups and exchanging information periodically, has potential influence on ENN's general behavior and is most popular due to its simple realization in multiple-processor machine and distributed computer network system.

## 2. PENN based on CCG parallel model in distributed environments

### 2.1 CCG parallel model in distributed computation environment

Although distributed computer network is more convenient, abundant and economical parallel environment compared to multiple-processor machine, the much lower coupling degree make it much difficult to coordinate and communicate among different processors, which needs global schedule and control by software programming. Meanwhile, the communication efficiency in distributed environment is subject to many external impacts, such as connecting material, flow rate, flow amount etc., which is much less steady and reliable than multi-processor machine. Designing and realizing parallel models for distributed system must take these differences under careful consideration, and thus more difficult to deal with, which may be the reason why there is so little related work now.

The centralized coarse-grained model we present here is spirited by Cantu-paz E<sup>[3]</sup> about the master-slave parallel algorithm(We still use the master-slave notation in our model)and other previous work on coarse-grained parallel model. Our parallel model takes advantage of both master-slave and coarse-grained parallel model and we consider it fit well for the distributed system. Taking three distributed paralleling processors for example, the CCG model is illustrated in Figure1.

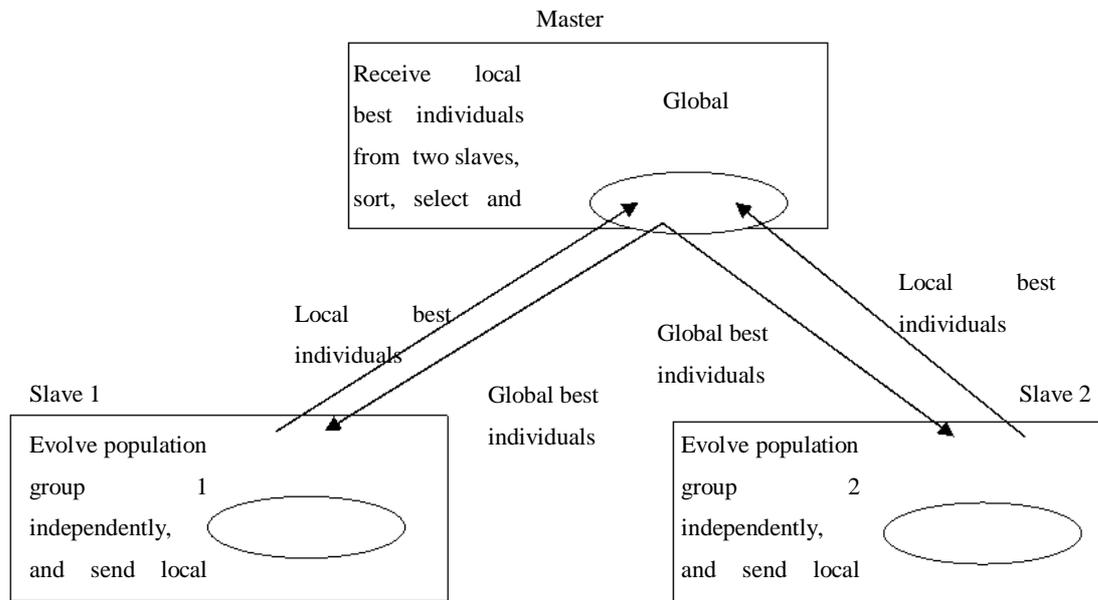

Figure 1 CCG model for three distributed paralleling processors

### 2.1.1 CCG model

According to different functions, divide distributed paralleling processors into one master and several slaves. On the other hand, following the idea of parallelization based on population grouping, divide the evolution population into several groups, one group for one slave. Each slave evolves its population group independently, and sends the master its local best individuals after a pre-specified number of generations. After the master receives all slaves' local best individuals, it incorporate them into one group, which is called global best population group, sorts the group according to individuals' fitness, selects global best individuals and broadcasts them back to slaves. Slaves keep waiting until they receive the feedback from master and continue their evolution process before next transfer.

In the model, the evolution processes on different slaves are paralleling, while the works on master and slaves are actually been carried on sequentially.

#### 1) Function specification

The main responsibility of master is receiving local best individuals from all slaves, sorting them by fitness, selecting the global best ones and broadcasts them back to slaves, also keeping record of the best individual and storing global best population group. In contrast, the slaves are in charge of ENN on its own population group, sending local best, receiving global best, replacing local worst.

#### 2) Communication and information exchange

In CCG model, inter-processor communication only takes place between master and slaves. This reflects the design intention for realization simplicity. When one slave finishes its current evolution period, it sends the master a signal as transfer request, begins data transferring if master isn't busy (if busy, blocks and waits for master's ready message), and then wait until receiving global best individuals from master.

For the master, it keeps sleeping until being woken by a slave's transfer request, and begins the uninterruptible data transferring (if another slave ask for service during this time, send a busy signal and put it to the end of the waiting line). After the transfer is finished, it arouses the first slave in the waiting line by sending a ready message and starts the next data transferring until it gets all slaves' local best.

#### 3) CCG versus traditional parallel models

The CCG model has inherited the population-grouping and information-exchanging ideas from traditional coarse-grained model, while introduces centralizing control to overcome the unstableness in distributed system. On the other hand, CCG is quite similar to traditional centralizing parallel model at the first glimpse, while compared to global evolution and selection in centralizing model, CCG performs local evolution and selection, which is the most distinct advantage of coarse-grained towards centralizing.

### 2.1.2 Key parameters

There are several key paralleling parameters in the design and realization of CCG, whose different values have great influence on CCG model's behavior and characteristics.

#### 2.1.2.1 Transferring Scale

The transferring scale of inter-processor individual exchanging is determined by two parameters: transferring rate and transferring period. Large-scale transferring will make CCG acting like global centralizing model, while small scale will enforce the independence of each ENN.

##### (1) Transferring rate

Transferring rate is the amount of the individuals transferred, which is often defined by absolute number or percent of the population group. A typical transferring rate is ten to twenty percent of the population group.

##### (2) Transferring period

Transferring period determines the time interval between two transfers, which is usually one or several evolutionary generations on slaves. Generally, higher transferring rate is accompanied by longer transferring period.

#### 2.1.2.2 Transferring Strategy

Transferring strategy includes two aspects, transferring selection and transferring replacement. Other than the strategy we mentioned in CCG description, there are still different choices.

##### (1) Transferring selection

Transferring selection is responsible for selecting individuals transferred. Common method is selecting one or several best individuals, while selection based on fitness proportion is also optional.

##### (2) Transferring replacement

In most cases, one or several worst individuals are replaced. While similar with transferring selection, the replacement can also be based on fitness-proportion selection, which can bring some selection pressure on better individuals in the population group.

## 2.2 Parallel Evolutionary Neural Networks

Just as we have mentioned, our PENN aims at evolving neural networks' architecture and connection weights simultaneously. Focusing on the three fundamental problems in ENN designing, below we will present the details for our evolutionary algorithm, which mainly deals with feedforward neural networks with linear threshold unit and sigmoid transfer function.

