Web-based e-commerce have developed through several phases: browsing static web pages, using mutual web tables, processing B2C commerce, till developing B2B application integration. More than half of the enterprises still rest on the phrases of static web pages and simple e-commerce. Up to present, the main form of e-commerce is B2C, which exhibiting its information through HTML, and many of its processes is launched by manual work. With the emergence of B2B and other more complicated commerce pattern, tradition e-commerce technique pattern could not guarantee for validity and could not complete tasks in time. E-commerce of next generation demands for automatic Web dealing initiated by application, decrease of error easily arisen in manual process, and efficiency. Automatization, intelligentization and integration should be embodied by the e-commerce technique pattern in next generation. More research in collaborative information technique and distributive computing pattern in new generation is the main approach to solve the problem. It will promote the development of collaborative e-commerce system that is the third generation of e-commerce. Due to its connatural advantage, mobile agent is applied in next generation e-commerce as a new technology.

Therefore, the primary aim of this paper is to give an architectural model and a framework for implementing mobile agent-based e-commerce system. Intelligent and mobile agents are applied to current e-commerce technology to meet autonomy, intelligence and integrity requirements. For the special requirement of electronic commerce, system security is the one of the most important elements to a successful system. The original idea is to establish a secure mobile agent system (SMAS) firstly, and then to build up the mobile agent-based e-commerce system framework based on the SMAS to ensure transmission security.

The remainder of this paper has the following structure: Section 2 gives an introduction to mobile agent firstly, and then establishes a secure mobile agent system

model for e-commerce. In the last portion of this section, a mobile agent-based e-commerce system framework is brought forth. A logic verification of the system framework is demonstrated in section 3. Section 4 describes some issues relevant to mobile agent applied in e-commerce. And the section 5 gives a conclusion.

## 2. MOBILE AGENT-BASED E-COMMERCE

### 2.1 Mobile Agent Introduction

The Object Management Group defines a software agent as "a computer program that acts autonomously on behalf of a person or organization"<sup>[1]</sup>. The following properties characterize agents:

- pro-active (support of the user's work)
- adaptive (learning the user's preferences or the ability to work on different platforms)
- autonomous (limited communication with its creator)
- intelligent (making 'intelligent' decisions)
- mobile (can actively migrate in networks to different systems and move directly to the local resources, like databases or application servers)

Mobile agents are programs that can migrate from host to host in a network, at times and to places of their own choosing. The state of the running program is saved, transported to the new host, and restored, allowing the program to continue where it left off. Lange and Oshima<sup>[2]</sup> give reasons why to use agents: e.g. improvements in latency and bandwidth of client-server applications and reducing vulnerability to network disconnection.

### 2.2 Mobile Agents in E-Commerce

Mobile agents are well suited for electronic commerce. A commercial transaction may require real-time access to remote resources such as stock quotes and perhaps even agent-to-agent negotiation. Different agents will have different goals, and will implement and exercise different strategies to accomplish these goals. We envision agents that embody the intentions of their

creators, and act and negotiate on their behalf. Mobile agent technology is a very appealing solution to this kind of problem.

An electronic commerce transaction may be viewed in terms of four different phases<sup>[3]</sup>: product brokering, merchant brokering, negotiation, payment and delivery.

Product brokering consists in the gathering of information about the product that is going to be bought.

Merchant brokering involves the evaluation of a set of alternatives in order to make the purchase. Making the decision implies considering all the tradeoffs that the various products offer: price, warranties, delivery time, and others.

During the negotiation phase the agent settles the final terms of the commercial transaction. The characteristics of the market directly influence the outline of this phase. In markets where prices and characteristics are fixed, negotiation may not even exist.

Finally, in the purchase and delivery phase of the transaction, the agent actually makes the acquisition and delivers the money (or its electronic equivalent) against the goods.

### 2.2.1 Secure Mobile Agent System

A number of advantages of using mobile code and mobile agent computing paradigms have been proposed<sup>[4, 5, 6]</sup>. One of the main obstacles to the widespread adoption of mobile agents is the legitimate security concern of system developers, network administrators, and information officers. It has been argued that once the security issues have been resolved and a collection of security mechanisms have been developed to counter the associated risks, then the users of mobile agent technology will be free to develop useful and innovative solutions to existing problems and find a wide array of application areas that will benefit from this technology. Using this collection of security mechanisms to mitigate agent-to-agent, agent-to-platform, and platform-to-agent security risks may, however, introduce performance constraints that could dictate design decisions or negate the benefit of using mobile agents for certain applications. Considering the special security requirements in e-commerce, a secure mobile agent system (SMAS) framework is presented in this paper.

SMAS consists of mobile agents and agent server (e.g. agent facilitator). Mobile agent has six modules: security shell, environment interaction module, state denotation module, task execution module, routing policy module and log file. The architecture of mobile agent is shown in figure 1.

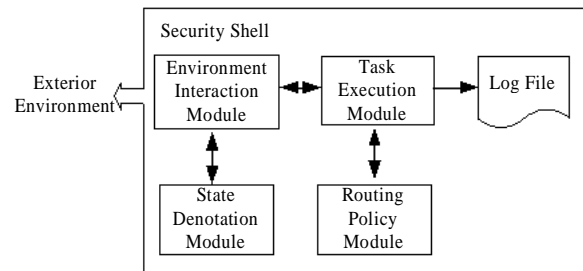

Figure 1 Mobile Agent Architecture Model

Security shell is responsible for protecting the agent from attacks of malicious hosts and other agents. The main functions include encrypting and decrypting the whole agent, authorizing the visit host, deploying the different security policy according to the different trusted level of host.

Environment interaction module is responsible for the maintenance of communication between agent and exterior environment that includes sensor (apperceive outside environment), message processor (process inter-messages, data communication between agent and environment based on KQML) and reactor (i.e. effector, output the result to outside environment).

Task execution module is the execution module of agent, which consists of action execution module and result integration module. According to the security strategy to different methods and data deployed by security shell, task execution module executes corresponding method, and makes integrated analysis of results for its goal.

State denotation module is responsible for recording the state of agent, which includes attribute value of agent and the sequence of agent's running environment. This makes agent to run successfully when it is hold up or resumed. Agent's state can also be recorded in fixed interval for its resuming in abnormal circumstance.

Routing policy module plans agent's migration route. There are two feasible routing policies, one is fixed routing, and the other is dynamic routing based on formula and catalog services.

Log file records every sensitive instruction and manipulation on agent executed by agent platform, it's used for audit afterwards. Log file must be encrypted so that it couldn't be juggled.

Mobile agent server (mobile agent service facilitator) is based on agent transfer protocol (ATP), it provides essential EE(execution environment) for agent's migration, execution, and other functions and services such as dispatch, reception, recovery, security management and service transfer. Mobile agent server includes security management, agent executing environment, agent API, agent service environment, communicating API, as shown in figure 2.

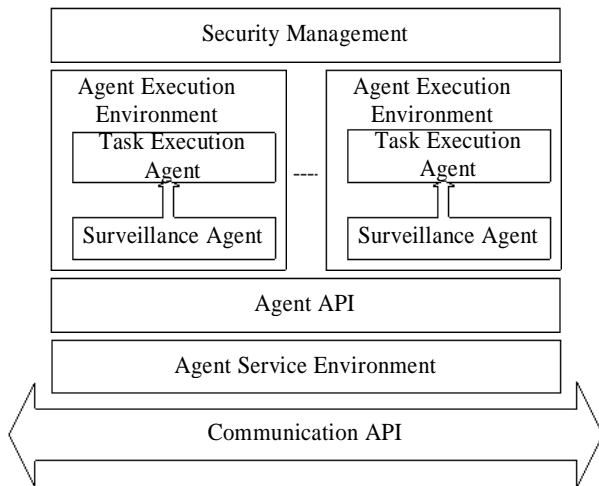

Figure 2 Mobile Agent Server Structure

Security management is responsible for the security of agent server and the agent executing on it, it takes authentication, encryption, visit controlling and other measures to protect system security.

Every agent server can process several agent EEs. Agent EE is the resource distributed for every agent by the agent server. It runs agent under the control of security management module. Every EE has two kinds of agents: task execution agent and surveillance agent. Task execution agent runs the program on behalf of agent user. Surveillance agent keeps an eye on the execution situation of the task agent. It can terminate the task agent once there is any unauthorized or illegal operation.

Agent API is the unique interface between agent and agent server. It provides many characteristic operations of mobile agent that can be utilized to finish the distributed task for the agent. For instance, agent calls Jump procedure explicitly before migrating to another host. Jump procedure captures the whole state image of the mobile agent and transfers the agent to the destination host. On the destination host, agent server loads the agent to the relevant agent EE and recovers the agent from the hold point. The primary agent will be terminated on the local host after the agent's state image being captured, transferred and recovered successfully on the destination host.

Agent service environment manages lifecycle, event and persistence for agent. Lifecycle management realizes creation, dispatch, migration, reception, storage and termination for mobile agent, event service provides agent communication mechanism for collaboration with other agents or application system, which supplies essential condition for agent collaboration. Persistence service ensures agent execution's persistence through corresponding mechanism, it helps agent to restart accurately when there is system or network disaster before agent reach its destination.

Communication API is responsible for transmitting mobile agents, data and messages, including network protocol API and email API.

### 2.2.2 Mobile Agent-based E-Commerce

Based on above construction of mobile agent system, this paper brings forth the mobile agent-based e-commerce system framework. Its model is shown in figure 3.

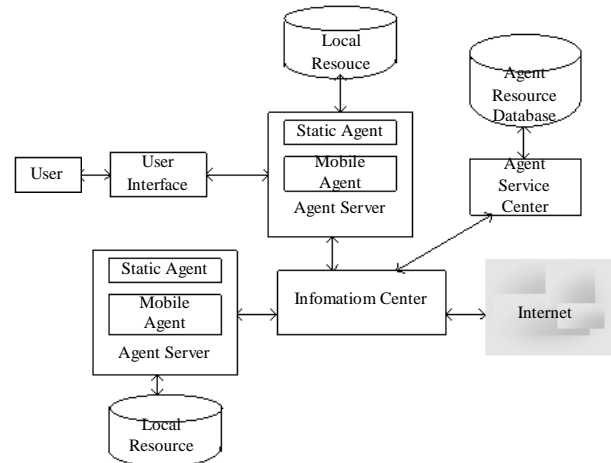

Figure 3 Mobile Agent-Based E-Commerce System Framework

In this system, agent service center provides catalog service, registers mobile agent's basic information, maintains agent's lifecycle, cancels illegal agent in time and provides agent query service. In order to enforce system security, especially for mobile agent protection, agent service center also maintains a table which records the history of host visitation, it gets task accomplish information of agent in visitation from its log files, calculates the host's credit degree, puts the result in the history table and re-calculates it so that mobile agent could optimizes routing strategy. Service center need to provide host service query function in order to help agent affirm the servers on which its task could be accomplished, and choose the best route.

Information center is responsible for security control of the whole E-Commerce system, it generates certain inbreak inspection agents, sends them to each sub-system, monitors real time condition of system execution, collects relative information of inbreak event, analyzes inbreak event, traces inbreak route and confirms its beginning. Control center takes corresponding measure when it received inbreak report and analyzed it. Control center is also responsible for downloading patches of application and operation system, upgrading virus-preventing software, after this it dispatches mobile agent to install them on every node in the system.

Following is the workflow of system:

- (1) User submits a request through user interface.
- (2) Agent Server analyzes the request and creates static agent or mobile agent according to the request of task, then registers the agent's information in agent service

center.

(3) Static agent visits local resource under security control of agent server, completes user's request and returns the result to user. In the meantime, it registers agent's logout information on agent service center.

(4) Mobile agent registers its information on agent service center, queries for host service table, returns agent server, works out migration route or plan according to routing strategy.

(5) Mobile agent queries the history table of host visiting on agent service center, gets credit degree of host on the route, returns the optimized migration route of agent server.

(6) Mobile agent sends out migration request to server, agent server makes agent hung up, encrypted, packed and sends it to destination host.

(7) Destination host accepts agent, authenticates each other.

(8) Destination host carries out security strategy according to authentication result, assigns limited execution environment for agent, and generates monitor agent to monitor the execution information of mobile agent.

(9) Mobile agent carries out different security strategy according to authentication result, executes task under assigned resource. If necessary, it could make alliance with other agents and accomplish the task collaboratively.

(10) Agent goes through hosts in routing table and completes its task, collects the results, returns it to user and submits log files to agent service center, registers logout information.

### 3. VERIFICATION

At present, many technology research and system development based on agent have been gotten along at home and abroad. However there is little research on agent system verification. Yanxiang He and Xinmeng Chen introduced an agent-mediated system verification method in 2001<sup>[11]</sup>. The definition of agent-mediated system verification can be described as follow: a system contains one or more claimed agent(s), it will be changed when some other claimed agent(s) add(s) to the system. That means:

(a) System behavior transformation doesn't indicate other process's running slows down the system processing speed. Otherwise it shows the claimed agents apperceive each other to a degree, and they adjust their actions accordingly.

(b) New added agent must have the same style with the claimed agents, viz., although it has different goal, knowledge and belief, it should have the same architecture and function.

(c) The existing agents and the new added agent don't always communicate with each other, and they not always be autonomous, persistent or intelligent.

According to the definition, following test should be done. We suppose X have two instances. If the behavior

when there is another instance to exist of each instance and its behavior while there are no other instances to exist are different, that indicates X is an "agent". On the contrary X is not an "agent". The verification has nothing to do with agent's mobility.

For example, a user submits a purchase requirement, two instances of information collection agent, agent1 and agent2, are created. Agent1 and agent2 move in the network according to their migration route and collect the required commodity information. Each agent apperceive environment automatically and make action according to the environment. When one agent's reaction reaches the existence of another agent, they communicate with each other and get the new task result and execution decision by negotiation. Then they regulate their behaviors based on the new strategy. So they are "agent" on the agent-mediated system verification definition mentioned above. The rest may be deduced by analogy, we can prove that the system established on the framework introduced in section 2 is an agent-based system.

This verification method is based on agent's sociability. For security and performance verification of the system, demonstration and simulation verification are needed.

### 4. RELATED AND FUTURE WORK

Security insurance and system reliability are the foundation and key for the popular application of the mobile agent-based e-commerce. In this paper, secure mobile agent architecture is designed for protecting agent from attacks of malicious host and other agents; surveillance agents are added for protecting the host from attacks of malicious agents; XML-PKI technology is provided for encrypting the sensitive data, code and states for transaction security of agent. Disaster recovery technology is applied to buildup system reliability.

There are many promising new research on mobile agent technology and its applications in recent years<sup>[8,9,10]</sup>. However we should see that we must solve some more technology obstacles on our way. The first one is the issue of agent standardization. FIPA and MASIF are working on that and there should be some standards about mobile agent system framework and so on. For agent in e-commerce, it is still in its infancy. The main trend in this area is to attack four problems: negotiation, information discovery, ontology and security. Furthermore, the use of electronic money in conjunction with mobile agent is particularly challenging. The integration of digital payment system into mobile agent-based e-commerce is important to realize the potential e-market. In a word, there are many jobs should be done for the mobile agent-based e-commerce application in the future.

## 5. CONCLUSION

Mobile agent-based e-commerce system framework mentioned above utilizes the virtues of mobile agent technology fully. It can realize the electronic transaction automatically and intelligently. It also can provide the better security protection for effective and convenience business cooperation and collaborative information sharing between enterprises. To realize the system concretely, Java language is adopted to implement the mobile agent for platform independence. Mobile agent communicates in KQML (Knowledge Query and Manipulation Language) with each other and accesses services provided by agent server. Mobile agent server adopts ATP (Agent Transfer Protocol) to dispatch and receive mobile agents.

## ACKNOWLEDGEMENT

The research work has got a lot of people's help and energetical support. Especially thank professor Yang for his guidance and support.

{cswkleung, csschan, cskchung}@comp.polyu.edu.hk

### ABSTRACT

Collaborative filtering (CF) based recommender systems have been proven to be a promising solution to the problem of information overload. Such systems provide personalized recommendations to users based on their previously expressed preferences and that of other similar users. In the past decade, they have been successfully applied in various domains, such as the recommendation of books and movies, where items are simple, independent and single units. When applied in the tourism domain, however, CF falls short due to the simplicity of existing techniques and complexity of tourism products. In view of this, a study was carried out to review the research problems and opportunities. This paper details the results of the study, which includes a review on the recent developments in CF as well as recommender systems in tourism, and suggests future research directions for personalized recommendation of tourist destinations and products.

**Keywords:** Recommender System, Collaborative Filtering, Personalization, Data Mining, Travel & Tourism

### 1. INTRODUCTION

In the past decades, the rapid development of Internet technologies has led to severe information overload. The amount of information available on the web, and the amount added daily, is too much for us to process. The use of recommender systems has therefore become increasingly popular. Such systems provide advices to users about items they might like to purchase or examine, avoid them from being drown in the vast amount of information [3].

There are three major types of recommender systems: content-based, knowledge-based and social- or collaborative-filtering (CF) based. Content-based recommender systems establish users' interest profiles by analyzing the features of their preferred items. In such systems, features of items are compared to those of the preferred items of the user. The more relevant items, measured by features similarity, are recommended. Knowledge-based recommender systems make use of knowledge about users and products to generate recommendations. They use a reasoning process to determine what products meet a user's requirements. Social-filtering or CF based recommender systems provide personalized recommendations according to user preferences. Such systems maintain data about users' purchasing habits or interests and from there identify groups of similar users. For a target user, known as the active user, items liked by other similar users are recommended.

In addition to providing personalized recommendations, CF offers a number of advantages over the other two techniques, making it one of the most promising solutions to information overload. As no content information is considered in the recommendation process, items being filtered need not be amenable to parsing by a computer. Besides, recommendations generated are based on tastes of users rather than more objective properties of the items themselves. The items

recommended to a user can therefore be very different (content-wise) from what the user has liked previously, overcoming a major limitation of content-based recommender systems [31]. When compared to knowledge-based recommender systems, CF techniques are much simpler and easier to implement. While the former requires a domain knowledge engineering process to build a knowledge base of items, the later can be fully automated. On the one hand, this allows CF to be easily applicable to any domain where a database of user preferences is available. On the other hand, this makes CF falls short when recommending complex items such as travel purchases [4]. Nevertheless, CF has become the most successful technology applied in recommender systems. To date, it has already been studied and applied to various domains such as the recommendation of books, Usenet articles and jokes.

In recent years, CF has gained research attention in the tourism domain for several reasons. By observing and predicting user preferences, CF prevents users from being overwhelmed by vast amount of travel information. This is particularly valuable in an information-intensive domain like tourism, which comprises a large variety of products such as accommodations, attractions, restaurants, and many others. Besides, one characteristic of the purchase of tourism products is that at the moment of decision-making, only information about the product, not the product itself, is available to users [26][33]. Current web-based tourist information portals can present archives of pre-defined destinations, some with rich multimedia content. While tourism product suppliers are always in favor of their own businesses, other visitors' experiences would probably provide more valuable and unbiased information about a destination. CF techniques would help users obtain such information according to their travel preferences [4].

Yet, CF is not readily applicable to the recommendation of tourism products [4][28], which are more diversified

and complex than products like books. With the objective to bridge the gap between CF and tourism products recommendation, a study was carried out to identify the problems in recommending tourism products, and to review the state-of-the-art in both areas. This paper details the results of the study, and suggests future research directions to work towards collaborative travel recommender systems.

### 1.1 Collaborative Filtering (CF)

The underlying philosophy of CF is that each individual belongs to a larger group of like-minded individuals. CD-based systems therefore make personalized recommendations to users based on the interests of similar users [7][20][27][31]. In a movie recommender system, for example, the movie Shrek may be suggested to a user Sam, after noticing that his taste is similar to that of another user Bob, who has liked Shrek.

Users' preferences provide the basis for making collaborative recommendations. Such preferences can be expressed explicitly by means of ratings, or implicitly such as in purchase history. CF algorithms may compute a predicted score (rating) of a particular item or a list of recommended items, known as Top-N recommendation, for the active user.

### 1.2 Recommending Tourism Products

Recommending tourism products poses additional challenges to existing CF researches. They are mainly caused by the complexity of tourism products, and the special taxonomies they can have.

Firstly, tourism products are highly heterogeneous even at a single destination. They include restaurants, hotels, theme parks, and many others. Recommending these products with pure CF techniques can be easy, as long as each item is uniquely identified (by a product code, for example) and no content information is considered. However, these make less sense for tourism products as content information may also be essential in the filtering process. For example, if a user is looking for a place to ski, a travel recommender system must be able to filter out irrelevant activities such as hiking. Some existing techniques such as [14] and [30] already allow content information to be used in the recommendation process. This, however, can be more difficult in recommending tourism products due to **product heterogeneity** since products can have different representations, and the filtering of content information may be based on different features for different products.

Furthermore, tourism products may also contain essential context information such as availability and location. For example, if a user is looking for a place to ski in June, a travel advisory system may consider Australia as a suitable destination. If his/she wishes to ski in December, however, it will be more suitable to recommend some places in Europe due to the availability of the desired activity at different locations

and points in time. **Context awareness** is therefore another important factor in designing a travel recommender system.

Lastly, tourism products have strong inter-item relationships. They may also be arranged into different hierarchies or taxonomies. For example, the is-a hierarchy may exist if products are categorized according to their type (e.g. Surfer's Paradise is a beach). Besides, the part-of or component hierarchy may also exist if they are categorized according to their location (e.g. Surfer's paradise is part of Gold Coast). Another special example of component hierarchy in tourism products is tour package, which comprises multiple heterogeneous products such as flight tickets, accommodation, as well as tourist spots (e.g. a visit to Surfer's Paradise is included in a 2-day tour to Gold Coast). These products may exist in multiple packages, or may be purchased alone as a single unit of product. To recommend tourism products, different **product taxonomies** should be taken into consideration.

### 1.3 Organization

The rest of this paper is organized as follows. In Section 2, different types of CF techniques are described and their strengths and weaknesses are commented on. In Section 3, several CF applications are introduced. Related work in tourism is also described. In Section 4, some CF techniques and related work introduced are further discussed with respect to their ability to recommend tourism products. From there some future research directions are identified. Lastly, Section 5 concludes this paper.

## 2. CF TECHNIQUES

CF algorithms were traditionally classified into two major types, namely memory-based and model-based [2]. Memory-based algorithms operate over the entire user database, and recommend products using statistical methods. Model-based algorithms construct compact models from the user database, and recommend products using probabilistic methods. Since such models can be constructed offline, model-based algorithms usually improve online performance.

Such classification mainly reflects how products are recommended in real-time – either based on the entire database or models constructed and stored in memory. To more specifically describe various CF algorithms, in this paper they are classified by the underlying techniques they used to make recommendations.

### 2.1 K-Nearest Neighbor (k-nn)

K-nearest neighbor (k-nn), also known as pure CF, was commonly used in early CF-based systems. It works in three major steps, namely similarity weighting of users, neighbor selection and prediction computation.

At the similarity weighting stage, *each user* in the

database is assigned a similarity weight using some measures (such as those analyzed in [2] and [27]). Such similarity is reflected in the ratings they have given on items. For two users to be comparable, only items that both users have rated are counted. At the neighbor selection stage, a number of  $k$  nearest neighbors, who are the users having the highest similarity weights, of the active user are selected as predictors for items. Based on the interests of the selected neighbors and some partial information of the active user, prediction score of an item is computed.

K-nn makes predictions that are ratings-based and content-independent. It can therefore be applied to domains where textual descriptions of products are not available, not meaningful, or cannot be easily categorized by any attribute. Furthermore, it uses statistical approaches that are easy to implement, and can be applied as long as a database of users preferences on items is available. Despite its simplicity, empirical analyses [2][12] proved that it produces good predictions, especially if the active user has rated a significant number of items. Besides, predictions are generated by performing real-time computations over the database. As no pre-compilation of data is required, new data points can be easily added to the application.

For the above reasons, k-nn was commonly used in recommender systems. This, however, has revealed a number of challenges for researchers. Among which the most essential ones are data sparseness, cold start problem and scalability.

Data sparseness arises as users can only rate the items, or part of the items, that they have access to (that is, they cannot rate any unobserved items). In k-nn, it is possible that the set of common items rated by the active user and his neighbors is very small, even if the selected neighbors are already the "nearest" ones. This resulted in poor prediction quality [29].

Furthermore, data sparseness implies that given a very large database of items, there may not be a complete set of ratings across all items. The cold-start problem, or the first-rater problem, arises when no prediction about a certain item can be made for the active user as no other users have rated it before [16].

Scalability is an important issue especially in real-time applications. K-nn has severe performance bottleneck in the similarity weighting stage, as it requires real-time computations to be performed over the entire database for each prediction. Performance of the algorithms degrades when the numbers of users and items grow in the system.

## 2.2 Classification

Some researches regarded CF as a classification problem [1][21]. Instead of predicting the rating of an item, classification techniques predict whether the active user would like or dislike it. To do so, user ratings are

first discretized, usually into two classes - *Like* and *Dislike*. Classification techniques, such as Bayesian network [2], are then used to make predictions for the active user.

A Bayesian network makes use of decision trees to predict the likeliness of items, conditioned on whether some other items have been liked previously. Since decision tree induction is beyond the scope of this paper, it is not described here. Please refer to [11] for details.

In this technique, decision trees induction is done offline. Only the decision tree built for the target item has to be inspected in real-time, resulted in improved online performance over k-nn. Prediction quality, however, degraded due to its probabilistic nature.

## 2.3 Clustering

### 2.3.1 User-based Clustering

The Bayesian cluster model divides the user base into many groups (clusters) according to their similarity [2]. The recommendation process first assigns the active user to the cluster containing the most similar users. Then, it uses the preferences of users in that cluster to generate recommendations. Since the active user is only compared to a controlled number of clusters, scalability is improved. Similar to the classification technique, it produces less personal recommendations.

Eigentaste [8], another user-based clustering technique, clusters users by their similarities reflected in the ratings they have given on a gauge set of items. Then, the mean for each non-gauge item in each cluster is computed based on the number of users who have rated that item. Lookup tables of recommendations for each cluster are built by sorting the non-gauge items in descending order of their mean ratings. In real-time, recommendations are obtained by querying the pre-computed lookup tables. This simple online process ensures scalability. Since users are required to rate a gauge set of items, the ratings matrixes representing their preferences are dense. Users can therefore be well correlated to preserve prediction accuracy.

### 2.3.2 Item-based Clustering

Sarwar et al. [29] explored the item-based clustering approach, in which recommendations are produced by finding items that are similar to those the active user has liked previously. As the number of items and their relationships are relatively static, as compared to the number of users and ratings, recommendations can be computed offline. This avoids the performance bottleneck of k-nn and improves scalability. However, prediction quality of this approach only shows slight improvement over k-nn. This might be due to the fact that data sparseness was not addressed in the research.

## 2.4 Association Rule Mining

Association rule mining (ARM) is a data mining technique for discovering interesting relationships between items by finding items frequently appeared together in transactional databases. An association rule is denoted as  $A \Rightarrow B$ , and measured by two measures known as support and confidence. For example, the rule  $A \Rightarrow B$  [20%, 90%] means that 90% of users who purchased item A also purchased item B, and 20% of all users purchased both of them [11].

ARM is usually used for market basket analysis. It can also be used to generate recommendations after interesting rules are mined. For example if  $A \Rightarrow B$  is interesting in a certain system, and the active user has liked item A previously, he/she will probably like item B also. Note that a rule is considered as interesting only if its support and confidence values are higher than the user-specified minimum.

#### 2.4.1 Adaptive Association Rule Mining

Lin et al. [18], however, pointed out that traditional ARM algorithms are inefficient for collaborative recommendation for two reasons. Firstly, such algorithms mine rules for all items in the database. Therefore, many rules mined will not be relevant for a given user. Secondly, the minimum support and confidence have to be specified in advance, which might lead to either too many or too few rules due to variations in user tastes and items' popularities.

To address these issues, they suggested an adaptive-support rule mining algorithm, known as AR-CRS, tailored for CF. AR-CRS mines rules for one target item at a time, and automatically adjusts the minimum support value to mine a user-specified number of rules. It can compute associations among users, items, or both.

#### 2.4.2 Multi-level Association Rule Mining

Kim & Kim [15] applied multi-level association rules mining (MAR) to address data sparseness and the cold start problem. MAR can be applied on items that are organized in a hierarchical category structure, such as the classification of goods in a department store (is-a hierarchy). Its key feature is to mine rules at different level of abstraction [10]. A major concern of MAR is that higher support is likely to exist at higher level of abstraction. Different minimum supports should therefore be used at different levels.

When applied in CF, MAR can compute preferences for items that are not covered by the traditional, single-level technique. To do so, the category  $C_i$  to which a preferred item  $i$  belongs is found. If any association rule among  $C_i$  and another category  $C_j$  exists, some preferences will be given to items that belong to  $C_j$ . The consideration of such product taxonomy allows recommending cold-start or less popular products.

### 2.5 Hybrid Techniques

Personality Diagnosis (PD) [25] combined k-nn and clustering to improve prediction quality. In addition to the traditional similarity weighting measures, it employs a probabilistic interpretation of results to provide better predictions. PD retains the advantages of k-nn such as simplicity and adding new data points with ease. In terms of accuracy, it outperforms several approaches including k-nn and the Bayesian network model although it does not address data sparseness. In terms of time and space performance, it does not provide any advantage over k-nn.

O'Connor & Herlocker [23] combined k-nn and clustering to improve scalability. Their technique uses existing data partitioning and clustering techniques to cluster items based on user ratings. Predictions are then computed independently in each cluster. Experimental results show that their technique is more scalable than k-nn, as its real-time prediction process only considers items in a single cluster. Consistent improvement, however, in its prediction accuracy could not be observed. A possible reason for this is that their algorithm restricts items to being exclusively in one single cluster. Items that might have significant predictive value for multiple clusters therefore could not reflect real user preferences.

Sarwar et al. [30] combined information filtering (IF) and CF to provide better recommendations. They integrated filtering agents, known as filterbots, that evaluate and rate items using syntactic features to provide a dense ratings set. This improves prediction accuracy, and its effectiveness was proved in [9].

The Item-based Clustering Hybrid Method (ICHM) also integrated content information into CF to improve prediction quality and solve the cold start problem [17]. In ICHM, items are clustered based on content information. In a movie recommender, for example, movies are clustered by their genre, director, actor, etc. For a new item with no ratings, its prediction score is computed as a weighted sum of the ratings given to other items in the same cluster. Experimental results show that this approach improves prediction accuracy. It is also able to recommend cold-start items with reduced accuracy, as compared to using a dataset with no cold-start items.

## 3. CF APPLICATIONS AND RELATED WORK

CF has been proven successful in both research and practice. A few examples selected from different domains are introduced in this section. Amazon.com [19] is one of the most successful and well-known online retailers. It makes use of purchase histories of customers to produce recommendations using the item-based technique. GroupLens [27][16] is a pioneering and well-known project in automated CF. It had used k-nn to recommend Usenet articles. Filtering agents were later integrated into the system to improve prediction quality [30]. MovieLens is another recommender system developed by the GroupLens team. It recommends

movies to users using GroupLens' technologies. Jester [8] is an online joke recommender. When it was first developed, it had used k-nn to generate recommendations. When the number of registered users increased, however, it was found that the processing time of the system increased linearly until it crashed. The constant time algorithm Eigentaste was therefore developed and adopted.

Some related applications in the tourism domain were also studied. They are mainly based on knowledge-based technologies. CF is only used to rank the recommended products according to user preferences.

Dietorecs [4] and NutKing [22] are two similar applications developed by the eCommerce and Tourism Research Laboratory (eCTRL) [6]. They recommend travel products and activities based on the Case-Based Reasoning (CBR) technology, which is a problem solving technique that solves the current problem by adapting solutions for previously solved, similar problems. The CBR cycle consists of 4 stages, namely Retrieve, Reuse, Revise and Retain. Detailed descriptions of each stage can be found in [34].

A case base refers to a repository of representative cases, which are previously adopted solutions and/or possible solutions to new problems. In Dietorecs and NutKing, it is actually a pool of travel products and activities recommended by domain experts with respect to different travel settings (e.g. duration of travel). To start generating recommendations, a new case containing the active user's profile and travel settings is created. Pre-defined recommendations are then retrieved from the case base (the Retrieve stage), and ranked according to the preferences of the active user. The retrieved cases can be accepted as-is, or modified by the active user by adding or removing elements in the recommended cases (the Reuse stage).

Ski Europe [32] recommends places for skiing in Europe based on the TripMatcher technology [4]. Similar to Dietorecs and NutKing, the system maintains a knowledge base of destinations, developed by professional researchers worldwide. For each destination, travel experts have ranked different activities during different times of the year. TripMatcher applies information filtering and text mining algorithms to such context information, products' content information and users' ratings to generate recommendations.

In CBR, management of the case base is an important issue as it directly affects the correctness and quality of the solutions produced by a system. The major concern here is the selection of representative cases, including the number of cases and their content. In the CBR cycle, the Revise and Retain stages allow domain experts to, based on the solutions modified by users in the Reuse stage, revise the cases originally stored in the case base, retain the cases by updating the original ones, or store them as new cases. Thus they are very important steps

to help maintain the quality of the case base. However, how these important steps have been addressed in Dietorecs and NutKing, is unclear. Although the TripMatcher technology does not rely on CBR, it faces a similar problem as it produce recommendations from a knowledge based of pre-defined trips.

Due to the complexity of tourism products, it is important to develop a data model for their representation. As mentioned before, tourism products are heterogeneous, complex, inter-related and may contain essential context and content information. However, existing CF algorithms are all based on very simple data models. In fact, only ratings/purchase data and the unique identifiers of products are used in most algorithms. Integrating data models in CF would facilitate the development of more sophisticated, flexible and interoperable recommendation engines.

The Open Tourism Consortium (OTC) [24] is a consortium of companies, government agencies, individuals, and universities participating in the development of publicly available standards and open source software to support tourism. Recently, they developed an XML-based data exchange language known as TourML to represent objects and events, such as hotels and restaurants, of interest to tourists. Although OTC is not doing any CF-related research, their work can provide reference for modeling different tourism products.

#### 4. FUTURE RESEARCH DIRECTIONS

As aforementioned, the widespread use of pure CF methods has revealed some fundamental challenges concerning the scalability and prediction quality of CF systems. Since then, CF researches have been focusing on developing more scalable and accurate algorithms. Although numerous approaches have been developed, the dominant paradigm for performing CF has been based on techniques regarding items in the domain as some simple, single and independent units. This paradigm, although has been proven successful in various domains, falls short when applied in the tourism domain which poses additional challenges namely product heterogeneity, context awareness and the existence of product taxonomies to CF.

Another problem in this paradigm is non-transitive association [14]. In user-based methods, if two users have both experienced or rated similar items but not the same ones, their correlation is lost. This is known as the user-based non-transitive association. In contrast, using item-similarity instead of user similarity avoids this problem, but results in the item-based non-transitive association problem if two similar items have never been experienced or rated by a user.

Due to the presence of content and context information, purely CF algorithms may not be sufficient for travel recommender systems. Existing solutions, such as TripMatcher [4], therefore combined different

techniques with CF to form a recommendation engine. Such technology has already addressed product heterogeneity and context awareness using information retrieval and text mining algorithms. However, it does not take into consideration product taxonomies in the recommendation process.

In fact in most CF algorithms, recommendations are generated based on the relationship between some attributes of items and users' profiles. The item-based technique [29] behaves differently in the technical aspect, but still it is based on the relationship between items and users identified earlier to generate recommendations. They do not take into consideration inter-item relationships and product taxonomies, which are likely to be found in tourism products. Obviously, treating items as single units in a recommender system is inappropriate in the tourism domain.

MAR has already shown that it is possible to integrate the is-a hierarchy to improve recommendations [15]. Such hierarchy, and other possible hierarchies, have not yet been considered in travel recommender systems. This reveals a potential research problem, which is to extend the existing techniques to incorporate different product taxonomies in the recommendation process. This may lessen the problems of non-transitive association in CF, because item similarities are already implied in the hierarchy itself.

Yet, MAR applied to the is-a hierarchy may not be readily extendable to other hierarchies such as part-of. The is-a hierarchy exercises the upward closure property which affects the generation and pruning of associations rules. In such hierarchy, the support count of a higher-level item must be equal to the sum of that of its child items. In other words, if a higher-level item is infrequent (with respect to the user-specified minimum support), all of item child items must also be infrequent. In contrast, if a lower-level item is frequent, all of its parent items must also be frequent. Due to the presence of this property, the algorithm in [15] recommends products of a certain category, if some associations between that category and the category of a previously liked item exist. Considering other taxonomies in the recommendation process, however, have not yet been studied in the literature of CF. Further research on this is required.

To apply MAR in travel recommender systems, its challenges and shortcomings should also be addressed. The major concern in MAR has been the determination of minimum supports at different level of hierarchies (is-a hierarchy). Whether this applies to other product hierarchies is unknown, but should be aware of in future researches. The adaptive minimum support method proposed in [18] may be considered, as it can adjust the minimum support value according to the desired number of resulting rules.

A shortcoming of applying ARM/MAR in CF was observed. Traditional ARM/MAR generate "interesting

rules" based on items' frequencies of appearance in transactions in a database. In other words, the appearance of an item in a user's transaction implies that it is liked by that user. In classical ratings-based CF, however, ratings can be positive or negative. Using ARM/MAR requires transforming ratings data into class labels such as like and dislike. In [15], for example, a certain rating given by a user is converted to 1 if it is greater than the average rating given by that user, or 0 otherwise. Applying this technique to the Jester dataset [13], ratings should first be transformed from a continuous rating scale (-10 to 10) to like (1) and dislike (0). Consider a case where all ratings given by a user are negative with an average -5. According to [15], a joke with rating -1 will also be considered as being liked by the user. This actually implies a loss of information in the user's likeliness of items. Fuzzy logic may be a possible solution to this problem.

## 5. CONCLUSION

CF has been a promising solution to the problem of information overload in the past decade. In recent years, it began to gain research attention in the tourism domain for its ability to produce personalized recommendations. However, existing CF techniques fall short when recommending tourism products which are heterogeneous and complex. With the objective to bridge the gap between CF and tourism products recommendation, a study was carried out to identify the problems in recommending tourism products, and to review the state-of-the-art in both areas. This paper details the results of the study, and suggests future research directions to work towards collaborative travel recommender systems.

# Web Service Based Universal Management of Workflow Resources

Jinyoung Jang, Yongsun Choi

Dept. of Systems Management & Engineering, Inje University, Kimhae, 621-749, Korea  
 pongsor2@hotmail.com, yschoi@inje.ac.kr

## ABSTRACT

Implementing business process solutions in the way of Web service is being positioned in the center of workflow management. However, there is no robust standard to expose and access workflow resources by Web service interfaces. In this paper, we propose a web service based workflow resource management framework named Universal Resource Management Framework (URMF) with declarations of web service interfaces and interaction protocols among them. We also introduce a substitutive workflow interface model employing Web services and URMF. Finally, a prototype implementation model of URMF with J2EE platform is also introduced.

**Keywords:** Web services, workflow, resource management, organizational resource, resource resolution

## 1. INTRODUCTION

Workflow management is getting more attention as a way of fostering efficiency potentials by eliminating transport and wait times between activities and providing a detailed level of control over the assignment of work to process participants ([25], [26]). Workflow implementation inside the boundaries of single organization is steadily increasing, however the use of workflow management for the coordination of inter-enterprise processes is still at a very early stage ([5], [31]). Recently, Web services technology, that carries interactions through the exchange of XML messages, provides an alternative approach to implementing interoperable business process solutions in an efficient and standard way ([8], [19]). Application integration through language-neutral and environment-neutral Web services model yields flexible, loosely coupled, and highly extensible business systems.

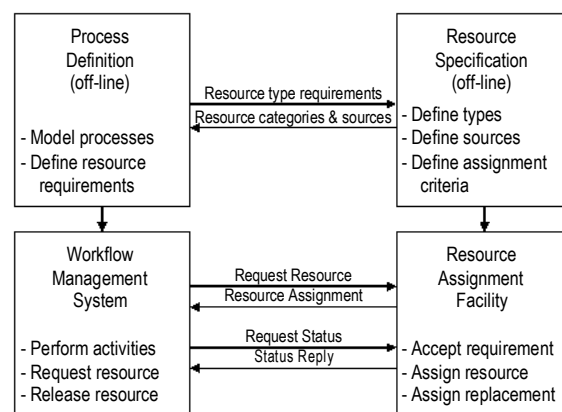

Current web service composition languages focus mainly on process control perspective but not much on organizational perspective. They lack seriously in managing the organizational elements, such as organization chart, roles, and worklists for human or non-human agents [1], which play important roles in executing business processes. For the successful implementation of workflows in organizations, it is required to enhance web services in supporting organizational resources management.

In this paper, we present a web service based workflow resource management framework named *Universal Resource Management Framework (URMF)* that declares Web service interfaces and the interaction protocols among them. We also introduce a substitutive workflow interface model employing Web services and URMF. Finally, a prototype implementation model of URMF with J2EE platform is also introduced. This paper is structured as follows. Section 2 introduces the issues of organizational resource management in workflow and the related works. Section 3 describes the advantageous features Web services as a resource

management facility. Section 4 describes our Web service based framework for the universal management of workflow resources, especially of organizational resources. An example implementation model of our framework with J2EE platform is described in section 5. Section 6 concludes the paper.

## 2. ORGANIZATIONAL RESOURCE MANAGEMENT IN WORKFLOW

Workflow management technology supports the execution of business processes through the automated coordination of tasks, data, application logic, and workflow participants (resources). Ideally, the workflow enactment service should be neutral to the organization and resource aspects. Building organization specific services independently from other perspectives, like of process control, can support the needs of wide variety of organizations and resources [33].

**Fig. 1.** Separation of resource management perspectives in workflow [21]

Fig. 1 illustrates the separation of resource management perspectives in workflow. Division between a process model on one side and a resource model on the other side fosters the separate evolution of both models. It gives robustness to workflow models independent of changes in the organizational structure. Separate

resource model shared by several workflow engines reduces administrative overhead and prevents possible redundancies [33]. Existing workflow management systems have difficulty in distributed worklist management resulted from the architecture of integrated worklists with the enactment service ([21], [22], [30]).

Resource management framework in workflow can be classified into three categories ([33], [34]). Fig. 2 shows the relationship among these categories and related studies. Main focus of each approach can be summarized as follows:

- *Organizational meta model*. Studies under this category suggest the meta models of organizational structure to be used for the mapping of an existing organization. These meta models is moving to be more generic and comprehensive to cover organizational objects such as organizational positions, position types, tasks, or units. Exposing too rich models tend to cause too tightly coupled and highly dependent architecture of resulting systems ([32], [33]).
- *Resource Resolution*. Upon the instantiation of a workflow activity, the workflow enactment service places work items on the work lists of qualified performers [30]. Resource resolution handles on the strategy and the mechanism for work allocation among competing process participants, utilizing role hierarchy, delegation rules, and various organizational constraints like “binding of duties” and “separation of duties”. Formal resource resolution languages like Resource Query Language (RQL) [16] are employed to provide a ‘view’ to access the inner organization model, in finding out eligible resource, without the direct exposure of the entire organizational model.
- *Resource Assignment / Coordination*. This layer provides a mechanism of how to reserve, cancel, or queue workitems into the worklists of selected workflow resources. Services in this layer may be exposed by APIs such as CORBA IDL.

<p><b>Resource Assignment / Coordination</b></p> <ul style="list-style-type: none"> <li>• <i>Work Activity Coordination System</i> [14]</li> <li>• <i>Enterprise Workflow Management Framework</i> [12]</li> <li>• <i>Resource Assignment Interface</i> [21]</li> <li>• <i>Workflow Resource Management Facility</i> [11]</li> </ul>
<p><b>Resource Resolution</b></p> <ul style="list-style-type: none"> <li>• <i>Resource Policy Model</i> ([6], [7])</li> <li>• <i>Resource Query Language</i> [16]</li> </ul>
<p><b>Organizational Meta Model</b></p> <ul style="list-style-type: none"> <li>• <i>OMM Organization and Role Model</i> [9]</li> <li>• <i>Organization and Resource Model (ORM)</i> ([23], [24])</li> <li>• <i>Generic Organization Model</i> ([6], [7])</li> <li>• <i>A Generic Resource Meta Model</i> [33]</li> </ul>

**Fig. 2.** Issues and related studies of organizational resource management in workflow

However, these works on organizational resource management in workflow are limited in handling the issues of interoperability and heterogeneity, which can

be overcome by the web service technologies. In next section, we will discuss how resource management framework can be modeled and implemented with the web services.

### 3. WEB SERVICES AND RESOURCE MANAGEMENT

Existing workflow resource management approaches are much dependent on the underlying models or technologies, resulting tightly coupled architectures. They have difficulty in allowing the flexible and coordinated interaction patterns, which can be provided by the web service architecture. Although there exist many distributed software platforms that could be useful to implement workflow resource facility, Web services technologies are getting more industry momentum with many advanced features, like language and platform independence, interoperability through wire level standards, and the ability to expose interfaces but hiding implementation [15].

Today, the most prevalent use of Web services is to carry out business processes and transactions, inside or across enterprises, by applying web service composition languages like BPEL4WS. However, there exist few studies of employing web services for the management of organizational resources in workflow. Recently, Aalst et al. [1] introduced their work on how to expose an organizational model in an XML DTD for the exchange of information in cross-organizational processes. But, their approach still bears tightly coupled architecture.

Managing organizational resources by Web services can be a sound alternative by utilizing tools and standards of Web services. Two of the existing works that can be employed to adapt workflow resources to Web services are introduced.

#### *Intermediary server*

An intermediary server is a component that lies between the service client (subscriber) and the service provider (publisher). It basically intercepts the request from the service client, provides the service of designated function, and forwards the request to the service provider. Similarly, it intercepts the response from the service provider and forwards it to the service client. Intermediary servers can provide value-added services, like authentication, quality of service, management service, or aggregation services. In our approach, we employ intermediary servers as to provide a uniform service of combining different types of organizational resources into a single unified interface.

#### *Web Service Management Framework*

Web Services Management Framework (WSMF) is proposed for the management of various IT resources, including Web services themselves, through Web services [15]. To encounter various management issues of more complex IT resources, an extensible interface

has been defined utilizing Web services standards and description language. However, WSMF focuses on the managerial aspects of IT resources, such as network management, system management, or database management, which are far from the management issues of organization resources, such as work reservation, work coordination, or organization charts.

#### 4. UNIVERSAL RESOURCE MANAGEMENT FRAMEWORK

Now, we introduce a web service based workflow resource management framework named *Universal Resource Management Framework (URMF)*. URMF provides several web service interfaces that support in browsing organization chart and belonging resources, interacting with human and non-human resources, and the dynamic selection of proper resources based on constraints.

##### 4.1. Design principles of URMF

The design principles of URMF, differentiated from the traditional distributed computing, are based on the concept of the service-oriented architecture (SOA) [20] to make the workflow resource management facility conform to the Web service environment:

- **Standardized.** The URMF architecture conforms to the web service standards (SOAP, WSDL, and UDDI) including the web service based process definition languages such as BPEL4WS. Resources declared and managed in URMF are universally discovered, bound and executed in web service environment.
- **Loosely coupled by coarse-grained interfaces.** Distributed object based systems are moving toward coarser-grained interfaces, which act as distributed façades, for less communication with each other across the network and loosely coupled implementation [20]. URMF provides coarse-grained web service interfaces, by employing generic organization model and resolving resources without the direct exposure of the entire organizational model. These features allow the flexible enrichment of organizational meta models, the employment of diverse underlying technologies, e.g. LDAP (Light-weight Directory Access Protocol) or SQL, and the flexible coordination of the services.
- **Asynchronous work coordination.** Tasks in business processes, especially those performed by human resources, need to be queued waiting to be processed. URMF supports the message calls for work order asynchronously as well as synchronously by the event-driven mechanism, to be explained more detail in sections 4.3, 5.2 and 5.3.
- **Dynamic selection of resources.** URMF provides web service interfaces, for the dynamic selection of resources, which supports the various organizational constraints represented in Resource Query Language (RQL) as well as browsing organizational structure, to be explained more detail in Sections 4.3 and 5.5.
- **Discoverable.** All Web services, inside or outside of

an organization, are discoverable as a benefit of SOA, either at design time or at run time. Organizational resources conforming to URMF can be discovered, at any time required regardless of the location, to be explained more detail in Sections 4.3 and 5.6.

##### 4.2. Entities of URMF and their interactions

Fig. 3 shows the four main entities of URMF, i.e., *WSWE (Web Services-based Workflow Engine)*, *URB (Universal Resource Binder)*, *OWQS (Organization Work Queue Service)*, and *AWQS (Agent Work Queue Service)*.

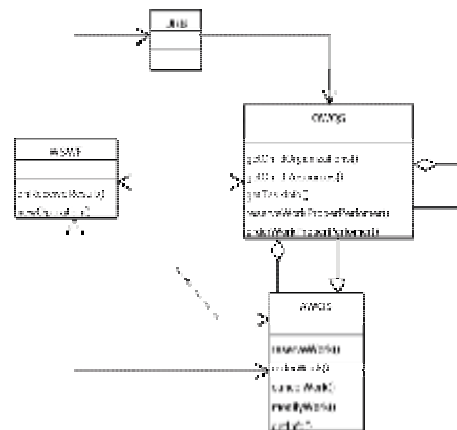

Fig. 3. Entities of URMF and their interactions

In URMF, every organizational workflow resource is represented as a web service, called *Work Queue Service (WQS)*, and acts as a service provider. Each *AWQS* is for a human or non-human resource [30] and takes the work requests of service requestors. Each *OWQS* is for an organization unit and acts as a hub or router for *AWQS*. On the other hand, *WSWE* or *URB* request the services provided by *WQS*. *WSWE* refers to the workflow engine capable of interacting with web services. *URB* refers to a GUI tool, intermediating *WSWE* and *WQS*, and supports for browsing organizational resources during process design or instantiation.

*AWQS* represents each workflow resource, such as a human agent, software, a machine, or a place. *OWQS* inherits the interfaces of *AWQS*, capable of acting as *AWQS*, and references one or more child *AWQS* or *OWQS*. This self-contained structure allows *OWQS* to cover any set of resources like companies, branches, departments, or teams. This composite pattern [13] allows each service unit to be declared for any number of *WQS*'s and lets URMF be applied to the organizations of any scale either in size or in complexity of policies. This advanced feature additionally allows *OWQS* to provide the functionality as an intermediary server. For example, *OWQS* can delegate or distribute work items to the appropriate child resources under its policy of delegation rules, access control, or security, etc. Furthermore, *OWQS* provides the RQL interfaces so that the service requestors can get the endpoint of the desired resource without browsing the whole organization charts inside. In this way, should-be secure

objects, like level or delegation, are encapsulated. These structural features of URMF entities support the design criteria of loosely coupled and coarse-grained interface.

#### 4.3. Services of URMF

With the design principles and the entity model, we have declared five categories of services for URMF. Specific Web service descriptions of URMF entities, classified into these categories, are provided in appendix A. In addition, an example process definition using these services in BPEL4WS is provided in appendix B.

- **Organization Chart Service** provides several subordinate services to access organizational structure and resources. This service is mostly invoked at the design time or when a process is instantiated, by a process designer or an administration tool with the functionality of URB, for the actual binding of endpoints of target resources.

- **Resolution Service** enables service requestors to select resources dynamically with the Resource Query Language (RQL). This service returns the endpoint of proper AWQS according to the input query, which can be dynamically built according to the flow of process instance. XML-based string manipulation expressions, e.g. 'XPath' [10], can be used to build changeable RQL statements automatically.

- **Work Coordination Service** enables service requestors to reserve, order, cancel, and modify work items to the target resources. It also provides the runtime-state information of started tasks and reservations. The service requestor may call the AWQS direct through the endpoints of each workflow resource. But this direct access to resources may cause security problems and is restrictively to be used only inside an enterprise. On the other hand, the service requestor may call the OWQS and the corresponding OWQS delegates the work order to the final AWQS. This delegated work coordination provides better security management in the form of an intermediary server.

- **Event Service** enables service requestors to subscribe and listen to the events of interested resources, tasks, or changes in the organization. This service allows the service requestors to browse the list of events of the objects and subscribe to the event with the event key. Task related events, like a work is reserved or queued, are notified to the corresponding service requestor without subscription.

- **Universal Discovery Support** URMF requires each WQS instance to have its own address of web service endpoint URI. With this universal addressing, each resource in URMF can be registered to and discovered by the UDDI directory. By utilizing some taxonomy of role keys at WQS registration, resource searching can be further enhanced.

#### 4.4. Web service based workflow interface model with URMF

Fig. 4 illustrates the substitutive workflow interface

model, modified from [30], employing URMF and underlying web services architecture. Each interface 1 through 5 is mapped with corresponding Web services standards. Each component in the interface model takes advantage of the Web services infrastructure such as universal discovery, transaction management, or security management. In this way, the URMF architecture offers workflow resource management capabilities in a standard way according to the evolving Web services specifications.

Web service composition languages (WSCL), like BPEL4WS [3], conform to the web service architecture and can be extended to describe resources by URMF. Interface 1 in our model (*IF1* in Fig. 4) focuses on the import and export of process definitions in WSCLs. In our interface model, web service interface AWQS substitute worklists of each end-user (*IF2*) or the non-human resources like software agents (*IF3*). Sharing URMF-conformed resources, with other workflow engines, provides a way of enhancing interoperability (*IF4*).

Finally, the Universal Role Binder (URB), a GUI tool of URMF, interacts with process designer, administration/monitoring tool, and work queue services. URB supports end-users in searching and binding the resources in the way of web service as shown in Fig. 4.

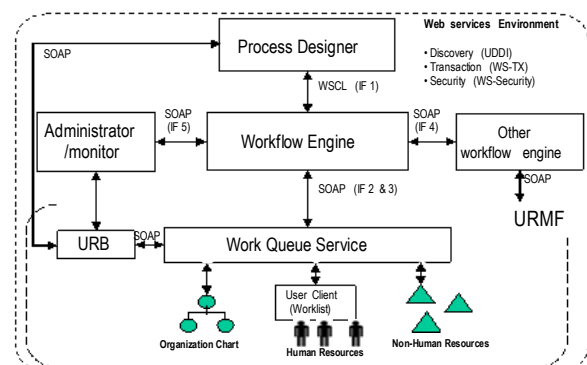

Fig. 4. Web Service based workflow interface model with URMF

As illustrated in Fig. 4, URMF complements the resource management facility of Web services environment. Since the interfaces and the tool declared in URMF extract and provide the resource management functionalities, the efforts of design and implementation on this part are relieved when to expose workflow resources as web services. In next section, a prototype implementation model of exposing workflow resources as web services with URMF is introduced.

#### 5. PROTOTYPE IMPLEMENTATION MODEL

In this section, we show an example implementation model of URMF and how the web service requests are processed by the implemented system. Two suggestions for the realization of universal discovery support in

URMF are also presented.

Fig. 5 illustrates the system architecture of the prototype implementation model. For better management of reliability, security, and scalability, we adopted one of the most concurrent technologies, i.e. J2EE platform [28]. The interfaces and components to support URMF are managed by the application server, and intermediate the service requestors and the workflow resources of service providers. Service requests in the form of web service invocations are received at the two interfaces (AWQS and OWQS), processed at the corresponding components, and provided with low-level access to the adequate resources. More detailed descriptions of the major components in the implemented model are provided.

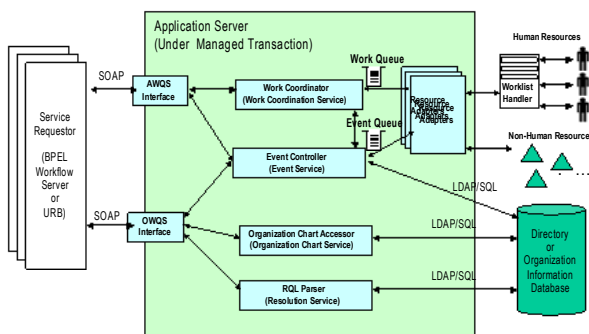

Fig. 5. System architecture of the prototype URMF Implementation

#### • Work Coordinator

*Work Coordinator* processes the requests of reserving, queuing, canceling and modifying work items from AWQS interfaces. For the reliable management of work requests, MQM (message queuing middleware) and managed-transaction of J2EE platform are adopted ([27], [28]). Each work order or work reservation is queued into the message queue named 'WorkQueue' and is ensured to be properly processed. The *resource adapters* let the work requests be uniformly processed at the heterogeneous system resources. *Worklist handler* provides a user interface for end users to handle workitems with adequate tools.

#### • Event Controller

*Event Controller* manages the subscription and notification of events. Event Controller listens to the events of interested resources, tasks, or organization changes. Each event fired from other components is queued into the message queue named 'EventQueue'. Event Controller distributes them to the subscribed service requestors (URB or WSWE). Task related events, e.g., 'onResult' or 'onReservationResult' of appendix A, are notified to the corresponding service requestor even without subscription.

#### • Organization Chart Accessor

*Organization Chart Accessor* processes the requests for accessing organizational structure or belonging resources on behalf of the *organization chart services* of

WQS interfaces. Each request is processed by accessing the directory services through LDAP [18] or the organization information database through SQL.

#### • RQL Parser

*RQL Parser* executes the requests for the endpoint of eligible resource (WQS) on behalf of *resource resolution services* of OWQS. The inquiry RQL statements are parsed and dispatched through LDAP or SQL.

#### • Universal discovery support

Web services are discoverable by their own nature. To be discovered by UDDI, WQS of each resource needs unique address and categories. Two suggestions to handle these issues are described.

**WQS endpoint (URI) addressing:** WQS of each resource in an organization needs a unique address, i.e. endpoint URI. Fig. 6 shows the suggested endpoint addressing policy for WQS. It is similar with e-mail addressing but contains more organizational information, i.e. names of department, branch or company as well as and user id.

Fig. 6. Suggested WQS endpoint (URI) addressing

**Role-based Taxonomy:** Mutually aware taxonomies are needed to search for adequate web services through UDDI. We suggest employing role-based taxonomy to be utilized in searching for adequate WQS of a resource. Utilizing role-based taxonomy, WQS of adequate human resources with required role or skill could be searched from UDDI servers.

Fig. 7 illustrates the suggested mechanism of universal discovery support, which allows each organization or person to advertise itself, as a resource, over the Web service world.

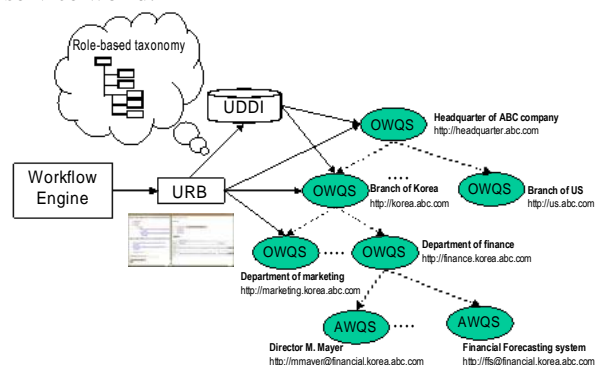

Fig. 7. Suggested mechanism of universal discovery support

## 6. CONCLUDING REMARKS

Organizational elements, such as organization chart, roles, and worklists for human or non-human agents, play important roles in executing business processes [1]. For the successful realization of web service based workflow management, a sound management of these elements should be provided. However, there is no

robust standard to expose and access workflow resources by Web service interfaces. In this paper, we proposed a web service based workflow resource management framework named *Universal Resource Management Framework* (URMF) with declarations of web service interfaces and interaction protocols among them. We also introduced a substitutive workflow interface model employing Web services and URMF, where each component of the model can take advantage of Web services infrastructure. To validate the viability of the suggested framework, a prototype implementation model of URMF with J2EE platform is also introduced. In this way, management of business processes composed of Web services is empowered great with the support of URMF in managing organizational resource.

Our framework is fully based on the service-oriented architecture (SOA) [20]. The resources, especially human resources, conforming to URMF are universally interoperable and discoverable as web services, and can be flexibly coordinated in the way of Web services standards. Loosely coupled and coarse-grained URMF interfaces, by the generic organization model and resolving resources with the encapsulation of the entire organizational model, features minimal technical requirements for the implementation.

Some of important issues related with the Web services environment are not dealt in this paper and left as further studies. First, Non-authorized work request or access to the organization should be prohibited. Since URMF is based on Web services, Web services security technologies may leverage the security of our framework. The SSL certificates with HTTPS or WS-Security [17] are examples of those technologies. Some access control mechanism may be applied to the URMF at the interface or operation level. For instance, OWQS can act as an intermediary server for security and provide an access control mechanism based on the service requestor or information requested. Second, an adequate business transaction mechanism to handle long-lived activities should be supported with URMF. To minimize latency of access, for other potential users, to the resources used by such activities, the results of interim operations need to be released before they are completed. URMF needs to be enhanced by applying such frameworks for transaction management, like WS-Transaction [4] or WS-CAF [2], which coordinates the execution of distributed operations in a Web services environment.

#### APPENDIX A. SERVICE DESCRIPTIONS OF URMF ENTITIES

**Table A1.** Service description of AWQS

Service Type	Service Name	Input & Output
Work Coordination Service	reserveWork	I: Role Key, Reply Endpoint, Expected Order Date, Due Date; O: Task (Reservation) Key
	orderReservedWork	I: Task (Reservation) Key, Parameter (any type); O: Task Key
	orderWork	I: Role Key, Reply Endpoint, Due Date, Parameter (any type); O: Task Key
	cancelWork	I: Task Key, Reason; O: None
	modifyWork	I: Task Key, Due Date, Parameter (any type); O: None
	modifyReservedWork	I: Task Key, Expected Order Date, Due Date; O: None
	getTaskInfo	I: Task Key; O: Task Information
Event Service	subscribeEvent	I: Event Type, Reply Endpoint, Duration; O: Event Key
Organization Chart Service	getInfo	I: None; O: Resource information

**Table A2.** Service description of OWQS\*

Service Type	Service Name	Input & Output
Organization Chart Service	getChildOrganizations	I: None; O: Endpoints of child OWQS's
	getParentOrganization	I: None; O: Endpoint of the parent OWQS
	getAgents	I: None; O: Endpoints of child AWQS's
	getRoleKeys	I: None; O: List of all the role keys the organization resources can play
Resolution Service	getProperPerformer	I: RQL Statement; O: Endpoint of the resolved WQS
Resolution Service + Work Coordination Service	reserveWorkProperPerformer	I: RQL Statement, Reply Endpoint, Expected Order Date, Due Date; O: Task (Reservation) Key
	orderWorkProperPerformer	I: RQL Statement, Allocation Policy, Reply Endpoint, Due Date, Parameter (any type); O: Task Key

\* Basically, OWQS inherits all the operations of AWQS as described in 4.2.

**Table A3.** Service description of WSWE

Service Type	Service Name	Input & Output
Event Service	onResult	I: Task Key, Result of work (any type); O: None
	onReservationResult	I: Task (Reservation) Key, Result of reservation; O: None
	onEvent	I: Event Type, Event Context; O: None

#### APPENDIX B. AN EXAMPLE BPEL4WS CODE EMPLOYING URMF

The following BPEL4WS code illustrates how the human resources can be dynamically selected and bound with URMF. The code describes parts of the trouble ticket process<sup>1</sup>, where each problem instance is recorded with human

<sup>1</sup> The trouble ticket scenario by OMG [29] is provided for the purpose of evaluating workflow facilities in the perspective of human intervention.

intervention. The process is initiated by the former “receive” activity, which receives the endpoint of the OWQS of the organization in charge of the given problem instance. Based on the request, the “assign” activity builds a RQL statement of inquiring eligible resource and set parameters for the invocation of corresponding WQS. The “invoke activity” calls the interface (**orderWorkProperPerformer** in this example) of the WQS for the resolution and assignment of this workitem. Actual selection and binding of the proper human resource (i.e. queuing the workitem in the corresponding worklist) is executed by the *resource resolution service* and the *work coordination service* of WQS. The latter “receive” activity waits for the result performed by the AWQS of actually assigned human resource.

# A Comparative Analysis of International and Chinese Electronic Commerce Research

Junyong Xiang, Jaekyeong Kim, Hyouk O

School of Business Administration, Kyung Hee University, Seoul, 130-701, Korea  
gysang@yahoo.com, jaek@khu.ac.kr, cuteing@gmail.com

## ABSTRACT

Due to the growth of the Internet and e-commerce, both practitioners and researchers are in the midst of a social, business and culture revolution. Internet and e-commerce related research has been developed and grown up by United States, but China has become one of the most exciting research areas. This literature review consists of 1044 journal articles published between 1993 and 2003 in fourteen International and Chinese journals. The articles are classified by a scheme that consists of four main categories: application areas, technological issues, support and implementation and others. Based on the classification and analysis of e-commerce related researches, we present the current state of International and Chinese research and discuss the differences between them.

**Keywords:** *e-commerce, classification of e-commerce, literature review, comparative research*

## 1. INTRODUCTION

With the development of Globalization and IT, business and organization are radically changing. In contrast with the weak performance of several key developed and developing economies in recent years, e-commerce have continued to grow at a fast pace. The United States and European countries leading in IT and e-commerce have experienced impressive GDP growth since 1995. This output expansion has been characterized by acceleration in productivity growth, very low unemployment rates, low inflation rates and a reduction of fiscal deficits. With the booming Chinese economy, WTO accession and 2008 Beijing Olympics, China's e-commerce is also experiencing a fast development period and is becoming a new driving force for the economic development. Therefore, it is very meaningful and interesting to compare the state of International and Chinese research on e-commerce.

Ngai and Wat [3] introduced a classification framework of topics in e-commerce that consists of four main categories: application areas, technological issues, support and implementation and others. They classified the e-commerce research published in international journals between 1993 and 1999. Their classification framework was eventually adopted in this research.

This paper presents a comprehensive review, classifies the literature of International and Chinese e-commerce research published between 1993 and 2003. The scheme we used represents our views of the e-commerce literature that point out the distinguishing features of this area. A classification of e-commerce research reveals that there has been an approximately exponential growth in the number and area of published articles. The current state and direction of research topics should be of interest to researchers and practitioners.

## 2. CLASSIFICATION SCHEME OF E-COMMERCE RESEARCH

### 2.1 Research Paper Collection

According to Zwass [7], the first popular Web browser, NCSA Mosaic was introduced in 1993 and it brought people and businesses to the Web. Therefore, we believe that this year may be considered to be the starting point of e-commerce.

We exclude conference proceeding papers, master's theses, doctoral dissertations, textbooks, and unpublished working papers. We believe that academics and practitioners alike use journals most often for acquiring information and disseminating new findings and represent the highest level of research. Then we analyze articles published in International and Chinese journals between 1993 and 2003.

All journals lie in areas of Management Science and IS. Based on existing researches [4,6], the list of Chinese Social Sciences Citation Index (CSSCI) and Chinese Science Citation Database (CSCD) and a review of most of the journals, fourteen journals are selected.

Seven International journals were selected in this study, namely: Communication of the ACM, Decision Support Systems, Electronic Commerce Research and Applications, Information & Management, International Journal of Electronic Commerce, Journal of Management Information Systems, and Journal of Organizational Computing and Electronic Commerce. Seven Chinese journals were selected in this study, namely: Journal of Management Science, China Soft Science Magazine, Science of Science and Management of S. & T., East China Economic Management, Modernization of Management, Journal of Industrial Engineering and Engineering Management, and Computer Engineering and Applications.

Online databases search were conducted. For International journals' databases, we used ABI/INFORM Global (<http://www.il.proquest.com/proquest>), Science Direct (<http://www.sciencedirect.com>) and the ACM Digital Library (<http://portal.acm.org>). And we used China National Knowledge Infrastructure (CNKI) Digital Library (<http://www.cnki.net>) as Chinese journals databases.

The literature search was based on four descriptors: "EDI", "Electronic Commerce (E-Commerce)", "Electronic Business (E-Business)" and "Internet Commerce"[3] related to e-commerce, we reviewed the full text of each article. As a result of our search, we identified 1044 e-commerce articles. Although this

search was not exhaustive because of some limitations, such as online Database update time, it served as a comprehensive base for an understanding of e-commerce research.

## 2.2 Classification of Topics in Electronic Commerce

The classification framework was based on the literature review, the nature of e-commerce research, the works of [2,5] and existing classification schemes of IS [1] (Figure 1). The articles were classified into four broad categories: (i) applications, (ii) technological issues, (iii) support and implementation and (iv) others; and each were divided into subcategories.

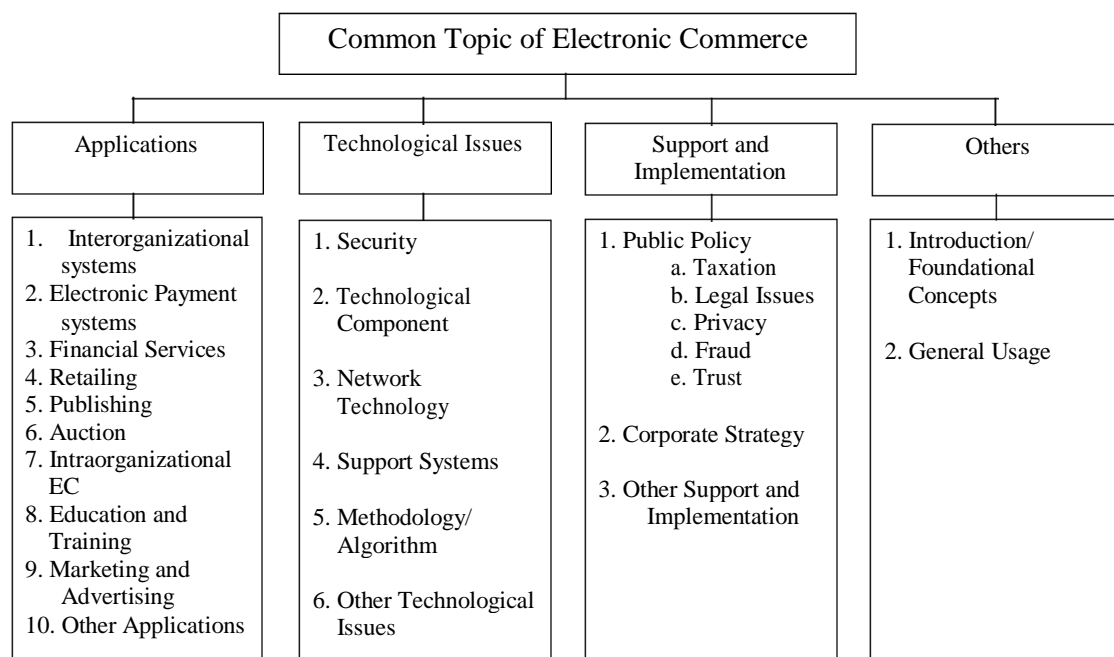

Figure 1. Classification of topics in electronic commerce.

**Applications:** This category covers literature on e-commerce research related to interorganizational systems (IOS), electronic payment systems (EPS), financial services, retailing, online publishing, auctions, intraorganizational EC, education and training, marketing and advertising, and other applications. IOS are automated information systems shared by more than one organization and allowing information flow across organizational boundaries. They include electronic data interchange (EDI), supply chain management (SCM), electronic funds transfer (EFT), electronic forms, electronic messaging and shared databases. EPS cover systems for online financial exchange between buyers and sellers. For examples, electronic or digital cash, electronic checks, online credit card-based systems, and other emerging financial instruments, such as debit cards, electronic benefit transfer cards, and smart cards. Financial services cover the common financial services provided in e-commerce. Retailing contains various publications associated with topics of retailing in

e-commerce, including online and electronic shopping malls. Online publishing contains publications that relate to electronic delivery of newspapers, magazines, books, news, music, videos, and other digitizable information through the Internet. Auctions contain published literature related to electronic auctions. Intraorganizational EC deals with helping a company to maintain and support internal business processes between individuals, departments and collaborating organizations. Education and training cover published literature on education or training pertaining to on-line education, virtual classrooms and online universities. Marketing and advertising consist of the application of e-commerce to marketing and advertising, including brand-name management, disseminating product catalogs, and sales information and product announcements. Other applications contain publications that discuss applications that are not among those in the above categories, such as Internet gambling, travel and tourism

service, employment placement and the job market, health care, on-line games, matchmaking, etc.

**Technological issues:** There are six categories pertaining to technological issues: security, technological components, network technology/infrastructure, support systems, algorithm/methodology and other technical issues. Security consists of publications that discuss issues related to data and system security, and individual security. Technological components consist of various Internet technologies, e.g. the common object request broker architecture (COBRA). Furthermore, markup languages, such as hypertext markup language (HTML), and programming languages like JAVA are the common Web software developmental tools. Network technology/infrastructure covers network technology that is at a lower-level, such as early technologies, the local area network (LAN) technology and the wide area network (WAN) technology; network protocols, hypertext transport protocol (HTTP) and transmission control protocol/Internet protocol (TCP/IP); plus network issues, like the shortage of bandwidth, quality of service (QOS). Support systems cover literature on decision support systems, negotiation support system or distributed applications. Algorithm/methodology covers technical algorithms or methodologies that assist, enhance, or improve e-commerce applications. Other technical issues contain publications that discuss other issues such as decision technologies, defense system, and virtual enterprise (organization, marketplace) technology.

**Support and implementation:** The literature in this category can mainly be divided into two broad categories: public policy and corporate strategy. And public policy covers taxation, legal issues, privacy, fraud and trust five subcategories. Taxation issues contain the characterization of the transaction, the source of the transaction, the creation of a permanent establishment from the transaction, transfer pricing implications, and tax administration and compliance. Legal issues include privacy, protecting intellectual property, controlling Internet indecency, preventing fraud, establishing a tax framework, controlling gambling, determining jurisdiction, and protecting both sellers and buyers. The major privacy issues are how to protect privacy and whose responsibility it is to do so. Some literature is related to fraudulent practices in e-commerce, such as online auction fraud, Internet stocks fraud and other fraud. The published literature refers to positive trust that is shown in the consistency and assurance between what a trading partner says and actually does. Corporate strategy covers publications dealing with EC strategies/methodology used in building successful implementations. Other support and implementation contain various publications that are not mentioned in the support and implementation categories, such as modeling the structure of brokered electronic markets.

**Others:** This category contains publications that discuss other aspects of e-commerce, such as a general

introduction to e-commerce, foundational concept of e-commerce, etc.

### 3. RESULTS

#### 3.1 Distribution of the Year of Publication

Notes: Forecast the Figure from November to December of 2003 of China.

Figure 2. Distribution of articles by year.

The distribution of articles published by year is shown in Figure 2 from 1993 to 2003. Although research outputs appear limited, yet the number of journal articles has increased substantially. International e-commerce research generally activated from 1996, and Chinese research generally activated from 1999. When it comes to 2000s, it does not show apparent difference in amount, yet there are still many gaps in width and depth of the research. It will take some time for China to bridge the gaps.

In 1995 e-commerce was just beginning and its potential was not widely recognized. Since then, B2B and B2C e-commerce has skyrocketed. During 1995 and 1999, American economy kept the 4% increase and about 2% inflation rate per year, and the unemployment rate decreased to 4%. The success of the United States made all countries and international organizations take a serious view of e-commerce. Consequently, the international researches on e-commerce were conducted robustly and kept substantial increase until 2000. The bursting of the new economy bubble late in 2000 made the research suffer a setback temporarily. Yet the increase trend is continuing, and the research will enter a new phase and become more active in recent years.

For Chinese research, the most distinguishing feature is the rapid increase speed. China's first move was the initiation of the Golden Projects. The Government initiated the "Government Online" and "Enterprises Go Online" projects in 1999, and it declared the year of 2000 to be the "Year for Chinese Businesses to Go Online". The national informatization program is given high priority in the 10th Five Year Plan (2001 to 2005). During this period, the information industry is expected to become the pillar industry to spur the national economic growth. Furthermore, the China e-commerce Association was established in June 2000. Therefore, China's e-commerce and research develop at a rapid pace while other countries temporarily suffered

stagnation of development. The research reached the peak in 2002 because of the special issue (2002, Vol.4) on e-commerce of China Soft Science Magazine.

### 3.2 Distribution of Articles by Topic

The distribution of articles by topic is shown in Figure 3. It appears that the most heavily published research area is in the “Technological Issues” of EC, all have more than 30% in this area (International—196 articles, 33%; China—166 articles 36%). It also shows that the International research maintains comparative equilibrium in four areas while Chinese research is not comparatively active on Applications.

Figure 3. Distribution of articles by topic.

### 3.3 Distribution of Application Articles

Distribution of Application articles by year is shown in Figure 4. The international research was activated in 1996, and the Chinese research was intensified till the later half of year 1999. Since then, there appears no apparent difference in amount. It also shows that the International research increased rapidly at first, then stagnated for a few years because of the burst of the New Economy Bubble, and began to increase recently with e-commerce's new development. Chinese research kept a fast increase trend with China's e-commerce boom and the rapid rise of economy. Because CNKI had not updated the database during the time of our research, we are short of the data of November and December 2003, therefore it appears a sharp decrease in 2003.

Figure 4. Distribution of Application articles by year.

From the figure of Distribution of applications articles, we can know that a large amount of this area is based on the IOS (International—52 articles, 30.8%; China—26 articles 26.5%), of which the majority is EDI systems. This is followed by topic on EC retailing

(International—30 articles, 17.8%; China—10 articles 10.2%), marketing and advertising (International—20 articles, 11.8%; China—22 articles 22.4%). Education and Training, Financial service and Auction also has increased greatly, such as the International research on Auction is 10.7% (18 articles). We can also know that International research has much more articles on IOS, retailing and auctions while Chinese research has the more on marketing and advertisements.

Figure 5. Distribution of Application articles.

### 3.4 Distribution of Technological Issues Articles

As shown in Figure 6, the research on Technological Issues is always increasing from the very beginning. This area has not been influenced by the Nasdaq Bubble generally, although the International research decreased in 2001 temporarily.

Figure 6. Distribution of technological issues articles by year.

From Figure 7, we can know that Support System is the very significant part for International (47 articles, 24.6%), and Chinese (46 articles, 27.7%) research. International research on technological component (54 articles, 28.3%) and Methodology/Algorithm (42 articles, 22%) is much more than Chinese researches. And Chinese research also has more articles on security (40 articles, 24.1%) than International researches. We can also know that Chinese research is very diverse in the area recently, and some researches are not limited to classification, therefore the research on others (39 articles, 23.5%) has a large percentage.

Figure 7. Distribution of technological issues articles.

### 3.5 Distribution of Support and Implementation Articles

As shown in Figure 8, the research on Support and Implementation is always increasing with a small range from the beginning. After the burst of dot.com bubble, Chinese enterprises and researchers are trying to find the right corporate strategy and business model that are suitable to the conditions of China. As a result, support and implementation became a matter of concern and interest, and journals published heavily on this part. At the end of 2002, research on this part had been completely conducted to some extent. Advanced research is difficult to be conducted until the research on other part of e-commerce, such as new technology. Also because of the inexhaustive data of 2003, the curve reached its flattest level in 2000s.

Figure 8. Distribution of support and implementation articles by year.

From Figure 9, we can know that Corporate Strategy is the most important part for International (51 articles, 45.5%), and Chinese (71 articles, 63.4%) research. E-commerce business strategy has to be re-created constantly in the ever-evolving world of cyberspace. For each enterprise, questions exist about how to develop the new business models, market strategy, what to do first, what to do next, and how to proceed. The answers are not always intuitive, and may not be reached the first time out. Therefore corporate strategy is always the focus of this part. International research on trust (31 articles, 27.7%) is skyrocketing recently, yet Chinese research still has no article on this area. Chinese research has much more research on taxation and legal issues than International research. On the other hand, it has no research on privacy, fraud, and trust.

Figure 9. Distribution of support and implementation articles.

### 3.6 Distribution of Others Articles

As shown in Figure 10, the research on others is increasing from the beginning. And the research became inactive between 1998 and 2000.

Figure 10. Distribution of others articles by year.

With the development of e-commerce, new concept, technology, and business model come up continually. International (73 articles, 64.6%) research on general introduction or about the foundation of e-commerce is more than general usage while Chinese research shows no apparent difference.

Figure 11. Distribution of others articles.

### 3.7 Distribution of International Articles

As shown in Figure 12, the International research increased from the beginning and Application was the most heavily published area. From 1999, research on Technological Issues ranked first and was followed by the research in the Application of e-commerce. The development and advance of technology made it impossible for e-commerce to appear and develop. E-commerce expanded its scope to more areas and showed the great impact to business and life, the research on applications had been heavily published during 1996 and 1999. Dot com and venture boom made e-commerce reach the peak and the progress of e-commerce also

required more technologies. Because of this business requirement, research on technological issues has become the focus of e-commerce research from 1999.

Figure 12. Distribution of International Articles

### 3.8 Distribution of Chinese Articles

From the figure of Distribution of Chinese articles by topic and year, we can know that although the research began later than International research, it advances more actively. The most distinguishing feature is that the research on Support and Implementation becomes more active than others. And the research on Technological Issues has ranked first from 2001 while the research on Application is inactive. The research on application is conducted comparatively less than International research; it might be the reason that the areas of application of e-commerce in China are not less widely. In order to activate the e-commerce development, it is necessary to conduct the researches on application much more widely and deeply.

Figure 13. Distribution of Chinese articles

## 4. CONCLUSIONS

In our research, we reviewed fourteen International and Chinese journals and identified that 1,044 articles published between 1993 and 2003 are related to e-commerce. Although this review cannot claim to be exhaustive, it does provide reasonable insights into e-commerce. We can also get some important conclusions and implications through the comparative analysis of International and Chinese e-commerce research.

1. The e-commerce research will increase significantly in future although it might receive the influence of economic environment and other factors, because e-commerce will continue to grow at a fast pace and it

has become an important focus of public, researchers, governments, and international organizations etc.

2. Research has a close connection with the development of e-commerce. The business requirement and development of e-commerce can push the research; on the other hand, the research also can pull the e-commerce's development. The International and Chinese research and e-commerce have begun to activate with a remarkable interval. The International research and e-commerce activated from 1996, while Chinese research and e-commerce activated from later half of 1999.

3. In application area, the percentage of research on IOS keeps a decreasing trend while research on retailing, auction marketing and advertisement is increasing. This area will be more active and divers in the future with the development of online and mobile financial services, payment systems, and education.

4. Research on public policy needs much more concern. And new methods or standards should be developed for coping with problems in this area. There were not many public policy articles related to taxation, legal issue, privacy, and fraud. However, the research on trust has become a significant research area in e-commerce. And Chinese also started to conduct research on this area.

5. The differences between International and Chinese research can show the variness among e-commerce development phase, culture, and regional factors etc. to some extent.

6. China has less research on application, and it has already become obstacle for e-commerce. In order to activate the e-commerce, more researches are demanded to be done on these areas.

All reviewed articles that correspond to the classification scheme can be found at author's web site. <http://jaek.khu.ac.kr/bbs/articlebbs>.

# A Conceptual Framework for E-tailing Quality and Its Evaluation

Jing Wang, Zhenquan Sha, Haiyuan Wang

School of Business Administration, South China University of Technology, Guangzhou 510640, China  
wjchris@126.com

## ABSTRACT

The Internet's influence in creating e-services has been revolutionary for retailer. Clearly, The Internet is fast becoming an important new channel for businesses in retailing, raising e-services as the emergent business paradigm in the industrialized world. Unfortunately, past research on measuring e-tailing quality is scarce. This paper provides a conceptual framework for e-tailing quality and discusses its evaluation. First, we summarize the main previous literature about service quality and e-service quality. Second, three analytical dimensions are identified: website quality, action quality and result quality, and each has its sub-dimensions. Each has different influence degree. Finally, we analyzing the evaluation way by comparing the online shoppers' perceived and expectation e-service. Future recommendations are also offered.

**Keywords:** E-tailing quality, E-service quality, E-service

## 1. INTRODUCTION

Since the 1960s, the Internet has been around, it was only a decade ago that the World Wide Web was born as a second segment of cyberspace. Undoubtedly, the digital revolution has changed almost every aspect of people's daily life, especially as stepping into the twenty-first century. In order to satisfy customers' sophisticated needs, many companies have set up their own web sites providing quality information and services to customers. When e-tailing was in its infancy, Web presence and low price were believed to be the drivers of success.

E-services, according to Roth [1], "are comprised of all interactive services that are delivered on the Internet using advanced telecommunications, information, and multimedia technologies." E-services are important in B2C e-commerce because they represent ways to provide on-demand solutions to customers strengthening the relations between customer and service provider, creating transactional efficiencies and improving customer satisfaction (Ruyter et al., 2001). While e-services are convenient and create efficiencies for their users, little is understood about how consumers evaluate them in operation and what are the important facts for customer choosing the E-services.

It is argued that better service quality can create better customer satisfaction (Zeithaml, Parasuraman and Malhotra, 2002). Consumers will satisfy or dissatisfy to a certain extent with the service, and will make the corresponding quality evaluation. This kind appraisal of service quality is actually a range degree function of quality between the consumer expectations and what they really get. However, according to an investigation [2], only 36% of the online shoppers are satisfied with their experience, and up to 28% of the online trade is end in failure, which prove the E-service Quality has already become one of the most important factors that

restrict customer to buy again. Nowadays, superior service quality has entered the picture as a differentiating strategy (Zeithaml, Parasuraman and Malhotra, 2002).

One of the main method for the website to be different from others, is to offer the higher service quality than its rival's. And the key is the service quality can satisfy the customer or exceed their expectations. In e-commerce, enterprises are unable to carry on the face-to-face communication with the customer, and almost all are offered through the website, here, it is impossible to carry on the proper adjustment by utilizing the feedback which through the oral communication with consumer even the physique language. In this case, it is very essential to understand the E-service Quality and how to evaluate.

## 2. LITERATURE REVIEW

Service quality has been recognized as an important strategic retailing weapon [3]. The most widely approach used to conceptualizing and measuring service quality has been developed by Parasuraman et al. (1985). Service quality has been defined as a form of attitude, related but not equivalent to the construct of satisfaction, which results from the customer's perception of service in relation to his or her expectations of service disconfirmation paradigm [4]. They also identify five dimensions of service quality and develop SERVQUAL, an instrument to measure customers' perceptions of Service quality [5]. The dimensionality and reliability of SERVQUAL has been the subject of many subsequent studies (e.g. Carman, 1990; Cronin and Taylor, 1992; Babakus and Boller, 1992; Cronin and Taylor, 1994; Parasuraman et al., 1994; Fischer and O'Bryan, 1995; Licata, Mowen and Chakraborty, 1995; Siu and Cheung, 1999, 2001; Siu and Woo, 1997 and 1999).

Study	Focus	Dimension
Berry, et al. (1988) and Parasuraman, et al. (1985, 1988)	Service quality	Tangibles; Reliability; Responsiveness; Communication; Credibility; Security; Competence; Courtesy; Understanding/knowing the customer; Accessibility
Parasuraman, Zeithaml and Berry (1988, 1991)	SERVQUAL	Reliability; Responsiveness; Assurance; Empathy; Tangibles
Harvey (1998) [7]	Service quality	Quality of actual results; Process to achieve those results (Consists of both technical and perceptual aspects)
Kaynama, Black (2000) [8]	Modifying SERVQUAL in travel industry	Responsiveness; Content and purpose; Accessibility; Navigation; Design and presentation; Background; Personalization and customization
Zeithaml, Parasuraman and Malhotra (2000, 2002)	E-SERVQUAL	Efficiency; Reliability; Fulfillment; Privacy; Responsiveness; Compensation; Contact
Li et al. (2002) [9]	E-SERVQUAL	Responsiveness; Competence; Quality of information; Empathy; Web assistance; Call-back systems
Yang, Peterson and Huang (2001) [10]	E-service quality	Ease of use; Content displayed on the Web site; Accuracy of content; Timeliness of response; Aesthetics; Privacy
Lociacono, Watson and Goodhue (2000) [11]	WEBQUAL	Informational fit to task; Interaction; Trust; Response time; Design; Intuitiveness; Visual appeal; Innovativeness; Flow (emotional appeal); Integrated communication; Business processes; Substitutability
Yoo & Donthu, (2001) [12]	SITEQUAL	Ease of use; Aesthetic design; Processing speed; Security
Wolfenbarger and Gilly (2002) [13]	. comQ	Web site design; Reliability; Privacy/security; Customer service

Figure 1: Comparison of Previous Studies

Superior service quality is widely acknowledged as a driver of perceived value, which, in turn, will enhance customer loyalty (Parasuraman and Grewal, 2000) and improve the provider's image, sales and profitability (Buzzell and Gale, 1987; Gummesson, 1993). Therefore, the study on service quality has been focus on in many studies of various industries. While the e-business has

become a grown-up point of new economy, the research on Service quality have been combine with the e-commerce. Based on the previous studies, Zeithaml et al. (2000, 2002) developed the new concept E-service quality and used the e- SERVQUAL to measure it to study how customers judge e-service quality.

E-service quality is defined as seven dimensions: efficiency, reliability, fulfillment, privacy, responsiveness, compensation and contact, which form two scales: a core e-serve quality scale and a recovery scale [6]. The first four dimensions are classified as the core service scale, and the latter three dimensions are regarded as a recovery scale, since they are only salient when online customers have questions or problems.

Although the development of e-service quality notion and measurements is at an early stage, the studies on this field have developed fast and varied in the evaluation way. **Figure 1** has shown this concept developing process and summarized the main ideas.

### 3. DEVELOPING A CONCEPTUAL E-TAILING QUALITY FRAMEWORK

E-service quality has so wide range of all operation in e-commerce, including e-tailing, but the existing

literature is not yet rich enough to provide a conceptual foundation of e-tailing quality and because of that, it was required to develop an understanding of the detailed determinants in e-tailing quality and their impact on consumer attitude.

After extensive literature review, we develop the E-tailing quality framework to enrich the Web-oriented studies. Gronroos (1990) had proposed the concept of perceived service quality, and it depends the comparison between customers' expectation and the perceive service level in service quality. In addition, he divided service quality into "technical quality" and "functional quality" [14]. Here, we use his conceptualization of technical and functional quality for reference, combining the E-SERVQUAL and .comQ. All the literature led to the development of the conceptual model of e-tailing quality, which is displayed below as **figure 2**.

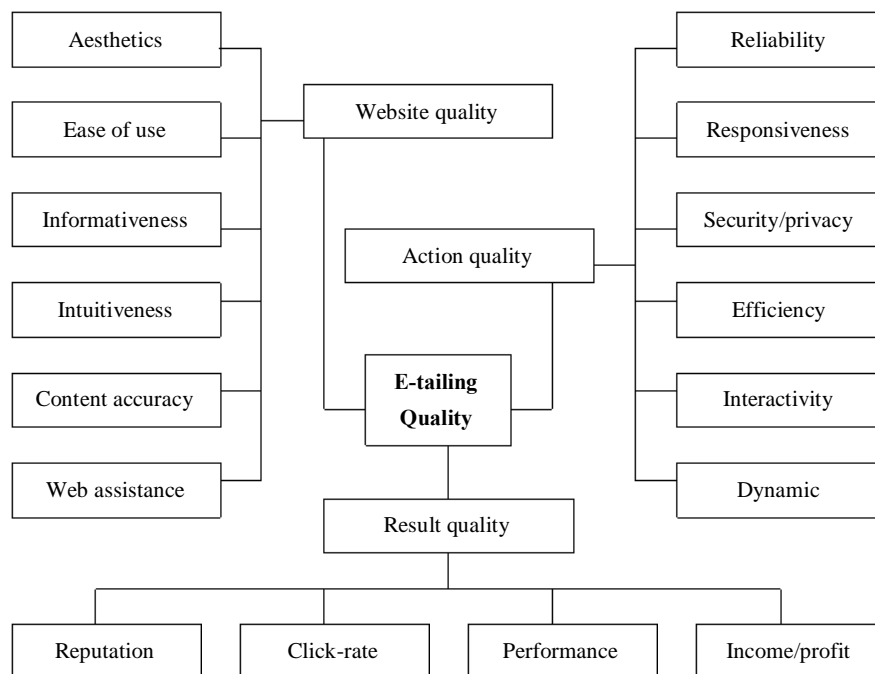

Figure2: E-tailing Quality Model

The quality of a web-based retail service depends on the perceived quality of the process of using the web for purchasing as well as the perceived quality of the outcome. E-tailing quality can be evaluated through three sections: website, action and result. Every section has serial dimensions. Website quality is mainly about the website design and customers' perception of the interactions that happen during their online-shopping. Action dimension deals with the process or the way in which service is delivered, and is main contributors of consumers' willingness to buy. That is, it reflects the outcome of the service or what is received. Result quality defines as the e-tailer image and quality. This integration may help identify the relationship between e-tailing quality and willingness to buy on-line.

The website quality is a basic factor, which means is a go without saying function, so customer can get the request out of clearly, even not consider. If customer satisfies with it, it may not improve their satisfaction obviously. If the website can't satisfy them, customer may give up the online-shopping. Therefore, it is one of the importance competition factors. The action quality is an expecting factor, which the more realize in the online service, the more satisfied the customer is. When missing these demands, the customer is unsatisfied. Through offering it, the customer's perceived value of service can be improved, furthermore, improve the customer's loyalty. The result quality is a factor usually be neglected. The quality of the result e-tailer get can greatly affect the customer's perceived service quality. But all above isn't

absolute; it will change in different e-tailing product or service.

In the practical operation, it can evaluate the e-tailing quality according to measuring the consumer's expectation and perceived service. But the disparity between the actual and expecting e-service quality does not shape simply, instead, it finally forms by many kinds of disparity in the practices. Using the e-tailing quality model, reasons can be found when there are problems in e-service quality, and the proper method to narrow various kinds of disparity can be known, which offer the theoretical foundation for the e-tailer making the strategy and tactics of improving the consumer's perceived service quality.

The proposed model employs ETQ as the whole service quality in e-tailing,  $P_{ji}$  as the point of perceived service quality the  $i$  dimension get in the  $j$  section,  $E_{ji}$  as the point of expectation service quality the  $i$  dimension get in the  $j$  section,  $W_j$  as the weight of each section,  $W_i$  as the weight of each dimension, then as following:

$$ETQ = \sum_{j=1}^3 w_j \sum_{i=1}^n w_i (P_{ji} - E_{ji})$$

If more than one consumer give the evolutions, the average point can be used ( $N$  means the number of the sample):

$$AVETQ = \frac{\sum_{j=1}^3 w_j \sum_{i=1}^n w_i (P_{ji} - E_{ji})}{N}$$

What we need is the comparison between ETQ or AVETQ and 0, which is the comparison between the perceived e-service quality and the expectation.

#### 4. CONCLUSION

In conclusion, this article proposes a e-tailing quality model based on the previous literature and the method to evaluate it. The objective of this article has been to present some preliminary frameworks for analyzing e-tailing quality, and the frameworks presented help clarify the discuss. The models of e-tailing quality consist of three section: website quality, action quality and result quality. Each section has its dimensions. It provide ways to understand the affected factors in e-tailing service, and what is leading to the success. In order to construct the model, a careful review of previous studies has been operated.