### 2.2.1 Encoding Scheme

We use a Java class to describe the neural networks, which is the encoding representation of the individual.

In the Java class, the first parameter represents the number of neurons in the hidden layer, and then we use an array to store all the weights and connection

information of the network. The final two parameters denote the individual's fitness and relative fitness.

In order to encode the weights and connections exactly and convenient for genetic operations, we adopt real number representation instead of binary code, which also makes the length of gene flexible and shorter. Using real number representation, we are able to take following additional advantages:

- Crossover can be made only between weights;
- Mutation is just adding a random number to the weight existing, instead of replacing it;
- Smaller population size because of the gene-length flexibility.

### 2.2.2 Fitness Function

Assume that use a training-set on individual  $i$  and get the total network error  $E(net_i)$ , which is the sum of the errors between the object output vectors and the simulative output vectors. Obviously, the higher the total error is, the lower the individual's fitness.

In addition to the error, we expect the structure of the neural network is as simple as possible, given the same network performance. The simpleness means the optimized architecture should have minimum number of neurons and connections. In order to control the complexity of the neural network, one control item is added to the error function: CH. C is a positive control constant, which we call the complexity coefficients of the network; H is the number of neuron of the hidden layer. Certainly, we expect a CH value as low as possible, given a pre-specified C value.

As a conclusion, we define our fitness function as this:

$$pop[i].fitness = f(net_i, t) = \frac{1}{1 + E(net_i) + CH} \quad (1)$$

The value of coefficient C is suggested to be in interval (0,0.5).

### 2.2.3 Genetic Operators

The usual genetic operators include selection, breeding, crossover and mutation, which are separately implemented to a certain individual in pre-determined probabilities.

**Selection strategy:** the evolutionary algorithm adopts standard roulette selection operator. The selection probability of individual  $net_i$ , according to the roulette selection strategy, is:

$$p_i = pop[i].relativefit = \frac{pop[i].fitness}{\sum_{j=1}^N pop[j].fitness} \quad (2)$$

$N$  is the size of the population group.

**Breeding operator:** select parents from the population according to the selection strategy and the individual selection probability (its relative fitness), and then copy these parents to current population without any change.

**Crossover operator:** the same number of weights is selected from the two parents stochastically and independently. Exchange the weights, and thus get two offsprings.

**Mutation operator:** as we are evolving neural network's architecture and connection weights simultaneously, the mutation operators should include architecture mutation and connection-weights mutation correspondingly.

#### 1) Architecture mutation

Four architecture mutation operations are carried out in certain probabilities, that is:

- Delete some neurons in hidden layer and (or) the connections and their weights. When only delete the connections, we set the corresponding weights zero.
- Insert some neurons into each hidden layer and (or) the connections and their weights, and generate the corresponding weights randomly.
- For those deleted connections, repair them with special probability.
- Mutate the connection weights with adaptive mutation rate.

#### 2) Connection-weights mutation

The mutation operation we present here is based on adaptive mutation rate, satisfying the evolutionary requirement that when the individual has lower fitness value, the mutation should be higher. So we introduce the simulated annealing algorithms, in which the mutation temperature can be defined as:

$$T = \frac{1}{f(net_i)} \quad (3)$$

Assuming the weight  $v$  will be mutated, the definition scope is (a,b), then

$$v' = \begin{cases} y + \Delta(T, b - v), & rnd(2) = 0 \\ v - \Delta(T, v - a), & rnd(2) = 1 \end{cases} \quad (4)$$

Here the value field of  $\Delta(T, y)$  is (0,y), and the probability that  $\Delta(T, y)$  gets close to zero increases when T reduces.

$$\Delta(T, y) = y(1 - r^{T^\lambda}) \quad (5)$$

Here  $r$  is a random real number from 0 to 1,  $\lambda$  is a parameter that determine the adaptive degree, the value is from 2 to 5 commonly.

## 3. Results and Discussion

PENN based on CCG is realized in a one-master-two-slave scope. The parallel experimental platform is constructed in a three-PC distributed LAN, using Java programming and data-package transferring

technology, which is convenient to build and easy to expand to larger-scale application.

The values of some key experimental parameters are listed in Table 1.

Table 1 Values of key experimental parameters

Population Size (Slave group)	100
Transferring Rate	5%
Transferring Period	10
EA Mutation Rate	0.001
EA Crossover Rate	0.2
Network complexity coefficient C	0.1
Adaptive Mutation parameter $\lambda$	2
Transferring Selection Strategy	Best
Transferring Replacement Strategy	Worst

### 3.1 Experimental Results

The initial experiment results demonstrate that the paralleling evolutionary algorithm based on CCG has remarkably quickened the search process and improve the solution quality at some extent. A typical experimental result is shown in Table 2, which is the comparison between ENN and PENN on XOR Problem.

Table 2 Comparison results of ENN and PENN

	Number of Generations	Searching Time (ms)	Best Individual Fitness	Population Error
ENN	200	883090	0.707	0.481
PENN	100 for each slave	471480	0.751	0.068

The improvement of solution quality illustrates that the PENN based on CCG model is not the simple sum-up of two independent paralleling processes, but has changed the fundamental behavior of ENN by best individual transferring and exchanging. That is similar to different offspring quality in marriages between close relatives or far relatives, the latter of which is often better because of gene mutation and exchange.

### 3.2 Efficiency Analysis

In order to measure the paralleling efficiency, we also examined the relative loading degree of the three processors and total communication expense. A typical result is shown in Table 3.

Table 3 Run-Time Data of PENN

	Run Time	Block Time	Package Time*	Compu. Time	Com. rate**
Master	341140	267970	15250	37930	88.9%
Slave 1	341140	25609	15630	299901	12.1%
Slave 2	341140	23555	15720	301865	11.5%

\*Including data packing and unpacking time, and time unit is ms

\*\*Communication Expense rate = (Block time + Data package time) / Run time

From the table, we can find that much of master's run time is spent on blocking, that is, waiting for slaves' evolutionary process. It is partly due to CCG's centralizing structure and is a big waste of master processor's resource. A further improvement on this problem is adding an evolutionary process to Master processor, which is to say, having the master assuming the responsibilities of both a master and a slave. It will hopefully reduce the master's idling time and increase global paralleling efficiency.

## 4. PENN in e-business

In the information era, more and more data are stored in enterprise database systems. It is still a big problem for enterprises to utilize these data well, especially for decision. The barriers are not the amount of data, but how to cope with mass data, that is, the efficiency of analyzing data is the bottleneck.

PENN provides an efficiency way for enterprise data analyzing, especially in the distributed environment. It can be used as data mining tools to classify or recognize the special pattern hidden in the data.

As a classifying tool, PENN can process the data in a distributed way, such as the customers' data in a commercial bank; it can be used to find the most promising customers. It also can be used as predicting tool, and time serial analyzing tool.