However, there are numerous existing questions that require further inquiry in order to get best practices. The determined factors of e-tailing quality are changing under the e-business environment, and the customer's appraisal on e-tailing quality will be different as the kind and the characteristic of e-tailing are different either. How great degree can this three section and each

dimensions can reflect customer's expectation in ETQ, which factor is more important, whether there are other factors can affect ETQ, all are questions needed studying further.

## A Multi-Agent System for E-Business Processes Monitoring in a Web-Based Environment

Xinyu Zhao, Cen Wu, Runjie Zhang, Chen Zhao, Zuoquan Lin

Department of Information Science, Peking University, Beijing 100871, China  
{xinyua, wucen, zrj, zchen, lz}@is.pku.edu.cn

### ABSTRACT

In this paper, we present a multi-agent system MAGS for the e-business processes monitoring in a web-based environment. We classify the types of agents in MAGS by their monitoring capabilities. An algorithm is given to explain the mechanism of supervising and controlling the execution of business processes. An abstract model of alerts, which can give warnings of infringement on business policies, is proposed. Access control can also be realized by MAGS, which manifests in delivering different view of the business process to different roles participate in it. Being successfully adopted in a customer service management system, MAGS has been proven flexible and practical.

**Keywords:** Business Processes Monitoring, BDI, Agent, Capability, Web Services

### 1. INTRODUCTION

A trend of e-Business is to wrap legacy applications with web services technologies, by allowing enterprises to integrate internal existing processes with the trading partners' in a manageable manner. As such, a business process specifies a potential execution order of operations from a collection of web services involving multiple organizations. With the number of complex business processes increasing, automated monitoring technology is in great demand. However, the traditional passive, centralized business process management system is not applicable for fully distributed applications in a web-based environment. For example, without initiative supporting and monitoring, it is hard to response timely and accurately to numerous events from other applications inside and outside the enterprise. Moreover, the detailed information about distributed business processes should be gathered by the requirements of different users and the relationships with the particular business process instances. Nowadays most traditional systems can not deal with the above issues well.

Software agent is an object which has autonomous actions of accomplishing specific task [1]. In multi-agent system, an agent interacts with other agents or environments to achieve its goal by communication, coordination and cooperation. Of various agent architectures which have been presented, BDI model [2] [3] [4], is probably the most mature and has been adopted in a number of research and industrial applications. There are some works introducing multi-agent into the execution monitoring of business processes [5] [6] [7]. The rationale-based monitors [5] aim at planning and removing the conventional assumptions in static and determinate. Classifications of monitors are proposed to suggest plan transformations. Execution Assistants [6] is implemented to assist human in monitoring robots' behaviors. A top-level categorization of alerts is presented, but the next lower

level of the ontology is not provided. Execution Assistants emphasize the VOI (Value Of Information) and VOA (Value Of Alerts) and analyses the relationships between the two domains. Continuous Planning and Execution Framework [7] defines a monitor to be an event-response rule. Taxonomy of monitor classes derived from the types of events is believed to enable simpler and more modular specifications of monitors. Considering in the new web environments, in which multiple services and applications interact with each other, richer monitoring capabilities, such as alert technology and access control, are in demand for the monitoring management of the business processes.

This paper presents a multi-agent system MAGS (*Monitoring AGent System*) for the monitoring management of the business processes in a web-based environment. Conventional BDI agent model is extended to BDIC (Belief, Desire, Intention and Capability) model with monitoring capabilities, which are induced from a real application. MAGS is assigned to supervise and control the business processes following the profile of requirements of administrators. Also, MAGS is able to continually monitor the incoming system events, and then carry out alerts to the corresponding service providers accurately and timely via multiple channels. MAGS is able to cooperate with other agents to get the role of the users involved in the business process instance and give the detailed information about the instance. We will demonstrate how the implemented MAGS is integrated in a customer service management (CSM) system and show some of its novel features.

This paper is organized as follows. In Section 2, an example drawn from a distributed call center is depicted to show our motivation throughout this paper. Section 3 presents the architecture of MAGS and the BDIC agent model. In Section 4 the implementations of MAGS are discussed. Finally, conclusions are drawn and future works are discussed in the concluding section.

## 2. MOTIVATING EXAMPLE

We will illustrate our motivations with a distributed call center example. Internet-Enabled Customer Services [8] have become the most important channel, through which customers can talk directly to the corporations. Customers can call and state their requests to the distribution corporation. When the call center receives a call from a customer, the broker of call center divide the requirements into different service types, e.g., advisement, repair and so on. The broker should find a business partner, for example Service Net, from which customers can get the services, to fulfill the customer's request. When the proper business partner is found, the broker will make an appointment with the customer. Meanwhile, the customer's information and requirement are dispatched to the Service Net via multiple channels, such as short message service (SMS), email, web and fax, etc. After the requested service is finished, the Service Net submits a service report to the call center. To keep a satisfactory service level, the call center will collect the customers' feedbacks and track the Service Net's performance measure daily. If there are customers making complaints, their requirements will be re-accepted. At the same time, the department of service quality control will evaluate the quality of the whole business process. A typical business process of dealing with the customer incoming call is shown in Figure 1. Due to the distributed properties of the system, the business processes might not be executed as we expected. Without automated support, the call center cannot deal

with numerous unexpected events correctly and timely. Usually, it might be required that 95% of received calls should be answered within 10 seconds. Automated alert technology is required to give the warning of exceptions. Different roles participating in the business processes, such as call center, Service Net and service quality control department, have different information requirements. The details of running and completed business processes should be given based on the roles of the requester. All above motivate us to make an investigation on the monitoring technology for cross-organizational business process in web environments.

## 3. MAGS ARCHITECTURE

### 3.1 BDIC Monitoring Agent Model

A belief-desire-intention-capability (BDIC) architecture includes an explicit representation for an agent's beliefs, desires, intentions and capabilities. In this paper, it's the capability component that determines agent's types and monitoring functions. We concentrate on monitoring mechanisms here and the details of agent capabilities can be found in [9]. We give the definition of BDIC Monitoring Agent first.

**Definition 1** BDIC Monitoring Agent is a structural Monitoring Agent = ( $B, D, I, C, Se, Ef, Pr$ ), where (see Figure 2.):

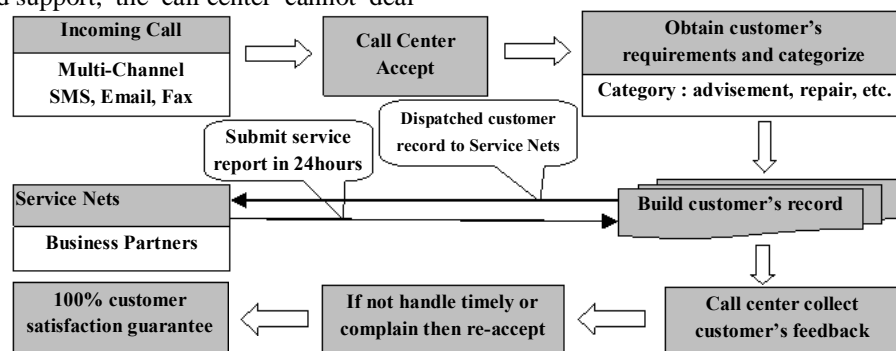

Figure 1 Closed loop diagram of an incoming call business process in call center

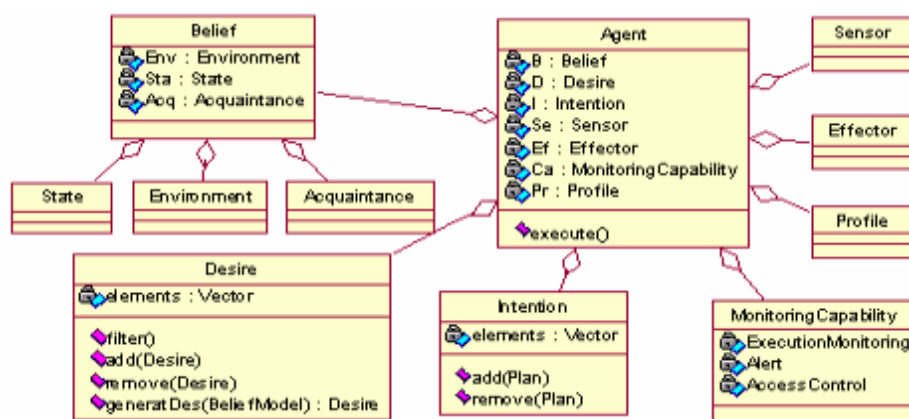

Figure 2 UML diagram of monitoring agent

$B$  is the beliefs of monitoring agent, that is, the informational state of the business process in which the agent is monitoring. The beliefs include State, Environment and Acquaintance.

$D$  is its motivational state, that is, what the monitoring agent is trying to achieve.

$I$  is the intentions of monitoring agent, that is, the planning for eventual execution.

$C$  is monitoring capability including categories of Execution Monitoring, Alert and Access Control. It will be further explained in the next sections (see Figure 3).

$Se$  is the sensors of monitoring agent. It sensors information from environments or other agents by the standard message format e.g. FIPA, ACL.

$Ef$  is the effectors of the monitoring agent by which the monitoring agent pursues its intentions.

$Pr$  is the information requirements profile of system users.

Figure 3 Monitoring capabilities

Monitoring agent is a typical BDI agent whose sensor perceives the information of business processes and revises beliefs. Desires is formed based on the current mental states ( $B$ ,  $D$ ,  $I$ ). Profiles are customized by the system users. Monitoring agent pursues intentions by effectors. The type of agent is determined by its monitoring capabilities.

following definition.

**Definition 2** A business process is a structural BP = {precondition, effect, body}.

### 3.3 Execution Monitoring Agent

Below is an agent monitoring-interpreter, which explains the mechanism of the execution monitoring of business processes.

```

Monitoring-interpreter
Initialize-state();
repeat
  if all of currentBP.effects are true
  then currentBP = getNextBP()      // Jump Action
  end if
  if one of currentBP.precondition is false
  then tempBPList = getBPList()
  // Get a list of business processes that will make the
  // false preconditions of the current business process true.
  if tempBPList == null
  // Cancel Action: no business process will
  // make the false preconditions of the current business process
  // true.
  then reportToAdmin()
  currentBP = getNextBP()
  else currentBP = getBestBP(tempBPList)
  //Add Action and Interactive
  Action: interact with human to get the best business process
  that can achieve the goal in high quality.
  end if
end if
execute(currentBP.body)
end repeat

```

According to the monitoring-interpreter, the execution monitoring agent has the following actions:

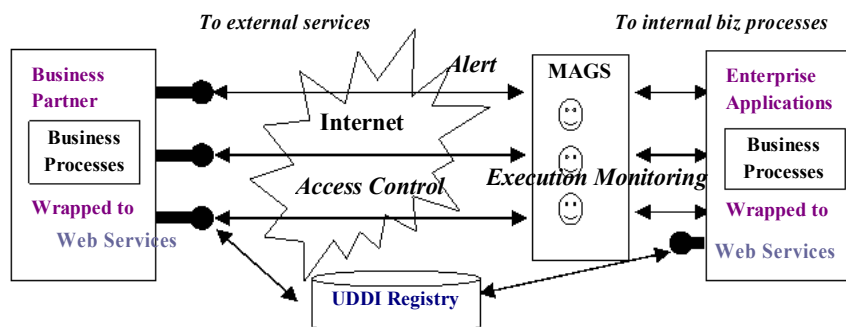

Figure 4 Integrated architectures

### 3.2 Integrated Architectures

In order to make the following explanations explicit, we give a kind of definition for the business processes here. A business process is a set of one or more linked procedures that collectively realize a business objective. By packaging business processes as services that are accessible over the internet, enterprises achieve new and better means to utilize their own and other's applications (see Figure 4). In general, a business process includes preconditions, effects and execution body as the

**Jump Action:** If all effects of current business process are true in the dynamic environments, it is not necessary to execute current business process in normal sequence. Whenever the effects of current business process are already true at the beginning of the execution, the execution monitoring agent will perform a jump action which changes the business process engine's focus of attention to the next process.

Considering the case in our application, when the broker has accepted the calls, yet not dispatched it to the Service

Net, the customer calls again to tell that he has solved his problem. It means that the goal of the Dispatch process has been achieved, thus the execution monitoring agent leads the Feed-Back process to be the current process.

**Add Action:** Changes of the environments may make the current business process preconditions false so that it could not be executed. The execution monitoring agent watches the preconditions continually. If one of preconditions fails, the execution monitoring agent will add a new process to execute which can make the false precondition true. Thus current business process can keep going on.

**Cancel Action:** During the execution of current business process, its preconditions may become infeasible due to the unpredictability of environments. Going on business processes with infeasible preconditions, the system may throw unwanted exceptions. The execution monitoring agent will watch the preconditions of current business process. If one of precondition cannot be made true through any Add-Actions, the execution monitoring agent will report to administrators and cancel current business process.

**Interactive Action:** In real-life domains, there may be multiple processes available for achieving a certain goal. It requires human experience and judgment for the business processes to execute in a high quality. Whenever multiple choices appear, the execution monitoring agent will interact with system users to get their knowledge and choose the most suitable business process to execute.

### 3.4 Alert Agent

A business process is usually constrained by policies or rules that must not be violated during its execution. Alert agents give warnings of infringing on business policies and try to avoid the failure of business process.

**Definition 3** Alert is a structure  $Al = (Id, Re, Ty, Le, Ch, Co)$ , where:

*Id* is the unique identifier of the alert.

*Re* is the receiver of alerts, which commonly are services provided by business partners.

*Ty* is the type of alerts, including temporal, resource and policy constraints.

*Le* is the emergent level of alerts.

*Ch* is the channel of alert sent through.

*Co* is the content of alert.

When the business policy is infringed during the business process execution, the alert agent sends an alert to the specific service provider. An alert has not only the identification information but also an emergent level of indicating its urgency. MAGS support alert agents to send alerts through different channels. Alerts are classified into three types by temporal, resource and

policy constraints.

**Temporal Constraints:** The business processes are commonly demanded to execute under temporal constraints. Each temporal constraint consists of a sequence of actions and one or more pairs of temporal constraint ontology and time. The temporal constraint ontology and its meanings are shown in Table 1. Temporal constraint has the following form:

*BPName TC\_Ontology Time [&TC\_Ontology Time...] action1 [; action2...]*

It indicates that the business process with the name of *BPName* must not violate the temporal constraints; otherwise the alert agent will perform corresponding actions. The alert will also be composed and sent by alert agent.

**Table 1.** Temporal ontology

TC_Ontology	Meaning
Start-at	Start time must be at given time
Start-lt	Start time must be later than given time
Start-et	Start time must be earlier than given time
End-at	End time must be at given time
End-lt	End time must be earlier than given time
End-et	End time must be earlier than given time

In our domain, CSM provides interfaces of getting the entire view of the business processes for system users. Generating the entire view of a business process is a complex and time-consuming process and it is restricted by time constraints. The following is a temporal constraint in the profiles of alert agent:

*GetBPView Start-et 8:00:00&Start-lt 20:00:00 reportToAdmin; rejectRequest*

According to the constraint, the business process *GetBPView* should start earlier than eight and later than twenty everyday. It makes the *GetBPView* process stagger the rush hour with other business processes and ensure CSM safety. If a system user attempts to invoke the *GetBPView* process in the interval of 8:00:00 and 20:00:00, the alert agent will compose an alert to administrators and reject the request.

**Resource Constraints:** The business processes in a resource-bounded environment should not overspend the system's resources. Resource constraint has the following form:

*BPName resource threshold [&resource threshold...] action1 [; action2...]*

It indicates that resources spent by the *BPName* process must not exceed by the threshold; otherwise the alert agent will perform corresponding actions to give an alert.

**Policy Constraints:** The business processes must maintain the business policies that must not be violated. Alert agent gets policies from its profile and continually monitors the incoming events unsatisfying conditions in the policy constraints. If any constraint is violated, the alert agent will perform corresponding actions to give alert. Policy constraint has the following form:

*BPName condition [&condition...] action1 [; action2...]*

(RBAC) system and can cooperate with MAGS in offering the desired security. The access control agents communicate with WebDaemon through Authentication and Authorization Protocol (AAP). Based on the user's role returned by WebDaemon, the access control agent can give the corresponding view of running or completed business processes to the particular user.

### 3.5 Access Control Agent

From the integrated MAGS architecture (Figure 4), we know that there are different kinds of requirements of business process information from inside the enterprise, e.g., supervisor, and from outside the enterprise, e.g. the business partners. There are problems if everyone can access no different information from the same process. In order to solve the security problem, the access control agents in MAGS expose interfaces to provide this function. WebDaemon [10] is a role-based access control

## 4. IMPLEMENTATION

The multi-agent system presented here has been successfully implemented and seamlessly integrated in a Customer Service Management (CSM) system of a company<sup>1</sup> (see Figure 5.). Agents act as intelligent session Enterprise Java Beans (EJB) within MAGS. Under the J2EE framework, session beans are components containing business logics associated with a

<sup>1</sup> TCL Group Corporation, <http://www.tcl.com>.

particular client session or task. MAGS runs on a J2EE application server, namely Weblogic, and adds intelligence in the sense of intention-based monitoring behaviors. CSM adopts a correlative work, called the contract-based interlayer [11], to integrate the layer of hardware-related functions (SMS, FAX) with the layer of business-related functions. With the contract-based interlayer, MAGS can send out alerts to business partners' services. MAGS cooperates with WebDaemon in providing access control functions. The statuses of the whole business processes can be monitored by web browsers based on the J2EE framework (as Figure 6 illustrates). We have got reliable and effective results in practice.

MAGS targets at providing a mechanism for business process management in a web services environment. MAGS is loosely coupled with other applications in architecture in the sense that it can be plugged into any potential systems, including e-commerce, web services and web-based applications. There is no implementary obstacle for these systems if only they hold out the specification of web services.

## 5. CONCLUSIONS

In this paper, MAGS, a monitoring multi-agent system for the management of business process in a web services environment, has been presented. MAGS can be integrated with applications in the enterprise and web services provided by cross-organizational business partners in architecture. Capabilities are added to BDI agent in MAGS to offer mechanisms of monitoring process execution, carrying out alerts and access control, which is described in detail with the examples of a typical business process in a customer service management system.

In the future, we will focus on developing richer monitoring capabilities and introducing MAGS into more domains, such as Semantic Web Services [12]. Semantic Web Services, in essence, is a kind of business processes. Its Semantic Markup OWL-S [13] should provide declarative descriptors for the state of execution of services. In fact, versions of OWL-S developed so far have not ventured into this area. In our view, introducing semantics into MAGS is a promising approach to make functionalities of automatic monitoring possible.

## ACKNOWLEDGEMENT

This work is supported in part by the National Science Foundation of China under the contract numbers

60373002 and 60496323, and in part by TCL group corporation. The authors thank for all the members of the CSM project.

## ABSTRACT

The objective of this research is to investigate the managerial competences for Electronic Commerce professional managers. Three research approaches have been adopted here: Focus Group, Fuzzy Delphi Method. The results indicated that professional skills and leadership competence are more important than other competences such as administrative skills and motivation. Comparing the competences of traditional managers and EC managers shows that the main difference is the emphasis on EC managers' professional skills.

**Keywords:** Competence of Electronic Commerce, Fuzzy Delphi Method

## 1. INTRODUCTION

While there have been quite a lot of studies on electronic business related issues, there are still very few researches on the competences of Electronic Commerce professional managers. The earliest research on competence was in late 1960s, which focused on the study of personality. Recent studies on competence, however, have changed the direction from the conventional understanding of competence as the quality, knowledge and skills one possesses to the notion that competence means not only the qualities one possesses but also those one does not own and therefore needs to learn. Murakami (1988) suggested that competence lies in the concrete performance one provides in the profession, which reflects on his/her substantial ability of achievement. Spencer & Spencer (1993) affirmed that competence is the "underlying characteristic" one has. They went further that the underlying characteristic is not only related to one's profession and position at work, but predictably or even actually affects his/her behaviors and performance. Yeung (1996) also indicated that the critical key to improve one's working performance is competence, which means the specific basic quality in a person. In addition, Ritter and Gemunden (2004) stated that both network competence and technological competence have a significant positive impact on a company's innovation success. Mansfield (1996) added that competence is the description of accuracy, skillfulness, and specific behaviors, which needs to be studied by the staff, so that they will have good performances and better achievements at work. Besides, as pointed out by Tseng (1998), competence is the crucial factor of achievements. Therefore, in spite of the fact that scholars from each school have had different definitions on competence, most scholars tended to agree that competence is closely related to one's profession, which is also the crucial key to one's performance and achievement at work.

The contribution of our study is to provide an insight into the competences of EC professional managers. It will offer the companies and industries a clear direction for training and hiring managers, which will also promote the managers' outstanding achievements. Besides, the indicators for EC professional managers can be adopted as the indicators for enterprises to evaluate the competences of their managers. Accordingly, this study proposed to achieve the following goals: 1. To examine the constitution of professional competence possessed by successful EC professional managers. 2. To find the indicators of competences for EC professional managers.

## 2. LITERATURE REVIEW

This paper discusses the aspects and indicators of managerial competences for EC professional managers. The first part of this literature review presents studies related to managerial competence, while the second part focuses on the methods of evaluation for competence.

### 2.1 Studies on Managerial Competence

Although the earliest study on competence appeared in late 1960s, recent studies on competence rarely focus on the research of managerial competence possessed by EC managers, and without mentioning the indicators for them. This study aims to start with the previous studies on managerial competence and managerial skills both in Taiwan and overseas. In this case, the managerial competence which needs to be possessed by EC managers be investigated, so that the research methods and procedure could be made. To this purpose, contemporary studies on managerial competence will be discussed as follows: (1) the personality trait school, (2) the functional school, (3) the situational school, and (4) the survey school.

The personality trait school tended to adopt "the moment of heroism" and suggested that successful

managers should have some special characteristics in their personalities. Hence, as long as a person has special characteristic in his/her personality, he/she could be trained and become a successful manager. In terms of personality, Gattell (1973) has made observations and analyses of various behaviors in our daily life. Eventually, the 171 types of personalities he found were sorted into 16 categories according to factors that would affect people's behaviors. Robbins (1985) tended to see from the managerial perspective and asserted that a person's ability is mainly composed of intellectual and physical abilities. Intellectual ability means the ability of mind activities, which includes the abilities of calculation, language, response, and logic. Physical ability denotes one's spirit, physical flexibility, energy etc. Professions of higher positions require more intellectual ability, whereas technical or mechanical jobs need people with more physical ability. Maslow (1954) proposed the hierarchy of needs theory and suggested that there are five levels of needs for every one. From the lowest-order need to the highest-order need they are: physiological need, need of safety, social need, need of self-esteem, and need of self-actualization. In general, for those who require less in life, physical need tends to be more important, while for managers the needs of self-esteem and self-realization would be more emphasized. However, there are quite a few uncertainties in the personality theory, such as the neglect of interactions between leader and staff, the fact that personalities are too complicated and difficult to be clarified, etc. Hence, theories in this school have gradually tended to be ignored.

Katz, the leader of the functional school, argued that managers of various levels require different levels of skills such as following: 1. professional skill, 2. social skill, and 3. technical skill (Katz, 1955). Those three skills would be different due to the different tasks required for managers of different levels, which was also confirmed in the theory of Guglielmino (1979). In other hand, the situational school emphasized the importance of circumstances, and believed that some specific situations could make some people become heroes. In other words, they denied the importance of the manager's personality and function. They took further that what makes one a successful manager was not necessarily his/her personality, but how to deal with the confronted situations. For instance, Fieldler (1967), a scholar of this school, proposed the leadership contingency model and suggested that the function of the leadership could be influenced by the relationship between the leader and the fellow group members, the structure of each task, and the authority of the leader. Besides, in his path-goal theory, House (1971) added that the manager's behaviors can be affected by the circumstantial factors, such as the structure of the work, the system of the official authority, and team involved in the work. Leadership can also be affected by the quality of staff members, such as their ability for internal and external control, experiences, and abilities.

All these factors would have influences on the manager's performance and satisfaction with the job.

The proper managerial competences for the managers were discovered via survey methods in the theory of investigation. Chang (1998) surveyed managers at various levels and suggested that the important managerial competence for managers at higher positional levels are "planning and coordination", "decision making", "management reforming", "strategies adopting", "prospect", "problem solving", "sensitivity to the market", "consultation and authority", "insurance managing", "social network", "outstanding performance", "and "perfectionism". The important managerial competences for managers of intermediate positional levels are: "project and procedure management", "goals setting", "communication skills", "staff training and supporting", "incident managing and group constructing", "innovation" and "negotiation". The major managerial competences for managers of basic positional levels are: "professional skills", "efficiency", "being active and enthusiastic", "executive ability", "time management", "quality management", "reliability", "good learning attitudes", "customer services" and "emotional control". Chung (1998) has researched on the managerial competence of higher positional managers in the high-tech industry, and his research focused on 159 junior managers of higher positional level in an industrial technology research institute (ITRI). The result showed that competences possessed by managers there were the abilities of "strategies adopting and coordinating", "problem solving", "quality control", "action directing", and "group constructing". The major competences that needed to be trained and improved are "sensitivity in management", "ability of negotiation", "strategies adopting and coordinating", "inspiration on others", "quality control". Wu (1993) asserted that managerial competence should include both personal qualities and managerial skills. In terms of personal qualities, personality and motivation would be the main factors, whereas managerial skills contain: social skills (including communication skills), administrative skills (i.e. planning and coordinating), cognitive skills (such as analysis and decision making), leadership skills (such as inspiring and tutoring), and technical skills.

Recent studies on managerial competence have tended to include theories and perspectives from different theories and have combined various methods to examine managerial competences. Ritter and Germunden (2004) discussed and analysis the impact of the dual nature of the key to competitiveness in the network economy. Lin (1996) has adopted the Fuzzy theory to the evaluation models of managerial competences, considering aspects on both personal qualities and skills. Personal qualities include ability, personality, and motivation, whereas managerial skills could be divided into the aspects of technical skills, social skills, and conceptual skills. Additionally, Wu

(1999) has also adopted the Fuzzy Analysis Hierarchy Process to construct the evaluation model of managerial competence and suggested that managerial competence contains eight aspects: (1) conceptual skills, (2) social skills, (3) leadership skills, (4) administrative skills, (5) professional skills, (6) personal qualities, (7) abilities and (8) motivations. Accordingly, the direction of his research has already covered the concepts from personal characteristic, functional and investigative theories. Chang, Huang, and Lin (2000) proposed a new fuzzy Delphi method and fuzzy statistics for managerial talent assessment. Their taxonomical approach was derived from the open systems view of firms. The new method was able to identifying and distinguishing different aspects of organizational competence. Sanchez (2004) also developed a taxonomy of five models of competences than an organization must develop and maintain in its various activities to reach overall competence.

## 2.2 Methods of Evaluation on Competences

The primary methods of evaluation on competences are as follows: 1. Evaluation on working ability (McClellan, 1973; Tseng, 1998). 2. Focus group. 3. Examination on competence models (Hsieh, 1998). 4. Peer Evaluation (Parry, 1998). 5. Assessment centers (Parry, 1998). 6. Circumstantial tests (Parry, 1998; Chang, 1997). 7. Evaluation tables of competence (Chuang, 1997). 8. Fuzzy theory (Ishikawa, et al., 1993; Lin, 1998; Wu, 1999). Apart from these, Richard & James (1995) had adopted the two-stages method which combined qualitative and quantitative methods for the research of competencies for computer software technicians. While in the first stage qualitative study approach was adopted for detailed interviews, in the second stage quantitative analysis was used to generate the final list of competence via Q-Sort techniques and discriminant analysis.

Ishikawa et al (1993) had adopted the Fuzzy theory for the purpose of solving some problems in the existing conventional Fuzzy Delphi Method. They used Max-Min and Fuzzy Integration to examine Fuzzy Delphi Method's workability, and the result has proven that the Fuzzy method has some advantages that the traditional methods do not have. Therefore, more and more scholars, such as Lin (1996), have started to adopt Fuzzy theories in the evaluation of managerial competences. Later, Wu (1999) and Huang, Chang, and Lin (1997) constructed his evaluation model of managerial competences through Fuzzy Analysis Hierarchy Process.

To sum up, from the literature review we found that in terms of competence there were no exact common consensus between theories from different schools, and the methods adopted were various. Therefore, it would be important to start with a more complete managerial structure, which should also be adoptable for electronic

commerce. Since the managerial structure proposed by Wu (1999) has included more aspects, our study proposes to adopt his structure of competences as the initial structure for the study of managerial competences, which is illustrated bellow. In terms of methodology, to increase the accuracy of our research and to follow the tendency of studies nowadays, we have adopted several methods and the combination of qualitative and quantitative methods. The Fuzzy Delphi Method used to choose suitable aspects and indicators of the managerial competences for EC managers.

## 3. METHODOLOGY

The objective of this research is to discover the managerial competences and indicators for EC managers. The initial construct of competences for EC professional managers is shown in Fig. 1. To achieve this goal, a both qualitative and quantitative approach is adopted in our research. In this way the advantages from each method could be integrated in this study, instead of relying too much on a certain type of methods and the disadvantages that might occur. Here, the process of this study could be discussed in two parts: 1. focus group, and 2. Fuzzy Delphi Method.

Figure 1. The Initial Construct of Competences for EC Professional Managers

### 3.1 Focus Group

After establishing the structure through literature review, a focus group of EC experts was held on for the purpose of discovering the managerial competences related to the job of EC managers, which also provided some suggestions for the adjustment to the initial structure of our study. To ensure that the experts invited would be representative, 12 experts from the industrial, governmental, and academic fields of the electronic commerce in Taiwan were invited for the focus group. The experts from the industrial field were the leaders who were responsible for electronic commerce business in a certain enterprises.

### 3.2 Fuzzy Delphi Method

From the opinions collected via the focus group for the adjustments on the items and aspects of managerial competences for EC managers, we proposed to adopt group-decision skills for the confirmation on those items and indicators. Among the group-decision skills, Delphi Method is the one that has usually been applied. The approach is to survey the opinions of experts in the specific fields with questionnaires. Without any

common consensuses or exchanges of ideas among experts, the negotiator will integrate the opinions from the experts and select the average or 50% of the result as the collective opinion. If the result does not satisfy the standard of converge, the survey will need to be repeated several times until the standard is achieved (Hsu, 1990). Therefore, the disadvantages of the conventional Delphi Method are: opinions from the experts might not easily achieve the standard of converge; the survey would often need to be repeated for several times until the acceptable standard is achieved, which might result in high expenses of the capital and time; and with the decrease of response rate, the result might be affected by the negotiator's subjective thoughts (Hsu and Lee, 1997). Hence, if the Fuzzy theory could be applied to the Delphi Method, apart from the benefit that the result obtained could be similar to the conventional Delphi Method, the repeating time for survey could be decreased and the time and capital could therefore be reduced. In particular, the individual characteristic of each expert could be reflected and the professional knowledge of each expert would be more reasonably and suitably dealt with (Ishikawa et al., 1993).

Therefore, our study adopts the reformed Fuzzy Delphi Method introduced by Hsu and Lee (1997), which based on the triangular fuzzy numbers. This method was applied to make confirmation on the managerial competences and aspects for EC managers, because it not only improved the disadvantages resulted from the conventional Delphi Method, but that the result would not easily be affected by the extreme opinions. The questionnaires for the survey on Fuzzy Delphi Methods were sent on 15 June 2002 to the recipients, who were members of EC association in Taiwan, and the experts invited for the focus group. The total numbers of the questionnaires sent were 120 and with 40 valid responses, which made it 33% valid response rate. Finally, the procedure of adopting Fuzzy Delphi Method to the structure of managerial competences for EC managers is described as follows:

**Step One:** Building the structure of managerial competences for EC managers. Our initial setting of managerial competences for EC managers could be discussed from 8 aspects, which were conceptual skills, social skills, leadership skills, administrative skills, professional skills, personal qualities, abilities and motivations.

**Step Two:** Setting up the evaluations of weights.

By using the triangular fuzzy numbers to integrate the opinions from experts, the problems of fuzzy human thoughts and inaccuracy could be reduced. Besides, the decision maker's real attempt could be more clarified. The approaches to integrate the group opinions were average number(s), total number(s), the maximum, the minimum, and the hybrid method of

average of the maximum and the minimum. Besides, as pointed by Saaty (1980), it would be better to present the opinions of the experts with the geometric average method, which has been applied frequently in practical studies. Moreover, because the result from the geometric average method would be suitable for the definition of fuzzy judgment matrix, in our study with Fuzzy Delphi Method we used geometric averages to demonstrate the collective opinions from experts. Hence, the triangular fuzzy numbers were adopted, which were the most often applied in fuzzy numbers, for the purpose of setting up the fuzzy membership function of the experts' opinions. In this chart, the minimum of the experts common consensuses is presented as point " $l$ ", whereas the maximum of them is showed as point " $u$ ". Accordingly, the satisfaction degree to these two extremes would be presented as 0, while the segments between  $u$  and 1 would be given the satisfaction degree between 0 and 1. Hence, the fuzzy number of the total opinions from experts is contained in our study, which is presented as  $\tilde{W} = (l, m, u)_{L-R}$ , whereas the fuzzy weight number of the indicator for the managerial competence item  $j$  by an individual expert  $i$  would be  $\tilde{W}_{ij} = (l_{ij}, m_{ij}, u_{ij})_{L-R}$ . Consequently, the approach described above could prevent from the problem of deleting information as happened in the conventional Delphi Method, and the common consensuses among experts were included as many as possible.

From the survey of Fuzzy Delphi Method, the evaluations of fuzzy weights from the experts were therefore obtained. Hence, the fuzzy weight number of expert  $i$  on managerial competence item  $j$  could be presented as follows:

$$\tilde{W}_{ij} = (l_{ij}, m_{ij}, u_{ij})_{L-R} \quad (1)$$

$$l_i = \text{Min} (l_j), i = 1, \dots, n; j = 1, \dots, m \quad (2)$$

$$m_j = \left( \prod_{i=1}^n m_{ij} \right)^{\frac{1}{n}}, i = 1, \dots, n; j = 1, \dots, m \quad (3)$$

$$u_j = \text{Max} (u_j), i = 1, \dots, n; j = 1 \dots m \quad (4)$$

While  $n$  stands for the numbers of experts,  $m$  shows the numbers of indicators for managerial competences

**Step Three:** Selecting the suitable items of managerial competences for EC managers.

1. The fuzzy weight number  $\tilde{W}_{ij}$  generated from Step Two could not be used for direct comparison. Therefore, the fuzzy method solution which was provided by Hsu and Lee (1997) was provided in our study, and the result was transformed into a single number  $of_i$ .

$$of_i = \frac{u_i + m_i + l_i}{3} \quad (5)$$

2. Then a threshold was provided by experts. From the references of previous studies on managerial

competences, we decided to set the threshold  $r=0.7$ , and used this for the selection of suitable managerial competences. If  $of_i \geq r$ , then the managerial competence item should be selected; If  $of_i \leq r$ , then the managerial competence item should be deleted.

#### 4. DATA ANALYSIS

After establishing the initial construct of competences for EC professional managers, a focus group method was used for the purpose of discovering the managerial competences related to the job of EC managers, which also provided some suggestions for the adjustment to the initial structure of our study.

Fuzzy Delphi Method is then applied in our study for the identification of managerial competences and aspects for EC managers. From the three steps for Fuzzy Delphi Method, the initial 73 items of managerial competences in 8 aspects, after deleting 33 less important items, 40 were left. The initial 73 indicators of managerial competences in eight aspects, after the selection with Fuzzy Delphi Method were all kept with 39 managerial competence indicators which have been selected, while the other 34 were considered by experts as unimportant managerial competences indicators and therefore have been deleted. The study result showed that professional skills, conceptual skills, social skills, leadership skills, administration skills and personal qualities were considered by the experts as important aspects. Therefore, most of the managerial competence items in these aspects have been retained; whereas the items deleted were mostly from the aspects of abilities and motivations, which eventually contained only 2 items for each aspect. Hence, the result also suggested that these two aspects were considered by most experts in the survey as unimportant aspects. Accordingly, the result of managerial competences for EC management also showed that viewpoints from the functional school and the investigation school tended to be more supported, while personal qualities and motivations were considered less important in the EC environment.

#### 5. CONCLUSIONS

From the results mentioned above, competencies for EC professional manager can be compared with the study of Chang (1998) on the managerial competences for managers, we could see that managerial competences for EC managers tend to be closer to those for the managers in the intermediate level. For instance, the managerial competences for EC managers correspond to the "professional knowledge" for managers in the basic level; similar to "communication skills", "training and supporting staff members", "incident management and group construction", "innovation" and "negotiation" for managers in the intermediate level; and closed to "strategies planning", "sensitivity to the market", "consultation and authorization" and "prospect" for the managers in the high level. In addition, among the

managerial competences for EC managers, "strategies planning", "problem solving" and "negotiation" also echo the study of Chung (1998) on the managerial competences of higher level managers in the high-tech industry. Hence, we found that in both the business and academic fields in Taiwan, EC managers were considered as the "intermediate" or "high" level managers. One of the reasons for internet bubble economy, as our study suggests, is that the skill aspect had been too much emphasized in the Electronic Commerce. Our study also points out that it would be not enough to concentrate on the skill level only. EC managers still have to possess the thinking, leading and management skills which are in the strategic level. For example, if they could help the enterprise or company build the prospect, plan the strategies and assign the resources; if they are innovative; if they could evaluate and make analysis of the environment and future tendency; if they have good communication skills, incident management skills etc. All these are the managerial competences for a successful EC manager.

From our study, we found that EC management could be divided into eight aspects: 1. professional skills, 2. leadership skills, 3. conceptual skills, 4. abilities, 5. social skills, 6. personal qualities, 7. Administrative skills, and 8. motivations. In these aspects, professional skills and leadership skills are the most important aspects, while Administrative skills and motivations are the least important ones. In terms of the managerial competence items, the main difference between the competences for EC managers and traditional managerial competences lies in the emphasis of professional skills. In addition, domain knowledge and information management have been recognized by the experts as the most important items in professional skills. As for other managerial aspects, such as leadership skills and conceptual skills are similar to traditional management theories, which are also included as managerial competences possessed by successful managers. Besides, in terms of practical usages, the managerial competences and indicators proposed by our study would be very suitable for the companies when evaluating and hiring EC managers. Even for educational trainings, these managerial competences and indicators would certainly provide as a good reference and direction.

## ABSTRACT

Before the emerging of Internet, traditional travel agencies had been an industry that adopted information technology greatly, and common for each travel agency to have Computerized Reservation System to connect with airlines and hotels through dedicated lines. This kind of inter-organizational information system has been adopted for years; while viewing the travel industry as a whole, the changes on value chain and competition and cooperation relation are caused by the commercial behavior of Internet, E-commerce (EC). Therefore, the objectives of this study are: to understand the influence of top managements' characteristics on introducing B2C EC, to understand the influence of travel agencies' attributes on introducing B2C EC, and to understand the decision-making factors travel agencies considered while introducing B2C EC. To the data analysis, we adopt scale reliability analysis, scale validity analysis, descriptive statistics, chi-square test, independent sample t-test, Pearson's correlation analysis, factor analysis and discriminated analysis, etc. According to the analysis results, this study found that "education level", "job position", "consuming experience in EC websites", and "viewpoint on EC prospective" of the top management's characteristics would directly influence the introduction of e-commerce and have positive correlation with the decision significantly; the travel agency's attributes of "type of travel agency", "company's age", "number of employees" and "participating in the promotion and assistance measure" would directly influence whether to introduce e-commerce or not, and the decision is positively correlated with significance of EC introduction. Decision factors are divided into six dimensions, "Product Competence", "Relationship of Investment Capital", "E-business' Level", "Consumers Demand", "E-commerce Environment", and "Management Knowledge Mode". Results show that the dimension "E-business' Level" affects the most and dimension "Relationship of Investment Capital" affects next the decision to introducing EC.

**Keywords:** E-commerce, decision-making, B2C EC, travel agencies

## 1. INTRODUCTION

The public has accepted travel industry as the biggest industry in 21st century which highly interrelated with each person. Traditional travel agency is the service industry that in charge of travel information brokered and management among all travel industry, and the major assets it possessed are customers. Before the emerging of Internet, traditional travel agencies in Taiwan had been an industry that adopted information technology greatly, and common for each travel agency to have Computerized Reservation System (CRS) to connect with airlines and hotels through dedicated lines. This kind of inter-organizational system (IOS) has been adopted for years. To view travel industry as a whole, changes on value chain, competition and cooperation relation are caused by the E-commerce (EC) behavior.

The increase in Internet users, growth in on-line order, open of Internet banking business's payment system operation, gradual mature of relevant environment for e-commerce and popular of on-line games, and markets for e-commerce will keep on growth, and Taiwan's on-line traveling market has been the biggest business among B2C EC now. However, it is true that Taiwan's traditional travel agencies are facing the same problems as most small and medium enterprises, namely, capital, technology, industrial standards and governmental

promotion and assistance measures, which result in the stagnancy of e-business degree. Therefore, the motivation of this study is to discuss and realize how the domestic enterprises' top managers of traditional travel agency look upon B2C EC and what are the required features, and to understand the decision-making factors on introducing B2C EC into traditional travel agencies.

The issues of this research is "What are the top managers' characteristics, travel agencies' attributes, influences of relationship between suppliers and governmental promotion and assistance measures on the decision-making of introducing emerging information technology e-commerce by Taiwan traditional travel agencies?" Therefore, the objectives of this study are:

- (1) To understand the influence of top managements' characteristics on introducing B2C EC.
- (2) To understand the influence of travel agencies' attributes on introducing B2C EC.
- (3) To understand the considered decision-making factors by travel agencies while introducing B2C EC.
- (4) To provide suggestions and references for government's relevant unit, higher education research institutes, system providers and relevant software suppliers, travel product suppliers, travel associations and travel agencies, to construct a well digitalized travel operation ecological environment jointly.

We attempt to use questionnaire survey to discuss how the traditional travel agencies shall find out their ways under this trend and develop business opportunities, and catch the important factors considered under traditional travel agencies' decision-making process, and what their required assistance and help are.

According to business natures, Taiwan travel agencies could be divided into three types, namely, Consolidated, Class A and Class B travel agencies. This study focuses on and sampled from the travel agencies that join the Taoyuan County Travel Agent Association. The amount of travel agencies in Taoyuan area are ranked fourth in Taiwan, and most are the localized traditional travel agencies without on-line traveling operation. In addition, since we are concerning the travel agencies' decision-making to introducing e-commerce and only top management could make such decision, it is more reliable for us to take them as our research objects.

## 2. LITERATURE REVIEW

This section reviews relevant literatures concerning the decision-making factors that influence the introduction of e-commerce into travel agencies. The following discusses ten of such factors:

- **Top Management's Characteristics:** Subjective factor that influences decision-making rationality is the decision makers, that is, manager's personal intuition, experience and proficiency [3]; McNulin and Sprague [12] considered that a top management with operation styles of perspective, adventure and brave in accepting challenges, also have higher acceptance on the introduction of new information technology; in the research of critical factors that influence top managements' support of information technology from sixty domestic enterprises made by Lin [10], it is found that top managements with higher education background are tended to support information technology due to their higher opportunities to get in touch with information technology.
- **Travel Agency's Attributes:** Scale is also one of the major factors that influence organization's application of information technology; numerous researches believed that organization scale and new technology introduction have positive correlation [1,5,9].
- **Policy Regulations:** With more governmental promotion and assistance measures, the enterprise could even more facilitated to adopt new information technology [6,13].
- **Consumer's Behaviors:** Engel et al. [4] defined consumer behavior as the relevant activities made directly by personal to product, service obtain, consumption or dispose, including causes, practical activity and decision-making process that decide various behaviors.
- **Construction Purpose:** We thought that a success enterprise does not pursue fashion or follow the trend. It must have been driven by certain purpose, which means that enterprise must have profits to obtain and select most appropriate project or technology. Moreover, methods for enterprise to gain profits including improve operation efficiency to reduce operation costs, increase business incomes to accelerate investment return, and expand market to increase new business opportunities.
- **Organization:** Travel agencies' technology maturity, information department's scale and top managements' cognition and support are all the factors that influence the decision-making of adopt information technology into organization; and more formalized company will adopt information technology earlier [1,9,11,14]. There are other researches indicated that if the computerized degree is higher among industry, the organization would correspond with higher formalized organization structure [2,15].
- **Supplier:** Rockart and Short [13] considered that the development of information technology enables the enterprise to link consumers and upper suppliers, and cross-organization's process could closely integrated, which highly increased the interflow of information and obscure the organizational boundaries. The service quality of vertical integration between information system supplier and enterprise will affect enterprise's IT adoption, and more marketing supports and understanding customers' requirements will make products easier to be accepted [9,15].
- **Environment:** (1) Pressure from the adoption of same business: As indicated in Lee [9] and Tseng [14], competition between same businesses, computerized degree between same businesses, and influence degree by the same businesses have positive correlation with the effects of the introduction of information technology; (2) Pressure from customer's demand to adopt: Based on Hwang's research [8] on enterprise's adoption of EDI and its benefits, it is discovered that when more customers request to adopt new information technology, the enterprise could even more facilitated to adopt new information technology; (3) Sporadic environment: According to Grover and Goslar's research [5] of the factors that influence enterprise's application of communication technology in USA, it is discovered that environment uncertainty and heterology would facilitate the adoption of new technology.
- **Internet Techniques:** Include network construction, management and maintenance costs, transmission quality, confidential and safety, integration of various computer systems, network applicable software, and network supplier's service; while these factors have positive development, the enterprise could even more facilitated to adopt new information technology [6,7].

- **Technological Recognition:** (1) Characteristics of Internet: Lee [9] in his study of the Internet adoption decision factor referred that it has different opinions on “whether to adopt or not” in terms of Internet risk; however, the negative factors of compatibility do not affect enterprises’ willingness to adopt Internet; (2) Characteristics of enterprise product/service: Product and service characteristics are unique in travel industry that also reveal their importance. Thus, there are researches addressed factors like product’s comparative profit, comparative risk, compatibility and cognition degree [8,15].

### 3. RESEARCH METHODOLOGY

This study proposes operational definitions of related variables in accordance with the research hypotheses. The conceptual framework of our research considers the influential factors such as the properties of the travel agency, travel products, environment, the Internet as well as the characteristics of the top management.

- (1) **Top Management’s Characteristics:** The six variables are gender, age, education level, job position, consuming experience in e-commerce websites, and viewpoint on e-commerce prospects.
- (2) **Travel Agency’s Attributes:** It includes type of travel agency, company’s age, number of employees, and degree of participating in e-commerce promotion and assistance measures of government’s relevant units or private organizations.
- (3) **Policy Regulations:** This mainly focuses on the travel agency’s participation in governmental promotion and assistance measures, which might influence the travel agency to introduce e-commerce.
- (4) **Decision Dimensions:**
  - **Consumer’s Behaviors:** This dimension highlights the behavior of the consumers to recognize the opinions of the top management of the travel agency toward what consumers think of e-commerce.
  - **Construction Purposes:** This includes the viewpoints of the top management toward the profit of e-commerce, marketing channel, market share rate and publicity of the company.
  - **Organization:** This includes decision factors such as the policy decision procedure, the document format, the e-business level of the enterprise, the e-commerce technicians, the participation and support of the top management and so on.
  - **Suppliers:** With the characteristics of the travel products and the property of the travel agency, the top management lays an emphasis on the behavior of the suppliers. This is because upstream suppliers are able to positively support the marketing activity and networking supply by sending technicians to assist or providing reasonable preferential prices.

- **Environment:** This includes adoptive pressure from the competitors, customer’s requests, the recognition and viewpoints of the top management on the domestic EC environment, and the consideration of the SARS impact on e-commerce.
- **Internet Techniques:** This aims at the EC establishment costs (implementation, management, maintenance, etc.) and the EC on-line transaction security problems.
- **Technological Recognition:** Whether the Internet is able to sustain marketing, reduce the enterprise operating cost, promote company’s competency, and extend the service district, and e-business is a commercial trend in the future.

The evaluative item of each variable in our research questionnaire is based on the theoretic basis of the literature review and related research subjects, further combined with the research objectives and conceptual framework. This mainly consists of two parts:

#### (1) Questionnaire Design

- **Pretest Part:** Having done effective analysis of the questionnaire pretest and deleted questions that don’t meet the criteria, a formal questionnaire is gained.
- **Formal Questionnaire:** The content of the formal questionnaire altogether is divided into three parts—Basic Information, Operating Status, and Decision Making Factors on E-commerce Introduction.

#### (2) Survey

- **Questionnaire Duration:** The survey duration of this research is from June 25th to July 31st, 2003.
- **Sampling Method:** The research adopts purposive sampling method. The population includes 19 branches of consolidated travel agencies, 95 head offices of Class-A travel agencies, 30 branches of Class-A travel agencies and 7 head offices of Class-B travel agencies, totally 151 travel agencies.

This research adopts SPSS for Windows as a tool for analysis. The flowchart of analysis is shown in Figure 1.

### 4. DATA ANALYSIS

We now proceed to present data analysis, including chi-square test, independent sample t-test, Pearson’s correlation analysis, factor analysis and discriminated analysis, etc. and explains the results in detail. For this study, 151 questionnaires were sent out and 88 were returned. The response rate was 55.63%. Among those received, 4 were incomplete and treated as invalid.

This study used the Cronbach’s  $\alpha$  value to analyze the reliability of scale in part of the questionnaire that concerns the decision-making factors of introducing EC in traditional travel agency. After measuring, the Cronbach’s  $\alpha$  value is above 0.94 which satisfies the internal consistency requirement and is highly reliable.

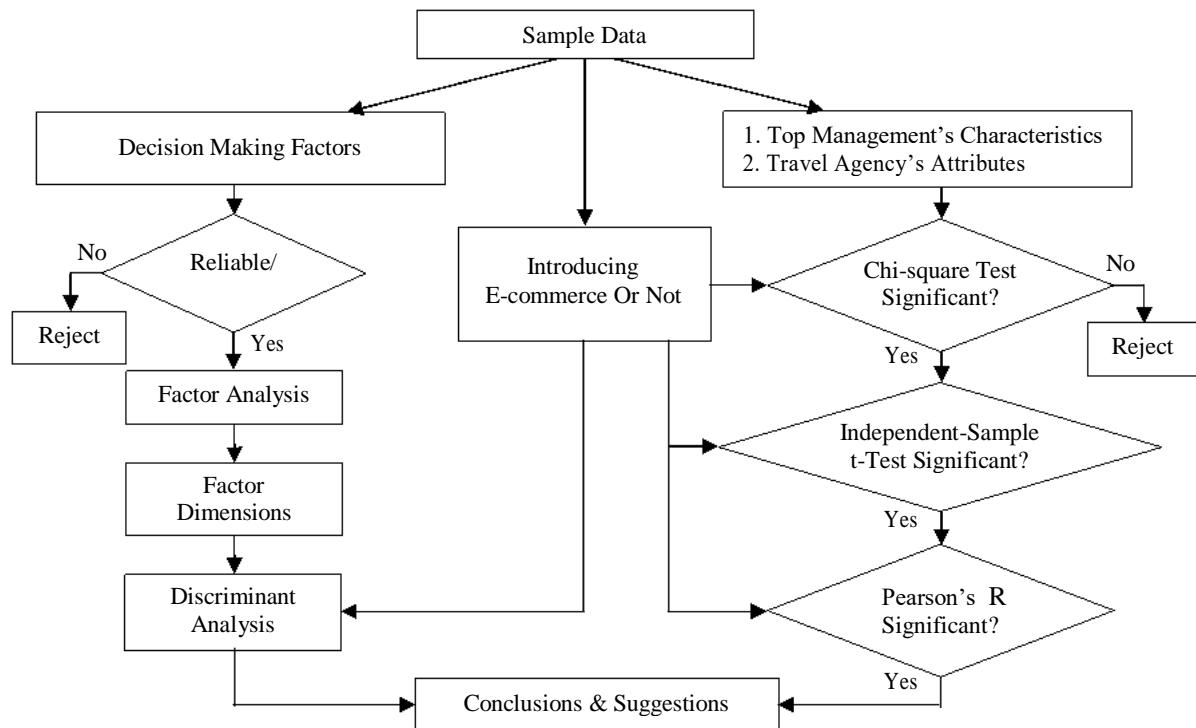

Figure 1. The flowchart of analysis

As shown in Table 1 and Table 2, the education level (Pearson  $R = .259$ ,  $p < .01$ ), job position (Pearson  $R = .254$ ,  $p < .01$ ), consuming experience (Pearson  $R = .243$ ,  $p < .05$ ), and the viewpoint on e-commerce prospective (Pearson  $R = .222$ ,  $p < .05$ ) of the top management in the travel agency would have significantly positive influence on the decision making of EC introduction; but the gender ( $\chi^2(1) = 3.385$ ,  $p > .05$ ) and age ( $\chi^2(1) = 1.911$ ,  $p > .05$ ) did not reach significance of confidence interval, so we can say that the gender and age of the top management will not influence the decision making of introducing EC.

Table 3 shows the correlations between travel agency's attributes and introducing EC or not are significant at 99% of confidence interval; so the type of travel agency (Pearson  $R = .337$ ,  $p < .01$ ), company's history (Pearson  $R = .338$ ,  $p < .01$ ), the number of employees (Pearson  $R = .369$ ,  $p < .01$ ) and participating in the promotion and assistance measure (Pearson  $R = .391$ ,  $p < .01$ ) of the travel agency's attributes would influence the decision making of introducing EC significantly and positively.

Before analyzing, we first check the correlation matrix between each variance to make sure that the factor analysis is representative. Results show that most related coefficient between variance of each dimension appeared as significance. Then after the KMO and Bartlett's test (KMO statistical value =  $0.762 > 0.6$ ;  $p = 0.00 < 0.05$ ), it shows the significance and hence is suitable to do the factor analysis. Clearly, the 26 questions against factor loading are all over 0.5, which is at the acceptable region. For the extracted 6 factor dimensions which has characteristic value bigger than 1, total variance explained is about 75.1%.

Table 1. Chi-Square tests for top management's characteristics on whether to introduce EC

Variables		84 Valid Cases			
Top Management's Characteristics (6 Factors)		Value	Df	p-value	
Education level	Pearson Chi-Square	5.631	1	.018	?
	Likelihood Ratio	5.581	1	.018	
	Linear-by-Linear Association	5.564	1	.018	
Job position	Pearson Chi-Square	5.427	1	.020	?
	Likelihood Ratio	5.571	1	.018	
	Linear-by-Linear Association	5.362	1	.021	
Consuming experience in EC websites	Pearson Chi-Square	4.941	1	.026	?
	Likelihood Ratio	4.999	1	.025	
	Linear-by-Linear Association	4.882	1	.027	
Viewpoint on e-commerce prospective	Pearson Chi-Square	4.153	1	.042	?
	Likelihood Ratio	4.095	1	.043	
	Linear-by-Linear Association	4.104	1	.043	
Gender	Pearson Chi-Square	3.385	1	.066	?
	Likelihood Ratio	3.344	1	.067

Note: \*Correlation is significant at the 0.01 level

Source: This study

The name of factors was based on variance on the factor loading of factor pattern, and extended to some other related variances. The higher variances, the more important the top management attach to themselves. Thus decision factors are named and classified to 6 dimensions as "Product Competence", "Relationship of Investment Capital", "E-business'Level", "Consumers Demand", "EC Environment", and "Management Knowledge Mode". Then, we implement Cronbach's  $\alpha$  value to prove and measure the reliability of each dimension; if the Cronbach's  $\alpha$ -coefficient is greater than 0.7, it means that the reliability is quite high and the questionnaire is well designed. After factor analysis, the reliability is as shown in Table 4.

This study uses Discriminant Analysis to analyze the effective decision dimension and whether travel agency is to introduce EC. We define "introducing e-commerce factor dimensions" as independent variables and "whether travel agency introducing e-commerce or not" as dependent variable. We shall discuss the decision on

each dimension affecting whether the travel agency introduces EC is significant in reality. Therefore, from the function test of discriminant analysis (Wilks' Lambda value = 0.772 and  $p = .000 < 0.05$ ) which has reached statistical significance level, we can have a standardized canonical discriminant function:  $D = 1.002 * \text{E-business'Level} + 0.817 * \text{Relationship of Investment Capital} - 0.640 * \text{Management Knowledge Mode} - 0.538 * \text{E-commerce Environment} - 0.395 * \text{Consumer Demand} - 0.078 * \text{Product Competence}$ . Results (see Table 5) show that the dimension "E-business'Level" affects the most and dimension "Relationship of Investment Capital" affects next the decision to introducing EC. The positive and negative symbol shows the direction of relationship.

Table 4. Reliability scale of the factor dimensions

## 5. CONCLUSIONS

This paper finally summarizes and concludes as below:

### (1) Structure of Respondents

According to the analysis, we understand that the decision-makers think EC would be a trend in the future that 76.2% of the sample think EC's future is good and keep on investing it; while 73.8% actively participate in government's or private organization's B2B2C EC promotion and assistance measure. In the characteristics of travel agencies, it appears that the scale and history of travel agencies in Taoyuan County is smaller and shorter. The head office of

Class A travel agency is the majority, mainly by regional business, which locally services customers.

## (2) Operating Status Analysis of Travel Agencies

- The Internet connection rate of travel agencies in Taoyuan County is beyond 80%, and the best is consolidated travel agencies. In the private website constitution rate, excluding members of "Travel Industry's Data Base System Program" is only 35.1% and it means the pressure of adopting EC is lower in this area. The rate of Class A (27.2%) and B (14.3%) travel agencies' self-own website is low.
- 84 respondents applied EC (including the travel agencies which plan to introduce EC) that takes 59.5%; among them 31% apply EC by self. In the investigation of travel agency's application of EC, most (62%) lack of IT professionals; while 28% of the travel agencies, which don't apply EC, take strategy on internal staff training. On the other hand, 74% of the managers are from internal who generally accept new technology and are familiar with computer. In the application of IT, beyond 90% of respondents use CRS for trading.

## (3) Relationships of Whether to Introduce E-Commerce

- In the education level, job position, consuming experience in EC websites, and the viewpoint on EC prospective of the personal characteristics would directly influence whether to introduce EC or not, and their decisions have positive correlation and are significant. But the gender and age of the top management have no related significant correlation.
- The travel agency's attributes of "type of travel agency", "the company's age", "the number of employees" and "participating in the promotion and assistance measure" would directly influence whether to introduce EC or not, and the decision is positively correlated and significant. Travel agencies which participate in promotion and assistance measures of government's relevant unit or private organization's B2B2C e-commerce are much more active in applying e-commerce.

## (4) Decision Factors Analysis of Affecting E-commerce Introduction

- To the opinions of the top management in the travel agency, the top 5 important effects on introducing EC ordered by average are: E-commerce is an inevitable business trend in the future, increase company's fame through customer's visit on the EC website, the company is able to understand customers' preferred habitual behavior, increase the interaction between the company and customer, and the additional EC's channel will increase company's market share.
- After the factor analysis, 26 applications for introducing e-commerce decision factors are divided into six dimensions; they are: "Product Competence", "Relationship of Investment Capital", "E-business Level", "Consumers Demand", "E-commerce Environment", and "Management Knowledge Mode". And after the cross validation, the total

predicted rate is beyond 71%.

## ABSTRACT

In this paper we explore the impact of electronic commerce on the industry structure and market power allocation of China's pharmaceutical industry. Firstly, we describe the overall characteristics of the pharmaceutical industry in general. Secondly, we develop a value chain based framework of analysis for China's pharmaceutical industry. We divide the pharmaceutical industry value chain into three tiers: the initial market, the middle market and the end market. Based on these works, we analyze the profound impacts of Electronic Commerce on the transformation of China's pharmaceutical industry, with particular emphasis on the evolution of market structure and the re-allocation of market power due to the introduction of E-Commerce procedures.

**Keywords:** pharmaceutical industry, Internet, E-Commerce, value chain

## 1. INTRODUCTION

In this paper we explore the impact of electronic commerce on the industry structure and market power allocation of China's pharmaceutical industry. Firstly, we will describe the overall characteristics of the pharmaceutical industry in general. Pharmaceutical manufacturers in the market could be divided into two types: pioneer firms and genetic (imitator) firms, and most of the Chinese pharmaceutical manufacturers belong to the second group. As for the pharmaceutical products, after the introduction of *the Pharmaceutical Regulation Rules*, the taxonomy of medical products in China is becoming similar to that of the US, which consists of prescription drugs and over-the counter drugs. As a result, the market for medical products could generally be divided into prescription market and over-the-counter market.

Secondly, we develop a value chain based framework of analysis for China's pharmaceutical industry. We divide the pharmaceutical industry value chain into three tiers: the initial market, the middle market and the end market. We focus on the situation of the industry structures and market conditions at present. Then in the last part of the paper, we analyze the profound impacts of Electronic Commerce on the transformation of China's pharmaceutical industry, with particular emphasis on the evolution of market structure and the re-allocation of market power due to the introduction of E-Commerce procedures. We conclude that pharmaceutical manufacturing industry will achieve a new stable structure with smaller firm quantity and stronger firm power. In wholesaling industry only a few big firms would exist in the national market. The three-class agent system may disappear. The relative market power of retailers will strengthen in the initial market that may result in monopsony. And The B2C in pharmaceutical retailing industry would pose a chance to re-allocate the

market share between hospitals and pharmacies.

## 2. THE OVERVIEW OF PHARMACEUTICAL INDUSTRY

Most of the pharmaceutical markets in the world are highly monopolized. In 2000 the top ten pharmaceutical manufacturers' market share was 50% in the world. In comparison with the world market, Chinese pharmaceutical market is highly competitive with a high number of manufacturers and distributors. That's the peculiarity of Chinese pharmaceutical industry, which we will explicate later. Firstly we're looking for some characteristics of the pharmaceutical industry in general.

The pharmaceutical manufacturers in the market could be divided into two types: pioneer and genetic or imitator firms. The pioneer firms are companies who undertake research and development to discover new drugs and bring them to market. They have the patent rights of these new drugs, which ensure them to be the monopoly before the patent expiration. But the R&D and marketing take long time and millions of dollars. That leads to a much higher price of the pioneer firm's product compared with that of the imitators'. Some famous pioneer firms in the world include Merck and Dupont, etc. Only a few of the Chinese pharmaceutical manufacturers belong to this group, such as Tongrentang. The genetic or imitator firms are smaller and don't do much R&D themselves. They produce some "bioequivalent" products to the original branded products after the patent expiration, and their prices are usually much lower. Most of the Chinese pharmaceutical manufacturers belong to this group.

As for the pharmaceutical products, after the introduction of *the Pharmaceutical Regulation Rules*,

the taxonomy of medical products in China is becoming similar to that of the US, which consists of prescription drugs and over-the-counter drugs. The over-the-counter (OTC) drugs could be bought in any pharmacy. Such as vitamins and parts of the antibiotics. This kind of drug's demand is great but not stable, and its profits usually are not very high. The total revenue in the US drug market in 2002 was 214.7 million dollars, the OTC only took 57.8 million dollars in it. And the sale of prescription drugs is controlled strictly. The buyers have to hold a prescription by doctors and can only buy the catalog and dose of the drug listed on the prescription. This kind of drug has much more danger for normal people, but its effect is better to the special patients. In fact the prescription drugs take the main market share and have stable demand. As a result, the market for medical products could generally be divided into prescription market and over-the-counter market. One of the most important characters of prescription drug is that the end consumers have less freedom to choose the products at

their will. Instead, doctors or apothecaries make their choices including the category of drugs and also brands within the category. The unique type of principal agent relationship causes problems in the market such as price insensitivity in the retailing market, asymmetric information, agency problem, necessary for regulation etc.

### 3. A MARKET TAXONOMY OF THE CHINESE PHARMACEUTICAL INDUSTRY AND MARKETS ANALYSIS

#### 3.1 Chinese Pharmaceutical Industry Value Chain

Though the revolutions in Chinese pharmaceutical industry push the industry closer and closer to the international standards. The value chain in China has some special characters. See Figure1.

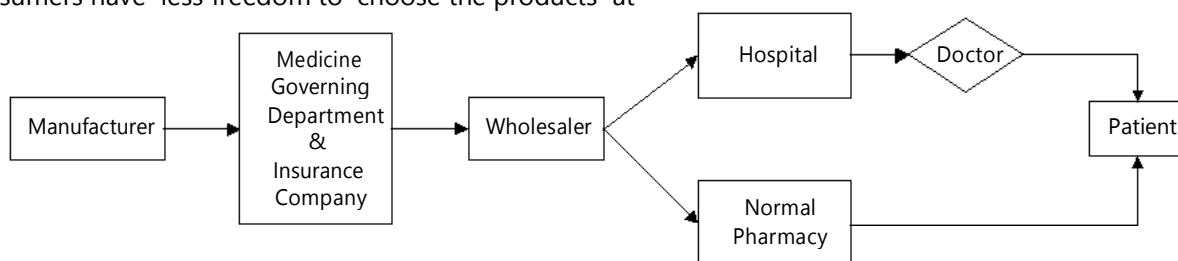

Figure 1 Chinese pharmaceutical industry Value chain

For example, there is no company like the PMB in US. In China the medicine-governing department and insurance companies decide what kind of drugs should be included in the insurance list. Another important feature is that the hospitals also sell medicines as the normal pharmacies in China. So Chinese pharmaceutical retailers include both the pharmacies and hospitals. The hospitals' market share is over 80% in the drug wholesale market. They are the most valuable customers to the wholesalers and manufacturers. In fact, in the prescription market the hospital nearly take almost the whole market share. But in the OTC market, the pharmacy's market share is increasing these years.

#### 3.2 A Market Taxonomy Based on Value Chain — Three-Class Markets

For convenience we divide the value chain into three-class markets and analyze them independently. The buyer in the former class market would turn to be the seller in the latter market. In this paper all the medicine products are thought to be the same (but the prescription and over-the-counter still have some difference which will be mentioned later). We define three-class markets as the initial market, the middle market and the end market, in which the sellers and buyers are manufacturers and wholesalers, wholesalers and retailers, retailers and consumers.

#### 3.3 The Analysis of the Three Markets

##### 3.3.1 The Initial Market

This market is the first market of pharmaceutical products. The manufacturers are the sellers, and the buyers are wholesalers.

At present there are more than 6000 pharmaceutical manufacturers in China. But most of them produce only one or several main products. The average firm size is very small. The biggest one's sale revenue is equal to 1% of the sale revenue in US. The isolation of different regions market is very notable. The firms are competing intensely and there's no real industry leader till now. Another feature is the manufacturers simply focus on production but don't pay much attention to the distribution channel. So they highly rely on the downstream firms who handle the market channel. That's why their market power is weak facing the distributors and agents.

We subdivide the manufacturers into four types and observe the top ten firms' market share from 1996-2002 (See Figure 2). It's clear that the market concentration rate is low. In 2002, the four subdivided markets' CR are 44%, 32%, 18% and 16%. Considering the fact that few of the top ten firms in the four subdivided types are inter-industry. The market concentration of the whole pharmaceutical manufacture is much lower.

Figure 2 The total market shares of the top ten pharmaceutical manufacturers

As for the wholesalers, the situation is similar. Now there are more than 16000 pharmaceutical wholesalers in China. Only 5% of them have got the revenue per year over ¥ 20,000,000. In 2002, there are 17 pharmaceutical wholesalers on the list of China top 500 wholesalers. The total market share of the 17 firm is 25.88%, CR<sub>10</sub>=18.98%. Compared with the situation in the US and Germany, the market concentration is very low. See Figure3

Figure 3 The CRs of three countries' pharmaceutical wholesale industries

To sum up, in the initial market there are a great number of manufacturers and most of them have little market power which leads to a low market concentration. The barriers to entry are actually lower than in some other mature product markets. Most of Chinese firms are generic firms whose R&D inputs and levels are relatively low. To the wholesalers who are the buyers in the initial market, there are low barriers to entry. In such a situation both the buyers and sellers do not have great bargain power. But in the regional markets some wholesalers have relatively high monopoly power due to the isolation of the markets from competition.

### 3.3.2 The Middle Market

The wholesalers are sellers in this market. The retailers

who are the buyers including two groups: pharmacies and hospitals. In theory the two kinds of retailers are the same, but actually the hospitals have obvious advantage, especially in the prescription drug market. They are the most important customers to the wholesalers. This tier of market has been very inefficient because of the wholesalers' iniquitous performance.

But the situation is changing in these years due to the newly adopted policy of the hospital procurement bidding system. Though this bidding system has not been fledged and adopted by all the firms in the industry. It has shown a very attractive tendency. It plans to take all the manufacturers, wholesalers and retailers together in one system including E-Commerce system and EDI. All the information about the drugs such as price, producer, agent or wholesalers will be supported in the E-Commerce system. The retailers would be able to choose the catalog, brand, and the wholesaler as the supplier of one product directly and efficiently. And the wholesalers and retailers could search and exchange the information through EDI. Now the government is trying to develop and propel this pharmaceutical industry electronic business system.

### 3.3.3 The end market

The sellers and buyers in this market are retailers and consumers. The total demand of the pharmaceutical products is very stable and has low price elasticity. The agent problem is very marketable in this market. That gives the hospital an unshakable advantage.

The demand of every consumer depends on the condition that the consumer is in. If the consumer is in healthy condition, his demand elasticity is zero but the demand is zero also. If the consumer is in ill condition, the demand isn't zero with a very small elasticity. We infer it's a concave function in a limited area whose slope changes from zero to infinity. So the end consumer's demand function could be written as a random variable  $D(\omega)$ ,  $\omega \in (\omega_0, \omega_1)$ ,  $\omega_0 = (\text{Healthy})$ ,  $\omega_1 = (\text{Sick})$ , that's the most simple space and the could be subdivided farther. Set  $P$  as price,  $Q$  as quantity, we have

$$D(\omega_0) = 0 \quad (1)$$

$$D(\omega_1) = Q(P) \quad \text{with } Q'(P) < 0 \text{ and } |Q''(P)| < 0. \quad (2)$$

## 4 APPLICATION OF E-COMMERCE IN THE CHINESE PHARMACEUTICAL INDUSTRY

Now the E-Commerce of pharmaceutical industry is just at the beginning in China. The trading amount is a quite small proportion of the big market. E-Commerce emerges mainly in B2B model. And there hasn't been an efficient regulation to this new model of business. But it's growing up in a remarkable speed. More and more companies have recognized the coming revolution from the new market factor and are going to join the process whether they wish it or not. With the government's effort, there is no doubt that the Internet will be a crucial

factor of the revolution of pharmaceutical industry in China.

In China some successful B2B models are coming in sight. Some of them try to build an information center and industry database such as [www.cpi.ac.cn](http://www.cpi.ac.cn), [www.gm.net.cn](http://www.gm.net.cn). Some of them focus on the E-commerce Service Provide (ESP) like [www.e135.com](http://www.e135.com), [yy.18-china.com](http://yy.18-china.com). The main customs of these businesses are pharmaceutical manufacturers, wholesalers or agents, pharmacies and hospitals. The most important investment comes from the relevant departments in government and companies. Though their market share is not high, the potentiality of them is very large. Such as [www.e135.com](http://www.e135.com), the trading amount in the first 8 months went beyond 15 million Yuan. The amount at the end of 2000 had reached hundreds of million Yuan.

## 5 THE PROFOUND IMPACT ON CHINESE PHARMACEUTICAL INDUSTRY OF E-COMMERCE: THE INDUSTRY AND MARKET POWER

The E-Commerce of pharmaceutical industry, especially the B2B, is being adopted and going to be the new focus of the Chinese E-Commerce with the support of government. B2C, which has been popular in US, is also a hot point in China. These new business models are the most immediate impacts of the Internet.

Relatively to the B2C, B2B is more practical in the initial market and middle market and may break down the original market structure. The Chinese market is has some remote regions that are inaccessible to the Internet. The barriers to entry of the regional markets are becoming lower, which will lead to emergence of more enters. So the regional monopoly will face more potential competitors and the small firms will have the ability to enter more markets. The result is the changes of the industry structure and the market power allocation of both upstream and downstream firms.

### 5.1 Manufacture Industry

In the manufacture industry the beneficiary would go to the middle firms. The large firms have paid great cost to get the national market share during the past time. But with the Internet the other smaller firms could get into the national market in a much cheaper way. That's impossible in the no-Internet days. So their prices could be much lower than that of the large firms', which makes them to be serious competitors to the large firms. Though the large firms could apply the Internet to decrease their cost too. The past cost and huge traditional market nets will be their disadvantages in the Internet time. There will not only be the finance problem but also the management problems transformation. And there don't exit such problems for the middle and small firms. They only get a new

competitive advantage from E-Commerce. That may lead to a revolution in the industry.

But what's the problem with the small firms? Why we say the winners should be only the middle ones? That's the special situation in China. Now all the pharmaceutical manufacturers are facing the GMP acceptance. To reach this level the firms have to pay much cost to improve the production conditions, otherwise they will have to quit. And in the new hospital procurement bidding system, some firms are usually not the chosen ones. Based on all the policies of recent years, we infer that the government wants to push the small firms who do not have competitive advantages out of this too-crowded industry. That's the first step to solve the problems in the ex-competitive pharmaceutical industry. The new competitive advantage supported by Internet can't fight with the government. Additionally the small firms in China are highly relied on the local markets. But the Internet will break the local market and bring all the middle and large firms into every regional market. That will be another hit to the small firms. So the winners would only be the middle firms who could catch this chance.

To conclude, The application of B2B in pharmaceutical industry will lead to a new structure: the small firms without competitive advantage will quit the market; some middle firms will have great development by this chance; the big firms have to undergo some revolution to deal with the new competitors to protect their market shares. More combinations will emerge for expansion, some of them will go beyond the regions.

### 5.2 Wholesaling Industry

In the retailing industry the Internet breaks down the limit of regions that is two-way relatively. That means in both the upstream and downstream markets the wholesalers faces the region limitation. This two-way region limitation may be one important reason for the low market concentration rate.

Comparing with the manufacture industry, the focus in retailing industry is the distribution channels. The Internet will break all the market bounders. That means every wholesaler will face incredible numbers of downstream retailers, which is impossible in the traditional market. Then every firm will have chances to win some new customers and lose some old costumers. That will lead to a higher competition. But the government will play an important role here. Similarly to the manufacture industry, new hospital procurement bidding system will help the powerful firms get more market shares in the future, even result in nature monopoly. There will be some problems of this method, such as the region limitation in retailing market. But the Internet would help overcome it. All the firms who win the bidding will come to one national market by the Internet and compete with each other. So from both

the policy and the technology perspectives, we suggest and prescription drugs respectively. that the government contracts the market and the Internet connects the market.

### Acknowledgement

### 5.3 Retailing Industry

The situation in retailing industry is a little different because the region is not the main factor to limit their development. And they also use the B2C model that has obvious advantage compared with the brick and mortar shops. The e-shop is a real sense 24 hours pharmacy and lower the consumers' supply cost and traffic cost. For the retailers the e-shop has no fixed cost and little running cost. The most attractive point is that it contains a no-inventory way during keeping a proper relationship with suppliers. Therefore in the future this B2C model must become a new focus in retailing market and expands the pharmacy's market share.

### 6 CONCLUSIONS: SOME PREDICT TO THE FUTURE OF CHINESE PHARMACEUTICAL INDUSTRY

At last the pharmaceutical manufacturing industry will achieve a new stable structure with smaller number of firms and stronger firm power that will lead to a higher market concentration. The market won't be divided into many regional markets with more beyond-regions companies who will compete together in the national market. Comparing with before, the manufacturers' market power will strengthen, but the downstream firms change also, the relative market power depends on both sides. In the wholesaling industry only several big firms would exist in the national market. The three-class agent system may disappear. The relative market power of retailers will strengthen a lot in the initial market that may result in a monopsony situation. The B2C business model in the pharmaceutical retailing industry denotes a chance to re-allocate the market share between hospitals and pharmacies. The final structures may be the pharmacies and hospitals handle the over-the-counter

The research is funded by the National Natural Science Foundation of China (Project Number 70231010 and 70321001).

## ABSTRACT

Hotels sell a great deal of their inventory by means of third party distribution through the use of technology and marketing intermediaries. More recently the Internet along with other emerging technologies has offered the potential to disrupt enduring distribution arrangements. The question of strategic change is important as the low-cost, multi-channel possibilities offer considerable potential benefits to hotels, but these are also linked to considerable risks. The focus of the study is on the drivers behind the choice of distribution intermediaries by hotel groups. A research questionnaire designed to establish the factors influencing hotels' choice of intermediaries, was developed from the extant literature. Subsequently principal component analysis uncovered an overriding factor, (referred to here as 'risk preference') which is shown to influence heavily channel strategy choice. This indicates the concern by hoteliers over the impact of negative direct or intermediary-related performance on hotel brand image and reputation. The results of this study further support the theory that the hotel industry has yet to define a strategic direction that will leverage the capabilities of the Internet.

**Keywords:** hotel distribution, Internet, channel choice

## 1. LITERATURE REVIEW

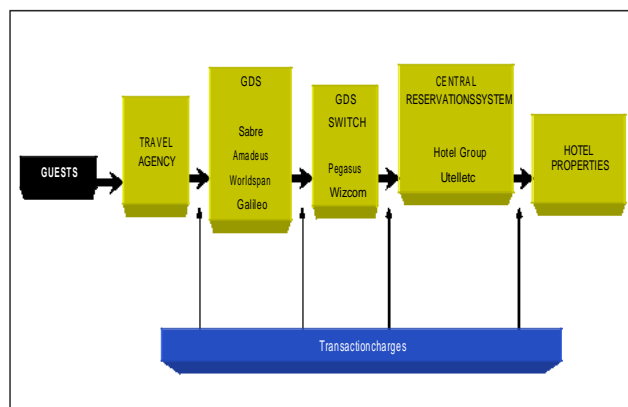

Figure1: The traditional path of online hotel reservations

Source: Price Waterhouse Coopers (1999). *Hospitality Directions European Edition - The Internet Transforms the Traditional Hotel Distribution System*, London, England: Price Waterhouse Coopers.

Distribution systems extend the number opportunities for a sale and facilitate the purchase of products in advance of their production. A traditional distribution path is illustrated in Figure 1 above.

The role of the various European travel agents is to act as the intermediary that brings travel products to the consumer. According to Dube and Renaghan [2] travel agents and meeting planners book almost half of all hotel reservations. As travel industry consumers normally cannot see the product at the time of reservation - agents therefore fulfil the key roles of advising customers, passing information between the different parties, and providing value-added services. Hence, travel agencies by tradition have played an important distributor role - their main advantage is that they are able to reach a larger number of potential

customers than if the provider were to distribute through their own outlets. As demonstrated in Figure 1, numerous intermediaries perform various functions along the transaction chain between the hotel guests and the hoteliers which result in transaction charges.

Global distribution systems (GDS) such as Sabre and Amadeus have been effective means of communication and inventory exchange between local, national and global suppliers, and the travel agencies. GDS accounts for about a third of all hotel bookings world-wide, and bookings are continuing to grow. Corporate travel agents have heavily influenced the development of the GDSs given they are able to control the relationship between the corporations they serve and the suppliers. The corporations required a global network of products which in turn required ownership of global databases, which meant the suppliers had to depend heavily on GDSs for distribution [9]. Another form of intermediary is the switch companies placed between the GDSs and the hotel central reservation systems (CRS). The need for switch companies exists because the wide variety of software and programming languages used by hotel reservation systems must be adapted to GDS software and vice versa [10]. Interestingly, these Switch companies are now able to communicate with consumers over consumer-oriented websites [7]. The CRS have enabled hotels to maintain a single image of inventory between their own systems, and (via the switch), the GDSs. Although the GDS channels attract an increasing volume of hotel reservations, it should be remembered that the bulk of world-wide hotel reservations are made directly with properties or with Central Reservations Office [6]. Although these channels account for a significant volume, they have high administrative costs attached. They both require toll-free telephone numbers in major markets, and trained multilingual staff to handle enquiries. There is evidence to suggest that hotels have been slower than

other industries to realign their distribution strategy towards Internet channels. For example, according to Harteveldt et al [3], in 2000 more than 75% of American online travel bookers bought air tickets, but only 59% booked hotels.

A new form of cyber-intermediary is the online consolidator who negotiates discounts with suppliers and then sells that capacity to consumers. Typically interacting with individual hotels, consolidators act as room brokers that purchase inventory at a deeply discounted rate, selling it on at a mark-up [11]. These online agencies (e.g. Travelocity, Microsoft Expedia and Internet Travel Network) pose a real challenge to the hotel providers since they are unable to match the intermediaries' experience and product/service range, leading O'Connor [6] to conclude that future growth will be driven through online agencies.

Webb [13] advises that hotels should employ a variety of online distribution channels as the benefits of a multi-channel strategy are highly applicable to hotel products:

- Greater responsiveness to customer shopping patterns
- Decreased dependence on existing channels (a single channel may not be suitable for all products)
- Increased outlets for distressed inventory
- Ability to penetrate new markets

From the consumer's perspective, despite the obvious attraction of the convenience of purchasing online, there has been a persistent concern about security, privacy, service levels and trustworthiness. It is also difficult to quantify value added by internet channels when many consumers still employ them purely as a means of pricing rooms perhaps because of the difficulty of physically checking products/services before purchase and the helplessness felt in offering credit card details during online purchase.

O'Connor [6] carried out a Delphi study amongst a group of experts in the field of electronic distribution to develop, validate and weight a list of core evaluation factors for electronic intermediaries. The research was focused on identifying evaluation processes, and it found that there is currently no widespread agreement in the industry on how channels should be evaluated prior to adoption. Financial factors were the most frequently cited group, while technical and operational factors received the highest individual scores - suggesting a need for prioritisation of factors in the evaluation process. Performance appraisal activities tend to be intuitive rather than based on formal guidelines or principles. A possible weakness in this study is its focus on corporate electronic distribution specialists, rather than including hotel-level operators.

## 2. RESEARCH METHODOLOGY

This study attempts to overcome the complaint in a recent paper [8] that indicated little is understood about

how electronic distribution studies might be evaluated. The research was carried out through a survey (see appendix) that was sent to a sample of key hotel operators with responsibility for channel management. The survey was based on a set of questions designed to measure attitudes towards twenty key attributes of online distribution channels. The responses to the survey are subjected to factor analysis to identify the underlying factors that influence their attitudes. The data collection phase was done by presenting a list of questions about the criteria used in evaluating electronic distribution media by hotel groups. The first task, therefore, was to establish a comprehensive and detailed set of decision criteria that would be assembled for this survey. An initial list of criteria was produced based on the views represented in the literature reviewed. This list was distributed to a reference group of knowledgeable academics, and their feedback was incorporated into a revised list. The revised list was then distributed to a group of five hotel industry e-commerce specialists –all of whom hold management positions in major hotel chains. Their feedback was reviewed and collated to produce a final list of items – these are listed in Table 1. This pool of twenty items formed the basis for the questionnaire.

The questionnaire investigated attitudes and used five point Likert Scales. A mixture of positive and negative statements was presented in the questionnaire to improve accuracy of response. For data collection purposes two separate populations were defined relating to the two sets of target respondents –individual hotels, and corporate level management with responsibility for distribution. The study was carried out with assistance from a number of major international hotel groups. In total, a base of 872 individual hotels was contacted for the study, and a survey instrument was distributed to every hotel in that database. The target recipients were the key rooms' management contacts in each property. A population of corporate hotel groups was also defined using assistance from industry contacts, and the survey was distributed to 70 distribution/channel managers from hotel groups in Europe. The questionnaires were distributed by email containing a link to a website, upon which a collection page was created. The responses from the website were forwarded by Email to a dedicated account from which the data were transferred to a database. The questionnaires were also sent as an attachment to the email, for those respondents with access to Email, but not Internet. Responses sent by email were added manually to the same database. From the 872 individual hotel contacts a total of 268 responses were received, representing a response rate of 30.73%. Of the corporate level respondents, 47 responses were received, representing a response rate of 67.1%. The total combined size of the sample was therefore 315.

**Table 1: Evaluation criteria for electronic distribution intermediaries**

Subject	Item
Technical capabilities of intermediary system	Method of reservations delivery
	Connectivity to the existing reservation systems
	Availability of booking data
	Security
	Hotel's ability to control price
	Ability to support revenue management strategy
Costs	Start-up/one-off charges for participation
	Commission costs
	Other transaction (eg switch, CRS)
	Processing (eg fax/voice reservations)
Supplier profile	Ability to reach specific markets
	Potential production volumes
	Ownership of medium
	Credibility of owners
User-facing capabilities	Speed and reliability
	Trust/privacy

	Customer experience
Representation of hotels	Appropriateness of site for the hotel's product
	Representation of price to customer
	Content (eg hotel-specific information capabilities)

### 3. RESEARCH RESULTS

The data collection exercise centred on a list of twenty questions that were administered to respondents. For this analysis, the responses to both the hotel and corporate-level questionnaires were combined to form a single data set of 315 cases, and subjected to factor analysis. The object of this phase of the analysis was to identify the dimensions or factors that are tapped by those twenty variables. The form of factor analysis used, Principal Component Analysis, achieves this by reducing the total number of variables, retaining only those factors that explain a significant proportion of the variance in the overall dataset. The result of the analysis has been to reduce the overall data set to six factors that explain the majority of the overall variance.

**Table 2: Summary of factors emerging from analysis**

Factor	* % Variance	Items	Subject	Loading	Alpha
1	15.00%	Q3	Security of connection to hotel CRS	0.62	0.6884
		Q12	Customers' trust and privacy	0.70	
		Q13	Appropriateness of site for hotel's image	0.68	
		Q19	Credibility of intermediary owners	0.73	
2	9.82%	Q7	Method of reservation transaction delivery	0.68	0.5733
		Q16	Ability to reach specific markets	0.80	
3	9.60%	Q9	Potential production volumes	0.61	0.4768
		Q14	Transaction charges (eg GDS, switch)	0.71	
		Q18	Hotel's ability to control price	0.57	
4	9.14%	Q4	Availability of management information on bookings	0.70	0.5068
		Q11	Ownership of the intermediary	0.79	
5	8.43%	Q5	Representation of prices	0.70	0.5162
		Q15	Speed and reliability of website	0.76	
6	7.87%	Q2	Connectivity to existing reservations systems	0.81	0.4254
		Q10	Commission rates	0.70	
* Rotation Sums of Squared Loadings					

The reliability of the factor analysis results was tested using Cronbach's alpha. The six factors extracted by the analysis are detailed in Table 1, along with the items from the questionnaire that loaded most heavily upon them. It should be noted that the analysis appears to

have identified factors quite different to those suggested by the academic and industry expert reference groups (see Table 1). Based on the responses to direct questions from a sample of industry operators, the logical groupings listed in Table 1 appear not to influence

individuals' attitudes in the way that was originally proposed. It is important, therefore, to understand the factors that have been identified by this analysis. The first factor accounts for a significantly larger proportion of the variance in responses than the others, and an alpha value of 0.69 suggests that it is a relatively reliable measure. Interestingly, the four items that load most heavily on this factor are drawn from four of the different groups defined in Table 1, meaning that this factor is not at all consistent with the groupings defined during the preparatory research phase. This does not mean, however, that the combination of these attributes does not make sense.

Security of connection and customer trust and privacy can be defined as hygiene factors –i.e. they are perhaps unlikely to be identified as a key source of competitive advantage, but the risk of failure in either area is generally unacceptable. The appropriateness for the hotel's image and the credibility of intermediary owners also load heavily on this factor, but like the others, the importance of these items is primarily associated with risk – in particular the damage that appearance on an inappropriate site may do to a hotel's brand image, and the risk of engaging in a partnership with a supplier that results in failure. In short, this factor appears to suggest risk has considerable influence on respondents. Of the seven factors, this was the only one that combined the internal reliability of scale with a plausible explanation. Although several other factors emerged, these had relatively lower reliability scores, and contained items that appeared to be unrelated. There are two possible explanations for this: Firstly the research instrument may not have been interpreted as consistently as the pilot phase suggested. The other explanation is that the approach of respondents to electronic distribution media is genuinely not governed by consistent, logical processes. This finding supports the literature review that suggested a lack of understanding of channel strategy in the hospitality industry.

#### 4. CONCLUSION AND RECOMMENDATIONS

Of the twenty questions in the survey, six relate to the capabilities and the costs of different intermediaries. Had any combination of these items loaded heavily on a single factor, a preference for particular attributes of intermediary offerings would have been indicated. This was not the case, so this survey has not provided such weighting of any future direction regarding online hotel reservations.

Much of the benefit of disintermediation identified in the literature review is associated with cost reduction [1, 3, 4]. The results of the survey, however, offer no clear indication of the importance of different costs in the channel management decision making process. This finding is consistent with other sources add that the cost benefits of online intermediaries are not being realised by hotels. The lack of clear factors influencing

respondents may be explained by the diversity of different job roles amongst the respondents. The survey was distributed to "Key Rooms Management Contacts". This may have impacted the research, although the appropriate contact for each hotel may have been correctly identified, the level of involvement of each individual in both the management of distribution channels, and in the overall strategy of hotels may vary significantly.

Solomon et al [12] further define involvement as the motivation to process information, suggesting that there is a perceived linkage between the user's goals, values, needs, and their product knowledge. It can therefore be argued that the nature of different job roles within the respondents to this survey may explain the apparent lack of factors that clearly dominate the responses. A hotel General Manager, for example, may have ultimate responsibility for their hotels' strategy; however, his or her level of familiarity with the practice of channel management may be very limited if the execution of the task is delegated within the hotel. Conversely, if the key contact is a Reservations Manager, he or she may be highly familiar with the operational procedures of channel management, but not ultimately accountable for the profitability of the hotel whose inventory they manage. Similarly, distribution and channel management positions at corporate level in hotels cannot be regarded as uniform throughout all companies as the roles, responsibilities and the seniority associated with a particular job title varies between hotel groups.

Although only one main factor emerged from the analysis, the overall results of the survey suggest that the opportunities offered by the Internet are not fully realised by the hotel industry at present. This is consistent with many of the views represented in the literature review [5, 3, 6]. Because the study focused on a B2B business model, the findings have implications for management of two groups of businesses: The hotel groups whose inventory is sold through the distribution channels and the intermediaries that provide the distribution services. For hotel operators an important observation from the results of the factor analysis (See Table 2) is that they bear no resemblance to the groupings of factors that were defined by industry experts before the research began. The items were grouped into: Technical capabilities of the intermediary system, costs, supplier profile, user-facing capabilities, and the representation of hotels. These groups appear to be based on entirely logical relationships; however, the factor analysis does not identify any of these groups as underlying psychological dimensions influencing the responses to the questionnaire.

For hotel groups, for example, the importance of cost cannot be understated –The literature review explains the relevance of channels of distribution to hotels, citing the efficiencies that can be realised through the use of distributors. However, none of the factors emerging

from the data grouped responses to the questions about distribution costs together. While this could be attributed to limitations in the research technique, it could also form the basis of the argument that the cost implications of distribution channels are not fully understood by those responsible for executing channel strategy. This is unsurprising – the definition and attribution of costs in hotel distribution is a complex matter. In addition to the structure of charges illustrated in Figure 1, the one-off set-up costs of the intermediary must also be considered – already this suggests a structure of fixed and direct costs. The existence of online consolidators who sell deeply discounted hotel inventory at a mark-up further complicates the issue. The margin between each intermediary's selling and buying prices for each hotel room night is an opportunity cost to the hotels, even though it is seldom if ever treated as a cost item by hotels. Although the complexity of distribution costs makes this a difficult area to understand, it should be a critical factor in channel strategy. The results of the survey suggest that currently it may not be.

Having identified that risk has a strong influence, suppliers could adjust their marketing communications and positioning to emphasise such qualities as the security both of customer details, and of connections to hotel reservations systems, and the image of their site and the owners' financial credibility. It could also be concluded that hotel groups appear not to have a consistent perception of the value associated with electronic distribution intermediary offerings. This view is supported by the survey responses, and it would logically support the recommendation that suppliers have not been effective in communicating the value proposition of their offerings to the marketplace. The sources in the literature review suggest that although technologies and intermediaries that disrupt the traditional reservations chain are now widely available, hotels have been slower than other travel-related industries to embrace the opportunities they offer. Perhaps the opportunity remains for intermediaries to educate the market in the importance of a clear channel strategy, and the implications of different channel offerings for different businesses.

### Appendix: Hotel Electronic Distribution Questionnaire

This questionnaire is part of a study into the electronic channels through which hotel rooms are sold. All responses are entirely confidential. Please answer all of these questions openly.

	<i>Please respond to each statement by entering "X" under <b>one</b> number on the scale. The scale runs from 5, that indicates "I strongly agree" through to 1, that indicates "I strongly disagree".</i>	I strongly agree			I strongly disagree	
		5	4	3	2	1
1	I only agree to distribute through websites that provide bookers with good and detailed information pages on hotels.					
2	I only look to sell through channels that can connect directly to my hotel's central reservations system.					
3	I would not consider connecting my hotel to a distribution channel unless I could be sure that it is secure.					
4	It is essential for booking channels to provide management information about bookings.					
5	Before agreeing to sell rooms through an electronic channel, the way that prices are represented must be made clear.					
6	The cost of subscribing to a channel is the most important consideration in deciding whether to sell rooms through it.					
7	The way that reservation transactions are delivered to the hotel is not important.					
8	It is essential that rate or inventory controls set by the hotel are correctly reflected through the online channel.					
9	Potential distribution partners must demonstrate their ability to deliver a large volume of business.					
10	Commission rates are basically the same for all electronic channels.					
11	My decision to allow rooms to be sold through a channel is not usually influenced by the company that owns the channel.					
12	Before I will allow rooms to be sold through a website, I must be assured that potential customers' trust and privacy are adequately protected.					
13	I always consider the brand image of a website, to decide whether or not it's suitable for my hotel.					
14	I pay particularly close attention to all the transaction costs (eg GDS fees, switch fees etc) associated with each channel.					
15	It is important to me that websites sites through which my rooms are sold achieve acceptable standards of speed and reliability.					
16	The target market of the website is not really important, as long as it produces bookings.					
17	I always try to avoid selling through websites that deliver reservations to the hotel by fax or telephone.					
18	I must have control over the prices that are displayed on partner sites.					
19	With all channel partners, I usually find out who owns the company and research them to see if they look like a viable business.					
20	I am most likely to choose to distribute my rooms through websites that offer the best customer experience.					

# An Initial Study on the Intensifying Enterprises Information Management

## ABSTRACT

The information management has become an important base of developing an enterprise's eBusiness. Although our country has spent abundant manpower, material resources and financial support on enterprise information management, most of the information systems were not so good to meet our need and they didn't bring the effect into play sufficiently. Based on the two large questionnaires, this paper has made an initial study and analysis on the status and actual questions of Chinese information management. And then this paper studies the current status of information management of some of the dominant enterprises in Sichuan Province. At last this paper presents some suggestions of intensifying enterprises information management.

**Keywords :** eBusiness, information management, information resource management

In recent years, Chinese enterprises have spent abundant resources on enterprise informationization, but most of the information systems were not so good to meet our need and they didn't bring the effect into play sufficiently. So the benefit of enterprise information management is rather low. The author believes that one of the main reasons is short of 'intensifying enterprises information management'.

The development of enterprises information management in Sichuan Province is behind of the east. The ulterior study of enterprises information management in Sichuan Province is very important to promote the development of west.

## 1 THE ANALYSIS ON THE STATUS OF CHINESE INFORMATION MANAGEMENT

### 1.1 THE STUDY FOUNDATION

This paper has made an initial analysis on the status of Chinese information management that is based on the two large questionnaires.

The report 1<sup>[1]</sup>: In 2001, the Economic Information Center of the State Economic & Trade Commission had made a questionnaire on the informationalization status, which reclaimed 638 effectual questionnaires. According to these questionnaires, they got valuable investigate result and analysis report. Among the investigated enterprises there are 231 national key enterprises and 510 state and state holding companies. The investigated enterprises cover the whole country and involve 33 industries such as mechanism, chemical industry, spin, electron, coal, automobile and so on, among which, state and state holding companies account for 79.94%, the other 12.23%, and oversize enterprises 15.36%, lager enterprise 59.4%, medium-sized enterprises 16.46%, other enterprise 2.66%.

The report 2<sup>[2]</sup>: In 2002, the State Enterprise Information Work Leading Group Office and the Information Center of the State Economic & Trade Commission made the 4th questionnaire of the level of informationization construct and application of 520 state key enterprises, 120 experimental enterprise groups and district key enterprises, which reclaimed 570 effectual questionnaires, and according to these questionnaires they gained the investigate report of national enterprise informationization.

The two reports carry preferable authority and reflect the information management status of the dominant enterprises in China by some degree. As there are some difference between the reports, this paper integrate them and give a complete analysis of the information management status of the enterprises in China.

### 1.2 RESEARCH CONTENT

(1) The management status of enterprise information human resource

The investigation of information human resource all takes the first place in the twice questionnaire reports, which reflect that the persons with ability is very important in enterprise information management.

According to the second report, some of the investigated enterprises in 2002 pay more attention to the information management.

83.3% enterprises have set up the position of CIO which is corresponds to vice general manager; 89.1% have set up the position of full time personnel to run and maintain information system; 86.7% enterprises have rebuild and upgrade their system according to the development of technology and operation requirement; 74.9% enterprises have taken training informationization talent as a focus of their work; the proportion of setting up the position of CIO in 2002 have increase 14% compares to that in 2001. But the information skilled personnel just account for

0.72% of the employee total number, namely, there is lower than one information skilled person among every 100 employees. The compound backbone personnel who not only knows well IT ,but also is familiar with operation flow and enterprise management is quite lacking, which infect the development of enterprise information management.

(2) The foundation establishment construction of enterprise information management (the report 2)

The rate of possession of computers and access Internet is elevated. Every one hundred persons have 7 computers, every manager has 0.77 computer. In some enterprises, one person has computer. The number of computers, which access to Internet is about 68.4%.

Most enterprises have established intranet, internet and Portal. The coverage and application range of all kinds network are extended which have held every administrative levels, especially management department and core operations.

The method to access Internet of most enterprises has been close to advanced lever and the bandwidth is widened. The intranet bandwidth of 77.7% enterprises is 100 MB to 1000MB, 76.4% enterprises' desktop bandwidth come to 10-100MB and most enterprises' internet bandwidth is more than 1MB, which reaches the lever of high speed transmit channels.

Most enterprise have spent abundant fund and are provided with foundation. Many enterprises have build their portal, but the content isn't updated in time, and the columns of many enterprise portal are the same and lack of individuality, which is hard to bring benefit to enterprises.

(3) The construction of enterprise information system (EntIS, the report 1)

Tab.1 is the summarization of the Report 1.

The implementation rate of some information system is quite low, the rate of CAD/CAM is tiptop but just close to 9%.

**Tab.1 The input and construct status of EntIS**  
(unit: Million Yuan)

CAD/CAM	Total input	Construct status			
	12.97	Full realization	Partly realization	Not take measures	Unknown
		9%	50%	19%	22%
Basal MIS (OA, MIS)	19.42	8%	59%	18%	15%
Integrated MIS (ERP, CMIS)	0.86	5%	31%	44%	20%
eBusiness system	2.78	1%	23%	55%	21%

In 2000, there are just 138 enterprises putting eBusiness in practice, which is 21.6% and those of full realization eBusiness system only occupy 1%. The collectively Level of eBusiness is just the age of primary stage.

(4) the status of information share (the report 2)

The proportion of inter-linkage and mutual communication in different system is lower than one third most of which just is limited to the range of department and local computers. The number of full realization information share is 41, which just account for 7.2%, the number of partly realization information share is 336 which just is 59%, and the number of unfulfilment information share is 193 which is 33.9%.

Unfulfilment enterprise information share will cause Information isolated Island, and the superiority of information management can't be brought into play. The most important reason is lack of collective layout、system design and durative optimize strategy.

(5) The value brought about by using MIS (the report 2)

About 36.7% companies enhance the ability of deliver the goods in time; 77.5% reduce the cost(such as buying cost and overtime cost); 67% reduce the total production maintenance and productive time of a working; 64.6% increase the sales income; 66.3% increase the velocity of flexible capital. Information management increases the value and benefit of the company, the application focuses on the operation management, and few involve management and strategy level.

Comparing report 1 with report 2, we have the finds:

(1) In report 2, there is the investigation about collective layout of enterprise informationization which isn't mentioned in report 1 and enterprises pay more attention to collective layout of informationization.

(2) The key system content has been changed and enterprises pay more attention to the technology of Data Integration and Data Warehouse.

ò The systems of ERP、Intranet、EC、OA were made as the four key systems in the report of 2001.

ò According to the Statistics of report 2, the systems of ERP、OA、Intranet、data integration and data warehouse were the emphasis of next one-step information construction.

### 1.3 EXISTENT PROBLEMS

The information management has made some progress in china, but now the level is low. The main problems are:

(1) The focus of information management is in the data processing in a low level.

(2) Enterprises are lack of reasonable and effective collective layout in implement of information management.

(3) Enterprises' information resource has not been made good use and the lever of share information resource is low.

(4) They just can be used as to deal with some simple affairs and can't provide effective decision making to middle and high level.

## 2 THE CONTRAST ANALYSE OF THE INFORMATION MANAGEMENT IN SICHUAN'S PREPONDERANT ENTERPRISE

According to the Report 2, there are 360,000 industry corporations in Sichuan province. Among them, there are 292 large enterprises, 578 medium-sized enterprises, 4230 state-owned enterprises, 60,000 collectively-run enterprises, 290000 individual enterprise in town including other 3195 industry enterprise such as private enterprise, foreign investor and Hongkong, Macao, Taiwan investment enterprise and 73 stock limited companies. There are 5 well-known enterprises in Sichuan province, they are Changhong Co. Ltd., Lu Zhou Ancient Cellar, Wuliangye Group, Langjiu Group and Sichuan Jiannanchun Group Co. Ltd. Besides, there are 216 province's famous-brand enterprise and 230 province's famous-brand products.<sup>[3]</sup>

### 2.1 RESEARCH SAMPLES

This paper choose 12 typical enterprises, they are Sichuan Changhong Electric Co. Ltd., Sichuan Electric Power Company, Pan Steel Group Co, Wuliangye Group Co. Ltd., Chengdu Aircraft Industry Corporation, Sichuan Jiannanchun Group Co. Ltd., Chengdu Enwei Group, Telecommunication Corporation of Sichuan province, Chengdu Cigarette Factory, Chengdu Pepple's Department Store (group) Co. Ltd., Dong Fang Steam Turbine Works, New Hope Group.<sup>[4]</sup>

Tab. 2 is the rank of the top five enterprise in Sichuan<sup>[5]</sup>

**Tab. 2: the rank of the top five enterprise in Sichuan**

Enterprise Name	Rank by sales	Rank by general asset	Rank by profit	Rank by tax
Changhong Co. Ltd.	1	5	3	6
Electric Power Company	3	1	9	4
Pan Steel Group Co.	2	3	2	3
Wuliangye Group Co. Ltd.	4	6	1	2
Chengdu Aircraft Industrt Corporation	11	10	96	157

### 2.2 DATAANALYSIS

Through analyzing the data of enterprise information management above-mentioned, there is a conclution of the 12 enterprises information management.

(1) The status of department's MIS and the construction of LAN.

Tab.3 is the status of department's information management

**Tab.3 The status of department's IM**

	Already established	unknown
Realizing department's information management system	7	5
Intranet been established	9	3

Among the 12 enterprises selected, a majority of them have equipped with computers in their departments and established the intranet, the cover and application range of which have increased and expanded to every lever of enterprise, especially management department and core operations.

(2) Ways of information exchange between enterprises and outside

Table 4 is the Way of information exchange between the enterprise and outside

Mostly, those who have constructed websites are successful enterprises. Among them, the website construction of the Chengdu Enwei Group is a successful one. By the year of 2003, its website has provided more than 30 channels, 500 items and 2000<sup>[6]</sup> web pages. Also, Sichuan Jiannanchun Group Co. Ltd. has set functions of inviting public bidding for providers and booking service on line, which ranges at the top of the website-construction.<sup>[7]</sup>

**Tab. 4 Ways of information exchange between the enterprise and outside**

	Website	E-mail	Center of customer service
Number of enterprises	10	8	2

Among the 12 enterprises, there is 8 ones which have opened their own email boxes. Sichuan Electric Company has communicated interior information through email. Meanwhile, Pan Steel Group Co uses email for information transmission and has established the internet node web which can transmit files, gather and publish information by means of FTP, WWW etc.<sup>[8]</sup> Likewise, Chengdu Aircraft Industry Corporation has realized the communication with some factories through internet, such as Boeing. Similarly, Changhong Co. Ltd. has

constructed the program of CIQ Computer-connected Supervision on machining and trading, and with the ERP system of SAP the efficiency of passing CIQ examination has been improved greatly<sup>[9]</sup>.

However, there are some problems existed as follows:

- ò Website columns are similar and there is lack of contents with characteristics.
- ò The supporting of enterprise's internet information is weak. The weak base of interior information management leads to that it is not timely and efficient enough to integrate, gather, transmit and share all kinds of information.

### (3) Establishment of the information system

Tab.5 is the establishment of the Information System

**Tab.5 Establishment of the Information System**

	Already realized	Not yet	Unknown
CIMS	6	5	1
OA	7		5
ERP	2	10	0

As we can see from the table above, most of the manufacture enterprises have realized CIMS and OA is a major project of enterprise-construction. Basically, nearly every enterprise has realized the Financial MIS. And some enterprises have realized ERP system such as Changhong Co. Ltd. etc.

Among the 12 enterprises, the investment of information construction of Changhong Co. Ltd. has reached 100 million Yuan, and another 100 million Yuan will continue to be used to perfect the construction<sup>[10]</sup>. Similarly, to popularize the enterprise's computer management, Chengdu Enwei Group has put the application at a higher level in the beginning. Several years ago, with large amount of money, Chengdu Enwei Group bought the PC system, top grade data storage and stock system, Sybase large relational database system from SUN Company. Meanwhile, other enterprises also have devoted much money into the information construction, such as Sichuan Electric Power Company, Sichuan Telecom, Chengdu Cigarette Factory, Pan Steel Group Co etc. As their conscious of information strengthened, the degree of information investment has increased.

However, there are still some problems existed: the degree of information construction fund devotion is still not enough. Take Changhong Co. Ltd for example, its total capital is 17637511700 yuan<sup>[11]</sup>. But the absolute devotion proportion in information is merely 0.58%, which is far away from oversea enterprises normally about 8% to 10%.

### (4) Application of information

Sichuan Jiannanchun Group Co. Ltd. has done quite well in gathering and using of information resources. And document information center of it plays double functions in document information storage, using and document administrative management and supervision. In the year of 2002, the corporation established the enterprise information base from its document library. With the international internet information from Xinhua News Agency, the corporation has directly saved more than 30million Yuan from material-purchasing, technology improvement, environment protecting and so such programs.

### (5) Implement of eBusiness

Many enterprises have made primary attempts in eBusiness such as Chengdu Pepple's Department Store (group) Co. Ltd., Chengdu Enwei Group, Sichuan Jiannanchun Group Co. Ltd.. But due to the limitation of capital, talent, the base of information, balance and safety of trading, the development of eBusiness still stays at a primary period.

## 2.3 Analysis of the results

As we can see from the above 12 dominant enterprises in Sichuan Province, their information management level stands for the advanced level of Sichuan Province in enterprise information management. However, these advanced enterprises are still at a lower level in information management. Thus, intensifying information management becomes an important task. Then from the present state of the enterprise information management in Sichuan Province, we can come to the following analysis:

### (1) Status of basic facilities of enterprise information management

- ò Hardware. Computer application has been popular in most enterprises of Sichuan and they can deal with data with computers.
- ò Network construction. According to report 1, in the year of 2000, among the key enterprises in Sichuan, 54% of them have established their websites, and 13% have simple web pages, but still 29% haven't established yet. By the year of 2002, the proportions of enterprises that have established websites have increased to 71%. Many famous enterprises such as Changhong Co. Ltd and Wuliangye Group Co. Ltd. own their special websites and domain name.

### (2) Construction of information system

Part of those enterprises, we take DongFang Steam Turbine Works for example. According to its trait as a discrete manufacture enterprise, it has realized enterprise information management, which helps the corporation to have been a supplier of America GE Company. Another part of those enterprises such as Chengdu Xuguang Electronics Co. Ltd., according to its characteristic in enterprise production and management, has designed and explored application software. Then step by step, it has realized information integration and data sharing of the process of purchasing, sale, stock, production and finance. Moreover, the functions of supervising, controlling, coordination become more normative, which strengthen the competition ability of the enterprise.

### (3) Management software

Most enterprises adopt the homemade software, which are suitable for the enterprises' actuality, such as Chengdu Cigarette Factory. The software can basically satisfy the present need of the enterprises, with better services and the cost is much lower than foreign software.

The main problems existing in enterprise information management of Sichuan Province are as follows: Low benefit of information management; lacking of efficient total layout; still focusing on low level data processing; low level of information resource sharing; lacking of efficient strategy support; weak economic strength as a whole of Sichuan enterprises, even smaller amount of money can be used in information management; serious flowing-out of informative people in Sichuan enterprises. Thus, intensifying information management of Sichuan enterprises should be paid special attention to, through which enterprises of Sichuan can strengthen their key competition ability efficiently.

## 3. STRATEGY OF INTENSIFYING INFORMATION MANAGEMENT OF SICHUAN ENTERPRISES

The process of intensifying information management in enterprises is complex. Then we can consider the following aspect as a manager.

### 3.1 MAKING STRATEGIC PLANNING ON ENTERPRISE INFORMATION RESOURCE MANAGEMENT (IRM)

Making strategic layout on enterprise IRM has a quite important meaning in intensifying enterprise information management. Fig. 1 shows the process.

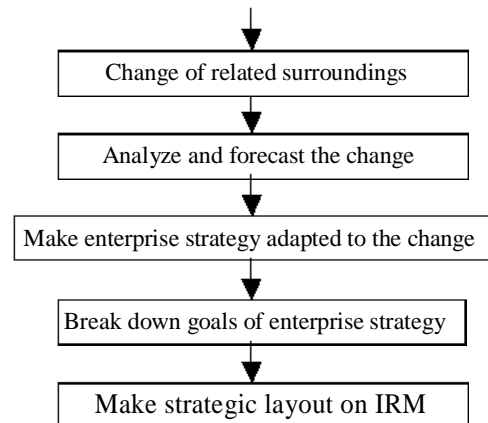

Fig. 1 Process of whole layout

### 3.2 STRENGTHENING THE ENTERPRISE' IRM

To strengthen enterprise' IRM, we can consider the following aspects: to make clear of the main task of enterprise IRM; to make strategic layout of enterprise IRM; to cultivate the information conscious of personnel; to set up right information concept; to set basic standard of IR; to improve the status of information management department and set related data management persons; to make plans that are scientific and reasonable in IR distribution and using; to develop and make use of information reasonably and efficiently; to supply different information according to different needs.

### 3.3 CONSTRUCTING ERP

It is important of BPR to intensify enterprise information management. The idea of BPR was first raised by Hamer and Qianpin<sup>[13]</sup>. Literature [14] puts up the idea of process management, which centralizes on constructing end to end business process in standardization, and it is a systematical method with the aim of continuing to improve the business performance of the organization. The idea of process management calls for systematization and continuous improvement of process, so as to reduce the manual resistance in practice, which is more suitable for Chinese enterprises.

Process management reduces the risk of BPR. The average level of the enterprise development in China is fall behind than developed countries. Therefore, in the process of putting BPR into practice, a complete, thorough process will bring up great risk to enterprises. Thus, of enterprises' managers should consider carefully before using the method of BPR, according to their ability to stand risks.

## 4. CONCLUSIONS

This paper has analyzed two authoritative sample survey materials of enterprise information in China. Besides, there are also some researches and analysis on the examples of 12 typed enterprises information

management in Sichuan. From these analyses, we find there are some common problems such as the information system aren't in full use and the benefit of information management is in a low state. One important reason of these problems is that enterprises didn't pay high attention to intensify information layout on enterprise IRM. Another is to strengthen the enterprise IRM. And the last one is to construct the enterprise MIS on the base of BPR.

### ABSTRACT

In order to further our knowledge on the use of the Internet and the Web in manufacturing SMEs, the present research seeks through an empirical study of 108 Canadian firms to explore the following questions: For what purposes are the Internet and the Web presently used, i.e., to what extent are e-business functions assimilated in manufacturing SMEs? What characteristics of the SMEs' environmental, strategic, managerial, operational, and technological context are associated with e-business assimilation?

**Keywords:** e-business assimilation, Internet use, Web use, SME, small business, manufacturing, growth, export, performance.

### 1. INTRODUCTION

Many small and medium-sized enterprises (SMEs) presently evolve in a complex business environment, characterized by globalization, the internationalization of markets, and the need for greater efficiency, effectiveness, and competitiveness based on innovation and knowledge. This has put increasing pressure upon the management of these firms, especially manufacturing SMEs that must now compete globally [1]. In order to lower their operating costs, increase productivity and quality, and respond to the increased requirements of their customers and other business partners, a number of these firms scan the technological environment and make sizable investments in adopting Internet-based or World Wide Web-based technologies as the infrastructure for e-business applications [2]. To the extent that e-business is assimilated by the SME, it can significantly affect the firm's key business processes and relationships such as servicing customers and collaborating with business partners [3].

The adoption and assimilation of information technology, and of the Internet in particular, are deemed to be influenced by a number of environmental, organizational, technological, and individual factors [4,5]. While a significant amount of research has been done on the determinants of e-business in large firms, much less is known in regard to SMEs, especially manufacturing SMEs, given that their use of the Internet is usually more recent and potentially subjected to different constraints and contingencies related to their specificity as organizations. The specific characteristics that fundamentally distinguish SMEs from large enterprises relate to their environment, structure, strategy and decision process, and psycho-sociological context such as the dominant role of the owner-manager, but also relate to their flexibility, proximity to markets, and quickness to react and reorient themselves [6]. For instance, the fact that

smaller manufacturers often act in a subcontracting capacity or in partnership with other firms within network enterprises can influence their assimilation of e-business [7]. Operating most often in "make-to-order" or "job-shop" production environments, rather than selling products as such to their customer, these firms "sell" their manufacturing knowledge and know-how within a particular industry (say, plastics) or industrial activity (say, machining). This makes for a more complex commercial cycle linking customers, suppliers, and other business partners [9].

In order to further our knowledge on the use of the Internet and the Web in manufacturing SMEs, the present research seeks through an empirical study of 108 Canadian firms to explore the following questions: For what purposes are the Internet and the Web presently used, i.e., to what extent are e-business functions assimilated in manufacturing SMEs? What characteristics of the SMEs' environmental, strategic, managerial, operational, and technological context are associated with e-business assimilation?

### 2. RESEARCH MODEL AND HYPOTHESES

Founded on the Tornatsky and Fleisher's [9] technology-organization-environment (TOE) framework, the research model is presented in Figure 1. Five constructs that represent the firm's environmental, strategic, managerial, operational and technological context are deemed to influence a manufacturing SME's assimilation of electronic business activities. In this study, the organizational assimilation of e-business is conceptualized as the use of the Internet (including intranet and extranets) and the Web. The first business aim of this use is communicational and informational (e-communication), the second is more strategic in nature (e-business intelligence) while the third is transactional and collaborative (e-commerce and e-collaboration). From this point of view, e-business assimilation is deemed to be more extensive when the

firm uses the Internet and the Web in support of more aims.

### **2.1 Environmental context of e-business in manufacturing SMEs**

Many small manufacturers must now operate within a business environment characterized by the emergence of new organizational forms such as the network or extended enterprise, whose information infrastructure is based upon inter-organizational systems and technology [10]. In a networked business environment, manufacturing SMEs would require Internet and Web-based capabilities to better support supply chain management and customer relationship management in particular. The emphasis placed upon communication and cooperation in such an environment is conducive to the assimilation of the B2B form of e-business. Greater use of the Internet and the Web would thus result from increased networking intensity on the part of the SME, that is, from the establishment of more partnerships with its customers, distributors, suppliers, competitors and other business partners such as research centers and consultants.

*H1 - The greater the firm's networking intensity, the greater its assimilation of e-business.*

### **2.2 Strategic context of e-business in manufacturing SMEs**

A firm's strategic orientation or posture is its response to its environment. As this environment becomes more hostile or complex, SMEs with a more aggressive or more entrepreneurial orientation increase their competitiveness by seeking new markets and putting emphasis on technological leadership and new product/market combinations [11]. Increased complexity in the environment is also seen as causing the acquisition of competitive, market and technological information to be more continuous, variant, and wide-ranging [6]. The strategic orientation of the SME must also be in alignment with its strategic management of information technology [12], including the Internet [13]. Given the goals of a more aggressive strategy in terms of market, product and technological developments, one expects e-business to be called upon more in support of such developments.

*H2 - The more aggressive the firm's strategic orientation, the greater its assimilation of e-business.*

### **2.3 Managerial context of e-business in manufacturing SMEs**

Small firms are deemed to be "organic" to the extent that their strategy, structure, and culture are embodied by their owner-managers. The primary goals and characteristics of entrepreneurs are thus crucial in determining the firm's innovativeness and orientation toward product/market development and technological sophistication [14]. In this regard, small business studies have shown that the previously acquired knowledge and experience of business owner-managers condition their

behavior as adopters of information technology [15]. In addition, a key component in the small firm's e-business learning experience is the owner-manager's individual learning [10]. Domain-specific knowledge that comes with experience in a specific industry or sector as well as more general knowledge obtained from a higher education would thus influence the entrepreneur's awareness of the various e-business functions and applications to be assimilated by the organization, hence the third research hypothesis:

*H3 - The greater the firm's owner-manager experience and education, the greater its assimilation of e-business.*

### **2.4 Operational context of e-business in manufacturing SMEs**

The appropriate choice of advanced manufacturing technologies is influenced by the manufacturing process structures used by an organization, i.e., by its production environment [16]. The flexibility required within a "make-to-order" production environment has led SMEs to adopt computer-integrated manufacturing [17]. In parallel fashion, make-to-order companies are seen to increase their level of vertical integration and improve their manufacturing planning and control decisions through e-business applications that allow them to better communicate and exchange information with their customers and suppliers [18]. Given the greater complexity of buyer-seller relationships in a make-to-order production environment, the fourth hypothesis follows:

*H4 - The more the firm's production environment is of the "make-to-order" type, the greater its assimilation of e-business.*

### **2.5 Technological context of e-business in manufacturing SMEs**

Advanced manufacturing technologies (AMT) are deemed to "significantly impact the design and outcomes of core organizational processes" [19, p. 995]. In looking at the links between strategy, AMT and performance, some studies have stressed the information processing capability inherent in AMT in addition to the flexibility dimension [20]. By linking with the information outputs and inputs of internal systems and applications such as CAD/CAM, MRP II and ERP, e-business applications can increase the manufacturing SME's level of external integration through their enabling of design and production information exchanges with business partners, coordination of trans-organizational business processes (e.g., just-in-time or synchronous production with "extended" ERP), and inter-organizational collaboration within a networked environment [3]. Given the compatible and complementary nature of e-business and advanced manufacturing applications, the fifth hypothesis follows:

*H5 - The greater the firm's assimilation of advanced manufacturing technologies, the greater its assimilation of e-business.*

### 3. METHODOLOGY

The data used in the study were obtained from the PDG<sup>®</sup> database [21], containing information on more than 350 manufacturing SMEs located in Quebec, Canada. Out of these, 108 completed a questionnaire about their use of the Internet and the Web. The number of employees of the sampled organizations ranges from 19 to 336, with a median of 60. Over fifteen industrial sectors are present, including metal products, wood, plastics and rubber, electrical products, food and beverages, and machinery.

In assessing the environmental context, the firm's networking intensity is measured by the number of distribution, marketing, design and R&D partnerships established with customers, suppliers and other third-parties such as research centres [22]. As the key informant on the firm's strategic orientation, the CEO is asked to rate the aggressiveness with which new markets were developed and new products are launched, and the proactiveness with which new technologies are introduced, on scales adapted from Covin and Slevin [23] and Julien and Raymond [24]. The production environment is assessed by the proportion of total production that is done in "make-to-order" mode as opposed to mass or continuous production modes [25]. Brandyberry *et al.*'s [19] classification is used to assess the firm's level of AMT assimilation: level 1) stand-alone AMT, level 2) functionally oriented AMT (CAM and FMS), and level 3) computer-integrated manufacturing. Growth is assessed by the average sales increase over the last three years whereas internationalization is measured by the mean percentage of sales turnover that has been generated via exports over the last two years.

The measure of e-business assimilation is based on a list of business activities for which the Internet and the Web is used by the firm. The grouping of these various functions corresponds to various stages of e-business assimilation, as adapted to the manufacturing SME context from previous studies [26,27,28,29]. The extensiveness of each type of use is measured by counting the number of activities checked by the respondents.

### 4. RESULTS

The partial-least-squares (PLS) method was chosen to test the hypotheses. The criteria of unidimensionality, reliability and discriminant validity of the measures were considered to be met. The research hypotheses are tested by examining the direction, strength and level of significance of the path coefficients calculated by the PLS method, as shown in Figure 2.

H1: The path coefficients first confirm that the environmental context influences the extent to which the sampled manufacturing SMEs have assimilated electronic business. The firm's networking intensity,

both upstream and downstream in the value-chain in the form of design, R&D, and marketing partnerships, is found to determine their use of the Internet and the Web for transaction or collaboration and business intelligence purposes, but not for communication or information purposes.

H2: Manufacturing SMEs whose strategic orientation is more aggressive in regards to new markets, products and technologies are found to assimilate e-business more extensively for purposes of communication or information, and transaction or collaboration with business partners, but not for business intelligence purposes.

H3: The hypothesis that the managerial context influences the assimilation of e-business is partly confirmed. SMEs are found to use e-communication, e-commerce and e-collaboration more when led by a chief executive with more experience in the sector of activity.

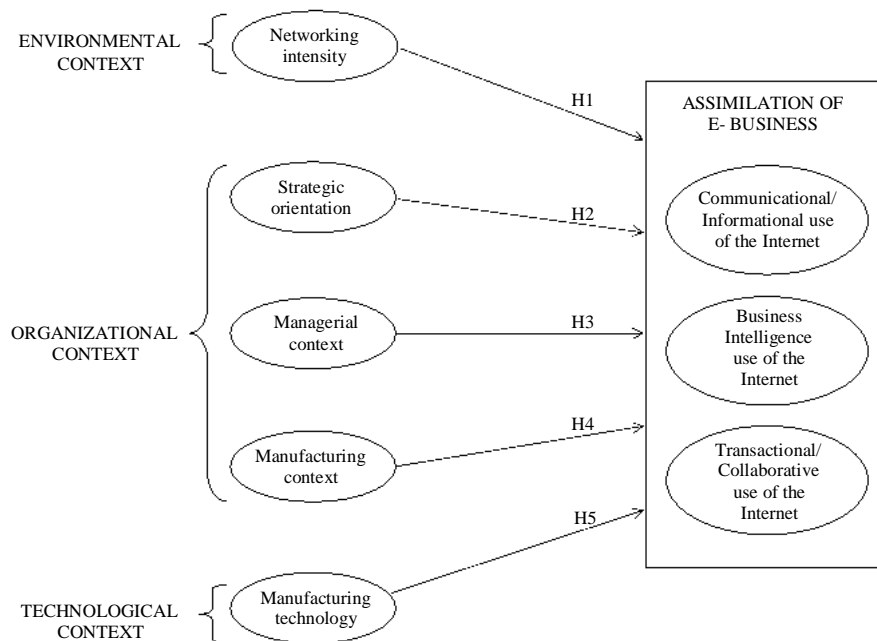

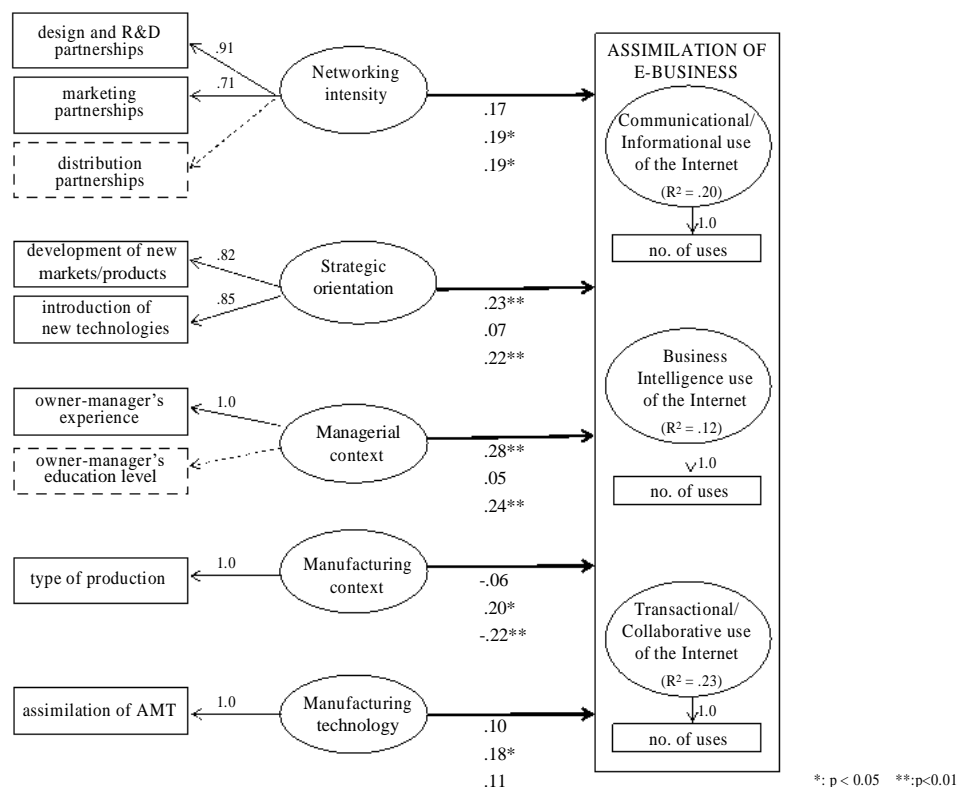

H4: A significant but negative path coefficient associates the production environment with the e-commerce and collaboration dimension of e-business. This result would indicate that the greater complexity of the inter-organizational business processes associated with "make-to-order" production make them more difficult to reengineer with Internet and Web-based technology, as opposed to the simpler catalog-based buying and selling processes associated with "make-to-stock" production.

H5: The technological context was partly confirmed as a determinant of e-business assimilation in small manufacturing firms. More precisely, the path coefficients indicate that the more integrated are SMEs in terms of their assimilation of advanced manufacturing technologies, the more they use the Internet and the Web for business intelligence purposes.

Globally, these results indicate that the hypothesized antecedents of e-business assimilation in manufacturing SMEs explain a significant percentage of variance in e-communication (20 %), e-business intelligence (12 %), and e-commerce and collaboration (23 %). In terms of growth, the assimilation of e-business by manufacturing SMEs explains 4 % of these firms' sales growth and 5 % of their export performance as there are obviously many other factors that contribute to these firms' performance.

### 5. CONCLUSION

With the advent of global competition and new organizational forms based on networks of cooperating firms, the successful assimilation of e-business is bound to take added importance for many SMEs in terms of survival, growth, and competitiveness. Given the dearth

**Figure 1: Antecedents of e-business assimilation in manufacturing SMEs****Figure 2: Results of the structural model analysis (PLS, n = 108)**

of empirical knowledge in this regard, the present study has contributed to a further understanding of the nature and state of e-business assimilation in small manufacturing firms, and of the antecedents and market development outcomes of this assimilation. It

is recognized that these organizations are highly flexible and adaptable to change, be it environmental, organizational, or technological. Some of these already possess advanced manufacturing systems and, in the now global business environment, must follow suit

with Internet and Web-based information systems such as e-business intelligence, e-commerce, and e-collaboration systems to improve their competitive position. E-business investments cannot insure greater performance unless they are coherent with the competitive environment, strategic goals, and business processes of manufacturing SMEs. Results of this study imply that future research on the assimilation of e-business in these organizations must further explore the competitive dimensions of this phenomenon. In this regard, better explanations depend on furthering our knowledge of the level of alignment or “fit” between the external (environmental uncertainties and pressures, networks) and internal (entrepreneur, strategy, structure, technology, culture) contexts in which e-business applications are introduced.

# Business Drivers for Application Servicing and a Software-as-a-Service Model

Jiri Vorisek

University of Economics Prague, W. Churchill Sq. 4, 130 67 Prague, Czech Republic  
vorisek@vse.cz

## ABSTRACT

Many organizations are re-evaluating their approach to delivering enterprise applications, and are looking for ways to control IT costs. There is growing evidence of reluctance to fund large-scale implementation projects, and of tighter budgets forcing more careful cost-benefit analysis to justify IT investments. These efforts to control IT costs lead to consideration of alternative models for delivery of enterprise applications, such as the Software-as-a-service model or ASP (Application Service Providing).

This paper discusses the business drivers for application servicing and gives a detailed description of the Software-as-a-service model in comparison to traditional one. It brings the arguments that the Software-as-service model constitutes a viable alternative to software licensing for many application types today, and will become the dominant method for delivery of enterprise applications in not too distant future.

**Keywords:** Software-as-a-service model, ASP, application service providing, Utility Computing

## 1. INTRODUCTION

The traditional approach to the implementation and operation of enterprise applications typically involves the purchase of hardware and software platforms from technology vendors and their implementation within the organizations, in most cases drawing on extensive assistance from external consulting organizations, in order to tailor the application software systems to the specific needs of the organization.

This model has been used extensively in the context of ERP systems, and has been applied to other types of application including CRM, Data Warehousing, and Business Intelligence applications. Almost invariably, situations where organizations own and maintain their entire IT infrastructure and application systems, lead to very high cost of ownership, and consequently high levels of IT spending which can detract from the core business that the organization is engaged in. Gartner research estimated that big global banks allocated 15-20 percent of their operating budget to IT in 2002; this percentage had grown by 50-60% over five years. There is now increasing evidence that traditional model, which involves *ownership* of software and the associated IT infrastructure, is not sustainable in the long term. Significantly, many businesses are now doubtful about IT benefits altogether, and are no longer prepared to fund large-scale implementation projects [3]. Some even argue that the productivity improvements once assumed to be the result of technology investment are an aberration related to other factors such as longer working hours [16]. In an attempt to improve ROI (Return on Investment) and improve focus on core business many organizations have adopted partial, and in some cases full outsourcing of IT systems. However, companies that provide outsourcing services tend to use the traditional software implementation and maintenance approach,

and hence suffer from similar high levels of cost.

As a result of these developments IT vendors are intensively evaluating more cost-effective models for the delivery of enterprise applications. In late nineties, a new *application service model* has emerged as an alternative to the traditional approach, mainly in the form of providing application services over the Internet. Delivering applications as services has a number of advantages from the point of view of user organizations.

This paper discusses the business drivers for application servicing and gives a detailed description of the Software-as-a-service model in comparison to traditional one. It brings the arguments that the Software-as-service model constitutes a viable alternative to software licensing for many application types today, and will become the dominant method for delivery of enterprise applications in not too distant future.

## 2. BUSINESS DRIVERS FOR APPLICATION SERVICING

In this section we consider the main business drivers that are forcing the transition to a new model for the delivery of enterprise applications.

### 2.1 High cost of IT projects

Problems of controlling the costs associated with IT projects are well documented. Notwithstanding the long experience that the IT industry has with the implementation of enterprise applications, costs of many projects significantly exceed their original budgets. According to a study of ERP implementation projects of 117 US companies 25% exceeded their

budgets, 20% were abandoned before completion, and 40% failed to achieve business objectives [17]. There have been many similar studies of this type that clearly demonstrate that the traditional model of implementation and maintenance of enterprise applications is associated with significant risks that are not being addressed by improved implementation methodologies and more technologically advanced software platforms. Outsourcing of the implementation and maintenance of enterprise application does not always bring anticipated benefits as the implementation methodologies and technology architectures used by outsourcing organizations do not differ substantially from methodologies used by end-user organizations.

## 2.2 Fast rate of technology change

Another significant risk factor associated with enterprise applications is the rapid development of underlying technologies requiring costly and time-consuming updates. There is growing evidence that end-user organizations are unable to absorb new technologies at the rate that vendors produce them, and are locked into a *vicious* cycle of migrations and upgrades. New technology platforms, or new versions of existing applications are often forced on end user organizations by technology vendors who are reluctant to support older versions of their products; implementation of new versions may not lead to any direct business benefit.

## 2.3 High demand on IT skills

The traditional model of implementation of enterprise applications is associated with high demand on IT skills, but many small and medium size enterprises (SMEs) cannot afford to maintain their own internal IT staff. Another contributing factor is that the expertise of IT specialists employed by end-user organizations and third-party consulting companies is often not up-to-date and significantly lags behind the expertise available from the technology vendors. This leads to poor implementation results, and is a major cause of high-rate of failure of IT projects.

## 2.4 Complexity of ERP systems

ERP vendors have attempted to deliver a comprehensive enterprise application solution that satisfies the requirements of a large number of organizations irrespective of the industry and the needs of individual businesses. This approach resulted in highly complex solutions leading to increased cost of ERP solutions that the client organizations are no longer willing to accept. The utilization of the overall functionality of an ERP system by end users is relatively low. Customization to suit the needs of individual customers requires high level of expertise to setup a large number of configuration parameters. Lack of knowledge of client's business processes by the consultants is another

key factor according to recent studies that inhibits successful implementation of ERP systems [13]. ERP systems are characterized by high complexity of operation even in situations where the corresponding business process is relatively simple, and that leads to high cost of training of end users. The demands on hardware resources increase as new versions of the software are released.

## 2.5 Globalization of business environment

Globalization has two important influences on enterprise applications. Firstly, as a result of globalization and the formation of regional economic blocks with standardized business processes and regulations, ERP systems are becoming more generally applicable and require less customization to suit individual countries. This is particularly significant in the European Union with growing number of member countries using identical business laws and regulation; this will eventually lead to standardization of ERP applications across the entire region. Second important influence is the global deployment of enterprise applications. Many large companies with worldwide offices implement global applications across the entire enterprise, in some cases using a single centralized data center and centralized applications accessible via the company's Intranet. This simplified environment, with standardized business processes across the entire organization is highly suited to implementation using the ASP model.

## 2.6 Increased acceptance of outsourcing

There has been an increase in awareness of alternative models for the implementation of enterprise applications, in particular of the outsourcing model. Organizations are aware of the need to focus on their core business, and are prepared to consider outsourcing other business functions, including their ERP applications.

## 3. RECENT TRENDS IN APPLICATION SERVICING

Application Service Providing (ASP) emerged towards the end of 90s with claims of extensive advantages for client organizations, in particular for SMEs. Notwithstanding many perceived advantages the ASP approach has not gained wide acceptance as the new model for delivery of enterprise applications. Many of the early ASP providers have not been able to establish a viable business model for application servicing, and have discontinued ASP services, or went out of business altogether. Other factors contributing to the failure of early ASP providers included lack of a suitable technological infrastructure for hosting a large number of complex enterprise applications in a scalable and secure manner, poor customisation capabilities, and almost total lack of integration facilities. As a

result of these shortcomings, early ASP providers failed to deliver major cost savings to their customers, resulting in poor acceptance of application servicing by the market place.

Recently, however, a number of important IT vendors have re-confirmed their commitment to application servicing in the context of the new Utility Computing approach, and have made large investments in infrastructure for the delivery of application services [6]. Given earlier experiences with traditional outsourcing and ASP most user organizations remain sceptical about ASP and are waiting to see if the benefits are going to be realized as claimed by the vendors.

### 3.1 IT business factors

As a result of the recent IT downturn the sales of new licenses for enterprise application software have stagnated and in some cases declined. There is some evidence that as the enterprise application software market matures, major ERP vendors are changing their revenue model to decrease their reliance on new software licenses towards income generated from software license upgrades and product support [18], [19]. This combined with the fact that most organizations spend as much as 80% of software-related costs on software maintenance and related activities [11], creates a situation where licensed software is *de-facto rented*. *It is precisely this high-level of on-going costs that motivate many organizations towards alternatives such as outsourcing and application servicing.*

### 3.2 Emergence of Utility Computing

The main idea of Utility Computing is that IT services are supplied on demand (i.e. as required by the end-user organization) via a grid of interconnected, dynamically configurable, highly reliable and scalable computing resources (i.e. servers, storage, and applications). Computing grid provides an ideal infrastructure for application servicing as it can host a large number of ASP applications in a scalable and reliable manner. *Resource sharing and improved hardware utilization of grid computing environments provides a more cost effective solution for hosting enterprise applications than a set of independent servers each dedicated to a specific application.*

A number of infrastructure vendors (IBM, HP, Oracle) are in the process of building large data centres with the view of moving towards the Utility Computing model [7]. *Investment in infrastructure on this scale clearly demonstrates a strategic commitment to Utility Computing and more specifically to application servicing as the new outsourcing model for enterprise applications.* Recent efforts to standardize Utility Computing infrastructure in order to facilitate interoperability between vendor solutions led to the

creation of Utility Computing Working Group under the auspices of DMTF (Distributed Management Task Force) [5] and with the participation of major IT players including Cisco Systems, EDS, EMC, HP, IBM, Oracle, Sun Microsystems and VERITAS. The main objective of the DMTF Utility Computing Working Group is to develop a set of interoperability standards in collaboration with other organizations including OASIS (Organization for the Advancement of Structured Information Standards) and GGF (Global Grid Forum) that will allow the assembly of comprehensive services from components supplied by different vendor platforms.

### 3.3 Role of SOA and Web Services

*Another key trend favouring application servicing over the traditional software-licensing model is the move towards service-oriented architecture (SOA) for enterprise computing.* The nature of enterprise applications have changed dramatically over the last five years; most enterprise applications today have requirements to interoperate across enterprise boundaries (i.e. requirements for e-business). Service-oriented computing based on Web services standards and technologies is widely regarded as having the potential to address the requirements for e-business interoperability and are likely to become the dominant enterprise computing architecture in the future. There is a close relationship between application servicing and service-oriented computing. Web services are regarded as the enabling technology for the integration of ASP applications, and for delivery of low-granularity application services [8]. The wide adoptions of Web services standards across the various computing environments (i.e. .Net, enterprise Java) makes Web services an ideal solution for application integration, and for exposing selected business functions of complex enterprise applications.

In summary, business and technological factors discussed above have created a situation where delivery of enterprise application in the form of services becomes both technically possible, and economically desirable. This is likely to have major impact on enterprise computing over the next five years, finally tipping the balance from licensed software towards software delivered as a service.

## 4. COMPARISON OF THE SOFTWARE-AS-A-SERVICE MODEL WITH TRADITIONAL MODEL OF APPLICATION DELIVERY

ASP or the software-as-a-service model has crystallized into specific service delivery model in the last two years. In Table 1 we analyse the application service model from three perspectives: design and technology, business, and IT management viewpoints [10], [14], [15], [20], [21]. We compare the ASP model

with the traditional approach in which software vendor sells the software license and the customer runs the software on its own technology infrastructure. This analysis emphasizes the features of the ASP model that

can help organizations to solve their IS/IT problems in new and more efficient ways than the traditional approach.

**Table 1:** Comparison of the software-as-license vs. software-as-service models for enterprise applications

differentiator	ASP (SW as Service)	Traditional Approach (SW as License)
Main characteristics	Application service provider controls all necessary IT resources and delivers application functionality to a large number of customers as a service via Internet. Many users from different organization at a time use the same application.	Software vendor develops the application; the application is implemented on customer's HW and customer is responsible for the operations.
<b>Design and technology Issues</b>		
Design premise	Designed from the outset for delivery as Internet-based service for a large number of customers. It includes specific HW and SW architectures, and business model.	Designed for implementation by specialist and for customer to operate and maintain.
Technological architecture	Multi-tenant service oriented architecture designed to run hundreds or thousands of users from different user organizations on a scalable technological infrastructure.	Architecture suitable for deployment by individual company on a dedicated IT infrastructure.
Client interface	Browser is the main and often the only interface for all applications. It eliminates the need to develop, install, and support multiple client interfaces.	Many SW vendors have added browser interfaces, but most support multiple clients – it increases development, installation and support costs.
Service management	Applications with embedded service management, monitoring metering and security capabilities.	Typically must add service management, monitoring and metering features subsequent to product development.
Upgrades	Frequent (every 3-6 month) upgrades possible. All customers are upgraded simultaneously resulting significant cost reductions.	Infrequent, major updates (every 12-24 months). Individual customers may be running different versions of software. Both, provider and customer, have to implement version management process.
<b>Business Issues</b>		
Readiness of the service	Short implementation cycle. Typically no requirement for new HW and SW	Long implementation cycle due to complex implementation of HW, SW, and knowledge transfer to customer sites.
Availability of the service	The service is available from any location (globally).	Could be limited to single organization via intranet or client/server interface.
Scalability of the service	The volume of the services delivered (i.e. number of users supported, number of transactions) can be scaled (up or down).	Configuration needs to support peak requirements, and cannot be scaled down.
Reliability of the service	Typically very high. Provider can more efficiently invest in network and systems redundancy. If he does not assure high reliability he loses customers' business.	It is very expensive to provision true fault-tolerance for desktop applications. Most companies remain at risk and typically experience periodic downtime.
Flexibility to business changes	Good if alternative service providers are available.	Good if the business change requires only minor application changes. Inflexible if the business change requires major application changes or new application development.
Customisation	Typically limited.	Extensive customisation possible (at both configuration and source-code levels), but expensive.
Functionality	Often limited functionality, application typically designed for narrow vertical market.	Extensive functionality, customers often use only small part of the available functions.
Evaluation of an application by user	The application can be evaluated before the purchase.	Application is evaluated after purchase, installation and customisation.
Internal sources utilization (people, technology, etc.)	Only few internal sources used for IT processes support. Most of the company sources can be used for core business processes.	Many internal sources used for IT processes support.
Costs of IT	Predictable, no investments required -operating costs only. The costs are highly correlated with the volume of services.	Both investments and operating costs. High overhead costs given by depreciation and amortizing of investments. The costs may not correlate with the volume of service delivered.
<b>IT management Issues</b>		

differentiator	ASP (SW as Service)	Traditional Approach (SW as License)
Subject matter of the contract	IT Service (SLA). The main parts of SLA: <i>content of the service</i> (functionality, data, training, support,...), <i>volume</i> (number of users, number of transactions, volume of data,...), <i>quality</i> (availability, response time, security,...) and <i>price</i> .	Usually, the contract divided into several subcontracts for hardware, SW licence, service (implementation, integration, training, upgrade,...).
SLA	The usage of SLA is a standard requirement	SLA in most cases not used.
Responsibility for IT infrastructure	Provider.	Customer (but some of the activities often realized by third parties).
IT sources utilization	IT sources of the provider (HW, SW, IT specialists) are used across all customers; provider has advantages of economies of scale. Customer IT sources are minimized.	IT sources are used only for one organization.
IT knowledge required at customer site	How to use IT for competitiveness enhancement, available services at IT market, SLA structure, and management of service delivery.	The same as in ASP plus: wide spectrum of IT knowledge. The required IT knowledge is dependent on number of platforms and types of application used. Extensive technical training needed
Size of IT personnel at customer site	Very small.	Large – different types of specialists needed.
Problem and change management procedures	Short feedback cycle - procedures enable almost immediate feedback. Support staff or programmer can directly identify and fix problems. Fixing a problem for one customer fixes it for everyone, which reduces support costs.	Problem solving is often indirect via intermediaries (VARs, SIs, etc). Patches and upgrades are implemented at individual customer sites. Costly and unreliable, as customers often delay installation of patches and upgrades.
Main risks	Loss of expertise that could be useful in the future. Stability of the provider (Exit strategy). Unsatisfactory customisation. Unresolved systems integration issues – who should be responsible for integration? Enhancements not under control of the customer. Security, satisfactory response time.	Stability of the provider – but not to the same extent as for ASP. Technology backwardness. High TCO (Total Cost of Ownership). Low flexibility and scalability.

The above table includes a number of compelling arguments that will make the software-as-service model a preferred solution for enterprise applications delivery in the future. Many of the benefits listed above are results of recent technology advances and increasing expertise of services providers.

Given the current ASP limitations suitability of applications for ASP delivery needs to be evaluated, as certain types of applications may not be suitable candidates for application servicing. More specifically, these applications include:

- [1] Mission critical core business applications – typically not available from external providers (the critical nature of these applications dictates in-house implementation and control),
- [2] Highly customized and specialized applications (providers can not gain economies of scale as the number of customers using such applications is very small),
- [3] Applications with extensive integration requirements (such applications have close dependencies on other enterprise applications and cannot be effectively managed externally).

On the other hand, standardized applications such as ERP or CRM are good candidates for application servicing.

## 5. THE IMPACT OF ASP ON THE IT LANDSCAPE

There are important consequences of the shift from the software-as-license model to the software-as-service model for the delivery of enterprise applications. The emergence of Utility Computing as the new paradigm for enterprise applications will have major impact on the IT landscape, creating new opportunities and challenges for both the providers and customer organizations. The reduction in the size of the traditional software license market, reduced demand for on-site implementation and the corresponding increase in demand for application services will lead to further rationalization of the IT vendor market [4].

The shift towards the service model for delivery of enterprise applications will take several years to be fully realized, but the impact on IT industry as a whole, and software vendors and third-party consulting organization in particular will be dramatic. It will result

in restructuring and re-alignment of the major industry players that will favor large software vendors who are already successfully delivering application services to end-user organizations. Consulting organizations whose main activity is implementing ERP systems and similar applications for client organizations will need to re-focus their business activities, as there not likely to be many large-scale implementation projects of this type in the future. The ASP model will be associated with new pricing models that are likely to dramatically reduce the cost of ownership of enterprise applications.

Reduction of demand for in-house IT specialists will lead to the restructuring of the IT labour market, and will demand important changes from user organizations that will need to implement suitable management structure and IT architecture that enable effective participation in the world of service-oriented computing.

## 6. CONCLUSIONS

In conclusion, the ASP or software-as-service model provides a viable alternative to traditional software licensing model for many application types today, and it is likely that the ASP model in combination with Utility Computing will become the dominant method for delivery of enterprise applications in not too distant future. *The main reason for it is that ASP model enables cheaper and more flexible IT service delivery than the traditional one.* This view is supported in the literature, for example Gartner ranked "software as service" as one of the current megatrends and predicts that up to 40 percent of all applications will be delivered over the Internet within the next 2 to 3 years.

### ABSTRACT

E-commerce becomes an important element of the business strategy for both small and medium enterprises (SMEs) and large enterprises as online business and cyber market space continue to expand its size and volume. E-commerce has a particularly important implication for SMEs because it can help SMEs overcome many handicaps of the SMEs, such as the economies of scale, and compete against the large enterprises on the level ground. The two groups of business firms, large enterprises and SMEs, are often different in not only their sizes but also their business practices. This may also extend to how they use e-commerce in their business. This paper is to study whether there are differences in using e-commerce between large enterprises and SMEs, and what are the differences and why the differences are made. We compare the two groups of business firms in two aspects, format of implementation and their performance. Data used for the study is collected from a group of Korean firms.

**Keywords:** Electronic commerce, Business strategy, Small firms

### 1. INTRODUCTION

Electronic commerce (EC) has caused many changes in the economic structure, and now begins to develop a new paradigm for business process (Kalakota and Whinston, 1996). Business firms are taking part in online business activities because they cannot survive without participating in e-commerce. Thus, e-commerce is now an essential part of business strategy for survival and growth (Kettinger and Hackbarth, 1997; Levy et al., 1999; Poon, 2000) for both large enterprises and small to medium enterprises (SMEs).

The research on e-commerce so far has some limitations. First, it lacks empirical study conducted with field data collected from business firms. Most of the past studies also focused on the issues of adoption and diffusion of e-commerce (Cragg and King, 1993; Fink, 1998; Mehrrens et al., 2001). E-commerce nowadays, however, is considered a must rather than a matter of choice. Thus, we need to discuss the issue of how to use e-commerce more effectively. Second, past studies tend to overlook the effect of the size of the firm on the implementation and the performance of e-commerce. There are clear differences in the way of conducting business such as marketing and operations between large enterprises and SMEs (Thong et al., 1996), and these differences would be reflected in the way of utilizing e-commerce and need to be studied.

The differences between large enterprises and SMEs can be summarized as follows: First is the issue of the firm size. Usually, large enterprises take advantage of the economies of scale by producing a few items in large quantities while SMEs tend to rely on the differentiation ability by producing a variety of items in small quantities. E-commerce is known to neutralize the effect of the firm size on the competition, and thought to help SMEs overcome the disadvantage of the size in the market. Especially the market presence, that is, the power of reaching a large number of customers, may be accomplished very easily even by a very small firm by using e-commerce. One of the examples may be a home-shopping company which advertises and sells its products on cable TVs. We would like to find out whether the firm size is really overcome by e-commerce and has no impact on the business results in the world of e-commerce and internet age.

Second, SMEs are small in size with a relatively small sunk cost, and thought to be able to adapt to the change of the market situation quickly compared to large enterprises (Poon and Swatman, 1998). This agility gives SMEs an advantage to be able to innovate fast in the fast changing business environment of today's world. Therefore, e-commerce is again considered to help SMEs more than large enterprises.

Third, large enterprises have advantages in human resource and capital, and therefore can implement

<sup>3</sup> Corresponding author

e-commerce in a more comprehensive manner. Also, the level of specialty is considered higher than SMEs that tend to hire generalists and use e-commerce for more general purposes.

As discussed above, large enterprises and SMEs are known to have differences in many aspects, but there has not been enough empirical study with field data to find out whether these differences extend to the e-commerce practices. This paper is to study whether there are differences in using e-commerce between large enterprises and SMEs, and what are the differences and why the differences are made. We compare the two groups of business firms by using the data collected from a group of Korean firms.

## 2. RESEARCH METHODOLOGY

### 2.1 Research Model and Hypotheses

The research model in Figure 1 shows the overall conceptual relationships of the variables affecting the implementation of e-commerce and its performance. While many of the previous studies only focused on the adoption issues (Cragg and King, 1993; Fink, 1998), our model is more comprehensive in that all the factors that affect adoption, implementation, and performance of e-commerce are included in the research model. Table 1 contains the explanations of the variables

Figure 1. Research model for E-Commerce.

Table 1. Explanation of the variables.

Variables	Contents
Environmental variables	Firm size
Implementation variables	EC characteristics EC format EC strategy EC type
Performance variables	Utilization Satisfaction Usefulness

#### H1: Hypotheses on firm size and E-commerce

#### implementation:

Firm size is an indicator of a firm's resource and capability. Management decision by a firm is often constrained by its resource and capability. Thus, firm size will affect a firm's decision on EC implementation in such areas as the characteristics, format, strategy and type of E-commerce. Four hypotheses are tested and the details are listed in Table 2.

#### H2: Hypotheses on firm size and E-commerce performance:

The E-commerce will produce different results for the firms depending on the firm's size when other conditions are equal because of the economies of scale. Regardless of firm's size, E-commerce requires a certain amount of investment, and it is thought that the return on investment will be greater for the large firms than for the small firms. The details of the hypotheses are listed in Table 2.

#### H3: Hypotheses on E-commerce implementation and E-commerce performance:

The impact of the EC implementation on the firm's performance is measured. A firm's business performance will reflect the results of E-commerce which the firm implements. While it is generally accepted that E-commerce affects the performance and provides many opportunities for business firms, we need to know the direction and magnitude of impact by E-commerce on the performance. Implementation decision includes determining the characteristics, format, strategy and type of E-commerce for the firm, and the firm's performance is measured by utilization, satisfaction and usefulness of the E-commerce assessed by the firm's management. The details of the hypotheses are listed in Table 2.

#### H4: Hypotheses on the moderating effect of firm size:

A firm's performance is generally improved by the implementation of E-commerce. The magnitude of improvement, however, would be different by the firm size due to the difference in the cost structure, staff capability, knowledge level, and the area of usage of E-commerce. Thus, it is thought that the firm size will have a moderating effect on the relations between E-commerce implementation and performance. The details of the hypotheses are listed in Table 2.

Table 2. Hypotheses.

Variables	Hypothesis	Content
Firm size and EC implementation	H1-1	Firm size affects the characteristics of EC that a firm implements.
	H1-2	Firm size affects the format of EC that a firm implements.
	H1-3	Firm size affects the strategy of EC that a firm implements.

	H1-4	Firm size affects the type of EC that a firm implements.
Firm size and EC Performance	H2-1	Firm size affects EC utilization.
	H2-2	Firm size affects EC satisfaction.
	H2-3	Firm size affects EC usefulness.
EC implementation and EC performance	H3-1	EC characteristics has an impact on EC performance.
	H3-2	EC format has an impact on EC performance.
	H3-3	EC strategy has an impact on EC performance.
	H3-4	EC type has an impact on EC performance.
Moderating effect of Firm size	H4-1	The impact of EC characteristics on EC performance is affected by firm size.
	H4-2	The impact of EC format on EC performance is affected by firm size.
	H4-3	The impact of EC strategy on EC performance is affected by firm size.
	H4-4	The impact of EC type on EC performance is affected by firm size.

## 2.2 Data Collection and Analysis

We have circulated survey questionnaires to collect data from business firms in Korea. A total of 124 firms returned the questionnaires, and 99 of these were used for analysis after excluding those with missing data. The profile of the respondents are as follows (Table 3). Statistical tests such as cross tabulation, factor analysis, analysis of variance, and t-test are used to analyze the data and to find out the answers for the hypotheses presented in the above.

**Table 3.** Profile of respondent firms.

Type of industry	Number of firms	Proportion
Manufacturing	40	40.4%
Sales/Distribution	20	20.2%
IT/Technology	23	23.2%
Service	16	16.2%
Total	99	100%

## 3. ANALYSES AND RESULTS

The reliabilities are tested for the measured variables, and the results in Table 4 (cronbach  $\alpha > 0.9$ ) show that all of them are well above the acceptance level. Also, factor analysis is conducted to confirm the validity of the performance variables. The 18 items in the questionnaire used to measure E-commerce performance were factor analyzed using principal component analysis with varimax rotation. We used

eigenvalue of one and the factor loading of 0.5 as the selection criteria. This yielded three factors with 3 items for each factor, as shown in Table 5. The three factors are named as usefulness, satisfaction, and utilization.

Tables 6 through 9 show the results of the tests to find out the relationship among the variables and to determine the acceptance of the hypotheses presented in the above.

**Table 4.** Reliability test.

Variables	Number of items	Cronbach $\alpha$
IS maturity	9	0.9096
EC utilization	6	0.9324
EC satisfaction	6	0.9236
EC usefulness	6	0.9550

**Table 5.** Results of the factor analysis for the performance variables.

Question items	Factors		
	Factor 1 utilization	Factor 2 satisfaction	Factor 3 usefulness
Hours used	<u>.874</u>	.208	.244
How often	<u>.805</u>	.220	.355
How much	<u>.738</u>	.263	.383
Satisfaction	.119	<u>.794</u>	.321
Work support	.212	<u>.848</u>	.285
Ease of use	.334	<u>.845</u>	.146
Advantage	.362	.334	<u>.807</u>
Business results	.333	.246	<u>.861</u>
Improving	.345	.302	<u>.811</u>

### 3.1 Firm size and E-commerce Implementation

The hypotheses about the effect of the firm size on the firm's decision on E-commerce implementation are tested by cross-tabulation analysis. The results are presented in Table 6. Four dimensions of the firm's implementation decisions are analyzed: the characteristics, format, strategy, and type of E-commerce.

Firm size does not affect any of the E-commerce implementation decisions. For characteristics, all firms tend to use E-commerce for value system, that is, to enhance transaction values. Also, firm size does not affect the format of E-commerce significantly. Firms, however, appear to have different formats for their E-commerce, that is, large firms have more structured E-commerce format, and small firms have less structured format. In terms of strategy, firms do not adopt different strategy by its size. Lastly, firm size does not affect the firm's decision on E-commerce type selection. Both large and small firms adopt Business-to-Consumer (B2C) more often.

**Table 6.** Impact of firm size on EC implementation.  
(Insert Table 6 here, available upon request)

### 3.2 Firm size and E-commerce Performance

We tested the relations between firm size and the firm's E-commerce performance measured in utilization, satisfaction and usefulness. The t-test results in Table 7 show that firm size does not significantly affect any of the performance measures. Thus, firms or its staff and employees do not feel the difference in E-commerce performance based on the firm size. In other words, the staff of small firms at least feel the same degree of satisfaction and usefulness about E-commerce, and utilize it as much as those of large firms.

**Table 7.** Impact of firm size on EC performance (t-test).

Performance variable	Firm size	Means	results
EC Utilization	Small	13.4769	t = 0.416 p = 0.678
	Large	13.0606	
EC Satisfaction	Small	12.7273	t = -1.542 p = 0.126
	Large	13.6061	
EC Usefulness	Small	12.2769	t = -1.014 p = 0.313
	Large	13.0909	

### 3.3 E-commerce implementation and performance

We tested the relations between the four E-commerce implementation variables discussed above (characteristics, format, strategy, and type) and the EC performance experienced by the firm measured in utilization, satisfaction and usefulness. The results of t-tests and analysis of variance (ANOVA) are presented in Table 8.

Some of the implementation variables have significant impact on the firm's E-commerce performance. Two implementation variables of E-commerce characteristics and format, significantly affect all three performance measures at the significance level of  $\alpha=0.05$ . E-commerce type has significant impact only on the utilization out of three performance measures. E-commerce strategy does not affect the performance at all. That is, firms do not show any difference in performance based on the strategy they adopted for E-commerce.

**Table 8.** Impact of EC implementation on EC performance  
(Insert Table 8 here, available upon request)

### 3.4 Moderating effect of firm size

We conducted ANOVA tests to see whether there is a moderating effect of firm size on the relations between E-commerce implementation and performance. The

results are presented in Table 9. To sum up, the moderating effect of firm size was found to be significant for only a few cases.

For small firms, firm size has influenced only the satisfaction measure of the performance when E-commerce format and strategy are concerned. For large firms, firm size has more influence on the relations between the E-commerce implementation and performance. Firms show large difference in E-commerce performance depending on what they decide on the implementation issues of characteristics, format, strategy, and type. These factors in fact define the shape of the E-commerce system of a firm, and the results imply that the impact of the E-commerce system design is relatively more important for large firms than for small firms.

**Table 9.** Moderating effect of firm size on the relations between EC implementation and EC performance (ANOVA).

(Insert Table 9 here, available upon request)

## 4. CONCLUSION

We have found that the impact of firm size is not significant for most cases of E-commerce implementation decisions and performance. Firm size has moderating effect on the certain cases of E-commerce implementation and performance. E-commerce are said to help small-and-medium enterprises (SMEs) compete against large firms on a more level ground by moving the competition from the physical market place to cyber market space, and thus reducing the marketing and distribution cost. From the results, it seems that small firms, at least, use E-commerce as extensively as large firms, and enjoy the same degree of satisfaction and usefulness. Thus, we can say that E-commerce helps small firms enhance their operations up to the level of large firms, if not to overcome the firm size disadvantage completely.

This study has been conducted with a relatively small sample size, especially, of large firms. We need to continue to collect data from more firms, and then the study will produce more reliable and meaningful results.

## ABSTRACT

This paper presents a scientific exploration of the analysis and assessment of high-tech enterprises' technologic innovation capabilities, by applying the method of system engineering and ISM. Combining with enterprises' practice of XI'AN high-tech development zone, it focuses on the application of these methods and the results analysis. Some proposals and solutions for management are also raised in the paper.

**Key words:** High-tech enterprise, Technology innovation capability, Interpretative Structural Modeling

## 1. INTRODUCTION

The analysis and evaluation of technology innovation capability for hi-tech enterprises is a important task for finding the problem, improving and boosting the level of technology innovation capability. Due to the complex of hi-tech enterprises' technology innovation capability, it is difficult to quantify the analysis and evaluation of technology innovation capability. So managers are facing a problem for finding a analysis method which can reflects hi-tech enterprises high technology innovation capability. In order to solve the problem, the paper adopts ISM to analyze and evaluate hi-tech enterprises' technology innovation capability.

## 2. SUMMARIZED ACCOUNT OF ISM

Interpretative Structural Modeling (ISM) is one of structural modeling technique developed by John Warfield in order to analyze some problems of complex social economy system. The characteristic is dividing complex system into some system elements, depending on the people's practice experience, knowledge and computer forming a hierarchical structural model. The working procedure of ISM is as follows:

(1) Found an ISM group. There are about 10 people for every group and everyone care about the problem needed to solve. Besides, the people must have the different ideas, if there is a person who can make policy timely in the group, the discussion will be more efficient. There are often three kinds of people taking parting the group and they are usually: Method technique experts, Coordinators and Participators. (2) Determin the key problem. (3) choose the causative factors which comprise the system and affect the key problem. (4) List the

correlation of causative factors. (5) According to the structural model, establish ISM.

## 3. SPECIFIC IMPLEMENTATION AND DEMONSTRATIVE ANALYSIS

### 3.1 Founding ISM group

There are more than 10 members in the ISM group including the leaders of Xi'an hi-tech industry development zone productivity promotion center, foundation management center, economy development bureau and the professors of northwestern polytechnical university.

### 3.2 Corroborate the key problem and causative factors, list the correlativity of each causative factors

Hi-tech industry development zone, corroborating the problem is the reasons of hi-tech enterprises' weak technology innovation capability, analyze the 12 causative factors (table 1). Members of group clarify the relationship between the 12 causative factors after many times' discussion and fill the table 2 according to the influential relationship as follows.

- (1) If  $S_i$  has influence on  $S_j$ , fill 1; whereas fill 0 ( $i, j=0, 1, \dots, 12$ )
- (2) For the mutual influential factors, choose the more influential factor as the influence relationship, i.e. having the influence

### 3.3 Establish reachcapability matrix

**Table1 causative reasons**

Key problem: reasons of sick hi-tech capability for hi-tech enterprises		S <sub>0</sub>
Causative reasons		
1	pay more attention to present benefit, overlook long-term benefit and fostering of technology innovation	S <sub>1</sub>
2	the separateness of technology strategy and enterprise development strategy	S <sub>2</sub>
3	lack of technology investment and improper investment	S <sub>3</sub>
4	value product innovation, overlook engineering innovation	S <sub>4</sub>
5	lack of continuous strategy core in choice and management of project	S <sub>5</sub>

### 3.4 Give the reachcapability matrix a multi-level partition and establish structure model

#### (1) Explanation relevant concepts

**reachcapability set:** the set of elements that can be reached by element S<sub>i</sub> is defined as the reachcapability set of element S<sub>i</sub>, expressed by K(S<sub>i</sub>). It's made up of the elements whose value is 1 in row S<sub>i</sub> of reachcapability matrix.

**Origin set:** The set of elements that can reach element S<sub>i</sub> is defined as the origin set of element S<sub>i</sub>, expressed by A(S<sub>i</sub>). It's made up of the elements whose value is 1 in column S<sub>i</sub> of reachcapability matrix.

**The most advanced element set:** The most advanced element set of multi-level and increasing degree structure, refers to the set whose element can't reach other

elements except itself. Its reachcapability set only include the element of itself, but in origin set, except that including element S<sub>i</sub>, it also includes the next-level elements that can reach it.

If  $K(S_i) = R(S_i) \cap A(S_i)$ , here  $i=j$ , then  $R(S_i)$  is the most advanced element set.

After finding out the most advanced element set, we can cross out the corresponding rows and columns in reachcapability matrix. Then, go on looking for the most advanced element in the leaving matrix. Go on as above, we can find out the most advanced element set included in each level.

(2) Looking for each advanced element set.(as table3 shown)

This degree only  $R(S_0) \cap A(S_0) = R(S_0)$ , so the most advanced element is 0 for this degree, and the first

degree element is  $\{S_0\}$ , cross out the corresponding rows and column, then get the second degree reachcapability set and origin set. Going on as the above, we can

similarly get the second elements set  $\{S_3, S_4, S_9, S_{10}, S_{11}\}$ , then, the third elements set  $\{S_7, S_8, S_{12}\}$ , finally, the deepest elements set  $\{S_6, S_2, S_5, S_1\}$ .

**Table3.the first reachcapability set and origin set**

$S_i$	$R(S_i)$	$A(S_i)$	$R \cap A$
$S_0$	0	0,1,2,3,4,5,6,7,8,9,10,11,12	0
$S_1$	0,1,3,4,7,9,10,11,12	1	1
$S_2$	0,2,3,4,7,9,10,11,12	2	2
$S_3$	0,3	1,2,3,5,6,7	3
$S_4$	0,4	1,2,3,4,5,6,7	4
$S_5$	0,3,4,5,7,8,9,11	5	5
$S_6$	0,3,4,6,7,9,11	6	6
$S_7$	0,3,4,7,9,11	1,2,5,6,7	7
$S_8$	0,8,9	5,8	8
$S_9$	0,9	1,2,5,6,7,8,9,12	9
$S_{10}$	0,10	1,2,10,12	10
$S_{11}$	0,11	1,2,5,6,7,11	11
$S_{12}$	0,9,10,12	1,2,12	12

(3) Reachcapability matrix divided by levels

	$S_0$	$S_3$	$S_4$	$S_9$	$S_{10}$	$S_{11}$	$S_7$	$S_8$	$S_{12}$	$S_1$	$S_2$	$S_5$	$S_6$
$S_0$	1	0	0	0	0	0	0	0	0	0	0	0	0
$S_3$	1	1	0	0	0	0	0	0	0	0	0	0	0
$S_4$	1	0	1	0	0	0	0	0	0	0	0	0	0
$S_9$	1	0	0	1	0	0	0	0	0	0	0	0	0
$S_{10}$	1	0	0	0	1	0	0	0	0	0	0	0	0
$S_{11}$	1	0	0	0	0	1	0	0	0	0	0	0	0
$S_7$	1	1	1	1	0	1	1	0	0	0	0	0	0
$S_8$	1	0	0	1	0	0	0	1	0	0	0	0	0
$S_{12}$	1	0	0	1	1	0	0	0	1	0	0	0	0
$S_1$	1	1	1	1	1	1	1	0	1	1	0	0	0
$S_2$	1	1	1	1	1	1	1	0	1	0	1	0	0
$S_5$	1	1	1	1	0	1	1	1	0	0	0	1	0
$S_6$	1	1	1	1	0	1	1	0	0	0	0	0	1

$\pm \pm$

(4) Found of structure model (figure 1)

**figure1 structure model**

### 3.5 Establishing ISM according to structure model((figure 2)

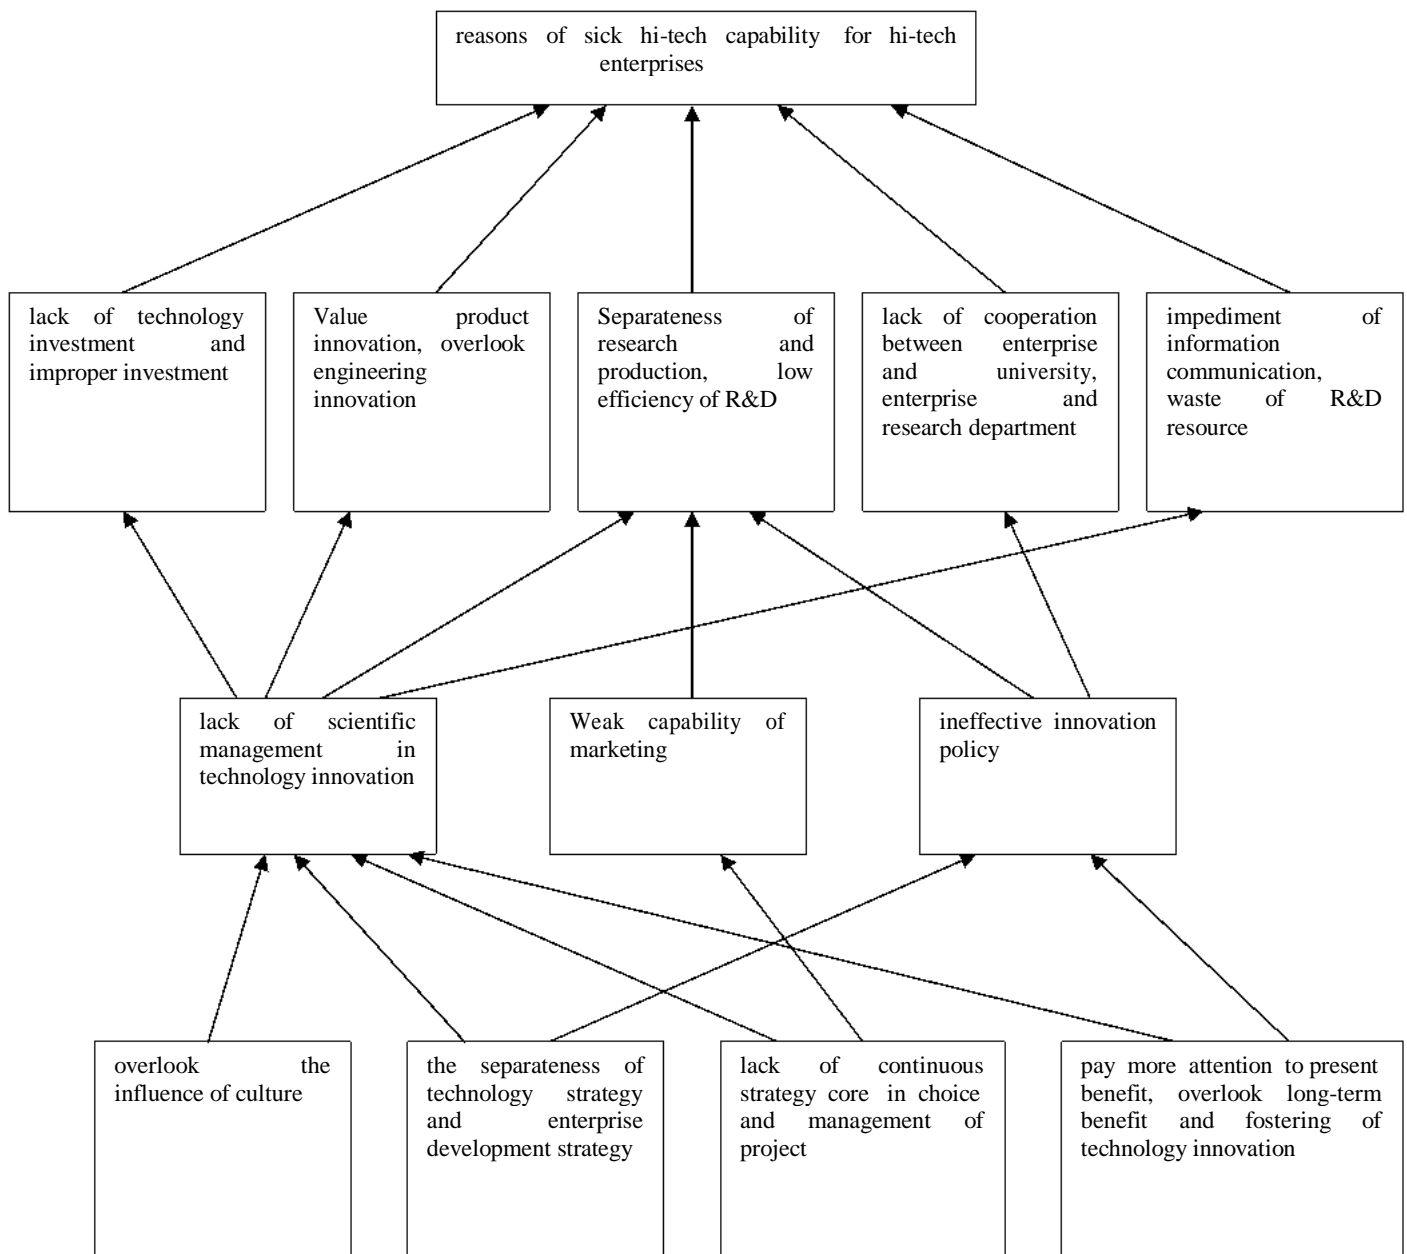

figure2 ISM of hi-tech enterprises technology innovation capability weakness

#### 4. ANALYSIS OF TECHNOLOGY INNOVATION CAPABILITY WEAKNESS BASED ON ISM

According to figure 2 , we know hi-tech enterprises technology innovation capability have four levels, the four causative reasons of the lowest level are: (1) overlook the influence of culture. (2) the separateness of technology strategy and enterprise development strategy. (3)lack of continuous strategy core in choice and management of project. (4)pay more attention to present benefit, overlook long-term benefit and fostering of technology innovation.

Peter.Drucker thinks innovation as a important pillar of

modern enterprise culture. If innovation culture becomes the enterprise's basic characteristic, innovation values will get all staffs' agreement, innovation system and behavior standard will be set up, motivation and operation mechanism of enterprise's technology innovation will form and operate efficiently. But hi-tech enterprises often overlook the influence of culture and organization, are unable to create culture atmosphere and environment which is benefit for technology innovation and lack of effective value orientation and motivation mechanism. Because some enterprises are lack of capability of making strategy and culture adjustment for changeable market, leading them to dilemma in market competition finally. For hi-tech enterprises, we must

combine the technology innovation strategy with culture development strategy. If they are separated, will lead to the low R&D efficiency, make research and production separation, at the lowest enterprise technology innovation activity can't sufficiently promote the economic development. Modern enterprise's overall strategy is resource employment methods of enterprise hierarchy, planning for enterprise's global and long-term exist and development. Overall management strategy is the premise of technology innovation. Only determining the type of overall management strategy, we can decide the basic methods of technology innovation. Enterprises core competition and technology is the core of continuous strategy. Enterprises must pay attention to the fostering and promotion the capability which can provide the long-term competitive advantage. If lacking of continuous strategy core on project's choice and management, paying attention to the present benefits, overlooking long-term benefits separating the technology connection, will lead to get no project package benefits. Lacking of systemic and packaged strategic ideas will baffle the development of technology innovation capability.

## 5. CONCLUSION

The example analysis of hi-tech enterprises technology innovation in hi-tech zone is accord with status quo of present hi-tech enterprises technology innovation capability. In order to foster and improve the technology innovation capability, hi-tech enterprises need to make the technology innovation capability as a system, analyze from whole angle, treat every sector seriously, especially solve the adverse factors. The main is: (1) paying attention to organization and culture influence (2) technology strategy is accord with enterprise development strategy (3) having the continuous strategy core in project choice (4) thinking highly of long-term

benefits and fostering of technology innovation capability.

Hi-tech enterprises only grasp the most basic factors which influence technology innovation capability, upswing and improve continuously, will ameliorate and improve technology innovation capability, overcome the character of sick technology innovation capability, accordingly improve the enterprises' competition capability, always make the enterprises as victors.

### ABSTRACT

A deep insight of determinants of e-commerce adoption process is needed to help small- and medium-sized enterprises (SMEs) to fasten up their e-commerce rush and overcome a great number of existed obstacles. This paper analyzed and classified factors taking effects on SMEs' e-commerce adoption into four groups, specifically: (1) perceived benefits, (2) organizational readiness, (3) external environment, and (4) leadership attitudes and competences. Especially, the paper also gets an overview on the role of leadership in motivating the uptake of e-commerce within SMEs. Thorough analysis within the research contributes not only a general view about core determinants of e-commerce adoption, but also the engine toward the success of e-commerce distribution channel in SMEs.

**Keywords:** E-commerce adoption, Determinants, Distribution channel, E-channel, and SME

### 1. INTRODUCTION

It has been observed and verified in many academic studies that SMEs have been actively looking for suitable solution and methods of adopting and integrating e-commerce into their business process. Based on different sense, researchers explored various factors that impact on SMEs in e-commerce adoption process. Focused on internationalizing SMEs, Tiessen (2001) suggested that SMEs' adoption e-commerce is driven both by market changes and by institutional norms. Following different approach, based on the Rogers (1995) model of innovation decision process, Kendall et al (2001) revealed that the compatibility issue is significant because it deals with their perception of the importance of e-commerce on their business now and in the future. Whereas, Levy and Powell (2001) demonstrated that the introduction of ICT into SMEs is fragmented and based on the operational support and transactions processing. Based on the discussion, they argued that a segmentation model, contingent on SMEs characteristics is applicable and may bring benefit for SMEs. Other existing researches indicated various factors appearing as enablers or limiters of e-commerce adoption in SMEs. Overall, they have been explored via interviews or surveys of SMEs implemented around the world (Poon and Swatman, 1999; Mehterns et al, 2001; Jeffcoate et al, 2002; Quayle, 2002; Lal, 2002; Olson and Boyer, 2003; Doherty et al, 2003; Drew, 2003; Pham, 2003). These previous researches showed a tendency for discussions about e-commerce to ignore the wider concerns involving distribution networks and hence the potentially crucial synergies.

Stemming from gaps in existing research, this study is aiming to answer the remaining question of "What are determinants of e-commerce adoption as novel distribution channel selection of SMEs?" During the

road, the study also portrays an in-depth insight in factors standing for the motivation leading a new e-channel design process distinguished from conventional ones, and consequently contribute a general view of an effective way to handle e-channel.

Section 2 of the paper is to discuss the whole picture of key factors affecting the e-commerce uptake process in a model of four components. Although some determinants composing these four components are widely recognized in the literature, the contribution of this paper is to synthesize the existing literature and adjust some factors including the role of government support, role of cultural factors, and the role of leadership attitudes into composing a conclusive model of determinants of e-commerce adoption. At the same time, the paper also suggests how to improve the insight of this important field in case of adopting e-commerce as a new digitalized distribution channel within SMEs.

The next part of the paper –section 3 –further discusses the important of considering these all components in a conclusive picture to accelerate SMEs to make a reasonable selection of electronic distribution channel.

### 2. DETERMINANTS OF E-CHANNEL ADOPTION AND E-CHANNEL DESIGN PROCESS

In general, enterprises may alter the most applicable model of e-commerce distribution channels based on three categories factors: (1) perceived benefits; (2) organizational readiness; and (3) influences external environment on the adoption decision process. However, for case of SMEs, the adoption of e-commerce model may depend on one more particular determinant –considered as the most important factor – the innovative attitude and knowledge about IT of the leadership. Figure 1 depicts determinants of SMEs'

e-commerce channel adoption motivation.

**Figure 1**

Factors impact distribution e-channel adoption

*Source: Author's original work*

## 2.1 Perceived benefits

The analytical results of Pham (2003) revealed that the more firms perceived the benefits they may gain from e-commerce implementation, the more firms are enthusiastic to engage e-commerce. In another words, as with many innovations, perceived benefits was often the characteristic that most influence its adoption and then affect their channel selection in fact.

From a theoretical point of view, and including the analysis of cases in which the e-commerce adoption has been successful, it is possible to identify a vast range of benefits that can be attained by SMEs companies via the e-commerce adoption. To get deep insight about the benefits that SMEs may gain from the so-called e-commerce, it is better to discover potential benefits into three groups, specifically: (1) communication, (2) generated information, and (3) business tools.

Enterprises experienced much of relative advantages from Internet as new methods of **communication** in comparison with traditional ones, such as telephones and faxes. With the support of information technologies, firms will easy to smooth up the cooperation between customer and supplier, and then, lead to the elimination of many causes of conflict and mistakes, and at the same time, lead to a closer working relationship. This allows supplier to concentrate on composing the product to meet the customers' needs and at the same time, encouraging these customers to focus on fewer suppliers as well. As the results, SMEs are enabled to maintain the central order and administration systems, and consequently, consolidate individual orders to regional loads.

It is easily identifiable and realizable that information

and communication technologies contribute much on **generating information**. The ability of generating information basically rewards a saving in costs regarding to document management. ICT allows firms to avoid re-inputting the data into the computer, reconciliation of documents, expenses of sending the documents by postal mail or fax, and cost related to filing and storing document including the space devoted to this. Moreover, ability of generating information network over all global allows SMEs to stockholding at central warehouse, and then, give a promise of comparatively low stockholding level.

The Internet was also viewed as a **business tool** and should be used as an integral part of every business day to support business objectives. The ability of direct delivery and installation to customer from regional warehouse speeds up the local delivery system. Besides, the ability to saving costs in the management of documents, ability to improve the efficiency of the internal organization of the firm and change its relationship with customers, ability to achieve greater quantity of generated information are closely related to the usage of the so-called e-commerce; and then, stand for major motivation toward diffusing e-commerce within enterprises over all the world.

## 2.2 Organizational readiness

Many organizational level variables such as centralization, size, complexity, slack, formalization, integration, functional differentiation, and specialization have been studied within the context of innovation diffusion (Kimberly and Evanisko, 1981; Damanpour, 1987; Meyer and Goes, 1988). These variables are important variables capturing the organizational context in which strategic decisions are made. However, in respect of e-commerce adoption, this study is essential to capture organizational readiness under two dimensions: the level of (1) financial and (2) technological resources of the firm.

**Financial readiness** refers to financial resources available for ICT to pay for installation costs, implementation of any subsequent enhancements, and ongoing expenses during usage. Usually, small firms with available financial resources will be better equipped to implement e-commerce. Consequently, firms that can afford more costly, e-commerce projects are more likely to enjoy higher benefits from the use of such systems. SMEs with enough equipped financial resource are more enthusiasms to adopt e-commerce as a distribution channel.

The second dimension of organizational readiness – **technological readiness** – is concerned with the level of sophistication of information technology (IT) usage and IT management in an organization. It is common that different companies have different processing needs and different information and communication technology

(ICT) infrastructures. It can be expected that the likelihood of adopting new information technologies or using IT in new business activities depend on the IT dependency or intensity of a company. For instance, the more a business depends on computerized information processes, the more likely the company is to be interested in a new type of IT usage.

The evidence from the survey on Japanese SMEs (Pham, 2004) supported the idea that the Internet was adopted by organizations that have the personnel who understand well about the technology. The more people within a company equipped relevant knowledge of information technology, the speedier firm accelerate to engage e-commerce.

### 2.3 External environment factors

#### (a) Industry

It is commonly accepted that distinguished characteristics of each industry facilitate its participants to adopt innovation in all manners: technological innovations, product innovations, managerial innovations and so forth. Regarding impacts of industrial characteristics on innovation adoption decision of the involving firms, inter-industry competition, product characteristics, and customers' traits are considering as major accelerators.

**Competition** from firms frequently involves innovation and subsequently promotional activity. When the innovations involve new communication technologies, their adoption enhances the overall communications infrastructure which, in turn, facilitates information innovations, particularly of new communication technologies. In this way, market competition has the unexpected effect on accelerating the diffusion of this new communication technology, particularly in regarding usage of Internet as an alternative distribution channel.

Beside the competitive status within the industry considered as an engine of e-commerce adoption intention of SMEs, **product features** are also considering as another major source to accelerate the adoption e-commerce as a new distribution channel within enterprises in all sizes. Product features are firstly considered as company has an intention of joining new economy because there are a lot of product is quite fit with e-commerce and performing e-commerce may accelerate the market share of this product in the market such as music, movie, software, and so forth. However, other product, in contrast, is in low level of relationship with e-commerce activities such as health care and beauty service.

**Customers** are always the major considerations of firms in designing appropriate distribution channels. In the information age, tougher than ever, customer acceptance and behavior become factors determining the

transformation of enterprises' distribution channels. The fact is that, for such a paradigm shift to be accepted by customers, firms have to develop resources and competencies that add value for customers. Rapid growth of customer acceptance has been witnessed recently, especially for websites assuring security and privacy, building with familiar interfaces, and providing rich information with reasonable download time.

Another particular characteristic of industry that may act as a driver to e-commerce is the existence of strong **national retail networks** such as in Japan. An example is Seven-Eleven's '7dream.com' service in Japan, which allows customers to place orders online then pick them up and make payment at a local store. This indeed plays an important role to enable e-commerce in Japan as a complement to, rather than a substitute for traditional brick and mortar retail outlets.

#### (b) Partners

Pressures from trading partners are expected to be one of the most critical factors for e-commerce adoption by small firms; as the weaker partners in inter-organizational relationships, small business are extremely susceptible to impositions by their large partners. Such pressures are especially prevalent in the case of e-commerce because of its network nature.

A powerful partner may pursue three different strategies to induce small partner to adopt e-commerce in the relevant way. The first type is recommendation. Powerful partner use information to alter their smaller trading partners' general perceptions of how their organizations might more effectively operate via the use of e-transactions. In contrast, the other two strategies require compliance from the smaller firms. Promises include all tactics that suggest that the larger firm will provide the smaller partner with a specified reward if it becomes e-commerce capable. Threats, on the other hand, refer to actions that convey the larger firm's intentions to apply negative sanction should be the smaller company to become e-commerce capable. Such threats have been evidenced by large automobile manufacturers and department store chains in recent years.

#### (c) National environment

This part investigates some national characteristics considered as the most important determinants toward e-commerce diffusion of SMEs in various regions around the world. They include: (1) level of government support, (2) level of national ICT infrastructure, and (3) national culture.

#### *Level of Government support*

Governments should be a facilitator of business networks among SMEs and between small and large firms. The supports of government for accelerating e-commerce within SMEs are various including training and consultancy, offering state-of-the-art facilities for

events and business transactions, building up Internet homepages for SMEs and other means to improve access to information on business opportunities in foreign markets, helping SMEs participate in foreign exhibitions and trade fairs, prepare marketing materials in foreign languages and circulate advertisement abroad, and above all, the leadership role in accelerating the uptake of e-commerce by SMEs.

The support of the government is reflected, at first, in one of the most complex factors toward SMEs - the technologies associated with e-commerce. Security, electronic identifiers, authentication, digital signatures and passwords and the like are considered to be outside the domain of most SMEs. However, at the stage of adopting e-commerce into their businesses, SMEs needed to become "overnight" experts in the technologies associated with e-commerce. Then, greater co-ordination of training and education activities in IT areas, greater co-ordination of government initiatives in IT areas, and more focused provision of information in an effort to reach more SMEs may give the right incentives for SMEs to involve into e-society.

#### ***Level of national ICT infrastructure***

Technological change creates new markets and business opportunities. EDI and other new Internet communication tools make cross-border networking easier and more practical for SMEs. They can reduce search costs for potential foreign business partners and improve a firm's visibility in global markets. They drive the internationalization of SMEs in various ways, owing to the growing ease of communications and the high costs of research and development. These tools allow firms in different locations can share know-how, information, distribution networks & other assets simultaneously. Rapid development of ICT has created a more favorable business environment for partnerships and encouraged growth in international strategic alliances. Increase use of ICT by national, regional and local geography, may create an incentive for SMEs to adopt e-commerce. In addition, it may provide a mechanism by which firms could reduce their administrative overheads.

However, the perceived barriers were pointed out in previous researches confirm that SMEs are facing specific problems in fully embracing the opportunities offered by ICT. With the distinguished standards of ICT, Japanese SMEs could not open their trading network toward new potential customers in other countries. Even that communication tools in Japan are powerful above all other advanced technology countries, Japanese SMEs could not diffuse this competitive advantage to more attractive markets overall the world.

Also, discussion in existing researches also figured out that in developing countries, lack of telephone lines, poor accessibility, limited and poor IT support services, poor quality of ISPs are key factors preventing SMEs

from uptake e-commerce as one competitive distribution channel.

#### ***Cultural differences***

It is commonly agreed that culture encompasses values, beliefs, practices, and traditions that unify a group of people. Therefore, culture is expected to strongly influence one's attitudes toward e-commerce adoption.

At first, cultural factors take greatly effects on e-channel design regarding to the intention to set up a novel distribution e-channel. Also, the influence of culture on marketing has been observed and discussed in a great number of previous studies. For the countries who are conservative like Japan, culture may become one of the highest barriers blocking SMEs in trading domestic instead of internationalization.

Looking on another issue - select trading partners, firms have intention to be based the decision on various decision variables, which could include: partner characteristics; bid characteristics, and the like. Firms placed varying degrees of importance on these variables, depending upon the actual situation. However, standing as socio-economic entity instead of just a pure economic one, Vietnamese SMEs set up its partnership alliances based on individual relationships. Long term association between the parties also provides a sense of community and enhances social bonding. This plays an important role especially for e-commerce diffusion wave.

#### **2.4 Role of SME's leadership toward the adoption of e-commerce**

Standing as enterprises with few persons involving, SMEs are lay on the decision and behavior of the leadership in every manner, even this is concerning with financial, human resource, or a technological issue. Then, it is not surprising that for case of SMEs, the diffusion ability of technological innovation in general and Internet in particular lay on the behavior of the leadership in deed.

Openness to new ideas, freedom from investigation of operation, and risk-taking attitude may lead the leadership toward the adopting e-commerce and taking challenges coming with this new innovation. It is well observed evidences of SMEs' leaderships with innovative attitude accelerating their company to engage e-commerce. Lal (2002) indicated that the leadership of this type even taught themselves the know-how of web designs and built up commercial websites without any supports from a professional service provider. Whereas, risk-adverse attitude, incompetence in managerial and technical skills concerning with ICT may prevent the leadership of SMEs from uptake of e-commerce, generate the lack of confidence concerning e-transaction, and then lead them to the decision of not taking the new chance of engaging virtual markets.

### 3. IMPLICATIONS OF THE MODEL OF DISTRIBUTION E-COMMERCE CHANNEL ADOPTION WITHIN SMES

The above discussed factors frequently indicated in the literature are not impact SMEs' e-commerce adoption decision individually but integrated in a four component model. Interestingly, this model does not just process in term of e-commerce adoption decision only, but also analyze determinants of designing digitalized distribution e-channel as well. This model proposes that new distribution channel with the support of ICT results as an interaction among four components: the collectively perceived benefits, the organizational readiness, the considerations on external environments and attitudes of leaderships.