At present, a new method for portfolio selection based on PENN is studied, and this work will optimize the portfolio in a distributed environment. A lot of this kind of works can be done, if we find a way to process data efficiently and effectively. With the rapid development of e-business, more and more data crowd in Internet. PENN can be used to treat this data traffic problem also, and we will improve PENN methods to fill this demand in the future.

## 5. Conclusion

In this paper, we introduce a kind of paralleling model CCG specially designed for distributed system, which takes the advantage of both classical centralizing and coarse-grained paralleling model and demonstrated to fit for parallel algorithms in distributed computation environments.

On the basis of CCG, a parallel evolutionary algorithm is designed and realized to optimize the architecture and weights of feed-forward neural networks simultaneously. It adopts the idea of simulated annealing and has been demonstrated better performance than sequential algorithms both in searching time and solution quality.

Further work is expected on the convergence and behavior analysis of PENN. For its practical application, the parameters also need further careful analysis and adjustment according to different tasks.

# The Evolution of Internal Representation

Ray Tsaih, Wen-Chyan Ke, Chia-Yu Liu  
 Department of Management Information Systems  
 National Chengchi University  
 Taipei, Taiwan  
 tsaih@mis.nccu.edu.tw

## Abstract

To develop an appropriate internal representation, a deterministic learning algorithm that has an ability to adjust not only weights but also the number of adopted hidden nodes is proposed. The key mechanisms are (1) the recruiting mechanism that recruits proper extra hidden nodes, and (2) the reasoning mechanism that prunes potentially irrelevant hidden nodes. This learning algorithm can make use of external environmental clues to develop an internal representation appropriate for the required mapping. The encoding problem and the parity problem is used to demonstrate the performance of the proposed algorithm. The experimental results are clearly positive.

Keywords: internal representation, Generalized Delta Rule, recruiting mechanism, pruning mechanism.

## 1. Introduction

In modern finance, derivatives such as futures and options play increasingly prominent roles in risk management and price speculative activities. Owing to the high-leverage characteristic involved in derivative trading, investors can gain enormous profits with a small amount of capital if they can accurately predict the market's direction. Financial markets, however, can be influenced by many factors, such as, political events, general economic conditions, and traders' expectations. Predicting the financial market's movements is considered to be rather difficult in general. Movements in market prices are not random. Rather, they behave in a highly nonlinear, dynamic manner. The standard random walk assumption of futures prices may merely be a veil of randomness that shrouds a messy nonlinear process (see, for example, [2][4][7]). To make the forecasting of futures prices more reliable, the application of Artificial Neural Networks (ANN), especially the multi-layered feed-forward network [10], have received extensive attention[7][8][15].

Instead of directly deriving the nonlinear equation, these ANN tries to develop an appropriate internal representation for such forecasting problem. In general, a nonlinear forecasting problem is like a problem of finding a nonlinear equation to capture the general pattern of a relationship between the independent variables  $x_j$ 's and the dependent variables  $y_i$ 's. The form of the equation is  $y_i = F_i(x)$ , where  $x$  is the vector of independent variables  $x_j$  and  $F_i$  is a nonlinear function derived from a given data set of samples  $\{(x_1, t_1), \dots, (x_N, t_N)\}$  with  $t_i$  being the

observed value of  $y_i$  corresponding to  $c_x$ . In the context of multi-layered feed-forward network, as shown in Figure 1, the information  $x$  coming to the input nodes is recoded into an internal representation  $h \equiv (h_1, h_2, \dots, h_p)^t$  and the output  $O_i$ , the estimated value of  $y_i$ , is generated by the internal representation  $h$  rather than by the original pattern  $x$ . "Input patterns can always be encoded, if there are enough hidden units, in a form so that the appropriate output pattern can be generated from any input pattern," as mentioned in [10].

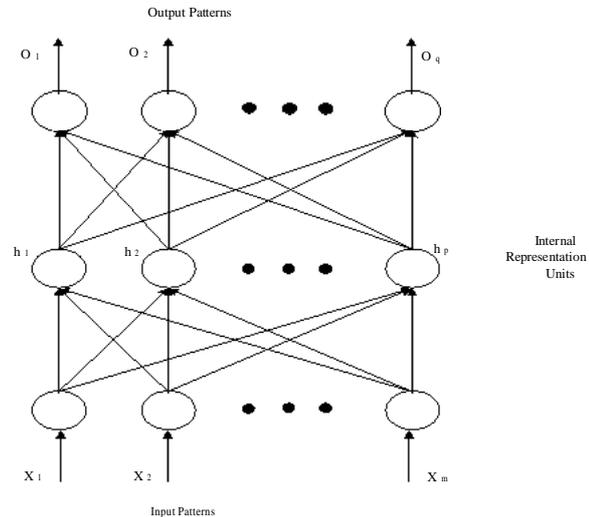

Figure 1. An ANN with a layer of hidden nodes.

Let's take the multi-layered feed-forward network with the hyperbolic tangent ( $\tanh$ ) function [14][10],

where  $\tanh(x) \equiv \frac{e^x - e^{-x}}{e^x + e^{-x}}$ , used in all output and

hidden nodes as the illustration. Given the  $c^{\text{th}}$  stimulus  $c_x$ , the activation value of the  $i^{\text{th}}$  hidden node  $h(c_x, {}_2w_i)$  and the activation values of the  $l^{\text{th}}$  output node  $O(c_x, {}_3w_l, {}_2w)$  are as follows:

$$h(c_x, {}_2w_i) \equiv \tanh({}_2w_{i0} + \sum_{j=1}^m {}_2w_{ij} c_x) \quad (1)$$

$$\begin{aligned} O(c_x, {}_3w_l, {}_2w) &\equiv \tanh({}_3w_{l0} + \sum_{i=1}^p {}_3w_{li} h(c_x, {}_2w_i)) \\ &= \tanh({}_3w_{l0} + \sum_{i=1}^p {}_3w_{li} \tanh({}_2w_{i0} + \sum_{j=1}^m {}_2w_{ij} c_x)) \end{aligned} \quad (2)$$

where  $m, p$  and  $q$  are the numbers of input, hidden and output nodes, respectively;  ${}_2w_{i0}$  is the bias of the  $i^{\text{th}}$  hidden

node,  ${}_2w_{ij}$  is the weight of connection between the  $j^{\text{th}}$  input node and the  $i^{\text{th}}$  hidden node,  ${}_3w_{i0}$  is the bias of the  $i^{\text{th}}$  output node, and  ${}_3w_{li}$  is the weight of the connection between  $i^{\text{th}}$  hidden nodes and the  $l^{\text{th}}$  output node. Denote the bold character a vector and the superscript  $t$  indicates the transposition:  ${}_2w_i^t \equiv ({}_2w_{i0}, {}_2w_{i1}, \dots, {}_2w_{im})$ ,  ${}_2w^t \equiv ({}_2w_1^t, {}_2w_2^t, \dots, {}_2w_p^t)$ ,  ${}_3w_l^t \equiv ({}_3w_{l0}, {}_3w_{l1}, \dots, {}_3w_{lp})$ ,  ${}_3w^t \equiv ({}_3w_1^t, {}_3w_2^t, \dots, {}_3w_q^t)$ , and  $w^t \equiv ({}_2w^t, {}_3w^t)$ .