One important omission in all of the current literature is the lack of real in-depth analysis of the contribution of the external environment component to the e-business venture of SMEs. Most studies are concentrated on the internal factors and tried to point out the different in e-commerce performing of SMEs in different locations. The lack of understanding the role of external factors such as government support, existing of appropriated partners, or cultural characteristics would lead SMEs to be lack of confidence in implementing e-transactions and consequently, hesitate in making a decision of adopting e-commerce.

In fact, due to always in lack of capital and qualified human resources, SMEs needed some general platform to facilitate not only their ICT implementation but also their e-transaction and e-partner finding process that may be facilitated by regional and local governments. The model proposed within the paper (figure 1) suggests that the support of government in building up general ICT infrastructure, general electronic payment system, general distribution systems and the like is a key component in the innovation process for SMEs, in both advanced technology countries and developing countries as well.

The other striking point is that the significant of the leadership characteristics and competences is not get the right attention in literature reviewed to-date. Very little existing researches (Lal, 2002), whereas discussing the role of leadership, just bounded in indicating the effort of SMEs' leadership in getting familiar with new ICT-related know-how and knowledge.

The model proposed in figure 1 suggests that characteristics and competences of leadership is a key component in the e-commerce adoption process for case of SMEs. This means the complex interaction of other three components may not accelerate SMEs to engage e-commerce if leadership of SMEs is conservative and risk-averse. These attitudes of the leaderships may lead SMEs not to recognize new prospectus generated by the digitalized global network.

However, the support of government or the participating in e-alliance solely does not able to accelerate SMEs to engage e-commerce. The integrate of external environment with all other factors such as organizational readiness, perceived benefit, and especially, the innovative attitude of entrepreneur will compose the powerful to accelerate SMEs in participating in virtual societies and answering the need of ongoing flexibility in the new digital age.

In short, the model demonstrated in figure 1 not just discovered critical factors separately but also reviewed them within comprehensive interactions. This enables us to better understand the nature and the importance of the individual contribution and interaction of the various model components. Studying these interactions would be considered as a starting point to identify how to select a right e-channel model for case of SMEs.

### 4. CONCLUSIONS

By exploring the literature, this work has identified a model of determinants of e-commerce channel adoption and performance with four major groups namely perceived benefits, organizational readiness, external environment, and attitudes of leadership. The analysis gave an overview of the engine bringing new business values SMEs need to compete, and to produce sustainable revenues in the years to come. The paper also contributes a new way to look at e-commerce innovation within SMEs and reflects a need to better perceive the detailed interaction of the four components of the model.

With the analytical framework composed within the paper, it is supposed that further studies may be taken to generate e-commerce scenarios applicable for case of SMEs. Further insights on each determinant may help to eliminate the tough barriers of supply-side gaps or demand-side gaps toward the uptake of e-commerce by SMEs and suggests the effective ways to gain much more benefit with help of e-commerce for case of SMEs. The framework may also be applied to further discover impacts of e-commerce on distribution channel performance and then to find out the mystery of success in adopting e-commerce as a domestic distribution channel vs. an international distribution channel.

### ACKNOWLEDGEMENT

The author would greatly appreciate Professors Eisaku Otsuka and Yoshiki Matsui (Yokohama National University, Japan) for invaluable support and guidance in writing this paper. I wish express my gratitude also to the Telecommunications Advancement Foundation for supporting my work.

## ABSTRACT

This management platform has been applied in e-business of the dealer. Based on coordinated center, and it is realized by intranet, extranet and Internet. The structure of the management platform has five parts: information center of management platform, customer relationship management system, purchasing management system, logistics management system and financial management system. With network security, data security, user security and backup etc., the system reliability and security are enhanced. Through Business to Business (B2B) and Business to Customers (B2C), it can help the dealer coordinate with the supplier and the retailer.

**Keywords :** dealer, e-business, management system, security, B2B, B2C

## 1. INTRODUCTION

Along with the development of market competition and network economy, traditional business has been transforming to e-business, and requiring higher and higher speed and accuracy of information much more than before. As a role in the marketplace, the dealer needs more and more information to coordinate with the supplier and the retailer. It has been an important problem for the dealer to improve management level and to fulfill the requirements of customers, the supplier and the retailer. Nowadays, the e-business of the supplier and the retailer has grown rapidly. And then, that makes all dealer's act depend on e-business, such as logistics, accounting and information etc. E-business is the development trend of management. By taking commercial activities as e-business system, the dealer can strengthen the competition capability in future. And now the cost of software and hardware is reduced, so the dealer need not pay large quantity of investment for e-business.

For the purpose of e-business, this system is built as a platform and coordinated center for the dealer. The system has the functions of B2B and B2C electronic business system, and can be remote controled through intranet, extranet and internet, connecting the supplier, the retailer and the dealer themselves. It is also realized by circle movement of logistics, information flow and fund in effect: logistics is by sale services and delivery, information flow is by Electronic Data Interchange (EDI) and Web Page Browsing, fund circulation is by electronic payment. Though this system, information feedback is in time. It can keep sensitive with the changes of external environment and relations from environment analysis, and can connect other enterprise, for example, the third party logistics. With this system, the dealer can be an excellent dealer in the era of e-business, which has competitive advantage, scales, coordination ability and management capability.

## 2. BUSINESS SYSTEM MODEL OF DEALER

The dealer has other titles, which to be used by people: middleman, broker or agent. Its responsibilities are keeping the cooperation relationship with the supplier and the retailer. It takes charge managing logistics, finance, inventory and customer satisfaction. It coordinates with the supplier, the retailer and customers, and exchanges information with the supplier and the retailer. The relation framework is illustrated in figure 1.

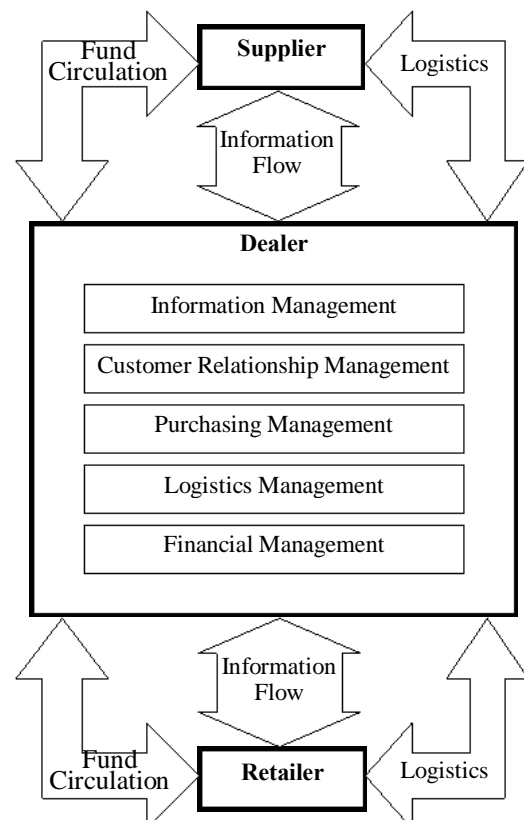

Figure 1. Business system model of dealer

### 3. STRUCTURE AND FUNCTION OF THE E-BUSINESS SYSTEM

Based on supply chain of B2B, e-business system is constitutive of the dealer, the supplier and the retailer, which exchanges information as a main platform. The system also has a function of B2C. Depending on large commodity database, the system can make directory of commodity, OnLine Analytical Processing (OLAP) order, give real time report of transaction and commodity inventory, publish commodity information and price. And it can support commodity searching in many aspects, online marketing, and have automatic analysis system with information from the supplier and the retailer, give service for customers' requirement and suggestion, query executive information of order, and have ability of safe payment.

The system has five parts, the main framework is illustrated in figure 2.

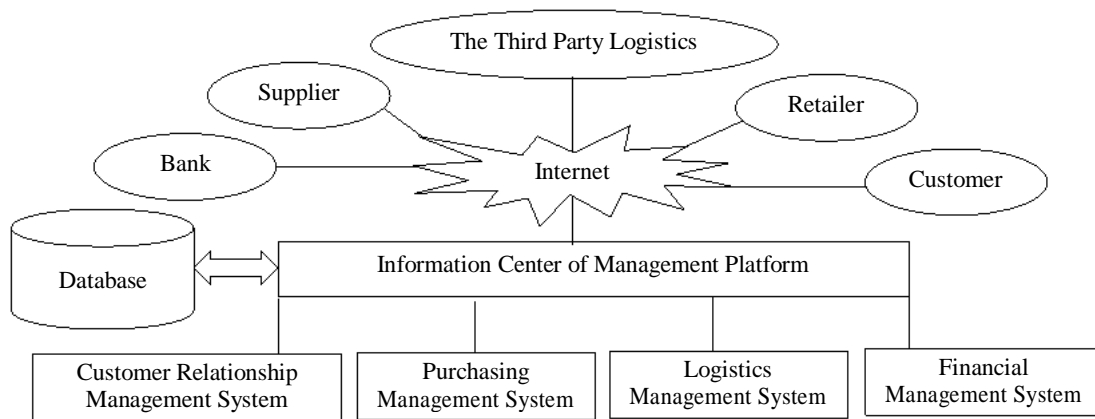

Figure 2. Framework of the e-business system

#### 3.1 Information Center of Management Platform

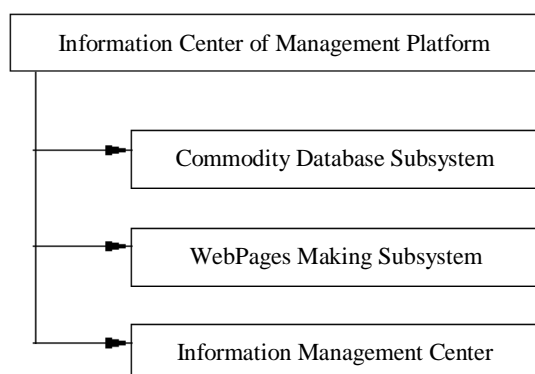

Figure 3. Structure of information center of management platform

Information center is one of the ways to integrate supply chain in Internet. With data storage and information

processing, admitting to download key data of supply and demand, the center can process and transfer information to all participants continuously. The whole network format a Hub-and-spoke system. And participant's information system in intranet is the auxiliary system of this center. For example: ERP and other enterprise's system. The concrete structure are as followed (illustrated in figure3).

##### 3.1.1 Commodity database subsystem

Base on the different types of commodity and the supplier, the subsystem makes classification and encoding of commodity, and inputs the information into database, which includes the supplier information, commodity introduction, commodity specifications, pictures, FAQ and price etc.. This can be completed by personnel, and can change the information of commodity in any time.

##### 3.1.2 WebPages making subsystem

This subsystem takes charge to make the WebPages of the dealer and puts into Internet. It has two subsystem.

Manual making subsystem: The personnel designs WebPages with software. It always applies in homepage and other irregular pages.

Automatic generating subsystem: This subsystem can automatically create specifications WebPages in fixed modes. Because the dealer need make introduction page for all commodity, and the dealer has much more types of commodity, it will be easy to create WebPages by the subsystem.

##### 3.1.3 Information management center

This center manages whole intranet and extranet to assure the information flow unblocked. It manages operation and maintenance of network and Website, supports net connection and management software.

Information publishing, maintenance and management:

The publication of news and information are automatic. This center can manage the information ,and supply users to query.

Notice information transfer: This subsystem can send notice of market by message or mail. It can send news and e-mail from Mail Server, send the important business information, such as customers' order and information feedback, and can connect with mobile phone in time, in case to miss market opportunity.

### 3.2 Customer Relationship Management (CRM)

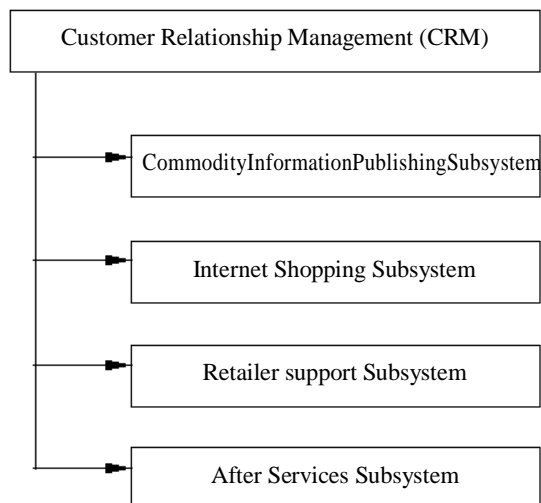

Figure 4. Structure of customer relationship management system

This system has two functions, sale management and customer support, and has two customer classification, one is customer and the other is retailer. It will realize Networked marketing and customer service, and provide customer analysis, consumer behavior tracking and One-to-One marketing strategy. The sale management can arrange work calendar and make up schedule, realize relation management, sale forecast, make suggestions, pricing management, distributive of market and cost report etc.. With this system, we can improve efficiency and reduce costs. The customer support can manage the customers' order, provide customer query, commodity directory and technical support. It also can provide online marketing guide to customer and retailer. It includes tracking order, customers concern, dispute solution and service management. There is a database to record problems and solution. It can make repairing, arrange scheduling, assist personnel to serve customers, solve problem quickly, and report deep market information. The structure of the system is illustrated in figure 4.

#### 3.2.1 Commodity information publishing subsystem

Customers can search the information and inventory of

commodity by two ways, classifying directory and keywords.

They can search the commodity which they need with the type and manufacturer. Customers can fast inquire with keyword, which is brand name, manufacturer name or others, and can be more than one.

#### 3.2.2 Internet shopping subsystem

The trade flow is a virtual supermarket. When customers are viewing commodity, they can put commodity into Internet shopping bag or replace to shelf. And they can check their bag, change commodity sums, settlement, choose payment mode and deliver mode in any time. After customers make an order, subsystem will send order message to customers and salespeople, and then update the content of order management system. Customers can query the execution of order.

#### 3.2.3 Retailer support subsystem

Every retailer has its own account. They can query price, support decision, market mode, information of new products and payment. They can send repairing message to the dealer and check the cost. And based on the user name and commodity code which customers sent to the dealer before, the dealer will check the information and give the cost.

#### 3.2.4 After services subsystem

The dealer can send information and answer questions to consumer, make commodity maintenance and repairing, or withdrawal.

### 3.3 Purchasing Management System.

This system has two subsystem: the supplier query subsystem, and order management subsystem, The structure is illustrated in figure 5.

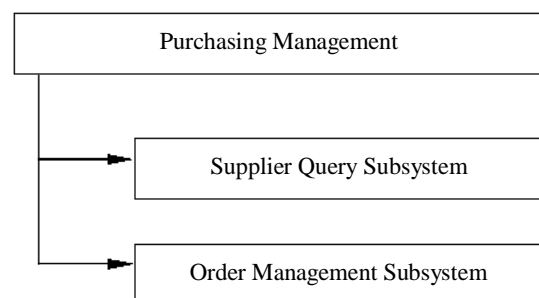

Figure 5. Structure of purchasing management system

#### 3.3.1 Supplier query subsystem

Through Internet, the supplier can query status of sales, accounting and inventory. So they can provide

commodity in time, and set good relations with the dealer.

### 3.3.2 Order management subsystem

This subsystem can make classification encoding of the supplier, the retailer, storage. And it can order and arrange dispatching according to customers' order. Purchasing department can communicate with financial department with the subsystem, practise purchase strategy, control purchase cost and design purchase process rationalization. So it can reduce cost, shorten purchase cycle and improve quality of purchase.

### 3.4 Logistics Management System

This system is one of keys for the dealer to realize MIS (Management information System). It is the basis of logistics management, which includes operation subsystem and inventory management subsystem. Assisted by Purchase-Sales-Inventory Management System, the dealer can control content of inventory and market, reduce costs of purchasing and logistics, increase turnover rate, optimize resource reorganizing, analyze marketing environment and get sale fluctuating, so to improve itself competition capability. The structure is illustrated in figure 6.

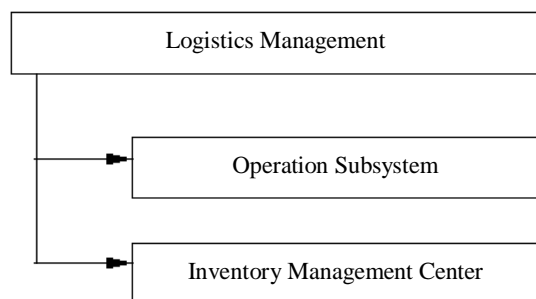

Figure 6. Structure of logistics management system

#### 3.4.1 Operation subsystem

Logistics delivery is the main task of operation subsystem. After customers send order, the subsystem will automatically send order message to the dealer. According to the order and inventory, the subsystem can arrange logistics delivery and vehicle routing to satisfy different requirement of customers

#### 3.4.2 Inventory management center

Inventory management includes management of commodity passed storage in and out, alarm for overstock and overtime, and purchase from the supplier. According to executive case of order, operation personnel can update the content of order to management system at any moment. The subsystem can support dynamic search with content of order management system and inventory, to help manager

understand the content of sales and inventory. Bass on inventory minimum limit, subsystem can automatic alarm, apply for purchase.

### 3.5 Financial Management

The system embodies stratagem management, business management and control so and so functions of accountant. It includes three parts as followed. The framework is illustrated in figure 7.

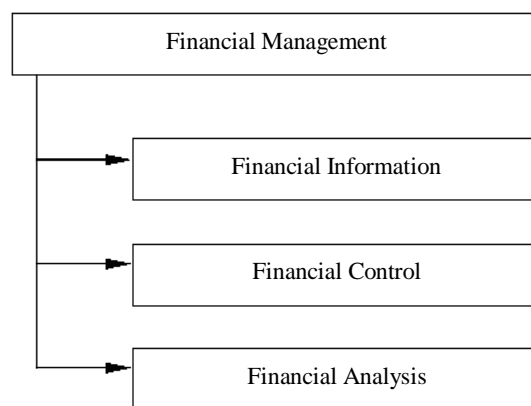

Figure 7. Framework of financial management system

#### 3.5.1 Financial information

The enterprise need collecting and save the information, and should assure the real-time and relevant, reliable and comparable, in order to keep the operation run normally.

#### 3.5.2 Financial control

Financial control can guarantee the validity of management, so as to improve the sale level, decrease expenses and realize the purpose of promoting the economy benefit of the enterprise. This system can manage accounting and realize reporting. It support electronic payment system, with which, customers can enter net-bank and use Secure Electronic Transaction Protocol or Security Socket Layer. After they input account number and password, they can query their accounting and payment. This system can realize user authentication, accounting and user management. The merit of this system are real-time performance, powerful security and RAS (Reliability Availability and Service).

#### 3.5.3 Financial analysis

The dealer need analyze finance and market information by analytical method and evaluation index system, which serve as a channel for managers to master financial status and evaluate the profit condition, for the financial state analysis of the typical state owned enterprises.

#### 4.METHOD DEFENDING SECURITY OF E-BUSINESS SYSTEM

As an e-business platform, this system needs good security to assure the reliability.

##### 4.1 Network Security

With data encryption, firewall and access control, the subsystem keeps network security well, and with RAID, Error Detection and Correction (EDAC) and software fault tolerance etc., to assure system reliability.

##### 4.2 Data Transmission Security

This subsystem can use instant messaging and electronic data interchange to change the electronic data from SSL, RSA and RES etc. to assure data security. And classified information is encrypted, before it is translated through Intranet.

##### 4.3 User Security

All the management and operation process are realized by the browser. And the privileges grading control is applied in the system. The only administrator has the highest-grade permission, who can change the username and password, but can not add and apply other administrator. When administrator accesses, he is not like an ordinary user, he can add other user and authorize grade permission. For example, he can add a specialty user for financial manager, who can only query financial information. And he can add another specialty account for salesperson and give corresponding permission. The user security can be assured by user password, mixed cryptogram and data encryption etc.. Because the permission of administrator is in the highest-grade, it is mainly used in setting and managing whole virtual market. Considering the system security, it should be better not to use the user frequently.

##### 4.4 Security, Data Backup, Log Recovery, Restore and Monitor

This subsystem can set the time interval of data backup, or backup immediately. And the manager can check log file and running state.

#### 5.CONCLUSIONS

Facing e-business and enterprise online, this system set up a platform for the dealer as a coordinated center. Based on the conception of Open, Cooperative and Services, union management of resource, with

e-business platform as background, the system builds a main supply chain with the dealer, the supplier and the retailer, which has transaction function of B2B. As an e-business platform, it can communicate with Website from Internet, and provide online marketing to customers as B2C. To whole management system, software adopts standard interface to connect the mainstream financial software and enterprise website. And it can connect with other e-business website, such as CRM, ERP and MIS etc. So it is adaptable. This system has good security, perfect service, standard common interface, friendly user interface, mass user capacity, processing ability and complete user management. This system has large commodity database, and can make directory of commodity, publish list and picture of new commodity and hot commodity, OLAP order, give real time report of transaction and commodity inventory, publish price. And it supports commodity searching in many aspects, and has automatic analysis system with information from the supplier and the retailer, gives service to customers' requirement and suggestion, query executive situation of order, and has online payment, all of these are secure. Based on Intranet of Web, the system brings great flexibility. The dealer can coordinate and communicate with the supplier, the retailer and customers with this system, so as to be an indispensable role between the supplier and the retailer.

#### ACKNOWLEDGEMENT

The authors are grateful for the support of the E-business Management System from Shenzhen Suige Industrial Development Co. Ltd., China.

### ABSTRACT

Online auctions, in the absence of spatial, temporal and geographic constraints, provide an alternative supply chain channel for the distribution of goods and services. This channel differs from the common posted-price mechanism that is typically used in the retail sector. In consumer-oriented markets, buyers can now experience the thrill of 'winning' a product, potentially at a bargain, as opposed to the typically more tedious notion of 'buying' it. Sellers, on the other hand, have an additional channel to distribute their goods, and the opportunity to liquidate rapidly aging goods at greater than salvage values. The primary facilitator of this phenomenon is the widespread adoption of electronic commerce over an open-source, ubiquitous Internet Protocol (IP) based network. In this paper, we derive an optimal bidding strategy in sequential auctions that incorporates option value assessment. Furthermore, we establish that our optimal bidding strategy is tractable since it is independent of the bidding strategies of other bidders in the current auction and is only dependent on the option value assessment.

**Keywords:** online auction; optimal auction; mechanism design

### 1 INTRODUCTION

#### 1.1 Auction theory

As an old price-discovering mechanism, auction entered the economics literature relatively recently. Two papers have been regarded as initial references [21, 44]. The full flowering of theory came only at the end of the 1970s. A very readable introduction to the state of this field by the late 1980s is in McAfee and McMillan [32]. Another helpful introductory article is Maskin and Riley [31]. Why should we study auction? McAfee and McMillan explained that auction theory provided one explicit model of price making. A less fundamental but more practical reason for studying auction is that auction is of considerable empirical significance. The value of goods exchanged each year by auction is huge. This fact in itself indicates that some theoretical study of auction is warranted. More over, as will be seen, the theory of auction is closer to applications than is most frontier mathematical economics [20]. Next, we will give an overview on this topic from three perspectives: definition, schemes and economic models.

#### *Definition*

Oxford Dictionary defines an auction as a "public sale in which articles are sold to maker of the highest bid". This definition describes the English auction, which cannot reflect the essence of auction. An authoritative definition is given by McAfee and McMillan [32] as follows: an auction is a market institution with an explicit set of rules determining resource allocation and prices on the basis of bids from the market participants.

#### *Basic auction schemes*

This section will give the reader a brief overview of the auction schemes.

Although there are various kinds of auction classifications, there appears to be no unified forms. Here we briefly summarized each classification and discussed them from traditional classifications.

a. According to the traditional view, we can divide auctions into "outcry auction" and "sealed-bid auction". Outcry auction includes the ascending-price auction (English Auction) and the descending-price auction (Dutch Auction). Sealed-bid auction includes the first-price sealed-bid auction and the second-price sealed-bid auction. It should be pointed out that it was Vickrey who first defined the second-price sealed-bid auction. As such, the second-price sealed-bid auction is usually also called the Vickrey auction. Jason and Margolis [23] presented an nth price mechanism, which, however, didn't receive any recognition from other researchers.

b. According to the market structure, we divide auctions into single auction and double auction. Single auction is a "one to many" auction in nature. Either buyer or seller monopolizes the market resource and holds the market. Double auction differs from single auction in structure. Double auction is "many to many". Both sides are related through supply and demand. An environment where vendors and buyers meet with the goal to sell and buy goods is commonly called a market. As there are many different interpretations of what a market is, such an environment should rather be called a market framework. Figure 1 shows an example of such a framework. There are four cases presented: 1. One vendor and one buyer directly *negotiate* in the classical sense; 2. Multiple vendors and one buyer are engaged in a *reverse auction*; 3. Multiple buyers and one vendor are engaged in a classical *auction* (English, Dutch, Vickrey,

etc.); 4. Multiple buyers and vendors trade in a *market*.

c. According to the value form, we divide auctions into common-value auction and private-value auction. In certain auction, because of the information asymmetry, only that buyer knows one buyer's valuation of a product; not all buyers may agree on a product's value; buyers may value a product differently for different reasons. We call this auction private value auction. The main commodities for this auction type are paintings, Egyptian thimbles, and Victorian snuffboxes etc. In a common-value auction, the actual value of (or any known measure of) the goods is the same for all buyers. Buyers start with different estimates or private information about the following aspects of the goods: quality of the goods, remaining economic life of the goods, and some "measure" of the goods. In a common-value auction, buyers can receive meaningful information about the product's "true value" from other buyers' bids. The typical commodity for this auction is mineral rights. In a private-value auction, buyers rarely get any information about the product's "true value" from other buyers.

d. According to the status of buyers and sellers, we can divide traditional auctions into forward auction and reverse auction. In reverse auction, sellers bid for a buyers' business. The seller that makes the lowest bid wins the auction. Just as there are open and sealed bid auction in the "regular" auction format—there are open and sealed bid formats in reverse auction too. The new e-procurement system is a typical reverse auction system. Buyers are on a good wicket, and sellers bid for commodity.

## 1.2 Auction online

Internet allows direct contact between buyers and sellers, and provides a suitable and popular place for conducting auction, which are usually called e-auction or auction online. We define e-auction as a web page, which displays information about a good or service with the intent to sell it through a competitive bidding procedure to the highest bidder. In fact, e-auction is an application environment of auction, so we cannot study e-auction as a separate research field. Most literature on e-auction is about its role in enterprise [2, 18, 24, 48].

There are many differences between traditional auction and e-auction. E-auction gives bidders increased convenience both geographic and temporal. These increased conveniences can also benefit the seller by creating a larger market for auctioned good. Furthermore, search engines and clickable hierarchies of categories for browsing make it more convenient for a bidder to find the goods she is looking for.

The earliest e-auction Web sites are Onsale and eBay which opened in 1995. It was the first to take advantage of the technologies offered by the Web, including the

use of automated bids entered through electronic forms, and search engines and clickable categories to allow bidder to locate their items of interest. In the past several years, two large Web-based companies, Yahoo! and Amazon, have announced their own person to person auction services very much like eBay's. It will be interesting to see whether these well-funded later entrants will be able to take business away from eBay. E-auction is potentially rich sources of study both for economic theorists and for empiricists.

In electronic auction, we can have readily available items and face global market; we can easily access information and have a large scale of operation; we have flexible duration and can compete with other auctions and retailers. The advantages mentioned above indicate that electronic auction will ultimately and inevitably replace traditional auction.

Business-to-consumer online auctions are heating up as an efficient and flexible sales channel. Along with the other two types of online auctions, namely consumer-to-consumer and business to business *auctions*, they represent a new class of mercantile processes that are ushering in the networked economy, but are not fully understood yet. Yong and Yum<sup>[51]</sup> have called for an extensive examination of the pervasive impact of advance electronic communication on the theory and practice of auctions. For a wide variety of goods sold over the Internet, consumers now have an interesting choice of mercantile processes to utilize to buy these goods. Broadly, these different processes can be broken into static posted-price mechanisms and dynamic interactive pricing mechanisms such as online auctions. In this context, online auctioneers are striving to find the correct strategic and tactical direction that ensures their long-term profitability. This involves optimizing existing as well as designing interesting new mercantile processes to sell their products. This paper is an attempt to analyze this emerging market structure with respect to the welfare of the different economic agents involved namely the *B2C* auctioneers (we implicitly assume the joint interest of the seller and the auctioneer, if they are different) and consumers. There already exists a vast body of literature dealing with the theory of auctions and optimal mechanism design. However, the majority of the work focuses on the analysis of single auctions and is carried out in isolation from the broader context of the markets in which these auctions take place. It should also be noted that despite the presence of a vast body of literature dealing with traditional auctions, one could not call these auctions 'mainstream' from a consumer's viewpoint. It is only after the synergetic combination of traditional auctions with Internet technology that this sphere of economic activity has blossomed into significance.

In the next section of this paper, we derive an optimal bidding strategy in sequential auctions that incorporates option value assessment. Furthermore, we establish that

our optimal bidding strategy is tractable since it is independent of the bidding strategies of other bidders in the current auction and is only dependent on the option value assessment.

## 2 OPTIMAL AUCTION DESIGN

What is the best auction design to use for a given selling situation? The work covered below all assumes a risk-neutral seller selling a single indivisible item to one of possibly several potential buyers.

In cases in which the bidder are risk-neutral, symmetric, and follow the IPV model, the Revenue Equivalence Theorem holds (RET). The RET says that under certain conditions, the four major auction types—English, Dutch, First Price Sealed bid, and Vickrey auction will deliver the seller the same expected revenue. In this case, the optimal auction requires the seller to set a reserve price below which he will not sell the item. This price is set to mimic the expected bid of the second-highest bidder, and is strictly greater than the seller's reserve valuation. Moreover, the seller should go ahead and announce this reserve price before the auction begins.

Weakening the assumptions of the RET leads to changes in the optimal auction design. In cases where the bidders are risk-averse, but the assumptions of symmetry and IPV still hold, the Dutch and the First price sealed bid auctions. A seller should still optimal set a reserve price and possibly add an entry fee as well.

In cases where the bidders have affiliated values but remain risk-neutral and symmetric, sellers should use the English auction because it yields the highest expected revenue, followed by the Vickrey auction, which is then followed by the Dutch and First price sealed bid. Moreover, a seller should still set reserve prices and entry fees; in fact, given a choice between two pairs which will attract the same set of bidders, it pays to choose the pair with higher entry fee and the lower reserve price. Side payments from the auctioneer to the bidders are sometimes optimal, but rarely used in practice.

Finally, when bidders are asymmetric, but remain risk-neutral and have IPV, the optimal auction format is highly variable.

The key is that auction mechanism design is theoretically well-grounded. There are different auctions are known to be optimal in different situations. Moreover, auctions for which truth-telling is the dominant strategy do exist and are quite feasible. Hence, an agent's best possible course of action could be carried out by a dumb agent simply telling the truth. There are two important issues in the problem of optimal auction design. One is strategy. The other is protocol. Generally, researchers are focus on one issue.

In the next section, we mainly discuss optimal bidding strategy in different condition.

## 3 STUDY OF OPTIMAL BIDDING STRATEGY

In this section, we consider a sale of two identical objects through second-price sealed-bid auctions. If a bidder wins an auction, she will leave the game. If she loses the first auction, she will bid in another auction with probability of 1. Each bidder intends to buy at most a single object i.e., the utility of a second object is assumed to be zero. In future work, we intend to relax this assumption. However, we conjecture that this will not qualitatively change the results obtained here as long as marginal utility is diminishing i.e. the utility gained from the second object is smaller than that from the first. In this paper, we define *new bidders* to be those that have not bid in any auctions selling the same item before. *Seasoned bidders* are those for whom the current auction is their second auction. It is easy to understand that a new bidder's expected utility comes from both auctions. The first component of a bidder's utility is the difference between her reservation value and price in the first auction; the second component is the corresponding difference in the second auction multiplied by the probability of losing in the first auction, because only if she loses in the first auction will she receive utility in the second auction. Since we use bidder's expected payoff as her utility function, we are assuming risk-neutrality here. We assume that  $U_1$  is the utility from auction,  $r$  is reservation value,  $U_2$  is the utility from second auction and  $P$  is the probability of losing first auction, then,

$$\begin{aligned} U_1 &= \begin{cases} 0, & \text{if she loses;} \\ r, & \text{if she wins} \end{cases} \\ U_2 &= \begin{cases} 0, & \text{if she loses} \\ r, & \text{if she wins} \end{cases} \end{aligned}$$

In the rest part of this paper, we will assume independent, private valuation, as in the private value model. We will also assume that within the same auction, there are two types of bidders—new bidders and seasoned bidders. We assume, mostly for ease of notation, that bidders of the same type adopt the same type of bidding function (strategy). From private-value model, we know that seasoned bidders would bid their reservation values. Hence, we take the following assumption: New bidders adopt the same type of bidding strategy  $b(v)$ , where  $v$  is a bidder's reservation value. Bidders' valuations are drawn independently from a distribution  $F(\cdot)$ .

## 4 BIDDING STRATEGY UNDER CERTAINITY

We start by assuming that bidders know the number of new and seasoned bidders that will bid in each auction. As in all private value models, the bidder is assumed to know the distribution of reservation values of other bidders but the actual value is private information to each bidder. A seasoned bidder  $A$  will bid his

reservation value, since for him there are no future auctions. On the other hand, a new bidder,  $B$  has to consider how her first auction bid affects the likelihood of being able to participate in a second auction. Before formally deriving  $B$ 's optimal strategy, a simple example provides some intuition for  $B$ 's strategy.

**Example 1:**  $B$  bids in two auctions. In either auction,  $B$  competes with another bidder whose bid is drawn from a uniform distribution  $U(0,6)$ .  $B$ 's reservation value is 4. We consider the following alternatives:

**Alternative 1:**  $B$  bids her reservation value in both auctions. Recall that since this is a second price auction,  $B$  wins at its opponents bid  $x$  when  $x \leq 4$ .

$$E(u) = 1.78$$

**Alternative 2:**  $B$  bids less than her reservation value in the first period and reservation value in the second period. If she bids 2 in the first auction, her expected utility is:

$$E(u) = 1.89$$

The increments in her bid will increase her expected utility initially. Once it reaches 2.67, her expected utility begins to drop. Simple calculations show that the optimal bid for bidder  $B$  in the first period is 2.67.

We define  $B$ 's expected utility if she bids  $x$  given her reservation value of  $v$  as

$$E(u(x, v)) = \int_0^x (v-z) d\Phi(z) + \int_0^v (1-\Phi(x))(v-z) d\Phi(x) \quad (4-1)$$

The first integral is the bidder's expected payoff in her first auction, where  $\Phi(z) = \Pr(b(x^{(1)}) < z \& y^{(1)} < z)$ , and where  $b(x)$  is the other new bidders' bidding strategy, and  $x^{(1)}$  is the largest reservation value among new bidders (excluding bidder  $B$ ) in auction 1. Hence the largest bid of new bidders is  $b(x^{(1)})$ . Similarly,  $y^{(1)}$  denotes the largest reservation value, and hence, also the highest bid among seasoned bidders in auction 1. Similarly, we define  $\underline{x}^{(1)}$ ,  $\underline{y}^{(1)}$  for the second auction as the highest bids among the new bidders and seasoned bidders (excluding  $B$ ). Therefore  $\Phi(x) = \Pr(b(x^{(1)}) < x \& \underline{y}^{(1)} < x)$  is the probability of  $B$  winning her first auction. The second term in equation (4-1) is  $B$ 's expected payoff in her second auction.

Solving the first order condition for an interior optimum with respect to  $x$ , we have the following optimal first period bid  $x^*$ :

$$x^*(v) = v - \int_0^v \Phi(z) dz \quad (4-2)$$

where  $\int_0^v \Phi(z) dz$  is bidder  $B$ 's expected payoff if she bids in her second auction.

From the above equation, we may derive the following properties of bidder  $B$ 's optimal strategy.

**Property 1:**  $x^*$  is  $B$ 's dominant strategy in the sense that it is independent of the strategies of other bidders in the first auction.

$\Phi(x)$  includes all the information about the remaining bidders in the first auction. In  $B$ 's optimal strategy, there is no  $\Phi(x)$ , meaning that her first period bid is independent of the strategies of all other bidders. The conclusion may seem surprising but it is easy to understand. If we let  $v_2$  represent  $B$ 's expected payoff from period 2 auction,  $B$ 's "real" valuation of the first auction is  $v - v_2$ . Hence, according to the private-value model,  $B$  should bid her "real" valuation.

**Property 2:**  $x^* < v$  This property explains why some experienced bidders would like to bid less than their reservation values in the first auction. Simply put, the option of being able to bid in a second auction is valuable. The smaller the value of this option, the greater is the probability of winning in the first auction. Thus the first period bid must trade-off the payoff from the first auction against the option value.

**Property 3:**  $x^*$  increases when  $2N$  or  $2M$  increases. Here  $N_2$  and  $M_2$  denote the number of new bidders and seasoned bidders respectively. Intuitively, when the number of bidders increases, bidder  $B$  faces more competition in the second auction, which makes the second auction less valuable to her. Hence,  $B$  increases her bid in the first auction.

## 5 CONCLUSIONS

Online sequential auctions are different from non-Internet sequential auctions. In most theoretical models of sequential auctions, the number of auctions is fixed; bidders enter and leave the auctions at the same point (or winners leave and the rest remain). So, the  $k$ th auction of bidder  $A$  is also assumed to be the  $k$ th auction of bidder  $B$ . However, in online sequential auctions, no such symmetry can be assumed. Each bidder faces a continuous stream of auctions. Bidders enter those auctions at different times and may have participated in different number of auctions. Thus, the principal contribution of this paper is a model of online sequential auctions that captures important features of these auctions neglected in earlier models of sequential auctions. Next, we will mainly study on how uncertainty affects bidding strategies

## **Economies of Information Consumer Commodities – An Introduction to Conceptualising Forms of Information Capitalism by Two Cases**

**Jussi Okkonen, Pasi Virtanen**

Institute of Business Information Management, Tampere University of Technology, Finland

### **ABSTRACT**

Change from tangible and place bound production to more flexible production of intangible information goods has challenged traditional ways of organising production. Innovative operating models have brought up also new logics of doing business, therefore one might suggest that it is not always clear which is the cause and which is the effect. The attention on general discussion is often on the nature of the product, yet at least as interesting is the meta-level, i.e. how the value is created.

The aim of the paper is to examine different operating models, i.e. ways to define operating environment. The focus is on the different models of competitiveness or how end-users are served and functionality of media service is maintained. The paper contributes to discussion on sufficient and sound ways to organise knowledge intensive value creating activities. Reflections to practice are made by examining two cases of content provisioning in digital media.

**Keywords:** business model, content provisioning, informationalism

### **1. THE CONCEPT OF INFORMATION CAPITALISM**

Social and economic changes in recent decades have shifted society from industrialism to post-industrialism and now to one based on systems of information and communications. This has affected all economical entities, including people, organisations, and technologies. It has had an impact on actors at both the local and global levels. This last progression is referred as one of informationalism, where the importance of information creation and transmission is accepted as critically important to all that society represents. It does not mean that economies would no longer break down in any physical sense, nor be able to break away from physical restraints, but it does mean that these traditional limitations would be modified by growth in information and knowledge

Castells (1996) emphasises the importance of different networks for informationalism. He argued that it is essential to have a medium for seeking, exploring and researching, thus modern economic structure is dependent on information networks. He (ibid., 61) defines a new paradigm for an information-based society. In information society the information is raw material as technologies act on information not only vice versa. New technologies have pervasive effects because information is an integral part of human activity and all processes of individual or collective existence are directly shaped by the new technologies. Networking logic of any system or a set of relationships using new technologies as the morphology of the network is adapted to increasing complexity of interaction and to unpredictable patterns of development arising from the creative power of such interaction.

The role of information as a commodity and a means of production is indisputable, yet the nature of value creation process requires closer examination. Change from tangible and place bound production to more flexible production of intangible information goods has challenged traditional ways of organising production. Innovative operating models have brought up also new logics of doing business, therefore one might suggest that it is not always clear which is the cause and which is the effect. The attention on general discussion is often on the nature of the product, yet at least as interesting is the meta-level, i.e. how the value is created. In this paper the value creation is approached from traditional, say Marxist, perspective. The aim is to point out that in the production of intangible commodities the rules of tangible production do not necessarily apply. In addition to that the cases employed herein are used for the discussion of the issue of value creation in more specific.

Taking focus back to two classics of economics Smith and Marx, the emphasis was on the organisation, division of labour and ownership of capital and labour (Smith 2001, Marx 1979). The situation is still the same, the contemporary production is tied to those three relationships, but their nature is changed. The same rules or laws apply, yet there are new extensions to be considered. The main point is that for information commodities there is a very large difference between marginal cost of the first unit and the second. According to Shapiro and Varian (1999) information is expensive to produce, but very inexpensive to reproduce. That point is the first conflict between traditional economics and informationalism. Large fixed costs and low variable costs patronise centralised production and economies to scale. On the other hand technology enables production and reproduction of

inexpensive information commodities that have high surplus value to end-users.

Bischoff (2003, 33-34) points out that information technology plays significant role in value creating process in all sectors of economic and social reality. The production itself is flexible, as content (production) and distribution (reproduction) are no longer simultaneous. Moreover, technology serves as an instrument of gaining economies to scale.

Garnham (2003, 49-50) challenges the idea of increased productivity by shifting to intangible products and to using information technology. However, there is a long tradition in discussion of how the value is actually created. Notions of arbitrary value emergence (cf. value creation) can be considered false, as even voluntary participation creates both economical and social value.

By definition information capitalism refers to system where technology and intangible assets, i.e. knowledge and competencies, are used in production of information commodities. In this paper those systems can be business-to-business or business-to-consumer production systems. It is important to notice the difference between traditional systems, e.g. service provisioning and information commodity. The following section takes closer look at two different value-adding processes.

In this paper the cases are aimed to start discussion of modern information capitalism. The first case is value chain where very expensive data-set is distributed for free via Internet. The revenue logic of such activity is reverse. Consumers are offered a surplus service for free if they are willing to use the primary service, which in this case are classified advertisements in the Internet. The second case is also a value chain of public communication. In television chat the activity itself has value as entertainment, i.e. social value. The revenue logic is also similar to that with ASP (application service provider), as service provider only offers medium to customers. The customers create the content and decide how the show goes on.

## 2. CASE DIGITAL MAP SERVICE

ASP-model refers to business model where information system's fundamental services are fully or partly outsourced. E.g., Krajewski (2001) states that application service providers offer access to software applications and services over the Internet, virtual private networks or leased lines, and describes the phenomenon with phrases "application outsourcing", "hosted applications" and "webifying applications". In their study on software business models, Rajala et al. (2001) distinguish the following subtypes of new service providers, that the so called "Service Provisioning Shift" has recently brought into the software market: Application Services Providers (ASP),

Hosting Services Providers (HSP), Communication Services providers (usually ISP's, Internet SP's), and also content providers (e.g., CSP's) are mentioned. They form a variety of partner networks and cooperation opportunities for software vendors, and typically these companies provide hosting services for other companies in an outsourcing agreement.

Servicing and implementation model is regarded as one element of a conceptual software business model (e.g., McHugh, 1999, Rajala et. al., 2001), while the others are product development, revenue logic, sales channel and sales approach (Rajala et. al., 2001). Software implementation requires some kind of servicing, either self-service or on-site delivery. Thus it is essential to make difference between regular maintenance activities and servicing. Maintenance is a part of daily activities and based on the requirements of any system, e.g. in ASP model maintenance is mostly outsourced and customer is responsible only for the access to the Internet. Moreover, installing and configuring a system for accessing to service provided should be called servicing.

Krajewski (2001) points out three obvious benefits of the model. Firstly, savings in personnel costs, secondly, savings in other costs and, thirdly increased competitive advantage. Savings in personnel costs come mainly from the need for less support personnel as service provider maintains the system. Savings in other costs are based on the earnings logic of ASP. If service provider charges customer by transaction ASP model is always more cost-effective to some point. On the other hand, if provider charges lump sum from the customers the economies of scale ensure lower price for individual customer. Competitive advantage is perceived through up-to-date hardware and software, competent support personnel and better focus on core functions. Actually ASP is decision of make or buy, which benefits mostly small and mid-size enterprises (Raisinghani and Kwiatkowski 2001).

If ASP is examined over the life span of the system there are three main benefits. Firstly, there is no need for specific system as access to Internet provides necessary services to customers. ASP model frees also from spatial restraints, as services are available in Internet. Secondly, maintenance is outsourced, thus the risk of additional maintenance and updating are minimised. And thirdly, the system is somewhat more flexible when it is time to discard it. Thus, as it is based on contract for e.g. certain period the cost are only semi-fixed. If the hardware and software were own the costs were more fixed.

The risks of ASP are raised from the same origin as the benefits. ASP model makes customer dependent on the provider, which is an invisible relationship when everything works but if the system fails there is not much to do. Remoteness makes systems vulnerable as

even temporal breaks e.g., in Internet connection make it unavailable. If the system is provided by several ASPs the difficulties in compatibility between the components decrease usability. Especially if the supply chain is long and consists of several individually produced components, the system is sensitive to disruption. If ASP model is applied to support core functions, it is essential to maintain functionality during breaks. The difficulty of such dependability is due to that, that the ASP, also the backup system, is more or less virtual.

### 2.1. Oikotie – shortcut to required information

Genimap Corporation<sup>1</sup> is innovatively developing location-based services for the Internet and mobile information society and applies ASP for digital map services. In this paper we examine a web map service that is integrated into a media portal. The portal is called Oikotie (Finnish for 'shortcut') and it is part of Helsingin Sanomat, the biggest newspaper in Finland ([www.oikotie.fi](http://www.oikotie.fi)). This kind of service can be considered as an Internet extension to a printed newspaper. The Oikotie-service sells media space, i.e. space for classified advertisements to companies and private individuals. The media space is also advertisement space for companies on the site. Owned by SanomaWSOY, the publisher of Helsingin Sanomat, Oikotie contains advertisements printed in Helsingin Sanomat, and moreover advertisements in several local newspapers as well.

Oikotie contains three categories of advertisements: *apartments*, *motor vehicles* and *vacancies*. Oikotie's revenue logic is straightforward: companies and private advertisers pay for the advertisement, and the service is free of charge for the end-users looking for information. The advertisement in Oikotie may contain more detailed information compared to the newspaper ad, and include e.g. photos and links. Therefore it truly extends the advertisements on the printed newspaper. The map service is value-added service for the end-users; hence it provides usable information on the location of advertised item. For example, if the advertised item is a pre-owned car, the end-user can view a map to locate the advertiser and find a route to the destination. Moreover, if the item is a home or a job, end-user gets information about the surroundings and nearby services as well. Oikotie thus increases the information on the commodity by adding POI's<sup>2</sup> to the map and giving for example bus routes and timetables to the site.

ASP is a fairly new business model for map content providers. It offers several advantages for both the

provider and the customer. The benefits from ASP concern especially the management and cost of map service. In traditional operating model the customer was responsible of establishing a map information system, purchasing the datasets, running and administering the system and having maps updated. ASP model has several benefits e.g. economical, technical and those linked to the quality of map content. Firstly, economical benefits are gained from revenue logic of ASP. As the map service is not the customer's core service, yet it is important part of the service, Oikotie wants to focus on the business of their own i.e. selling advertisements and media space. The ASP model enables lower costs in the phase of evolving business. The reason is twofold as the capacity exceeds the use. The surplus capacity is free for other purposes for ASP and similar service can be duplicated for other customers. Secondly, technical benefits are gained from operating model of ASP. ASP model decreases maintenance costs as technology is dispersed over the value chain. Also the investments and re-investments are allocated over the network, thus need for capital, technical expertise and technological risk are dispersed more evenly. As map service provider has outsourced hosting and other support activities, it is supposed that the resource allocation is optimal. And thirdly, ASP model enables the access to most up-to-date map data, as content provider network is responsible for updating it. However, it still depends on the cycle of updates how up-to-date the maps are.

The value chain of Oikotie consists of three layers, which we call the component provider layer, the ASP layer and the front-end layer. The component provider layer contains software providers and content providers. As the map service provider integrates both the content from different sources into one service, and the information system using software components from different vendors.

The ASP-layer is a middle-layer that enables the use of map service to customers. ASP-layer contains map service by Genimap, hosting service, i.e. the physical place for database server with 24-7<sup>3</sup> secured service, and communication service, i.e. channel to access data. Genimap concentrates on the development and maintenance of map services, other services on the ASP-layer are outsourced. The customer's portals are placed on the front-end layer that is accessible for the advertisers and end-users. It consists of different portals, which are connected by some common content. For example, the Finnish real estate agent Huoneistokeskus advertises in Oikotie, but most of the content is in its own portal. All of the front-end providers are not linked, but they all utilize map service provided by Genimap.

### 3. APPLICATIONS UTILISING MOBILE COMMUNICATIONS – CASE TV-CHAT IN FINLAND

By now there are numerous entertainment applications that are used via mobile communication devices. Mobile communication devices can be interpreted in most cases as mobile telephones, but also communicators. On market there are games to be played in mobile phones, games to be downloaded from various web sites to the mobile phones and even games that can be played by using mobile phones as interfaces and television screen and program as display. One perhaps more communicative new way of doing business is to use television and mobile phone in interaction. In this sector there are at least two types of applications in use in Finland. Firstly there is the TV-chat, which is introduced more closely in this paper and secondly the game sector.

By now at least every Finn has probably seen these short messages that are seen on TV-screens, called chats or chat boxes. The phrase is also adapted to Finnish everyday language “chatti” from the English *to chat*. The action itself is quite straightforward. One sends a SMS-message<sup>4</sup> to a channel specified number and the sent messages are then aired in almost real time. The phrase “almost real time” is used, because the difference between the more quiet moments (=less TV-viewers and thus less *chatters*) and the busy rush hour can be several minutes.

As the product was new, one might have wondered what it was all about. After a short, closer look at things, it may be stated that a new entertainment for the youth and a lucrative moneymaker for the TV-channels was born. Lucrativeness is constituted by the fact that the content of this service is provided by the users themselves, the service provider, TV-channel, only offers the possibility to do this against a fee and airs the messages.

TV-chat is real time communication between two or more persons through mobile phones, computers and the Internet. *The chat area* is like a virtual town square to which people gather together to discuss with each other. The communication is primarily made by typing notes to one another with and through the mentioned tools (mobile phones, computers). To enable *the chat* also a server is needed. The chat service is located at the server on the service providers' premises and this server then upholds the *chat area*. (Vuorinen & Hendrell 2003)

There is a control or a controller on behalf of the service provider to monitor the SMS-messages and that the messages follow the given, sometimes unwritten

rules. The rules include among others following: no contact information is to be shown, no abusive or offensive messages are aired whether it is about gender or race. The TV-companies are bound by the Finnish law and general ethics. The messages may be edited, shortened or not aired at all, depending how the controller sees fit. Mainly the messages are displayed as they were written so they are not corrected concerning their writing.

The chat services differ from one another to some extent. At some TV-channels the controller takes part in chat conversation and comments on the messages. Also some channels display live footage taken by a web cam of the controller simultaneously on the rim of the screen. It seems that the controllers have become sort of celebrities themselves and that some of them are more popular than others.

TV-chat started in the Internet and its model is a Finnish originated IRC (Internet Relay Chat), which enables web-users' multiple conversations on different channels (Note the difference in Finnish terminology to chat and to irc, *chätätä* and *irkata*). IRC was developed in Finland in the summer of 1988 by Jarkko Oikarinen of the University of Oulu.

Chat found its way to the television through the text-television. For example during the fall 2002 Finnish TV-broadcaster MTV3 had five text-TV pages through which the messages could be sent 24 hours a day. All of these pages are controlled like the TV-chats (Kivimäki & Saarinen 2001). The main difference between a text-TV-chat and a TV-chat is that one can send contact information through the text-TV-chat and that the control does not comment on the messages. Of these two the TV-chat is more popular in Finland (Kangaspunta & Huusko 2002). Sometimes the two are used in connection with each other.

First to start with this hype-to-be was a TV-channel called TVTV! (which changed its name in autumn 2001 to SubTV) in June 2000 (Kuorilehto 2003). Now the chat-service is provided by major commercial TV-channels such as MTV3, TV4 and also TV Tampere and SportChannel. At the beginning the service was just meant to fill the odd hours of the night when there was no program on. As the whole concept grew more popular, the services spread to other hours of the day. Now they are offered also in the mornings and in the afternoons, summing up to multiple tens of hours each week. First night the MTV3 had their TV-chat service, they received thousands of messages almost blocking the service. In the morning when the service was about to close there was a queue of hundreds of messages still to be displayed (Ryöti 2003). It was mainly the youth who sent each other greetings, “philosophical” notes and quotations and seemingly irrational comments such as “Tappara rulez” (Finnish ice-hockey team). Today the services display a “no-more-messages” notice,

<sup>4</sup> SMS=short message service in mobile telephoning context

when their air-time threatens to end before all the messages can be displayed (Ryöti 2003).

The sending of messages is possible at least for the subscribers of teleoperators DNA, Radiolinja, Sonera and Telia. Price of a message to a chat service varies a little. It generally is 0,84 euros (MTV3 chat, 28.10.2003) another source declares that for Radiolinja subscribers the prices are 0,59 euros for the SMS-messages (the "normal" text message) and 1,00 euros for the MMS-messages<sup>5</sup> (TTV 02.11.2003).

### 3.1. The technical side of the chat services

The chat begins with a normal SMS-message from one's own phone to a given number. These chat-numbers are TV-channel specific and they differ from the "ordinary" telephone numbers significantly (for example 173222 instead of 040-5556789), so there is little or no risk of accidentally calling these numbers. The messages are directed from one's "own" tele-operator to central for the SMS-messages and further to a third party, another service provider, which claims to be a value-added service for communication networks. One such service is INA Finland Oy in Tampere (Hynnä 2003).

A server hosted by the third party service provider then 'chops up' the message and separates from it the information not needed or wanted for the chat purpose. Contact information of the sender is this kind of information among other things. After this chopping up the message is then sent to the TV-chat service provider, to TV-channel, there it ends up at the computer of the chat controller. In this stage the chat controller can edit, comment or remove the message as shown earlier. Finally the chat controller approves the message, which is the most common case. (Hynnä 2003)

The approval sends the message back as "raw text" to the third party service provider again. There it goes onto another server, where the message is converted to a form in which it can be sent on air. The conversion is actually already done, in this stage a previously created alias can be added to the message or a specific colour or some other chosen options and parameters. After these procedures the message then returns for the final time to the TV-channel to a so called "air-server", which actually is a web-based screen that only sends the message on air. At this final stage no alterations are possible. (Hynnä 2003)

Previous systems were not so, at least seemingly, complicated. However, practice has shown the supremacy of these newer systems. They are better and easier to maintain and uphold, because each machine

does only one part of the whole. The system is easier altered and programmed, for example creation of aliases. Also in case of problems the damages can be bound not to whole system but to a more controllable part of it. (Hynnä 2003)

The provider of the actual chat service must have adequate communication channels. However this presents a lesser problem because the text messages present a rather small burden to the net connection. In the interviewed company the connection was a 2 Mb's (megabit's, millions of bits per second) connection to prevent any possible collisions, which is to make sure. This was said to be far more than adequate. They also had an automated service which checks the new messages twice a second. This stage of automatisaton and these connections result in for a sent message to be shown on the chat controller's screen in five seconds from sending it and in another five to be aired. These numbers depend somewhat on the fact how quick the chat controller is to accept the message, how busy the networks are and how many messages are sent simultaneously. (Hynnä 2003)

Finally, one interesting fact related to this activity is that according to the Finnish law, all messages must be kept for a certain period of time. As time goes by the storage capacity of the chat service provider must also be considerable. This is yet another question for the TV-chat provider to answer, but this area is marked out in this paper.

## 4. CONCLUSIONS

Comparing the two cases some contradictory notions can be pointed out. The most important notion on digital business is, that content is often costly to create but inexpensive to reproduce. That is the fact along the maps, but untrue with the TV-chat (cf. Shapiro and Varian 1999, 21-22). In fact there is a brilliant revenue logic on idea that customers pay for the joy of providing media content. It seems that in both cases the revenue logic is bound around information content, but the relationship between the "true" content and surplus service is blurred. In the map-case the once produced material is sold over and over again whereas in the chat-case the content is actually not sold at all.

In the case of TV-chat the idea is that people entertain themselves by public communication. The platform that enables such activity is domain or service provider not the content. Such operating model is the most inexpensive one, yet it is still productive. Taking TV-chat as an example of production, there is fuzziness about the mutual relationships in the value chain. The beginning of the value chain is clear. There is hardware and software that the systems consist of, but when the content is added the fuzziness appears. The show, the TV-chat in itself, is co-operation between viewers/chatters and the controller. It might be claimed

<sup>5</sup> MMS=multimedia message service in mobile telephoning context

that people are willing to pay relatively high fee for participation. The actual media content is free for all those who possess a television set.

TV-chat can be considered a sort of exception that confirms the rules, but still it raises interesting questions on relationships in production. For the chat service there is logical explanation on people's willingness to have their time on TV. As the mobile phone penetration in Finland is close to 90 % (Digitoday 2003) and there are some 3,6 million TV-receivers in the country there is bound to be people willing to take part in this. However the publicity in that forum is still very limited. Other notion is that people do not pay for viewing the chat messages, but posting them.

In the case of digital maps the explanation for such model is that as the data-sets already exist and there is a lucrative way to use them for minimum marginal cost, the operating model is ready. Moreover, if digital maps were only content in the service there might be fee for using them. There are several other examples of such operating models where people get something free of charge, but according to famous tag by Milton Friedman "there is no such thing as a free lunch".

These two cases point out that if there is possibility to produce and reproduce information with low costs, the information can be used as an independent service or a surplus service. The revenue does not necessarily come straight from the service, more likely from other sources. Information can, and will, be used in different combinations, thus the information goods are often complex combinations and layers of information and knowledge. What seems to be clear at the first sight, can be very complicated at the second.

## ABSTRACT

This paper reports the findings of an empirical study of Electronic Reverse Auctions (e-RAs). This study seeks to better understand the underlying and emerging issues in e-RAs to comprehend the implications of e-RAs on organizational procurement. The study contributes to practice and research by providing insight into emerging e-RA adoption issues, and by discussing strategies for improving e-RA processes, thus improving the effectiveness of e-RAs.

**Keywords:** Electronic Reverse Auctions, Electronic Procurement, Electronic Sourcing

## 1. INTRODUCTION

In recent years, the use of Electronic Reverse Auctions (e-RAs) for sourcing and procurement has attracted significant interest from the public and private sectors [1, 2, 3, 4, 5]. In 2001-2002, up to \$40 billion worth of procurement transactions were conducted via e-RAs [6]. Beall et al. reported that e-RAs generate an average savings of 15% on the prices paid for goods, and decrease procurement cycle time by up to 90% [7]. GlaxoSmithKline, a major pharmaceutical supplier, achieved cost savings of \$165 million, from a series of 190 e-RA events worth \$912 million [7]. Procurement represents a major spend area for organizations. Modest savings of a few percentage points can translate into multi-million dollar savings in the longer term. e-RAs promise to improve the bottomline of organizations by reducing the prices paid for supplies, as well as lowering the cost of transaction through process improvement [7].

It is not surprising that purchasing executives often face questions such as “Why should their organization adopt e-RAs for sourcing supplies?”, “Which supplies should they source through e-RAs?”, “How could organizations leverage the benefits of e-RAs?”, and “What are the potential challenges associated with e-RAs?” These questions do not have conclusive and generalizable answers as the outcome of e-RAs depends on factors such as the amount of planning and preparation, the existing relationships between the buyer and seller, and the attributes of products that are to be purchased [8]. Opponents of e-RAs are doubtful of the sustainability of e-RA benefits. They argue that incumbent suppliers view e-RAs as divisive; a mechanism that damages well-established relationships between buyers and sellers [9]. Supporters and critics of e-RAs argue passionately for and against e-RAs, clouding the discussion over how to leverage the strengths of e-RAs, and to avoid the potential pitfalls. This study aims to identify, and better understand the emerging issues in

e-RAs. The study addresses the research question:

**“How should organizations adopt e-RAs effectively?”**

This paper describes a case study of a series of six e-RA events hosted by a major multinational organization in Australia. In answering the principal research question, the study is also motivated by additional guiding questions that ask: *What’s new? So what? and Why so?*

## 2. BACKGROUND OF ELECTRONIC REVERSE AUCTIONS

Kambil and van Heck describe e-RAs as an auction process in which a single buyer places a request for a quote for a product it intends to purchase, and multiple sellers (the suppliers) place bids to sell to the buyer [10]. The bids are placed until the lowest price is discovered when the auction closes at a pre-determined time. e-RAs are also commonly known as “Online Reverse Auctions”, “Downward Price Auctions”, and “Electronic Procurement Auctions” [11, 12]. The e-RAs idea was conceptualized by Glen Meakem, who subsequently founded Freemarkets Inc [2]. e-RAs differed from English Forward auctions in that the roles of the buyer and seller are swapped, and a decremental bidding mechanism is used. They are used in procurement mainly for evaluating the offerings of competing suppliers, and for determining the purchase price of goods purchased. According to Kambil and van Heck’s Basic Trade Processes framework [13], e-RAs fulfill the business process phase known as “valuation” which is described as

*“negotiating and discovering a purchase or sale price for a product. A variety of different price discovery and bidding processes exist that differentially attributes costs to buyers, sellers and intermediaries. ... Price discovery mechanisms can also be biased to shift surplus from the trade to specific transaction stakeholders.”*

Literature supporting the e-RAs model typically relies on empirical evidence that illustrates the quantifiable financial savings that can be attributed to e-RAs. Jap asserts that organizations adopt e-RAs to achieve three goals – (i) immediate financial savings, (ii) process efficiency gains, and (iii) enabling capabilities such as global and multiple sourcing [5]. In a similar vein, Stockdale and Standing found that apart from direct financial savings, e-RAs also help organizations standardize procurement processes, and develop staff purchasing skills [14]. Kambil and van Heck concluded that apart from achieving financial savings, e-RAs enable buyers to gain useful market information, such as suppliers' bottomline or reserve price [10].

Critics and sceptics of e-RAs argue that the e-RA model damages buyer-supplier relationships. To win contracts through e-RAs, suppliers are pressured to sacrifice profit margin to levels that are unsustainable in the longer term. It was found that e-RAs achieve local optimization of business processes, an effect that leads to chronic underutilization of internal and external resources [11]. In a subsequent study, Emiliani and Stec also found that incumbent suppliers attempted to charge buyers higher prices to compensate for their participation in e-RAs [15]. Another strong argument against e-RAs relate to the importance of price in buyer-seller relationships. Some attributes of a product, such as delivery, settlement, after-sales support, do not feature prominently in e-RAs negotiations.

These apparently different perspectives may suggest that the e-RAs model was not fully understood by organizations, practitioners and researchers. Also, e-RAs continue to undergo evolution, with new challenges emerging every so often. This study addresses some of the above issues. Without placing too much emphasis on literature and testing of existing theories, this study concentrates on identifying the emerging issues in e-RAs from the perspectives of buyers and sellers. The study recommends strategies that target the source of the problem encountered in e-RAs [16].

### 3. METHODOLOGY

The study describes an exploratory study that draws data collected from a series of six e-RA events. An interpretivist approach was adopted, as many of the issues emerging may be incomplete and continue to evolve. The interpretivist approach allows for a belief that the reality is subjective, and is the product of social construction, to be viewed upon by humans, who are the social actors [17]. In capturing the properties of the subject, reality is interpreted according to the different beliefs, value systems, and consciousness of the social actors.

The study does not intend to develop a metric for determining the descriptive variables, nor is it our aim

to use inferential statistics for producing generalizable and reproducible outcomes. The aim is to develop a deeper level of understanding of the e-RA phenomenon, and aid the understanding of important concepts, themes, and their implications. Data was primarily collected through informal, semi-structured interviews. The interview questions were developed from an understanding of the constituent nature of the relationships between the stakeholders and the phenomenon, which are garnered from existing literature. Interviews were conducted with executives of the focal organization and its suppliers. Publicly available literature was used as a secondary data source. Data was then synthesized using a hermeneutics cycle to determine emerging concepts, and also for summarizing common themes.

The focal organization in the case study represents an Australian branch of a multinational organization. The parent business has a diversified portfolio of businesses, but the focal organization operates primarily in the financial sector. Its financial products are either resold by other businesses in Australia, or sold directly to the general public. Confidentiality restrictions prevent details that may lead to the identification of the participants from being included in this paper. For the purpose of the study, the focal organization is referred to as FinanceCo. FinanceCo conducted a series of e-RAs in 2000 and 2001, of which six are included in this study. e-RAs were not intended to complement FinanceCo's existing procurement channels. This paper reports the observations made, and suggests possible explanations for describing the phenomena.

### 4. RESEARCH FINDINGS

Analysis of the interview data and synthesis of secondary data yields the following emerging themes. The themes are presented here in no particular order of importance.

#### 4.1 The Negotiation Parameters and Lotting Strategies

The adoption of e-RAs for procurement limits the negotiation parameters available to buyers and sellers. The only negotiation parameter that suppliers could vary in e-RAs is the purchase price. Traditionally, other non-price parameters like settlement, logistics and inventory management could be negotiated upon. In preparing the tender for the e-RAs, FinanceCo conducted substantial research on the product and the potential suppliers. It needs to find out the product's specifications, costs, the market demand and supply, and the attributes of the potential suppliers. This is to ensure that the e-RA tender document covers all possible aspects of the product. The performance, quality, and expectation of the product are usually benchmarked to industry-backed standards, or mutually agreed upon standards. Once finalized, these negotiation parameters

become non-negotiable to ensure that in evaluating and comparing the bids, a fair and just environment exists for “comparing apples with apples”.

In the e-RA event for courier and forwarding services, it was observed that a particular supplier attempted to differentiate their offerings. The supplier was willing to match an existing lowest bid by providing services that are higher in quality, but was not keen to lower the purchase price. Superficially, this bid appear to be of better value than competing bids, but FinanceCo adhered to the terms and conditions for the e-RAs strictly, and advised all bidders that all bids that satisfy the required specifications are being treated equally. In doing so, FinanceCo signaled that suppliers could add value to a bid by offering over-specifying a product, but will not win the auction if a lowest price bid was not placed.

The transparency of information in e-RAs raised other challenges associated with the absence of non-price negotiation parameters. e-RAs led to the bundling and unbundling of purchases. Components of a purchase which were bundled in the past could be purchased individually due to the increased ease in sourcing, and the ability to individually determine the price of the components. Commoditization of products also occurred, with the emergence of no-frills products, with suppliers removing free of charge value-added services in order to lower prices. For example, in the auction for hotel accommodation for staff, the inclusion of breakfast was halted to simplify the comparison of standard room accommodation. The unbundling of the purchase enabled FinanceCo to view the cost structure of its suppliers, as well as optioning-in (or -out) non-essential features of a product. Nevertheless, a re-bundling of value-added services was also observed. In the e-RA for computing peripherals, FinanceCo added a new service – a requirement for suppliers to dispose of superceded old peripherals. In e-RAs, the buyer has to be explicit in specifying delivery, settlement, product specifications and other special requirements when preparing the tender document. It is not surprising that the competitive nature of e-RAs encourages suppliers to do away with “frills” in their products, or charge for such “frills” separately.

In the absence of non-price negotiation parameters, FinanceCo has used alternative approaches for purchasing a “basket” of products. Instead of purchasing a large lot of identical products, FinanceCo was able to purchase products of different quality or performance separately. The breaking up of large purchase lots into several smaller ones meant that the smaller lots could either be sourced from the same supplier, or from multiple suppliers. This represented an opportunity that was not exploited before the implementation of e-RAs as the search costs involved in sourcing various components individually often outweigh the cost of purchasing a bundled product.

In terms of aggregating purchase volume, e-RAs enabled FinanceCo to purchase in larger lots at some occasions by combining its purchase with other arms of its parent business. For example, in the e-RA for hotel accommodation, FinanceCo had aggregated its purchases with other business divisions of its parent company. By combining their purchases, they took advantage of economies of scale and achieving critical mass for less important purchases. From a supplier’s perspective, selling to FinanceCo via e-RAs represents an opportunity for the supplier to supply different components of a larger product, and where possible, supply a fully-packaged product.

The observation regarding the change of behaviour in FinanceCo’s purchasing indicate the possibility in optimizing its procurement. Apart from increasing the competition amongst suppliers that could lead to lower purchase prices, FinanceCo gained a better understanding of its purchases, enabling it to optimize purchasing decisions to take advantage of individual supplier’s capabilities. The common rule of thumb for organizations sourcing through e-RAs is to purchase from the lowest-priced suppliers. However this poses a new challenge for FinanceCo in the determination of “value for money” of purchases. The absence of non-price negotiation parameters could make suppliers market their products opportunistically. For example, products that require after-sales support may be marketed with a low initial purchase price, but the cost of subsequent after-sales support would be priced higher to counter the initial low purchase price. While such practices are despised, the buyer has to understand “you get what you paid for” and e-RAs are principally a more effective mechanism for determining prices, and possibly the allocation of resources. Buyers will also need to take into account the Total Cost of Ownership of a product as the initial purchase price could only be the tip of the iceberg. This issue creates complications for the sourcing of indirect supplies, whereby repair, maintenance, upgrading and disposal of equipment incur significant costs. For commodity-like direct supplies, the Total Cost of Ownership could be less of a worry, but the quality, delivery and settlement flexibility should be taken into account in the purchase price. Additionally, the value of collaboration between suppliers and the buyer in product research and design could be overlooked in e-RA transactions. Flexibility in delivery, inventory management and settlement were important reasons why organizations adopted Supply Chain Management, and organizations sourcing through e-RAs need to consider the implications from the loss of such collaboration. Additionally, the intangible attributes of the product, unique capabilities of the suppliers and process improvement (e.g. Just In Time manufacturing) cannot be expressed in terms of prices, nor can they be assumed to be the same. Thus, e-RAs present a significant challenge for buyers and sellers in pricing intangible attributes of products, and the attributes of the suppliers.

## 4.2 The Timing of Electronic Reverse Auctions

In determining whether to source supplies through e-RAs, FinanceCo first evaluated various attributes of the product involved. A major consideration was given to the number of suppliers for the product, and their tendency to bid for the contracts competitively. If a product is only sold by one or two suppliers, FinanceCo would decide against sourcing it through e-RAs. When there is a small pool of suppliers, the suppliers tend to know each others' operations and cost structure well, and will only be willing to match their competitors' bids. Under such circumstances, the e-RAs business model will not deliver substantial benefits to the buyer in terms of price reduction. Similarly, if a product is sold by many suppliers, but none has spare capacity to satisfy the volume required by FinanceCo, then e-RAs will not generate significant competition.

A strategy that FinanceCo has applied to raise the interest of suppliers to place competitive bids and thereby increase competition in the market is through aggregating the purchases of all its branches, and at times, its sister companies. At the same time, FinanceCo evaluated the market for a particular product, determining periods of excess capacity. After analysing the purchasing patterns of other organizations, FinanceCo scheduled its e-RA events before other organizations purchase, ensuring that potential suppliers have not made substantial commitment to other customers. By coordinating its purchasing timing to pre-empt other organizations, FinanceCo was able to get the best participation rate and possibly the best outcome from its e-RA events. Also, suppliers who wish to secure future business when their existing contracts terminate would be able to participate in e-RAs without being caught in a capacity shortfall. This two-pronged approach in enlarging a purchase order, and choosing a period of excess supplier capacity enabled FinanceCo to maximize competition among potential suppliers.

However, FinanceCo was aware that e-RAs should not disadvantage suppliers to the extent that healthy competition is diminished, especially during periods of economic downturn. Reliable supplies require profitable suppliers in the long term. Thus, FinanceCo treads a fine line in increasing the competitiveness of its suppliers, while not driving the suppliers to oblivion. FinanceCo also constantly searches for new suppliers that have the expertise and capacity to satisfy its needs.

## 4.3 Education and Awareness

e-RAs introduce the notion of the shift from place to space. It enables suppliers to bid for the tenders remotely through the Internet instead of physically attending RA events. While such practices have been common in seller-hosted forward auctions, it is not often that suppliers have to bid against their competitors in a live environment to win the privilege of selling their

products. To prevent suppliers from colluding, yet to ensure that suppliers do not view e-RAs simply as a mechanism to obtain price quotations, the host of e-RAs must adhere to mutually agreed terms and conditions, and provide some level of transparency. As observed in all of the six e-RA events, suppliers' pricing strategies were reactionary. They were not willing to be the price-leader. Rather, suppliers were keen only to match the prices of the price leader. However, the way that e-RAs were designed ensures that they deliver most benefits to the lowest price bidder. To further enhance incentives for suppliers to participate in e-RAs, the e-RA sponsors (either the buyer, or the buyer's representative) have to educate potential suppliers. This is to increase awareness of participating bidders about their obligations and rights, as well as about acceptable practices by the buyer and sellers.

To ensure that suppliers do not experience technical difficulties or have inadequate infrastructure for participating in the e-RAs, FinanceCo organized a trial run for the auction on the day before the actual auction. However, to distinguish the trial run from the real auction, FinanceCo reminded the bidders not to place bids based on their true pricing strategies. The purpose of the trial auction was to provide bidders with a "simulated" experience, and to iron out potential misunderstandings of the e-RA process. FinanceCo also ensured suppliers that it did not embark on e-RAs purely for the purpose of price discovery, but that it was serious about switching suppliers.

The training and education of bidders raise their awareness of the binding nature of e-RAs. They learn that although e-RAs facilitate price determination, bids placed are not retractable. Therefore bidders will need to have a clear knowledge of their own cost structure before the e-RA to ensure that the bids they place are achievable and realistic. In addition, the training and education exercises also reduce the anxiety and emotional experiences bidders may face in e-RAs. Bidders are encouraged to place bids rationally, and not be affected by a spur of the moment emotion, or be intimidated by competitors' bids. The training and education efforts also ensure a consistent familiarity of participants with the auction process.

The above are observations that were picked up over several e-RA events. The importance of some of these issues may change depending on the e-RA event. Nevertheless, the host /sponsor of e-RAs has to consider all possible eventualities, and come up with practical and equitable solutions.

## 5. IMPLICATIONS FOR RESEARCH AND PRACTICE

The present study highlighted several key issues that are emerging in e-RAs. A major challenge for buyers in deciding whether to implement e-RAs in sourcing and

procurement would be the ability to pre-determine the negotiating parameters, enabling price to be the sole negotiation parameter. But often, this is not the case; if the buyer continues with e-RAs, then a set of different pricing and costing methodology is required. The pricing and costing methodology will have to take into account the Total Cost of Ownership, as well as the ability to separate complex pricing strategies into their individual components. While this may appear as an attempt to commoditize non-commodity supplies, organizations that pursue the outsourcing approach are facing similar challenges to individually price components of a complex bundle of products. Multiple-attribute e-RAs [18] that take into account the various attributes of a product auctioneered could overcome some of the challenges of a price-based e-RA. The different attributes are assigned different weightings, and a scoring system that calculates the total “worth” or “value” of a product could substitute the use of price as the negotiating parameter, i.e. develop a negotiating parameter that represents the attributes of a product better than price.

The second issue is the ability for e-RAs to produce “Win-Win-Win” situations, that is, to reward more than just the buyer and the winning supplier. Efforts to reward non-winning bidders will encourage their future participation. Non-winning bidders should be made to appreciate that by participating in e-RAs, they gain access to market price and competitors’ information. A possible solution to this problem is a multiple-sourcing e-RA model. Instead of awarding the whole auction lot to the winning supplier, the buyer may find that a 70/30 or 60/40 split between the winning bidder and the second lowest bidder could provide additional motivation for suppliers to participate in e-RAs, as well as encouraging suppliers to bid competitively. Attempts to source supplies through variable lotting strategies indicate efforts by the buyer to spread its purchase among several suppliers.

Finally, organizations need to recognize the role of e-RAs in procurement and sourcing in price-determination and supplier selection. Supplier selection is a process that is not totally influenced by a product’s price. In e-RAs, the pre-auction qualification process represents initial supplier selection whereby the unreliable suppliers are weeded out, and capabilities of suppliers verified. Organizations also need to recognize the variance among the different types of procurement they undertake. Direct and indirect supplies require different procurement strategies. In preparing for an e-RA, the buyer should consider whether it would be willing to place competitive bids if it were placed in the position of a supplier.

## 6. CONCLUSION

This paper summarizes key observations from a case study of e-RAs. Using empirical data collected from

stakeholders involved in e-RAs, this paper provides insight into the emerging issues in e-RAs and suggests possible explanations for describing the observations made. While not attempting to generalize the observations, the explanations provide cues for developing strategies for overcoming specific challenges that arise from e-RA implementation.

The study’s findings contribute to practice particularly in the determination of e-RA negotiation parameters. Current practice to use price as the sole negotiation parameter introduces substantial limitations for e-RAs.

A multi-attribute weighted scoring system could provide a more complete and definitive indicator of a product’s attributes and properties, and hence could be the basis of a single and more holistic negotiation parameter.

A major limitation of the present study is that the e-RA events involved the sourcing of indirect supplies. Direct supplies are more critical to an organization’s operations, and the applicability and effectiveness of e-RAs may be limited as incumbent suppliers could have more control over the buyer-supplier relationship, preventing the buyer from switching suppliers without incurring significant costs and risks.

## How E-Ready is E-Sri Lanka?

Velauthapillai Dhayalan<sup>1</sup>, Reggie Davidrajuh<sup>2</sup>

<sup>1</sup> Computer Science, Bergen Univ. College, Norway, vdh@hib.no

<sup>2</sup> Electrical & Computer Eng., Stavanger Univ. College, Norway, Reggie.Davidrajuh@tn.his.no

### ABSTRACTS

First, this paper assesses e-readiness of Sri Lanka using a measuring tool that utilizes 52 socio-economic indicators. Second, based on the assessment, this paper suggests methods for improving e-readiness of Sri Lanka. The uniqueness of this paper lies in the quantitative analysis of the e-readiness of Sri Lanka, whereas many other works engage in qualitative exposure.

**Keywords:** E-government, e-Sri Lanka, e-readiness

### 1. INTRODUCTION

In November 2002, the government of Sri Lanka launched *e-Sri Lanka* – the information and communication technology development roadmap to achieve e-governance by the year 2007. Sri Lanka's first ever e-government conference was held in May 2003. The event was given utmost importance by the government of Sri Lanka, and was supported by some of the inter-governmental organizations such as the United States Agency for International Development (USAID) and the Swedish International Development Agency [19].

According to the official document, the main purpose of e-Sri Lanka is to achieve the desired levels of development, by enhancing national competitiveness, reduce or eradicate poverty by realizing enhancements in the quality of life of its citizens [10]. The government of Sri Lanka believes that the vision will

take the dividends of information and communication technology (ICT) to every village, to every citizen, to every business and also transform the way Government works [19].

The main purpose of this paper is to assess e-readiness of Sri Lanka. The uniqueness of this paper lies in the quantitative analysis of the e-readiness of Sri Lanka, whereas many other works engage in qualitative exposure. Based on the assessment, this paper also suggests methods for improving e-readiness of Sri Lanka.

In the next section (section 2), a tool for measuring e-readiness is presented. E-readiness of Sri Lanka is measured in section 3. In section 4, a set of proposals is presented to improve e-readiness and hence e-governance and e-commerce activities in Sri Lanka.

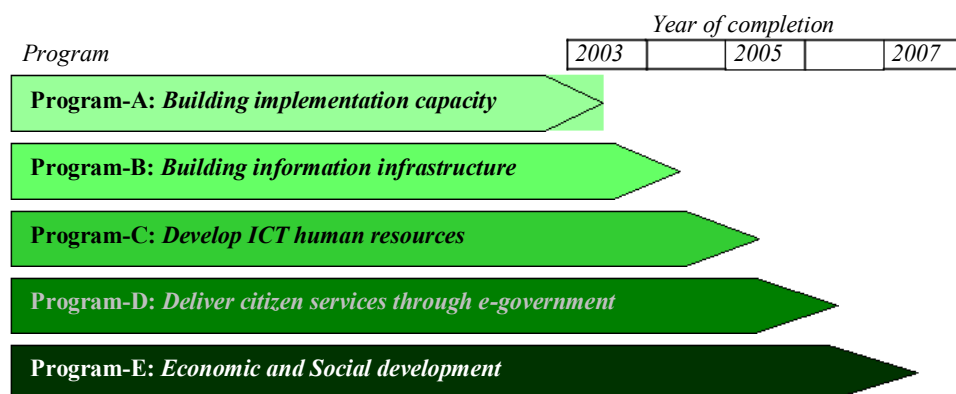

Figure-1: Five-program implementation strategy to achieve the vision of e-Sri Lanka (based on [GoSL, 2003])

### 2. A TOOL FOR MEASURING E-READINESS

There are many tools available to measure e-readiness of a country. In this work, a tool developed by Bui et al

[2] is used. This tool is selected because it is easily extensible, easy to use and has a large set of indicators.

## 2.1 The tool

The tool developed by Bui et al [2] consists of three basic building blocks. The three basic building blocks are (figure-1):

- I. Demand forces
- II. Supply forces, and
- III. Societal Infrastructure

The three basic building blocks are divided into eight major factors, and each of these major factors has a set of indicators. The major factors and the number of indicators that come under these factors are given below:

I: Demand forces:

- i. Culture, understanding and effectiveness: 4 indicators

- ii. Knowledgeable citizens: 6 indicators

II: Supply forces:

- i. Industry competitiveness: 7 indicators

- ii. Access to skilled workforce: 6 indicators

- iii. Willingness and ability to invest: 4 indicators

III: Societal Infrastructure:

- i. Cost of living and pricing: 3 indicators

- ii. Access to advanced infrastructure: 10 indicators

- iii. Macro economic environment: 12 indicators

The tool uses a total of 52 indicators.

## 2.2 Measuring e-readiness

All 52 indicators ( $e_i$ ) are assigned values on a 1-5 scale; 1 is the worst score and 5 is the best score. Then e-readiness of a country is calculated by a simple Figure-of-Merit (FOM) calculation. In this calculation, all the indicator values are multiplied with corresponding weights and summed together.

$$\text{E-readiness} = \frac{\sum_{i=1}^{52} IWeight_i \times e_i}{\sum_{i=1}^{52} IWeight_i} \quad [2]$$

## 3. MEASURING E-READINESS OF SRI LANKA

In this section, all 52 indicators are evaluated on a 1-5 scale (1 - worst score, 5 – best score).

### 3.1 Measuring the demand forces

There are two major factors under this block.

#### 3.1.1 Major factor-1: Culture, understanding and effectiveness

Indicator-1. English Language usage: English is commonly used in government and is spoken competently by about 10% of the population [32]. Score:  $e_1 = 1.4$

Indicator-2. Percentage of urban population: Urban population in Sri Lanka was 22% in 1998; it was 77% in USA [27]. Score:  $e_2 = 2.1$

Indicator-3. Percentage of population over 65 years or older: The percentage for Sri Lanka in 2000 was 6% [20]. Score:  $e_3 = 4.9$

Indicator-4. National culture open to foreign influence: N/A

#### 3.1.2 Major factor-2: Knowledgeable citizens

Indicator-5: Adult literacy rate: Sri Lanka has a 91.4% literacy rate [12]. Score:  $e_5 = 4.8$

Indicator-6: Secondary enrollment: Sri Lanka has 71% gross secondary enrollment rate in 1998; Norway is one of the leaders under this topic with 117% [28]. Score:  $e_6 = 3.4$

Indicator-7: Tertiary enrollment: Tertiary enrollment rate for Sri Lanka is 5%; the rate for Canada is 90% [28]. Score:  $e_7 = 1.2$

Indicator-8: MGMT education available in first-class Business Schools: [9] gave 3.7 points to Sri Lanka on a 1-7 scale. Score:  $e_8 = 2.8$

Indicator-9: 8<sup>th</sup> grade achievement in Science: No data available for this indicator. However, going by the diverse material (e.g. [11]) stating that Sri Lanka students perform just about the international average in mathematics, a value of 2.5 is justifiable. Score:  $e_{10} = 2.5$

Indicator-10: Flexibility of people to adapt to new challenges: N/A

### 3.2 Measuring the supply forces

There are three major factors under this block.

#### 3.2.1 Major factor-3: Industry competitiveness

Indicator-11: Technology achievement index: TAI value for Sri Lanka was 0.2 whereas Finland got the highest rating 0.744 [22]. Score:  $e_{11} = 2.0$

Indicator-12: Gross tertiary Science & Engineering enrollment ratio: Sri Lanka had 5%. Canada had the highest value for this indicator, 85% [13]. Score:  $e_{12} = 1.2$

Indicator-13: Administrative burden for start-ups: On a 1-7 scale, Sri Lanka received 4.9 points [9]. Score:  $e_{13} = 3.6$

Indicator-14: Private sector spending on R&D: On a 1-7 scale, [9] awarded 3.10 points to Sri Lanka. Score:  $e_{14} = 2.4$

Indicator-15: High-Tech exports as percentage of manufactured exports: Sri Lanka high-tech export is 3% of its total exports. For Singapore, it is 61% [30]. Score:  $e_{15} = 1.2$

Indicator-16: Patent applications granted by USPTO: N/A

Indicator-17: Total expenditure for R&D as percentage of GNI: N/A

### 3.2.2 Major factor-4: Access to skilled workforce

Indicator-18: Public spending on education as percentage of GDP: Citing again [30], Sri Lanka allocated 2.6%; Norway has the highest spending (6.8%) on education as a percentage of GDP. Score:  $e_{18} = 2.5$

Indicator-19: Extend of staff training: On a 1-10 scale, [29] gave 2.2 points to Sri Lanka. Score:  $e_{19} = 3$

Indicator-20: Research collaboration between companies and universities: On a 1-10 scale, [29] gave 3.0 points to Sri Lanka. Score:  $e_{20} = 1.9$

Indicator-21: Number of technical papers per million people: Sweden has the highest papers per million (6.82). For Sri Lanka, it was 1.44 [13]. Score:  $e_{21} = 1.8$

Indicator-22: University education meets the needs of economy: Though no valid data is available, according to [11], general literacy for ICT development and growth is insufficient. Score:  $e_{22} = 2.0$

Indicator-23: Well-educated people do not emigrate abroad: N/A

### 3.2.3 Major factor-5: Willingness and ability to invest

Indicator-24: Composite ICRG risk rating: [23] gave 64% (low risk) to Sri Lanka. Score:  $e_{24} = 3.6$

Indicator-25: Availability of venture capital: Sri Lanka received 3.1 points on a 1-7 scale [9]. Score:  $e_{25} = 2.4$

Indicator-26: Entrepreneurship among managers: [29] awards 5.19 points to Sri Lanka on a 1-10 scale. Score:  $e_{26} = 2.8$

Indicator-27: Foreign Direct Investment as percentage of GDP: FDI in Sri Lanka was 1.22%; Singapore has the highest FDI, which is 9.34% of its GDP [20]. Score:  $e_{27} = 1.5$

## 3.3 Measuring the societal infrastructure

There are three major factors under this block.

### 3.3.1 Major factor-6: Cost of living and pricing

Indicator-28: International cost of living based on US\$ 100: Osaka, Japan is the most expensive place to live (COL index 126.1) and Asuncion, Paraguay is the least expensive place (COL index 36.5). Colombo, Sri Lanka is rated with an index 60 [17]. Score:  $e_{28} = 4.0$

Indicator-29: Inflation rate – CPI in percentage: Currently Sri Lanka endures a rate of 8%. Among the best performing countries are USA and Norway both with 1% [3, 20]. Score:  $e_{29} = 4.7$

Indicator-30: GDP per capita (PPP) in US\$: PPP for Sri Lanka is US\$ 3279. Norway has one of the highest GDP per capita, currently US\$ 36,000 [30]. Score:  $e_{30} = 1.4$

### 3.3.2 Major factor-7: Access to advanced infrastructure

Indicator-31: Telephone per 1000 people: On a 1-10 scale, Sri Lanka received 4.17 points [30]. Score:  $e_{31} = 2.6$

Indicator-32: Mobile phones per 1000 people: On a 1-10 scale, Sri Lanka received 3.17 points [30]. Score:  $e_{32} = 2.0$

Indicator-33: Computers per 1000 people: On a 1-10 scale, Sri Lanka received 1.72 points [30]. Score:  $e_{33} = 1.3$

Indicator-34: Internet hosts per 10000 people: On a 1-10 scale, Sri Lanka received 0.65 points [30]. Score:  $e_{34} = 1.0$

Indicator-35: International telecom, cost of call to US: It cost US\$ 0.30 to make a 5 min call from Norway to USA. From Sri Lanka, the cost is 7.50 [18]. Score:  $e_{35} = 1.0$

Indicator-36: E-government: According to [1], USA leads with a score of 3.11 points whereas Sri Lanka got 0.92 points. Score:  $e_{36} = 2.2$

Indicator-37: Computer processing power as a % of worldwide MIPS: Sri Lanka's computer processing power is negligible. Score:  $e_{37} = 1$

Indicator-38: Freedom on the Internet: [8] gives 52 points out of 100 points. Score:  $e_{38} = 2.5$

Indicator-39: Investment in Telecom as a percentage of GDP: N/A

Indicator-40: ICT expenditure as a percentage of GDP: N/A

### 3.3.3 Major factor-8: Macro economic environment

Indicator-41: Trade as a percentage of GDP: Trade as percentage of GDP should be as low as possible; rate for Sri Lanka is 78 [30]. Score:  $e_{41} = 1.8$

Indicator-42: Protection of property rights: On a 1-7 scale, Sri Lanka scored 4.2 points [9]. Score:  $e_{42} = 3.1$

Indicator-43: Tariff and non-tariff barriers: On a 1-10 scale, Sri Lanka scored 6 points. Hong Kong and Singapore scored 10 points [29]. Score:  $e_{43} = 3.4$

Indicator-44: Soundness of banks: On a 1-7 scale, Sri Lanka received 5.3 points [9]. Score:  $e_{44} = 3.9$

Indicator-45: Local competition: On a 1-7 scale, Sri Lanka received 5.10 points [9]. Score:  $e_{45} = 3.7$

Indicator-46: Regulatory framework: Singapore is on the top of the list with 1.82 points; Sri Lanka scored 0.38 points in-line with Peru (0.36). Ethiopia was one of the worst performers with -0.71 points [13]. Score:  $e_{46} = 2.5$

Indicator-47: Government effectiveness: Singapore is on the top of the list with 2.16 points; Sri Lanka scored -0.44 points among the worst performers like Kazakhstan (-0.61), Maruritania (-0.66) [13]. Score:  $e_{47} = 1.3$

Indicator-48: Political stability: Finland is most politically stable (1.61 points). Sri Lanka was awarded -1.63 points, one of the worst performers [13]. Score:  $e_{48} = 1.0$

Indicator-49: Press freedom: A press survey [8], places Sri Lanka in the middle of the list. Sri Lanka received 52 points on a 0 (best score) – 100 (worst score) scale. Best performers were Sweden, New Zealand and Iceland, all of these received 8 points; worst performers were Iraq and North Korea, which received 95 and 96 points respectively. Score:  $e_{49} = 3.8$

Indicator-50: Rule of law: Singapore is again on the top of the list with 1.85 points; Sri Lanka scored -0.31 points, whereas Nigeria scored -1.13 [13]. Score:  $e_{50} = 2.3$

Indicator-51: Control of corruption: Finland is the best performer with 2.25 points; Sri Lanka scored 0.00 points, whereas Nigeria (one of the worst performers) scored -1.05 [13]. Score:  $e_{51} = 2.3$

Indicator-52: Adequacy of regulations and supervision of financial institutions: N/A

### 3.4 The results: the total e-readiness

Assuming equal weights of 1 to all the indicators, we summarize the e-readiness value for each major factor.

Major factor-1: Culture, understanding and effectiveness:  $e_{mf\_1} = 2.8$

Major factor-2: Knowledgeable citizens:  $e_{mf\_2} = 2.9$

Major factor-3: Industry competitiveness:  $e_{mf\_3} = 2.1$

Major factor-4: Access to skilled workforce:  $e_{mf\_4} = 2.2$   
Major factor-5: Willingness and ability to invest:  $e_{mf\_5} = 2.6$

Major factor-6: Cost of living and pricing:  $e_{mf\_6} = 3.4$

Major factor-7: Access to advanced infrastructure:  $e_{mf\_7} = 1.7$

Major factor-8: Macro economic environment:  $e_{mf\_8} = 2.6$

E-readiness values for each building block is given below:

Basic building block-1: Demand forces:

$$e_{DF} = \frac{e_{mf\_1} + e_{mf\_2}}{2} = 2.9$$

Basic building block-2: Supply forces:

$$e_{SF} = \frac{e_{mf\_3} + e_{mf\_4} + e_{mf\_5}}{3} = 2.3$$

Basic building block-3: Societal Infrastructure:  $e_N =$

$$\frac{e_{mf\_6} + e_{mf\_7} + e_{mf\_8}}{3} = 2.5$$

Summing all these values together:

$$\text{E-Readiness} = \frac{e_{DF} + e_{SF} + e_N}{3} = 2.5$$

## 4. ANALYSIS

By simply going through indicators, it is easy to find out where Sri Lanka should concentrate to improve its e-readiness.

E-readiness values for all the major factors are below average (the average value is 3.0). And hence, the building blocks and the total e-readiness values are all below the average value. Figure-2 plots e-readiness of Sri Lanka against e-readiness of other well-known economies like G7, USA, and Norway; data for Norway is taken from Davidrajah (2004); data for G7 and USA is taken from Bui et al (2001).

Figure-3 depicts detailed benchmarking of e-readiness of Sri Lanka based on the eight major factors. For comparison, values for Norway are also shown in the figure.

In Sri Lanka, demand forces (capability of the people) are about the average value. However, supply forces and societal infrastructure are poor. In some of the

areas (English language usage, tertiary enrollment, high-tech exports, GDP per capita, computers per 1000 people, and telecom costs) Sri Lanka performs poorly. Some other indicators (political stability = 1.0, and government effectiveness = 1.0) show that there is a serious problem in running the country.

Investment in ICT sector is low. After many technology investment debacles, private investors are not so enthusiastic about telecom ventures. The government has also problems in investing in technology sector mainly due to ever increasing health care costs.

### ABSTRACT

Small and Medium-sized Enterprises (SMEs) play a crucial role in the economic development of national economies and their growing internationalization. The development of information and communication technologies (ICT) has allowed SMEs to break different barriers, be they economic or regulatory, and to move towards more international positions of doing business. Considering the importance of ICT developments, particularly with regards to international marketing activities and the business opportunities they offer, still few researchers focus on the impact of ICT on international marketing and the internationalization issues it entails. This paper presents findings from a research project which focused upon the use of the Internet by SMEs in Lithuania. It investigates how the level of Internet use in SMEs is related to firm internationalization and Internet marketing activities. The analysis of main factors affecting successful use of ICT such as the role of the Internet in strategies of internationalization, the reduction of barriers through use of the Internet, the influence of the Internet on international marketing activities, and problems of using the Internet for internationalization.

**Keywords:** *Internet, SMEs, Internationalization*

### INTRODUCTION

ICT offers significant opportunities for all enterprises, especially for SMEs, looking to market their products and services internationally. The Internet, for instance, can provide SMEs with a low cost gateway to global markets by helping to overcome many of the barriers to internationalization commonly experienced by small businesses. Such companies are able to compete more easily in the global marketplace, and consumers in emerging markets, in particular, they benefit from expanded range of products, services and information to which the Internet gives them access.

Applying knowledge and using ICT for enterprise internationalization creates the preconditions of development of a knowledge economy. The new opportunities for SME, which can be achieved by using Internet, have become vitally important for US and European enterprises. In Lithuania various aspects cause a problematic situation — lack of knowledge, low level of computerization and Internet usage — with the result that the Internet possibilities for competing in international markets remain largely neglected. The appropriate analysis of using the Internet for internationalization as well as implication for knowledge economy development is a critical task whose solution requires theoretical grounding and research of practical and feasible possibilities.

**Problem.** *This article is orientated to study the role of Internet for internationalization activities between Lithuania SMEs. The new opportunities for SME, which can be achieved by using Internet, become vitally important for USA and European enterprises. In Lithuania various aspects cause a situation — lack of knowledge, low level of computerization and Internet usage, that the Internet*

*possibilities for competing in international markets remain neglected. The appropriate analysis of using internet for internationalization is very important task which solution requires theoretical grounding and research of practical possibilities.*

**The purpose of research.** *The purpose of the research is to analyze the use of Internet between Lithuania's SMEs identifying the internationalization barriers which are removed by Internet, the success factors of using Internet for internationalization and Internet influence on international marketing mix.*

### THEORETICAL FRAMEWORK

The Internet offers big opportunities for all enterprises, especially for small and medium-sized enterprises (SMEs), looking to market their products and services internationally. The Internet can provide SMEs with a low cost gateway to global markets by helping to overcome many of the barriers or obstacles to internationalization commonly experienced by small businesses. Such companies are able to compete more easily in the global marketplace, and consumers in emerging markets, in particular, they benefit from expanded range of products, services and information to which the Internet gives them access. However, the problem here is that small businesses have rapidly exploited the new opportunities on their own, but these opportunities also brought many obstacles facing these enterprises.

Firstly, speaking about the internationalization process one has to define what it is and how it affects businesses and especially small and medium-sized enterprises. Internationalization by J.Hamill (1997) is understood as

evolutionary, incremental process whereby SMEs become more and more international over time; the driving force being increased international knowledge, experience and confidence which are seen as breaking down the cultural barriers and reducing the risks associated with further internationalization. Although some important differences exist, the various studies agree that internationalization is a step-wise process which evolves through various stages; for example, the completely uninterested firm, the partially uninterested firm, the exploring firm, the experimental firm, the experienced small exporter, the experienced large exporter.

The main barriers experienced by SMEs when “going global” are psychological, operational, organizational, product/market. At all points one has to understand that the Internet does not provide a panacea for such problems. However, if used effectively, it can be a very powerful tool to assist SMEs in overcoming the main barriers experienced, resulting in more rapid internationalization.

Closely related to the issues of barriers is the question of “critical success factors” in SME internationalization. It is important to observe that there is no such thing as an absolute success factor in the sense of guaranteeing good performance abroad since the factors influencing export success are complex and varied. However, there is sufficient empirical evidence to arrive at some general conclusions concerning the most important factors in successful exporting, such as Finding the “right” overseas agent or distributor, international awareness, knowledge and orientation, etc.

Marketing on the Internet is a very different process from traditional marketing. The international Internet marketing has changed some elements of the marketing mix. The scope of this part was focus on marketing mix dimensions that may be facilitated through the use of the Internet. However, one has to admit that the changes in the four Ps are the result of the interactive nature of the Internet, but this is already the subject of a new international marketing paradigm where the key to a more successful marketing effort on the Internet will be an interactive strategy.

## RESEARCH RESULTS

The empirical research has been carried out among Lithuania's SMEs using a questionnaire on Internet. The point of this survey was to get information preferably from the people who were responsible for the strategic decisions in various enterprises and to acquire a better understanding of the problem. The total number of 147 respondents took part in the survey.

When the respondents were asked for what purposes they used the Internet in foreign markets they had the possibility to mark those answers that best fitted for the

activities of their enterprises. 69% of respondents who answered this question remarked that they were using the Internet for communicating with business partners. As far as this answer was chosen by a good many of respondents it can be stated that primarily the Internet is used for communication with business partners. A little less (67%) account for dissemination of information. Communicating with customers got 60% of the answers, while providing oneself with supplies amounts to very little - only 33% of all answers (See Figure 1).

In conclusion, such results show that for the most part the Internet is used for communication process –either way with business partners and customers; and for the dissemination of information.

**Figure 1 Purposes of using the Internet in the activities of enterprises (%)**

The next step in the survey was to sort out what means of the Internet are usually used in the day-to-day activities of enterprises. Answering this question the respondents had to arrange the answers from 1 to 5, where 1 is not used at all and 5 –very important and used much of the time. Hence, the respondents had to evaluate such answers as the Internet website; e-mail; databases; chat rooms, the Internet advertising and the Internet search engines. It can be noted that the majority of respondents (80%) gave 5 points to e-mail which they are using most of the time. 35% of respondents who answered this question stated that using the Internet website in the activities of enterprises could be treated as very important and also gave 5 points to this medium. The same proportion of 24% of the respondents gave to Internet advertising 3 and 4 points which means that using advertising on the Internet is supposed to be less important than using e-mail or the Internet websites. Using databases and the Internet search engines was also evaluated in 5 points respectively by 38% and 27% of respondents. The situation is much different with chat rooms because 76% of respondents gave only 1 point to this medium which means that basically it is not important and not used in enterprises.

**Table 1 Means of the Internet most commonly used in the activities of enterprises**

	1	2	3	4	5	Response Average
The Internet website	10%	10%	23%	23%	35%	3,6
E-mail	3%	0%	6%	11%	80%	4,7
Data bases	10%	17%	24%	10%	38%	3,5
Chat rooms	76%	16%	4%	0%	4%	1,4
The Internet advertising	14%	17%	24%	24%	21%	3,2
The Internet search engines	15%	15%	18%	24%	27%	3,3

Therefore, these two questions clearly show the trends of the usage of the Internet in the activities of Lithuanian SMEs. The main tool which can embody successfully communication with business partners and customers is e-mail which has been marked by most respondents and surpasses greatly other means like the Internet website; data base; chat rooms; the Internet advertising and the Internet search engines. To show the ratio of the repartition between the means of using the Internet more visibly the response average was calculated and can be seen in Table 1. As it was stated above much importance was attached to e-mail with the average response of 4,7 –the highest from all others. On the subject of chat rooms the response average calculated was only 1,4.

One of the main goals of this survey was to learn more about the importance of obstacles Lithuanian SMEs face in the process of internationalization. The respondents were asked again to evaluate the answers from 1 to 5 where 1 is not important and 5 means that this factor has a large impact on the activities of their enterprises. The results of this question were surprising because the majority of the respondents marked 1 for all the answers. This means that in their estimation there are no obvious barriers for the further internationalization of enterprises in Lithuania. 38% of respondents marked 1 for financial resources while the same factor is very important to only 18% of those who evaluated it with 5 points. 28% of those who answered this question don't feel the lack of ICT at all and 7% of respondents admit that it is a crucial factor for their enterprises. The majority of respondents also gave 1 point to distrust and lack of knowledge in using ICT, correspondingly 28% and 22%. The ones who marked 5 points for these two factors amount to 19% and 16% respectively. To see this striking contrast between matters of substance and factors of no importance only answers which have got points 1 and 5 are presented in Figure 2.

**Figure 2 Structure of obstacles affecting the usage of the Internet in the process of internationalization (%)**

This figure shows the positive trends towards the process of internationalization and the further development of e-business among Lithuanian SMEs. It is clear that the growing availability of ICT (with prices declining markedly and new models of ICT introduced to the market) has made this factor one of low importance. Nowadays when the development of information society is a top priority more and more models of ICT from low to high prices are available to households, enterprises, national and local government institutions.

Analyzing the results of barriers that the use of the Internet can overcome it is important to find out how the Internet contributes to the diminution of obstacles related to the activities of enterprises when “going global”. 21% of those who responded to the survey stated that the Internet helped their enterprises reduce psychological barriers, which means that through the use of the Internet the enterprises started to think more globally (see Figure 3). They are no longer thinking of exporting as something unrealizable, which is “too risky” “or not for us”. The Internet has helped them overcome initial fears and supported in implementing long rather than short time perspectives. The majority of respondents (64%) admitted that the Internet was of great use in reducing organizational barriers which arise from the lack of limited financial and managerial resources; lack of internationally experienced personnel and their training; lack of knowledge of foreign markets and problems in finding suitable agents and distributors. 57% of respondents declared that usage of the Internet determined the decrease of operational barriers. It became simpler to handle all export documentation through electronic data transfers and make electronic payments. 31% of the respondents noted that the use of the Internet resulted in the reduction of barriers related with product and market. It has become easier to identify and select the most appropriate foreign markets having limited resources for country screening and export research. It is easier to identify the differences of foreign markets and then adapt the products. Only 14% of all who answered noted that using the Internet resulted in having more competitive ability among other enterprises. Nowadays the Internet offers competitive survival rather than a competitive advantage in the

global marketplace. Given that from a competitive standpoint a presence on the Internet is a must in today's business (See Figure 3).

**Figure 3 Barriers diminished by using the Internet (%)**

It can be concluded that usage of the Internet in Lithuanian SMEs has influenced mostly the reduction of organizational and operational barriers by 64% and 57% respectively in the view of the respondents. But what does this say about the role of the Internet in these processes? How does it contribute to these changes? Firstly, enterprises have access to low cost market research resources. Their knowledge of international markets and culture has improved and at the same time they can reduce their dependence on traditional agents and distributors. The Internet can resolve many of the problems related with the lack of information because much of it can be gathered without any fees or for much smaller ones than in the enterprises of market research.

This questionnaire was formed not only to evaluate the influence of the barriers but also to identify the benefits for the process of internationalization brought by the usage of the Internet. The majority of the respondents who answered (77%) declared that the Internet benefited mostly in the improvement of the communication process. If we look again at the question when the respondents were asked about the purposes of using the Internet in foreign markets, the Internet was used mainly for communication with business partners. Once again the conclusion may be drawn that the Internet is the source of communication that is facilitated greatly through the use of this medium. The same percentage of respondents (23%) gave 1, 2 and 4 points to the first answer about finding new markets with the help of the Internet. Such results show that the Internet hasn't helped much in finding new markets for almost half of the respondents. The situation is different with finding new customers because 50% of respondents gave 4 and 5 points to this answer. In sum, the majority of the respondents believe that the Internet is more useful in finding new customers than new markets. The biggest share of the respondents also acknowledged that the Internet reduced the costs of their activities and gave quick access to all the information. These two answers were evaluated at the maximum with 5 points, respectively by 38% and 57% of the respondents. To see the results more clearly the response

average again was calculated. The figure of 4,6 confirms once again that the Internet is the most effective medium for the process of communication. The reduction of financial costs is evaluated with the average of 3,8 which means that the impact of the Internet on communication process and quick access to the information is bigger than that on financial costs. The response average of 2,9 (the lowest from all others) implies that the Internet is less useful in finding new markets than in any other areas.

**Table 2 Benefits originated from the use of the Internet**

	1	2	3	4	5	Response Average
Helped to find new markets	23% (7)	23% (7)	13% (4)	23% (7)	17% (5)	2,9
Was useful in finding new customers	4% (1)	25% (7)	2% (6)	25% (7)	25% (7)	3,4
Contributed to the improved communication process	6% (2)	0% (0)	3% (1)	14% (5)	77% (27)	4,6
Made the costs of the activities lower	9% (3)	12% (4)	12% (4)	29% (10)	38% (13)	3,8
Gave quick access to all the information necessary	6% (2)	0% (0)	11% (4)	26% (9)	57% (20)	4,3

The respondents were asked which factors they considered to be crucial for successful usage of the Internet in the internationalization process by Lithuanian SMEs. The most critical factor given by the survey respondents has to do with knowledge and skills (see Figure 4). The next two factors are financial resources and new technologies. The respondents had to choose among the factors, which helped to use the Internet successfully in the process of internationalization. Most of the respondents believe that knowledge and the ability to use the skills properly is a determining factor in the successful use of the Internet. When calculating the response average, this factor got 3,8. New technologies with the average figure of 3,4 is the second important factor and financial resources with the average of 3,2 is supposed to be less important than knowledge and new technologies. Figure 4 shows the percentage of respondents who gave 1 point to unimportant factors and 5 points to significant factors.

**Figure 4. Structure of factors which contribute to the successful use of the Internet (%)**

In summary, it can be stated that for Lithuanian SMEs knowledge and skills (human resources on the whole) is likely to play a key role in the industry base of technology and knowledge-intensive economic development. It is clear that these factors cannot be separated from one another because in order to develop the skills and acquire relevant knowledge one has to have some financial resources to purchase a computer and have the Internet access. The point to be stressed here is simply that support of the educational sector is a crucial condition for a sustainable transition to a knowledge economy. It is desirable that pupils and students have a higher level of computerization and the Internet access in educational institutions where they develop their knowledge and skills to become highly skilled ICT manpower. Such people are the backbone of electronic business development in Lithuania and further process of internationalization in enterprises. One of the most interesting aspects of the process of internationalization is the effect of the Internet on the changing face of the marketing mix. According to various authors the Internet has created a new environment for international marketing and similarly the changes of this environment resulted in the changes of 4 Ps (Product, Price, Place, and Promotion). The Internet has often led to faster discovery of customer needs; increasing competition and standardization of prices; interactive communication with customers and reduced importance of traditional intermediaries.

**Figure 5 The impact of the Internet on marketing mix (%)**

It was necessary to identify the importance of these changes of marketing mix in the activities of Lithuanian

enterprises. 33% of our survey respondents stated that the usage of the Internet resulted in the average changes of the product or service (see Figure 5). There were average changes in customization of the product, discovery of customer needs and product testing in the biggest part of Lithuanian enterprises. The biggest share of the respondents about price (34%) declared that there were no changes in prices in their activities in foreign markets. 39% of respondents experienced average changes in distribution channel and 32% of respondents admitted that the use of the Internet has also caused average changes in promotion.

These figures indicate that the Internet has average influence on almost all of the components of marketing mix except price. The majority of Lithuanian SMEs don't experience any changes of prices when "going global". Figure 5 shows the trends more clearly. Speaking about promotion, 10% of enterprises believe that the Internet is the source of innovative ideas. This could be explained by the nature of online promotion techniques, especially advertising which is perhaps the best developed use of the promotion can be implemented in various ways and there is always space for creative ideas. From this standpoint the Internet is understood as a mean which can quicken generation and realization of the ideas. One has to understand that features valuable in promotion don't fit at all to the process of fixing prices where thoroughness and accuracy but not creativity is valuable. Maybe it is for this reason that use of the Internet has less power to change prices in enterprises.

## CONCLUSIONS

Summarizing the research results it can be stated that the largest part of Lithuanian enterprises (67%) use the Internet for communication with their national and foreign partners. The main purposes of using the Internet are primarily communication with business partners, customers and dissemination of information. The Internet is used least while providing oneself with supplies. The most popular and widely used tool of the Internet is e-mail. It surpasses greatly other means of the Internet like the Internet websites; data bases; the Internet advertising and search engines. These tools are used much less while chat rooms are not popular at all in the activities of Lithuanian enterprises.

The structure of obstacles affecting the usage of the Internet shows the positive trends towards the process of internationalization. This may be explained by the fact that the majority of Lithuanian SMEs do not consider distrust; lack of financial resources, lack of communication technologies and knowledge as significant obstacles for internationalization.

The survey also shows that the Internet reduces organizational barriers more than any others. As well Internet plays important role in reducing operational and

product/market barriers.

The main benefits of Internet use in the day-to-day activities of Lithuanian SMEs result in improved communication process and quick access to all the information necessary.

The prior factor which contributes to the successful use of the Internet in the process of internationalization is knowledge and skills. Financial resources and new technologies are ranked as less important.

The Internet has average impact on three elements of the marketing mix: product; place and promotion. However, the majority of Lithuanian enterprises do not feel any changes of prices when operating in global environment.

Consequently, 77% of enterprises believe that the Internet use is essential and has large impact while operating in foreign markets and only 6% of enterprises assume that the Internet has no power in the process of internationalization.

Unless the technological backbone is easily accessible for internationalization activities, the lack of knowledge for using technologies prevents companies from productive use of technologies. Nevertheless the importance of Internet in competing in global market is recognized by many businessmen's.

# Investigating the Use of the Business Model Concept through Interviews

Alexander Osterwalder, Yves Pigneur

HEC Business School, University of Lausanne, Switzerland  
{Alexander.Osterwalder, Yves.Pigneur}@unil.ch

## ABSTRACT

The term *business model* is widely used and is increasingly gaining importance as a business concept and management tool, particularly in e-business. Several authors propose the application of the business model concept in different domains, such as for e-business planning, IS alignment, visualization, innovation, e-business process design or improving communication between stakeholders. Yet, little has been said on the business world's perception of the use of business models, which this paper attempts to investigate through semi-structured interviews with company executives and business consultants.

**Keywords:** Business Models, Business Model Concept, E-Business, Management, Interviews, Ontology

## 1. INTRODUCTION

The term and concept of business models is continuously gaining in acceptance and importance after overcoming its passage as a buzzword. A query in Business Source Premier, a leading electronic database for scholarly business journals, shows that in the 1990s a veritable boom of the expression business model has taken place (see Figure 1). The term is found in numerous variations, such as “new business models”, “e-business models” or “internet business models” and has occurred 144 times in an abstract and 29 times in the title of a peer-reviewed article in the above-mentioned database.

Figure 1 : Occurrences of the term business model in Business Source Premier

Yet, far more interesting than the number of occurrences of the term is the appearance of the business model concept as a management tool as outlined in a number of literature reviews by Stähler [12], Pateli and Giaglis [9], Rentmeister and Klein [10] and Osterwalder [6]. Most promisingly, several authors propose a conceptual approach to business models by describing and modelling a business model's elements and their relationships [1, 2, 4, 6, 13]. Furthermore, they outline a number of possible applications for such a conceptual approach, like business planning, IS alignment, visualization, innovation, process design or improving communication.

This paper aims at taking up the use of conceptual business models by investigating how the business world perceives the use of business models as a management tool. So far, little business model research has attempted to describe the confrontation between concepts and business world, with the exception maybe of Linder [5] and Gordijn [3]. The former has conducted interviews with company executives investigating business model relevance while the latter has applied the e<sup>3</sup>-value business model framework in consultancy work and published the experiences.

The originality of this paper is that it explores the business world's interest in and perception of different uses of the business model concept. In a dozen semi-structured interviews we captured the opinion of business leaders and consultant and subsequently analyzed the interview transcripts.

The paper is structured as follows. In the next section we explain the business model ontology that has served as the basis of the interviews on the use of business models. The third section outlines the methodology. In section four we describe the interview outcome and analysis before concluding in section five.

## 2. THE BUSINESS MODEL ONTOLOGY

To explain the interviewees the concept of business models we used Osterwalder and Pigneur's business model ontology as it represents a consolidation and synthesis of ongoing research in the business model domain [7, 8].

The business model ontology captures the money earning logic of a company and consists of nine main components. These so-called business model building blocks are *value proposition*, *customer relationship*, *distribution channel*, *target customer*, *value configuration*, *capability*, *partnership*, *revenue model* and *cost structure* (see Figure 2).

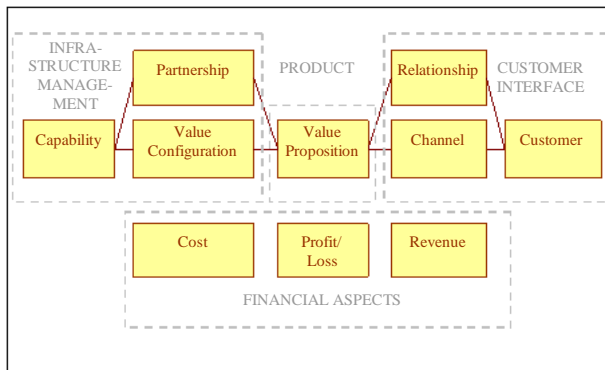

Figure 2 : The Business Model Ontology [6]

The starting point for investigating business model use in the interviews was the presentation of easyJet.com's business model (see Figure 3). The business model building blocks of this bird's eye view were also presented in more detail and in more fine-grained examples.

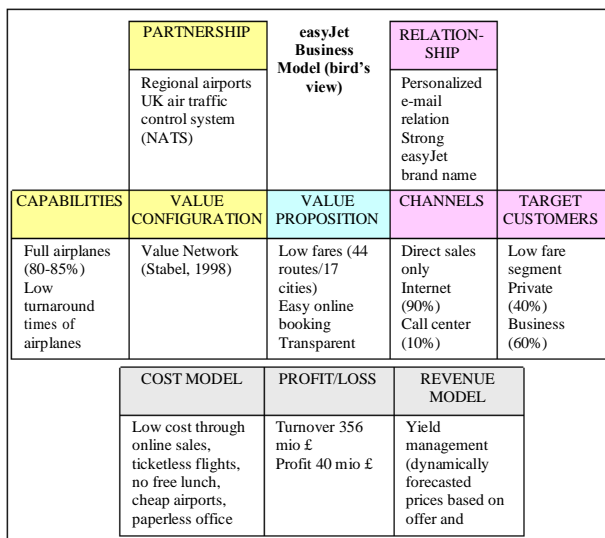

Figure 3: easyJet.com business model

### 3. METHODOLOGY

Between June and October 2003 we conducted a dozen 60 to 90 minutes long interviews with managers and consultants to assess the use of business models in the firm. These were a series of semi-structured interviews that aimed at investigating the relevance of business model research exploring possible uses of the business model concept. The interviews were all transcribed and subsequently compared and analyzed.

We introduced the interviewees to the business model concept by explaining the business model ontology described in section two. The interview itself then focused on the business model concept and its use in general.

The interview was structured into four parts (see Table 1). A first part was composed of questions on the use of models, formal models and business tools in the

interviewees' companies. The second part consisted of a short explanation of the business model ontology by presenting a number of examples of business models or parts of a business model, such as easyJet.com, ColorMailer, Barnes&Noble and Nokia. The third part was destined at discussing Osterwalder and Pigneur's business model ontology. The goal of the most extensive fourth part was to investigate in which fields the business model concept could make a contribution.

Table 1: Business Practitioner Interview Structure

Question Domain	Questions
Questions on the use of business concepts & tools	How do you plan the general business objectives of your company? Do you use any conceptual tools to plan your business or to sketch the general direction in which your firm is heading?
	If yes, do you use any specific formalism(s) to do this?
	If yes, do you use any specific software tool to do this? If yes, which one(s)?
Demonstrations & Explanation of the Ontology	easyJet.com, ColorMailer, Barnes & Noble, Nokia
Questions on the fidelity with real word phenomena	In your opinion, what elements are missing in the model presented before?
	In your opinion, what elements should not belong to the model presented before?
	How could such a model help you define business indicators?
	How could such a model help you or a group of managers make better decisions?
	How could such a model improve some parts of strategic planning?
	How could such a model make it easier to chose and design appropriate information systems (e.g. software purchases like Customer Relationship Management or Supply Chain Management...)
	How would it be able to foster innovation in a company with such a model?
	How do you think such a model could improve business process design and engineering?
	How could it be helpful to have such a model to communicate your business model. (when making decisions, to communicate with employees)
Final discussion	Do you have any final comments?

The interviewees were conducted with 8 managers and 3 consultants. The managers represented companies in the domains of transport (1), media (1), services (4), retail (1) and industry (1) (cf. Table 2). All enterprises except the industrial company had a strong Internet component. Company sizes ranged from 3 to 3'315 employees. From the companies addressed and asked to participate in the interviews only one did not take part after initially agreeing. A general impression was that the interviewees were all quite receptive to the topic of business models. One manager of a start-up company mentioned: *"I'm already happy that somebody tries to define the term business model. It was one of the most violated terms. Everything was a business model. Everybody asked me what a business model is. I could never really define it. It is good that somebody is looking at this"*.

#### 4. INTERVIEW OUTCOME AND ANALYSIS

The first part of the interview aimed at examining if the interviewees and their companies used models, formal models or even more sophisticated business tools in business planning. Of course this was not aimed at giving us such detailed insights to business concept use, as for example the study by Rigby [11], but it can serve as an indicator for companies being comfortable with the use of concepts. Not surprisingly, very few companies, but all the consultants used concepts or models. One consultant put it very clearly: *"I have seen very few managers use concepts or models, but then that*

*is one of the reasons why they bring in us consultants"*. The CEO of the industrial company that actually used some formal concepts said that *"it took quite a lot of work to use these concepts, but it was very helpful. What was not satisfying was that we didn't exploit them sufficiently once the work was done"*. At another point he mentioned that *"at the end of the day there stays very little time for doing prospective business planning"*. Surprisingly, the smallest company interviewed used a conceptual tool for business planning. In the CEO's opinion the most important aspect of using a concept was consistency. Concepts would only bring advantages when rigorously applied.

 q = quote

The younger companies had all made business plans during their start-up phase. This could also be seen as the use of some sort of concept, as most of them had structured their business plan according to recommendations in books available on the market. One executive compared the business model concept to the business plan approach and saw it as a quite useful checklist, particularly for start-ups.

A surprising finding was that a large number of companies relied deeply on trial and error to introduce new aspects to their business. The planning for this relied essentially on drafting text documents with a Word processor and calculating the financials with a spreadsheet program.

The fourth and major part of the interview aimed at investigating the interviewees' opinion on different business model concept applications. Seven areas were

identified and presented to the interviewees, namely the definition of indicators, decision making, strategic planning, designing information systems, innovation, process design and improved communication.

The two most important themes that were isolated from the answers to the seven questions were transparency and communication. They appeared several times as answers to several different questions. Transparency was particularly mentioned by two managers and two consultants. For example to the first question on business indicators one manager mentioned: *"it is important to make things transparent to show where cost and risks come from. Transparency is very important. [...] Such a framework can be interesting"* (cf. quote q1 in Table 2).

Communication was another recurring theme throughout the answers and explicitly addressed in the last question on communication. Especially in question

two on decision making communication was mentioned by four interviewees in combination with transparency: *"it's also about transparency. Somebody puts up the sheet and says this is our company and this is the way it works. Not everybody understands the same thing under the functioning of a company"* (q33). One manager that was less enthusiastic about the business model concept's role in improving decision making acknowledged: *"it helps in communicating, in that sense it may improve decision making. But at least this way people talk about the same thing"* (q12). One CEO of an industrial company said that a business model *"can be very helpful if not too complicated and adapted to specific managerial levels for decision making: employee communication; customer presentations (screened); and training purposes (employees and customers)"* (q26) and that *"it [the business model] is a very useful instrument to initiate discussions with employees, partners or customers about process improvements. The visualization helps also in the internal or external communication of business decisions"* (q25).

Table 2 gives an overview of the interviews depicted in the following sections of the paper, showing the interviewee's economic domain, the number of employees, the company's use of concepts and tools, as well as the use of trial & error, and, the interviewee's position concerning the questions. As outlined above the questions ranged from *"can the business model concept help in defining indicators"* to *"can the business model concept improve communication"*. Favourable answers are indicated in green, reluctant ones in red and neutral ones in grey.

#### 4.1 Defining Indicators

The first question concerned defining indicators in a rapidly changing business environment characterized by ICTs and e-business. While quite a few interviewees seemed favourable to the idea that the use of the business model concept could improve defining business indicators they particularly stressed financial indicators. One interviewee pointed out the importance of transparency regarding costs and risks (q1). A consultant insisted on the financial relationships: *"If I can change parameters in the model and see how this impacts costs, profits, then yes. If you can model cost structure and profitability you have to integrate it with the how and who [infrastructure and customer relationship]. I have to understand how factors influence each other and then I will look at evolutions more closely with my controllers"* (q32). The chief operating officer (COO) of a company with 15 employees was rather critical and remarked that *"in a company like ours everything is in the heads of the people"*. He saw the value of the business model approach elsewhere: *"Where it can be very important is on the venture capital side or the investor side where you have to map business models quickly"* (q11).

Astonishingly, few interviewees bought in on the idea of not only defining financial indicators, but defining indicators throughout the business model pillars. One consultant that understood this asked in what the idea of deriving indicators from the business model was different from the balance scorecard concept (q39).

#### 4.2 Improving Decision making

The reactions to the second question on improved decision making through tools based on the business model approach were mixed. Many of the interviewed saw an indirect influence on decision making through discussing the fundamentals of a business (q34, q40, q18, q28) and through improving communication. The executive from the transport industry saw the force of schematizing in asking fundamental questions: *"You will have to ask yourself in which box [element] I put what - it allows me to look at things from a new angle. It forces you to ask questions. But I see this rather as a tool for start-ups"* (q28). One manager of a start-up company talked about his experience at a large corporation where they used a simple conceptual model to communicate during meetings. As regards the business model concept he noticed that it may help people talk about the same thing and thus improve decision making (q12). Another COO was quite enthusiastic stating *"it would certainly help to make better decisions. Oh yeah, I'd love to see this in my department"* (q16). One of the interviewed consultants acknowledged the value of the business model concept in communication but perceived it as too static to improve decision making (q44). The founder of a software company in the mobile industry felt that the problems he experienced in decision making were much more related to human aspects of the deciders (q6). The CEO of an industrial company was rather favourable, but questioned the availability of business data, *"the framework can help to better set priorities, however, to better support the decision process, the availability of business data needs to be ensured"* (q22). Furthermore, he stressed the importance of having to be able to *"introduce such a business model framework within reasonable means and resources"*.

#### 4.3 Improving strategic planning

The business model concept's possible direct or indirect contribution to improving strategic planning was perceived by all but two interviewees that answered the question. The CEO of the smallest company interviewed saw the business model concept as a way to outline the steps necessary to achieve a strategic goal (q2). Another manager saw the advantage in taking into account all the elements of a business model (q7). A consultant proposed combining business model and scenario approach in order to have an impact on strategic planning: *"[The business model concept] can indirectly influence direct strategic planning through scenarios and transparency"* (q41). One executive that was

reluctant stated: *"We would think what kind of skills we need. We would make a cost model and a revenue model. We would make a prototype and look if it works. If it doesn't work we would stop the test"* (q13). This approach remarkably resembles some of the structures of the business model concept. The executive from the transport industry was also reluctant and thought that the ontology could have an impact on strategic planning if it allowed simulation (q29). Finally, the executive from the entertainment industry observed that looking at his enterprise through the business model lens opened up new perspectives that were not usual to his business (q27).

#### 4.4 Helping in the Design of ISs

The fourth question on improving the design of information systems (IS) was not answered by all the interviewed practitioners because not all of them felt expert enough to reply. The answers that were given were quite mixed and split between three supporters and three opponents of the idea. Noteworthy, the supporters felt very strong about the necessity to describe the business logic of a company to improve IS design. The CEO of the industrial company, the COO of the financial platform and one of the management consultants strongly backed the link between business model and IS design. The first declared *"once business models/processes are clearly defined and evaluated, respective appropriate information systems can be easily defined. There are significant differences in the business processes supported by off-the-shelf information systems. Therefore, a business framework can not only help, but is almost required to identify the information system with the best fit"* (q23). The second proponent mentioned: *"I think you make things much easier here... much, much easier. Well I think what we've done is that [...] it presents it [the business model] in a clear way. So everybody starts in the same place. Picking up on your point about taking it out of a manager's head and putting it on a piece of paper"* (q17). The consultant answered like the CEO: *"You absolutely need a model before you can do anything"* and *"especially if the dependencies and interactions of the different building blocks become clearer. Transparency is important for understanding what we do and how the building blocks interact"* (q35). The CEO of the small Internet retailer felt that the business model concept would probably not improve IS design because of its static nature (q3). Similarly, the co-founder of the small software company remarked that the tools based on the business model approach *"may influence IS design, but will not essentially help to improve it"* (q8). An executive from an Internet industry platform had the impression that according to his experiences *"engineers would not be favourable to use such a tool as the business model concept"* (q19). Another manager saw the use of the ontology in IS design particularly for new economy companies of a networked type (q30).

#### 4.5 Increasing innovation

With regard to innovation there were two positions, the first accentuated the human capability aspect of innovation (q9, q14, q42) and the second drew attention to the fact that the visualization and transparency created by business models could improve innovation (q4, q36, q31). A proponent of the first view stated: *"What is important is thinking it through. That is what takes time. If we look at the value proposition it is the thinking behind it that is important. If we are in front of investors the important thing is that it is innovative, that there's a prototype, that it was tested and that it comes over technically. And that thinking takes time"* (q14). Similarly, another one mentioned that *"innovation is more about the people"* (q9). A consultant commented that the business model approach may help in innovating but that *"the tool will not generate innovation. You still need the creativity of the people"* (q42). A proponent of the positive effect on innovativeness pointed out that thinking through a business model will automatically stimulate innovation: *"Establishing/elaborating business models and business processes requires thorough and in-depth analyses which leads by itself to innovative ideas and incentives on how to improve key indicators and elements of business models and how to better process steps or phases"*, (q24). Similarly, another executive had the impression that structuring the thought process could be an advantage for brainstorming and have an effect on innovation (q20).

#### 4.6 Improving Process Design

The interviewees that answered the question on improving process design were all relatively positive except for one that underlined the model's static nature as he had already done for information systems (q5). They saw the business model's value in its high level business logic description: *"I think something like this model is the foundation. Before you can describe processes you have to have something like this at the generic high level"* (q37). The executive of a start-up, however, emphasized that this is too sophisticated for small companies, *"in a small company this would be overkill"* (q15). The executive from the Internet industry platform had the impression that such a model would help people keep in mind the whole, because they would often forget other parts of the company when designing processes (q21).

#### 4.7 Improving Communication

As explained above its ability to improve communication between different parties was seen as one of the strong points of the business model concept. One consultant saw it as *"a formalism that everybody understands to speak the same language"* (q43). Another one pointed out that it helped people to talk

about the same thing: "First you have to assure that everybody is talking about the same thing. For example in customer relationships you can imagine talking about hundred different things. It's about presenting things in a simple way that is certainly the most important" (q38). One interviewee saw tools based on the business model concept as a means to communicate with employees, customers and for training purposes (q26). The interviewee opposed to the positive effect on communication felt that "it's too complicated to represent a business model in 9 elements. It's [a business model] more about how I make my money" (q10).

## 5. CONCLUSION

Recapitulating, the interviews have shown a number of different things. The executives of very small companies have mixed opinions concerning the use of the business model concept, particularly in applying it to their firm. Though not completely reluctant to the use of the business model concept they feel that the business model of their company is already sufficiently clear. It also seems that the larger the companies of the interviewees were the more favourable they tended to be regarding the use of the business model concept - with the exception of the executive from the transport industry. The consultants all seemed quite comfortable with the idea of applying the business model concept to a number of different problem domains. The main strengths of the business model concept that came out of the interviews were threefold:

- a) The ability to create a transparent big picture of a business and to externalize the relationships and dependencies of the business elements.
- b) Its use is comparable to the use of a commonly understood language to enable communication.
- c) It can stimulate approaching and understanding the fundamental questions of a business.

Of course the above mentioned strengths are simply impressions of the interviewed business practitioners. Yet, they give a good impression of how business practitioners feel of the use of the business model concept in different applications. However, further research would include applying different business

model approaches to different concrete cases and application domains in order to assess their performance in the field.

## ABSTRACT

In many Northern European countries, the sale of convenience goods through the Internet is experiencing a slow but undeniable growth. The emergence of this new distribution channel has brought into existence an extremely productive research area on the key factors which food e-tailers need to master for a lasting success in this field. The central nature of a perfect logistical organization is particularly emphasized in the areas of cost and service quality, both in terms of order fulfillment and order delivery. There is no question of minimizing the importance of logistics in the success of online transactions, as e-consumers obviously expect to be delivered at home in good conditions. But can we affirm that logistical performance systematically plays a crucial role for food e-tailers in obtaining a sustainable competitive advantage? By critically examining the relevant literature, this paper attempts to prove that the answer may be negative. The authors refer to three paradoxes relating to e-grocery logistics: one, the pressure of national and local Authorities leads to the sharing of resources to reduce environmental pollution (first paradox); two, the recognition of an e-marketing mix dissolves logistical performance in a set of non-logistical variables whose weight is probably significant in e-consumers' behavior (second and third paradoxes).

**Keywords:** consumer expectations, e-grocery, e-marketing mix, Internet shopping, logistics, order delivery, order fulfillment, package deal of services

## 1. INTRODUCTION

The sale of convenience goods by the Internet, known under the generic term of e-grocery, is experiencing an appreciable development in many European countries, even if the online channel still remains marginal compared to the traditional in-store channel. The act of physical shopping is still often “*a socially valuable and personally relaxing experience*” [12, p.231], but a new generation of highly educated and professionally hyper-active young consumers find an increasing interest in online transactions for convenience goods which do not create any “retail therapy” buzz of in-store shopping. Numerous works now focus on e-grocery, systematically emphasizing the importance of logistics –the order fulfillment and order delivery processes– as key factors of success for e-grocers [8]. Of course, delivering the right product at the right time at an acceptable cost is an important stake. However, it should not be assumed that logistical performance alone will always exert a lasting power of attraction on e-consumers leading them to remain loyal to a website. In other words, are we really sure that the logistical performance associated with a website creates a source of competitive advantage?

This paper wishes to underline three paradoxes tending to put in perspective the importance e-grocers should give to logistics in their business plans. As a reminder, the word paradox comes from the ancient Greek *paradoxos*, meaning “contrary to the general opinion.” Following early academic research on e-grocery

logistics, a consensus –a kind of general opinion– seems to arise on several points. We wish to adopt a critical attitude toward this consensus. Each of the paradoxes offers food for thought from elements drawn from literature, and ends with a research question making up one of the components of a research agenda to develop on e-grocery logistics. The objective is not to provide final answers on its future, but rather to state how it is possible to moderate the influence of logistical performance on the food e-tailing industry's efficiency. To do so, the paper is divided into three parts successively summing up the three identified paradoxes, i.e. that the general opinion on logistics as a key factor of success for e-grocers is questioned:

- (1) By the forced sharing of logistical resources, under the pressure of local Authorities wishing to avoid the anarchic development of private “last mile” organizations;
- (2) By the existence of a package deal of services underlining the major importance of other elements in the offer of e-grocers (privacy, sales promotion, security, etc.); and
- (3) By a level of e-consumers' expectations in terms of service quality not necessarily requiring “order fulfillment and order delivery excellence” on the part of e-grocers.

The research program whose basis is suggested here starts with the idea that several research subjects on

e-grocery logistics developed since the end of the 1990s, each leading to independent interesting and operational results. Among other things, it seems undeniable that decision-makers can now rely on computer simulations including a set of parameters to create efficient home delivery systems. Similarly, in matters of urban development, studies were started in France, in Germany and in the UK, among others, to measure the environmental impact that a rapid growth of food e-retailing could have [3] [6], and to consider a better planning of flows through the intervention of local Authorities (coordinated implementation of warehousing and transport infrastructures). If isolated information is therefore available on trends in e-grocery logistics, a comprehensive approach based on the integration of the various elements produced by a pluridisciplinary research program is still to appear. The present paper is a first step in this direction.

## 2. THE FIRST PARADOX—A FORCED SHARING OF THE LOGISTICAL ADVANTAGE

E-grocery (or food e-tailing) obviously questions traditional logistics, at least the final stage of (physical) contact between customers and the product assortment: it forces firms to solve the thorny problem of conveying products to e-consumers' homes —or places of work— in satisfactory conditions of cost and quality of service. Works on e-grocery logistics in the last five years have made it possible to identify the different available alternatives at order fulfillment and order delivery level [6] [10] [26]. Concerning order fulfillment, e-grocers choose warehouse picking, in-store picking or hybrid

in-store/warehouse picking. As for order delivery, attended delivery, unattended delivery and consumer pickup in third party locations all occur. No model seems to emerge durably for the time being in European countries [8]. Each food e-tailer operates with its own organization. But it is important to note that most firms offer attended deliveries based on warehouse picking, which enables e-consumers to choose a time window to receive their products ordered online (see Table I).

All observers of the e-tailing industry consider the organization of home delivery of groceries complex and expensive, whatever the order fulfillment model chosen: to contact customers, it is necessary to organize delivery rounds to service residential areas that are often uneasy to access, in limited time windows (evening, beginning of week-end). Of course, several alternatives to conveying goods to e-consumers' homes or places of work are conceivable, for example the implementation of collection and delivery points (CDP) or the use of convenience stores where e-consumers would recover the ordered products. Browne [1] gives several concrete illustrations for small packages: service stations, leisure centers (like swimming-pools or tennis clubs), railway or bus stations, etc. But is it likely that e-consumers would systematically accept using CDP or convenience stores when using e-grocery shopping is precisely a way of getting rid of such time-consuming logistical tasks? In fact, the generalization of home delivery remains the most likely scenario for the evolution of e-grocery logistics [9]. Hence the attention given to order fulfillment decisions in the academic literature (for a summary, see [26]).

**Table I**  
*Alternative e-grocery logistics models for a few firms*  
(adapted from Hays et al. [10])

	Warehouse picking	In-store picking	Attended delivery	Unattended delivery	In-store pickup
<i>Alberstons</i>					
<i>Cold Storage</i>					
<i>Fairprice</i>					
<i>Grocery Gateway</i>					
<i>Homegrocer</i>					
<i>NetGrocer</i>					
<i>Peapod</i>					
<i>Safeway/GroceryWorks</i>					
<i>Sainsbury's</i>					
<i>Streamline</i>					
<i>Tesco</i>					

The main limitation of works on e-fulfillment decisions is that they stay within a very technical view of the problem, practically in a perspective of operational research. An example would be the work of Wittgreffe & Memmory [29] who review the information

technologies best adapted to optimize the store range in the in-store picking model, or also de Koster's [17] paper on distribution structures for food home shopping. To suggest the best solution to food e-tailers (warehouse picking vs. in-store picking), de Koster [17] introduces

the notion of operational complexity, measured through the number of weekly orders, the product assortment width and the product assortment type (presence or absence of frozen and fresh products, in addition to non-perishable products). Although these studies present an obvious interest at micro-economic level, they ignore –as many others do– the macro-economic implications of decisions made by the different firms. But it is impossible to ignore a global vision of the e-grocery logistics stakes. Without such vision, there is a high risk of development of overcapacities in logistical equipment, each e-grocer investing in its own distribution network. The overcapacities will have a social cost which will quickly become unbearable in the eyes of e-consumers who are also citizens. For example it would lead to congestion of residential areas with an anarchical multiplication of delivery trucks, leading to environmental (CO<sub>2</sub> emissions, recurrent traffic jams) and economic problems (inability to meet time windows).

At the moment, food e-tailing represents only a low percentage of consumer sales in Europe. For example, in France, the turnover of the four major e-grocers equals the average turnover of a single large hypermarket! But national and local Authorities prefer reflecting on the potential impacts of a rapid and uncontrolled development of sales of groceries by Internet. There seems to be a desire to control product flows in towns and cities by obliging firms to use shared logistical infrastructures, at warehousing and transport level: *“Urban land use planning policy can control the number and location of home delivery fulfillment facilities... and the times at which home delivery vehicles can operate at them. Planners can also decide whether there is a role for the urban authority in the development and operation of such facilities, and whether they will be operated by one or many companies”* [2, p.34]. This planning, imposed for environmental and ecological reasons, could therefore unify the level of logistical performance, since all firms would have to use the same integrated freight centers at the same time in the same urban area [11]. If the Authorities’ interventionism in e-fulfillment is confirmed, with food e-tailers unable to co-ordinate and avoid the multiplication of private “last mile” organizations, it will be obviously difficult for a given food e-tailer to use his potential logistical excellence to distance his competitors. This is the first paradox of e-grocery logistics: it is presented as a source of competitive advantage for a firm, but the sharing of resources is going to spread this competitive advantage to all firms.

**Research question No. 1:** Taking into account the increasing involvement of local Authorities in the organization of urban logistics, what elements in the logistical organization will enable food e-tailers to create a difference and develop a competitive advantage?

### 3. THE SECOND PARADOX–THE REAL IMPORTANCE OF LOGISTICS IN THE E-MARKETING MIX

As Ricker & Kalakota [27] stated, e-consumers do not buy a product, but a product plus the “service envelope” accompanying it. Logistics is obviously one of those services, but not the only one. Logistics is but one component of a package deal, the quality and the coherence of which are crucial elements that will condition the positive or negative view of a website by e-consumers. Through the package deal of services, e-consumers try to find a turnkey solution to their problems, for example limited opportunities for in-store shopping because of a busy work schedule or occasional or lasting health problems making it difficult to regularly handle heavy or bulky products [21]. Here again we find the bases of a strategic service vision developed more than twenty years ago in academic literature [19], which retains all its relevance in a computer-mediated environment.

To state that logistics is one element of a package deal of services does not seem very original, at least when referring to works conducted on services marketing. They note that consumers acquire not a product or a service, but a more or less complex “goods-service:” any service relies on material elements which make service construction and delivery possible, any product is finally assessed in function of the service rendered. This is why it seems pertinent to reason from the generic concept of services associated with products: *“Services associated with products are services supplied in complement of a product so as to optimize their use and increase their value for customers... Expected by customers, they induce the demand for products and are the source of differentiation in firms’ offers”* [9, p.99]. The approach was applied to the French case by Paché & Bonet [23], among others, to find out whether food e-tailers try to develop the various elements of the package deal of services harmoniously or are on the contrary focusing on some of the elements (if so, why).

The interest of Furrer’s [9] analysis lies in clearly dividing the services associated with products into two categories. The first category is made of *value-added services*, relatively independent from the products they accompany and representing a sort of bonus (for example, the possibility for consumers to use a call center 24 hours a day seven days of the week). The second category is made of *services acting as barriers to entry*, an integral part of the basic offer and which must absolutely be offered under penalty of losing customers (for example, free parking space offered by large retailers). This approach is completely applicable to online purchases on the Internet. In addition to a simple product as tangible goods, e-consumers will surely investigate the overall quality of the complex service offered to them, associating after-sales support and warranties. According to Kotzab & Madlberger [18],

the package deal of services refers to three complementary dimensions –or functions– that firms should attempt to develop equally:

- A product assortment function;
- A logistical function; and
- An advice, communication and financing function.

There is no doubt that logistical performance is one of the services associated with products, but e-grocers must not neglect other at least as critical components, such as payment terms and conditions, the number of product lines offered or online advice. In a way, this echoes the notion of the e-marketing mix proposed by Kalyanam & McIntyre [14], summed up by the acronym  $4Ps + P^2C^2S^3$ , where 4Ps stands for the traditional marketing mix,  $P^2$  stands for personalization and privacy,  $C^2$  stands for customer service and community, and  $S^3$  stands for site, security and sales promotion. Although Kotzab & Madlberger [18] do not use the notion of e-marketing mix, this is what they analyze. It is evident from this that a strict process of marketing audit, should make it possible to put in perspective the importance of services that the trade press often presents as being value-added (security, customer service, etc.), when they perhaps only serve as barriers to entry. It should be noted that some current academic studies ask a rather similar question: to what extent does an efficient logistical service contribute to the loyalty of e-consumers to e-grocers? For the time being, no clear answer has been given. A qualitative study conducted with the key informants of ten retailers in a major metropolitan area located in the USA shows for instance that they do not really know much about e-consumers'

needs and wants in terms of Internet shopping [5].

In the end, food e-tailers need to imagine a balanced e-marketing mix –whose variables reinforce themselves mutually– rather than attach themselves to the sole best logistical service possible. It is quite clear that e-consumers look for the performance of the online shopping transaction itself [25], a performance that will come from a set of closely interactive elements. The food e-tailers' objective will be to offer the highest delivered value, i.e. the most important differential between the total benefits to consumers, some examples of which are presented in Table II, and the total costs of the e-marketing offer [21]. For example, the promotional promise of a home delivery within a narrow time window to avoid long waiting times at home will require an order fulfillment and an order delivery capable of fulfilling this promise. If this is not possible, it would be better to modify the content of the promotional promise: a well-known rule of logistics management, sometimes forgotten in the computer-mediated environment. This is the second paradox of e-grocery logistics: it is most often considered as the food e-tailers' main key factor of success, whereas it is only one of the sometimes secondary components of their package deal of services.

**Research question No. 2:** What weight should food e-tailers give to logistical performance in their e-marketing mix, and with what other strategic variables is the place variable in direct interaction vs. indirect interaction?

**Table II**

*Some potential benefits to consumers offer by the e-tailers  
(adapted from Jones et al. [12])*

- Convenience of comparison shopping from, and delivery to, the customer's home
- Creation of a pleasurable e-shopping experience
- Good quality and topical information on products and services
- Availability of products or services that may not be available from local traditional stores
- Potentially range of high quality products and services at competitive prices
- Speedy and reliable home delivery systems
- Online support for after-sales service
- Guarantees about the security of online transactions and the privacy of personal information

#### **4. THE THIRD PARADOX–E-CONSUMERS' LEVEL OF EXPECTATIONS IN LOGISTICAL PERFORMANCE**

An attentive reading of recent works on e-grocery shows that in fact the real influence of logistical performance in the process of e-consumers' decision-making, particularly regarding timely delivery, could be revised downward, or at least be considered as one key factor of success among others: the functionality of computer interfaces or the absolute security of payments, for example [7][22]. Cases's [3]

research on the perceived risk associated with purchases on the Internet places delivery risks far behind private risks (potential violation of e-consumers' privacy) of performance risks (products and/or services not corresponding to e-consumers' expectations). Of course, at first, when the market is gradually structuring itself, good logistics appears to be a source of competitive advantage. Will that still be the case with the rapid alignment of each website to the same cost/service standard? The difference between e-grocers will then develop on their capacity to establish, and then to maintain an individual, long-term and customized

relationship with consumers, while the traditional bricks-and-mortar model lies on a rather intermittent, distant and impersonal relationship [18].

The first field investigations conducted on e-consumers' practices underline the central nature of convenience relations that occur between for example a delivery man and an e-consumer when orders are regular. Kessous [14] lists numerous, often amusing cases of complicity building up between both agents, as in the case of a delivery man who knows that Mr. Smith, whose habits he is perfectly aware of, must receive delivery at 9 am just after his morning walk with his dog! We are here faced with the construction of a real joint service and delivery, the efficiency of which directly determines the level of satisfaction perceived by the customer. Beyond simply adhering to delivery times, the ability to customize service becomes a key factor of differentiation for e-grocers. More generally, e-consumers consider that it is normal to be delivered on time without error in order picking. But they will expect increasingly sophisticated and customized services associated with products, such as technical information, as the preliminary results of the Swedish program *Households in Cyberspace* show [26].

The central question is to know what is the level of service quality perceived as necessary and sufficient by e-consumers (in their online shopping transaction), when numerous European food e-tailers essentially try to offer better order fulfillment and order delivery than those of their major competitors. It is highly likely that e-consumers represent a heterogeneous population in their expectations about logistical performance. For some of them, the strict adherence to the time window stated on the website is capital, for others, with more available time at home during the day, the lowest possible delivery charges will make the difference. Systematically proposing high service quality standards may well be unnecessarily expensive for food e-tailers, since some e-consumers will be impervious to them. It would be better to study the expected levels of service quality per market segment beforehand, offer a highly differentiated logistical performance (in terms of delivery charges, in extended time windows, etc.), and above all to comply with what was promised. This approach puts customer concern at the heart of the analysis, focusing on operational issues that are currently largely underestimated [13]. In fact, some of the components of logistical performance may not be deemed essential by some e-consumers, and food e-tailers would make a serious management mistake if they went on considering them as a key factor of success.

This last point seems all the more important for the future of e-grocery logistics since works conducted in the USA by Morganosky & Cude [21] [22], from a longitudinal study on e-consumer behavior, show that e-consumers are above all loyal to a website, to which

they gradually dedicate an increasing part of their online shopping, playing on a phenomenon of experience. As has been said, it is the overall online transaction that provides a value of variable importance, not just the quality of the order fulfillment and order delivery processes. E-consumers gradually "learn," get to know the website's logistical performance and increase or reduce their level of expectations accordingly. Thus, when e-consumers have the possibility to control the shipping function, for example by freely choosing a particular carrier on the website, they link it to a level of logistical performance related to its image, particularly in terms of service customization via the delivery man, and adapt their delivery-related expectations accordingly [7]. In brief, an e-consumer loyal to a website for extra-logistical reasons could very well make do with a very indifferent level of service quality, compared to other websites. This is the third paradox of e-grocery logistics: the total efficiency of the order fulfillment and order delivery processes does not necessarily have a significant impact on the satisfaction felt by e-consumers.

**Research question No. 3:** How does the level of expectations of market segments develop in terms of logistical performance, and to what extent does a high (low) level of logistical performance influence loyalty (disloyalty) to a website?

## 5. CONCLUSION

In the last few years, works on e-grocery logistics have multiplied, particularly in Northern European countries, widely involved in online Internet sales. Reflections are already quite advanced on possible alternatives in order fulfillment and order delivery; they have led to extended simulations to define the best solution according to variables such as population density in the residential area to serve, the frequency and size of orders in households, or the last mile management cost [15] [26]. Without minimizing the interest of this approach, it should be admitted that it relies on an implicit but debatable postulate: e-consumers' high awareness of logistical performance and, by extension, the crucial nature of "logistical excellence" for e-grocers wishing to get ahead of their competitors in the long-term. The present paper questions this postulate, referring to the three paradoxes of e-grocery logistics.

The suggested research program still has to be developed in two directions. One belongs to the BtoB type: it studies the impact of the legal environment on logistical strategies. The second direction belongs to the BtoC type studying the place of e-grocers' logistical performance in e-consumer behavior, compared to the place held by other variables in the e-marketing mix. This will become a reality only if it is possible to eliminate a number of disciplinary compartments, as the research agenda involves resorting to marketing tools, logistics management tools, political science and strategic management tools. Hence the importance of

building managerial teams with complementary competencies, the only way to go beyond the technical approach to e-grocery logistics still dominant in today's literature, and far too simplistic for understanding the true challenges being faced.

### ABSTRACT

On the basis of analyzing the relationship between the equipment system and spare parts inventory, this paper proposes two-level equipment and spare parts system management based on the Theory of Constraints. From the system point of view and according to the Theory of Constraints, the manufacturing organization identifies bottleneck equipments in equipment system and makes the bottleneck equipments operate continuously and effectively on the basis of two important aspects of materials supply and spare parts supply. Finally, the spare parts' ABCD-TOC inventory classification and control method based on the Theory of Constraints is introduced. This method classifies spare parts according to different demands of bottleneck and non-bottleneck equipments, technical rules of spare parts failure and waste and purchase characteristics. Then the suitable control strategies for each class are adopted to focus on bottleneck equipments without sacrificing the spare parts supply for non-bottleneck equipments, as well as to reduce inventory investment.

**Key words:** Theory of constraints, Equipment management, Spare parts management, Inventory

### 1. INTRODCUTION

During the past two decades, as a result of serious global competition, the modern company depends on the high-effective equipments increasingly to strengthen its competitive capacity. And along with the development and progress of science and technology, equipments tend to the large-scale, high precision and complexity and their automation degree has enhanced. The maintenance expenses and fault loss of equipments account for an increasing fraction of the production costs. It has a great effect on the competitive ability that companies keep and improve equipment utilization. But equipment utilization is decided not only by its reliability and maintainability but also by spare parts supply which is the essential physical foundation<sup>[1]</sup>. The spare parts management also is an important part in management activities of company equipment.

Spare parts inventories differ from other manufacturing inventories in several ways. First, the functions are different. Raw material inventories exist to offer the required raw materials for production. Work-in-process (WIP) inventories exist in order to smooth out irregularities in production flow. Finished product inventories exist to provide a source of products for delivery to customers and are designed to protect against irregularities in differences in quality levels, scheduling problems, and other well-known production characteristics. The function of spare parts inventories, however, is to assist a maintenance staff in keeping equipment in operating condition and promoting continuous production process. Second, WIP and final product inventories can be increased or decreased by changing production rates and schedules, improving

quality, etc. Spare parts inventory levels, however, are largely a function of how equipment is used and how it is maintained. Therefore the spare parts inventory and the status of equipments promote mutually<sup>[2]</sup>.

For avoiding excessively long equipment downtime due to lack of spare parts required and corresponding loss of time, output and profit, companies always prepare adequate spare parts to promptly supply. However, inventory is expensive especially when spare parts are stocked too much and the total investment in spare parts is very large. Therefore there is the conflict of spare parts inventories, equipment operation and investments for the goals of enhancing competitive ability and realizing high profitability (see Fig.1). Managing and controlling effectively equipment and spare parts system may be of vital significance to balance these goals of maintaining high equipment availability, minimizing inventory investment and attaining high profitability.

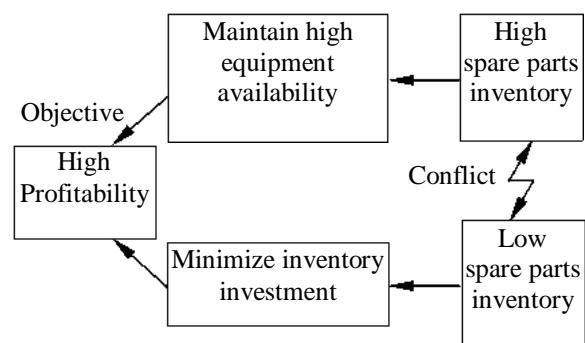

Fig. 1. Relationship between spare parts inventory and equipment system

The Theory of Constraints (TOC) on a basis of

Optimized Production Technology (OPT) was expounded by Israeli physicist Eliyahu M. Goldratt (1986), which was developed from initial manufacturing management principle to "Thinking Process" of solving problems logically and systematically. The theory was applied to many fields beyond production management [3].

The organization of this paper is as follows. The basic concept of TOC is sketched in Section 2. Next, Section 3 proposes two-level equipment and spare parts system management based on the Theory of Constraints. On a basis of analyzing two important supporting resources for equipment operation, the spare parts' ABCD-TOC inventory classification and control method is introduced. A summary and concluding remark is given in the final section.

## 2. BASIC PRINCIPLE OF TOC

The Theory of Constraints considers the production and operations of manufacturing organizations from the entire system point of view. Goldratt argues that the goal of a company is to make money and develops a different set of measurements which express the goal: throughput, inventory and operational expense. They are defined as follows. Throughput is the rate at which the system generates money through sales. Inventory is all the money that the system has invested in purchasing things which it intends to sell. Operational expense is all the money the system spends in order to turn inventory into throughput [4].

In any system, if any link output is decided by the outputs of one or several stages before it, the link with the least output determines the output level of the whole system, that is, the strength of a chain is determined by the weakest link. The link is called a constraint and also a bottleneck. TOC is the management idea and principle that help companies to identify, exploit and eliminate constraints and then to maximize throughput and reduce inventory and operational expense. Companies can apply the Theory of Constraints through five-step focusing process as follows [4]: (1) Identify the system's constraint(s); (2) Decide how to exploit the system's constraint(s); (3) Subordinate everything else to the above decision; (4) Elevate the system's constraint(s); (5) If in the previous steps a constraint has been broken, go back to step 1, but do not allow inertia to cause a system's constraint.

The process of implementing these five steps is also three steps thinking process: "what to change?", "what to change to?" and "how to cause the change?". Then, companies can achieve their goal by focusing on the key point-the constraint and can promote continuous improvement because the constraint is not static but dynamic and changing.

## 3. TWO-LEVEL EQUIPMENT AND SPARE PARTS SYSTEM MANAGEMENT BASED ON TOC

### 3.1 General Framework

Market competition is more and more fierce and customers' demands for diversified products tend to enhance, which cause shorter product life cycle and decrease product quantities of each order [5]. For abstaining from risks, companies do not purchase or update expensive production resources easily and exploit the utilization of existing equipments as far as possible. So the overall productivity appears insufficient in the growing and mature period of product life cycle. According to TOC, we regard several or a set of equipments producing one kind of product or a series of products as an equipment system. In this system if any segment (the equipment or equipment group) hinders the overall system to increase throughput or decrease inventory and operational expense, the segment is a constraint, that is, the bottleneck equipment. The bottleneck equipment whose capacities are not sufficient restricts the system throughput and decides the degree of other non-bottleneck resources utilization. As the physical base of equipment system, the main task of spare parts inventory is to assure all equipments in good condition. A spare part, especially for bottleneck equipments, is called the bottleneck spare part so long as it affects the system throughput, which is the important point of the spare parts management. The structure of two-level TOC-based equipment and spare parts system management is depicted in Fig. 2.

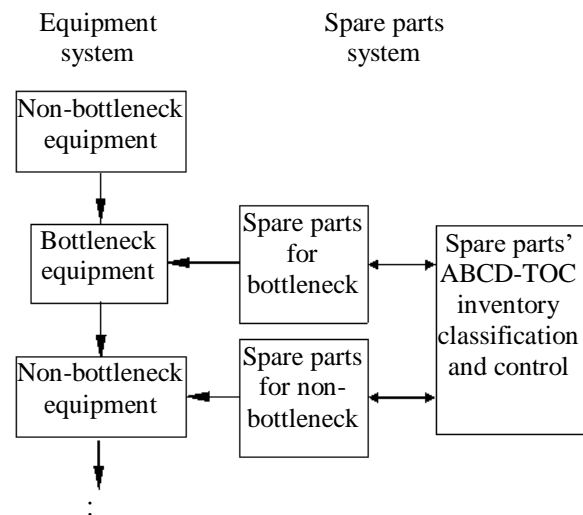

Fig. 2. Two-level equipment and spare parts system management based on TOC

### 3.2 TOC-based equipment system management

The fundamental task of TOC-based equipment system management is to identify the bottleneck of the entire system and manage the bottleneck and resources before

and after it to maximize system throughput. The bottleneck equipment of the equipment system is the equipment or equipment group whose actual capacities are smaller than or equal to production loads (demands), that is, the system's constraint is the equipment experiencing the highest load rate. The equipment load rate is defined as its duty to its available capacity during the plan period, which is given by equation (1).

$$L_t = \frac{\sum Q_t S}{TA_t} \times 100\% \quad (1)$$

Where  $L_t$  is the equipment load rate over the plan period  $t$ .  $Q_t$  represents quantities of each product that the equipment should produce during  $t$ .  $S$  is defined as the planned time standard of each produce.  $T$  indicates the institutional time of the equipment during  $t$ .  $A_t$  is the probability of equipment availability which comprehensively reflects reliability and maintainability.

After the bottleneck equipment is identified, how to make full use of the equipment is the first problem that needs to be solved. Considering the direct resources required to produce products, we may establish the material buffer to make equipment run continuously. The buffer is often classified into inventory buffer and time buffer. Inventory buffer is a kind of insurance Work-in-processes. Time buffer is required materials handed over advancing a period of time from the planned time to eliminate influences of stochastic fluctuation in production processing, which is measured by processing time length of bottleneck. On the other hand, from the technical resources supporting equipment system viewpoint, we should increase the overall equipment effectiveness (OEE) and reduce unscheduled downtime especially caused by equipment failure as far as possible, which depends on maintenance resources such as maintenance men, maintenance tools and supply of spare parts. However, compared with the service men and tools, spare parts investment is higher and lack of spare parts is the most main influence factor frequently. Thus, this paper introduces TOC-based spare parts inventory management to keep equipment, especially bottleneck equipments, run well and maintenance efficiency as well as reduce costs.

### 3.3 TOC-based spare parts inventory management

Generally companies have large quantities of and many types or specifications of spare parts inventories. To manage inventories through Stocktaking, placing and accepting orders endlessly would be time-consuming. Then companies manage spare parts inventories through classification.

Dickie proposed ABC classification method <sup>[6]</sup> in 1951. The purpose of this method is to measure and classify the degree of importance and concentration of inventory

items in terms of the value of items and Pareto principle. The method is simple and wieldy and so is adopted by many companies for a long time. However, the value of spare parts has no inevitable relations with their influences on the equipments and production.

In accordance with the special characteristics of spare parts inventory, 3A inventory control method <sup>[7]</sup> classifies spare parts into 27 different kinds of rank from AAA to CCC according to the important degree of spare parts to equipments. Considering actual operations conditions of equipments, the method decides essentiality and specific rank and order of each spare part according to three aspects: equipment and its components belonging to, production load enduring and its effect on product quality. Then the method adopts the corresponding control method. Guo Zhimin et al. <sup>[7]</sup> offer ABCD inventory control method in terms of several criterions such as influence of spare parts on productive condition, the rules of fault and wasting, and agility of supply channels. Dekker et al. <sup>[8]</sup> classify demand for spare parts into critical and non-critical demands according to the influence caused by the disabled equipment that a spare part is installed. In this paper we analyze classification and control methods of spare parts from the system point of view, not only from single equipment viewpoint, and according to the Theory of Constraints that to our knowledge have not been discussed in the literature so far. The method is called spare parts' ABCD-TOC inventory classification and control method which classified spare parts into four classes.

A class includes special spare parts that are installed to the bottleneck equipments and can not be checked in advance or their failure and wear time can not be forecast, and that are installed to the non-bottleneck equipments and supplied by few providers and/or with long purchase lead time (such as purchased from abroad). Because an hour lost at the disabled bottleneck equipment is an hour out of the entire system and part of these spare parts are only used by the bottleneck equipment, this type is very important. Compared to the bottleneck equipment, non-bottleneck equipment always has idle time. But if purchasing time exceeds idle time, non-bottleneck equipment will affect production system throughput. Thus, this class may be called the bottleneck spare parts and is controlled by an  $(S-I, S)$  policy, or equivalently, by a base stock policy <sup>[2]</sup>. The base stock  $S$  is defined as maximal possible consumption during an order lead time. Concretely, it can be calculated through adding historical average consumption over an order lead time to a suitable safety quantity. The safety quantity is achieved by multiplying fluctuation average of historical consumption by certain safe factor as a kind of buffer which is considered comprehensively according to production task, usage years of equipments, etc. Stock level will be inspected and checked after spare parts are used or continuously. When the actual valid inventory level is lower than  $S$ ,

one purchase order should be placed with the order quantities which is decided by subtracting the current stock level from  $S$ .

B class includes spare parts with predictable replacement time used by bottleneck and/or non-bottleneck equipments. Companies can forecast the time when need to replace this type spare parts through checking in advance, tracking and analyzing their conditions in time. Or they track daily usage of these spare parts in a long time and statistically analyze the rule of their fault and waste to estimate their replacement time cycle. When companies have predicted the replacement need during equipment operating period, they should estimate the earliest time and advance several days according to specific situations of the time and then order ahead of purchase lead time. Thus companies can supply required spare parts timely while reduce occupied time and fund of inventory.

C class is the special spare parts with many supply channels and/or short purchase lead time which can be sucked by idle time of equipments. For avoiding depletion in stock and reducing investment, this type can be controlled by zero inventory policy, that is, these spare parts are not stocked. When production department demands the spare parts, it applies for the purchase immediately. Then purchase department orders immediately from suppliers. After spare parts arrive, purchase department checks and accepts and warehouse registers. The spare parts are sent to the production center directly.

All general spare parts fall into D type. The general spare parts are installed at some even all equipments, so their reflections of production and maintenance change are not obvious. When a general spare part is requested by bottleneck and non-bottleneck equipments synchronously, it must meet bottleneck first that helps to assure and increase system throughput. This type has many kinds of spare parts whose usages and investments are large. The class can be controlled by periodic review  $(t, s, S)$  inventory policy<sup>[9]</sup> where  $t$  presents fixed review period,  $s$  reorder point,  $S$  maximum stock level. We estimate  $s$  by computing consumption of each spare part during purchase lead time after examining its daily average usage over a long period of time, and take  $S$  as three or four times of  $s$ . Suitable  $t$  can be set according to the spare part with the fastest consumption rate in this type as long as all spare parts of the type are not short during the period  $t$ . Inventory levels of these spare parts are checked and compared to  $s$  every other  $t$ . If inventory level is lower than  $s$ , the spare part would be ordered and order quantity is the balance of  $S$  and current level. If the level is larger than  $s$ , there is no any order. This type of periodic review reduces massive work as a result of continuous review and keeps proper inventory level without short of spare parts and with lower investment.

It is worth explaining that the classification of A, B, C and D classes is not always changeless but dynamically adjusted and transformed one another. For example, after some measures for improving equipments capacity are taken constantly, some bottleneck equipments change to non-bottlenecks and then some spare parts of A class are transformed into C class. When more advanced statistical analysis technology make the fault and waste rule of equipment and spare parts learned, some A class spare parts may be classified into B class.

#### 4. CONCLUSION

This paper analyzes the relationship between the equipment system and spare parts inventory and proposes two-level equipment and spare parts system management based on the Theory of Constraints. From the system point of view and according to the Theory of Constraints, the company identifies bottleneck equipments in equipment system and makes the bottleneck equipments operate continuously and effectively. Companies can take measures such as buffers to supply enough materials. However, the same important thing that companies should do is to supply enough spare parts timely. So the spare parts' ABCD-TOC inventory classification and control method based on the Theory of Constraints is introduced. This method classifies the spare parts according to different demands of bottleneck and non-bottleneck equipments, technical rules of spare parts failure and wasting and purchase characteristics. Then the suitable control strategies for each class are adopted to focus on getting bottleneck equipment operate without sacrificing the spare parts supply for non-bottleneck equipments, as well as to reduce the occupied fund of inventory. This paper explores the management of equipment system and spare parts inventory from the entire system viewpoint and it provides the theory and application values for modern companies.

## Semantic Innovation Management

Jianqiang Li, David O'Sullivan

Digital Enterprise Research Institute, National University of Ireland, Galway, Ireland  
{Jianqiang.Li, David.osullivan}@deri.org

### ABSTRACT

Innovation within industrial environment can be viewed as a cyclic loop consisting of four distinct phases, i.e., recognition, initiation, implementation, and stabilization. Different information technology enabled innovation management tools supporting the lifecycle of innovation are classified as five layers, i.e., individual innovation, project innovation, collaborative innovation, distributed innovation, and semantic innovation. According the fact that the current state is evolving from distributed innovation to semantic innovation, this paper focus on the realization of Semantic Web technologies enabled semantic innovation. To explicitly and formally specify all the different perspectives of innovation related information, a shared ontology is proposed as the common language of innovation management, which describes the critical and minimal information about the innovation process in a holistic way. Then, a technical framework which employs the machine readable innovation ontology to actually improve innovation management inside an organization and among loosely coupled organizations is presented. Finally, some features of the semantic innovation are discussed.

**Keywords:** Innovation management, Semantic Web, Innovation ontology, Goals collaboration

### 1. INTRODUCTION

Innovation [1] is “the process of making changes in something established by introducing something new”, which can be viewed as a cyclic loop consisting of four distinct phases, i.e., recognition, initiation, implementation, and stabilization. Within a typical organisation, there are various degrees of innovation from simply suggesting ideas or managing a single project to managing an entire programme of change comprising various performance indicators and portfolios of projects. To support the lifecycle of innovation, different innovation management tools or tool families have been developed. Conceptually, they can be classified as five layers, i.e., individual innovation, project innovation, collaborative innovation, distributed innovation, and semantic innovation.

Individual innovation concentrates on the development of effective ways to enhance creative potential for individual work. There are many tools or techniques available (e.g., mind mapping, brainstorming, cause-effect diagrams, Delphi forecasting) to support individuals and small groups engaged in single innovation tasks such as problem solving and idea generation. Project innovation concerns about the systematic techniques that support the change manage of project teams in a distributed asynchronous environment. This area is currently saturated with various software tools that support distributed project management and information sharing between distributed individual or small groups in a project teams. However, very few tools explicitly link project actions (e.g. tasks) with project goals. Collaborative innovation focuses on the change management among a large group of individuals within a whole organisational unit and where there is typically a portfolio of projects (rather

than one single project). In this type of innovation, the organizational unit will also typically have multiple goals such as a strategic plan, group of performance indicators or international standard, and the goals of the organization unit replace project goals. Current research focuses on the development of structured collaboration environments, and the entire system is designed to be used collaboratively by every user of the system to gather information and update their own contributions to their community. Distributed innovation is innovation across a particular intranet within an organizations supply chain and even a specific virtual team. This level of innovation is defined by all of the ‘collaborative’, ‘project’ and ‘individual’ innovations, taking place lower in the innovation hierarchy. The tools required for distributed innovation, which build mostly on portal servers (e.g., Sharepoint, Lotus Notes, and Plumtree), are in their infancy. Principal design features include enterprise wide search and navigation, user personalisation, integration and content management, notifications (push technologies), workflow, and application integration to other information sources. Since current state of the art is manual browsing, a well designed collaboration/management structure is necessary to allow any individual easy access to the information that they are looking for.

The generation of semantic innovation is derived by the emerging semantic web technology. According to Tim Berners-Lee [2], the Semantic Web can be envisioned as an extension of the current web, which makes the web more understandable to computer programs, and then allows data to be shared and reused across application, enterprise, and community boundaries easily. The original intention the proposition of semantic innovation is to exploit the potential of semantic web technology to improve the effectiveness and efficiency of innovation

management in the large networked organization.

## 2. INNOVATION ONTOLOGY

An ontology [3] is a general conceptualization of a specific domain in a both human and machine understandable format. In general, it consists of classes, properties, relationships, and axioms. As the backbone technology for the Semantic Web, ontology promise a share and common understanding of a domain that can be communicated between people and application.

To realize semantic innovation, it is necessary (as the prerequisite) to build a formally and explicitly expressed conceptual framework (i.e. ontology) about innovation related information. It should include all the necessary information for innovation management to facilitate the collaboration and innovation management in a networked organization and provide the conceptual underpinning for making the semantics of innovation related metadata machine interpretable.

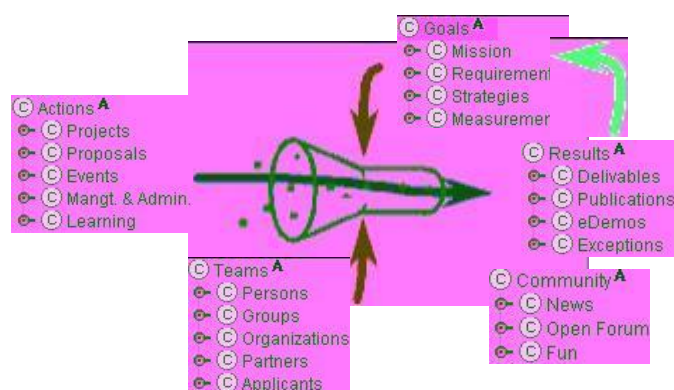

Figure 1. Conceptual Framework for Innovation Management

Considering the fact that different organizations have different concepts and relationships of their work activities and context, but on the other hand they all have a set of innovation related information for their very own, local (private) and shared (public) ontologies are distinguished here. The semantics of an organization's specific working context is captured by its local or private ontology which serves the problem solving purposes (particularly in communication and information exchanges) of this organization. A public or shared ontology are used to articulate the intersectional semantics about a common subject (or domain) which need to be shared and communicated across multiple local contexts. The main role of shared ontology is to support the common subject related interoperation across multiple organizations. Obviously, the ontology we try to build here is a shared ontology and the common subject refers to innovation management.

Since innovation can be visualised as the interaction of various types of information and in particular the organisations Goals, Actions, Teams and Results. The ontology for innovation management derived from the

iTeam methodology [4] includes five correlated concepts or classes as shown in Fig. 1.

In this innovation management oriented ontology, all the information about innovation management is classified as five categories and specified as five abstract classes, i.e., Goals, Actions, Teams, Results, Learning, and Community. Goals are defined as the objectives of a networked organization's effort. It can be embodied as Mission, Requirements, Strategies, and Measurements. Obviously, these four subclass are closely relevant each other. For example, the performance indicators of the Measurements are the quantitative estimation of the Strategies. Actions are defined as expenditure of the effort to achieve the goals, which are materialized as Calls, Proposals, Projects, Events, Learning. To realize the alignment of goals and actions, the concept of Goals should be linked with the concept of Actions. For example, a projects is aligned with which strategies and how to measure the performance of the project. Teams describe the human elements of the organization that interact within the innovation process and permit the effective management of their involvement. It includes five subclasses, i.e., Persons, Groups, Organizations, Partners, and Applicants. All individuals should be linked to the goals of the development process through an inbuilt performance appraisal system. In fact, most parts of the Teams classes are inherited form FOAF and extend FOAF with innovation related information, such is each person or organization has a property representing his/its goal. Results specify the extensive yet concise reporting of outcome for all goals and actions, which are refined as for subclasses, i.e., Publication, eDemos, Deliverables, and Exceptions. The results area deploys effective management techniques such as the 'traffic lights' metaphor and control charts that allow results to float within predefined limits before they attract attention. Community provides team members with different collaboration spaces for their different interest. Currently, it is divided into News, Fun, and Open Forum, which are necessary supporting tools for goals directed collaboration.

Using a same conceptual framework to formally specify different perspectives of innovation related information extracted from different specific organization context, the innovation ontology can serve as the common language to describe the critical and minimal information about the innovation process in a holistic way. It is independent of the specific work context whichever the corresponding organization resides in and can be constructed from scratch or by composing selected parts of existing ontologies in the networked organization.

It is generally accepted that it is impossible to achieve a comprehensive and globally consistent ontology about the world [3]. In fact, it is even difficult to build a generally accepted ontology about a specific domain. The innovation ontology built here is mainly suitable for

semantic innovation of a research institute. But it can easily be adapted to the semantic innovation of other kinds of organization or other levels (e.g., 'collaborative', 'project', and 'individual' innovations) in the innovation hierarchy.

The ontology in which information is given well-defined meaning and accessible to potential semantic web applications will enable computers and people to work cooperatively and efficiently in the innovation process. It also serves as the base for the design and implementation of specific tools or application for semantic innovation management.

### 3. A FRAMEWORK FOR SEMANTIC INNOVATION

Creating such an ontology—a consensual understanding of the key terms used in innovation management is only the first step to realize semantic innovation management. How to employ the machine readable metadata to actually improve innovation management inside an organization and collaboration among loosely coupled organizations is the next step to be considered. A framework for exploiting the potential of semantic web technology to improve the flow of innovation process is proposed as Fig. 2.

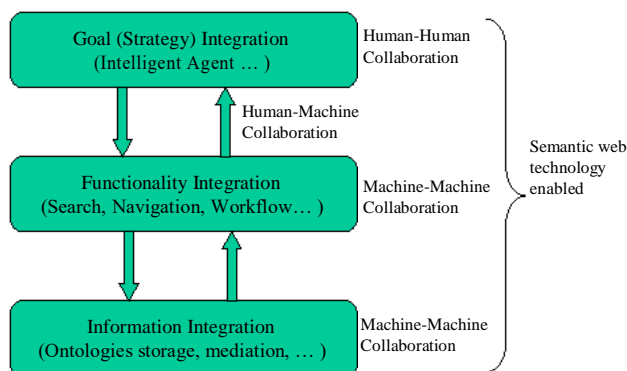

Figure 2. A General Framework for Semantic Innovation

The technical framework for semantic innovation includes three levels, i.e., information, functionality and goal (strategy) integrations. Ontology-based information integration is the foundation of the semantic innovation. Relevant information about innovation management are marked up using innovation ontology, then semantic web based application existing in the level of functionality integration can better understand the semantics and therefore more intelligently locate and integrate data for a wide variety of organizations or projects. Through ontologies storage, mediation, evolution management, it facilitates the smooth flow of relevant information among different involved parts of innovation process. To use the machine accessible information model to realize semantic innovation management needs specific application (e.g., semantic inference, context aware search and navigation, workflow management, and so on) that allow

'machine-machine' interrogation and interpretation of innovation related data. That is what function integration level cares about.

It employed the integrated semantic information to enable the different functionalities and their interoperation required by corresponding innovation process. To encourage the different levels members (individual, project, an organization) to participate in the interactive innovation process, the prerequisite is that there are shared goals or interdependent goals existing in these members. The high level goal integration is the guarantee for the realization of low level information and functionality integration. The goals alignment in distributed innovation is conducted by the human intuitively and manually. However, in the semantic innovation process, intelligent agents specified in terms of the respective goals and obligations are employed as representative of corresponding master (an individual, a project, or an organization) to cooperate with one another to realize goal directed collaboration.

Obviously, goal integration corresponds to human-human collaboration, functionality and information integrations correspond to machine-machine collaboration. The interaction between goal and functionality corresponds to human-machine collaboration. Obviously, the ultimate goal is to improve goal integration by effective and efficient machine-machine collaboration.

#### 3.1 Interface

According to [2, 5], the integration of agent technology and ontologies could significantly affect the use of Web services and the ability to extend programs to perform tasks for users more efficiently and with less human intervention. Agent is naturally selected as the interface for the human-human and human-machine collaboration in semantic innovation process (In fact, software agent is also the generally accepted user interface of Semantic Web). The effectiveness of such software agents will increase exponentially as more machine-readable Web content and automated services (including other agents) become available. In the scenario of semantic innovation, different intelligent software agents work together in anticipating user's information requirements and thus avoid manual browsing for common information gathering tasks. The shared ontology allows for the development of search tools and intelligent agents that can automatically find any information requested by the user and thus avoid inefficient or manual 'surfing'. With semantic innovation any user will have instant access to all of the innovation going on anywhere within the organisation, regardless of language, structure, or location of the information. These semantically rich applications will be capable of real-time event monitoring and handling alerts, ensuring the stakeholder is constantly engaged and provided with priority data.

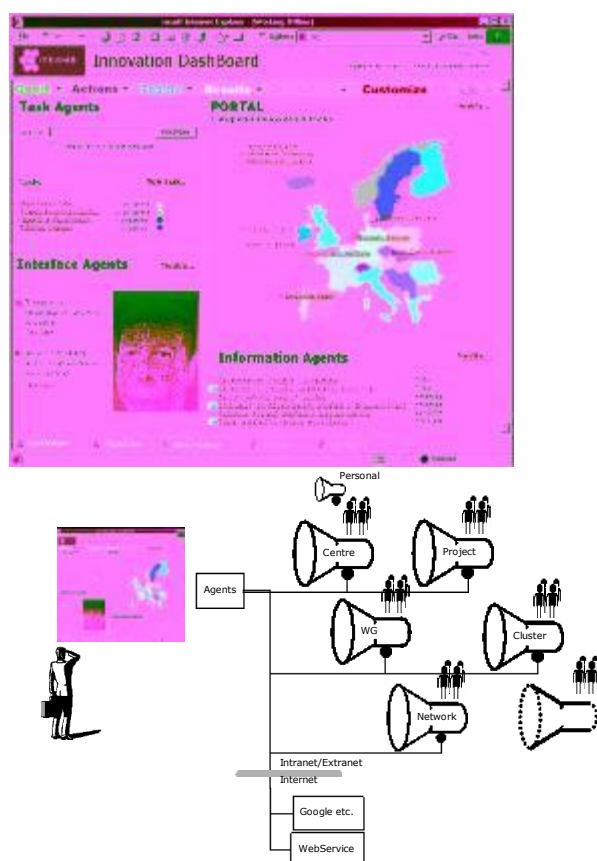

Figure 3. Interface of Semantic Innovation Management

Figure 3 presents a schematic representation of semantic innovation. The user has available to him or her a wide range of innovation funnels –some dealing with product innovation, others based on individual projects and others perhaps for the specific development plans of the corporation. In this vision a number of software agents are deployed across the corporations intranet to communicate with each other regarding the exchange and sharing of innovation information. Interface agents will monitor and track the information needs of the user.

### 3.2 Semantic Inference

The explicit description of innovation related information makes their formal analysis (e.g., goals or goal-action matching among different part of an organization, detecting partially defined and possibly inconsistent goals, actions, or the relationships between them) feasible, which will reduce the human intervention in distributed innovation management. Ontology inference or reasoning, which can improve the efficiency of query and processing of innovation related instance data, will play the role in realizing the alignment analysis among different goals, actions, and results existing in different organizations, projects, and even individuals. Until now, several semantic specification languages, such as RDF [6], DAML+OIL [7], and OWL [8], have been proposed for semantic web. Correspondingly, inference systems for semantic innovation can adopt Description Logic [9], F-Logic

[10], or Horn Logic [11] as its theoretic foundation for the reasoning of innovation related information.

### 3.3 Semantic Mediation

According to the fact that different organization or project contexts can make statements about the same innovation process using different language, semantic mediation which can make use of concepts and relations defined elsewhere and facilitate the interaction between shared ontologies and different local ontologies is another technical pillar for semantic innovation. Semantic mediation [12] includes ontology consolidation, ontology mapping and alignment. Through ontology consolidation, different parts of a local or several local ontologies are merged as a new shared ontology supporting a specific domain or topic (e.g., innovation management) oriented collaboration. Ontology mapping and alignment allow different terminologies and modelling styles are linked together by creating bridges between separated pieces of knowledge in some domain specific ontologies. These consolidated ontology and the bridges along with domain specific ontologies are then used to perform cross contexts innovation related information search and retrieval (with the ability to query different information sources with different kinds of semantics).

## 4. SEMANTIC FEATURES

The semantic web is about adding machine-processable semantics to data. The computer can “understand” the information and therefore process it on behalf of the human user. Semantic innovation employs the semantic related technologies to improve the collaboration capability inside or across a networked organization. Every organization or individual use the innovation ontology to describe themselves and published in the trust worthy semantic web. This allows software to process these descriptions, perhaps as part of an automated search engine, to discover information about your and the communities of which you're a member. Semantic innovation has following features:

**Goal directed:** In the networked organization, different individuals, projects, or department have different goals. To reduce the uncertainty that exists in the networked organization, the innovation ontology gives an explicit and formal specification of the goals in terms of its mission, requirements, strategies and performance indicators. Then the process of formulating goals that reflect a holistic perspective of the organization and horizontal goals matching are done through the supporting of intelligent agent. It allows the organization overall direction to be communicated to not only the human but also the application or machine and empowers them to participate in the innovation process, which assure the high level alignment among these different but overlapping goals.

**Action based:** Innovation process can be looked on as

the temporal sequence of activities or events that occur in developing and implementing new ideas. To support the correct flow of actions through the various stage-gates of the innovation process, innovation ontologies based semantic mediation and inference are employed in the semantic innovation to ensure a low level consistency within the decision making (about plans and their execution) over time. Ontology-based context aware application is implemented to support the decision-making process concerning selection of actions or plans for projects execution.

**Team centered:** On the one hand, employee of the networked organization are provided functionality by ontology enabled intelligent agent to capture minimum critical information relating to innovation. On the other hand, the innovation process requires much creativity, problem solving and teamwork, which require a diverse skill base hence any management practice. Each action of the innovation process must have an efficient number of personnel (with corresponding knowledge and skills) assigned to them with a leader being ultimately responsible for action achievement. Inheriting from the class "Agent" of FOAF ontology and extending the attributes of its "Person" class with relevant information of innovation management, the individual member in the networked organization is described in terms of role (academic, engineer or manager), task description (which person is responsible for which goal or action), core competency (knowledge & skills), and relevant area of the task in the innovation process. Through the ontology inference and mediation, semantic matching is realized among goal, capability requirement of action execution, as well as role and the expertise.

**Result oriented:** The reporting of outcome for all goals and actions are specified extensively and concisely in the innovation ontology, which facilitate the agent which represents corresponding responsible manager to identify all the actions and goals that require immediate attention due to their red status.

## 5. CONCLUSION

Business competitiveness and sustainability depends on the effective management of innovation. Effective innovation needs to take place within every area of an organisation and by association within key suppliers and strategic partners. Since Semantic Web promises a vision to make information and knowledge machine accessible in the Web rather than displaying them for interpretation by human, a vision of semantic innovation, which exploits the potential of Semantic Web technologies, is presented in this paper to improve effectiveness and efficiency of innovation management in a large networked organization. Several pillar technologies enabling semantic innovation is discussed.

Of course, to actually implement semantic innovation, many other Semantic Web related technologies are also needed to be considered, such as ontology editing, ontology evolving management, semantic annotation, semantic web services, and so on. Until now some of these related technologies are still in their infant stages, more work needs to be done before this semantic innovation vision comes true.

## ACKNOWLEDGEMENT

The research work in this paper is supported by the Science Foundation Ireland.

### ABSTRACT

From 1999, China started the project of "Development of Western Region of China" and many preferential policies were issued by the central government. However, after almost 5 years, compared with eastern region, the development of infrastructure is still relatively lower. As to the development of E-commerce, the most typical phenomenon is unbalance which means that the eastern region is much faster than the western because of territorial and economic factors. So it is necessary to get a whole picture and get a clear understanding of problems of current situation of E-commerce in west part of China in order to accelerate it. In this article, the difficult points of E-commerce development in west region are discussed, such as the law issue, infrastructure, information service providers and talents people and some strategies will be given finally based on the current situation of E-commerce in west part of China.

**Keywords:** Western Development, Electronic Commerce, Internet, Informationization

### 1. INTRODUCTION

Because of advanced economics environment, E-Commerce of the eastern region has been growing quickly in China. After 1999, China started the project of "Development of Western Region of China" and at the same time many preferential policies were issued by the central government. From then, the E-commerce in western region has been developing dramatically. According to the reports of CNNIC, from 1999 to 2004, the proportion of the Internet users in the Eastern developed region (Including Peking, Guangdong, Shanghai, Jiangsu, Shandong, Zhejiang) and the western non-developed region (Including Chongqing, Sichuan, Yunnan, Guizhou, Xizang, Shanxi, Gansu, Ningxia, Qinghai, Xinjiang, and Neimeng, Guangxi) has been changing gradually. The proportion of the Internet users in the Eastern region occupied in total amount all over the country has been cutting down slowly. But the proportion of the Western region has been growing obviously and the unbalance between Eastern and Western region has improved. Now the infrastructure of E-commerce in the Western region has been improving very quickly and the Internet environment has also been ameliorated gradually. Now almost all kinds of E-Commerce business model and network companies based on business website can be found in west part of China. However, Compared with the Eastern developed region, the level of the infrastructure is still relatively lower. At present, the networks available still can not satisfy with the needs of development of E-Commerce there. If the Western region wants to walk the road of developing its E-Commerce, it is necessary to find the whole picture of existing difficult points of the western E-Commerce. Then, based on the current situation, the proper developing strategies of E-commerce for the Western region will be given.

### 2. THE EXISTING PROBLEMS ON DEVELOPING E-COMMERCE IN THE WESTERN REGION

Developing E-commerce of western region can promote the economic development greatly and improve its benefit as well. The Western region should grasp the good developing opportunity to make the government and enterprises advance side by side. In the meanwhile, the propagation and study can promote each other to speed up and make the Western region E-Commerce develop healthily through building a good business environment. In order to realize the unity between developing Western region E-Commerce and coordinating the whole western economy, it is necessary to analyze and study the existing problems of E-Commerce in the western region.

#### 2.1 The improvement of market environment of developing E-Commerce in western China

##### 2.1.1 Law issues

E-Commerce is the main content of Network economy, which is a manifest form of market-oriented economy. To some extent, the market-oriented economy means legal system economy. To develop E-Commerce, apart from solving technical problem, it is important to know how to rule the law problems related to the business activities. How to ensure the secure performance of trade on the Internet and other E-Commerce activities is not only a problem of western region, but also is a difficult problem in all China. It is necessary to restrain some problems related to E-commerce such as proof problem, request of the written form, attestation to trader, consumer, the bank of settling accounts, attestation way of contract effectiveness, working out the effective

electronic contract, the time and place of contract establishment, the rule of exchange behavior between trader and medium, exchange risk and duty problem etc.

E-commerce is a kind of new models of doing business, so there is not a standard legal document in China, even in the world. Although China published its Electronic Signature Regulation of Republic of China (draft) in July, 2002 and made public the Measurement of Management for the Internet Publish and the Temporary Supervision Rules of E-commerce on August 1 2002. But it still can't adapt to the development of E-commerce far and far because part of laws and regulations of electronic trade need to be emended, and some laws and rules need to be added such as the law of Electronic Signature, the law of Electronic Contract etc. So in order to speed up the E-commerce, a fair legal environment is important to protect the consumer rights and secure the trades between the sellers or buyers.

As to the western region, one of vital tasks is familiar with the related laws and rules existing now and to set up additional regulations to improve the law environment of E-commerce there. However, the most import thing is learn to solve the contradictory dispute and issues to safeguard the consumer's legal rights and benefits.

### 2.1.2 The issues of the infrastructure

In the western region, the start of infrastructure for the networks is later than the eastern China, which resulted in the weak of network applying service. So the networks existing now can not satisfy the need of the development of E-commerce. According to the latest report of CNNIC, most of the Internet users there still use the way of dialing the phone to access to the Internet. The speed of internet is slow and the connecting time is longer too. Although most of new buildings there lay the internet access line into doors while they build them, most of them can not provide any practical content and services except the basic facilities for the community. Especially, the breadth grows slowly because many real estate developers just take the breadth network as a selling spot. Most Internet users can't understand the technical index of breadth network, speed and network service in community as well as some developers. To some extent, those facts restrain the development of E-commerce in the western region.

In western region, the universal rate and the applying level of the computer are law. For example, many people there don't know how to use computer and the Internet. At present, the applying level of the computer in many enterprises is behind, meanwhile, many of them lack the information system to support there work. Even for the enterprises who introduced computer and the Internet into their companies, the main uses of computer are word process and calculation. Most of business activities in companies, such as product, supply, market, management of human resources are lack the support of

information technology. Such undeveloped management only enable the computer to simulate the operating process of original handicraft simply, and make it difficult to realize E-commerce system and increase the invest cost as well as cut down the rate of E-commerce returns.

As the third-part authority provider and fair attestation department, CA is an important part which ensures the safe activity of E-commerce. However, an effective supervisory of CA and the safety system of information are lack or weak. Because the rights and duties of CA can offer a person's true ID and use higher encrypt technology, it also related to the function of government department and the safe problem of the network. Up to the present, many organizations which take CA as their main business started because there is no integral measurement for CA from stating to operating in China. However, many CA owners may lack the capability and reputation, and technology. In case that the CA owners lost their business, it will be a big problem to handle the user's data.

Electronic payment system of the bank hasn't been established completely in the western region. The payment system of E-commerce has been set up by China Telcom, China Agriculture Bank, Chinese Bank, Merchant bank and other domestic bank etc. But because the system is not perfect, only half of the users who shopping via the Internet pay online. Another half still adapt the cash payment means on delivery.

As for the logistics, the modern logistics and its socialization are still staying in the stage of conception. In the logistics enterprises, it is obvious shortage on the information application, overall planning and the fine turns organization, as well as the ability of the management. On the other hand, the level of the specialization and technique in logistics system of the western region are all lower that they can't adapt to the requests at all on developing information flow and funds flow of E-commerce.