Given a set of training samples  $\{(x_1, t), \dots, (x_N, t)\}$ , the learning goal is to seek a  $(w, p)$  that renders  $|O(c, x, {}_3w_l, {}_2w) - c_t| < \varepsilon$  for all  $c \in \{1, \dots, N\}$  and all  $l$ , where  $\varepsilon$  is a given acceptable tolerance, says  $10^{-6}$ . In general, the learning can be recognized as a minimization of the sum of residual squares  $E(w, p)$  via setting as

$$\min_{w,p} E(w,p) \equiv \min_{w,p} \sum_{c=1}^N \sum_{l=1}^q (O(c, x, {}_3w_l, {}_2w) - c_t)^2 \quad (3)$$

This is a complicated unconstrained nonlinear programming problem.

The process of an optimization algorithm applied to problem (3) is similar to the process of searching along the surface defined by the sum of residual squares in the  $\{w, p\}$  space composed of all possible  $(w, p)$ . Instead of desperately obtaining the globally optimal solution  $(w^*, p^*)$  in a complicated nonlinear environment, many research are motivated to develop a reasonable algorithm for searching an acceptable learning solution  $(w, p)$  that renders  $|O(c, x, {}_3w_l, {}_2w) - c_t| < \varepsilon$  for all  $c \in \{1, \dots, N\}$  and all  $l$ .

Developing such algorithm is not easy due to managing with the following characteristics: (1) the  $\{w, p\}$  space is unbounded since the number of possible  $(w, p)$  is infinite; (2) the surface defined by values of  $E(w, p)$  over the  $\{w, p\}$  space is non-differentiable since, for example, changes in the value of  $p$  is discrete and can have discontinuous effects on the value of  $E(w, p)$ ; (3) the surface is non-analyzable since the mapping from  $(w, p)$  to the value of  $E(w, p)$  is not yet analyzable; (4) the surface is complex and deceptive since values of  $E(w, p)$  with similar  $(w, p)$  may be dramatically different, and with quite different  $(w, p)$  may be very similar. These characteristics lead to hardly having any solid theoretical support in developing a reasonable learning algorithm.

In the context of internal representation, equations (1) and (2) state that (1) the vector of activation values of all hidden nodes  $h(x, {}_2w) \equiv (h(x, {}_2w_1), \dots, h(x, {}_2w_p))^t$  is the internal representation of the input pattern  $x$ , and (2) the activation values of all output nodes are calculated based on this internal representation, i.e.,  $O(c, x, {}_3w_l, {}_2w) \equiv O(h(c, x, {}_2w), {}_3w_l)$  for all  $l$ . The activation functions adopted on all hidden nodes are predefined and fixed; usually, they are semi-linear [10]. Thus the internal presentation evolves when the values of  $p$  and  ${}_2w$  are altered.

The internal representation is a level-adjacent mapping from the  $\{x\}$  space to the  $\{h\}$  space. Level-adjacent mapping means that level-adjacent points in the previous-layer space are mapped to neighboring points in the latter-layer space [14]. While the nearness of two points in the latter-layer space is measures with their

(direct) distance, the level-adjacency between two points in the previous-layer space is measured with the difference of their associated activation level. Owing to the linear characteristic of computing the net input value and the semi-linear characteristic of the activation function adopted in equations (1) and (2), there are level-adjacent mapping from the input layer  $\{x\}$  space to the hidden layer  $\{h\}$  space, and from the hidden layer  $\{h\}$  space to the output layer  $\{O\}$  space.

In the learning stage, the position of the training stimuli  $\{x_1, \dots, x_N\}$  in the  $\{x\}$  space are given and fixed; however,  $\{h(x_1, {}_2w), \dots, h(x_N, {}_2w)\}$  are determined by  $p$  and  ${}_2w$ , and each  $O(c, x, {}_3w_l, {}_2w)$  is determined with  $h(c, x, {}_2w)$  and  ${}_3w_l$ . As stated in [14], (1) no matter what kind of learning algorithm is used, the resulting mapping between two consecutive layers is always a level-adjacent mapping; (2) the crux of learning is to adjust  $p$  and  ${}_2w$  to render the internal representation appropriate for the learning task. An internal representation is appropriate for the task if there is a  ${}_3w$  such that  $|O(h(c, x, {}_2w), {}_3w_l) - c_t| < \varepsilon$  for all  $c \in \{1, \dots, N\}$  and all  $l$ . Although the learning of ANN should derive appropriate  $p$  and  ${}_2w$  from the training samples to obtain an appropriate internal representation, the development of the internal representation is relevant with the current value of  $p$  and  $w$ , not the current value of  $p$  and  ${}_2w$ .

In literatures, there are two categories of learning algorithms for multi-layered feed-forward network: the evolutionary ANN (EANN) algorithms, which are stochastic, and the weight-and-structure-change learning algorithms, which are deterministic.

Over past years, researchers have applied evolutionary computation to problems whose solution space is so large and highly complex that it is difficult to employ conventional optimization procedures to search for a global optimum. Evolutionary computation refers to a collection of stochastic searching algorithms whose designs are based upon the ideas of genetic inheritance and the Darwinian principle of the survival of the fittest (natural selection). There are several different styles of evolutionary algorithms: evolutionary strategies (ES), evolutionary programming (EP), genetic algorithms (GA), and genetic programming (GP). All of them model the searching process over the solution space by mimicking a biological evolution process. They differ mainly in the evolution operators involved and the representation of the solution space. Most researchers believe that, basically, evolutionary computation should not be considered as a kind of optimization technique to compete with other alternative techniques, but an optimization principle to be incorporated into existing techniques. Thus, they propose to apply EP, GA and GP to the determination of the network structure of an ANN. This gives rise to three classes of ANN, EPNN, GANN, and GPNN. All of these classes are portions of EANN. The most promising EANNs involve a global search algorithm that is stochastic [17].

In contrast, all weight-and-structure-change learning algorithms alter  $w$  and  $p$  in a deterministic way; for example, the tiling algorithm [9], the cascade-correlation

(CC) algorithm [5], the upstart algorithm [6], the W&S algorithm [16], the CTN algorithm [3], and the softening algorithm [12][13][14]. Without following the ideas of genetic inheritance and natural selection, they adjust the network structure in one of the following ways:

(1) Destructively: using excess hidden nodes initially and pruning (removing) least effective hidden nodes during the learning process; e.g., W&S algorithm and CTN algorithm;

(2) Constructively: using less hidden nodes initially and recruiting (adding) more hidden nodes during the learning process; e.g., the tiling algorithm, CC algorithm, and the upstart algorithm;

(3) Aggregately: using only one hidden node initially, and recruiting as well as pruning hidden nodes during the learning process; e.g., the softening algorithm.

These deterministic learning algorithms have an ability to develop an appropriate internal representation via recruiting/pruning hidden nodes and altering the weights during the learning process.

Here we introduce a deterministic learning algorithm that makes use of sequentially presented training samples to adjust the values of  $w$  and  $p$  to develop an internal representation appropriate for the required mapping. More over, this learning algorithm guarantees an acceptable learning result, without the binary output restriction. Recall that a learning result is acceptable if  $|\mathcal{O}(c, x, w) - c| < \varepsilon$  for all  $c \in \{1, \dots, N\}$  and all  $l$ , where  $\varepsilon$  is a given acceptable tolerance.

This paper is organized as follows. The proposed learning algorithm and its theoretical justification are introduced in Section 2. Empirical justification of the proposed algorithm is given in Section 3. The encoding problem and the parity problem [11] will be used to demonstrate the performance of the proposed algorithm. Finally, conclusions and future work are presented in Section 4. For the simplicity of presentation, all theoretical proofs are given in the Appendix.

## 2. The Proposed Learning Algorithm

To simplify the presentation, without lose of the generality, we let  $q = 1$  in the explanation of our design. Table 1 presents the general procedure and Figure 2 displays the flow chart of the proposed algorithm. The key mechanisms are (1) the recruiting mechanism that effectively recruits proper extra hidden nodes, and (2) the reasoning mechanism that effectively prunes potentially irrelevant hidden nodes. The details of the proposed algorithm at each step are given below.

The pairs of  $(c, t)$  are presented sequentially. At the  $k^{\text{th}}$  stage, the stage when the  $k^{\text{th}}$  sample  $(k, x, t)$  enters, the goal is to seek the values of  $(w, p)$  so that

$$|\mathcal{O}(c, x, w) - c| < \varepsilon \text{ for all } c \in I(k) \equiv \{1, \dots, k\} \quad (4)$$

The learning proceeds via evolving the internal representation to render it appropriate for accomplishing the goal (4). The internal representation that can accomplish the goal (4) is an appropriate one.

Table 1. The proposed deterministic algorithm.

Step 0: Set one hidden node with weights assigned randomly; set $k = 1$ .
Step 1: If it is the end of the sample input sequence, STOP
Step 2: Present the $k^{\text{th}}$ given sample $(k, x, t)$ .
Step 3: If $ \mathcal{O}(k, x, w) - t  > \varepsilon$ , then
Step 3.1: Store the weights.
Step 3.2: Apply the weight-tuning mechanism to adjust weights until one of the following cases occurs:
(1) If $ \mathcal{O}(c, x, w) - c  < \varepsilon \forall c \in I(k)$ , then go to Step 4.
(2) If an unacceptable result is obtained, then
(a) set $\lambda = 1$ .
(b) Restore the weights.
(c) $p+2 \mathcal{A} p$ and recruit two extra hidden nodes with ${}_2w_{p-1}^t = (\zeta - \lambda \alpha^t_{k, x}, \lambda \alpha^t)$ , ${}_2w_p^t = (\zeta + \lambda \alpha^t_{k, x}, -\lambda \alpha^t)$ , $\zeta = 10^{-6} \min_{c \in I(k-1)}  \alpha^t(k, x - c, x) $ , ${}_3w_{p-1} = {}_3w_p = (\tanh^{-1}(t) - \sum_{i=1}^{p-2} {}_3w_i h(k, x, {}_2w_i)) / 2 \tanh(\zeta)$ , where $\alpha$ is a unit vector that $\alpha^t(k, x - c, x) \neq 0 \forall c \in I(k-1)$ .
(d) Apply the weight-tuning mechanism to adjust weights until one of the following cases occurs:
(i) If $ \mathcal{O}(c, x, w) - c  < \varepsilon \forall c \in I(k)$ , then go to Step 4.
(ii) If an unacceptable result is obtained, let $\lambda * 2 \mathcal{A} \lambda$ and $p-2 \mathcal{A} p$ , then go to (b).
Step 4: Prune all potentially irrelevant hidden nodes.
Step 5: $k+1 \mathcal{A} k$ ; go to Step 1.

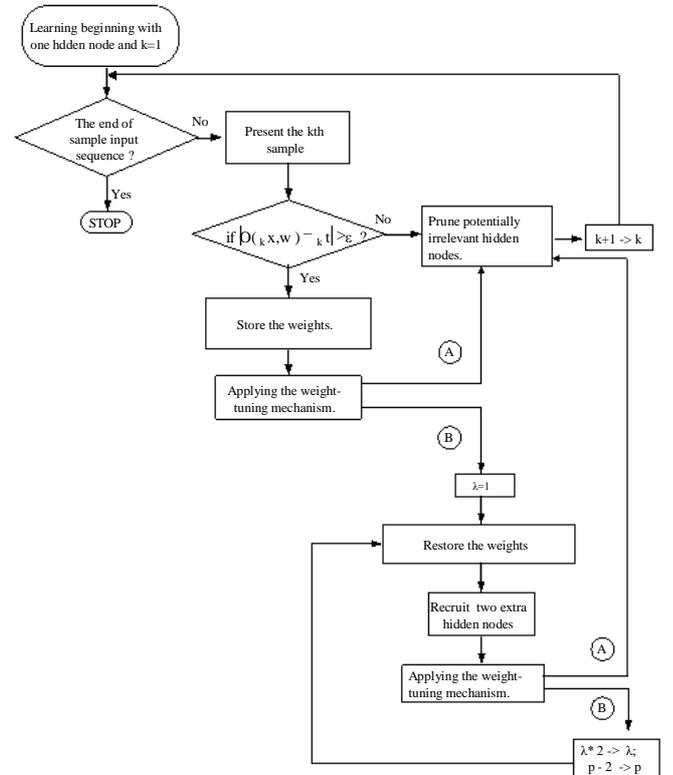

Figure 2. The flow chart of the proposed learning algorithm.

Note that, obtaining an appropriate internal representation is a necessary condition, but not a sufficient condition, of accomplishing the goal (4).

However, the effort of checking regularly if the current internal representation is appropriate is huge. Furthermore, it is useless when the current network structure is a defective one, i.e., the number of adopted hidden nodes is less than the necessary number of hidden nodes for accomplishing the goal (4). These arguments account for the reason of adopting accomplishing the goal (4), instead of obtaining an appropriate internal representation, as the stopping criterion.

The algorithm ensures that goal (4) is accomplished at the end of each stage. Consequently, it guarantees an acceptable learning result at the end.