In summary, the government of the western region should pays attention to the infrastructure of E-commerce, and increases the investment into the construction of hardware facilities in order to solve the existing problems.

## 2.2 The development of information industry in the western region can't be satisfied with the need of the E-commerce.

### 2.2.1. The current situation of information system in western region

The developed countries such as Europe, American and Japan, the integration of the three greatest systems including SCM (supply chain management), ERP(business enterprises resources),and the CRM(customer relation management)have been ripe

basically. From MRP, MRPII to ERP, SCM, CRM, its development has gradually experienced for more than ten years. But the western region sprang over the developing process gradually, they introduce advance management thoughts and technique directly, most adapt the difference E-commerce business mode in many large enterprises, only a few make a success. This states that the western region business still can't break away from the traditional business mode in the course of carrying out E-commerce at the present stage. The information turns of the western region business is still in the stage of the beginning and exploring. They should set up electronic commerce terrace according to the present condition, all kinds of technique and developing conditions in the present business flows.

### 2.2.2 The information service industry in the western region

The software and hardware products mainly depend on the products of the foreign companies because the manufacture of the Chinese information equipments and

the software industry can't satisfy with the demands of soft-hardware products in the course of the development of the information and E-commerce in the western region .In addition, the actual strength of economy in the western region is poor.

### 2.3 Lacking strategic planning on developing E-commerce because of lower information level in western region business

On account of the proportion of the websites amount is one of the index to measure the level of the information, according to the reports of CNNIC, the proportion of the registered websites under CN in South west and northwest has increased a bit in recent years, but at the same time the proportion of registered websites in the North, the South, the East and Northeast has been occupying more than 85%, this reflects the gap between western and eastern region in the development of information infrastructure.

Figure : The registered area name and area distribution under CN

There are 2000,000 enterprises in the western region in China, and 10,000,000 families in the town, but the proportion of Internet access is relatively smaller. There is a very great margin between western and eastern region. According to the study of national statistic center, the ability of the information in the western region not only fall behind the developed regions such as Peking, Guangdong, Shanghai, but also fall behind other region such as Hubei, Henan and Liaoning as well. The development in domestic is very imbalance. There is a big margin in Internet users and computer owners between the western and eastern regions. Because the computer application in the western region starts lately,

at present, the construction of the business information in the western region is low, especially in the aspect of Network. The most only registered local area name and announced the basic business information on Internet. About Internet applying, many enterprises were still in the stage of exploring. Most business haven't realize the information turns, the means of information process and handle lags behind, so does the ability of information processing. So the demand of business for E-commerce is still at the primitive stage. Though the Internet users in the western region have increased doubly, the number of the Internet users only 1600,000.

Lacking the long-term planning of the E-commerce for many enterprises in the western region, even though many business begin to give energetic impetus to E-commerce, the invest returns to build their website is less, and prestige is also lower. The business website constructed themselves can get the purpose of publicity, but it is unknown that how many people can buy commodity on Internet because of influencing under the scales of business and the position of the website in the same industry. The repeated construction of the website will become the disadvantage for sharing Internet resources with the same industry. Therefore, only by working out the developing E-commerce plan consequently, the business in the western region will have a long-term development.

#### **2.4 The issue of lack talent people**

The talented people that the E-commerce needed can be divided into three levels. The first is the support layer of technique service. The staff in the first layer has mainly pay their attention to the technical aspect of E-commerce such as Network building, system management, main page creation, developing program etc. In China, the amounts of programmers is enough, the means of education can't basically meet the need of development. The first grade talented persons on system management are still scarce, especially in the western region. Lacking of web manager, Unix system manager, and the payment of training is still expensive. The level of many system managers is low, which only can be used to do some daily upholding work. They can do little job on higher management like safety and performance adjusting, for this reason, many systems in the western region exist hidden trouble. The second is the manage layer (middle-level manager, financial staff, middle and lower government staff etc). The secondary staff is the largest and they are the personnel of the business or section and the direct beneficiary of E-commerce. They don't care about the technical details about E-commerce. It's enough for them to do their work under the electronic way. But to a large extent, the E-commerce education neglected the needs to this layer. The third is the higher level of the manager. To the third level of structure, that means higher manager, it is not considered on the whole by E-commerce education. It is a very key link to push the popularization and training of E-commerce quickly if the E-commerce can grow smoothly in the western region in China. And go a further step, paying attention to attract the talented person, train and educate them are the key factors too.

#### **2.5 The issue of the role of the local government**

Compared to the developed region, the information technique in the western region fall behind, it will contribute to introduce technique and promote the development of E-commerce if the government can participate in it. The macroscopic planning and guide of the developing E-commerce will contribute to coordinate

the developing balance and the benefits among various areas. But the main role of the E-commerce development still belongs to enterprises. The government should mainly have the eyes on the macroscopic planning and guiding, not interfere the business, on the contrary, they should put the power to it and obey the international standard of E-commerce. At present, the western region is faced with the following environment such as a part of enterprises can't be separated from the government, the credit system is incomplete and the local protectionism is very severe too. Facing this kind of situation, how can the government department work well and adjust and guide positively will play an important role to the development of the E-commerce in our western region.

#### **2.6 The issues of conception and consciousness**

Because the development of E-commerce is still on its early stage, the consumers still remain the traditional consume habits of "see, touch, hear" and this shopping habits is deep-rooted, the majority still remain the shopping principle of "delivery when pay". Most consumers suspect the security of pay, quality of goods and hesitate to shop online because they can not see and touch the good via the Internet. At the same time, the density of the physical market is very large in the city structure in western region, so the consumers can buy anything what they like as soon as they go out. Compared with the E-commerce that has unperfected in the current logistics system, on the contrary, the consumers feel that the traditional shopping ways is more convenient. This makes the advantage of the "convenience", "fast", and "a good function of alternativeness" that the E-commerce depends on can't be reflected, to some extent, it will restrain the development of E-commerce in the western region.

On the other hand, there is a little information that Internet can directly bring economic benefits for business, but the general information is more. They often can't find profit about what they imagine on Internet and this will discourage the initiative of business.

### **3. The strategies on developing E-commerce in the western region**

Developing E-commerce is a social system project which relate to the government, business, financial industry and individual as well, and it needs the coordinating of the social environment, overall planning gradually and cultivating actively in the course of construction of the basic facilities. Therefore, the western region should grow according to the whole designs and goals on developing E-commerce.

The first, having the positive attitude, the government will play an important role to push the development of E-commerce. Particularly, on establishing Internet basic facilities, building common terrace, forming electronic attestation and the standard of electronic payment, at the same time, they should create a good support

environment of technique, finance, legal system etc. At present, the government is issuing the law related to the E-commerce, regulations and management methods to ensure it to be developed healthily. With the development of the western region, the local government should be based itself on the actual states and worked out the developing plan of local E-commerce. Besides this, they should coordinate the basic facility construction of the Network and communication, they also should try their best to save funds and reduce the repeated funds to minimum. In the meanwhile, giving the preferential policy of the tourism, industry and finance, tax revenue, communication, financial examine, funds and science study to the mature region and unit to encourage experimental unit and other invest businessman to invest strongly, At the same time, They should develop and study the E-commerce so that they can further explore the road to develop E-commerce.

The second, introducing the medium to enlarge the publicity dint degree of the E-commerce and encouraging scholar and business managers to study and publicize the E-commerce in order to get a good ready for developing E-commerce in the western region. It is a good way to enhance the correct knowledge of E-commerce to the business managers in a discussing way at a proper time. It is necessary to organize the business managers to study theoretical knowledge systematically. It also can organize them to put into practice where the E-commerce can be carried out well. It needs to make a long effort in the whole society to change the shopping habit of the public and establish the reliable system of consume as well as the operating ways of market.

The third, we should attract and educate the talented person to adapt the development of E-commerce. This is a basic and difficult point. It is difficult to attract the higher talented person because the western region is located in remote place, the level of economy and productive force falls behind, and the living standard is poor, too. So we should try our best to take the feasible measure to attract those who are willing to contribute themselves to the development of the western region. At the same time, it is important to provide a good working environment for them to enable them elaborate their talent. At the same time, it is important to pay attention to training the existing talented persons.

The fourth, with the market and performance as a target to enhance the of business management when the construction of the information is proceeding. Some famous enterprises in the world can keep the competitive advantage because they think highly of coordinating all kinds of productive forces and enable the links of decision, production and market to operate efficiently through gathering every kind of technique together. So the construction of business information turns can't only consider the business itself, they should still consider to connect with other unit through Internet including some

issues about the sign, confirm, pay, goods arrival of national contract etc. That is to say, the enterprises should improve their modern management level and establish internal information management system of the computer to enable itself to adapt the development of E-commerce in the future. The local government can specify technique organization or scholarship groups to offer consult and technical support for internal information management system of the computer and the development to ensure the business to get a good development in the future.

The fifth, it is important to draw lessons from the domestic and international advanced experience and take the current situation as a development base. Up to now, about the development of the E-commerce, there are many experiences in the advanced country and domestic examples of success for the business in the western region to learn from. For instance, the three greatest Bottle Neck problems on Internet attestation, ration system, electronic payment that had been restrained the development of E-commerce in China, now have already solved some to some extent. Some Internet businesses are also exploring a little successful experience in their actual operation. Combined the condition by themselves, the western region enterprises should use the successful experience and study carefully about which business and areas can fit to develop E-commerce in order to explore a new road for the western region to develop E-commerce and ensure it to have a good beginning in the western region.

The development of E-commerce is a systematical project which concerns with the corporate, consumers and government as well. The development of E-commerce in the western region is in its early stage and many difficult points are still there, so it will be a long way to go to catch up with the step of E-commerce in eastern China. It need the whole society makes a joint effort to coordinate and cooperate to promote E-commerce of the western region.

## ABSTRACT

To identify the customer value provided from the business process and to seek additional opportunities to fortify a firm's competitive advantages, we explore the value chain mentioned in (Porter, 1985) at a greater extent. The study results in a framework where an information-processing infrastructure is added to the value chain concept to provide a basis for the business process investigation. The essential concept of this framework is the **process-wide information organism** (PWIO) approach for describing and examining mechanisms of managing the information flow that contributes to customer value creation.

**Keywords:** process investigation, customer value, value chain, linkage.

## 1. THE PROCESS MANAGEMENT AND THE VALUE CHAIN CONCEPT

A business process consists of a series of related business tasks to be performed. An ordering process and a transaction-based revenue cycle are commonly seen business processes. Business processes create and deliver a value proposition for customers through the (value-added) product or service<sup>1</sup>. Thus, the performance of business processes is a leading indicator of subsequent improvements in (customer) value and financial outcomes. To well manage business processes and to seek (additional) opportunities to fortify a firm's competitive advantages are important issues nowadays.

In the literature, there are many studies of (business) process analyses. In terms of describing and analyzing processes, these studies can be grouped based on two distinct viewpoints for different targeted readers: one focuses on the technique issues and the targeted readers are engineers (for example, the IDEF0), and the other talks about a firm's strategy and the targeted readers are executives (for example, the value chain concept). Each viewpoint has its predicaments.

More specifically, the Process Management (PM) method suggested in (Elzinga, *et al.*, 1995; Stefano and Giovanni, 2003) is set out in the following six basic stages:

- (1) *Preparation*. Defining the crucial factors for business success and a firm's basic strategic targets; designing the organization structure (for example, steering committee, PM teams, etc.) for PM.
- (2) *Process selection*. Identifying the process to be analyzed and improved.
- (3) *Description*. Agreeing on a common definition of the process by documenting workflows.

(4) *Quantification*. Defining the process in terms of cost, quality and time performance.

(5) *Selecting improvement opportunities* based on acquired knowledge of the process, information about the crucial factors for business success, and of company targets.

(6) *Implementing improvements* that have been identified.

The cycle can be repeated downstream of the improved process, in order both to select new processes and to seek further improvement opportunities within the same process. Integration Definition for Function Modeling (IDEF0) stated in (Sandie, 1997) can serve stages of *Description*, *Quantification* and *Selecting improvement opportunities* of the PM method. IDEF0 is a model used to present structured information about the functions performed by an organization and has been proposed to analyze and identify process improvement opportunities. In addition, simulation modeling proposed in (Hlupic and Robinson, 1998) could offer great potential in analyzing business processes through dynamically modeling different samples of parameter values such as arrival rates or service intervals which can help in discovering process bottlenecks and investigating suitable alternatives. Some drawbacks in IDEF0 and simulation modeling are the excessive usage of technique and the inability to simplify the analysis.

On the other hand, some studies claimed that business process analyses should be based upon the customer value and a firm's strategic viewpoint. For instance, Porter (1985) stated that the issue should be the value, the amount customers are willing to pay for what a firm provides them. To discover a firm's competitive advantages, Porter proposed the value chain concept to analyze buyers, suppliers and a firm via disaggregating them into discrete but interrelated activities from which (customer) value stems. Furthermore, Kaplan and Norton

<sup>1</sup> Such service includes the ones for internal and external customers.

(2001) observed that organizations focusing on strategy and customer value tend to be more successful. With a clear picture of business direction and customer value propositions, organizations can deploy (or redirect) its resources at implementing strategy initiatives. In addition, the availability of knowledge of information system infrastructure and applications that align information capital to the strategic business processes is nowadays required to support the implementing strategy initiatives. As such, the expected outcomes are more attainable. Unfortunately, these studies did not release any solid methodology for examining the customer value delivered from the business process.

For instance, each value chain in Porter (1985) was designed to fulfill a set of value-adding activities. Across activities, there are linkages where information flows allow *optimization* or *coordination* to take place. Linkages are “relationships between the way one value activity is performed and the cost or performance of another.” (Page 48) However, Porter stated that it is much more difficult to recognize and manage linkages than managing value activities themselves, and the ability to recognize and manage linkages “yields a sustainable source of competitive advantage.” (Page 50) Without a solid knowledge for recognizing and managing linkages, it is difficult to effectively examine the customer value provided from the business process that covers a subset of activities.

These unsolved predicaments motivate this study. This study tries to explore the customer value delivered through the business process. For such an exploration, this research proposes a framework where an information-processing infrastructure is added to the value chain concept to provide a basis for the business process investigation. The essential concept of this framework is the process-wide information organism (PWIO) approach for describing and examining mechanisms of managing the information flow that contributes to customer value creation.

In the following sections, we will first introduce the PWIO approach, followed by the presentation of the business process analytical methodology. Promising managerial applications and future work are given in the last section.

## 2. THE PROCESS-WIDE INFORMATION ORGANISM (PWIO) APPROACH

Every firm maintains a variety of groups of functionally interrelated contact points (CPs) which work together for performing activities of the value chain mentioned in (Porter, 1985). The value chain concept is proposed to analyze activities a firm performs, and how these activities interact to procure competitive advantage. After receiving request for service from other (intra- or inter-organizational) activities, each activity plays the dual role as a server of value-adding provider (executing

business tasks for the client) and, if necessary, as a client (releasing information for asking for support from other activities). In other words, there are two kinds of information-processing infrastructures practiced in performing a business task: (1) CPs to process information and conduct the corresponding business task, and (2) information channels (ICs) to carry the information flow.

The practice of each CP processes information and undertakes business tasks for value-adding. In the CP, there are mechanisms capable of (1) receiving the information delivered from other CPs, (2) executing business tasks based upon the received information, (3) feeding back the corresponding information, and/or (4) releasing information to the supporting CPs. Between two different CPs, a client and a server, the (intra- or inter-activity's) information flow should pass forward or backward through the IC seamlessly to request or provide a service. Thus, each CP accompanies with the inbound and outbound ICs for carrying the in-coming and out-going information, respectively.

Hereby, a business process consists of a series of related business tasks that the practice of a group of functionally well-connected CP/IC is designated to perform.

In practice, a staff, an ad hoc team, or an information system could act as the practice of a CP. And a memo, a post mail, a phone call, a face-to-face meeting, a teleconference meeting, an intra net, an email, a (beeper or wireless) message, or a web information system could act as the practice of an IC. Furthermore, there may be multiple practices of a CP/IC. In brief, the practice of the CP/IC is in one of the following forms: manual, automatic, or parallel (have both manual and automatic practices simultaneously).

The practice of each CP/IC should create value (in the form of lower costs or improved performance) for the client CP. Difference in practice of a CP delivers various level of quality of coping with the corresponding business task, which differentiates the outcomes of its value-adding. For instance, an experienced manager can deal with unexpected business scenarios better than a decision support system and a junior manager. Difference in practice of an IC also differentiates the outcomes of the associated CP's value-adding. For instance, a phone line at a time epoch can serve only one customer, but the audience served by an Enterprise Information Portal at any time epoch may be more than one. The costs associated with different practices of each CP/IC may vary as well.

The discussion of the ICs explores the identification and management of linkages among value activities because, as mentioned in Porter (1985), exploiting linkages requires information or information flow which allows optimization or coordination to take place. Each IC identifies the existence of a linkage between two CPs,

and to identify the degree of integration of CP/IC is to explore the management of linkages. A better integration of CP and IC can render a better optimization or coordination happened in the information flow to leverage linkages between (value) activities. For instance, a firm provides an email practice in the (outbound) IC to customers, but some customers are incapable of receiving emails. In other words, practices of this very (inbound/outbound) IC between two CPs are asymmetric. The asymmetry existing in practices of the (inbound/outbound) IC between two CPs would impede the effectiveness of communication, the performance of the task, and thus the corresponding customer value.

The collective quality of information and the smoothness of the information flow associated with a business process are determined by the practices of all involved CP/ICs. The higher the degree of the collective quality and smoothness of information flow is underlying a business process, the larger the value a company can derive from these connected CP/ICs. However, a poor practice of an individual CP deteriorates the collective quality of information and the smoothness of the information flow in a business process.

The PWIO of a firm embodies all practices of all CP/ICs of a business process. Business processes that are critical to business success are expected to proactively responsive to the dynamic business environment. As such, each group of functionally well-connected CP/IC is adaptive in term of its functionality and practice. This adaptation leads to an analog between the PWIO and an organ in the living body.

Collectively, a firm maintains a PWIO for a business process. Via the practices on all CP/ICs in the PWIO, the firm handles not only the corresponding (transaction and non-transaction) information flow, but also performs all the involved business tasks. Furthermore, a firm uses its PWIO to do all the involved business tasks in a whole, not separately, for doing business. Whether a firm has a good performance in the (decisive) business process in value-adding for its customers depends on how well it manages the corresponding practices of CP/ICs of the associated PWIO.

In closing, the PWIO approach stems from the value chain concept and provides a solid description of the business process without too-much technique.

### 3. THE BUSINESS PROCESS ANALYTICAL METHODOLOGY

The proposed business process analytical methodology basically follows the first four stages of the PM method. Executives practicing the art of strategy must identify the decisive business processes that are the most essential for creating and delivering the differentiating customer value propositions. And the identification should be aligned with the vision of the firm. The revenue cycle, for

instance, is a decisive business process.

For each decisive business process, the following steps are proposed for accomplishing stages of *Description* and *Quantification* of the PM method: (1) to develop the corresponding business process table, (2) to develop the associated practice tables, (3) to complete the performance measures of CP/IC shown in practice tables, and (4) to integrate the summarized performance measures derived at the step (3) into the decisive business process table. The detail of each step is presented below.

(1) Developing the business process table: There are four columns in a business process table: responsibilities, functions, objectives, and performance measures. At the current step, only the responsibilities and functions columns are determined and filled in.

(2) Developing the associated practice tables: The practice table is to explore the practices on all associated CP/ICs for each function listed in the business process table. There are seven columns in the practice table: the practice of the associated CP, the job requirement of the CP, the practice of the associated inbound IC, the job requirement of the inbound IC, the practice of the associated outbound IC, the job requirement of the outbound IC, and the associated objectives and performance measures. At the current step, except the column of the associated objectives and performance measures, all the other six columns are determined and filled in. The corresponding practice of the other connected CP is shown in the parenthesis. The redundant CP/ICs and less important CP/ICs should be omitted.

(3) Completing the performance measures of CP/IC shown in all practice tables: Management cannot take place if the object needed to be managing cannot be measured. The measurement however would be impossible without a good description of the object. Therefore, for each practice table, we first determine and fill in the associated objectives of CP/IC, and then assign the performance measures correspondingly.

In each practice table, only the summarized performance measures are listed, and there are no detailed performance measures, the ones corresponding to the connected CP. For instance, when the CP in the sales department asks the corresponding CP in the production division for the backing up order information, the summarized performance measure is the process time of asking backing up order, and the detailed performance measures are process times of checking production schedule (performed by the CP responsible for production scheduling) and raw materials (performed by the CP responsible for raw materials warehousing).

(4) Integrating objectives and summarized performance measures associated with all practice tables into the columns of objectives and performance measures

appeared in the business process table, respectively.

In brief, the former two steps correspond to the stage of *Description* via following the PWIO approach presented in Section 2. The latter two steps correspond to the stage of *Quantification* of the PM method. In the literature, there are bodies of performance measures that we can borrow from for accomplishing the step 3. For instance, we can reference the measures of IT/IS's profitability, productivity and customer value (cf. Hitt and Brynjolfsson, 1996; Laudon and Laudon, 2000, pp. 353-360; Devaraj and Kohli, 2002, pp. 6-8; DeLone and McLean, 2003) to get the candidate performance measures of the practice of each automatic CP/IC. The candidate performance measures include, but not restricted to, an amount of errors, severity of errors, response time (process time), rate of tasks performed, the reduction in process/search costs, sales growth, market share, customer satisfaction/loyalty (repeat purchases), old customer retention, new customer acquisition (growth in new sales), and customer profitability contribution. There are also references in the human resources (cf. Bohlander, Snell, and Sherman, 2001), for the measure of the practice of manual CP/IC. But to measure the practice of manual CP/IC is much more difficult than to measure the practice of automatic CP/IC since the former involves not only the productivity and the profitability, but also the personality, including intelligence, experience, creativity, and (sometimes) ambition. A simplest way is to adopt the same candidate performance measures to both automatic and manual CP/IC.

Table 1 gives the illustration of a business process table corresponding to the revenue cycle of a specific firm<sup>2</sup> and Figure 1 gives the corresponding depiction. Tables 2 and 3 give the illustration of practice tables for functions of developing new customers and asking for backing up order shown in Table 1, respectively. In Figure 1, the parenthesis shows the corresponding practice of the connected CP.

#### 4. PROMISING MANAGERIAL APPLICATIONS OF THE PWIO AND FUTURE WORK

Business objectives and performance measures are rather common to all companies for planning, controlling, and performance evaluation purposes. However, the

alignment of objectives and performance measures without targeting at business direction could be detrimental to organizational performance (Kaplan and Norton, 1997). Thus the development of objectives and measures should depend on business direction/strategy of the firm. As the proposed business process analytical methodology is based on exploration of information flow underlying value chain activities, the business direction, building up customer value, is clear. With the clear business direction, a strong coherence of process objectives and performance measures buttresses implementations of customer value-oriented business processes. In this perspective, the analysis resulted from the PWIO approach helps the analysis of the implementation of business strategy.

It is worthy of noting that, for carrying the information, the practice of IC alone is always a necessity in the business environment, and nowadays gradually becomes a utility that is rather irrelevant to the competitive advantage. Furthermore, since the effectiveness of the integration CP/IC and thus quality of business processes determine how value get created and sustained, the proposed business process analytical methodology provides a venue to the business process evaluation.

Some knowledge extended from the PWIO approach, for example, the one in Figures 1, also depicts the level of integration of practices of CP/IC in forms of manual, automatic, or parallel. The automatic practices of CP/ICs correspond to the information system infrastructure and applications. In a sense, the information systems evaluation can be done implicitly via examining the extent and the importance of the corresponding automatic practices of CP/ICs in the whole (decisive) business process. Thus, the PWIO approach also provides a means of obtaining the knowledge of information system infrastructure and applications that align information capital to the strategic business processes. A future work is to strengthen such a sense and complete the associated studies.

#### ACKNOWLEDGEMENT

This study is partly sponsored by Institute for Information Industry, Taiwan, China, Grant No. 92-0524

<sup>2</sup> The study of this revenue cycle is based upon the case study of a project sponsored by Institute for Information Industry, Taiwan, China. For details of all practice tables please send a request to the corresponding author.

# The Internet and the Organizational Adoption of Electronic Business: A Research Agenda

Sanjiv D. Vaidya, Merlin Nandy

MIS Group, Indian Institute of Management Calcutta, Joka, Kolkata 700104, India  
{sdvaidya, merlin}@iimcal.ac.in

## ABSTRACT

The late nineties witnessed adoption of the Internet by organizations, on a very large scale. However, not every organization did experience an equally deep penetration of the Internet in its business. It was followed by the dot-com bubble burst. Many researchers have studied the phenomenon of organizational adoption of the Internet and the associated success factors. However, the available literature is fragmented in nature and does not take into consideration certain fundamental concepts. Therefore, there is a need for an enhanced understanding of the phenomenon. It will enable executives to plan for and implement Internet adoption in a more effective manner. This paper discusses the literature and brings out the inadequacies in the current findings. Subsequently a framework is developed to indicate directions for future research.

**Keywords:** Internet, IS adoption, E-Business adoption, E-Business drivers

## 1. INTRODUCTION

Information technology (IT) has been a part of virtually every business, particularly in the developed world, for the last two decades. The advent of the personal computer (PC) in the early eighties brought in a quantum jump in the scale of adoption of IT by organizations. The late nineties witnessed yet another wave of IT – the widespread adoption of the Internet by organizations, on a very large scale. Many researchers, from the fields of business strategy and information systems alike, have studied the phenomenon of adoption of the Internet by organizations in general [Stephan 2002], and the Internet boom and bust in particular. It has been observed that at one extreme of the spectrum of adoption of the Internet, organizations just put up a website with skeletal information. While at the other extreme, organizations carry out their entire business through their website, have adopted a web-based architecture and totally integrated the Internet into all their important business processes.

It is necessary for practising managers to understand the factors responsible for the above differences observed across organizations. Often organizations cannot use the Internet as planned or in an effective manner for their business. An understanding of the factors behind Internet adoption will enable them to evaluate the suitability of their organizational environments and their management strategies to the desired levels of Internet adoption. It will also enable them to plan for and implement Internet adoption in a more effective manner.

While the currently available research studies do describe some factors which influence the phenomenon of Internet adoption by an organization, they do not discuss the collective influence of the factors on the phenomenon. The studies do not also explain the nature of their influence on the level of Internet adoption.

Therefore, these studies do not lead to concrete managerial implications or actionables for managers. At the same time however, rapid acceptance and evolution of the use of the Internet has made it imperative for organizations to utilize it very effectively in their businesses. For effective deployment, they are required to have an understanding of the factors behind successful adoption of the Internet at different levels. Against this background, this paper intends to:

1. Summarize in a critical fashion the recent literature on the phenomenon of e-business adoption, with focus on the different individual influencing factors.
2. Identify the gaps in the current understanding and opportunities for further research.

## 2. EXISTING AREAS OF RESEARCH

Examining the existing literature, it is observed that there are numerous strategies adopted by traditional firms to implement operations on the Internet. The decision to adopt a particular strategy was influenced by several factors. We study and analyze those factors in the following sections.

### 2.1 Internet: Perceived benefits

Internet is now the most popular communication medium for conducting business. Characteristics of the Internet [Eder and Igbaria 2001] include:

- $\frac{3}{4}$  global, open information and communication platform
  - $\frac{3}{4}$  not owned by any single organization
  - $\frac{3}{4}$  flexible and powerful platform for communicating and interactively sharing information
  - $\frac{3}{4}$  The cost, time and expertise required to connect to this vast network of information is very low
- [Beatty et al 2001], [Lal 2002], [Amit and Zott 2001], suggest that firms push for developing their own websites with the intention of realizing potential

benefits like reduced transaction, advertising and distribution costs, elimination of intermediaries, reduced time to complete transactions, capture of market intelligence, faster information to stakeholders and faster responses to new market opportunities. A few of the other expected benefits include mass customization, building of stronger business relationships, greater degree of channel coordination, improved communication and enhanced customer service [Griffith, Plamer 1999], [McKinney 1999].

Another important driver behind Internet adoption has been the increasing trend towards thin-client computing. Thin clients are essentially slimmed-down desktop computers running applications from a central server [Whittle, Sally 2004]. The evolution of the Web has given users an attractive alternative to implement this architecture. As companies move toward Web-enabling internal applications and as enterprise software vendors increasingly provide Web-enabled software, users can access business applications through Web portals and virtual private networks [Mitchell, Robert 2004]. [Costanzo and Chris 2004] discuss the problems with fat client architecture. One of the solutions is adoption of thin-client architecture. Thin client architecture is more scalable, manageable and flexible than a PC-based architecture [Costanzo and Chris 2004].

## 2.2 Levels of Penetration of the Internet

[Sohn and Wang 1999] talk about how firms implement Internet market / e-Commerce (EC) at different levels, namely, non-adopters, firms planning to adopt, firms with limited users and firms with sophisticated implementation. [Cockburn and Wilson 1995] studied websites of a sample of 500 companies and classified them based on their use as, website providing basic company information, web presence with company information and information about products and services, website carrying company information, products and services information with price details, further step was adding online ordering to above, and website with online ordering and payment. [Liu et al 1997] have in their study identified ways in which large US firms use their corporate web sites to support pre-sales, sales and after-sales business activities. [Dave and Sambamurthy 1999] in their paper discuss how companies have used the WWW platform to capture the capabilities and business potential of this technological innovation.

[Young and Benamati 2000] visited web sites of all fortune 500 countries to identify predominant types of site content and suggested four categories – customer sales, customer service, communication and informational. [Beatty et al 2001] classify organizations into five categories based on the point in time when they adopted the innovation (Internet) relative to other organizations in their social system, namely, pioneers, early adopters, early majority, late majority and laggards.

Another study conducted for Singapore firms, [Timothy et al 2001] proposed four levels of website development – information and catalogues, database, basic transactions, search and integrated site. [Coleman 1998] developed a framework to represent website evolution from the first generation of organization-centric and intranet based homepages to the fifth generation's business-centric and marketplace integration type of delivery platform expansion. [Enders and Jelassi 2000], [Lal 2002] discuss different modes of e-business (EB) transaction, offline (through emails and messaging systems, online (through dynamic URLs), and using shared or individual portals. [Phan 2002] classified EB applications into three categories of electronic markets, inter-organizational systems and customer support applications. In a different study where New Zealand firms were surveyed [Stephan 2001] suggested that primary motivations for EB initiatives and building websites are to list products and services, provide company data, carry out promotional activities, link to alliance partners, and receive customer orders.

[Teo et al 2003] examined factors influencing Internet adoption at four levels – email adoption, web presence, prospecting, business integration and business transformation. [Mahajan et al 2003] studied the intensity of EB adoption in firms and explained the phenomenon using a matrix, along two dimensions, viz., the implemented process and degree of implementation. A different classification of EB information systems based on information integration and timeliness of information was developed by [Pant and Ravichandran 2000]. [Dutta and Segev 1999] examined and classified web sites based on specific features that had been transformed to the Net.

## 2.3 Adoption of Technology

Many researchers have proposed technological diffusion models explaining causal factors and outcome variables. [Dewar and Dutton 1986] concentrate on the adoption of technological innovation based on parameters like external exposure, complexity, knowledge depth, management attitudes towards change and centralization. [Iacovou and Benbasat 1995], [Crook and Kumar 1998], [Thong 1999], [Premkumar and Ramamurthy 1997] in their papers suggest that EDI adoption is influenced by perceived benefits, organizational readiness and external pressure. [Teo et al 1996] also attempted to identify a set of factors that a firm requires to concentrate on to enhance its ability to employ IT strategically, the factors being IT drivers, business needs, competitor position, external environment, economies of scale and top management guidance. [Kaun and Chau 2001], [Chau et al 1997] conducted further studies to contribute another EDI adoption model using the technology – organization - environment (TOE) framework.

## 2.4 Factors driving Electronic business adoption by organizations

Various studies have identified factors, which influence the adoption of EB. These factors can be classified into Internal and External factors. Factors internal to the firm are control variables and are within the firm's control. External factors include the firm's external environment and cannot be directly under the control of the organization. These are disturbance variables.

The different factors have been described below.

#### **Internal Factors**

##### **ORGANIZATIONAL FACTORS**

Studies in this category have identified sub-categories that influence the adoption of EB.

(a) *Inclination towards New Technology.* A favorable attitude towards systems innovation and inclination towards new technology increases the adoption of EC technologies [Iacovou and Benbasat 1995, Sohn and Wang 1999, Mehrtens et al 2001]. [Premkumar et al 1994, 1995] and [Chircu and Kauffman 2000] argue that different organizations feel the need for EC to different extents. Moreover, early adopters of web technologies laid more stress on the technology being consistent and compatible with organizational norms, existing technology, past experiences and present needs than late adopters [Beatty et al 1999, 2001]. In related findings, by [Grover 1993, Premkumar and Ramamurthy 1995], [Crook and Kumar 1998] and [Sohn and Wang 1999] it has been observed that active support of the top management and users lead to EC systems adoption.

(b) *EB Know-how.* EB know-how (executives' knowledge of EB) and Internet skills are complementary to physical assets and provide the business and managerial skills to adopt and manage EB effectively [Zhu and Kraemer 2003]. Organizational learning ability [Mahajan et al 2003] is an important determinant of EB adoption. Firms with superior IT capabilities, technical knowledge and skills [Mehrtens et al 2000], digital literacy [Slywotzky 2000] and IT sophistication [Chwelos et al 2001], [Crook and Kumar 1998] facilitate the adoption of different EC technologies. Existence of champions and better absorptive capacity of the firm facilitates faster and better adoption of new technologies [Sohn and Wang 1999]. [Chircu and Kauffman 2000] suggest that inability to acquire skill and expertise in new technologies, lack of training and education, and inability to learn new technology, form significant barriers to the adoption of EC systems. Organizations with an aggressive and forward-looking technology strategy [Thomson et al 2003] are more likely to leverage new technologies and Internet to respond to market and environment changes.

(c) *Information Intensity.* Organizations with information intensive products will utilize the Internet technology differently than hard goods manufacturers [Palmer and Griffith 1998], [Takacs and Freiden 1998]. The information content of the product and the

information processing content of the production process determine the applicability of Internet. Organizations with information-intensive value chains or value systems will also differ in their adoption of EB than firms with less information-intensive value chains. Product characteristics, the way customers access it and use it, and the information processing required to be carried out by the customer for the same, affect the adoption of EB technologies [Tarafdar and Vaidya 2002]. The requirement of accompanying information for the product, inherent characteristics determining whether it is digitizable or not and information intensity of the product and processes also act as influencing factors. These are findings from studies by [Porter and Millar 1985 and Grover 1993], [Malone et al 1987], [Straub and Watson 1995, Choudhury et al 1998], [Palmer and Griffith 1998].

(d) *Organizational readiness.* IT infusion in an organization is influenced by the MIS climate in the organization and MIS maturity [Eder and Igarria 2001]. [Timothy et al 2001], [McIvor 2000] observed that existing capabilities and prior competencies (existing processes and routines, technology, experience with customer groups) make the transition to a new technology easier. Firms with managerial and IT competencies show a strong commitment to EB and website development. [Kuon and Zmud 1987] discussed the importance of internal technology resource for successful IS adoption. Studies that have used the (T-O-E) framework, show that organizations, which are willing to allocate sufficient resources for the development of IS, tend to have a high degree of IS adoption. [Iacovou and Benbasat 1995], [Kuan and Chau 2001] have reported that organizational readiness which is the availability of adequate financial and technical resources, is an important determinant of the extent of IS adoption. The availability of technically skilled human resources is also a crucial factor influencing the adoption of EB [Crook and Kumar 1998, Chircu and Kauffman 2000]. Internal need and top management support [Premkumar and Ramamurthy 1995], pre-existing distribution structure and channel relationship [Palmer and Griffith 1998], determine Internet applicability [Takacs and Freiden 1998], [Gibbs et al 2004].

(e) *Other Organizational Parameters.* A strong grasp of the expected outcomes, issues and requirement of EB facilitates successful adoption of EB. A few authors have reported the effect of various organizational parameters such as business size [Grover 1993], [Hart and Saunders 1997], [Crook and Kumar 1998], [Thong 1999] and centralization [Grover 1993] on the extent of EB adoption. CEO characteristics (innovativeness and IS knowledge), customer loyalty, trust with regard to the integrity of the information and security of transactions conducted on the Internet, [Thong 1999], [Choudhury et al 1998], are also influencing factors. More informed firms, with greater scope [Zhu et al 2003] are more

likely to adopt EB. Cultures of existing business and EB should gel well.

### TECHNOLOGY CHARACTERISTICS

The characteristics of the Internet and other new technologies influence organizational decisions for EB adoption. IS characteristics like complexity, relative advantage, compatibility and the perceived benefits also act as facilitators. Additionally, EB technologies which are compatible with existing applications, hardware and software platforms, and with existing cultural value (related to technology) [Thompson 2003] are more likely to be adopted. Different level of adoption need different combinations of Internet related technology. These findings have been reported by [Grover 1993], [Premkumar et al 1994], [Beatty et al 2001], [Thong 1999], [Iacovou 1995], [Kuan and Chau 2001], [Gibbs et al 2004] and [Zhu et al 2004].

### PERCEIVED BENEFITS

Organizations pursue EB adoption with the intention of realizing operational and strategic benefits. [Mehrten et al 2001] have found that organizations realizing the greater information reach offered by websites, actively adopt the Internet as a communication medium. Direct perceived benefits as discussed in the section earlier and expectation of indirect benefits (customer service, productivity increase), also influence the extent to which organizations adopt EB / EC technologies [Premkumar et al 1994, Crook and Kumar 1998, Kaplan and Sawhney 2000, Beatty et al 2001, Chwelos et al 2001, Mehrten et al 2001].

### External Factors

Pressures from the firm's external environment, competitors' moves and customer expectations have been a major factor influencing the adoption of EB.

### ORGANIZATIONAL ENVIRONMENT

Competitive pressures drive an organization to adopt EB [Grover 1993], [Iacovou and Benbasat 1995], [Premkumar and Ramamurthy 1995], [Sohn and Wang 1999] and [Teo et al 2003]. Support and motivation from customers and suppliers, their changing orientation also help organizations to move to EB systems [Grover 1993], [Iacovou and Kumar 1995], [Crook and Kumar 1998], [Hart and Saunders 1998], [Chwelos et al 2001], [Mehrten et al 2001]. A higher level of consumer readiness (customer willingness and Internet penetration) drives firms to adopt EB [Zhu et al 2003]. Lack of trading partner readiness to engage in Internet transactions is a significant inhibitor for EB adoption. EB intensity of the country [Zhu et al 2003] and industry level [Young and Benamati 2000] factors also act as drivers. [Zhu et al 2004], [Gibbs et al 2004] find legislation barriers, external pressure, government promotion, policy environment and country effects as significant predictors of scope of use of EB technology. [Hart and Saunders 1997, 1998] observe that trust and interdependence between a company and its suppliers

and customers are facilitators for EC adoption.

### 3. INTERNET ADOPTION BY ORGANIZATIONS: A FRAMEWORK

As we have seen, various classifications of websites have been proposed in the literature. But there is no direct explanation for the differences between them. Most other studies just discuss the intent to adopt EB and the influencing drivers.

Figure 1. below represents a possible framework explaining the phenomenon of Internet adoption. This framework emerges out of our observations.

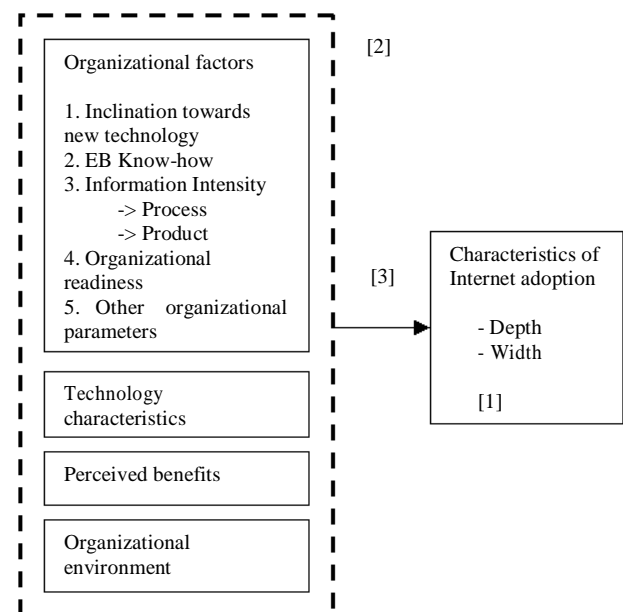

Figure 1. Future research directions

The literature emphasizes the differences in activities that organizations have implemented on the Internet. However, it does not take explicit cognizance of the differences in the involvement of the different stakeholders in the Internet-based business (Refer [1] in Fig.1).

Also, while the literature identifies the individual causal factors in a rather exhaustive manner, it does not explicitly address the nature of their influence on the phenomenon of Internet adoption, their collective influence and the interactions among themselves (Refer [2] in Fig.1).

Information Intensity, particularly along the value system, is a very important determinant of EB adoption but has not been discussed much in EB adoption models (Refer [2] in Fig.1).

Finally, the literature does, very justifiably, try to classify websites, which represents at least partially the degree of Internet adoption. However, the

conceptual linkages between the relevant drivers and the different characteristics of the websites have not been studied in depth (Refer [3] in Fig.1).

#### 4. CONCLUSION

It is observed that there are significant differences in the level of Internet adoption among organizations. Also, often organizations cannot use the Internet as planned or in an effective manner for their business. In this paper we have tried to examine the factors responsible for successful EB adoption and identified gaps in the present literature. Subsequently we have developed a possible framework for explaining the phenomenon of Internet adoption, which also suggests directions for future research efforts. Such analysis would provide organizations an adequate understanding of the factors that would enable them to evaluate the suitability of their organizational environments and their management strategies to their desired levels of Internet adoption.

### ABSTRACT

This paper reports the results of a study aimed at understanding and characterising IT management sophistication in small businesses. A multiple-case study approach was therefore used to explore the IT management practices of small businesses. Data collection involved four small-medium chartered accountancy (CA) firms and three IT firms closely associated with the CA industry. The case results combined with past research suggested 30 individual indicators of IT management sophistication. Further investigation of these 30 indicators yielded five underlying factors characterising IT management sophistication, namely *planning*, *controlling*, *organising*, *leading* and *external expertise*. The results provided a useful foundation for examining the impact of IT management sophistication on organisational performance and developing appropriate improvement strategies. Directions for future research are also discussed.

**Keywords:** small businesses, IT management, IT management sophistication, accounting firms

### 1. INTRODUCTION

The significance of the small business sector in national economies has been well documented (e.g. Vos & Nyamori, 1997). Computer based information systems have grown in importance to small firms (Fuller, 1996), and are now being used increasingly to help them compete (Mata, Fuerst, & Barney 1995). IS researchers have also emphasised the importance of managing the IT resource in small businesses in an effective manner (Raymond & Pare, 1992; El Louadi, 1998). Although the significance of IT management in the context of small businesses has been emphasised in the IS literature, so far a consensus has not been reached with respect to the definition of this construct. Further, a valid instrument to measure the 'IT management sophistication in small firms' construct is yet to be developed.

This study aimed to characterise 'IT management' in the context of small firms with a view to exploring the concept of 'IT management sophistication', that is, of some firms being more sophisticated than others in their approach to IT management. This objective was addressed using case study research of four small chartered accountancy firms in New Zealand. The case studies explored the practical and operational issues related to IT management in small businesses, to derive a pool of indicators that can be used to measure IT management sophistication. This paper reports the results of the case studies, suggesting a pool of operational indicators that can be used to characterise the construct of IT management sophistication in small business.

This paper is organised under five sections. The literature review is presented next and the research approach is outlined in section 3. This is followed by a discussion of the case study data and the resultant pool of indicators that characterise IT management

sophistication in small businesses. Research conclusions and limitations are presented in section 5.

### 2. LITERATURE REVIEW

Table [1] summarises the existing frameworks that suggest key aspects of IT management. These frameworks provide useful insights for identifying potential areas and sub-functions of IT management that could be adapted for this study.

The diversity of IT management dimensions identified in Table [1] shows that there is no commonly accepted definition of the term 'IT management'. Planning, organising and controlling are common to many of the frameworks characterising IT management, although some include aspects not shared by the others. For example Feeny & Willcocks (1998) identify IS/IT leadership, relationship building and business systems thinking as core IS capabilities, but not Earl (1989), Nolan (1973) and Guptha et al., (1997). Furthermore, while large firms are concerned with IT management issues such as architecture planning, contract monitoring and IS function management (Feeny & Willcocks, 1998), small firms deal with issues such as educating the users, involvement of external consultants and implications of top management (Pollard & Hayne, 1998). The importance of external expertise in the management and implementation of information systems, especially in the small business sector, has been highlighted by several researchers (e.g. Fink, 1998; Gable, 1996; Thong et al., 1996).

Although Fink (1998) asserted that the management effort towards IT in small firms is negligible compared to large firms, it is not proper to infer that small businesses have absolutely no practices to manage their IT. For example, Rodwel & Shadur (1997) confirmed that the practices related to human resources management are more sophisticated than one may be led to believe. However, Cragg & King (1993) found that with the maturity of small firms, only minor changes had been observed in the management of IT while many small firms had experienced growth with respect to the number and type of IT applications.

Raymond & Pare (1992) asserted that IT sophistication may be characterised under two major dimensions: IT usage and IT management (See Figure [1]). This paper focuses on the IT management dimensions to better understand the concept of IT management as it applies to small firms. Although there are certain commonalities in the characterisations of IT management, it is evident that a commonly accepted means to define IT management in small firms has not evolved. Examination of two small firm studies, that is, Pollard & Hayne (1988) and Raymond & Pare (1992) cited in

Table [1] showed little agreement with respect to major issues contributing to the characterisation of IT management.

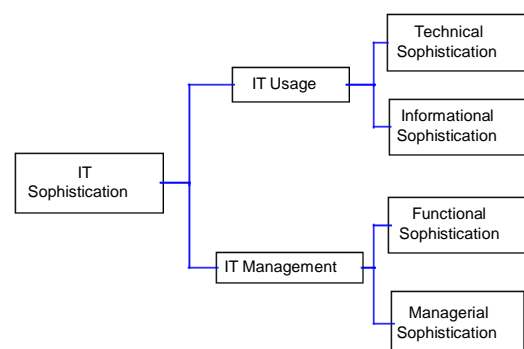

**Figure [1] Dimensions of IT sophistication  
(Raymond & Pare, 1992, p. 7)**

Table [1] also suggests that the general management sub-themes, *planning, organising, controlling and leading* (Daft, 1988, Earl, 1989, Nolan, 1973, Schermerhorn, 1989) with respect to IT management

may provide a useful basis for characterisation of this concept in broad terms.

### 3. RESEARCH APPROACH

As indicated above, this research relied on the case study method. This method found to be useful in small firm studies and also in IS research leading to theory development (Ramano, 1989, Yin, 1994, Zinatelli & Cavaye, 1994). Case studies were conducted in four small and medium sized chartered accountancy (CA) firms in Christchurch, New Zealand.

Chartered accounting firms offer accounting and other services to individuals and other firms. For example, many CA firms help other small firms create their annual accounts. They also offer business advice, for example, on the structure of a firm, tax liability, and employment issues. The intensive use of IT by CA firms for information processing in their main business activity and in producing information for clients, and the similarity of technology used across the firms in the industry, were the major reasons for choosing CA firms for this study.

Case study interviews were conducted between February to May 1999. Number of partners in this sample of firms ranged from 1 to 9 and the full-time accounting staff ranged from 3 to 50. Two of these firms were using APS accounting software, and one used CA systems (MYOB Office Systems). Three of these firms employed external IT consultants. (The case study firms are identified as CAF1, CAF2, CAF3 and CAF4 in this paper).

The case studies were aimed at identifying the issues representing the key IT management practices in small firms to explore the concept of IT management. The information gathered from the case studies was supplemented with comprehensive discussions with two IT consultants, who were closely associated with CA firms, and the general manager of a major software supplier to the chartered accountancy industry in New Zealand and Australia. (They are identified as CON1, CON2 and CON3 in this paper).

### 4. DATA ANALYSIS AND DISCUSSION

The case study data comprised mainly of transcribed interviews. There were two major phases to the case study data analysis process. Firstly, the case study data were scrutinised to identify the issues, concerns and important points that were indicators of IT management practices in small firms. The preliminary pool of likely indicators so derived was examined in the light of past research findings. Consideration was given in this review process to examining if a particular issue was actually IT management related. Emphasis was placed on those issues which were identified in more than one case and which have also been dealt with by past

researchers. Also, a few items were added to this pool of indicators to reflect certain critical IT management issues that were strongly supported by past researchers, although not brought to light through the case studies. Table [2] lists four draft item statements derived in this phase of the analysis. (Due to page restrictions, the full set of 30 items is not provided here but is available from the first author).

The second phase of the case study analysis focused on assessing the content validity and to determine the potential sub-dimensions of IT management sophistication represented by the 30 indicator statements. Similar to the approach adopted by Chan et al. (1992), the item statements were reviewed by nine experts in this phase of the study. These experts represented academics/researchers and technical staff from the IT/IS and Management disciplines. In the review process each expert was provided with a set of cards on which one item statement was printed. They were asked to sort the cards into a number of piles representing the likely dimensions of IT management. The four major sub-functions of management (i.e. planning, organising, controlling and leading) were suggested as a basis for investigation. However, the experts were encouraged to present their own views about the factors that may represent IT management sophistication. The sorting exercise was followed by detail discussions with the experts.

All participants of the expert opinion review agreed that these 30 statements, in general, would reflect the important issues of IT management in small firms. They also agreed that examination of these issues would provide a sufficient understanding of IT management in small firms, which in turn could be used to measure the level of IT management sophistication.

Participants generally agreed that the concepts underlining the statements presented can be categorised into the four broader factors of planning, controlling, organising and leading, and most statements were classified under the four factors accordingly. However, the participants were not always unanimous in their classification decisions with respect to certain statements. For example, the item *"We use a rigorous IT planning process within our firm"* was classified under planning by seven participants; whereas one participant placed this item under controlling and another under organising. Such issues were resolved by reviewing them in the light of past research references (e.g. definitions of planning, organising, controlling and leading by Schermerhorn, 1989).

At the end of the review process, there were three items that did not appear to fit into any of the four factors identified above. All three item statements were related to obtaining support from external expertise and gathering information from parties external to the firm. Presence

**Table [2] Draft Item Statements, Case Study Evidence and References ( a Sample)**

<b>Item #1</b> <ul style="list-style-type: none"> <li>• <b>We have comprehensive procedures for maintaining the security of information stored on the computer.</b> ( Davis et al., 1995 and Raymond et al., 1992)</li> </ul>
<ul style="list-style-type: none"> <li>• It's amazing how much faith you're putting in your staff in small businesses and how little security; ... [ of ] the most valuable part of the business; the data you have... (CON2)</li> <li>• [A] lot of firms are not backing-up [their data]. Quite recently we had a major problem with our product. ... [Due to some unforeseen problem] the data were corrupted [when the new system was up and running for the first time]. About twenty firms around the country got affected by it. ... and still believe that a lot of firms have very very poor security. (CON3)</li> <li>• At the moment internally we don't really have much [internal] security. (CAF4)</li> <li>• We're trying to convince most people to take care of their data. The importance of security of data. (CON1)</li> </ul>
<b>Item #2</b> <ul style="list-style-type: none"> <li>• <b>We have comprehensive procedures for managing the use of IT resources.</b> (Raymond et al., 1992)</li> </ul>
<ul style="list-style-type: none"> <li>• No, there's no procedure written down; it's really just casual knowledge.(CAF3)</li> <li>• ..no we don't write too much [procedures] down.. Because by the time you write it down, it would have changed.. Personally I don't believing in writing things down too much. (CAF4)</li> <li>• There is no control over what software has been loaded on the PCs... ; there is often different versions of all software on all the PCs depending on when they brought them. (CON2)</li> </ul>
<b>Item # 3 and # 4:</b> <ul style="list-style-type: none"> <li>• <b>We closely monitor the progress of our IT projects.</b></li> <li>• <b>We closely monitor the performance of the IT function.</b></li> </ul> (Raymond et al., 1992; Sabherwal & Kris, 1994; Boynton et al. 1994; Pollard & Hayne., 1998; Feeny & Willcocks., 1998; Gupta et al., 1997)
<ul style="list-style-type: none"> <li>• We've got meetings with all the staff every fortnight ... .Probably our monitoring is based on identifying how many problems we have. (CAF1)</li> <li>• We monitor obviously the profitability of the firm and we could tell that really within six months [whether] we have actually recovered [the cost of a particular IT investment] (CAF1).</li> <li>• Probably in three months down the track they [CA firms/software users] should ask for some consultation and review from the supplier. (CON3)</li> </ul>

of IT consultants (Raymond et al., 1992) and obtaining advice from external experts (Thong et al., 1996, Yap et al., 1992, yap et al., 1994 ) have been identified as significant feature in IT management in small business. Cragg & King (1993) also identified the consultant's support as a factor that encourage IT growth. Referring back to the case studies, it could be seen that the CA firms gather external information from other means such as involving in the software user groups, mostly for purposes related to managing IT, and not for other operational activities of CA firms. Research shows that SMEs also value information about IT provided by external sources (e.g. vendors and consultants) for successful IT adoption (Fink 1998). Fann & Smeltzer (1989) have shown that suppliers/vendors and competitors are important sources of information for operational decision making in small firms. Accordingly, a fifth factor, namely *external expertise*, was proposed for characterising IT management sophistication in small business. The finalised list of item statements classified under the likely major factors (i.e. sub-dimensions) of IT management sophistication in small firms is given in Table [3].

## 5. CONCLUSIONS

This case study research examined IT management

within small businesses. The study identified 30 item statements/indicators of IT management sophistication. These 30 items were then classified into five factors: planning, organising, controlling, leading, and external expertise. These results fit well with the findings from past research. Many of the indicators relating to planning, controlling and organising have been used in prior research to characterise IT management sophistication. Leading emerged as a relevant factor of IT management sophistication in small business according to the current study. Past research and the case study evidence also supported the inclusion of indicators pertaining to *external expertise*.

The development of 30 items statements representing, and identifying the associated five major factors/sub-dimensions are the major contributions of this research. IS researchers can use them to characterise the 'IT management sophistication in small business' construct and further explore the relationships between this and other related constructs, such as IS success, IT enabled organisational performance and competitive advantage. Practitioners could use the results to help them determine strengths and weaknesses of IT management in small firms, and then formulate appropriate strategies aiming at achieving organisational success and to gain competitive advantage.

A major limitation of this research was the restriction of the study to four small and medium sized chartered accountancy firms in New Zealand. Given the diversity within the small business sector, this element restricts the generalisation of findings. Further investigation, by way of additional case studies, may be directed towards clarifying the role of external expertise in IT management sophistication in small business. Ascertaining the validity of the derived item statements as measures IT management sophistication in small business construct is another direction for further research. Survey research using the derived measures

(the 30 item statements in table [3] ) of IT management sophistication in small firms and data analysis aiming at instrument development and validation are suggested to peruse this end.

### ACKNOWLEDGEMENT

This research was supported by the department of Accountancy, Finance and Information Systems of the University of Canterbury, New Zealand.

## ABSTRACT

This paper proposes a framework that can be used to explain and improve enterprise integration practices. It draws on the traditions of quality management and organizational learning to understand how implementation of advanced information technologies such as enterprise resource planning and customer relationship management may be explained and improved. Enterprise systems implementations at two subsidiaries of two separate large conglomerates are used to illustrate this framework. In particular, it is posited that quality management and organizational learning principles and practices are essential for successful advanced information technology implementation. This is because advanced integrative information technologies like ERP and CRM are in essence process management tools and are evolving to become knowledge management tools.

**Keywords:** Enterprise Resource Planning, Customer Relationship Management, Quality Management, Organizational Learning

## 1. INTRODUCTION

Enterprise integration underlies e-commerce, enterprise resource planning, customer relationship management and other advanced uses of information technology to create business value [1-3]. Despite the proliferation of literature on e-commerce, the social and organizational aspects of enterprise integration are not well understood. Also, holistic approaches in enterprise integration research are rare. This paper aims to contribute to our existing understanding of e-commerce by proposing a framework that links organizational learning, quality management practices and the use of advanced information technologies such as enterprise resource planning and customer relationship management. The use of the framework will hopefully facilitate actions that create business value through the implementation of advanced information technologies. The theoretical framework has been derived from existing frameworks of organizational learning and quality management [4-12] and information systems implementation [13-15]. An assumption here is that information technology adoption would lead to better organizational effectiveness if it facilitates 1) practices that improved the quality of the product and services provided by the firm and 2) organizational learning.

Both quality management and organizational learning have been touted as approaches to improve organizational effectiveness [16-18]. While the link between quality management and organizational learning has been suggested by various authors [4, 9, 19], the nexus between information technology implementation, quality management and organizational learning is less pronounced.

## 2. THEORETICAL FRAMEWORK DEVELOPMENT

The framework has undergone three stages of development in the last eight years. First, it was developed to understand the link between organizational learning and quality management. The first stage of development involved a post-positivist qualitative and quantitative multi-level in-depth case study [20] of two organizations (herein called Netweb and Stark) that were fully owned subsidiaries of two multi-billion dollar (US\$) conglomerates. The first stage was conducted between early 1995 and early 1997. Then, the framework was adapted to understand the impact of information technology on the linkage between quality management and organizational learning in theoretical research in late 1998. Currently it has been recently adapted to understand the impact of advanced information technologies specifically enterprise resource planning and customer call center management (a subset of customer relationship management systems). The last stage involved a study of Stark within the wider context of the conglomerate to which it belonged using ethnographic approaches [21] in a multi-level multi-functional manner, and revisiting the evidence collected in phase I.

Netweb was a firm in the service industry and deployed advanced information and communicational technologies. The staff education levels of Netweb were comparatively high in relation to Stark. On the other hand, Stark was a manufacturing firm in a comparatively low technology industry. While Netweb experience high turnover rates being in a high tech industry, employees of Stark worked with the same company for relatively long periods, some even for decades. Netweb and Stark are summarized next.

Name	Netweb	Stark
Service/ Manufacturing	Service	Manufacturing
Technology	High	Low
Staff Turnover	High	Low
Staff Education	High	Low

**Table 1 - Stark differences between two firms studied**

The following table summarizes the fieldwork conduct of Phase I and Phase III. Note that Phase II involved only a theoretical adaptation of the framework developed in Phase I to account for the impacts of information technology implementation.

Phase I (positivist case study)	No of org. levels studied	Number of Interview- ees	Surveys	Other sources
Stark (focused on MaxCo ET site of Stark)	5 levels (From Stark CEO to Machine Operator)	7 (Note: repeat interview- ees were conducted for some)	Organizational Learning Survey Learning Org. Profile	Observations, Meetings, documentation, informal conversations
Netweb (focused on the National Call Center)	5 levels (From Netweb CEO to call center operator)	10 (Note: same as above)	Same as above	As above
<b>Phase II</b>				
<i>Theoretical development. No field work in this phase</i>				
Phase III (ethnography)	No of org. levels studied	Number of Interview- ees	Surveys	Other sources
Stark within context of the wider Solteria conglomerate	9 levels From former CEO of Solteria to Stark Truck Driver.	69 (Note: repeat interview- ees with many respondents)	Not applicable.	As above

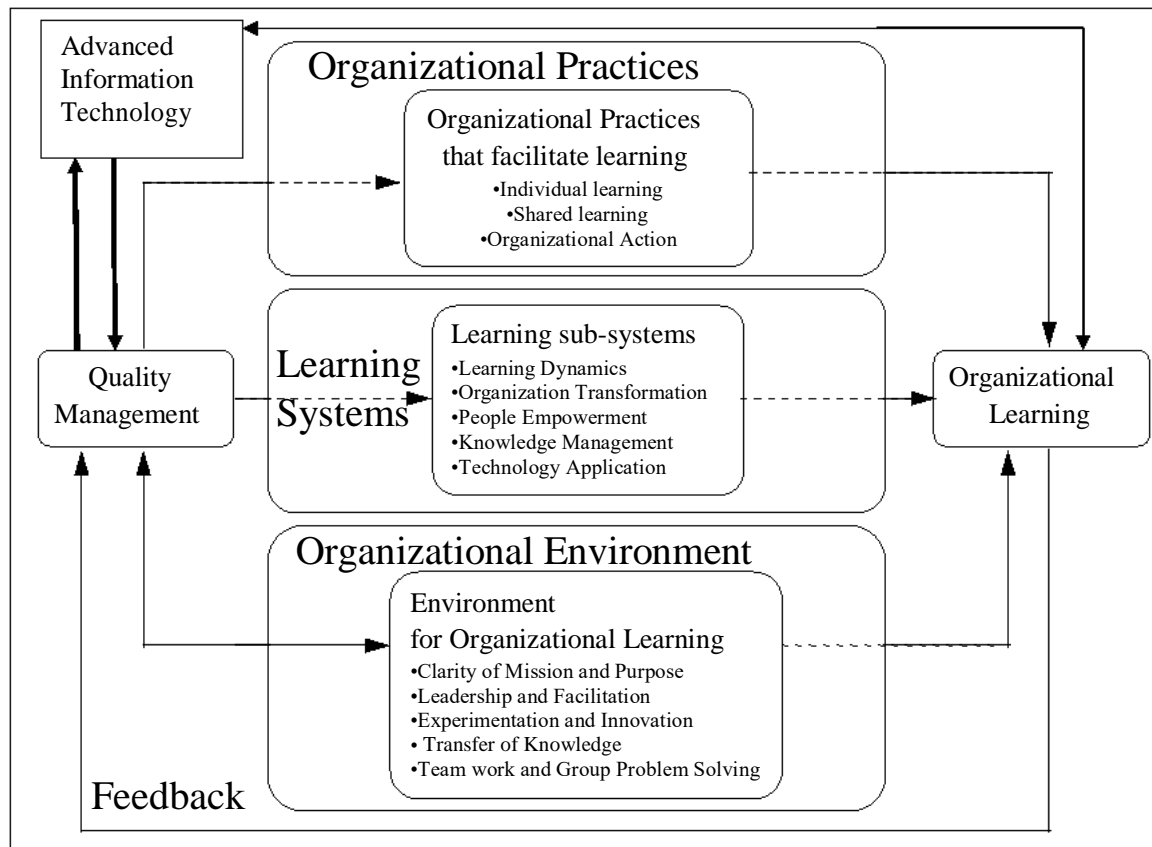

**Table 2 - Summary of conduct of fieldwork for Phase I, II and Phase III**

From the table above, while efforts in Phase I involved testing a framework linking quality management and organizational learning, the critical ethnography in Phase III helped the author understand in a deeper manner the social and organizational aspects of enterprise systems implementation. This offered a very rich background against which to develop, question and extend theory [22]. For example, in phase III, over 40,000 pages of documentation were collected at Stark. Access was given to privy viewpoints that could not easily be gained using any other method except very in-depth case study methods (or ethnography). It should

be noted that Phase III started off as an interpretive ethnography to understand information technology-enabled enterprise integration. Constructs being studied were at that time ill-defined in the literature. Hence, ethnography was necessary.

The organizational learning survey (OLS) [10-12] and Learning Organization Profile (LOP) [7, 8] mentioned in previous table were instruments designed by other authors. They were among the few available instruments at the time the research was conducted (mid-1996 to early 1997) that assessed how the characteristics of an organization was in line with a learning organization [e.g., 17, 23]. It was not applied in phase III because the purpose of phase III was to achieve a deep understanding of the impact of enterprise resource planning on organizations. Moreover, Phase III began with the use of interpretive methods. Thus the use of survey methods was ruled out in phase III. Also, using a positivist framework at the start of the phase III was deemed inappropriate.

Combining the previous studies under a interpretive hermeneutic lens [24], allows one to conduct meta-studies that enrich current existing frameworks. Here, positivist frameworks are interpreted through an interpretive lens within the current context and applied to derive rich insights. This is because every act of research involves a double hermeneutic [cf. 25]. (Even positivist frameworks have to be reconstructed and reinterpreted within new context every time they are applied [cf. 26]). From this process, an updated framework is derived that involves data of previous case studies and ethnographies being reinterpreted within a new framework presented in the next diagram. It is posited that advanced information technologies are involved in a structuration process of organizational practices, learning systems and the wider organizational environment for organizational learning. Also, quality management initiatives that are facilitated by information technologies (especially those that enable better process management capabilities such as customer relationship management and enterprise resource planning) impact on organizational practices, the learning systems and organizational environment for learning. The extent that information technology facilitates the linkages between actions that positively impact on the creation, maintenance and enhancement of organizational practices, learning systems and organizational environment that are conducive to organizational learning, is the extent that IT implementations may positively impact on organizational effectiveness and success. (The concept of success is dependent on who, when and how it is measured [27]. The author considers success to be related to the ability of the firm to implement information technologies to facilitate organizational learning. Also the framework has some overlaps between the areas of organizational practices, learning systems and organizational environment because they

**Figure 1 - Framework linking information technology, quality management practices and organizational learning**

are not meant to be strictly independent or dependent variables but rather perspectives through which one understands organizational learning.

Organizational practices in the diagram above refer to institutionalized social practices that facilitate the linkages between individual learning, shared learning and organizational action [9]. Learning sub-systems refer to a perspective where several organizational sub-systems constitute a learning organization, namely learning dynamics, organizational transformation, people empowerment, knowledge management and technological application [7, 8]. Organizational environment for organizational learning is comprised of five characteristics: clarity of mission and purpose, leadership and facilitation, experimentation and innovation, transfer of knowledge and, team work and group problem solving [10-12]. Information technology through a structuration process may enable and constrain quality management initiatives that would then impact on organizational practices, learning systems and organizational environment. This then impacts on organizational learning that may also in turn impact the implementation of use of advanced information technologies. The use of advanced information technologies would also impact organizational learning directly through other means.

### 3. ANALYSIS

With Netweb, its call center was recognized widely as one of the best in the country at the time of research. When Netweb's parent company started to expand its activities to another country, it showcased Netweb's call center that had won a quality award that year as the epitome of excellence of its customer service. An examination of the social practices, learning systems and environment for organizational learning reveals that Netweb's context was extremely conducive for organizational learning. Information technology used in this context facilitated the linkages referred above.

In contrast to this, Stark's ERP implementation was not as successful. Although an environment conducive for organizational learning was created at Stark's MaxCo ET site earlier, the overall organization and in particular, its order acceptance and delivery process was far from exhibiting characteristics of a learning organization. The ERP implementation was widely touted as a failure even after two years going live. This could be explained by the lack of the institutionalization of social practices that translated individual learning, to shared learning and eventually effective organizational action. The environment for organizational learning and the learning systems were also not conducive for organizational learning.

In the case of Netweb, the call center that was show-cased had strong Clarity of Mission and Purpose. The mission of the center was clearly defined and employees were clear about the purpose of the organization. There was clear Leadership modeled by the manager of the center who held monthly call center meetings where problems were resolved or escalated to more senior management if they had not already been resolved at the team level. However, with the Experimentation and Innovation, due to the center's emphasis on stability and predictability, there was not much emphasis put on devising new ways doing things. The Transfer of Knowledge was aided by the use of call center management software that recorded each problem that was logged with the center. This enabled all members of the center to view the problems that customers were experiencing and ensure all problems were resolved within the agreed time frames outlined in service level agreements. The environment for team work and group problem solving was facilitated by a team-based structure and rewards system which rewarded the teams as whole rather than just individuals.

The adoption of quality management principles by Netweb as whole institutionalized some of the aspects mentioned above. For example, the principle of Leadership modeling as prescribed by the Malcolm Baldrige criteria was adopted by the center's manager who was also an ardent supporter for Netweb's quality framework that was based on the Baldrige criteria.

With regards to learning sub-systems, Netweb had systems to facilitate Learning Dynamics. Single loop learning was facilitated by the adoption of a standard methodology for problem solving. However, at the senior executive level, organizational defensive routines hindered double loop learning [28] in the organization. With Organizational Transformation, the importance of being a quality oriented organization and a learning organization was understood and strongly supported by Netweb's senior management team. People Empowerment for learning was encouraged where managers and non-managers worked together to solve problems together. On the transfer of knowledge, Netweb's call center staff would store solutions to customer problems as quality system procedures so that important knowledge is coded, stored and made available to those who need and use it. Finally, Netweb among other things used Lotus Notes to manage group processes such as project management, team process and meeting management (an example of Technology Application to support organizational learning).

Organizational practices that facilitated learning were encouraged where for example; a customer logged a problem with the call center. This call is noticed by a customer service representative at the center. He solves that problem and writes a quality system procedure detailing the resolution procedure. So individual learning is then shared. The next time the same problem occurs, the quality system procedure to solve that

problem is applied. Thus there is a linkage between Individual Learning, Shared Learning and Organizational Action. Other practices that facilitated this linkage were weekly team meetings and monthly center meetings where problems and solutions were discussed and workers implemented these solutions.

Contrast this to Stark's call center. It was formed from an integration of the order acceptance and delivery processes of three of Stark's business units: MaxCo, CamCo and Xenon. For CamCo, the call center also merged the order acceptance and delivery processes that were previously localized at the level of each CamCo plant. This call center used an ERP system from a major vendor that was interfaced with a then state-of-the-art expert system for dynamic truck allocation. The dynamic truck allocation system recommended the best truck to delivery the order to the customer. However, due to the lack of Clarity of Mission and Purpose where a conflict of strategic orientations existed between the senior management, the call center did not fulfill its original purpose of ensuring on-time delivery of products. Certain dominant actors occasionally forced large orders from big customers through the system to maintain good relationships with these big customers; causing every order to be late. On Leadership and Facilitation, while the call center manager attempted to facilitate learning, the call center was part of the wider volatile centralized order acceptance and delivery cycle. Overall, there was no clear Leadership across this cycle that facilitated the environment for organizational learning. Experimentation and Innovation were constrained by frequent firefighting of problems. Furthermore, the transfer of knowledge across that order acceptance and delivery process was poor. For example, a sales person related to the author how the same problem of how add-ons to the product were not included for the third time in a row for the same customer! Furthermore, the plants that were integrated into the order acceptance and delivery cycle had previously competed against each other on the volume of product delivered. Thus teamwork and group problem solving were not practiced effectively.

With regards to learning sub-systems at Stark's call center, single loop learning was problematic where corrective actions to ensure the processes met their goals were not taken as discussed above in the case of missing add-ons to products. Double loop learning at the strategic level was also hindered. Refer to [29] for further information. Organizational transformation towards a learning organization was hindered by a change in leadership where the new CEO of Stark held different ideas of how best to generate value for the conglomerate than his predecessor. Furthermore, the senior manager who championed the learning organizational movement at Stark had already left. On people empowerment, Stark had a culture of cascading authority and autonomy to the lowest levels practicable. However, the call center impinged on prior established

autonomy and authority structures that involved delegating certain aspects of authority and autonomy to plant managers. Thus there was lack of cooperative behavior between managers throughout the order acceptance and delivery cycle. On knowledge management, although a Quality Improvement Reporting System was in place, it was not used effectively. There was a gap in the link between reporting a problem and ensuring it got fixed. On Technology Application for learning, Stark had implemented ERP, an expert system to assist in assigning the best truck to deliver products and a host of other then advanced information technologies. These supposedly could support a learning system. However, the use of these technologies to support a learning system was hindered due to the lack of overall process management throughout the order acceptance and delivery cycle that could have used data generated from these systems to improve performance.

From an organizational practices perspective, individual learning (such as the sales person discovering a problem described above) was not translated into shared learning (collective procedures and mindset to ensure that this problem does not occur) which is then translated into organizational action (the add-ons to the product for a customer are added and delivered correctly).

#### 4. DISCUSSION

One could suggest that organizational learning is a criterion for effective advanced technology implementation such as enterprise resource planning and customer relationship management. For effective technology implementation, the applications would need to impact on processes to generate business value. However, as practice-based research shows, it is the tacit relationships between people and things that make processes work [30]. Moreover, these tacit relationships are highly contextual. The importance of improving social practices, learning systems and learning environment so that information technology supports linkages between quality management and organizational learning is underscored in this paper.

The areas outlined in the framework provide some key areas that practitioners and academics can focus on to ensure that implementation of advanced information technologies such as enterprise resource planning and customer relationship management contribute to a firm's performance. Theories, methods and tools established in other fields may be adopted to improve implementation success. For example, Argyris' ladder of inference and the left and right-hand column can be used to facilitate double loop learning [29].

#### 5. CONCLUSION

It is posited that quality management and organizational learning principles and practices are essential for

successful advanced information technology implementation. This is because advanced information technologies like customer relationship management and enterprise resource planning are used to support process management [31] and will be increasingly used to support knowledge management. Thus principles, practices, frameworks, theories, methods and tools learnt in the last few decades from previous movements can surely be applied to ensure implementation success of these technologies. This paper has presented evidence to support the assertion that insights generated from the integration of quality management, organizational learning and information technology as illustrated in the framework presented in this paper could be used to explain if not improve IT-enabled enterprise integration success.

# Towards Integrated Document Management in Networked Product Development

**Hannu Laesvuori, Paavo Kotinurmi**

Software Business and Engineering Institute, Helsinki University of Technology, Finland  
{hannu.laesvuori, paavo.kotinurmi}@hut.fi

Product development (PD) in a network of collaborative companies is different from the traditional way of doing PD within single organization. Parallel way of doing PD increases the need for synchronization of PD activities, but the flow of design information in the company network is difficult to manage. There are indications that the automation of document management should improve the performance of networked PD projects. However, the dynamic nature of networked PD is an obstacle for this, as it requires such flexibility and speed from the setup and further maintenance of integrated document management that is currently unavailable. This article is a work-in-progress publication about research that seeks ways to reduce the setup time of integrated document management for a network of companies that collaborate on PD. This article reviews literature to create the basis for developing solutions to solve this problem, presents our suggestions, and define the following research steps in the road towards integrated document management in networked PD.

**Keywords:** Product development, Product data management, PDM, integration, e-business, RosettaNet

## 1. INTRODUCTION

From business process perspective, e-business means automation of business processes by using electronic networks [25]. Vital for the automation of business processes is to ensure that the different information systems participating in the business processes can communicate with each other. E-business frameworks such as Electronic Data Interchange (EDI) and RosettaNet are collections of standards that can be used to achieve interoperability between the different information systems participating in a business process, thus enabling their communication [16][19][22].

The most important business processes of an enterprise are typically order fulfilment and product development (PD) [10]. Enterprises have been automating their order fulfilment processes for a considerable time, and e-business framework support for order fulfilment process automation exist. The benefits, such as reduced order fulfilment process costs, have also been reported [17]. PD process automation has progressed slower, and the e-business framework support for PD process automation is partly inadequate [12][13].

Previous research indicates that many PD projects have significant shortcomings, such as poorly functioning engineering change (EC) management that could be substantially improved by automated document management [2][10]. Besides the reported e-business framework support shortcomings for PD process automation, one important reason that prevents the automation of PD processes is that PD projects cannot afford as much time for setting up and maintaining the process automation, as order fulfilment processes. In networked PD the formation of the network may change on every new PD project, and often also during the PD project. This temporary nature of PD projects is a

fundamental difference in comparison to order fulfilment processes, which are typically continuous [10].

In this paper, we proceed to define the methodology for our work-in-progress research to support EC process automation in PD projects by enabling fast setup and configuration of Product Data Management (PDM) systems integration. The integration of PDM systems facilitates the automation of design document management, which has been found important in EC management and networked PD [2]. We also provide background information for the relevance of the research objective, and the results of a literature review that we conducted at the early part of the research.

Rest of this article is organized as follows. In section 2, we discuss certain networked PD project characteristics, and what role e-business frameworks play in automating PD processes. Section 3 presents our literature review. In section 4, we define our research protocol and a suggestion for a solution to enable faster setup of automated document management in networked PD. Section 5 presents our concluding remarks.

## 2. BACKGROUND

### 2.1. Product development in company networks

Recently companies have started to do PD in company networks instead of within a single organization. This is partly due to the increasing outsourcing of PD activities, but also because the shortening life cycles of products in many industry sectors, such as consumer electronics has increased the demand to reduce PD project lead-times [2]. The shift to do PD collaboratively in company networks instead of within a single organization has created problems. Organizational boundaries reduce the

informal communication between people involved in the PD project, and doing PD activities in parallel creates a need to synchronize the PD activities between all companies in the PD project. In addition, with multiple companies involved, the PD project is now being done in a more heterogeneous environment than before [2]. For example, when doing PD within a single company the design data can be managed with the company's PDM system. In networked PD, the functionalities offered by PDM systems, such as version control management, are typically not available as the design data is distributed across several different PDM systems that cannot interoperate [13].

Eloranta et al. [10] argue that project oriented business processes, such as PD, could benefit from partially automated document management conventions, and that the economic potential of the approach could be considerable. They argue that information sharing is the common denominator of all project oriented business processes and that the use of electronic documents would facilitate the information sharing.

The need to improve information sharing in networked PD has been reported in a case study of product geometry changes in injection moulding company network [2]. In this company network, there was a client company that developed consumer electronics products that required demanding plastic components developed by several supplier companies. The impact of product geometry changes to the initially estimated lead-time of the projects varied from 140% to 257%. According to the case study, PD processes are driven by the exchange of design documents such as CAD-models and improvement in the design document exchange process could have substantially reduced the impact of the product geometry changes. Two sources of extra work were found: working with an out-dated version of a design document or the absence of a design document. The case study suggested that the automation of design information flow between the enterprises could ensure better controllability and performance of the PD projects.

## 2.2. Support for automated document management in PD networks

Despite the advantages of automated document management in PD projects, it is not a common practice in the industry although a proof-of-concept demonstration exists [13]. PD in company networks involves collaborating with multiple companies that may change each time a new PD project is started. Thus, heterogeneity of the involved information systems, such as PDM systems, is inevitable and a solution supporting automated document management in PD networks should be based on standards.

Kotinurmi et al. [12] argue that e-business frameworks are the standards that could support automated

document management in PD networks. Approaches such as point-to-point integration and portal were considered infeasible, as portals require more human involvement and the management of point-to-point integration is not feasible in a large company network. Kotinurmi et al. evaluated 15 different e-business frameworks based on their support for process integration, secure messaging, PDM related messages and industry usage. Based on the evaluation, RosettaNet was considered best suited to support automated document management in PD projects.

The most important part of the RosettaNet standard are the inter-company business process definitions called Partner Interface Processes (PIP). RosettaNet marks each PIP with maturity level information, and the highest maturity level has been assigned to several order fulfilment PIPs. PIPs for PD processes typically have a lower maturity level, and although the PIP category "Collaborative Design & Engineering" existed already in the beginning of year 2002, it still contains not even drafts [20]. This PIP category would likely contain the PIPs for enabling automated document management that are currently missing from RosettaNet [12]. Thus, even if RosettaNet is the best-suited e-business framework to support networked PD, it lacks process definitions to support it [13].

Case studies of RosettaNet implementations, such as the Arrows case study conducted by the Stanford University, suggest implementation times measured in months [20]. Indeed, even with mature vertical industry standards, it is necessary to agree with trading partners (TP) on how to use the standard, which can take considerable time [6]. An implementation time measured in months is clearly infeasible for a PD project that may last only a few months. It appears that networked PD requires different approach to the process automation implementation than has been used before.

## 3. LITERATURE REVIEW

This section presents our literature review process and the methodological background. We classify the key articles found in the literature review, and present a short summary of each.

Literature review was performed to find existing scientific knowledge on e-business architectures, PD information systems integration and the requirements for IT support in networked PD projects. Research was carried out according to the structured approach recommended by Webster and Watson [28].

The first step of literature review was performed by looking through the relevant top journals of Computer Science and Management Information Systems. Our choices were MIS Quarterly, Communications of the ACM, Computers in Industry, Production Planning & Control, Journal of Manufacturing Technology

Management (formerly Integrated Manufacturing Systems), Information Systems Research, Journal of Systems and Software, and Computer Standards & Interfaces. Due to recent upraise in e-business and business process automation, we examined the journals starting from year 2001. The full text of each article was reviewed in order to eliminate those articles that were not related to our research problem.

From the key articles found from the journals, we reviewed the citations for the articles. The key articles were also forward examined to find more articles for the review. Using these methods, we found a few more articles. In addition, we defined a set of keywords such as 'e-business architecture' and 'PDM integration'. Then we searched a number of electronic collections such as Science Direct, the ACM digital library, IEE Explore, Citeseer, Web of Science and Lecture Notes in Computer Science using the keywords for full text searches. This led to a discovery of few new articles relevant to our research. Validation was accomplished by comparing the articles we found against those we had found previously by unsystematically observing research publications on the field. The literature review had found all important articles and many new ones, 48 articles in total.

### 3.1 Fast collaborative network setup, research on virtual enterprises

The research on virtual enterprises (VE) and virtual organisations has covered issues related to integrating participating enterprise information systems within virtual enterprise partners. Virtual enterprise, defined as a network of autonomous firms that co-operate to achieve common business goals, has received considerable attention in the academic community [4][14]. Although multiple software architectures to support virtual enterprises have been defined, e.g. ones listed in [4][14][30], there are still many challenging issues requiring further research [4]. These include collaborative network support for setting up networks, operating them, and the evolution and dissolution of the network. In addition, definition of ICT infrastructures and identifying relevant standards that enable co-operation are needed. E-business frameworks are expected to have an impact on the development of support software for virtual organisations and other collaborative networks [5]. The use of Standard for the Exchange of Product model data (STEP) and Internet communication have also been proposed to support the data exchange between the different systems used at the different companies participating in the VE [30].

### 3.2 E-business architectures

Several publications present software architectures supporting e-business [1][3][4][7][14][16][23][24] utilizing XML. However, most of them are only suggestions without reporting experiences on

implementation and use. Only a few experience papers using modern XML-based e-business frameworks exist [18][19][21].

### 3.3 PD collaboration and PDM integration

Liu and Xu [15] state requirements for web-based PDM systems supporting collaboration. They propose web browser PDM interface as a solution. The modern PDM systems have web interfaces, but they differ in usage logic. This is why integration is needed also between participating systems. For PDM integration, agent-based systems have also been developed [27]

There are many collaboration infrastructures for PD collaboration based on the use of Common Object Request Broker Architecture (CORBA) and STEP [8][9][29][30]. The modelling capabilities distributed over the Internet using CORBA facilitate collaboration between product designers, and STEP provides the common terminology. These papers lack industrial validation, and most concentrate just on laboratory testing. The use of STEP in industry is limited, concentrating in geometry based applications.

## 4. RESEARCH PROTOCOL

In a research project conducted at Helsinki University of Technology, we are trying to improve the performance of engineering change (EC) processes in networked PD. A key element in this is to use standard, automated inter-company processes between the members of the PD network. We have identified two obstacles for this: 1) standard process definitions for inter-company engineering change management do not exist 2) current approaches to achieve systems integration are too slow. The two obstacles are inter-connected, as the process definitions and their use set requirements for the systems integration needed to enable them. We are working on the process definitions and currently they are based on a case study of two separate PD networks.

In this paper, we define the methodology for our work-in-progress research to address the second obstacle, i.e. how to setup integrated document management for new, networked PD projects, in a short time.

The rest of this section is organized as follows. First we give a brief overview of the design research methodology on which our research protocol is based. Then, we proceed to identify how the different design research phases relate to our research.

### 4.1. Design research

Our research approach is based on the design research methodology [11]. Design research views the creation of new knowledge as a loop, as illustrated in figure 1. The loop starts from awareness of a problem, followed by a suggestion how to solve it. The suggestion is then

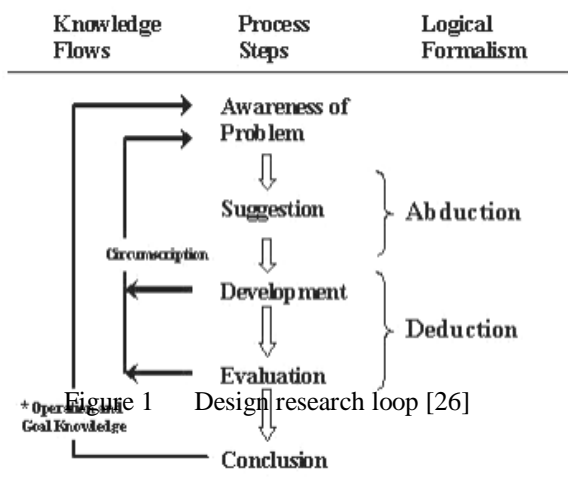

developed, and the result is a new artifact. The artifact is then applied to the problem, and the results are evaluated. If the artifact solved the problem, the conclusions present new knowledge that can be used on subsequent research. If it did not solve the problem, a new suggestion, development and evaluation follow.

In design research, the suggestion is usually done intuitively, but it must always be novel and innovative, either solving a new problem or solving an old problem in a more effective way than previously. Moreover, the created artifact must always be clearly defined, evaluated and reported [11] [26].

The position of our research in the design research loop is currently in the initial stage of development. We are now aware of the problem and have a high-level suggestion on how it might be solved. We expect that the development work will proceed iteratively together with a more detailed solution suggestion.

#### 4.2. Awareness of the problem

In our case, the design research loop started with the awareness of the research problem through talks with several industry experts in previous PD related research projects. Next, we reviewed existing knowledge by conducting a literature review to confirm that we are facing a new and valid research objective. The results of the literature review, and the commitment from the companies represented by the industry experts to

participate in the research, convinced us that we are facing a real research problem.

#### 4.3. Suggestion

The project-oriented nature of networked PD would require repeatable systems integration work, if done in the traditional way. Because of the inevitable ambiguity of standard specifications and how different individuals understand them, and the diverse needs of companies using the standards, PDM systems integration using e-business frameworks will likely continue to consume considerable time in the near future [6][13][20].

In our opinion a solution to support fast setup of systems integration might be based on the concept of reusing past systems integration work between different PD projects. This seems feasible, as networked PD is usually done within fairly small and stable network of companies, with only the roles and project teams changing frequently. Thus, only the first systems integration work between two TPs collaborating in networked PD would require considerable time. Systems integration work for subsequent networked PD projects between the two TPs would be small.

The limited size of the network and relative stability of the partnerships in networked PD, is different from the requirements for VEs. However, there are still many commonalities between the requirements for networked PD and VE, so the research for VE might be used in our research.

#### 4.4 Development

We are now in the early phase of the development of an artifact to enable fast integration of PDM systems in networked PD. The artifact will consist of a concept, a software tool, supporting software architecture and a management process.

The reuse of past systems integration work between two TPs in future networked PD projects would in our opinion require dividing the parameters of PDM systems integration in two groups: PD-project related parameters and TP related parameters. For example, parameters such as 'Document Type' that derive from the PDM systems that the TPs use, or IP-addresses required for data exchange are likely to remain same in all networked PD projects between the two TPs. However, parameters, such as project identifiers and contact persons for exceptional situations, typically change on every project.

These two groups of parameters must be defined, as not only is their speed of change different but typically they are controlled by different parties. For example, the TP related parameters may be controlled by people with technical background who are responsible for the IT infrastructure of the company. The project related parameters, however, may be controlled by a project manager in a PD group. People with different backgrounds may require different software tools, or at least user-interfaces, for managing the parameters. Moreover, if the people reside in different divisions of the company, it may be an obstacle for the information flow between them.

Previously these two groups of parameters have been treated as one. B2B integration architectures such as the one presented by [3] recognize the need for TP management, but not for project data management. In our experience, the software tools for configuring systems integration parameters are suited for

configuring TP parameters, but not for project related parameters.

#### 4.5 Evaluation and conclusions

The artifact will be iteratively designed and evaluated by an industrial focus group. Once this preliminary validation has been achieved, the adoption of the artifact by industry would bring stronger market validation. The artifact and results of the evaluation will be reported publicly, and evaluated against the other related research we found during the literature review.

#### 5. CONCLUDING REMARKS

Previous research indicates that engineering change (EC) management in a network of companies collaborating on product development (PD) is often functioning poorly. Automation of design document exchange process between the companies could offer considerable potential for savings, but it has been found difficult. The use of e-business frameworks, particularly RosettaNet, in the automation of the design document exchange process has been suggested.

In this paper, we argue that there are two obstacles for using RosettaNet in the integration of the design document exchange process: unsuitable or missing process definitions for EC management, and typical implementation times that are too long for networked PD.

We define the methodology for work-in-progress research to seek ways to reduce the setup time of automated document management for a network of companies collaborating on PD. Our approach is to introduce basis for reuse in systems integration work, so that subsequent PD projects between two trading partners could benefit from past integration work.

The contributions of this article are the definition of the research objectives, the methodology for solving it, a potential solution suggestion and the literature review.

The literature review indicated that project oriented business processes, such as PD, would benefit from increased integration, but that e-business frameworks have not been previously specifically discussed within PD needs as older standards such as STEP and CORBA have dominated the research applications. We have found previous research that can be compared to our approach, and can aid to position our research in relation to other research on the subject.

# Transaction Governance Structures of Brick-and-Mortar and Click-and-Order: An Instrument Design Study

Aimao Zhang

Department of Information Technology, Georgia Southern University, P. O. Box 8150, Statesboro, GA  
30460-8150, USA {aimao}@georgiasouthern.edu

## ABSTRACT

Since the inception of the construct of transaction governance structure (TGS), transaction cost economics (TCE) has become an important anchor for the analysis of a wide range of economic and organizational issues. As theory of TCE advances, the perception of TGS has shifted from a polar classification (market/hierarchy) towards a continuum of market-hierarchy [17][20]. Despite the development in conceptual framework, empirical work based on the idea of the market-hierarchy continuum is scarce. Part of the difficulty is the lack of clear defined and operational dimensions of TGS. Although dimensionalization of transaction has received early and explicitly attention, the dimensionalization of TGS is relatively limited. This paper is an initial effort in instrument building. In this paper, we will (1) review the literature on TGS, (2) survey 40 empirical studies from 1982 to 2002, (3) present dimensions of TGS based on Williamson's work of 1991, (4) run a preliminary test to compare TGSs of brick-and-mortar and click-and-order.

**Keywords:** Transaction governance structure, industrial economics, contract law, e-commerce.

## 1. INTRODUCTION

In the recent years, we have observed the broad shifts of TGS in the United States such as a large-scale integration among banks, security firms, and insurance companies [34] and a continuous migration toward market TGS in the computer industry in which component manufacturers are replacing fully-integrated computer manufacturers [23]. This confusing landscape of TGS changes raises questions about reasons for the TGS shift, the nature of the new TGSs, and the influential factors in designing and selecting a TGS. At the macro level, the answer to these questions will help policy makers in developing economic and governmental policies. At the micro level, the answer to these questions will help company managers to make decisions regarding TGS, such as what to buy, where to buy, or how to buy.

The fundamental construct for answering these questions is TGS. Since the inception of the construct of transaction governance structure (TGS), transaction cost economics (TCE) has become an important anchor for the analysis of a wide range of economic and organizational issues. As theory of TCE advances, the perception of TGS has shifted from a polar classification (market/hierarchy) towards a continuum of market-hierarchy [17][20]. Despite the development in conceptual framework, empirical work based on the idea of the market-hierarchy continuum is scarce. Part of the difficulty is the lack of clear defined and operational dimensions of TGS. Although dimensionalization of transaction has received early and explicitly attention, the dimensionalization of TGS is relatively limited. This paper is an initial effort in instrument building. The organization of the paper is as follows. Section 1 is an introduction. Section 2 reviews the literature on TGS. Section 3 surveys 40 empirical

studies from 1982 to 2002. Section 4 presents dimensions of TGS based on Williamson's work of 1991. Section 5 runs a preliminary test to compare TGSs of brick-and-mortar and click-and-order. Section 6 is a conclusion.

## 2. LITERATURE REVIEW

### 2.1 Transaction Cost Economics (TCE)

The construct of TGS is defined as the structure that mediates exchanges of goods or services between technology separable entities—businesses, subdivisions of a business, or individual buyers and sellers [46][47]. Ring and Van de Ven further defined TGS as “the legal forms of governance that apply to different kinds of transactions (ranging from markets to hierarchies), and the structural and procedural safeguards that parties negotiate into a transaction” [38]. Traditional TCE perceives TGS from a dichotomous view in which market and hierarchy are mutually exclusive [11][47]. At one end lie purely market-based TGSs, in which price is the invisible hand that mediates supply and demand [40]. At the other end, one finds purely hierarchical TGS, in which a central authority controls and allocates resources [9]. Typically, attempts to explain the selection of a TGS for a particular good or service have been based on comparisons between market and hierarchy transaction costs [11][46][47]. Generally speaking, when asset specificity of a transaction is low, market TGS is more economical and preferable. When asset specificity is high, hierarchy has the advantage of lower governance costs. A substantial amount of research has produced results consistent with transaction cost theory [4][26][27][42][44].

## 2.2 Network

TEC rests on the premise that market and hierarchy are mutually exclusive. Powell [35] does not agree with this premise or the concept of a market-hierarchy continuum, which is suggested by John and Reve [20]. Powell describes the network as the third independent form of governance structure. Ouchi [30] claims that price, rule, and trust are control mechanisms for markets, hierarchies, and networks, respectively. Bradach and Eccles [7] argue that three control mechanisms (price, authority, and trust) can be combined in a variety of ways under each structure, e.g., price and authority mechanisms under a market structure or a price and authority combination in a hierarchy.

## 3. REVIEW OF 40 EMPIRICAL STUDIES 1982-2002

This paper reported 40 empirical studies on TGS from 1982 to 2002. These studies had examined the construct of TGS either as an independent variable or a dependent variable. The review of these studies was focused on the dimensionalization of TGS and the type of instrument developed (see Table 1, available from the author upon request).

The majority of studies in 1980's perceived TGS as dichotomous and developed single-dimension and single-item scales [1][2][3][4][43][44][27]. These dichotomous single-dimension and single-item scales used 1 and 0 to record the decisions such as buy or make, integrate or not integrate, use internal work force or use external agents. Following that, some multichotomous scales were developed [5][15][21][22]. These multichotomous single-dimension and single-item scales measured TGSs into discrete categories (market, joint venture, partner relationships, hierarchy) along the market-hierarchy continuum. In 1990's, as the perception of TGS shifted from a polar classification (market/hierarchy) towards a continuum of market-hierarchy, multi-dimensional and multi-items instruments were developed to incorporate the variety of cooperative relationships [8][17][19][20][18][29][32][33]. Table 1 categorized the 40 empirical studies into groups according to the types of scale used.

There were two interesting trends among the multi-dimensional instruments. First, several multi-dimensional instruments captured the dimensions of formalization, centralization, flexibility and control [8][19][20]. Such dimensionalization gave a flavor of organization theory from Pugh who provided the theoretical framework for study organization structure [36][37]. According to Pugh and others, "six primary dimensions of organization structure were defined: (1) specialization, (2) standardization, (3) formalization, (4) centralization, (5) configuration, (6) flexibility" [37].