Specifically, when the  $k^{\text{th}}$  sample  $(kx, kt)$  enters, we first check if the goal (4) is accomplished. If so, the current internal representation is appropriate and there is only a reasoning effort involved. Then the next given sample is presented. If not, in our next step (Step 3), the weight-tuning mechanism implementing the momentum version of the generalized delta rule [10] with automatic adjustment of learning rate [13] is applied to  $\min_w E_k(w)$

to adjust weights, where  $E_k(w) \equiv \sum_{c \in I(k)} (\tanh(\sum_{i=1}^p {}_3w_{0i} + \sum_{j=1}^m {}_2w_{ij} cX_j) - ct)^2$ . Namely, the objective

function used in the optimization process at the  $k^{\text{th}}$  stage  $E_k(w)$  is now defined as the current sum of residual squares and the parameter  $p$  remains the same. Such a weight-tuning mechanism attempts to achieve the goal (4).

(Rumelhart, Hinton & Williams, 1986a) has claimed that a mechanism that implements the generalized delta rule can “learn internal representations by error propagation.” Unfortunately, this weight-tuning mechanism has the power to alter the weights, yet no power to add/delete hidden nodes. More over, this mechanism may converge to the neighborhood of an undesired attractor of  $\min_w E_k(w)$  in which  $\nabla_w E_k(w) = 0$ ;

for example, a relatively optimal solution or a saddle point solution. Another possible failure is the case that the current network structure is a defective one. All of the above lead to an unacceptable result. These were indicated in Figure 3: Path B indicates the situation when the result of implementing the weight-tuning mechanism is an unacceptable one; while Path A indicates the situation when the result is an acceptable one.

A perfect weight-tuning mechanism that can avoid the predicament of converging to an undesired attractor is desirable, because the defective network structure will be the only cause of obtaining an unacceptable result. Unfortunately, there is no such perfect weight-tuning mechanism currently. Under this confinement, together with the consideration of the computing complexity, the current weight-tuning mechanism is adopted. The consideration of the computing complexity is very important because the weight-tuning mechanism will be triggered very frequently during the learning process.

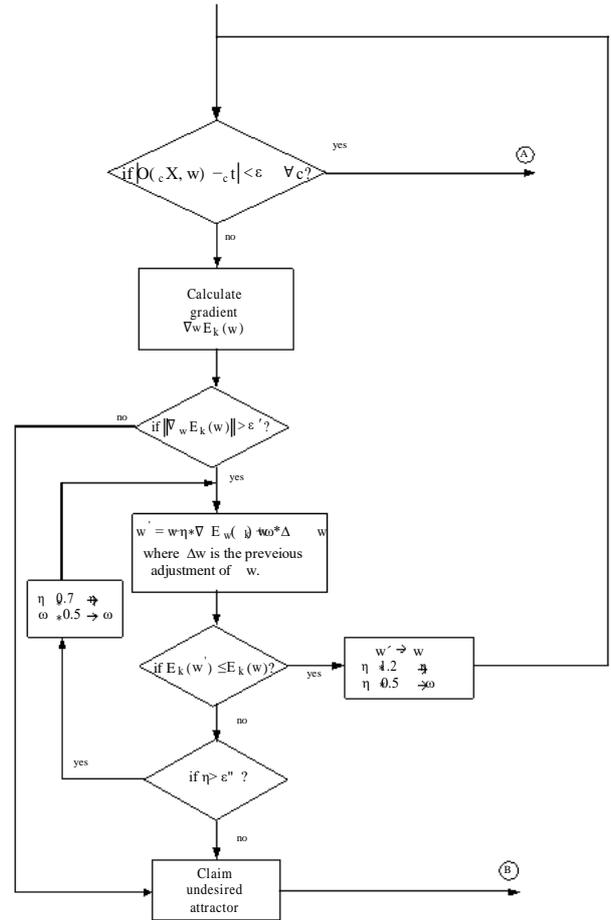

Figure 3. The flow chart of the weight-tuning mechanism implementing the momentum version of the generalized delta rule with automatic adjustment of learning rate.  $\epsilon'$  and  $\epsilon''$  are given tiny numbers.

Recruiting extra hidden nodes is adopted to handle these problems in Path B of Figure 3 as follows. Action (b) in Step 3.2 restores the weights stored in Step 3.1. Assume the goal of the previous stage is accomplished at the end of the previous stage. Then, by restoring the weights stored in Step 3.1, we return to the internal representation that renders  $|O(cX, w) - ct| < \epsilon$  for all  $c \in I(k-1)$  and  $|O(kX, w) - kt| \geq \epsilon$ . For Action (c) in Step 3.2, there is a recruiting mechanism arranged to recruit two extra hidden nodes with a gain parameter  $\lambda$  whose value is initially 1 set via Action (a) in Step 3.2. These two new-added hidden nodes, the  $(p-1)^{\text{th}}$  and  $p^{\text{th}}$  ones, have weights  ${}_2w_{p-1}^t = (\zeta - \lambda \alpha^t) {}_kX$ ,  $\lambda \alpha^t$ ,  ${}_2w_p^t = (\zeta + \lambda \alpha^t) {}_kX$ ,  $-\lambda \alpha^t$ ,  $\zeta = 10^{-6} \min_{c \in I(k-1)} |\alpha^t({}_kX - cX)|$ ,  ${}_3w_{p-1} = {}_3w_p = (\tanh^{-1}(kt) - {}_3w_0 - \sum_{i=1}^{p-2} {}_3w_i h({}_kX, {}_2w_i))/2 \tanh(\zeta)$ , where  $\alpha$  is a unit vector that  $\alpha^t({}_kX - cX) \neq 0 \forall c \in I(k-1)$ . For Action (d) in Step 3.2, the  $\lambda$  value is fixed and the weight-tuning mechanism is applied to render the goal (4) accomplished. If an unacceptable result is obtained, we multiply the  $\lambda$  value by 2, and repeat Actions (b), (c), and (d). The Actions (b), (c), and (d) are repeated until the goal (4) is accomplished.

The arrangement of Actions (b), (c) and (d) is capable of solving (1) the defectiveness of the network structure via adding two hidden nodes, and (2) the predicament of converging to an undesired attractor via introducing extra dimensions in the weight space such that the trapped attractor could be no longer an attractor in the new weight space.