Secondly, dimensions of information exchange and interaction started to appear in middle 80's [18][29][31][32][33]. This trend was coincided with the time period when global competition intensified, firms moved towards flatter and more horizontal structures, and management emphasized cooperation rather than competition among self-managed teams and among inter-organization alliances [12]. In the same time period, we had seen the new research streams in managing dynamic processes [14], social network analysis [35], and information processing and conflict management [10][28].

## 4. DIMENSIONS OF TGS

### 4.1 Williamson's Framework

There was no consistence on the dimensions of TGS among the previous studies. Different scholars emphasized different dimensions of the construct. In defining dimensions of TGS, this study is going to follow the dimensionalization framework put forward by Williamson [45]. Williamson's framework was a recent contribution to TCE studies, and it incorporated dimensions of TGSs arrayed on the entire range of the market-hierarchy continuum. Williamson identified the key dimensions that differentiate three generic forms of TGS (market, hybrid, hierarchy). These dimensions are incentive, control mechanisms, adaptabilities, and types of contract law. The incentive is the degree of the price acting as an incentive to trigger and control actions. Administrative controls are the level of control and manipulative power gained through monitoring, career rewards, and penalties. Adaptation (A) is the ability to take the right actions to adapt to the new equilibrium whenever there are changes in the demand or in supply. Producers and buyers independently and autonomously response to the price changes to maximize their profits. Adaptation (C) is the ability to coordinate among interdependent parties to align with a collective goal. According to Williamson [45], firms, hybrid, and hierarchy are governed under different laws—classical contract law, neoclassical contract law, and forbearance respectively. The role of court becomes less important from classic to neoclassic to forbearance law. Table 2 (available from the author upon request) exhibits how market, hybrid, hierarchy are different along these dimensions.

### 4.2 Fit the 40 studies into William's Framework

In Table 3, the existing dimensions from 40 empirical studies were assigned into the five dimensions defined by Williamson. Although the assignments were subjective and crude, this exercise was helpful in mapping relationships and identifying the dimension that needed further development. As you can see from Table 3, the incentive dimension was underdeveloped. There was limited number of item designed for identifying suppliers' or buyers' price sensitivity or

readiness of adjusting quantity when price and demand fluctuated.

**Table 3. Assignment Of The Existing Dimensions Into Williamson's Framework**

Incentive through price <ul style="list-style-type: none"> <li>• Exclusivity [8]</li> <li>• Pattern of payoffs [32]</li> </ul>
Administrative control <ul style="list-style-type: none"> <li>• Monitoring [41]</li> <li>• Buyer's control over supplier decision making [17]</li> <li>• Centralization [21]</li> <li>• Centralization [20]</li> <li>• Centralization [19]</li> <li>• Control [19]</li> <li>• Financial incentives [8]</li> <li>• Monitoring of supplier [29]</li> <li>• Operating controls [33]</li> </ul>
Adaptation (A) <ul style="list-style-type: none"> <li>• Replaceability of commission income [17]</li> <li>• Exit costs [40-A]</li> <li>• Exit barriers [8]</li> <li>• Restraint in the use of power [18]</li> </ul>
Adaptation (C) <ul style="list-style-type: none"> <li>• Collaboration [40A]</li> <li>• Collaborative interaction [40-A]</li> <li>• Joint action [17]</li> <li>• Interactions [20]</li> <li>• Behavioral transparency [32]</li> <li>• Frequency of interaction [32]</li> <li>• Flexibility [18]</li> <li>• Information exchange [18]</li> <li>• Shared problem solving [18]</li> <li>• Supplier flexibility [29]</li> <li>• Supplier assistances [29]</li> <li>• Information provided to supplier [29]</li> <li>• Exchange information [33]</li> <li>• Sharing benefit TGS and burdens [33]</li> <li>• Adaptation [31]</li> <li>• Types of adjustments [31]</li> <li>• Information exchange for long-term planning [31]</li> <li>• Information exchange for structural planning [31]</li> </ul>
Contract law <ul style="list-style-type: none"> <li>• Buyer's and supplier's commitment to the relationship [4A]</li> <li>• Formalization [21]</li> <li>• Expectations of continuity [17]</li> <li>• Formalization [20]</li> <li>• Formalization [19]</li> <li>• Formality [8]</li> <li>• Time horizon [32]</li> <li>• Expectation of continuity [29]</li> <li>• Contractual focus [33]</li> <li>• Relationship focus [33]</li> <li>• Method of enforcement [31]</li> </ul>

## 5. A PRELIMINARY TEST

### 5.1 Instrument development and test

The emergence of e-commerce has provided a variety of choices of TGS such as online exchanges, distributor consortia, supply chain networks, auction, and mass catalog compilers [6]. TEC can help us answer the questions of what product is suitable for E-commerce (digital or tangible products), where to buy (brick-and-mortar or click-and-order), or how to buy (auction or private network). In this study, we will conduct a preliminary test on TGSs of brick-and-mortar and click-and-order.

A panel of expert has generated 24 items (see Table 4) along the five dimensions recommended by Williamson [45]. All items were presented with 5-point Likert scale ranging from "strongly disagree" to "strongly agree". Each item is applied to "online" and "offline" separately and respondents checked their level agreement accordingly. One dependent variable was coded 0 for online and 1 for offline, and five independent variables were summated scales of five dimensions. Each summated scale equaled to the average of measurements of all items of the same dimension. The respondents were college students. Out of all respondents, 20% had shopped online at least 5 times, 30% had shopped online at least 10 times, and 50% has shopped online at least 20 or more times. The sample of 124 was divided into an analysis sample of 102 observations with the remaining 22 observations constituting the holdout or validation sample.

### 5.2 Result

We performed logistic regression on the data set based on the equation below [16].

$$p(y = 1 | x) = \frac{e^{ax+c}}{1 + e^{ax+c}} \quad (1)$$

Where:

$ax = a_1x_1 + a_2x_2 + a_3x_3 + a_4x_4 + a_5x_5$ ;

$e$  is the base of natural logarithms;

$y$  is dependent variable (0, 1);

$x_1, x_2, x_3, x_4, x_5$  is summated variables representing incentive, administrative control, adaptation(A), adaptation(C), contract law respectively.

$a_1, a_2, a_3, a_4, a_5$  were obtained from regressing result (Table 5, available from the author upon request). Thus  $ax = .187x_1 + 2.503x_2 + 1.799x_3 + .692x_4 + 1.349x_5 - 19.297$ .

**Table 4. Items For Comparing TGSs Of Brick-And-Mortar And Click-And-Order**

Incentive
• There is a big price discrepancy among the same type of products offered by different sellers.
• I do a lot of price comparison among different sellers when I'm shopping. *

Administrative control
<ul style="list-style-type: none"> <li>• A seller has influence over a buyer's decision-making.</li> <li>• A buyer has influence over a seller's decision-making.</li> <li>• A seller does not know very much about you as a buyer.*</li> <li>• You as a buyer do not know very much about a seller.*</li> <li>• A seller can monitor your shopping behaviors.</li> <li>• A seller can manipulate your shopping behaviors.</li> <li>• It is easy for a seller to cheat and misrepresent a product.*</li> </ul>
Adaptation (A)
<ul style="list-style-type: none"> <li>• A seller adjusts his price and production quantity according to demand.*</li> <li>• Fluctuation of market demand has little impact on price.</li> <li>• There are many suppliers making the same or similar products.*</li> <li>• The goal of a seller is to maximize his profit regardless of loss of gain of any other players.*</li> <li>• The goal of a buyer is to minimize his cost regardless of loss of gain of any other players.*</li> <li>• It is easy to become a seller in terms of initial investment and market entry cost.*</li> </ul>
Adaptation (C)
<ul style="list-style-type: none"> <li>• Negotiations or discussion between a buyer and a seller is required to complete a transaction.</li> <li>• Explicit communication is required to coordinate activities among sellers and buyers.</li> <li>• A seller and a buyer usually settle a problem by cooperation and negotiation.</li> <li>• I would negotiate and cooperate with a seller.</li> </ul>
Contract law
<ul style="list-style-type: none"> <li>• A supplier and a buyer usually go to a court to settle a dispute.*</li> <li>• A supplier and a buyer usually settle a dispute through discussions, meetings, or arbitration.</li> <li>• A seller usually has to obey the rules and laws set up by a local community.</li> </ul>
* Reserved.

Hosmer and Lemeshow test measured the correspondence of the actual and predicted values of the dependent variable. A better fit would be indicated by a smaller difference in the observed and predicted classification or by a non-significant chi-square value. Our chi-square value was 10.093, which was not significant because  $p=0.259$ . Table 6(available from the author upon request) presented the classification result. In the analysis sample, 74% percent of cases were predicted correctly. In the holdout sample, 63% of cases were predicted correctly.

## 6. CONCLUSION

In summary, perception of TGS advanced from dichotomous to continuous [17][20], from single dimension to multiple dimension [29], from local focus of by-or-make decision [43] to global discussion of international alliances [21][22]. We also observed the influence from other disciplines on TCE, such as organization theory [16A] and information theory [13].

“Big ideas often take a long time to take on definition. Thirty-five years passed between Coase's 1937 article

and efforts to operationalize transaction costs in the early 1970's (Williamson, 2000. pp.31)” by [46] and another twenty years passed before Williamson dimensionalized the construct of TGS [45]. The previous theoretical and empirical works have laid a solid foundation for us to bring the research forward. The future research is to conduct empirical studies to verify the construct of TGS, to apply TEC in analyzing the whole range of cooperative relationships, to move TEC beyond traditional commerce into e-commerce.

## A Study on Design Process Integration between Marketing and R&D of Notebook

Linglang Tang, Yubin Chiu, Hungsheng Lin

Graduate School of Management Yuan Ze University Taiwan, China  
balltang@saturn.yzu.edu.tw

### ABSTRACT

This study focuses on building a framework which calculates the weights of FAHP (Fuzzy Analytical Hierarchical Process) method, then integrates the analysis tools such as FQFD (Fuzzy Quality Function Development) and FFMEA (Fuzzy Failure Mode and Effects Analysis) into the framework to construct a two-phase product specifications evaluation process. Therefore, this study builds a framework and process of the new product specification evaluation which integrates the marketing attributes (the evaluation of the customers' demands), research attributes and development attributes and manufacture attributes (the evaluation of the failures and defects of the product specifications). It allows the product specifications which are produced by brainstorming to be proceeded the evaluation before the prototype test phase and find the optimum product specification. It also can further the companies to optimize the organization resources. This research focuses on not only determining, but also transferring the market attributes to the product R&D specification in order to realize the relationship between the consumers' demands and the product specification. According to the methodologies represented, this study attempts to fill the gap in the literature by providing an integrative research framework and offers this framework to contribute the tasks and operations in the initial phase of the new product development and build the framework of multidimensional product specifications evaluation. Finally, an example of Notebook is used to illustrate the proposed approach.

**Keywords:** Marketing attributes, Fuzzy theory, AHP (Analytical Hierarchical Process), QFD (Quality Function Development), FMEA (Failure Mode and Effects Analysis), FQFD (Fuzzy Quality Function Development)

### 1. INTRODUCTION

Due to the increasing and more diversification of the consumers' demands for Notebook product, it offers an opportunity which the OEM/ODM Notebook companies transfer to OBM (Own Branding & Manufacturing) companies through building own brand. Besides, it also can develop new business model and business profits. The related literatures about the product design concepts which focus on the demands of consumer are always refer to QFD (Quality Function Deployment). QFD is a structured approach to ensure customers' demands to be satisfied and transform into the product design and development process. And it can contribute to increase in customer satisfaction and shorten product design and development time. However, existing QFD implementations have limitations. Two main problems are summarized as follows:

1. QFD unable to evaluate and integrate the possible problems in advance during the design and manufacture period of product development.
2. In the evaluation process, experts often exhibit some forms which are often vagueness and uncertainty and hinder the experts' description of conceptual phenomena.

For this reasons, the main objective of this paper is to build a framework and process of the new product specification evaluation which integrates the marketing attributes (the evaluation of the customers' demands), research and development attributes and manufacture attributes (the evaluation of the failures and defects of

the product specifications). It can allow the product specifications which are produced by brainstorming to be proceeded the evaluation before the prototype test phase and find the optimum product specification. It also can further the companies to optimize the organization resources.

Through the framework of two-phase product specifications evaluation is represented. Firstly, it performs FAHP (Fuzzy Analytical Hierarchical Process) to collect marketing experts with regard to authority evaluation of demands of customer and integrates it into FQFD (Fuzzy Quality Function Development) to proceed first phase evaluation of 「the degree of the consumers' satisfaction」. Secondly, to collect the evaluation of FFMEA (Fuzzy Failure Mode and Effects Analysis) of the design and manufacture experts about the product specifications which is allowed into the second phase and integrate it into FQFD to proceed second phase evaluation of 「the degree of the assembly manufactured」. Finally, it is able to find the optimum product specifications and allow it into the prototype test phase.

According to the methodologies represented by the paper, this study attempts to fill the gap in the literature by providing an integrative research framework and offers this framework to contribute the tasks and operations in the initial phase of the new product R&D and build the framework of multidimensional product specifications evaluation. Finally, an example of

Notebook is used to illustrate the proposed approach.

## 2. LITERATURE REVIEW

### 2.1 The marketing attributes

Sung et al.[10] showed 48 dimensions of usability were identified, which were classified into two groups based on the new definition of usability. The first group includes performance dimensions that could be used to explain the performance side of the usability concept. The second one consists of image/impression dimensions that are related to the image and impression of the product perceived by the users. Besides, aesthetic attributes are evaluated concurrently with analytically obtained objective attributes of the product's characteristics. The interaction of these aesthetic and objective attributes, as it relates to the product's utility and manufacturing cost, is clarified [14]. Sethi [8] indicated new product quality has been found to have a major influence on the market success and profitability of a new product. His research founded that quality is positively influence on the product development process, and quality orientation in the firm. But, moreover, the results showed product innovativeness has a negative effect on quality. And functional diversity and time pressure have no effect on new product quality. The relationship between information integration and new product quality is weakened by quality orientation in the firm. Information integration mitigates the negative effect of product innovativeness on quality.

Based on the above, this study is purported to classify and form the marketing attributes of Notebook. Consequently, the definition of the marketing attributes for Notebook product will be proposed. It is composed of the quality of product performance, the dimension of image/impression, and the dimension of price. The three dimensions will be discussed later.

### 2.2 AHP and FAHP

Saaty [7] showed the Analytic Hierarchy Process (AHP) that is known as an additive pair wise weights identification method. AHP is often applied to find the relative weighting of each criterion.

Nevertheless, there are many researches, which pointed out that the assumption of AHP may cause the evaluation results departure from the experts' opinions. Therefore, there are many researchers using FAHP (Fuzzy Analytical Hierarchical Process) to resolve the problem. Laarhoved and Pedrycz [5] used Fuzzy Sets Theory and Fuzzy Arithmetic. Buckley, Feuring and Hayashi [1] indicated that a new method of finding the fuzzy weights in fuzzy hierarchical analysis which is the direct fuzzification of the original method used by Saaty[7] in the analytic hierarchy process is presented. Fuzzy number is introduced in the pairwise comparison of AHP by Kwong and Bai [4]. An AHP based on fuzzy

scales is proposed to determine the importance weights of customer requirements. They founded the new approach can improve the imprecise ranking of customer requirements which is based on the conventional AHP.

### 2.3 Failure Mode and Effects Analysis, FMEA

Thomas [11] pointed out that FMEA method could examine all potential causes or modes of failure, of critical processes and of methods designed to prevent failure of those processes. That is, FMEA examines all potential causes or modes of failure, of critical processes and of methods designed to prevent failure of those processes. Sharon [9] showed how key aspects of quality function deployment (QFD) and failure mode and effects analysis (FMEA) can be used in product and service development at a strategic level rather than in traditional engineering applications.

Pillay and Wang [6] evaluated the risk analysis tool FMEA assumes a failure mode, which occurs in a system/component through some failure mechanism; the effect of this failure is then evaluated. They described a risk ranking is produced in order to prioritize the attention for each of the failure modes identified. The traditional method utilizes the risk priority number (RPN) ranking system. This method determines the RPN by finding the multiplication of factor scores.

### 2.4 Fuzzy QFD

Yang et al.[13] presented the findings of a research effort to adapt House of Quality (HOQ) to meet the needs of buildable designs in the construction industry and to develop a fuzzy QFD system. They thought the differences between the proposed fuzzy QFD system and the traditional QFD methodology is that the QFD-relevant data are expressed and represented as linguistic terms rather than as crisp numbers, and the linguistic data is processed by algorithms embedded in the system's internal environment [13]. Chen et al. [2] determined the revised priority of the customer demands using a fuzzy logic inference because many tools did not offer specific methods to determine a revised priority for product redesign.

We transfer the market attributes to the product R&D specification in order to realize the relationship between the consumers' demands and the product specification.

## 3. METHODOLOGY

### 3.1 Marketing attributes of Notebook

Based on the literature review, we provide a definition of the marketing attribute for Notebook product, which is composed of the quality of product performance, image/impression, and price.

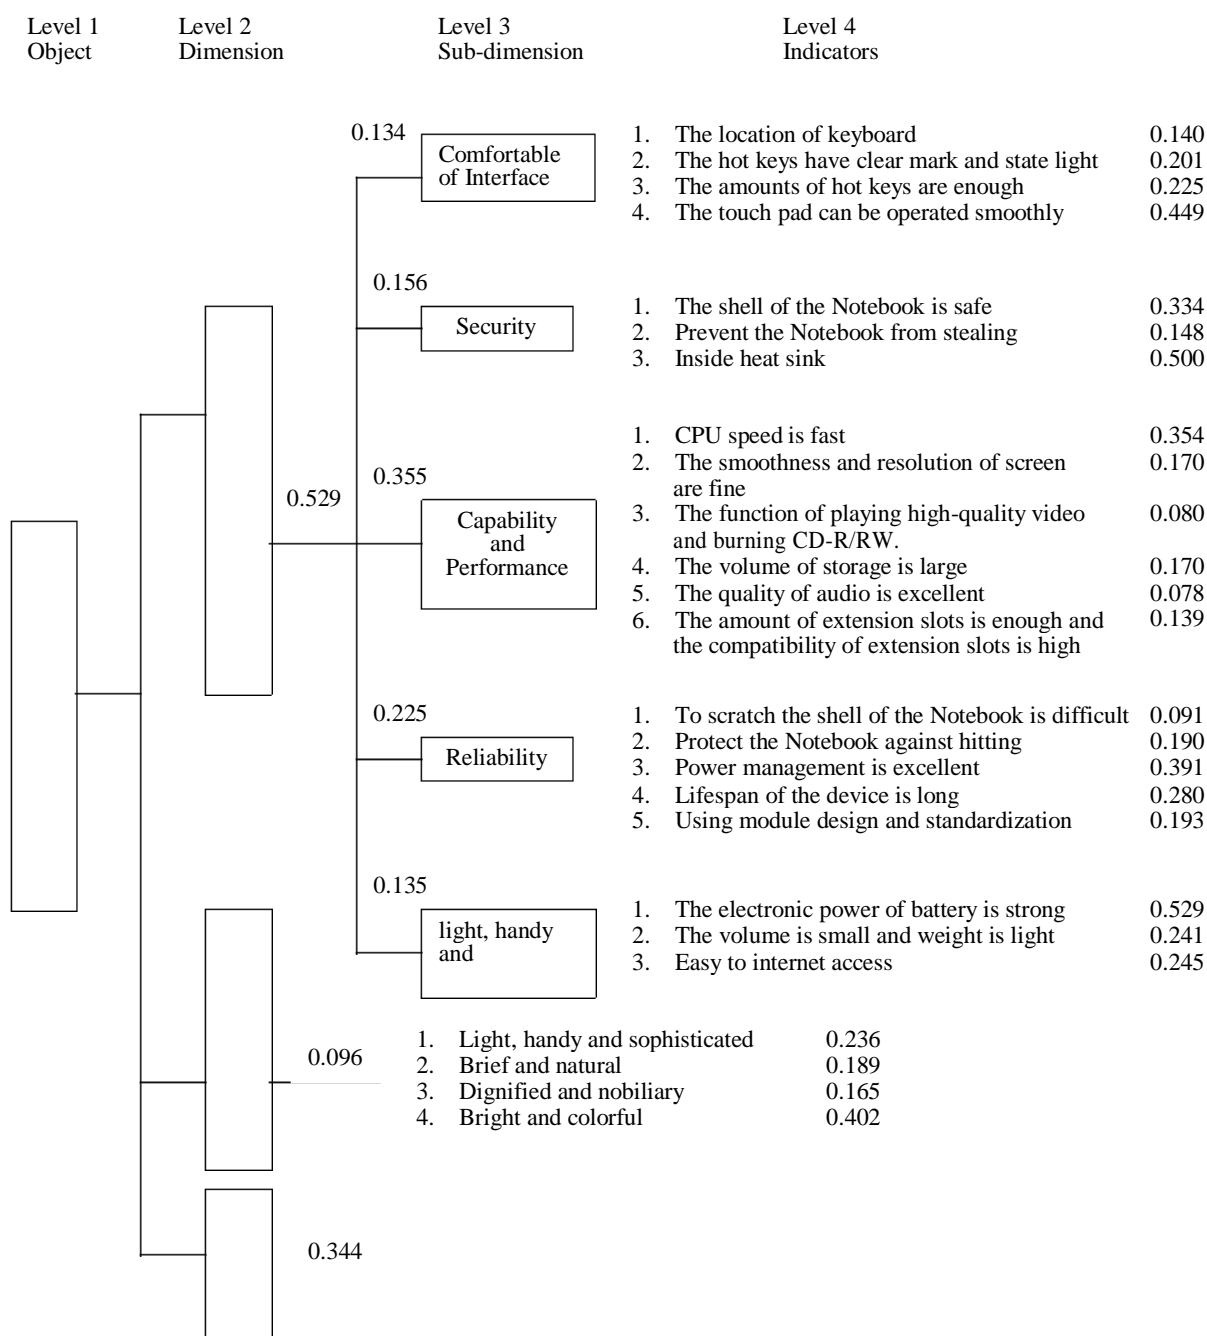

Figure 1 The weights of the marketing attributes

### 3.1.1 The quality of product performance

According to the researches made by Garvin[3] and Sethi[8]? Sung *et al.*[10] we defines the quality of product performances such as ? comfortable of interface?, ? security?, ? capability and performance? , 「reliability」 and? light, handy and convenient? .

### 3.1.2 The dimension of image/impression

Yamakawa *et al.* [12] indicated aesthetic attributes are very important while designing new product except high product performance and quality.  
In order to develop the items of image/impression

dimension in the Notebook market, study results from related areas were examined. This study follows the example of Sung *et al.*[10] to proceed extensive literature survey and find out the similes or metaphoric expressions to describe the image of the consumer Notebook products and various expressions about subjective feelings toward them. Also the experts and consumers opinions were collected, furthermore, the principal concepts used in the product design department were studied. Finally, we define the dimension of image/impression for Notebook products.

### 3.2 The integration of analysis methods

In order to complete the new product specification

evaluation, firstly, we use FAHP method to collect marketing experts with regard to authority evaluation of demands of customers, and integrates it into FQFD to proceed first phase evaluation of 「the degree of the consumers' satisfaction」. Secondly, to collect the evaluation of FFMEA of the design and manufacture experts about the product specifications and integrate it into FQFD to proceed second phase evaluation of 「the degree of the assembly manufactured」. Thus, we could find the optimum product specifications and allow it into the prototype test phase through the framework of two-phase product specifications evaluation.

This study defines the evaluation rules of consumer satisfaction and assembly manufactured scores. The first phase evaluation of 「the degree of the consumers' satisfaction」 would be accomplished. The score of consumers' satisfaction in the first stage should not be under five points, otherwise it will be eliminated or corrected its specification. The equations (1) and (2) are listed below.

$$CS_i^k = (\sum_{j=1}^n \bar{E}_j^k \times \bar{R}_{ij}) \times C_i \quad 1 \leq i \leq m \quad (1)$$

$$CS^k = \sum_{i=1}^m CS_i^k \quad 1 \leq i \leq m \quad (2)$$

$\bar{CS}_i^k$  : the i item satisfaction of product k

$\bar{E}_j^k$  : the j item specification degree of product k

$\bar{R}_{ij}$  : standardization triangular fuzzy membership number of the i marketing attribute item and j specification item

$C_i$  : the weights of the i marketing attribute item

$CS_i^k$  : the total satisfaction of product k

According to the data evaluated at the first phase, we could proceed the second phase, named evaluation of 「the degree of the assembly manufactured」. IF the result is not under five points, the product prototype can proceed pilot runs, otherwise it will be eliminated or corrected its specification. The equations needed (3) and (4) are listed below.

$$AD_i^k = (\sum_{j=1}^n \bar{E}_j^k \times \bar{R}_{ij} \times \bar{F}_j^k) \times C_i \quad 1 \leq i \leq m \quad (3)$$

$$AD^k = \sum_{i=1}^m AD_i^k \quad (4)$$

$\bar{AD}_i^k$  : the i item assembly manufactured degree of product k

$AD^k$  : the total assembly manufactured degree of product k

#### 4. EXAMPLE OF NEW PRODUCT SPECIFICATION EVALUATION

##### 4.1 The weights of FAHP analysis for the marketing attributes

This study found six marketing experts to proceed the FAHP analysis about the multimedia entertainment style Notebook. The result is showed as Figure 1 (See Figure 1 for the weights of the marketing attributes). It indicates the most important dimension is the quality of product performance (0.529). In the next place, the price (0.344) dimension will be considered. The last one is 0.344 for the image/impression dimension. Furthermore, the sub-dimension named Capability and Performance is the most important, it got 0.355 points. So we may see the development direction in the future from the data.

##### 4.2 The FQFD analysis for the marketing attributes and product R&D specifications

In order to transfer the market attributes to the product R&D specification, the FQFD method was proceeded. Six professional specialist in the R&D and assembly manufactured area participated the analysis process.

##### 4.3 The first phase evaluation of 「the degree of the consumers' satisfaction」

Through survey of Notebook consumers, we got the comparison result of consumers' satisfaction and assembly manufactured between two kinds of products, and the table is presented as follows (See Table 1 for result). According to the data, the satisfaction score of product A is 5.598 and B is 5.682, so, these two kinds of products could proceed the second phase, the evaluation of 「the degree of the assembly manufactured」 because the satisfaction scores both these two products get are more than 5 points.

##### 4.4 The possible problems evaluation in R&D and assembly manufactured

To find out the possible problems of these two kinds of products, six professional specialists in the R&D and assembly manufactured area participated the FFMEA analysis process. They transferred the possible problems in different conditions to the FRPN (Fuzzy Risk Priority Number). The FRPN value is between 1 to 9. The higher the score, the more serious the problem. And table 2 illustrates the weighting of problems in two kinds of products.

##### 4.5 The second phase evaluation of 「the degree of the assembly manufactured」

Finally, we integrate the FRPN of each possible problem into the specification to proceed second phase evaluation of 「the degree of the assembly manufactured」. As table 1 shows, the degree of the assembly manufactured for product A is 4.964 and B is 5.135. It illustrates that product A should be corrected in

some specifications, even its satisfaction score is 5.598 there are still problems. Product B could proceed pilot runs. On the other hand, the total gap of satisfaction between A and B is 0.085 (1.5%), but the total gap of Assembly manufactured between A and B is 0.172 (3.5%). It conspicuously increases.

## 5. CONCLUSIONS AND SUGGESTIONS

The conclusions of this study are as follows:

According to the methodologies represented, this study attempts to fill the gap in the literature by providing an integrative research framework and offers this framework to contribute the tasks and operations in the initial phase of the new product development and build the framework of multidimensional product specifications evaluation. Besides, we provide a methodology to integrate the FAHP, FQFD and FFMEA methods. So, through considering the consumers' demands and the new product specification evaluation, companies could integrate the opinions of different departments.

This research focuses on not only determining, but also transferring the market attributes to the product R&D specification in order to realize the relationship between the consumers' demands and the product specification so that it can further the companies to optimize the organization resources.

## A Web-based Operation Management System for Distributed Divisional Organizations

Wei Shang, Yijun Li, Qiang Ye, Wenjun Sun

School of Management, Harbin Institute of Technology, Harbin 150001, China  
{shangwei, liyijun, yeqiang, wjsun}@mail.hit.edu.cn

### ABSTRACT

Operation Management is an important and complex task for a divisional structured organization, especially when the divisions are distributed geographically. In most cases, such organizations didn't not urge all of it's divisions to use an integrated information system at the very beginning. But with the development and the expanding of the organization, they sometimes found themselves in the trouble of information exchange and almost lost control of their divisions. At such time, however, on one hand the head quarter inquires more detailed information and more business control on the divisions. On the other hand, some divisions are well built and have its own business processes and information systems. It's impossible for them to rebuild the information system to integrate with the other divisions and the head quarter as well. Operation Management System (OPMGT) enables real-time inspection of the divisions' operational data and flexible operation evaluation of each division via the Internet and without much change on the other information systems. The OPMGT presented in this paper was originally developed for the head quarter of a distributed divisional based organization to govern the distributed divisions. System analysis, design and implementation of OPMGT are discussed in detail. Having been developed on the basis of eFramework, a J2EE framework, OPMGT is proved to be highly sufficient in operation management of a distributed divisional structured organization, and it may also do some help to integrate information systems in some degree.

**Keywords:** Operation Management System, Distributed divisions, Enterprise Information System, J2EE framework, Operation Evaluation

### 1. BACKGROUND

With the development of information technologies, Enterprise Information System (EIS for short) has been playing an important role in the enterprise management. The new generation of eBusiness (electronic business) becomes more rational and focuses more on the IT (Information technology) revolution inside the organizations [1]. And the enterprises tend to be geographically distributed with the development of the global economics. To control the operation of the whole organization, information system together with the Internet is a possible facility. There are three basic organization structures in practice: functional, divisional and matrix. Different kind of organization structure calls on different emphasis in operation management.

In a functional structure, each part of the organization should work together in a coordinated manner and operational management should be performed upon the vision of the whole organization. While in a divisional structured organization, each division is quite independent financially in most cases, and the top management usually does not interfere with the operation details of each division, but tends to supervise their operation situation as a whole. Matrix structured organization simultaneously implements both structures mentioned above by having a division manager and a functional manager at the same time to keep control of productive and managerial affairs.

The operation management function in most existing EIS is designed for functional structured organization. And in a matrix-structured organization, project management is the commonly used and effective method to manage the operation of the organization. As for the divisional organization, unlike the other two types, cooperation among divisions is loose and organizations today might have their divisions in different cities or even different countries. Unfortunately, in many geographically distributed organizations, operation management is usually emphasized inside each division only, and operation management of the whole organization is neglected. The importance of developing an effective operation management system for distributed divisional structured organizations has been recognized. We have built such a system, called OPMGT, which is web-based and tailored for a design company of the petroleum industry to manage their distributed divisions.

System requirements are discussed in the following section. The eFramework on which we built our OPMGT is introduced in the third section. Then there goes the detailed design and development. Implementation and conclusions are discussed as the last part of the paper.

### 2. SYSTEM REQUIREMENTS

OPMGT is an information system for operation management, especially for distributed divisional structured organizations. Here, we limit our research in

the organizations that have more than three divisions and tend to control the operation of each division at a relatively high level instead of a detailed level. Since the divisions might be distributed geographically, we should build our system as an Internet based application. Only in this way, different divisions can access the system easily and interact with the head quarters continently. To understand what problems the OPMGT solves and how the OPMGT works, we need to take a look into the operation system requirements and infrastructure.

To supervise the divisions and make a future strategy, the top executives of a divisional organization usually care about the following aspects of the divisions' operational affairs.

- ó How do they fulfill their part of the whole organization's goal? Do they make more profits or do they spend more over the annual budget? Finding the weak points of the organization's operation is essential to improve the performance of the whole organization.

- ó How to evaluate their operation effects compared with other divisions? Bonus distribution among the divisions is not an easy task. You cannot just scatter the money according to the profit per person. Some divisions do not make much profit or even do not make any profit at all, but their contributions to the overall organization are the same or even more.

- ó How to make the anticipated profit or cost-based budget of the next year referenced with their historical operation data? Identifying the increase or decrease in efficiency is due to accident or an unavoidable trend is a rather statistical problem that needs the support of a large amount of operational data.

- ó How the division manager's leadership affects the whole division's operating situation? Since the division is independent in many aspects, the divisional manager is quite important to the performance of the whole division.

The employees in each division are also concerned with their performance in some of or all of the above aspects. The key of operation management in divisional structured organizations is how to evaluate each division. This measurement should be fair and open.

Technically, we adopt a Web-based J2EE framework to build the OPMGT as a browser and server (B/S) application. In this way, the system can be accessed anywhere through the Internet and has the enterprise features of expansibility and reusability.

### 3. A WEB-BASED J2EE FRAMEWORK

#### 3.1 Infrastructure

The JAVA 2 Enterprise Edition (J2EE) is one of the most popular technologies used in EIS development by its features of platform-independent, object-oriented, component-based and multi-tier-supported. There are

more and more enterprise applications developed totally or partly using the J2EE technology. J2EE framework is a set of tools to enhance the efficiency and reliability of the enterprise application development. Here we introduce a web-based J2EE framework, eFramework (developed and maintained by Polysoft International Corp.), which is especially designed for EIS.

J2EE introduced a component-based method to design, develop and deploy enterprise applications. Despite of the various J2EE design patterns, J2EE infrastructure is composed of three tiers: client, server and background system (e.g. the database system). The J2EE specification defines the following component:

- ó Client component, which is a web page browser to parse the HTML document and support the JavaScript dynamic effects.

- ó Server component, which contains Servlets and JSPs.

- ó Business Component, which is possibly implemented by EJBs.

eFramework supports the new stable version of JSP and includes the newest Servlet APIs. EJB is included by eFramework as a solution for complex business logic. Applications based on eFramework can be deployed to any application server that supports the J2EE specifications.

#### 3.2 The MVC design pattern in eFramework

The Model-View-Controller (MVC) design pattern has been recognized as a brilliant software design pattern that enforces the separation between the input, processing, and output of an application. eFramework adopts MVC pattern in web-based applications with J2EE technology. (Shown as Figure1.)

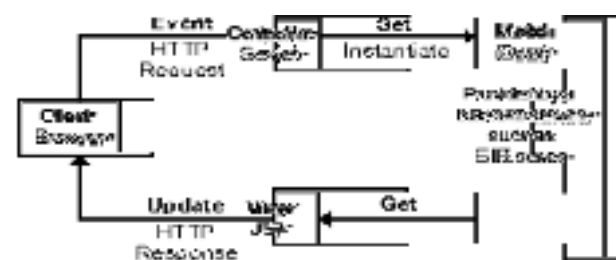

Figure1. M-V-C design pattern of eFramework

When a HTTP request reaches the web server, the following events occur:

- ó All the requests are captured by the Controller.

- ó Controller receives the request from a browser and decides where to send it by parameters assigned before hand.

- ó Controller sends instructions to Handler Factory and demands for a specific Handler to process the request.

- ó Controller commands the Handler to deal with the request.

ó Handler presents the Model of M-V-C pattern, traces the states and implements the business logic. Each Handler knows its duty of combining multiple data beans into a Page Bean.

ó Handler asks Persistence Manager for data and put these data into a web Page Bean.

ó Persistence Manager is responsible for saving and getting data through JDBC and hides the detail of stateless session beans to implement the encapsulation rules of software engineering.

ó If any exceptions occur during the process above, the Handler will decide whether to generate exception pages, for instance, error page beans specially designed for present error messages.

ó Handler passes the assembled Page Bean to Controller.

ó The Page Bean, which has been sent to the Controller, will give out its Presenter.

ó The Controller passes the user request and response parameters to the Presenter, and asks them to present the Page Bean.

ó The JSP page appointed in the Presenter only needs to get data from the Page Bean, convert them into HTML document and send it back to the user.

The whole closed loop is shown in Figure 2:

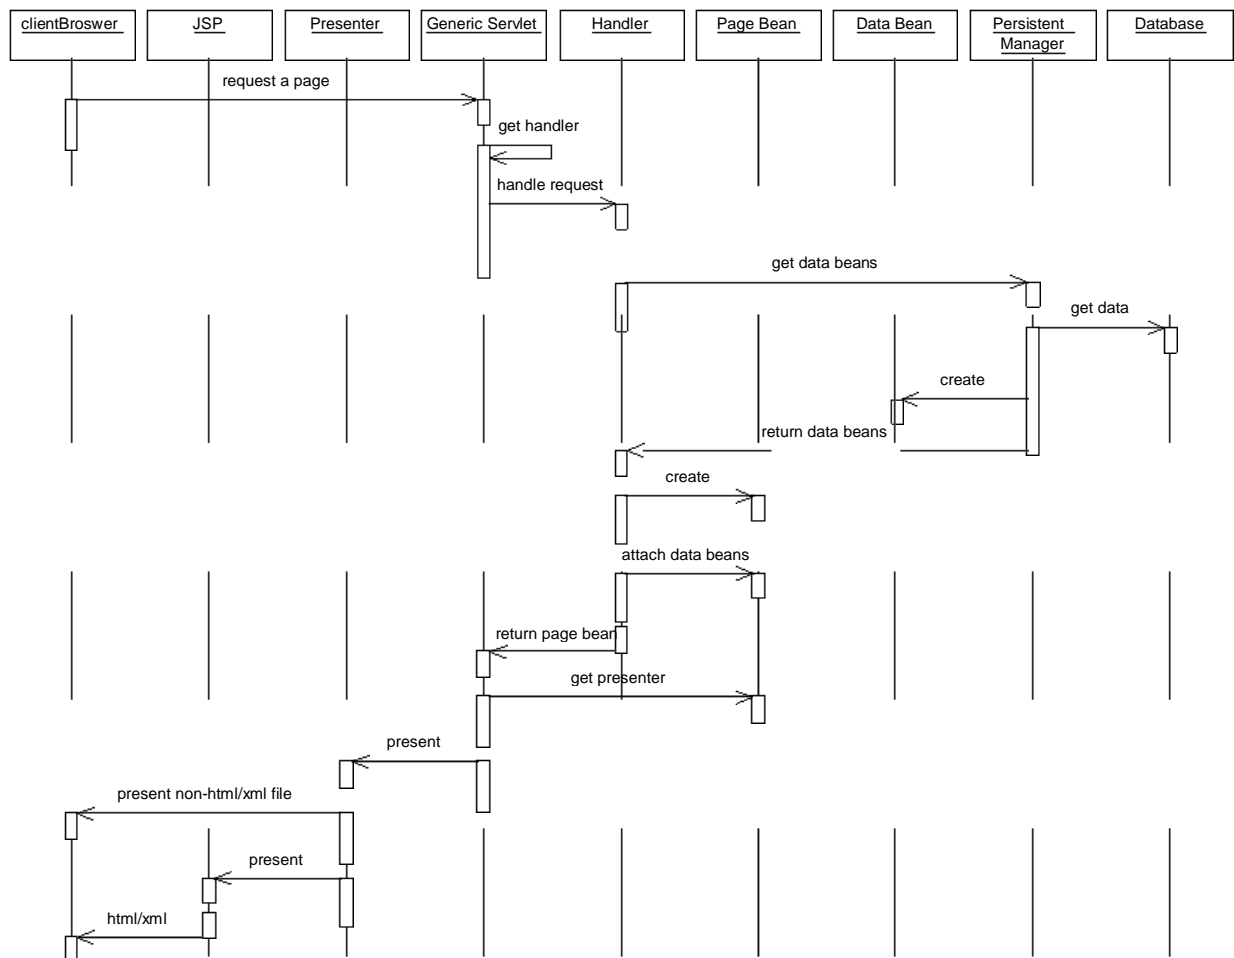

Figure2. M-V-C design pattern of eFramework

### 3. 3 Features

Presentation, business logic and persistent data management are separated clearly in the eFramework. Multi-language, customizing, and application diagnostics are supported as well. By supporting the mechanism of independent development on JSPs and Servlets, eFramework also enables non-Java developer to built JSP pages. Multi-tiered logging functions

enhance the just-in-time inspection and effective debugging on the system. J2EE infrastructure enables flexible deployment on any Servlet container and JSP Engine compliant with the J2EE specifications. Although eFramework seems more complicated than other J2EE frameworks, such as struts and cocoon etc., it is more suitable for building large EIS for its outstanding features.

## 4. SYSTEM DESIGN

### 4.1 System structure

Main function of OPMGT is to help the executives take control of the operation management. OPMGT should

be a subset of an EIS, therefore coordination with other part of the EIS must also be carefully considered. The system structure is shown in Figure 3.

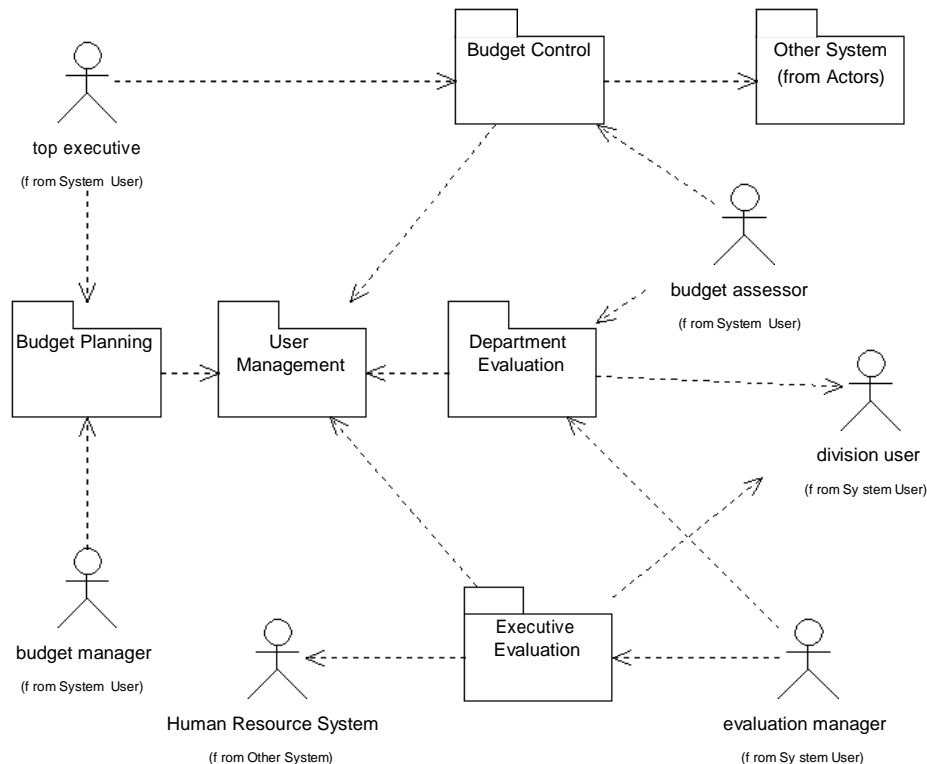

Figure 3. System Structure Diagram

Five packages are needed to satisfy the system requirements: user management, budget planning, budget control, department evaluation, and executive evaluation.

### 4.2 Database management strategy

eFramework provides a database connection pooling management mechanism to manage the JDBC database connections. Since OPMGT is related to several databases, several connection pools should be built for the system to contact with the background databases. Information of these connections is specified in a special type of configuration files (java property files to be specific). This kind of file may have its content changed without having to force rebuilding of the whole project. Therefore, agile development on database connection management is implemented.

Small data unit, such as user information, is designed as a Java class. A persistent manager is a final class to manage the instances of those classes that interact with the databases to obtain small data units. This helps to

encapsulate the database access by letting eFramework manage the lower level details of data exchange and ensure data transfer security and data consistency.

In OPMGT, historical data may be required for querying. We design a backup database to store a more recent historical data, for example, a two-year old dataset. When a request for historical data occurs, a connection to the backup database is built dynamically. After the processing of historical data, the connection is released automatically, since there is not a single active communication for a certain time. With the aid of eFramework, developers may concentrate on the database management logic and leave the routine database communication to eFramework.

### 4.3 User authentication and authorization design

User authentication and authorization is pretty indispensable in OPMGT. Without authentication, a user can only access very limit information, for most of the operation data of an organization could be confidential. Authentication is not enough, in the case that users of

different managerial levels need to have different levels of rights to use the system. A top executive checks raw operating data of each division but cannot modify it. While a common division user may evaluate the operation of his division but cannot change the evaluating method. Authorization is complex and may change often during the run-time of the system also.

We therefore design two inheritable handlers: `AuthenticatedRequestHandler` and `AuthorizedRequestHandler`. The former class contains the default user authentication logic that ensures that the user has been logged into the system with right user ID and password. The latter class checks if a user has the right to do a certain operation by checking whether the request identity sent by the user has been assigned legal for the user to execute. The relations between user IDs and corresponding request identities are stored in a table. Only the system administrator has the right to maintain this information.

By inheriting from the `AuthenticatedRequestHandler` or the `AuthorizedRequestHandler`, each handler has its own security level. The build-in rules of authentication and authorization release the developer of each module from the trifle work of deciding the user's rights in every operation.

#### 4.4 Detailed design of the system

##### 4.4.1 Budget planning module

The budget-planning module is concerned with the operation control in the organization level. Making the annual income budget and outcome budget is the main function of this module. Tracing the implementation of the budget and compare the actual budget with the planning budget is another function of this module. An annual budget may contain several sub budgets for each division. Both the top executives and the division managers have the rights to check these budgets.

Making and tracing these budgets with a visual statistic chart may help all level of the managers to have an impressive understanding of the overall situation of the organization. We design a statistic figure generation package based on the `JFreeChart` library. A chart factory manages the instance of three kinds of charts: pie chart, bar chart and line chart. When a user requests to draw a figure, the chart factory offers a specific chart drawing class and return the user a JPG format figure. This statistic figure generation package can be used in other part of the OPMGT also.

##### 4.4.2 Operation data management

There are two means to gather the operation data: collecting from the existing information system and inputting it into the OPMGT manually. If there's already electronic data in the EIS, this kind of data could be

read from the enterprise database directly. But in some cases the data may be collected by commercial software that does not open its database. For example, the expense flow may have been collected by an existing accounting information system. In this instance, the OPMGT has to import some kind of output document from that software. The output document could be a Microsoft Excel file or a XML file or some other formatted data file. We design an XML import module based on Xalan APIs and an Excel import module based on JXL library to import existing operation data from existing EIS. If not all the operation data has been collected electronically, it's the OPMGT's responsibility to propose a convenient, user-friendly operation data input interface. An input form with combo boxes and check boxes is designed as a manually data input interface in OPMGT.

Querying and summarizing the operation data is also designed as an important function in operation data management module. Once the data has been input into the system, nobody can revise them or delete them. If there's any mistake in the raw input data, the only thing to correct it is to add a negative income or outcome noted the corresponding income or outcome ID. This rule just presents the common sense of accounting information system.

##### 4.4.3 Division evaluation and executive evaluation

Evaluation measurement of the division's performance could be complicated and inconstant. Accordingly, we develop an equation parsing and calculating package. The equation is converted into a reverse Polish notation and a binary tree is used to present the equation and the sub equations. With the flexible equation mechanism the evaluation measurement can be defined and revised in the run time. Some variables in the evaluation equation are from the gathering of the operating data and others may be coefficients which value is different according to different year and different division. These two kind of variable are distinct in that gathering of the operating data is dynamic and could be obtained from the system automatically, while the value of the coefficients are decided subjectively by the evaluating operator. Thus we present and store these two kinds of variable separately.

The executive evaluation differs from the division evaluation only in the presentation of the equations and the source of the variable values. Therefore, we use the same module but different storage to design the executive evaluation module.

## 5. SYSTEM IMPLEMENTATION AND CONCLUSIONS

The OPMGT is developed among a small group consists five developers. We built a CVS depository to store the code and coordinate the team development process.

Taking the advantages of the eFramework, the development process is efficient and efficient. Testing and debugging work is also smooth according to the well-structured design pattern and the eFramework logging mechanisms. Since the OPMGT do not have heavy traffic, an Apache server with a tomcat plug-in is enough for a web application server.

In developing the OPMGT, eFramework is proved to be an efficient in information system development. But due to its powerful infrastructure, it is not easy for a developer to master the spirit and exert the best performance of the framework. The starting of our development is much harder than the following period. Consequently, a long term and relatively steady develop team may be better for building an information system using this eFramework.

The authentication and authorization mechanism is sufficient for the access control of the system functions. The flexible design of the evaluation equation enables various dynamic measurements of the divisions in an organization. The organization testing the OPMGT has found it practical and effectual in managing the operation of the divisions as a whole. Further more, as an application based on J2EE technology, the OPMGT has the cross-platform feature and this makes it possible to be integrated into existing enterprise system. The excel file input and figure output functions also make it

convenient to exchange data and express information in a distributed divisional structured organization. The design company who raised the request of building this system is very satisfied with it. However, they have not used it for long time. And with time past, more improvement of the system must be done.

# Apply MDA to E-Business: MDA Based Workflow Solution as an Example

Jiawei Lee, Jungsing Jwo

Department of Computer Science and Information Engineering, Tunghai University

## ABSTRACT

This paper introduces how to apply OMG's Model-Driven Architecture (MDA) to develop a cross-platform workflow solution. A workflow solution first is modeled as a PIM (Platform Independent Model) model. The PIM model will be translated into a PSM (Platform Specific Model) model according to the selected workflow platform and then the corresponding process definition is automatically generated. In this paper the result shows MDA can help preserve the knowledge of an application as a PIM model. The quality of the application also can be dramatically increased since the translations from PIM model to PSM model and from PSM model to the final production codes are automatically performed.

**Keywords:** e-Business, MDA, meta-model, WfMC, workflow management system

## 1. INTRODUCTION

In an enterprise workflow solution is one of the major building blocks for e-Business. In fact, workflow related solutions are widely studied recently [3, 4, 5, 7, 17, 19]. Among these researches, WfMC (Workflow Management Coalition) is the key organization to define the standard for workflow management system [4]. However, even with the standard, the migration of a workflow application from one platform to the other is still quite difficult since different workflow platforms have different philosophy to model their workflow processes.

MDA (Model-Driven Architecture) is a new technology for developing software applications proposed by OMG (Object Management Group) [12-15]. In the past, an application is modeled by also considering the IT platform and therefore the software design can not be reused when the platform is changed [1, 2, 8, 9, 18]. In MDA technology, an application is modeled only from the application logic without considering the IT platform [16]. This model is called a PIM (Platform Independent Model) model. When the IT platform for the application is decided, a corresponding model translated from the PIM model is created automatically. The new model is called a PSM (Platform Specific Model) model. Based on the PSM model and the translation rules, the production codes of the application are also generated automatically [10, 11]. Since the knowledge of the application is captured in the PIM model, it can be reused much easier later when the application needed to be migrated to another platform. The quality of the application is also dramatically increased since the translations from PIM model to PSM model and from PSM model to the final production codes are automatically performed.

In order to show the superiority of adopting MDA technology for building e-Business related solutions, we

propose a new workflow application development methodology based on MDA. Figure 1.1 is the illustration of the idea. We define a workflow PIM meta-model named MyWF meta-model. In this paper, we chose WfMC's XPDL process model as the experimental PSM meta-model. We also define the translation rules for MyWF model to the XPDL model and for XPDL model to the final XPDL process definition.

The organization of this paper is as follows. In section 2 we briefly introduce WfMC's XPDL model. MyWF meta-model is defined in Section 3. The implementation of the translation rules is described in Section 4. Section 5 is the conclusion remark of this paper.

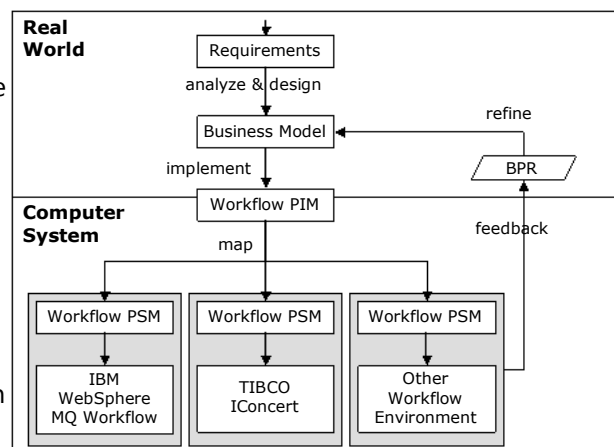

Figure 1.1. The architecture of applying MDA to build workflow application

## 2. XPDL

According to the workflow reference model proposed by WfMC, a workflow application has three different modes, namely, build-time functions, run-time control functions, and run-time interaction functions. Therefore, a workflow application can be considered as an

application with multiple operation steps such that it is routed automatically by following its corresponding process definition. The process definition standard of WfMC is called XPDL (XML Process Definition Language). XPDL is based on W3C's XML Schema [19]. Figures 2.1 and 2.2 are the meta-model and the package meta-model for XPDL, respectively.

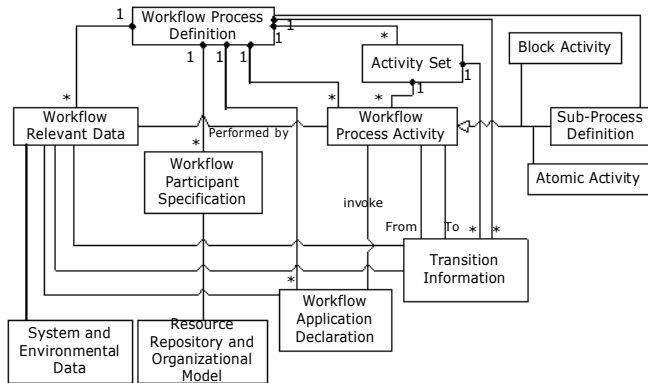

Figure 2.1. XPDL meta-model diagram.

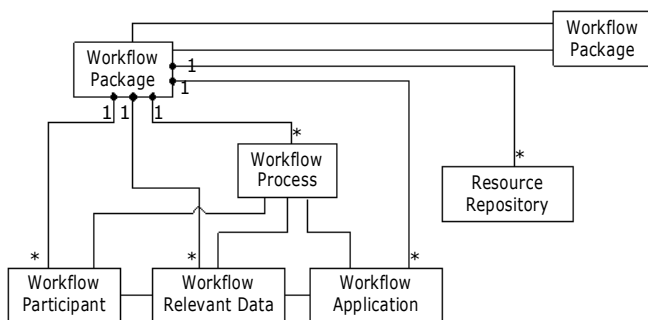

Figure 2.2. XPDL package meta-model diagram.

### 3. MyWF META-MODEL

In this section we define a generic workflow platform independent meta-model named MyWF. Figures 3.1 and 3.2 are the design of the MyWF meta-model. In this PIM model, there are five elements, namely, Process, Task, Transition, Resource and RelevantData. Process element is used to describe a workflow's operation steps. Task element is to store the information of the operation in each step. The information about the routing between two steps is defined in Transition element. The information of the resource required for the workflow application is stored in Resource element. RelevantData element contains the information across different steps. Each Process element can have more than one Task and various Transition, Resource and RelevantData elements. Task is subdivided into two different types, namely, GroupTasks and SubFlow elements. Resource could be either Application resource or user Role elements.

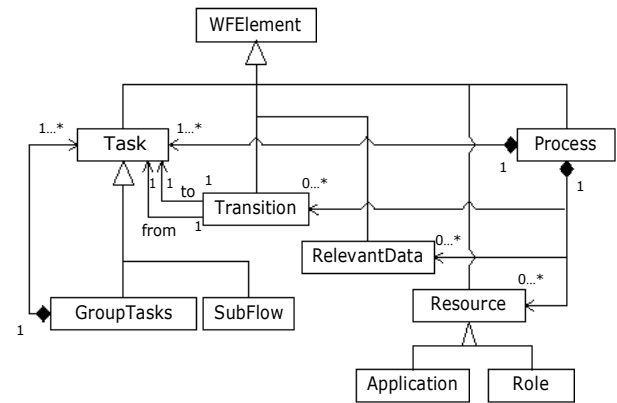

Figure 3.1. MyWF meta-model diagram.

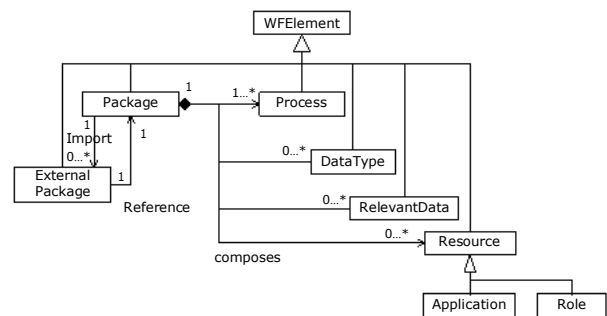

Figure 3.2. MyWF package meta-model diagram.

### 4. MyWF TO XPDL TO PRODUCTION CODE TRANSLATION

In the previous two sections, we have a generic workflow PIM model called MyWF meta-model and a well known workflow PSM model named XPDL meta-model. In this section, we describe how to transfer a MyWF application model into XPDL model and then transfer the XPDL model into its corresponding production codes.

#### 4.1 MyWF PIM Model to XPDL PSM Model

The translation design between MyWF PIM model and XPDL PSM model is separated into two solutions. The first part is to guarantee that the traversal of the PIM model elements is complete. The second part is to define the translation rules among the elements between two models. We use Bean Script Framework (BSF) to implement the two solutions. The reasons of selecting BSF to build the MDA translation solution are:

- *Flexibility*: the interpreting based script language is more flexible when translation rules are changed and are required to be re-implemented.
- *Friendly implementation*: BSF is easier for MDA developers to use when implementing the translation rules among different models.

The translation algorithm is described as follows.

- (1). Retrieve the next element in the MyWF PIM model.
- (2). Identify the element type of the current element. If the type is unknown then throw `UnknownTypeException` and interrupt the traversal.
- (3). According to the translation rules, fetch and execute the corresponding script code and perform the translation. If the script is not found, throw `NoScriptException` and interrupt the translation step.
- (4). Retrieve the related translation required information and put it into the `ScriptEngine`.
- (5). Execute the corresponding script code to build the translated XPDL elements. If the execution can not be executed correctly, throw `TransformException` and interrupt the execution.
- (6). Inspect the current MyWF element and make sure if there is any related element. If yes, go to step 1, otherwise go to step 7.
- (7). Return the translated XPDL elements. Go to step 1.

#### 4.2 WfMC XPDL to Production Codes

In this section, we describe the translation rules between PSM model and the final production codes.

For each element in the PSM meta-model, we define one or more than one templates. Each template is a code pattern. The translation algorithm is as follows.

- (1). Retrieve the next element in the PSM model.
- (2). Identify the element type of the current element. If it is not known, throw `UnknownTypeException` and interrupt the execution.
- (3). Retrieve the corresponding templates. If there is no template is available, throw `NoTemplateException` and interrupt the execution.
- (4). Parsing the template pattern code. Identify the required information for the template from the element. If there is no corresponding information, throw `NoTemplateAttributesException` and interrupt the execution.
- (5). Return the generated production codes. Go to step

#### 5. CONCLUSION

Figure 5.1 is the diagram to show how to define the roles and development process when applying MDA technology to build a workflow application. Figure 5.2 is the screenshot of our example implementation using Java and JMI [6]. From our experience of this research, we find that MDA indeed can greatly reduce the effort when implementing e-Business solutions on different platforms.

### ABSTRACT

Companies across all sectors with increasingly smaller size rely on alliance relationships to bolster revenues during times of economic uncertainty. When forming alliances, large firms typically hire vendors such as investment banks to help identify potential alliance partners. However, small businesses with intention to build alliance find difficulties to search desired partners especially on a global arena due to three causes: 1) lack of skills, resources and information; 2) too small to capture the attention of investment banks or alike; 3) not affordable to the high search fee charged by vendors. Thus, reliable information about small business market is often limited. The odds of successful search and match become very low given their limited access to right information. In fact, traditionally labor-intensive search and match either by investment banks or by firms themselves have been both costly and time-consuming. On the demand side, small businesses are searching for more alliance opportunities than ever before while deal size has been increasingly declining since the last two decades. The globalizing, deregulation and internet are attributed to the driving forces of this trend. Under this circumstances, E-Alliances is able to close the huge gap between the demand side which represents the tremendous alliance search needs of small businesses worldwide and the supply side which is constrained by search capacity. In this paper, the author will interpret how E-Alliances is able to help worldwide small business companies to reach their desired partners in a fast, cheap and DIY manner. The author will also discuss the outlook of alliance.

### 1. INTRODUCTION

Companies across all sectors with increasingly smaller size rely on alliance relationships to bolster revenues during times of economic uncertainty. Indeed, the percent of total business involving alliances continues to grow rapidly over time. Alliances enable companies to pursue new growth opportunities without incurring the costs and risks associated with other development options.

Source: McKinsey 2001

Figure 1. Growth of alliance activities

When forming alliances, large firms typically hire vendors such as investment banks to help identify potential alliance partners. However, small businesses with intention to build alliance find difficulties to search

desired partners especially on a global arena due to three causes: 1) lack of skills, resources and information; 2) too small to capture the attention of investment banks or alike; 3) not affordable to the high search fee charged by vendors. Thus, reliable information about small business market is often limited. As a result, many companies in the small market have developed their own methods to identify and obtain information concerning potential alliance targets, rarely engaging investment banks during the identification phase, but occasionally employing them as the deal progresses. The odds of successful search and match become very low given their limited access to right information. In fact, traditionally labor-intensive search and match either by investment banks or by firms themselves have been both costly and time-consuming. To a large extent, this explains why investment banks are lured by large deals while rejecting small ones. On the demand side, small businesses are searching for more alliance opportunities than ever before while deal size has been increasingly declining since the last two decades. The globalizing, deregulation and internet are attributed to the driving forces of this trend. Under this circumstances, E-Alliances is able to close the huge gap between the demand side which represents the tremendous alliance search needs of small businesses worldwide and the supply side which is constrained by search capacity. The purpose of this paper is to examine how E-Alliances is able to help worldwide small business companies to reach their desired partners in a fast, cheap and DIY manner. The author will also

discuss the outlook of alliance. The results suggest that the entry of e-Alliances should stimulate alliance activity and enhance the efficiency of market.

In an alliance market, there exist huge numbers of firms which look for alliance opportunities. E-Alliances provides an online marketplace for firms to search and match each others. Each firm will first register in by offering its company information and desired partner criteria through a series of simple click of either single or multiple choices. To obtain an even higher quality partner list, searching firms can even enter more selection criteria by category method such as alliance type, locations, industry and/or by weighted preference of criteria called Deal Fit Index (DFI). The criteria designated basically enables specific firm to sort potential partners according to its alliance objectives and appropriate alliance structures which varies from equity-based alliances such as merger & acquisition, joint venture, etc. to non-equity-based ones such as joint-R&D, license agreement, OEM, etc. With all individual firm's information inside, E-Alliances automatically matches the firms and provides a shortlist of potential partners for each member firm. For advanced members, they are able to view a highly selective shortlist based on DFI, which are sorted from a huge member database throughout the world. The search and match of E-Alliances are 7×24 real-time based which automatically send email to logged-out members to inform them of new prospects which show interest in them. E-Alliances also provides mailbox for members to connect each other for further relationship building. The author concludes that E-Alliances significantly improves firms' ability to search quality partners from both scale and scope in a real time, global reach, and cost effective way. To facilitate the deal progress and provide the members with total solution, E-Alliances will strive to create the value chain by providing customer education programs to develop members' alliance skills and inviting qualified vendors to provide professional services like due diligence, valuation, negotiation, accounting and law, post-alliance integration, etc.

## 2. PERFORMANCE OF STRATEGIC ALLIANCE

Research has reported that building alliance will improve performance of both allying firms and market with an example of OEM partnership<sup>[1]</sup>. (Ren 2003) Consider a simple economy with only two firms: firm A and firm B. The both firms make same product. Firm A is legally allowed to sell its product in region B; in symmetry, firm B is legally allowed to sell its product in region A. Firm A and firm B can only make decision on the quantity of their own production, i.e., Cartel is prohibited.

The product price is the function of production in both region A and B, denoted by the following equation (1):

$$P(z) = a - z \quad (1)$$

The marginal cost is denoted by  $c$  and suppose there is no fixed cost of production. However, a firm must incur a fixed cost of distribution channel management in order to sell in a region, denoted by  $D$ .

Furthermore, in order to sell in an outside region, a firm has to not only incur the distribution cost but also bear the shipment cost. This suggests that the total cost of making and shipping one unit product is  $c/g$  with  $1 < g \leq 1$  (shipment cost is zero if  $g=1$ ).  $Q$  is the rental cost of one firm pays to another for the use of its infrastructure and distribution channel.

In direct competition, the two firms pursue each own profit maximization as equation (2) and (3):

$$\text{Firm A: } \underset{x}{\text{Max}}(x p_{(x+y)} + x^* p_{(x'+y')} - cx - \frac{c}{g} x^* - 2D) \quad (2)$$

$$\text{Firm B: } \underset{y}{\text{Max}}(y p_{(x+y)} + y^* p_{(x'+y')} - cy - \frac{c}{g} y^* - 2D) \quad (3)$$

On the other hand, when two firms ally in OEM model, they agree on the equilibrium point for a rental value  $q$ . Because the two markets are symmetric, we only consider the region A. In market region A, the profit maximization conditions of two firms are as shown below:

$$\text{Firm A: } \underset{x}{\text{Max}}(x(p_{(x+y)} - c) - D + y(q - c)) \quad (4)$$

$$\text{Firm B: } \underset{y}{\text{Max}}(y(p_{(x+y)} - q)) \quad (5)$$

To evaluate market performance, Ren (2003) examined the respective impact of the above two models on total surplus of welfare. In the Nash equilibrium of direct competition in market region A, the total surplus of welfare is as below:

$$W_1 = [\int_a^z p_z dz - z_{e1} p_{z_{e1}}] + [z_{e2} p_{z_{e2}} - c x_{e1} - (c/g) y_{e1} - 2D] \quad (6)$$

In the Nash equilibrium of OEM alliance model in market region A, the total surplus of welfare is as below:

$$W_1 = [\int_a^z p_z dz - z_{e2} p_{z_{e2}}] + [z_{e2} p_{z_{e2}} - c x_{e2} - c z_{e2} - D] \quad (7)$$

Obviously,  $W_1$  and  $W_2$  are the functions of the fixed cost  $D$  to set up distribution channels. To compare the performance of the above two situations, we find the partial derivative of the difference between  $W_1$  and  $W_2$  against variable  $D$ . as shown below:

$$\frac{\partial(W_1 - W_2)}{\partial D} = \frac{\partial(W_1 - W_2)}{\partial q} \cdot \frac{\partial q}{\partial D} = \frac{c - a + 9\sqrt{D_{\max} - D}}{8\sqrt{D_{\max} - D}} \quad (8)$$

Ren (2003) further discussed how  $W_1 - W_2$  differs in two cases when  $D=D_{\max}$  and  $D=0$ , respectively. He drew the conclusion that OEM alliance helps increase the total welfare and thus improve the market efficiency.

Studies of alliance performance are discussed in many other business literatures. Jay<sup>[2]</sup> (2002) suggested that alliance relationship building can be considered as real option so that its performance could be valued through adjusted Black-Scholes equation. However, he did not illustrate how to do that but instead, went back to a more intuitive NPV rule to value the synergy of allying firm A and firm B as below:

$$NPV(A+B) > NPV(A) + NPV(B) \quad (9)$$

### 3. ALLIANCE SEARCH AND MATCH THROUGH INTERMEDIARIES

#### 3.1 Cost of direct search and intermediary search

Consider a market with many heterogeneous firms who search and match for alliance. We review a simple economy with two firms: Firm A and Firm B, to seek each other for partnership. Before alliance, the two firms maximize their profit  $V_A$  and  $V_B$ , respectively. They directly reach each other to bargain and finally decide to ally. After allying, they achieve a profit  $V$ . However, a search cost is  $C$ . We suppose the alliance brings in a positive gain for both parties as below:

$$V - C > V(A) + V(B) \quad (10)$$

For simplicity, we suppose the both parties equally share the gain:

$$\frac{V - C}{2} \quad (11)$$

Given the uncertainty for search directly, suppose a intermediary can help both firms to find each other. The intermediary incur the search cost  $T$ . Apparently, when and only when the intermediary can reduce the search cost, the indirect transaction through intermediary can really happens, that is

$$T \leq C \quad (12)$$

The deal volume processed by intermediary is far exceeding that of an individual firm. Moreover, an intermediary stay much longer in the market than any single firm and thus build up a credibility which lasts much longer than that of an individual firm. The deal volume and brand longevity of intermediary create cost advantage over the direct search.

#### 3.2 Cost of human search and internet search

The search by intermediary can be human-based historically (e.g., investment banks, accounting firms, etc) and web-based which is innovative E-Alliances. Because of the uncertainty of search business, both human search and internet search will incur search cost. For instance, search results via internet can immediately appear on the screen while human search must wait for longer time. After wait, the alliance gain which is  $V - T$  is achieved and equally shared between the allying two firms. If the two firms discount the future alliance gain with ratio  $\delta$ , then the present value of the human search equals to

$$\frac{\delta(V - T)}{2} \quad (13)$$

This implies that the human search cost is

$$H = (1 - \delta)(V - T) \quad (14)$$

When and only when

$$I \leq H = (1 - \delta)(V - T) \quad (15)$$

The internet search is better off than the human search. Since the human reach is limited by time and space, the human search can find the right match at a probability  $\beta$ . Suppose the website of internet search is widely known, thus the human search cost will be

$$H = (1 - \beta)(V - T) \quad (16)$$

If the matching process by human search is inefficient, then  $\beta$  is very small; consequently, internet search will be superior to the human search. In reality, while big firms have a broad network, professional expertise and good money to guarantee efficient search (increase  $\beta$ ), small business is inferior to this situation with limited access, few talents and less money to lure attention of search vendors ( $\beta$  is fairly low). Accordingly, a new approach to search and match for small business partnership is essential. E-Alliances becomes appealing to alliance search for small business due to its self-service, global reach and low cost.

### 4. WORKING MODEL OF E-ALLIANCES

E-Alliances provides an internet search marketplace for firms to search and match ideal partners. In particular, small business firms are targeted customers for this marketplace with driving factors in three folds: 1) neglect by human search institution because the deal is too small to capture the attention of investment banks or alike; 2) inaffordability to high human search cost; 3) liquidity generated by positive feedback of internet which follows the Metcalf Law. The online alliance search engine is supposed to provide small business a perfect tool to search and match at low cost, high speed and global reach.

#### 4.1 Quick match through Aladdin setting

To increase liquidity by attracting as many as possible firms to join in paid-membership, E-Alliances develops a quick match functionality to quickly show real-time match results by asking search firms to create their own Aladdin setting, which requests the firm to make single or multiple choices against a designated questions reflecting a series of search criteria of the firm. Once the firm finish and submit its result, it instantly shows on the screen a list of prospects which satisfy its Aladdin settings, as shown below

Figure 2. Illustrated list of quick match

The sequence of prospect list is sorted in Basic Match status based on their match level of criteria preset in Aladdin setting. The search firm can further review a prospect's profile by clicking its username as shown below

Figure 3. Illustrated prospect profile

If the firm is interested in the prospect, it can either send a email to the prospect or add the prospect into its hot list for later contact.

## 4.2 Browse profiles through demographics

To satisfy firms' need to search by demographics, E-Alliances provides category search such as alliance type, geographic and industry. The prospect list then further sequenced according to matching level with the above demographics, as shown below

Under this search mode, search is more accurate and time is further saved for the member firms.

## 4.3 Advanced search through Deal Fit Index®

To identify potential partners, searching firms should formulate the criteria for evaluating potential partners, and determine which candidate best meets these criteria. The main goal of the firm is to determine if there are suitable partners that can help it fill its capability gap. Making this selection requires that the firm understand and rank each prospective partner's critical attributes in terms of how well they meet the firm's criteria. E-Alliances provides the paid members with a designated criteria with weighted preference through single or multiple choices by simple clicks. As result of this exercise, the firm can quickly present the conceptual structure of the alliance to the candidates for their matching criteria. At the end of this stage, the firm should have a shortlist of prospects with best fit on its objectives for entering into the alliance, which are ranked by their Deal Fit Index (DFI®). The firm may also wish to re-examine the list of required partner attributes to confirm that the criteria is realistic by going back to its original setting to make adjustment of weight and preference.

## 5. CHALLENGES FOR E-ALLIANCES

Besides the functionalities designated, three other factors appear intrinsic to any marketplace able to sustain itself over the long term: liquidity, credibility and value-added services. These elements determine whether a marketplace can enlist users and provide them sufficient value to continue their participation. A marketplace initiative must manage these key issues well.

### 5.1 Liquidity

Generating liquidity by attracting enough customers is the most significant challenge to a marketplace's success. A new, electronic marketplace must compete against traditional methods of alliance service. While the e-business may offer administrative savings through automation, the presence of too few participants will leave marketplace prices out of alignment with regular channels.

### 5.2 Credibility

As a new, shared model for conducting business, marketplaces depend upon the trust of their participants. The marketplace host maintains access, at least theoretically, to all information that parties exchange. This insight into pricing and purchasing behavior can scare off participants fearful that the information may be turned against them in some way. While regulators will set rules limiting the worst abuses, consortia must take additional steps to demonstrate neutrality and build trust among marketplace users. Methods include setting up independent management executives and information firewalls between owners and participants. Pure plays

can attempt to claim the high ground as disinterested parties because the owners never buy or sell goods in the marketplace. However, as pure plays begin to accept equity investments from industry incumbents, the lines between ownership models begin to blur. Yet, in the end, liquidity cannot develop if users mistrust the marketplace and conduct transactions on other sites or through other channels.

### 5.3 Value-added services

To succeed in a long run, E-alliances must effectively integrate the value chain services into an alliance solution to the client.

Regardless of the alliance structure, alliance process is inherently complex at variety of difficulties which are far beyond small firms' capability because it heavily involve in people, process and tools. In other words, E-Alliances alone is not sufficient to satisfy firms' alliance needs. Alliance services typically comprise the following phases:

**Alliance needs assessment.** This services encompasses strategy consulting, including needs assessment, assistance with a decision on whether alliance is a feasible and beneficial option, evaluation of various options (m&a, joint venture, divestiture, OEM, channel sales agreement, joint R&D, etc.), and assistance in choosing the right option. The strategy work requires a deep knowledge of the client's business and tight alignment of merger options with the overall short- and long-term business strategy of a company.

**Partner selection.** The imperative task in this phase is assessing the strategic value of the partner. It is important not to treat it as a standalone activity. The valuation process must be closely integrated with the business strategy and integration plan to achieve the desired result.

**Due diligence.** Due diligence is conducted by the lead alliance services provider, or it is outsourced to an independent party.

**Transactional services.** Transactional services include negotiation and financial/legal advisory. A partner is chosen either by the alliance services provider together with the client.

**Customer education services.** Customer education programs seek to deliver information that enables customers to more effectively utilize a company's product.

## 6. OUTLOOK OF E-ALLIANCES

So far, I have interpreted how E-Alliances will help small business address their critical alliance issues from a market microstructure perspective. Since E-Alliances has intrinsically a global orientation, both from an alliance point view and internet standpoint, we are optimistic that it will become the world's largest base of

alliance. Its success will be not only measured by hit rate of customers, but also by the alliance deal success rate. Furthermore, E-Alliances provides an emerging market like China with a unique value to attract foreign direct investment, facilitate knowledge and technology transfer, and boost trade volume among countries. It will also help stimulate information transparency and establishment of national credit system. In essence, E-Alliances will contribute to accelerate the growth of worldwide small business by fostering successful alliances among them wherever they are.

## 7. CONCLUSIONS

Firms with complementary value are more likely to achieve synergetic performance through alliance than that of they work alone, even though the success is not guaranteed (according to David and Tammy<sup>[3]</sup> 2000, 50% of the alliance failed). To seek a partner, a firm can search by itself or by use of intermediary. The decision depends on the cost incurred by each alternative. For intermediary search, internet search reshaping the alliance economics by competing with the traditional human search. Giving its self-service, low cost, speed, global reach and 7×24 working mode, internet is gaining competitive advantage over the human search. Small business firms can benefit from the internet search most for they have limited access, few talents and less money. As an online marketplace, E-Alliances provides the small business with variety of search approaches to meet their search needs for alliances. However, while E-Alliances offers creative, promising functionalities, it faces challenges of liquidity and credibility generation, too. In particular, E-Alliances' success largely relies on the ability to restructure the alliance value chain by integrating E-Alliances and necessary value-added services into customer solution. To look ahead, E-Alliances will become the world's largest base of alliance and contribute to both micro- and macro economy by facilitating firm collaboration around the world.

### ABSTRACT

One of the key issues in e-business research is how established companies can gain competitive advantage by exploring e-business. Despite the interest in e-business applications by traditional firms, few empirical studies have been carried out to look at how 'clicks-and-mortar' approaches offer competitive advantages, especially from a specific industry perspective. This study investigates the key sources of competitive advantage gained from e-business applications by Chinese real estate developers and whether the value chain theory and its related theories can explain this phenomenon. By using a qualitative case study approach, the study shows that the value chain framework is useful to identify and categorize possible e-business application areas. Moreover, this categorization makes identification of key sources of competitive advantage explicit. However, this framework cannot fully explain the success of e-business applications nor the realization of intended motivations. Hence, further research and work are needed to make the value chain model become an easily-used, practical guideline for e-business implementation.

**Key words:** e-business, competitive advantage, value chain, real estate industry

### 1. INTRODUCTION

This study investigates the key sources of competitive advantages gained from e-business applications made by Chinese real estate developers and whether the value chain theory and its related theories can explain this phenomenon.

One of the key issues in e-business research is how established companies can gain competitive advantage by exploring e-business. Despite the interest to e-business application by traditional firms, few empirical studies have been carried out to look at how 'clicks-and-mortar' approaches offer competitive advantages, especially from specific industry perspective (Steinfeld *et al.*, 2002).

Therefore, the aim of this research is to address this gap in the current literature by investigating sources of competitive advantage gained from e-business adoption by established real estate developers in Mainland China.

This aim can be broken down into the following questions:

- 1) What are the key sources of competitive advantage gained from e-business application by real estate developers?
- 2) How effectively can the value chain model capture the key sources of competitive advantage?
- 3) Does the transformation to value chain made by some researchers pass the empirical tests in specific industry? Or,
- 4) Can any new framework/theory of transformation arise from empirical data analysis?
- 5) Do any links exist between value chain framework explanation to sources of competitive advantage in e-business and other alternative explanations?

### 2. RESEARCH METHOD

A case study and qualitative research approach will be adopted in this research. Following the suggestions given by Yin (1994), this research design will be based on multiple cases and multiple evidences.

Large spatial diversity between Chinese real estate developers, and time and resource limitations would suggest a strategy initially focused on established real estate development firms whose main activities focus on three geographical locations, namely Beijing, Shanghai, and Guangdong Province, because these cities are the most prosperous housing markets in Mainland China.

According to the e-commerce definition, that is "e-commerce is the sharing of business information, maintaining business relationships, and conducting business transactions by means of tele-communication networks" (Zwass, 1996), adopted in this research, we define established real estate developers with e-business application as the company who conducts one or more than one of the following activities:

- the buy-side e-business transactions with suppliers;
  - the sell-side e-business transactions with customers;
  - the use of Internet technologies within the firm.
- Here, the key business activities refer to the nine generic categories of interdependent activities which compose a firm's value chain. For example, Floris *et al.* (2001) give an insight into the reach of e-business technologies into the value activities. (Shown in **Figure 1**)

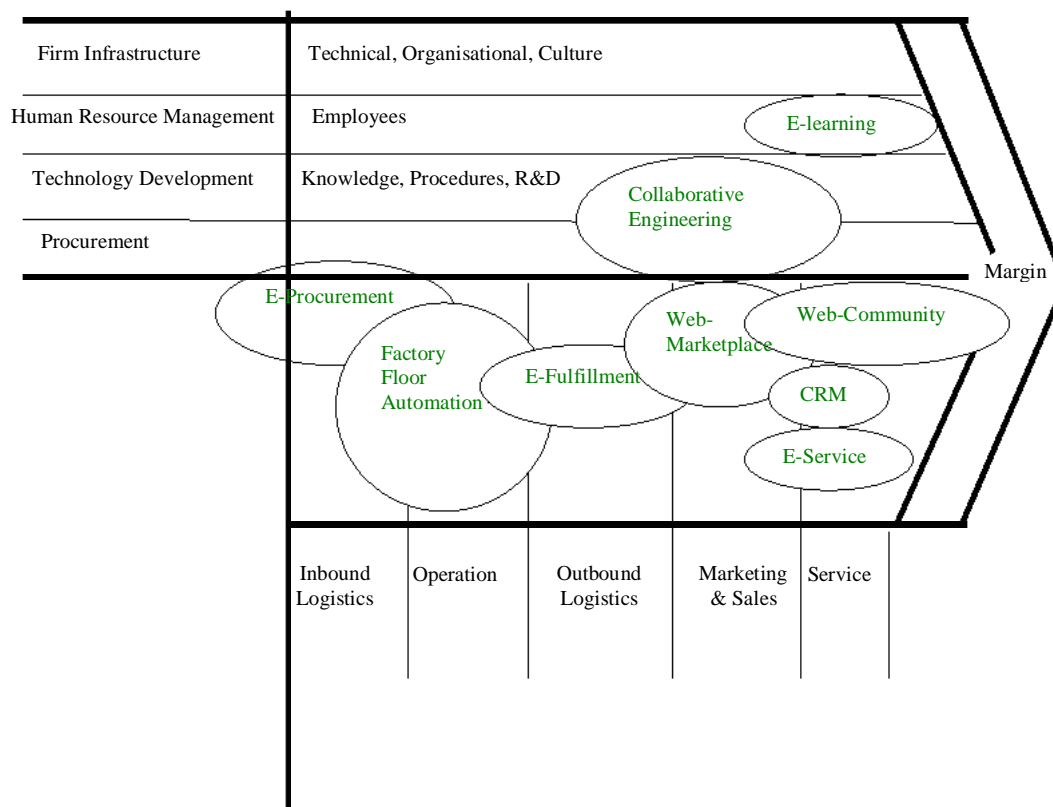

Figure 1 E-business technologies applications in the value chain

Source: Floris *et al.* (2001)

Cases were identified by combining the databases of real estate developers with first-grade qualification, top ten real estate developers in 2002 and top 35 public real estate development companies in 2001. Additional criteria were used which identified companies with continuously better than average performance, an e-business application, and geographic focus. Twenty companies were initially chosen and their websites scanned to confirm whether they are using e-business. The initial finding is that most companies in the database only use websites as e-brochures and only a few companies have used e-business actively. This narrows down the cases into five companies, who are located in Beijing or Shenzhen.

The data analysis is influenced by grounded analysis, four principles of high quality analysis given by Yin (1994): namely use all relevant evidence, consider all

major rival interpretations, address the most significant aspects of the case and use your own prior expert knowledge and value chain theoretical framework.

### 3. RESULTS AND ANALYSIS

The five case companies are Mainland China-based real estate development companies, among them three in Beijing and two in Shenzhen. All of the companies are well established in the real estate industry with property development as their core businesses and have, to some extent, tapped e-business. Some key features of the case companies and their use of e-business are summarised in **Table 1**.

A cross-case comparison on the key features from each case for is shown in **Table 2**.

Table 1 Main features of the case companies

Company	Market segmentation	Organizational structure	E-business application
I	Mainly middle-end; partly high-end Focuses on multiple cities with marketing expansion potential	Centralizes management cross regions	1) Marketing promotion and advertisement; 2) E-procurement; 3) Intranet for email system; 4) Automation of internal management processes.
II	Mainly middle-end; partly high-end Focuses on Shenzhen, Shanghai, and Beijing with marketing expansion potential	Centralizes management cross regions	1) Marketing promotion and advertisement; 2) Business to Employee platform for knowledge management; 3) Automation of internal management processes; 4) Customers' e-forum.
III	Mainly middle-end; partly high-end Focuses on Beijing with marketing expansion potential		1) Marketing promotion and advertisement; 2) Automation of internal management processes; 3) Secondary housing market.
IV	High-end Focuses on multiple cities with marketing expansion potential		1) Marketing promotion and advertisement; 2) B2C platform to allow customers order houses.
V	Mainly low and middle-end; partly high end; focuses on multiple cities	Independent management by subsidiary companies	1) Marketing promotion and advertisement; 2) Intranet and financial system.

Table 2 Cross-case comparison

Case	Definition to e-business	E-business adoption motivations	E-business application	Advantages gained from application	Main concerns of E-business adoption
I	No clear idea but thinks it has no big difference with preceding information systems	1) To Share information; 2) To improve operation efficiency; 3) To reduce procurement cost; 4) Marketing promotion.	1) Marketing promotion and advertisement; 2) E-procurement; 3) Intranet for email system; 4) Automation of internal management processes.	1) Better information sharing; 2) Reducing purchasing cost; 3) Facilitating employee training; 4) Standardising operation process; 5) Reducing redundancy;	Integrate different information systems adopted by different functional departments.
II	E-business including Web-based transaction. Definition is not important to them.	1) To Share information; 2) To manage customer relationship and achieve strong interactions with customers; 3) Marketing promotion.	1) Marketing promotion and advertisement; 2) Business to Employee platform for knowledge management; 3) Automation of internal management processes; 4) Customers' e-forum.	1) Reducing redundancy; 2) Facilitating employee training; 3) Promoting innovation; 4) Better management through customer monitoring; 5) Better information sharing.	
III	E-business including Web-based transaction.	1) Marketing promotion; 2) To improve management efficiency;	1) Marketing promotion and advertisement; 2) Automation of internal management processes; 3) Secondary housing e-market.	1) Better information sharing; 2) Facilitating strategy formulation.	Integrate different information systems adopted by different functional departments.
IV		To facilitate the implementation of the company's management concepts	1) Marketing promotion and advertisement; 2) B2C platform to allow customers order houses.	1) Reducing business risk. 2) Strong interaction with customers.	
V	E-business is a new technology facilitated tool of transaction and providing transaction-related service	To redefine the value chain and standardizing real estate development process	1) Marketing promotion and advertisement; 2) Intranet and financial system.		Organization-al structure makes difficult to implement e-business

The following key issues emerge from the analysis of the cases.

- 1) Main e-business applications by Chinese real estate development companies;

- 2) Main motivations and benefits of e-business application;
- 3) The main hurdles of e-business application.

Main e-business applications by Chinese real estate development companies include e-procurement, automation of the internal management process and marketing efficiency.

The companies' motivations for e-business adoption initially arise from trying to solve key management problems, especially operational problems, by using e-business applications such as e-markets, intra- or interorganizational systems, and providing customer service. Another common motivation identified is sharing information between internal users (shown in **Table 2**). Additionally, the adoption of information systems is also motivated by cost saving. A further motivation is to achieve strong customer interactions.

**Table 2** shows the main advantages gained from e-business application.

This advantages can be categorized according to Porter and Millar (1985)'s statement that information technology is permeating the value chain at every point by:

- 1) transforming the way value activities are performed;
- 2) transforming the nature of the linkages among value activities;
- 3) affecting competitive scope.

**Figure 2** illustrates the main transforming of the way value activities are performed.

By adopting e-business to perform these activities, the case companies can achieve the competitive advantages listed in **Table 2**. **Table 3** illustrates the relationship between value activities and competitive advantages achieved.

The main problems of e-business application include internal interorganizational systems integration and the impact of organizational context such as organizational structure, management style and the customer base.

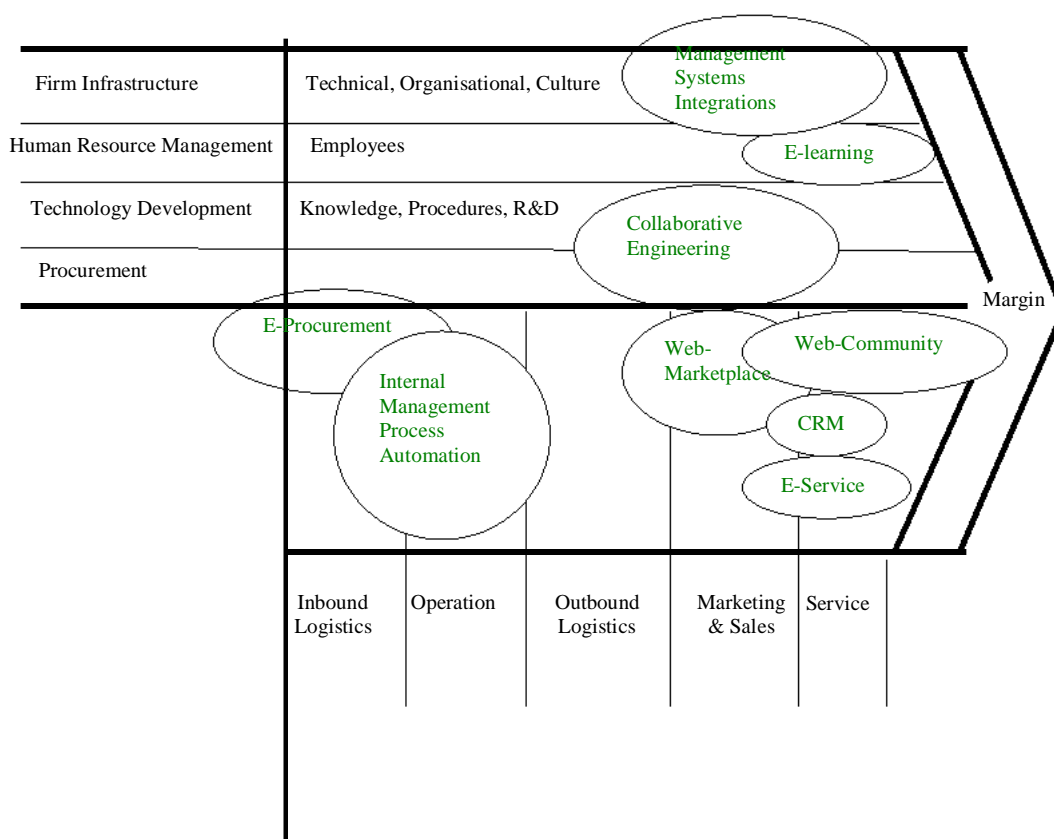

Figure 2 E-business technologies applications in the value chain in Chinese real estate industry

Source: Adapted from Floris *et al.* (2001)

Table 3 Relationship between value activities change and competitive advantages achieved

Value activities	Adopted by companies	Competitive advantages achieved	Advantages achieved by companies
E-procurement	I	1) Reducing purchasing cost; 2) Standardizing operation process which leads to simplifying complex internal processes and reducing costs; 3) Reducing redundancy.	I
Internal management process automation	I,II,III,IV, V	1) Better information sharing; 2) Reducing redundancy.	I,II,III
Web-marketing	III (has intention to adopt, has not adopted yet)		
Service including e-service, CRM, Web-community	I,II, IV	1) Better management through customer monitoring; 2) Strong interaction with customers; 3) Reducing business risk.	II—better management; IV—strong customer interaction and reducing business risk
E-learning	I,II	1) Facilitating employee training; 2) Reducing redundancy.	I,II
Management systems integrations	III	Facilitating strategy formulation through better information sharing.	III

#### 4. CONCLUSIONS

As **Figure 2** shows, in general, the value chain framework is useful to identify and categorize possible e-business application areas. Moreover, this categorization makes identification of key sources of competitive advantage explicit as **Table 3** has illustrated. However, this framework cannot fully explain the success of e-business applications and the realization of intended motivations for example the impacts of organizational structure, management style, and the customers base.

Floris *et al.* (2001)'s framework is instructive in asking interview questions about possible e-business applications and identifying possible e-business application areas. However, one common application, namely automation of the internal management processes, is not stated in this framework although it is similar to Factory Floor Automation.

Evans and Wurster (1999)'s suggestion of using e-business to resolve the trade-off between reach and richness helps in interpreting Company IV's e-business applications and competitive advantage gained from these applications.

Steinfeld *et al.* (2002) and Daniel and Grimshaw (2002)'s frameworks help in identifying and interpreting the motivations of e-business application and benefits achieved from e-business adoption.

Based on Floris *et al.* (2001)'s framework, **Figure 2** gives categorization of e-business applications adopted by established, big Chinese real estate development companies.

The findings illustrated in **Table 3** reinforce Porter (1985, 1998)'s finding that key sources of competitive advantages come from: redefining the role of traditional activities, optimising the linkages, and choosing competitive scope. This finding tends to support Porter (2001)'s claims that the fundamentals of economics and strategy have not changed and the underlying assumption that Internet is the latest stage in the ongoing evolution of information technology is valid.

However, further research and work are needed to make the value chain model become an easily-used practical guideline for e-business implementation. Practically, few case companies use the value chain model as theoretical instruction for their e-business experiment although Company I has used value chain theory to redefine its value chain but not for e-business application purposes. This is partly because of the reason described by Stabell and Fjeldstad (1998) that the value chain model is more suitable for the analysis of production and manufacturing firms than for service firms where the resulting chain does not fully capture the essence of the value chain. Another reason may be more explanation work needed to be done to make the value chain model more easily understood by enterprise managers.

Facilitated by government policy, as the Chinese real estate market becomes more and more transparent, it is anticipated that e-business will play a more and more important role in helping companies to achieve these three advantages. However, this conclusion is contrary to views given by most of the interviewees. The main reason for this is that they are working with different definitions of e-business. According to them, e-business must include Web-based transaction. However, in this

research, we would like to adopt the definition given by Zwass (1996): "E-commerce is the sharing of business information, maintaining business relationships, and conducting business transactions by means of telecommunication networks."

In summary, through case studies, the study shows that the value chain is helpful and primary in terms of understanding the different kinds of e-business applications in the practical world.

#### ACKNOWLEDGEMENT

The authors thank all the case companies for providing valuable information for this research.

# Research on Collaborative Commerce Model Based on Web Services

Liwen Wu, Yingqiang Duan

School of management, Dalian University of Technology, Dalian, Liaoning 116024, China  
feagleme@sina.com

## ABSTRACT

The concept of collaborative commerce was put forward by Gartner Group in 1999, and Web Services becomes one of the best implementation technologies of collaborative commerce for that it is loose-coupled, based on open standards and etc. In this paper, based on service oriented architecture of Web Services, we construct collaborative commerce model, analyze business process integration of collaborative commerce and design the implementation way of conversation mechanism in transaction process.

**Keywords:** Web Services, Collaborative Commerce, Transaction Process

## 1. INTRODUCTION

Collaborative Commerce is a new business mode on the background of global economics becoming one whole body. It can make enterprises easily collaborate with each other in the supply chain or cross supply chain. As result, the management mode is changed and resource is used economically<sup>[1]</sup>. Collaborative Commerce is an evolution of the rudimentary point-to-point B2B transaction and it is a multi-point interaction among multiple parties for a single transaction.