Recruiting two extra hidden nodes has introduced two extra dimensions in the  $\{h\}$  space, thus has introduced two extra dimensions in the internal representation. The arrangement of  ${}_2w_{p-1}$  and  ${}_2w_p$  has made the new corresponding point  $h({}_kx, {}_2w)$  placed at the positive side of each of these two new-added dimensions, and all other new corresponding points  $h({}_cx, {}_2w)$ 's placed at the positive side of one new-added dimension and at the negative side of the other new-added dimension. A large  $\lambda$  value renders the behavior of the activation functions of the newly recruited  $p-1^{\text{th}}$  and  $p^{\text{th}}$  hidden nodes similar to the behavior of a threshold function, and results in a phenomenon that  $h({}_cx, {}_2w_{p-1})$  and  $h({}_cx, {}_2w_p)$  numerically equal 1 or  $-1$  for almost all  $c \in I(k-1)$ . Thus, as stated in Lemma 1, the arrangement of such two new-added hidden nodes with a large  $\lambda$  value has made the new corresponding point  $h({}_kx, {}_2w)$  placed near the  $\tanh(\zeta)$  position of each of these two new-added dimensions, and all other new corresponding points  $h({}_cx, {}_2w)$ 's placed near the  $-1$  corner of one new-added dimension and near the  $+1$  corner of the other new-added dimension. Therefore, as stated in Lemma 2, if the internal representation is appropriate to render  $|O({}_cx, w) - {}_ct| < \varepsilon$  for all  $c \in I(k-1)$  and  $|O({}_kx, w) - {}_kt| \geq \varepsilon$ , after recruiting such two hidden nodes, the new internal representation can be appropriate for all  $k$  training samples. In other words, the arrangement of such two new-added hidden nodes with a large  $\lambda$  value is capable of solving the defectiveness of the network structure via adding two hidden nodes.

It is difficult to identify the scenario (the sample input sequence and the value of  $\lambda$ ) for which the weight-tuning mechanism will (or will not) achieve the goal (4), because the surface defined by  $E_k(w)$  over the weight space is not possible to analyze. However, Lemma 2 shows that the goal (4) can be accomplished immediately via recruiting merely two extra hidden nodes with proper weights and  $\lambda$ . More over, Lemma 2 shows that there is no infinite loop in Step 3.2. In other words, the arrangement of Actions (b), (c) and (d) is capable of solving the predicament of converging to an undesired attractor via introducing extra dimensions in the weight space such that the trapped attractor could be no longer an attractor in the new weight space.

Therefore, Step 3.2 does ensure that the goal of each stage is accomplished at the end of each stage, thus guaranteeing an acceptable learning result obtained at the end.

The recruiting mechanism handles the situation of encountering an unacceptable result without involving the reason. A defective network structure triggers the recruiting mechanism; the situation of converging to an undesired attractor also triggers the recruiting mechanism. The recruiting mechanism triggered due to the situation

of converging to an undesired attractor may recruit excess hidden nodes that later become irrelevant. At each stage, a hidden node is irrelevant if the goal (4) is still accomplished with this hidden node being deleted. The irrelevant hidden nodes are useless with respect to the goal (4); furthermore, they may contribute significant effort to the performance of network and result in bad generalization ability. More over, more samples typically lead to more concise information about the appropriate internal representation, and thus fewer hidden nodes are required. It is therefore necessary to prune irrelevant hidden nodes, and an internal representation is better if it accomplishes the goal (4) with smaller amount of adopted hidden nodes.

In Step 4, a reasoning mechanism is arranged to prune all potentially irrelevant hidden nodes. At the  $k^{\text{th}}$  stage, a hidden node is potentially irrelevant if it is deleted and the goal (4) can be accomplished via applying the weight-tuning mechanism. In Step 4, every hidden node is checked whether it is potentially irrelevant. Each potentially irrelevant hidden node is deleted after being identified.

### 3. The Performance and Analysis of the Proposed Algorithm

Here we use two popular examples to examine how the current arrangement for the recruiting and reasoning mechanisms works: the encoding problem [1][11] and the parity problem [11].

[1] has posed the encoding problem where a set of  $N$  orthogonal input patterns are mapped to a set of  $N$  orthogonal output patterns through a small set of hidden nodes. Such problem requires a rather efficient way in encoding an  $N$  bit pattern into a small set of hidden nodes and then decoding this (internal) representation into the output pattern. [11] has proposed that a set of  $N$  orthogonal input patterns are mapped to a set of  $N$  orthogonal output patterns through a small set of  $\log_2 N$  hidden nodes. The reason behind such design is that if the hidden nodes take on binary values, the hidden nodes must form a binary number to encode each of the input patterns. They present an encoding problem with an 8 input patterns, 8 output patterns, and 3 hidden nodes, and, as shown in Table 2, they find the learning system develop solutions that use the intermediate values.

Table 2. The mapping of the encoding problem generated in [11].

Our simulation result is encouraging: the proposed algorithm employs the ability of the intermediate values in a more efficient way. Table 3 shows the mapping of the encoding problem generated by the proposed algorithm. The proposed algorithm also uses intermediate values to result in an appropriate internal representation. The appropriate internal representations shown in Table 2 and Table 3 are similar, except that the former uses three hidden nodes and the latter uses two hidden nodes. It seems that the reasoning mechanism effectively prunes a potentially irrelevant hidden node, which is likely to be the middle one in Table 2.

Table 4 shows the mapping of the 4-bit parity problem generated in [11] and by the proposed algorithm. [11] has proposed  $m$  hidden nodes required for the  $m$ -bit parity problem, and noted that “the internal representation created by the learning rule is to arrange that the number of hidden units that come on is equal to the number of zeros in the input and that the particular hidden units that come on depend only on the number, not on which input units are on.” By contrast, as shown in Table 4, the

appropriate internal representations developed in [11] and by the proposed algorithm are similar, except that the former uses four hidden nodes and the latter uses three hidden nodes. The appropriate internal representations developed by the proposed algorithm is to arrange that these three hidden nodes also activates also via through detecting the number of zeros in the input, not on which input units are on.

Table 5 shows the summary of the simulation results of  $m$ -bit parity problem, with the value of  $m$  from 2 to 6. For each value of  $m$ , there are 100 cases, each with a different randomly-generated input sequence. As shown in Table 5, the average final number of adopted hidden nodes for the  $m$ -bit parity problems is smaller than  $m$  and the final number of adopted hidden nodes is less than  $m$  in most cases.

Table 5. The minimum, maximum, mean and standard deviation of number of adopted hidden nodes for the  $m$ -bit parity problem, with the value of  $m$  from 2 to 6. For each value of  $m$ , there are 100 cases, each with a different randomly-generated input sequence.

$m$	2	3	4	5	6
Minimum	2	2	3	3	4
Mean	2	2.28	3.38	3.47	5.65
Maximum	2	4	5	5	17
Standard Deviation	0	0.5924	0.5464	0.6428	2.3154

In summary, it seems that the current arrangement of the recruiting and reasoning mechanisms in the proposed algorithm works well that the internal representations evolves in a better way than the one developed by the generalized delta rule. Recall that an appropriate internal representation with smaller amount of adopted hidden nodes is better.

#### 4. Discussions and Future Work

In this paper, a deterministic learning algorithm that guarantees an acceptable learning result is proposed. The proposed algorithm does not follow the ideas of genetic inheritance and natural selection. During the process of the proposed algorithm, the internal representation evolves in a deterministic way to an appropriate one. The key mechanisms of the proposed algorithm are (1) the recruiting mechanism that can recruit proper extra hidden nodes, and (2) the reasoning mechanism that can prune potentially irrelevant hidden nodes. We provide theoretical justification to explain why the proposed algorithm guarantees an acceptable learning result.

The experimental results show that the proposed algorithm also employs a similar ability of developing the internal representation with the one shown in [11]. This is not surprised since the proposed algorithm also adopts in its weight-tuning mechanism the generalized delta rule proposed in [10]. However, the experimental results show that the current arrangement of the recruiting and reasoning mechanisms in the proposed algorithm works

well that the internal representations evolves in a better way than the internal representation developed by the generalized delta rule.

There is a criticism when we apply the ANN to practical problems: a black box obtained from the learning. A further study is to explore the appropriate internal representation obtained from the learning to provide the knowledge behind the application and to get rid of that criticism.

The simulation results show that the number of adopted hidden nodes is a function of the sample input sequence. As expected, some sample input sequences cause difficulties in the associated processes, due to encountering a defective network structure or the predicament of converging to an undesired attractor. A further investigation (theoretically or numerically) on the surface defined by  $E_k(w)$  over the weight space is currently under study to identify the scenario (the sample input sequence and the value of  $\lambda$ ) for which the weight-tuning mechanism will (or will not) achieve the goal (4). Another study involves exploring (1) a better recruiting mechanism to recruit hidden nodes and (2) a better reasoning mechanism to prune potentially irrelevant hidden nodes in a much more efficient way.

## 5. Appendix: Theoretical Supports and their Proofs.

Lemma 1: Let  $\{c_x | \forall c \in I(k)\}$  be given, and assume  ${}_{2w_{p-1}}^t = (\zeta - \lambda \alpha^t_{kX}, \lambda \alpha^t)$ ,  ${}_{2w_p}^t = (\zeta + \lambda \alpha^t_{kX}, -\lambda \alpha^t)$ , where  $\lambda$  is a given large number. Then, there exists a unit vector  $\alpha$  and a tiny positive number  $\zeta$  that render  $h(c_x, {}_{2w_{p-1}}) + h(c_x, {}_{2w_p}) \cong 0.0$  (Hereafter,  $F(x) \cong y$  means that, numerically, the value of  $F(x)$  is  $y$ ).  $\forall c \in I(k-1)$  and  $h(k_x, {}_{2w_{p-1}}) + h(k_x, {}_{2w_p}) = 2 \tanh(\zeta)$ .

Proof:

$$\begin{aligned} \because {}_{2w_{p-1}}^t &= (\zeta - \lambda \alpha^t_{kX}, \lambda \alpha^t), \\ \because {}_{2w_{p-10}} + \sum_{j=1}^m {}_{2w_{p-1j}} c_{Xj} &= \zeta + \lambda (\alpha^t_{cX} - \alpha^t_{kX}). \end{aligned}$$

$$\text{Similarly, } {}_{2w_{p0}} + \sum_{j=1}^m {}_{2w_{pj}} c_{Xj} = \zeta + \lambda (\alpha^t_{kX} - \alpha^t_{cX}).$$

$$\begin{aligned} \because \{c_x | \forall c \in I(k)\} &\text{ is given,} \\ \because {}_{kX} - {}_{cX} &\text{ is known for every } c \in I(k-1). \end{aligned}$$

With a reasonable assumption that the amount of samples is finite, i.e.,  $I(k)$  is a finite set, there exists a unit vector  $\alpha$  that  $\alpha^t_{(kX - cX)} \neq 0 \forall c \in I(k-1)$ . Then,  $\zeta$  is assigned as  $10^{-6} \min_{c \in I(k-1)} |\alpha^t_{(kX - cX)}|$ .

$$\text{Since } \lambda \text{ is a large value and } \zeta = 10^{-6} \min_{c \in I(k-1)} |\alpha^t_{(kX - cX)}|,$$

$$h(c_x, {}_{2w_{p-1}}) = \tanh(\zeta + \lambda (\alpha^t_{cX} - \alpha^t_{kX})) \cong \tanh(\lambda (\alpha^t_{cX} - \alpha^t_{kX})) \text{ and } h(c_x, {}_{2w_p}) = \tanh(\zeta + \lambda (\alpha^t_{kX} - \alpha^t_{cX})) \cong -\tanh(\lambda (\alpha^t_{cX} - \alpha^t_{kX})). \text{ Thus, } h(c_x, {}_{2w_{p-1}}) + h(c_x, {}_{2w_p}) \cong 0.0 \forall c \in I(k-1).$$

$$\because h(k_x, {}_{2w_{p-1}}) = h(k_x, {}_{2w_p}) = \tanh(\zeta),$$

$$\therefore h(k_x, {}_{2w_{p-1}}) + h(k_x, {}_{2w_p}) = 2 \tanh(\zeta).$$

Q.E.D.

Lemma 2: Assume  $O(c_x, w) = \tanh(\zeta w_0 + \sum_{i=1}^{p-2} \zeta w_i h(c_x, {}_{2w_i}))$ ,  $|O(c_x, w) - c_t| < \varepsilon \forall c \in I(k-1)$ , and  $|O(k_x, w) - k_t| \cong \varepsilon$ . With recruiting two hidden nodes,  $h(c_x, {}_{2w_{p-1}}) \equiv$

$$\tanh(\zeta w_{p0} + \sum_{j=1}^m \zeta w_{p-1j} c_{Xj}) \text{ and } h(c_x, {}_{2w_p}) \equiv \tanh(\zeta w_{p0} + \sum_{j=1}^m \zeta w_{pj} c_{Xj}), \text{ the new value of } O(c_x, w) \text{ equals } \tanh(\zeta w_0 + \sum_{i=1}^{p-2} \zeta w_i h(c_x, {}_{2w_i}) + \zeta w_{p-1} h(c_x, {}_{2w_{p-1}}) + \zeta w_p h(c_x, {}_{2w_p})).$$

Then, there exist  ${}_{2w_{p-1}}$ ,  ${}_{2w_p}$ ,  ${}_{3w_{p-1}}$  and  ${}_{3w_p}$  that render the new value of  $|O(c_x, w) - c_t| < \varepsilon \forall c \in I(k)$ .

Proof:

Let  ${}_{c_y'}$  and  ${}_{c_y}$  be the values of  $O(c_x, w)$  before and after introducing two hidden nodes, respectively. Also let  ${}_{c_{net}}$  be the value of  $\zeta w_0 + \sum_{i=1}^{p-2} \zeta w_i h(c_x, {}_{2w_i})$  before introducing two hidden nodes. Thus,  ${}_{c_y'} = \tanh(c_{net})$  and  ${}_{c_y} = \tanh(c_{net} + \zeta w_{p-1} h(c_x, {}_{2w_{p-1}}) + \zeta w_p h(c_x, {}_{2w_p}))$ .

$\because |O(c_x, w) - c_t| < \varepsilon \forall c \in I(k-1)$  and  $|O(k_x, w) - k_t| \cong \varepsilon$  before introducing two hidden nodes,

$$\because |{}_{c_y'} - c_t| < \varepsilon \forall c \in I(k-1) \text{ and } |{}_{k_y'} - k_t| \cong \varepsilon.$$