Since the concept of collaborative commerce was put forward by Gartner Group, its implementation was researched from different aspects<sup>[1]</sup>. Now, there are two partly implementation ways of collaborative commerce. One is web enabled c-commerce, which is a one dimensional, single e-enabled business process that allows certain internal data to be visible to external trading partners, and vice versa. Typically, this meant implementing a web presentation of the data, and allowing partners access to it. This is a limited form of c-commerce, with very limited value, saving only labor cost. Typical applications would be displaying demand for production materials, showing sales forecasts to suppliers, or presenting bills electronically. The other is B2B exchanges in markets such as steel, auto parts, chemicals or airline equipment. Buyers, sellers and suppliers are integrated through a web portal. In this stage, each enterprise can reconfigure its supply chain through the marketplace to leverage aggregated buying power and eliminate brokerage fees and middlemen<sup>[2]</sup>.

Those two ways of C-Commerce have never reached the critical mass required for mass adoption by all industries, because of the cost of integration. Information systems of two sides in the transaction are cannot communicate directly and isolated information islands are formed between them. And also, one complete transaction not only includes the two transaction sides, but also needs the third parties such as logistics, bank and etc. How to incorporate the third parties value-added service providers into business process and communicate each other between different systems freely is critical to

completely implement collaborative commerce, and one effective way is needed in order to implement transaction process integration.

Now, there are mainly two ways on implementing collaborative commerce. One is expanding the existed information systems such as SAP, the other is by adopting distributed component technology<sup>[3]</sup>. But these methods have different defects. By expanding the system function, it can partly improve business process, but it cannot satisfy the need of easily process integration and reengineer, especially between heterogeneous systems. Distributed component technologies, such as DCOM, CORBA and RMI, are complex, their message format are not open, and are difficult through firewall. So, they cannot satisfy the demand of transaction process integration of collaborative commerce.

Web Services, which are loosely coupled, cross-internet, based on open standards, can be one effective technology of integrating transaction process of collaborative commerce. Charles Abrams, Gartner Group expert thinks that "Web Services have made a good development on those facets, including tools, infrastructure architecture, technique, standard. But, research on business model is short<sup>[4]</sup>." So, based on Web Services, collaborative commerce model will be constructed and transaction process integration of collaborative commerce will be researched.

## 2. WEB SERVICES ARCHITECTURE

A Web service is an interface that describes a collection of operations that are network accessible through standardized XML messaging. A Web service is described using a standard, formal XML notion, called its service description. It covers all the details necessary to interact with the service, including message formats (that detail the operations), transport protocols and location<sup>[5]</sup>.

The Web Services architecture is based upon the interactions between three roles: service provider, service

registry and service requestor. The interactions involve the publish, find and bind operations. Together, these roles and operations act upon the Web Services artifacts: the Web service software module and its description. Figure1 illustrates these operations, the components providing them and their interactions<sup>[5]</sup>

Figure1 Web Service architecture

In a typical scenario, a service provider hosts a network-accessible software module (an implementation of a Web service). The service provider defines a service description for the Web service and publishes it to a service requestor or service registry. The service requestor uses a find operation to retrieve the service description locally or from the service registry and uses the service description to bind with the service provider and invoke or interact with the web service implementation. Service provider and service requestor roles are logical constructs and a service can exhibit characteristics of both.

### 3. COLLABORATIVE COMMERCE MODEL BASED ON WEB SERVICES

#### 3.1 Building Collaborative Commerce Model Based on Web Services

In web-enabled collaborative commerce and e-market mentioned above, only the buyer and seller interact with each other. However, it doesn't include the seller's interaction with the transportation company that will pick up and deliver the goods. This transaction also relies on the buyer and seller having an agreement to do business before the electronic transaction occurs<sup>[6]</sup>. Obviously, the transaction process is not complete, and doesn't include value-added service.

Based on Web Services Service Oriented Architecture, collaborative commerce model was constructed as figure 2. This model expands the transaction boundary and incorporates all parties at the time of the transaction including third party logistics, third party storage, bank and etc. Thus, it can integrate all transaction process and all transaction data can flow freely between different systems. As a result, isolated information islands between different entities are eliminated. And also, it

provides accurate fulfillment information, dynamic trade agreement, and increased revenue recognition. Accurate fulfillment is a critical requirement for direct materials procurement. There's no tolerance in this market for out-of-stock conditions or backorders. The ability to dynamically trade with sellers will open up opportunities for e-hubs to emerge. These hubs can manage complex interactions for many businesses. Finally, directly incorporating creditors into the process will ensure faster revenue recognition for the seller and create a new financial market for underwriting and insuring these transactions<sup>[6]</sup>.

Figure2 Collaborative commerce model

Collaborative commerce model includes three kinds of entities:

- o Direct transaction entities, including buyer and seller. Anyone can be the service provider, also can be the service requestor. For example, manufacturer can publish order service to UDDI registry. At the same times, it also can request the third party logistics service.
- o Third party entities: including storage, logistics, bank and etc. The third party entities mainly are the role of services provider and provide services for business transaction.
- o UDDI Registry. It provides functions of publishing and finding of service.

#### 3.2 Transaction Process of Collaborative Commerce Based on Web Services

Here on background of TV industry, we analyze how to integrate transaction process of collaborative commerce by Web Services. Supposed that there are five business entities included in the whole transaction process, TV distributor (buyer), TV manufacturer(seller), third party storage, third party logistics and bank. TV manufacturer published order service (OrderTV) to UDDI registry. Third party storage provides product query service (ProductQuery) to check product amount. Third party logistics provides service of transporting product (ProductTransport). Bank provides service of payment (AccountTransfer).

According to market forecasting, TV distributor plans to order one thousand of TVs. The whole transaction process of collaborative commerce is described as following:

- o TV distributor looks up order service(OrderTV) that TV manufacturer published in UDDI registry. There

Service  
Requestor

Service  
Description  
Registry  
Find  
WSDL  
UDDI  
Bind  
SOAP

are some open source software of UDDI registry, such SOAPUDDI and JUDDI. We can use find\_business(), find\_service(), find\_tModel() and etc functions to get concrete information such as TV manufacturer, service list, bindingTemplate of every service, accessPoint of services and WSDL OverviewURL.

- ò According to returned WSDL document URL, TV distributor can use client tools to produce client proxy class, and use this proxy class invoke order service(OrderTV) of TV manufacturer. Here, we can use the tool of Axis, org.apache.axis.wsdl.Wsd12java, to produce client proxy class.

Figure3 Transaction process of collaborative commerce

- ò TV manufacturer invoke the product query service(ProductQuery) of third party storage to check the amount of TV in storage.
- ò According to the returned amount, TV manufacturer decided to accept order or reject.
- ò If accept order of distributor, TV manufacturer invokes transportation service(ProductTransport) of the third party logistics.
- ò After receive confirmation information of the third party logistics, TV manufacturer returns the state of order to TV distributor.
- ò The third party logistics delivers to TV distributor, order is fulfilled.
- ò TV distributor invoke service of payment (AccountTransfer) to give payment for TV, and the whole transaction is complete.

From above transaction process, we can see that every entity doesn't log on web site to fill in web form. Through direct interaction between systems, we integrate transaction processes of collaborative commerce and data of transaction seamlessly flow in and out of different system of business entities.

### 3.3 Implementation Way of Conversation Mechanism for Collaborative Commerce

In the ordering TV transaction process above, Web services of different business entities are included, and maybe the whole transaction last several days, even several weeks. So we should make mechanism of

conversation to keep track of execution process of whole transaction.

We can implement it by adding conversation state information to SOAP Header of buyer and seller. Conversation state information was inserted into SOAP Header by Service requestor's conversation state process module, and service responsor's conversation state process module use the information of services requestor. Concretely, we can use TPP/TPA of ebXML or cnXML.

The following is a simple demo of requestor's message, ConversationState SOAP Header item defines message exchange protocol of two sides of transaction, AgreementID element is ID number of protocol. ConversationID element is used to identify concurrent conversations under the same conversation agreement.

Conversation message demo of service requestor in SOAP message as following:

```
<env:Envelope xmlns:env="http://www.w3.org/2003/05/soap-envelope">
  <env:Header>
    <n:ConversationState xmlns:n="http://www.dlut.org/conversation">
      <n:AgreementId>
        uuid:0236223-8688-266b-f891-9dfdfj3j6jf
      </n:AgreementId>
      <n:conversationID>
        uuid:1323212-46bf-36fh-2323-dy1q2w5124
      </n:conversationID>
    </n:ConversationState>
  </env:Header>
  <env:Body>
    .....
  </env:Body>
</env:Envelope>
```

Message response uses ConversationState SOAP Header item which is produced by message requestor, so they are identical. During the life cycle of the whole transaction conversation, values of AgreementId and ConversationID don't be changed, and they are included in SOAP request message and response message.

## 4. CONCLUSION

Web Services are loosely coupled, based on open standard, and provide dynamically discovery transaction object. It becomes an effective technology in transaction process integration of collaborative. Deeply research on Web Service will promote rapid development of collaborative commerce.

### ABSTRACT

Business processes of traditional functional organizations are hard to respond to the rapidly changing market in the information era, so modular organizations are given attentions. In this paper, business processes in modular organizations based on the commitments between competence modules are analyzed and process reengineering of the Haier Company is used to illustrate the characteristics of modular organization processes.

**Keywords:** modular organizations, process, competence, commitment

### 1. INTRODUCTION

It is hard to predict market needs in the era of electronic business. With unpredictable change, organizations are expected to focus on not only the efficiency of processes, but also the flexibility and adaptability. Traditional functional organizations with large-scale production organized under the predictable requirements are product-driven, and concentrate on the business efficiency. The coordination among departments is made by management. In doing so, business processes are fragmented and rigid, being clumsy in responding to the competitive market. How to meet customers' needs rapidly becomes the challenge the sense-and-respond Organizations face (Stephan, 1999). By sense-and-response Organizations we mean that are customer centered, and assembled by numerous competence modules. The coordination among the competence modules is customer-driven by sensing and responding market change in complicated environments. Relative customer relations are formed by particular commitments between competence modules, which are managed and tracked by the commitment management system in order to integrate the ability and responsibility of them.

In this paper, we discuss how to apply the commitments between competence modules to analyze processes in sense-and-respond organizations, and a case study is illustrated.

### 2. PROCESS AS A COMPETENCY

Integrating organization elements such as information, material and human resources, a business process can transform certain inputs into outputs, which actually reflect one kind of competence that the process itself is a competency carrier. A value chain involves a few processes in the organization operations in order to create value for customers needing the cooperation of different departments such as procurement, manufacturing, sales, customer service and human resources, which form the multi-dimension of the

competence and present the modularity of the process. On the other side, the hierarchy of the process makes the competence module hierarchical. Several low-level complementary competence modules perform high-level processes, so the hierarchy and complementarity of processes represent the structure of organizations. Different processes involve different competent modules; the way in which they combine is also different. The relations of the main body of the competence module - the team or individuals who play one role and whose cooperation determines the performance of processes to a great extent - reflect the organizational form. Process change management such as BPR emphasizes breaking the bounds between functional departments to reduce the loss brought by the cooperation and intercourse or to build up the competence of one single module making the work team or individual responsible for more steps of the whole process.

From the view of the source of organization competitive advantages, it's important for an organization to possess more advantageous and heterogeneous resources than other organizations, but it can't create true value if the resources aren't transformed into the products or service customers need by organization units that add values (Colli, 2001). In essence, the real source of organizational competitive advantages is to create value for customers through the inimitable coordination between organizational competence modules and the effective use of the resources. The transformation needs the cooperation of interrelated competences, which make up a process. The operation, in fact, creates value for customs through the activities and cooperation of organizational units from different hierarchies. The competence of the organizational units is the ability to create values for the organization with resources allotted. The competence is delaminated, from individuals, departments, to teams or virtual organizations across departments or even organizations. The low-level competence is the basis of the high-level one; meanwhile the high-level competence takes on the integration effect because of the cooperation of the

low-level competences. From the low-level to high-level, the scope of integrations and degree of added values increase fast, causing more difficulties in organizational coordination. Organizational unit competence depends on not only specific resources and expertise, but also the structure of the organization, the way of organization units cooperate with. However, it will bring the negative effect if the units don't work well together. From the discussion above, a process is a harmonious value-adding carrier because it assembles various units to build the core competence of an organization. Of course, the harmonious environment will not appear automatically, and good organization structure, surveillance and adjustment of organization performance are needed. Herein, resources are the basis of the competence; organization units are the main body of the competence

The competitive strategy theory suggests that the competence is the embodiment of a set of business processes, which are well comprehensible from the view of business strategy. If an organization want to gain competitive advantage, it's necessary to transform its core business processes into the inimitable strategy, implementation and provide super-value for customers. The essence of the transformation is to assemble different competence units into an inseparable whole across functions and even organizational boundary driven by market opportunities, which need close connection among interrelated processes. To do so, the adjustment in the organizational structure, strategic investment in IT and control of top management are necessary to guarantee the success of the transformation. It seems that the transformation is to determine and integrate necessary business processes to respond to customers, but it is not easy to change processes into strategic competence. Among the key success factors, the inventory replenishment process of Wal-Mart, for example, makes it an excellent retailer, which connects its suppliers, distribution centers and numerous POS in superstores via satellite communication systems and Internet, so that each actor in the supply chain can acquire necessary information in time, thereby the sale process of suppliers, distribution process of distribution centers and the order process of the POS conjoin closely.

### 3. THE PROCESSES OF MODULAR ORGANIZATIONS

With increasingly intense competition, it's vital for organizations to sense and respond to ever-changing environments quickly. As for this, the research has been done on adaptive organizations. In this paper, we discuss modular organizations based on the adaptive organization. Modular organizations are different from traditional ones, centering on customers and consist of competence modules. More importantly, these competence modules can be combined dynamically to build up stronger competence modules. Each

competence module owns necessary qualification and resources to play a certain role. Modular organizations are, therefore, highly adaptive, which are characterized by reengineering, agility and flexibility. Organizations can deploy the competence modules and their relations to satisfy customers so that the structure of modular organizations adapt to rapid reengineering of organization processes.

Customers are the reason and goal for the existence of competence modules, and market changes attribute to the reengineering of the competence modules. In modular organizations, the relationship between competence modules is customer-performer, which can request or provide service. Here, customers are a relative concept, referring to either external consumers (receivers of organization output) or internal customers.

The value of products or service provided can be evaluated by customers as the foundation of rewards. In process analyses, role-based cost management is taken to compare cost/return and discover the weak points in processes based on the value that each competence module creates for organizations. Besides, the contents and results of service are prescribed by commitments, which are one kind of formal or informal contract between competence modules. The commitments between the modules can be adjusted as a result of uncertainty of customers' expectations, which is achieved by continuous negotiations of the two. For instance, in the BPR of China Unicom Limited Heilongjiang Branch, operation units, as a customer of maintenance department, give the maintenance request and checkup standards. Then, the maintenance department will perform the maintenance and how well it work resorts to the operation units. In order to improve the efficiency of processes, commitments between competence modules can be managed by workflow management systems.

The adaptability of modular organizations depends largely on the smooth communication between competence modules, which needs an open atmosphere and active interactions, breaks the fencing of work dividing of functions and makes all parties participate in decision-making of organization planning.

Each module is authorized in modular organizations according to its capacity and responsibility. Decentralization and coordination are sometimes hard to compromise. How to coordinate competence modules to form an organic process system without strict command and control is a challenge to modular organizations. Generally speaking, common goals and effective coordination mechanisms between competence modules determine the way an organization runs as a whole. New competences will appear when the complementary modules are assembled organically, which avoids the isolation of traditional function departments and reduces the high cost of coordination. End consumers can't be satisfactory until commitments in every part of

processes are fulfilled. Therefore, commitment management is needed by all participants. On the other hand, how to capture external consumers to deploy competence modules and coordinate these modules is a problem.

From the view of point of commitments, roles of employees and work team etc. are identified and their contributions in the organization development are also easy to understand. Normative and authentic commitments simplify coordination management of modular organizations. In order to guarantee the cooperation among competence modules, commonly accepted protocols have to be designed. For instance, the commitment management of communication-based workflow models consists of four phases: definition, negotiation, execution and evaluation (Gregory, 2001). Commitments between competence modules are complex, speech and act theory, which is the basis of communication-based workflow models, are only simple abstraction of reality.

Modular organization processes are initiated from identifying customers' needs and then required competence modules and their commitments are designed. Herein competence modules are the combination of work teams of horizontal organizations. Actually, process management circulates the following four phrases: sensation, analysis, decision-making and execution. Change information in business environments is handled in the first two phases to provide the basis for subsequent reactions. To emphasize, competence modules can be taken by other organizations or even competitors (commitments between them may be more complicated). The commitment between competence modules is not to explain how results are accomplished, but to detail what the responsibilities are because the competence modules are automatic and, they can plan for their sub goals. The uncertainty of external customers may lead to the obscurity of the commitments, so the commitments between external customers and competence modules have to be adjusted repetitively. So do commitments between in-house modules of processes. Usually, commitments taken by a competence module are dual corresponding to its dual roles in a process: both a customer who requests service from the front role and a performer, who provides service for the next competence module in the process.

A process is, in essence, to transform external consumers' expectations into internal customers' requests, via the customer-performer chain of competence modules. When external consumers need new service, adjustments will be made along the chain. As a system, process modules must be well coordinated:

- Decompose process goals, and identify roles played and responsibilities taken on by competence modules. Every competence module should recognize that the

organization can satisfy external consumers and it can be rewarded only if it can satisfy its own "customer". Competence modules are designed to realize goals of organization processes, which is a top-to-bottom process of decomposing the goals

- Competence modules are customer-centered to establish the customer-performer chain through trust mechanism and commitment management. This actually introduces market mechanism to organization inside in order to improve the performance of competence modules, and to integrate external consumers with internal competence modules, even competitors into a whole for faster response.

- Competence modules can change commitments or reengineer. Changes from outside drive the commitments adjustment one-by-one along the customer-performer chain. On the other hand, information technology plays an important role in the establishment and maintenance of commitments among competence modules.

#### 4. CASE STUDY: BPR OF HAIER GROUP

Linked by the market chain, the BPR of Haier encourages the initiative of employees and improvement of customer satisfaction. By the market chain we mean that market mechanism is introduced into organizations to prevent the coordination cost from exceeding the efficiency increase in labor division when organizations expand. That means that market is used as a coordination mechanism in Haier. The market chain turns internal relationships among processes, working procedures and employees into equal market relationships. Through the relationships, external market orders can be transformed into a series of internal "orders", forming a business process, which centers on orders with positions cooperating with each other and adjusting automatically. Customer-performer chains exist in organizational units. Whether commitments among units are fulfilled determine their revenues directly. The method above is essentially to build a benefit adjustment mechanism between internal organization units that reduces internal coordination costs. In doing so, the market chain transfers end consumers' requirements to every organizational unit, which facilitates information flow and feedbacks, making every organization unit aware of the competitive pressure and focusing on customers. In conclusion, the business processes of Haier are typical of a modular organization.

The market chain of Haier decomposes end consumers' needs into closely related customer-performer chains connected by commitments (market) as a whole. The market chain has overcome the embarrassment of isolated departments and no one being responsible for the whole process. Moreover, the market chain of Haier not only integrates internal organizational units through commitments, but also brings the suppliers and

customers together.

systems thinking.

### 5.SYSTEM THINKING

From the discussion above, it's concluded that each competence module in modular organizations plays a definite role in a process, and they can make their own plan independently. The process model takes a look on a customer-performer chain whose spots are competence modules. Can the goal of the whole process be achieved if every role has "satisfied" its own customers? The question is noticeable. A good example is the beer game mentioned in Peter Senge's *The Fifth Discipline* (Peter, 1990). This story is about the "game" among retailers, wholesalers and manufacturers in a beer supply chain. The three roles all attempt to meet customers' needs to gain more profit, but they are constrained by the limited rationality and have not considered upstream suppliers and downstream wholesalers, who are lack of communication and information sharing. As a result, when demands fluctuate, orders will be magnified along with the supply chain. This is the so-called bullwhip effect. This illustrates the necessity to alter the mental models of competence modules and strengthen the

# Research on Multi-Agent Based Information Management Platform for Enterprise Business Cooperation

Haigang Li

School of Management, Shanghai Jiao Tong University, Shanghai 200052 China  
lihg@sjtu.edu.cn

## ABSTRACT

The Enterprise Business Cooperation Mode is analyzed, as a result, an multi-agent based business cooperation framework is presented. The agent configuration in the framework is explained respectively, and a case of business process reengineering with multi-agent is discussed to prove the feasibility of the framework.

**Key words:** business cooperation; information integration; multi-agent technique; business process reengineering

## 1. INTRODUCTION

Looking back to the operation process of the well-known enterprises at home and abroad, it's easy to get a thought of enterprise' development in the future: internet provides more choice to the customer, customer's loyalty decides enterprise' survival and development in the age of internet economy, the enterprises will be sure to turn to pursuing the maximum of customer's satisfaction from simply pursuing the maximum of profit. In order to fulfill this goal, manufacture enterprise should make order-form-centered strategic cooperation with supplier, realizing interactivity, equity, win-win. Its core is to realize business cooperation including the information sharing and business cooperation of all the enterprises in the supply chain.

With the development of manufacturing industry mode and information technique especially, the enterprises are faced with a great amount of different distributing information resource. However, in the customer-oriented, rapidly changing and vehemently competitive market at present, enterprise's surviving room is tending to a state of "upper-flow" and "chaos"<sup>[1]</sup>. The information system in Enterprise Business Cooperation Mode presents a characteristic of intermixing huge system. Traditional calculation mode can't deal with the complicated tasks in function and in structure. The appearance of CSCW (computer supported cooperative work) provides a better method to solve the problem, while Agent and MAS (multi-agent system) is the base of CSCW. Starting with analyzing the technique means, management notion and method adopted in enterprise's operation, business cooperation mode is discussed in aspect of system engineering, and combined with the Agent theory, an integrated framework suitable for business cooperation mode is constructed, providing a new approach for the study on Enterprise Integration System.

## 2. ANALYSIS OF ENTERPRISES' OPERATION ENVOROMENT

The worldwide market economy is rapidly developing

and the competition among enterprises is becoming more and more vehement. Traditional manufacturing industry including process enterprise operation mode has changed ultimately, from traditionally long-time, orderly manufacturing in manufacture plan organization to contemporarily short-time, random manufacturing in order contract organization; from traditionally manufacturing characterized in large volume, single type, normative to contemporarily manufacturing in small volume, various types, non-normative, from traditionally emphasizing on guaranteeing the carrying out of the manufacture techniques during the manufacture operation control to contemporary gaining the maximum economic benefit under the condition that the manufacture resources such as the material ,energy, human resource, capital and storage are limited. Therefore, many research organizations and scholars at home and abroad are studying in the field of E-commerce supply chain. Some advanced enterprises are trying to optimize the product's design and manufacture by using PDM (Product Dada Management) and CPC (Cooperative Product Commerce) , reduce the internal cost by using ERP (Enterprise Resource Planning) , improve the whole supply chain's efficiency by using SCM (Supply Chain Management) , broaden the market and confirm the customer's loyalty by using CRM (Customer Relationship Management) , and operate from electron purchasing to solving problems in supply chain.

With the further studying of information technique and E-Business, the emphasis of supply chain's construction has been transferred from simply stressing on exchange to the whole transfer of business body (enterprise) and business activities in the network environment. To those enterprises that have adopted business cooperation mode, the application of "cooperation-trade" will bring the return of income and profit. The development of "cooperation-trade" will bring up highly agile dummy enterprises and bring change to some business models, such as material, the design and manufacture of products<sup>[2]</sup>.

### 3. ENTERPRISES BUSINESS COOPERATION MODE

#### 3.1 The Thought of Business Cooperation Mode

Business cooperation means not only the internal departments of the enterprise but also the associates including supplier, distributor, retailer and customers should be tied closely to exploit and meet the market's demand together, forming enterprise's dynamic union and cooperation. With unified plan and unified data mode, all the supply chain node enterprises make the product's cooperatively exploiting and material's cooperatively purchase, manufacture, distribution and delivery under the operation of unified plan. In a word, the cooperation among enterprises can be defined in three layers, one lies on operation layer, such as the purchase, promotion and order, etc, the second one lies on tactics layer, including the task-base forepart cooperation that work flow's upper-flow and down-flow enterprises make, and the third lies on strategic layer, that is, tight cooperation that work flow's upper and down. Enterprises start on phase of seeking for task. Enterprises involved the cooperation try their best to take advantage of the combination to form strong competition in addition to making use of their own advantage.

As a new subject, "cooperation" has been widely used as a crossing subject to study the common essential characteristics among different things. The notion of cooperation can be explained by simple mathematic symbols. The combination of any kind of product and market will have influence on enterprise's whole profit level. Suppose the price of some product is  $\text{¥}S$ , the expense on manpower, material, management and so on is  $\text{¥}O$ , and the investment on research and development, tools, workshop, inventory and etc. is  $\text{¥}I$ . The investment income per year on  $P_1$  can be expressed as follows:

$$ROI = \frac{S_1}{O_1 - I_1} \quad (1)$$

As to other products  $P_2, P_3, \dots, P_n$ , the same expression can be got. If there's no relativity among products, the income of enterprise can be expressed as follows:

$$S_T = S_1 + S_2 + \dots + S_n \quad (2)$$

The whole operation cost and investment can be expressed as follows.

$$O_T = O_1 + O_2 + \dots + O_n \quad (3)$$

$$I_T = I_1 + I_2 + \dots + I_n \quad (4)$$

Therefore, the whole investment efficiency of enterprise is,

$$(ROI)_T = \frac{S_T - O_T}{I_T} \quad (5)$$

As long as the income, operation cost and investment of different products are irrelevant, all of the above relations will exist<sup>[3]</sup>. Most enterprises have scale benefit. To a big company whose income is equal to the sum of

several small enterprises, its operation cost may be less than the sum of the small enterprises', or its total investment is less than the sum of theirs, which can be expressed as follows:

$$S_s = S_t; S_s \leq S_T; I_s \leq I_T; \quad (6)$$

In which, index  $s$  represents an enterprise, index  $t$  represents the aggregation of several single small enterprises. Therefore, when the income is equal, the investment income of the company is higher than that of the aggregation of several single small enterprises, that is:

$$(ROI)_s > (ROI)_t \quad (7)$$

When the total investment amount is equal, we can get the similar conclusion:

$$S_s \geq S_T; O_s \geq O_T; I_s = I_T \quad (8)$$

So we can know, manufacturing cooperatively can create higher income and/or lower operation cost. Taking advantage of cooperation can achieve all kinds of operating goal. If an enterprise has the ability to make use of the combination of products and market to increase the cooperation effect, the competition means offered will be very amplitude.

#### 3.2 The Signification of Information Management Platform for Enterprise Business Cooperation

The information management platform for enterprises business cooperation integrates all the application and data into one platform, and supply the unitary user interface, which make enterprises build the information platform quickly between business to business, and business to its own employees. This platform is a comprehensive implementation mode of electronic business, and also a web based application system, which makes enterprises delivers all kinds of information stored inside or outside to employee, customer, suppliers and the firm comates, as a result, the information accessed by them is customization. The characteristics of the information platform can be summarized as the following, using unitary information access canal form which user can access their need information in order to optimize business operation and heighten productivity of company; using uninterrupted services through network and secure mechanism to make user access information anywhere and anytime; using strong content management capability to support almost all structure and non-structure data, identify the data from variant of data bases and collect and dispose all kinds of document; using individuation application services to set and supply the customization data and application such as enterprises portal in order to heighten the working efficiency of employee, intensify the affinity and attractive force; using integration with existing system to make the existing data and application be integrated together; using strong expansibility to adapt to new readjustment and change of enterprises, so to meet the need of business readjustment and expanding; using infallible and secure indemnity to guarantee the privacy and integrity of data; using collaboration and share to make user access and supply information for special

organization including individual.

### 3.3 Construct the Framework of Business Cooperation Model based on MAS technique

With introduction of mutual communication, distributed self-government agent, advanced enterprises cooperation business can be regarded as a heterogeneous multi-agent system which integrates all kinds of manufacturing action such as order, design, manufacturing and marketing together. This heterogeneous multi-agent is a polyphyletic cooperative system, in which each agent

team works for the same aims. We build the interactive enterprises cooperative business information management platform using object-oriented methods and MAS technology of artificial intelligence (see figure 1). From view of function realization, Agent is classified into two kinds, transaction agent and intra agent, the former take charge of information and communication between the key company in enterprises cooperative supply chain and the other node companies, while the latter is responsible for the information interflow and data commutation of different department within a enterprise.

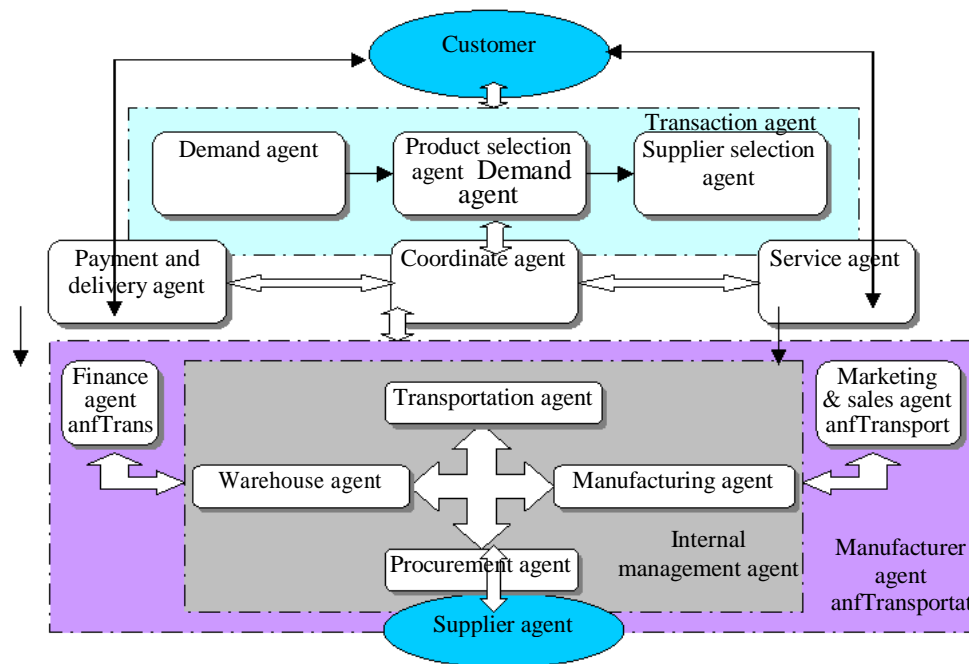

Fig.1 Enterprises business cooperative information management platform

## 4. CSASE STUDY

### 4.1 Design and implementation of MAS

Agent has the ability of manipulating multi-dimension information real time, impacting and communicating each other, which adapts to requirement of manipulation real time and concurrent for software development. On the other hand, development of internet technique make it possible for each agent unite to resolve problem cooperatively by teamwork in internet, with space distributed intelligence, information and technical resource. An integrated agent unite includes information model, resource model, organization model and cooperation model. Agents between upper layer and subordinate layer coordinate besides those in same layer. I.e., the original equal relationship is combined with the upper layer and subordinate layer relationship to form hierarchical relationship. The whole agents comprise an association in which agents are divided into several programmer teams according to task scope of agent. In a programmer team, agent is divided into three types

including management agent, function agent and service agent. The three type of agent lies in deferent layer and forms an agent tree, in which type and hierarchical relationship defines the status and power of the agent. Management and function agent comprise the key layer of programmer team, and all the agent association comprise the forest showed in figure2.

At different stage of design and development including view building and process flow model building, and agent model design and information support flat building of implementation stage, different modeling tool system and information integration techniques is needed. At requirement analysis stage there are all kinds of modeling tool software for function view and information view developed by IDEF0 and IDEF1 standard<sup>[4]</sup>, e.g., CASE and ARIS At design stage object modeling tool based on agent can be adopted such as ABE of IBM Co. Ltd. At implementation stage practical execution system is built in light of process flow model, the key to which is designing and packaging agent, building the information integrated flat for the object and

agents.

Fig. 2 Programmer organization model based on multi-agents

For the aim of inter-manipulation, multi-agent system needs support of standard and operation system. One is KQML standard, a language and protocol for exchanging information and knowledge. It supports the information share among agents as a language standard and information management protocol; meanwhile it is used as an interface among multi-agent system for resolving protocol problem as application programming language. Another is CORBA standard, provides service from abstract distributed object model and coincidence depiction of language, shields isomer of operation flats and data resource, to make different application transplant and manipulate each other. The third is COM/DCOM standard, a binary unit model defined for inter-manipulation of units, is a basement unit model which is irrespective of programming language and suitable for application and system development of units.

#### 4.2. Application in sales workflow of cooperative business information platform

Fig.3 Sales and consignment process of a company

### 5. CONCLUSION

Today in the world, the enterprise is up against new challenging from the tendency of economy globalization and the enterprises development idea of centering on customer service. It is seems very necessary and important for corporations to reengineering the business process, integrated the forthcoming application, data and

The process flow modeling based on Agent expresses all the process flow activities and their relations by Agent model. Agent's characteristics of autonomy, agility, interaction and cooperation facility enterprise to restructure and reengineer the manufacture and operating process and to combine tightly with the information supporting flat during the implementation. The topological structure and incidence relation of agent Network in the Cooperation Layer are the reflection of the model of enterprise business disposal process. Every agent in cooperation layer corresponds coarse grain business disposal process in real life and has certain stability and atomicity. According to the value chain transitive theory, there is some un-value added action in figure 3. Suppose each business disposal spot corresponds to an agent in cooperation layer, in order to support business dynamic adjustment, every knowledge base of business disposal agent should include the knowledge on dynamic business disposal. For instance, if the following rules are added to the knowledge base of consignment agent, the consignment flow can be decides according to the priority of the contract.

*If contract data agent.priority (contract number)>xx then*

*consignment agent.consignment (bill of lading number)*

*else*

*If invoice agent.completion (contract number) =Ture*

*then consignment agent.consignment (bill of lading number) else consignment agent.hanging*

*End if*

*End if*

Every agent has the unitive expression about its own information and the interface information of the related agent (which composes the topological structure of agent network and reflects the enterprise business model), invoke of methods between different agents can be fulfilled naturally and conveniently, as a result, it can support the dynamic enterprise model strongly.

frames, to achieve the business cooperation by dependent on information technology, especially by network technique. This paper builds the enterprise integrated system model by means of multi-agent technique belonging to knowledge engineering. This model has high flexibility, distribution, concurrent, self-compatibility, and self-corroborate ability. As a result, such agent will have a direct effect on improving

the performance of enterprises integrated flexibility.

## Study of cooperative product business support platform for new product development

Haigang Li

School of Management, Shanghai Jiao Tong University, Shanghai 200052, China  
lihg@sjtu.edu.cn

### ABSTRACT

The development phases of e-business is described firstly, then the new product development process in cooperative product business is presented in detail, the cooperative product business support platform including technical platform and information platform is discussed finally.

**Key words:** new product development; e-business; cooperative product business; platform

### 1. INTRODUCTION

With the more and more fierily of market competition, enterprise is obliged to adopt new administration operation mechanism and new business model, the key to this is electronic business. The kernel meaning can be presented like this, firstly, new business model should be built and the existing business model should be integrated on the basis of the Internet techniques platform; secondly, organization structure of enterprises should be reengineering and improved systematically by the technique of business process reengineering for the purpose of enhancement of enterprises operation; thirdly, relationship among manufacturer, supplier and customer should be redefined and extended by the technique of

supply chain management and customer relationship management; fourthly, internal and external resource of enterprises should be integrated, and attention to internal value chain should be changed to external one by the method of business process integration; finally, digital operation and decision should be fulfilled by the method of business intelligence.

Product is the key to manufacturing operation of enterprise. For manufacturing industry, cooperative business based on Internet is the senior type of electronic business, which includes electronic commerce and collaborative product commerce. Figure 1 gives us the development process of electronic business.

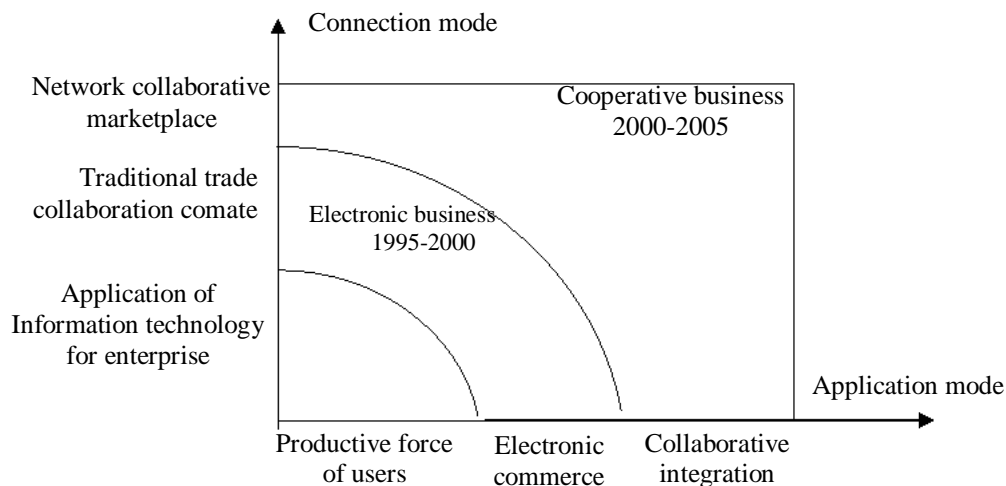

Fig. 1 The development phases of e-business

### 2. NEW PRODUCT DEVELOPMENT PROCESS IN COOPREATIVE BUSINESS MODE

With the coming of electronic business times, more and more manufacturing enterprises is thinking about how to integrate the company itself, suppliers and customer together and fulfill the collaborative development and sales of product by the network. As a result,

manufacturer and supplier will face the market together in electronic business times, and form the firm dynamic alliance by the method of collaborative product business. In this mode, the firm alliance subject builds its own collaborative business platform and fulfills the development and collaborative management of digitization prototype inside the kernel firm.

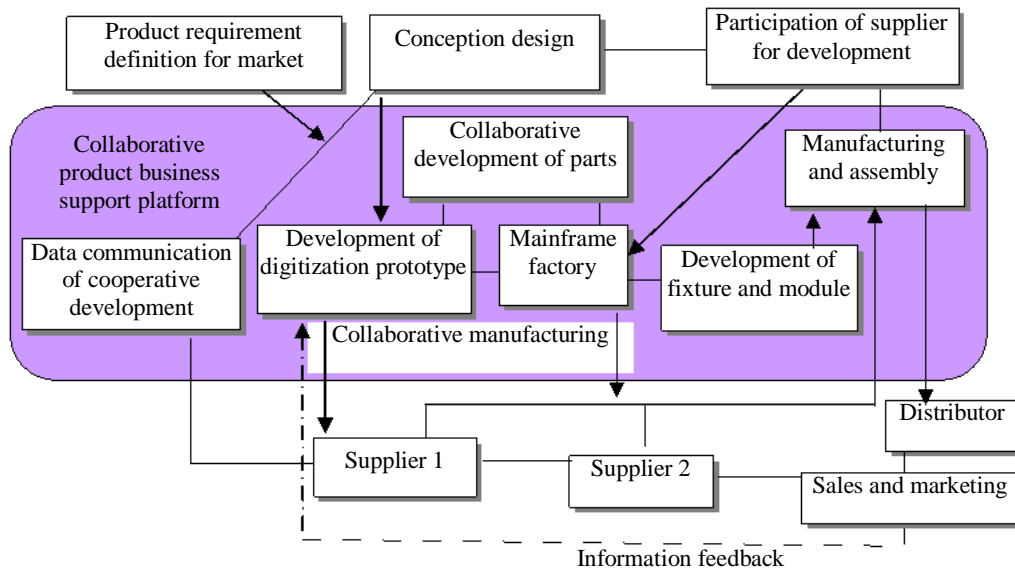

Fig. 2 A new product development process under cooperative business environment

On this platform, digital prototype development and collaborative management is fulfilled within the key firm, extends forwards to customer end through product requirement definition of customer, customer relationship management for market projection, and backward to maintenance, subassembly supply, distributor and customer relationship management for afterservice. In the medial product development link, the platform extends to supply chain to assure business to business model. Figure 2 gives us the new product development process under cooperative product business environment. Firstly, the function, performance, market object price, time putting on sale, supply chain and other strategy is defined by the key firm so as to map out the new product development plan according market

requirement and customer value added factor. Secondly, development project team of new product is built including the technique department inside the firm and supplier so as to develop the whole or parts of the new product with support of cooperative product business support platform,. During the process, the information of design, manufacturing, test and feedback for new product is exchanged and shared. Finally, when the new product has been cast to market, value added service after sale is extended to distributor and eventual customer though the cooperative product business support platform, including of supply chain management of parts, fault diagnosis and maintenance, and also the new product innovation information can be acquired form market and customer as the reference of the next new product development cycle.

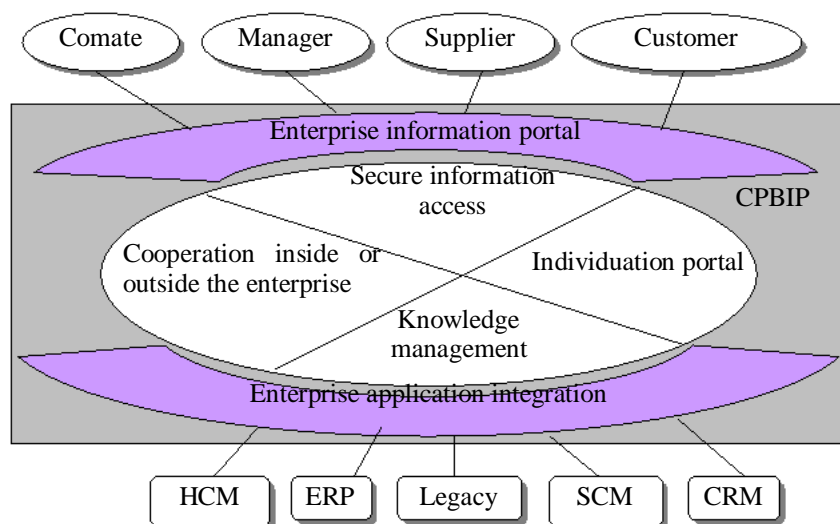

Fig. 3 the architecture of CPBIP

### 3. COLLABORATIVE PRODUCT BUSINESS SUPPORT PLATFORM FOR NEW PRODUCT DEVELOPMENT

The collaborative product business support platform

(abbreviated as CPBSP) for new product development is constituted by two main parts, one is CPBIP, a information support environment formed by Enterprise information portal, enterprise application integration,

knowledge management system and some secure information access techniques. the other is CPBTP, a technology support environment formed by series of product design and manufacturing techniques for virtual digitization prototype mode such as computer aided designing (CAD) /computer aided engineering (CAE)/ computer aided manufacturing (CAM) , virtual product data management (VPDM) / product data management (PDM).

The cooperative product business information platform uses the new Internet technology to fulfill the different business coordination inside the whole supply chain or across the supply chain, and change the enterprise business operation mode. The architecture of CPBIP is showed as figure 3.

Figure 4 gives us the architecture of the CPBTP. In organization, CPBSP is a network system formed by

persons from different tasks team such as product design, product analysis, manufacturing, simulation and support. In process, CPBSP supply the digital and virtual support for new product development, the new product is developed in method of concurrent engineering. In formality, the product under the support of CPBSP is a digital model actually which can be observed, analyzed, communicated and regenerated in demand, thus the design, analysis, producibility, maintainability and marketability of the product can be coordinated at the same time. In benefit and effectiveness, one product model is used in development such that the non-value added time is shorted and problem can be found and solved in time. Communication and coordination between enterprises in different place can be executed better so every worker in participation of the new product development can acquire his needed information in demand.

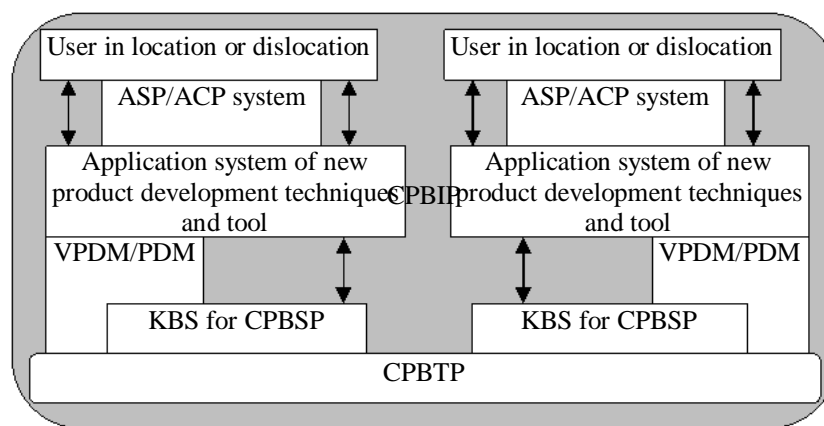

Fig. 4 The collaborative product business support platform

#### 4. CONCLUSION

As an advanced technique, the cooperative product support platform is used in the new product development process by enterprise to response to customer rapidly and flexibly, so the new product can be cast to market with prescriptive time, cost and quality. Through the CPBSP, different users within the key firm can use CPBTP to support the development of new product, and cooperative strategy comate can use either its own CPBTP or CPBIP to communicate with the member firms in the supply chain. The new product development under the cooperative business environment is becoming a strong measure to carry out the strategy translation for manufacturing industry and is paid high attention by the enterprise. The study of cooperative product business support platform is significant to the new product development of the future.

## ABSTRACT

A key planning activity within a Virtual Enterprise (VE) is to establish agreed inter-organizational processes. This activity, or meta-process, has to allow for gradual evolution of the VE processes and for a multi layer development from informal business agreements to precise workflows. To support this meta-process, a collaborative electronic whiteboard supported by a tuplespace is proposed. The whiteboard supports a mixed graphical and text interface, with support for keeping track of the changes made. The participating organizations upload workflow definitions from their own IT systems into the tuplespace. Workflows are then discussed, modified and evolved before being downloaded again and mapped to the partners' individual systems.

**Keywords:** Virtual Enterprises, B2B Collaboration, Inter-enterprise workflows, Electronic Whiteboards, Tuplespaces

## 1. INTRODUCTION

In an earlier paper [1], two of the current authors addressed the issue of IT support for developing shared workflows in Virtual Enterprises (VEs). VEs are characterized as formalized, but not permanent, alliances negotiated between autonomous organizations, where the goal is to present seamless business services to customers. Members are encouraged to agree upon and then enact processes that follow overarching guidelines evolved by the VE. These processes may evolve during negotiations to establish the VE or during the lifetime of the VE as conditions of the alliance are changed. Processes may eventually be discontinued when the alliance is dissolved. Negotiating efficient cross organizational processes can be of critical importance to the business value of the VE.

In this paper we define a *shared workflow* as a business process that two or more organizational entities agree to follow. A shared workflow is related to the private workflows of the individual organizations, but may only contain a partial view of them; each participating organization may not want elements of its internal processes to be externally observable. The term *evolutionary* means that shared workflows have not all been settled in advance, but need to be negotiated incrementally in step with the evolving business agreements between the organizations. A *meta-process* is a procedure – or process - whose purpose is to establish a business process that will be enacted for operational business cases. The term *multi-layer* derives from the earlier paper, in which several layers in the meta-process were identified, the first three being a) informal discussion b) agreeing a business process model and c) agreeing an executable workflow system.

The VE, or the subset of members involved in each particular business collaboration, needs to reach a final agreement on one or more inter-organizational processes that represent the way they agree to inter-operate. However each individual organization will usually also need to adjust its private processes to fit in with the new collaboration. For example, it may need to provide additional facilities for notifying partner organizations of progress, for responding to requests for status reports, or for dealing with exceptions such as non-response from the partner.

The question is - how best can IT be used to help the meta-process? Our intuition is that even if the VE has developed guidelines, the meta-process can never be as strictly predefined as with typical production workflows. But it is equally unrealistic to assume that the meta-process is totally informal. One possible intermediate paradigm is a negotiation model, but typical negotiation models focus on a limited number of measured utility parameters such as price, delivery time etc. Our task is to find something equivalent to a negotiation model that will allow the parties to make proposals, counter-proposals and agreements on a whole range of issues such as the nature of tasks, the order they should occur in, the data that should be provided, the persons that are authorized to commit to a decision, the rules governing exceptional situations - and so on.

This paper proposes a way to support the collaborative meta-process of evolving a set of workflows that will coordinate the activities of a VE. The collaborative activity is assumed to take place over the internet in the online equivalent of a meeting room [2], and that communication can be abstracted to the exchange of a series of events related to the collaboration. It includes the use of graphics exchange protocols for real time.

However our approach aims to avoid explicit dependence on any particular process model diagram or language standard, other than that the model can be represented in XML.

In this paper, section 2 summarizes the related work in business process modelling in B2B, business contract architectures, inter-enterprise workflows, evolutionary workflows, whiteboard/blackboard models, and coordination models using tuplespaces - with related software developments. Section 3 describes the architecture and basic model of our proposed approach. Section 4 discusses a possible way of implementing our approach with available software. Section 5 presents our conclusions and directions for further work.

## 2. RELATED WORK

ebXML [3] has been proposed as a standard approach to B2B e-commerce. It envisages that, at the level of the structure and sequence of messages to be passed, each organization proposes a Coordination Protocol Profile (CPP); the organizations then negotiate an agreed protocol (CPA). However ebXML has not yet recommended a meta-process for agreeing a CPA – use of an ebXML-familiar broker (consultant) is assumed.

Automatic and formal approaches for aligning business processes from different organizations have been proposed by Mahleko [4] and Grossmann et al [5]. However the orientation here is to find an *integrated* process, rather than the shared sub-process that represents only what happens *between* the organizations.

Negotiation of a shared process and negotiation of a contract are very closely linked. The contract will specify the duties of each party in both physical and informational terms. A description of our work in conjunction with the Business Contracts Architecture of Milosevic et al is given in [6] and [7].

The CrossFlow project [8], which is based on services-based cross-organizational workflow (SCW), looks at contracts as the key element in defining inter-enterprise workflows. Other important issues in CrossFlow include reliability, trust and service management (see also [9]).

Collaboration involving workflows in virtual enterprises has been addressed by Ludwig and Whittingham [10] and Wynen et al [11].

Analyses of alternative architectures for inter-organizational workflow have been made by van der Aalst [12]. Schulz and Milosevic [13] have carried out a good analysis of cross-organizational process architectures, primarily oriented to B2B E-commerce. Wing, Liu and Colomb [14] introduced the notion of incremental trading, implying a loosely-coupled VE in which the members gradually get to know more about each other. Action Workflow [15] is also relevant as a well-established workflow approach (and software

product) that is based on a pattern of exchanges of information along the lines of offer and acceptance. This closely mirrors the situation in many shared inter-organizational workflows.

In terms of the process of evolving workflows through collaboration and negotiation, the most notable work was done on the ORCHESTRA Esprit project [16].

In the pre-electronic age, the people negotiating the shared process would most likely meet in a room with a white (or black!) board and interactively agree the processes and data standards. The web based equivalent of this environment is a virtual meeting room [2] with support for a shared digital whiteboard. Shared whiteboards are used by many desktop conferencing systems, including Microsoft's NetMeeting. A state of the whiteboard is determined by its initial state and a sequence of events that are incrementally applied to it. Some of the issues involved in transmission of data streams used by common shared whiteboard tools are described in [17].

The idea of a tuplespace has its origins in coordination languages such as Linda [18]. A tuple is a vector of fields. Users of a tuplespace can post and retrieve tuples using coordination primitives [19]. A number of extensions of the Linda primitives have been introduced; some of these offer *reactive programming* [20] functionality. This can support, for example, triggering of user notifications or program calls on an event such as the insertion of tuples into a tuplespace.

An XML document can be stored in a tuple field value (or values). The ability to match on nodes in the XML document using some form of query language such as XQL is supported by tuplespace implementations such as TSpaces [21] and XMLSpaces [22]. TSpaces also includes reactive programming primitives, including the ability to register with the server for notifications based on whether a tuple that matches a specific template is written to the server by any client.

The most relevant work to date in combining Linda-based workspaces with workflows is described by Tolkdorf [23].

## 3. ARCHITECTURE AND BASIC MODEL

### 3.1 Multi-layer model

The previous paper [1] saw the evolution of business processes for a VE as a multiple set of layers, each of which would need to be agreed as part of the meta-process. Since the system level implementation of the processes will generally involve application layer protocols, it is useful to regard the layers as an extension of the standard seven layer ISO/OSI (Open Systems Interconnection) reference model. The extra layers introduced were as follows:

Table 1: Layers of a meta-process as an extension above the ISO/OSI communications profile, from [1]

Layer	Nature of interaction
11	Informal discussions of terms of agreement, procedures and rules
10	Tailoring of proposed or potential process patterns by cooperative and interactive use of whiteboard technology.
9	Agreeing formal and/or executable models incorporating process and data, using shared data and workflow models
8	Agreeing domain-specific models for terminology, and for task and data transfer
7a	Agreeing standard message structures (XML schemas etc) for carrying transferred processes, tasks and data
7b	Coordinating requests between computer software systems across data communication facilities

At layer 11 the negotiation is between senior business managers. They may introduce a mediator, or may resort to a tried and tested set of choreographed exchanges to perform the negotiation, similar to an auction with set rules. The emphasis is on the broad principles of the collaboration. This includes determining which parts of the process are to be under joint control and which are a purely local responsibility. The data being passed at this layer is mainly informal. If it is recorded at all, it is likely to be free text based, e.g. emails with optional attachments. These text messages can be supported in our system as message based tuples.

At layer 10, more detailed negotiation takes place (involving business process analysts, lawyers, accountants etc) to work out potential process patterns. The subject matter includes not only the basic control flow in the process model, but also such things as required data, authorized roles, time limits, action to be taken on exceptions – in fact anything that could appear in a legal clause. At this level, the parties may not be using compatible – or indeed any – formal diagramming notations. However whiteboard-style negotiation will be easier if some simple diagramming is used.

At layer 9 the meta-process would work with formal diagrams representing data structures and process patterns. The process diagram needs to show the process dependencies in the shared workflow. Since the organizations may use different modelling conventions, a standard format is used on the whiteboard, which is mapped to the individual organizations' models using WfXML. However it should be noted that many workflow systems include more than just control flow, and may employ more than one type of diagram for capturing the total design of a workflow pattern.

At layer 8 the meta-process is limited to agreement on whether or not to use a certain domain-specific standard, e.g. RosettaNet [24] for the IT electronics industry. We are not concerned with what happens below layer 8. Agreement on standard message structures and basic request-response communications

is made between the IT managers of the organizations. In many cases, the decision will be made when each organization chooses its B2B software.

### 3.2 Motivating example

We consider a simple case where two organizations currently both offer a set of business services that allow customers to place single and multiple orders, enquire about prices and availability etc. Because they operate in related markets, the organizations wish to introduce a number of shared processes to streamline the service they can offer the customers. The idea is that each organization will offer the other organization's products as well as its own, but would need to check availability and prices across the organizational boundary. As a result, a) each partner's service interface would need to be adjusted and b) a shared process would need to be started up.

A tuplespace is also useful for supporting dynamic groups of users where participants can join and leave at any time. A participant who joins an ongoing session can retrieve, by matching against a set of tuples, existing data exchanged by other participants since the start of the session. This is useful in the support of the changing membership of alliances that is often common in VEs.

A tuplespace is also useful for supporting dynamic groups of users where participants can join and leave at any time. A participant who joins an ongoing session can retrieve, by matching against a set of tuples, existing data exchanged by other participants since the start of the session. This is useful in the support of the changing membership of alliances that is often common in VEs.

Figure 1: Overview of the whiteboard-assisted meta-process

The meta-process changes the situation from two separate processes  $P_A$  and  $P_B$  to a shared process  $ShP_{AB}$  flanked by two private processes  $P'_A$  and  $P'_B$ , as shown in Figure 1 above.  $ShP_{AB}$  may be more than a simple choreography if brokers or other intermediaries are

involved. Figure 2 explains what is contained within the processes  $P_A$  etc. The interface (at the front) can be with either a human user or a program (e.g. part of an end customer's purchase order system). The control flow determines the hierarchy, sequence, branching, parallelism and iteration of a set of activities (human or computer). Secondary perspectives cover all other information necessary to fully define the process.

### 3.2 Representation of the model as a tuplespace

A tuplespace approach has advantages for the type of collaboration scenario we wish to support because it offers functionality similar to both active database and pattern-based messaging. It can also support situations where the relationship between data items is dynamic and transitory rather than following rigid data models.

Figure 2: Contents of a customer process

A tuplespace is also useful for supporting dynamic groups of users where participants can join and leave at any time. A participant who joins an ongoing session can retrieve, by matching against a set of tuples, existing data exchanged by other participants since the start of the session. This is useful in the support of the changing membership of alliances that is often common in VEs.

The workflow definitions being evolved could be in many different forms, such as a) a business process modelling tool; b) a workflow management system or c) workflow facilities within an enterprise resource planning (ERP) system such as SAP [25]. The key to being able to correlate processes is the existence of reliable mappings between the workflow definitions and the XML data represented in the tuples in the tuplespace. We use Wf-XML [26] as a unifying format, although this will not in general be sufficient to cover all the process semantics. We propose to supplement Wf-XML with the use of a *constraint document* encoded in OCL (Object Constraint Language) [27]. Beyond this there may still be a need to hold other tuple-based data structures as required.

In our approach we first translate the definitions of the existing workflows into Wf-XML, which provides the initial state of the tuplespace. The combined workflows are then presented for discussion in a neutral graphical format, using swim lanes to distinguish the different

partners and intermediaries. Input and output messages are also shown on the graph, and can be expanded by clicking. In the discussion the order of actions may be changed; actions may be inserted or removed; or the constraint document modified to change triggers for certain actions, or to change the conditions for transitions between actions to occur. When a participant in the meta-process makes a change, we capture these changes as generic whiteboard events, by adding tuples to the tuplespace. In order to preserve the order of incremental state changes, we keep track of event sequence numbers.

### 4. IMPLEMENTATION APPROACH

A tuplespace implementation which matches our requirements for shared virtual data spaces on the internet is TSpaces [21] developed by IBM. A TSpaces server can support multiple tuplespaces instances and a client can locate a TSpaces server on the web and then attach to a named tuplespace instance hosted on the server. Once a client connection to a tuplespace is established the various supported TSpaces operations can be used to interact with tuples (read, write, take, update, delete etc). Access control is implemented at the tuplespace level so that each operation requested by a client to be performed on a particular tuplespace instance has a related list of AccessAttributes that need to be satisfied for the operation to be allowed. As part of the supported operations there are blocking commands where a client can use a WaitToRead or WaitToTake command. The TSpaces server implements a callback functionality which can be used to inform clients of the arrival of tuples matching an outstanding query. Clients can therefore setup notifications which can be used to keep track of a set of required tuples (e.g. client can wait for tuples required to perform an action).

In terms of XML support, the TSpaces server supports the use of an XML field in a tuple and creates a *tuple tree* for XML documents which mirrors the DOM (Document Object Model) tree which corresponds to the XML structure. A subset of the XQL query language is supported to allow path expression based matching on data within an XML document. IBM has also developed the TSpaces services suite, which helps to automate the development and management of web services using tuplespaces. It is interesting to note that XMLSpaces [22], which is a direct extension of TSpaces, has added new functionality to provide a more detailed incorporation of XML into tuple fields and XML support for the original Linda definition of the matching relation for tuples. XMLSpaces also extends TSpaces by offering distributed tuplespace support across multiple servers.

We are experimenting with Version 2.1.2 of the TSpaces server software running on a web server with an additional software layer that is used for transformations and connectivity with SAP Netweaver [28]. Netweaver is a Wf-XML compatible tool for

orchestrating both SAP and non-SAP services that is based on SAP Business Workflow. Examples of transformations needed by the system are the mapping of whiteboard protocols to coordination primitives and the use of XSL [29] for transformation between various XML document structures. A limited set of basic TSpaces tuple data structures have been defined to represent evolutionary workflows to be exchanged in the system:

```
WorkflowTuple = (PartnerRole, Id,
Timestamp, XMLDoc, [ActionTuple] +)
ActionTuple = (PartnerRole, Id, XMLDoc)
MessageTuple = (PartnerRoleTo,
PartnerRoleFrom, Id, Subject, Text,
XMLDoc)
```

where + represents a field which can be repeated multiple times, PartnerName identifies a particular business partner, Id is a unique number which can be used as a way to track sequences and set membership, and XMLDoc represents an XML document structure. TSpaces-supported coordination primitives can be used to interact with these tuples and to generate other temporary data tuples as needed, using reactive programming techniques.

## 5. CONCLUSION AND FUTURE WORK

Our proposed system supports collaborative activities for evolving workflows for a virtual enterprise, based upon (a) interactive use of a shared whiteboard (for tailoring potential process patterns based on graphical interaction) and (b) cooperative discussions of the terms of agreement, procedures and rules using a blackboard architecture (interaction based on message exchange). We have described how this can be achieved using tuplespaces, and are working on a prototype implementation using IBM's TSpaces.

Future work plans include 1) improved handling of the secondary perspectives, possibly incorporating a general ontology for process negotiation; 2) specialization of the whiteboard interface for the different layers (i.e. top management (layer 11), business analysts and lawyers (layer 10), and line managers and process specialists (layer 9); and 3) catering for volatile N-way negotiations including intermediaries as well as partners who join and leave VE agreements.

We also intend to continue working towards the presentation of a full prototype implementation.

## 1. INTRODUCTION

In an earlier paper [1], two of the current authors addressed the issue of IT support for developing shared workflows in Virtual Enterprises (VEs). VEs are characterized as formalized, but not permanent, alliances negotiated between autonomous organizations, where the goal is to present seamless business services to customers. Members are encouraged to agree upon and then enact processes that follow overarching guidelines evolved by the VE. These processes may evolve during negotiations to establish the VE or during the lifetime of the VE as conditions of the alliance are changed. Processes may eventually be discontinued when the alliance is dissolved. Negotiating efficient cross organizational processes can be of critical importance to the business value of the VE.

In this paper we define a *shared workflow* as a business process that two or more organizational entities agree to follow. A shared workflow is related to the private workflows of the individual organizations, but may only contain a partial view of them; each participating organization may not want elements of its internal processes to be externally observable. The term *evolutionary* means that shared workflows have not all been settled in advance, but need to be negotiated incrementally in step with the evolving business agreements between the organizations. A *meta-process* is a procedure – or process - whose purpose is to establish a business process that will be enacted for operational business cases. The term *multi-layer* derives from the earlier paper, in which several layers in the meta-process were identified, the first three being a) informal discussion b) agreeing a business process model and c) agreeing an executable workflow system.

The VE, or the subset of members involved in each particular business collaboration, needs to reach a final agreement on one or more inter-organizational processes that represent the way they agree to inter-operate. However each individual organization will usually also need to adjust its private processes to fit in with the new collaboration. For example, it may need to provide additional facilities for notifying partner organizations of progress, for responding to requests for status reports, or for dealing with exceptions such as non-response from the partner.

The question is - how best can IT be used to help the meta-process? Our intuition is that even if the VE has developed guidelines, the meta-process can never be as strictly predefined as with typical production workflows. But it is equally unrealistic to assume that the meta-process is totally informal. One possible intermediate paradigm is a negotiation model, but typical negotiation models focus on a limited number of measured utility parameters such as price, delivery time etc. Our task is to find something equivalent to a negotiation model that will allow the parties to make proposals, counter-proposals and agreements on a whole range of issues such as the nature of tasks, the order they should occur in, the data that should be provided, the persons that are authorized to commit to a decision, the rules governing exceptional situations - and so on.

This paper proposes a way to support the collaborative meta-process of evolving a set of workflows that will coordinate the activities of a VE. The collaborative activity is assumed to take place over the internet in the online equivalent of a meeting room [2], and that communication can be abstracted to the exchange of a series of events related to the collaboration. It includes the use of graphics exchange protocols for real time.

However our approach aims to avoid explicit dependence on any particular process model diagram or language standard, other than that the model can be represented in XML.

In this paper, section 2 summarizes the related work in business process modelling in B2B, business contract architectures, inter-enterprise workflows, evolutionary workflows, whiteboard/blackboard models, and coordination models using tuplespaces - with related software developments. Section 3 describes the architecture and basic model of our proposed approach. Section 4 discusses a possible way of implementing our approach with available software. Section 5 presents our conclusions and directions for further work.

## 2. RELATED WORK

ebXML [3] has been proposed as a standard approach to B2B e-commerce. It envisages that, at the level of the structure and sequence of messages to be passed, each organization proposes a Coordination Protocol Profile (CPP); the organizations then negotiate an agreed protocol (CPA). However ebXML has not yet recommended a meta-process for agreeing a CPA – use of an ebXML-familiar broker (consultant) is assumed.

Automatic and formal approaches for aligning business processes from different organizations have been proposed by Mahleko [4] and Grossmann et al [5]. However the orientation here is to find an *integrated* process, rather than the shared sub-process that represents only what happens *between* the organizations.

Negotiation of a shared process and negotiation of a contract are very closely linked. The contract will specify the duties of each party in both physical and informational terms. A description of our work in conjunction with the Business Contracts Architecture of Milosevic et al is given in [6] and [7].

The CrossFlow project [8], which is based on services-based cross-organizational workflow (SCW), looks at contracts as the key element in defining inter-enterprise workflows. Other important issues in CrossFlow include reliability, trust and service management (see also [9]).

Collaboration involving workflows in virtual enterprises has been addressed by Ludwig and Whittingham [10] and Wynen et al [11].

Analyses of alternative architectures for inter-organizational workflow have been made by van der Aalst [12]. Schulz and Milosevic [13] have carried out a good analysis of cross-organizational process architectures, primarily oriented to B2B E-commerce. Wing, Liu and Colomb [14] introduced the notion of incremental trading, implying a loosely-coupled VE in which the members gradually get to know more about each other. Action Workflow [15] is also relevant as a well-established workflow approach (and software

product) that is based on a pattern of exchanges of information along the lines of offer and acceptance. This closely mirrors the situation in many shared inter-organizational workflows.

In terms of the process of evolving workflows through collaboration and negotiation, the most notable work was done on the ORCHESTRA Esprit project [16].

In the pre-electronic age, the people negotiating the shared process would most likely meet in a room with a white (or black!) board and interactively agree the processes and data standards. The web based equivalent of this environment is a virtual meeting room [2] with support for a shared digital whiteboard. Shared whiteboards are used by many desktop conferencing systems, including Microsoft's NetMeeting. A state of the whiteboard is determined by its initial state and a sequence of events that are incrementally applied to it. Some of the issues involved in transmission of data streams used by common shared whiteboard tools are described in [17].

The idea of a tuplespace has its origins in coordination languages such as Linda [18]. A tuple is a vector of fields. Users of a tuplespace can post and retrieve tuples using coordination primitives [19]. A number of extensions of the Linda primitives have been introduced; some of these offer *reactive programming* [20] functionality. This can support, for example, triggering of user notifications or program calls on an event such as the insertion of tuples into a tuplespace.

An XML document can be stored in a tuple field value (or values). The ability to match on nodes in the XML document using some form of query language such as XQL is supported by tuplespace implementations such as TSpaces [21] and XMLSpaces [22]. TSpaces also includes reactive programming primitives, including the ability to register with the server for notifications based on whether a tuple that matches a specific template is written to the server by any client.

The most relevant work to date in combining Linda-based workspaces with workflows is described by Tolkdorf [23].

## 3. ARCHITECTURE AND BASIC MODEL

### 3.1 Multi-layer model

The previous paper [1] saw the evolution of business processes for a VE as a multiple set of layers, each of which would need to be agreed as part of the meta-process. Since the system level implementation of the processes will generally involve application layer protocols, it is useful to regard the layers as an extension of the standard seven layer ISO/OSI (Open Systems Interconnection) reference model. The extra layers introduced were as follows:

Table 1: Layers of a meta-process as an extension above the ISO/OSI communications profile, from [1]

Layer	Nature of interaction
11	Informal discussions of terms of agreement, procedures and rules
10	Tailoring of proposed or potential process patterns by cooperative and interactive use of whiteboard technology.
9	Agreeing formal and/or executable models incorporating process and data, using shared data and workflow models
8	Agreeing domain-specific models for terminology, and for task and data transfer
7a	Agreeing standard message structures (XML schemas etc) for carrying transferred processes, tasks and data
7b	Coordinating requests between computer software systems across data communication facilities

At layer 11 the negotiation is between senior business managers. They may introduce a mediator, or may resort to a tried and tested set of choreographed exchanges to perform the negotiation, similar to an auction with set rules. The emphasis is on the broad principles of the collaboration. This includes determining which parts of the process are to be under joint control and which are a purely local responsibility. The data being passed at this layer is mainly informal. If it is recorded at all, it is likely to be free text based, e.g. emails with optional attachments. These text messages can be supported in our system as message based tuples.

At layer 10, more detailed negotiation takes place (involving business process analysts, lawyers, accountants etc) to work out potential process patterns. The subject matter includes not only the basic control flow in the process model, but also such things as required data, authorized roles, time limits, action to be taken on exceptions – in fact anything that could appear in a legal clause. At this level, the parties may not be using compatible – or indeed any – formal diagramming notations. However whiteboard-style negotiation will be easier if some simple diagramming is used.

At layer 9 the meta-process would work with formal diagrams representing data structures and process patterns. The process diagram needs to show the process dependencies in the shared workflow. Since the organizations may use different modelling conventions, a standard format is used on the whiteboard, which is mapped to the individual organizations' models using WfXML. However it should be noted that many workflow systems include more than just control flow, and may employ more than one type of diagram for capturing the total design of a workflow pattern.

At layer 8 the meta-process is limited to agreement on whether or not to use a certain domain-specific standard, e.g. RosettaNet [24] for the IT electronics industry. We are not concerned with what happens below layer 8. Agreement on standard message structures and basic request-response communications

is made between the IT managers of the organizations. In many cases, the decision will be made when each organization chooses its B2B software.

### 3.2 Motivating example

We consider a simple case where two organizations currently both offer a set of business services that allow customers to place single and multiple orders, enquire about prices and availability etc. Because they operate in related markets, the organizations wish to introduce a number of shared processes to streamline the service they can offer the customers. The idea is that each organization will offer the other organization's products as well as its own, but would need to check availability and prices across the organizational boundary. As a result, a) each partner's service interface would need to be adjusted and b) a shared process would need to be started up.

A tuplespace is also useful for supporting dynamic groups of users where participants can join and leave at any time. A participant who joins an ongoing session can retrieve, by matching against a set of tuples, existing data exchanged by other participants since the start of the session. This is useful in the support of the changing membership of alliances that is often common in VEs.

A tuplespace is also useful for supporting dynamic groups of users where participants can join and leave at any time. A participant who joins an ongoing session can retrieve, by matching against a set of tuples, existing data exchanged by other participants since the start of the session. This is useful in the support of the changing membership of alliances that is often common in VEs.

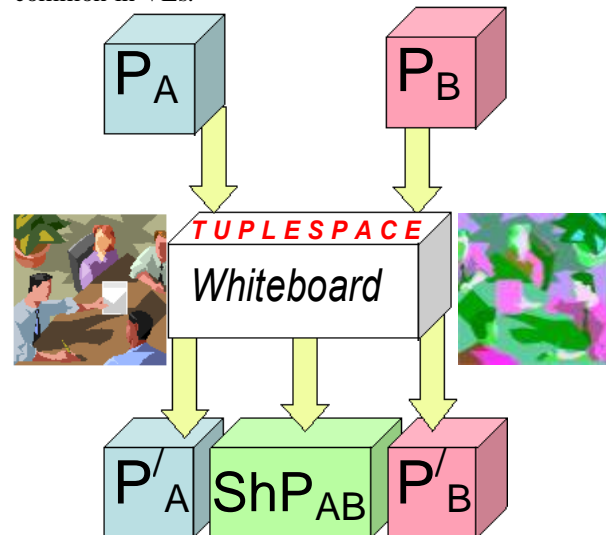

Figure 1: Overview of the whiteboard-assisted meta-process

The meta-process changes the situation from two separate processes  $P_A$  and  $P_B$  to a shared process  $ShP_{AB}$  flanked by two private processes  $P'_A$  and  $P'_B$ , as shown in Figure 1 above.  $ShP_{AB}$  may be more than a simple choreography if brokers or other intermediaries are

involved. Figure 2 explains what is contained within the processes  $P_A$  etc. The interface (at the front) can be with either a human user or a program (e.g. part of an end customer's purchase order system). The control flow determines the hierarchy, sequence, branching, parallelism and iteration of a set of activities (human or computer). Secondary perspectives cover all other information necessary to fully define the process.

### 3.2 Representation of the model as a tuplespace

A tuplespace approach has advantages for the type of collaboration scenario we wish to support because it offers functionality similar to both active database and pattern-based messaging. It can also support situations where the relationship between data items is dynamic and transitory rather than following rigid data models.

Figure 2: Contents of a customer process

A tuplespace is also useful for supporting dynamic groups of users where participants can join and leave at any time. A participant who joins an ongoing session can retrieve, by matching against a set of tuples, existing data exchanged by other participants since the start of the session. This is useful in the support of the changing membership of alliances that is often common in VEs.

The workflow definitions being evolved could be in many different forms, such as a) a business process modelling tool; b) a workflow management system or c) workflow facilities within an enterprise resource planning (ERP) system such as SAP [25]. The key to being able to correlate processes is the existence of reliable mappings between the workflow definitions and the XML data represented in the tuples in the tuplespace. We use Wf-XML [26] as a unifying format, although this will not in general be sufficient to cover all the process semantics. We propose to supplement Wf-XML with the use of a *constraint document* encoded in OCL (Object Constraint Language) [27]. Beyond this there may still be a need to hold other tuple-based data structures as required.

In our approach we first translate the definitions of the existing workflows into Wf-XML, which provides the initial state of the tuplespace. The combined workflows are then presented for discussion in a neutral graphical format, using swim lanes to distinguish the different

partners and intermediaries. Input and output messages are also shown on the graph, and can be expanded by clicking. In the discussion the order of actions may be changed; actions may be inserted or removed; or the constraint document modified to change triggers for certain actions, or to change the conditions for transitions between actions to occur. When a participant in the meta-process makes a change, we capture these changes as generic whiteboard events, by adding tuples to the tuplespace. In order to preserve the order of incremental state changes, we keep track of event sequence numbers.

### 4. IMPLEMENTATION APPROACH

A tuplespace implementation which matches our requirements for shared virtual data spaces on the internet is TSpaces [21] developed by IBM. A TSpaces server can support multiple tuplespaces instances and a client can locate a TSpaces server on the web and then attach to a named tuplespace instance hosted on the server. Once a client connection to a tuplespace is established the various supported TSpaces operations can be used to interact with tuples (read, write, take, update, delete etc). Access control is implemented at the tuplespace level so that each operation requested by a client to be performed on a particular tuplespace instance has a related list of AccessAttributes that need to be satisfied for the operation to be allowed. As part of the supported operations there are blocking commands where a client can use a WaitToRead or WaitToTake command. The TSpaces server implements a callback functionality which can be used to inform clients of the arrival of tuples matching an outstanding query. Clients can therefore setup notifications which can be used to keep track of a set of required tuples (e.g. client can wait for tuples required to perform an action).

In terms of XML support, the TSpaces server supports the use of an XML field in a tuple and creates a *tuple tree* for XML documents which mirrors the DOM (Document Object Model) tree which corresponds to the XML structure. A subset of the XQL query language is supported to allow path expression based matching on data within an XML document. IBM has also developed the TSpaces services suite, which helps to automate the development and management of web services using tuplespaces. It is interesting to note that XMLSpaces [22], which is a direct extension of TSpaces, has added new functionality to provide a more detailed incorporation of XML into tuple fields and XML support for the original Linda definition of the matching relation for tuples. XMLSpaces also extends TSpaces by offering distributed tuplespace support across multiple servers.

We are experimenting with Version 2.1.2 of the TSpaces server software running on a web server with an additional software layer that is used for transformations and connectivity with SAP Netweaver [28]. Netweaver is a Wf-XML compatible tool for

orchestrating both SAP and non-SAP services that is based on SAP Business Workflow. Examples of transformations needed by the system are the mapping of whiteboard protocols to coordination primitives and the use of XSL [29] for transformation between various XML document structures. A limited set of basic TSpaces tuple data structures have been defined to represent evolutionary workflows to be exchanged in the system:

```
WorkflowTuple = (PartnerRole, Id,
Timestamp, XMLDoc, [ActionTuple] +)
ActionTuple = (PartnerRole, Id, XMLDoc)
MessageTuple = (PartnerRoleTo,
PartnerRoleFrom, Id, Subject, Text,
XMLDoc)
```

where + represents a field which can be repeated multiple times, PartnerName identifies a particular business partner, Id is a unique number which can be used as a way to track sequences and set membership, and XMLDoc represents an XML document structure. TSpaces-supported coordination primitives can be used to interact with these tuples and to generate other temporary data tuples as needed, using reactive programming techniques.

## 5. CONCLUSION AND FUTURE WORK

Our proposed system supports collaborative activities for evolving workflows for a virtual enterprise, based upon (a) interactive use of a shared whiteboard (for tailoring potential process patterns based on graphical interaction) and (b) cooperative discussions of the terms of agreement, procedures and rules using a blackboard architecture (interaction based on message exchange). We have described how this can be achieved using tuplespaces, and are working on a prototype implementation using IBM's TSpaces.

Future work plans include 1) improved handling of the secondary perspectives, possibly incorporating a general ontology for process negotiation; 2) specialization of the whiteboard interface for the different layers (i.e. top management (layer 11), business analysts and lawyers (layer 10), and line managers and process specialists (layer 9); and 3) catering for volatile N-way negotiations including intermediaries as well as partners who join and leave VE agreements.

We also intend to continue working towards the presentation of a full prototype implementation.

## ABSTRACT

As an important discipline of the learning organization, vision provides guidance about what core to preserve and what future to stimulate progress toward. It had been proved by the experiences of foreign companies' successful practice that visionary management was an actually new managerial philosophy and tool after the corporation reengineering theory to support sustained firm growth. It should be worthy our stated-owned enterprises and short-life's to learn and practice.

**Keywords:** vision, visionary management, performance, sustained firm growth

## 1. INTRODUCTION

Learning organization has been praised as the "Bible of management" and successful mode of future enterprise since Peter Senge (1990) put forward the learning organization theory. The origin of leaning organization theory is the outcome of deep thought for the sustained development in the dynamic and complex environment. As an important discipline of learning organization, vision provides guidance about what core to preserve and what future to stimulate progress toward. Visionary management has been a new organizational mind and management tool after the theory of corporation reengineering. Visionary management companies often achieve superior long-term performance and sustained growth, such as Hewlett-Packard, 3M, Johnson & Johnson, Procter & Gamble, Sony etc al. Hewlett-Packard employee have long known that radical change in operating practices, culture norms, and business strategy does not mean losing the spirit of HP way-the company's core principles. Johnson & Johnson continually questions its structure and revamps its processes while preserving the ideals embodied in its credo.

## 2. VISION AND ITS ORGANIZATION FUNCTION

### 2.1 What's the Vision?

Leaning and innovation is the best way to assure organization existence in dynamic and complex environment. Each organization should have five disciplines including building shared vision in order to create learning organization. Vision has become one of the most overused words conjuring up different images for different people. Vision is an image of the desired future. Collins and Porras (1996) argued that a well-conceived vision consisted of two major components: core ideology and envisioned future. Core ideology defines the enduring character of an organization - a consistent identity that transcends product or market life cycles, technological breakthroughs, management fads, and individual leaders. In fact, the most lasting and significant contribution of

those who build visionary companies is the core ideology. It likes the glue that holds an organization together as it grows, decentralizes, diversities, and expands globally. Any effective vision must embody the core ideology of an organization, which in turn includes two distinct parts: core values, a system of guiding principles; and core purpose, the organization's most fundamental reason for existence.

The core values stem not from market requirements but from the founder's inner belief. The key is not what core values an organization has but that it has core values at all. So a company should not change its core values in response to market changes but change markets if necessary to remain true to its core values. Core purpose is the organization's reason for being. An effective purpose reflects people's motivations for doing the company's work. It captures the soul of the organization, and doesn't just describe the organization's output or target customers. It is like a guiding star on the horizon - forever pursued but never reached. The role of core ideology is to guide and inspire, not to differentiate. Two companies can have the same core values or purpose. Core ideology needs to be meaningful and inspirational only to people inside the organization; it need not be exciting to outsiders. A clear ideology attracts to the company people whose personal values are compatible with the company's core values. Conversely, it repels those whose personal values are incompatible.

The envisioned future is what we aspire to become, to achieve, to create something that will require significant change and progress to attain. It consists of two parts: an audacious goal plus vivid descriptions. Visionary companies often use BHAGs (Big, Hairy, and Audacious Goals) as a powerful way to stimulate progress. All companies have goals. But there is a difference between merely having a goal and becoming committed to a BHAG - such as climbing Mount Everest. In addition to vision - level BHAGs, an envisioned future needs a vivid description of what it will be like to achieve your goals.

## 2.2 Organization Function of Vision

Vision has strong organizational function. Firstly, shared vision could strength organizational cohesion. Vision holds together all organization members who have different background. And it would change the relationship between the employee and organization. Employee's attitude to organization would change radically in a visionary company. They would think that firm isn't "their firm" but "our firm". Resentment to reform and passive obedience to vision would be replaced by active commitment and dedication to firm. Secondly, vision points out right direction for organization just like rudder of a ship, especially when organization encounters disorder or resistance in process of growth. Lastly, vision could inspire endless creativity and enterprising spirit of all members, and change the learning mode from adaptability learning to creativity learning. The essence of innovation is to reshape the world according to a special vision (Ikujiro Nonaka, 1991).

## 3. A VISIONARY MANAGEMENT MODEL

Visionary management is a key issue for all organizations. It's both a kind of managerial philosophy and a set of guidelines to form the basis for a never-ending journey toward competitive advantage. The visionary management process comprises of a cycle of successive phases, which can be distinguished into personal vision development, organizational vision development, situation analysis, strategy formulation, and planning and implementation (Rampersad, 1997). Figure 1 shows a model representation of visionary management. It begins with the formulation of personal vision, then expanding this vision to develop a common vision and core values of the whole organization. We should balance the personal vision and the organizational vision. The development of the personal and organizational vision does not only take place at the management level, but also at all lower organizational level. Everyone in the organization needs to be actively involved in this top-down and bottom-up visionary management process (Senge, 1990).

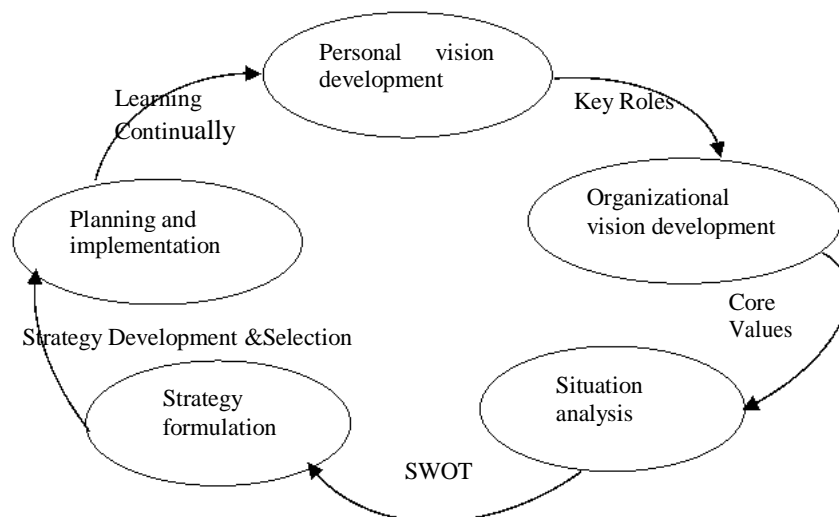

Figure 1 A visionary management model

### 3.1 Personal Vision Development

Each employee has to formulate his/her own personal vision. Personal vision development acts as key roles in the process of organization vision formation. Personal vision statement is a description of where are you going, which values and principles guide you to reach that point, what you want to help realize in your life, what ideal characteristic you would like to have. The key roles regard the way you fulfill or want to fulfill several roles in your life to realize personal mission. According to Covey (1993), personal vision helps to discover your inner feeling and clarifies what is important to you. You can eventually adapt vision in case your living conditions or thinking patterns change in the course of several years.

### 3.2 Organizational Vision Development

An effective developed organizational vision gives direction to personal ambitious and creativity, creates a climate through drastic changes, strengthens belief in the future, and releases energy in people. Organizational vision forms an important management instrument that expresses the soul of the firm. It gives direction to firm growth and functions as a compass and road map. The convincing propagation of an active, inspiring, challenging, and fascinating vision usually lead to more effort, satisfaction, and commitment. An organization will be successful if it succeeds to create a sense, a meaning that releases energy in people, raises involvement and puts people in movement. The organizational vision is linked to core values in order to strengthen the one-mindedness of the employees. The core values determine what approach is used to realize the vision. After all, core values in an organization

usually inspire commitment, loyalty, and devotion in all parts of the organization.

### 3.3 Situation Analysis

Situation analysis is the following step in the visionary management process and regards the evaluation of the strategic position of the organization and document of the organization's objectives. From strategic perspective to analyze the strengths and weaknesses of the organization (internal) and the opportunities and threats from the environment (external) is very useful to strategy formulation. Benchmarking is an important instrument here that is focusing on improving performance with respect to the leading competitor.

### 3.4 Strategy Formation

Alternative strategies are developed and choices are made, which based on the visible gap between the present and desired situation. Strategy indicates how the objectives can be realized and which choices should be made. It is the answer of SWOT analysis. Strategy should be translated into critical success factors (CSFs) to carry out it effectively. These key factors determine the competitive advantage of the organization because they are strongly related to its core competence. A CSF is that in which the organization must be outstanding to be able to survive, or that which is of decisive importance to the success of the organization. Examples of CSFs are: well-motivated and skilled employees, customer orientation, time to market, efficient dealer's organization, and good customer service etc al. They should be determined through brainstorming with the entire management team.

### 3.5 Planning and Implementation

In the last phase, the chosen strategies are thus translated into operational plans for the different departments or units within the organization, after which they will be implementation. The actions to be undertaken are worked out in the operational plans for the different business function. The use of project management techniques is usually necessary during the process, as well as creating awareness for change. Continually learning and communication will help to form new personal vision and to be harmony with organization vision.

After this phase the visionary management will start again. Visionary management is not a one-time activity, but a process of continuous improvement. By making visionary management as a part of your daily routine, you will integrate it into all aspects of your work.

## 4. VISIONARY MANAGEMENT AS THE SUPPORT OF FIRM GROWTH

Visionary management provides ideology and guidance for firm growth, just like the lighthouse of navigation.

Firm performance provides finance guarantee and possibility of growth, just like catalyzer of chemical reaction. We construct a relational model of visionary management and sustained firm growth. In figure 2, visionary management and firm performance act on firm growth through path I and II respectively. There are a strong correlation between visionary management and firm performance (broken line in figure 2), and which had been confirmed by many researches. So visionary management supports sustained firm growth on one hand through path I, on the other hand through path II in virtue of mediating variable performance. Consequently, we hold that visionary management is the footstone of sustained firm growth on the earth. Vision should be matched with firm growth. And the firm growth is changing continually along with internal and external environment, so visionary management is also a dynamically adaptable process.

**Figure 2 Visionary management and firm growth**

Many world companies were pride of having definite and vivid vision, for example Microsoft, Hewlett-Packard, and Sony etc al. Effective management is the radical reason of sustained firm growth. Scholars also proved the relationship between visionary management and sustained firm growth from different aspects. Peter Senge (1990) pointed out that vision was an important factor to steer organization growth. The learning organization couldn't exist without vision. John P. Kotter (1995) carefully observed over 100 companies with different size, nationality and phase by ten years. And he found that some companies' change and transformation were very successful, but others were actually opposite. So he indicated that vision served as a connecting link between the preceding and the following in the process of leader change. Lack of vision and effective visionary management would influence the firm growth and successful transition. A lot of experiences of transitional companies also made clear that transitional endeavor were usually to fail without a solid visionary plan. The conclusion of Cranfield Global Executive Competencies Survey demonstrated that it played an important role for firm growth by forming a meaningful vision and future direction. Collins and Porras (1994) studied companies in their book of "Successful Habits of Visionary Companies" and found that they had outperformed the general stock market by a factor of 12 since 1925. Collins and Porras (1996) observed many company's growth status spending six years and concluded that the match of core values and visionary plan was the source of company life force. These companies holding clear

vision often have higher learning speed and accordingly bring higher firm performance.

## 5. CONCLUSION

(1) Visionary management as another bran-new managerial philosophy and tool after cooperation reengineering theory, which had been widely used by big companies in developed countries. The concept was just introduced to China companies and rarely practiced. Using foreign successful visionary management experience for reference has positive meaning to promote our firm performance.

(2) Visionary management provides source of power and new management tool for firm growth. It also reins to go forward along right direction. The strength of maintaining status couldn't be broken to buck for firm growth if there is no vision as road map to lead firm development.

(3) Visionary management is especially more meaningful to two kinds companies that are the state-owned companies and short-life companies. Now our state-owned companies are standing at the crossroad of reform and transition. Oversea experience has proved that effective visionary management could advance the probability of successful reform and transition. The relationship between visionary management and

sustained firm growth should cause thinking by large quantity of short-life companies.

### ABSTRACT

Virtual enterprise is the potential mode of future enterprise under global economic environment and the risk management for it is a popular research area recently. Risk identification is the key phrase of risk management. Considering the risk identification problem in the virtual enterprise, a new identification method based on the BP network is provided in this paper. Using this method and the data related to the problem, the possible to take place of the risks could be obtained by training the neural network, so that risks can be investigated in time and managed effectively. The simulation results prove its validity.

**Keywords:** virtual enterprise, risk management, risk identification, BP network learning algorithm

### 1. INTRODUCTION

Global economic environment is experiencing tremendous changes in recent decades as information technology and its application advance rapidly. Market demand is changing even rapidly and becoming more difficult to predict as the global market competition heats up. Under such background Virtual Enterprise (VE), a new organizational mode for enterprises, is gradually replacing traditional modes of enterprises [1] for it's more adaptive to new challenges. VE enables enterprises related to one product to combine together to form a temporary economic body so that they can grasp new opportunities and response to latest market demand as soon as possible. The new mode is considered profitable though it also brings in risks and uncertain factors, which might have harmful influences on enterprises involved. Traditional risk identification methods, depending on personal experiences and subjective judgments, are mostly qualitative [2,3]. They do not perform well in identifying new risks under the recent economic environment. Such shortage calls for a better risk identification method to ensure the secure operation of enterprises. Data mining (or knowledge discovering) technology, a process based on artificial intelligence and database technology in which some models or modes that are useful to data owner(s) are extracted from a large amount of data, is providing a new thought for resolving this problem. The present functions of the technology mainly include mode identification, association analysis, sorting, predicting and cluster analysis, etc.[4, 5] on the basis of algorithms and technologies of artificial intelligence. In the research risk identification problem is solved by data mining method based on BP network and with the help of Statistical Analysis System (SAS) software, the application is proved to be satisfactory.

procedures. The process of risk management includes risk identification, risk estimation, risk evaluation, risk programming and effective risk control based on the previous steps. During risk identification, the primary step of risk management, it is necessary to determine the general objective of enterprise and the partial objectives needed for realizing the general one. Based on this, risks factors within the general objective and partial objectives are investigated and analyzed, which can be achieved through survey/ questionnaire, organization chart analysis, financial statement analysis, checking chart analysis, process analysis, input-output analysis, sensitivity analysis, accident-tree analysis, hierarchical holographic modeling analysis and expert investigation, etc [2,3]. These methods:

- 1) Require investigator or analyst's deep understanding of enterprises and long-term information accumulation;
- 2) Require long-term investigation and analysis;
- 3) Respond slowly to environmental changes.

However, the VE is formed dynamically, which means operators can only acquire information and data of pre-existing VE and original enterprises. Consequently, VE should decide based on the data whether the current risks are possible to take place. A new method towards such a problem is introduced in the research --- BP-network-based risk identification of VE. According to this method, every possible kind of internal or external risks is firstly analyzed and the information concerned defined; then the possibility of each kind of risk is got according to data of pre-existing VE, original enterprises and information of current VE.

### 2. PROBLEM DESCRIPTION

Successful risk management depends on scientific

### 3. NEURAL-NETWORK MODEL

BP-network is one of the most widely-used neural

networks at present. Before putting BP-network into practice, the number of hidden hierarchies and that of units in each hierarchy have to be fixed so as to determine a network topology. Figure 1 shows a 3-hierarchy forward neural network with only one output nodal point. From left to right aligns input, hidden and output hierarchy. Combination function between hierarchies is a lineal function. The net input of each unit  $j$  in hidden or output hierarchy is:

$$I_j = \sum_i w_{ij} o_i + q_j \quad (1)$$

Among the function,  $w_{ij}$  is the linking weight from previous unit  $i$  to unit  $j$ ;  $o_i$  represents the output of unit  $i$ ;  $q_j$  denotes the offset of unit  $j$ , which also presents a threshold here. Appropriate offset help to change the activity of the neuron.

Figure 1 BP-Network

After estimating the net input in each unit, an activating function has to be chosen to estimate the output value. Simoid activating function, the most common type, is chosen here:

$$o_j = \frac{1}{1 + e^{-I_j}} \quad (2)$$

In BP-network training, classical BP algorithm is applied, showing a forward transmission of input and a backward transmission of error. Linking weight and offset are modified by calculating the error between the neural network predicted and the value of sample. If linking weight and offset end up in convergence after a number of iterations, the learning process stops; otherwise re-training or adjustment of the network structure is needed.

#### 4. APPLICATION AND KEY PROBLEMS

SAS, one of world's most famous statistical software, is developed by SAS Institute of the US and used to help realize the process of risk identification in this research. As the technology of data mining thrives these years, SAS institute has developed for this field a tool called SAS/EM (Enterprise Miner), which then became a best data mining software because of its integrated and

powerful statistical function. The outcome of data mining also shows a progress since the software has been worked on as a product and improved. Its user-friendly interface also brings in convenience to the data mining process [6-8].

Before data mining, should be processed for preparation so as to ensure validity and high accuracy:

##### 1) Data Set Division

Over-fitting is considered a very significant problem in neural network training. It can be defined as a process in which a neural-network model fits the current data set too well (this might even mean a transitional fitting) to adapt to a new set flexibly. A common way to avoid over-fitting is to divide the data set into a training set and a valid set so that the training process may be applied to two sets at the same time. Training set is for BP-network training and valid set for evaluation to the model. Taking the average error as a performance measurement of training process, it shows a continuous decrease of average error in training set as the training process goes on while the average error in valid set decreases first and then increases. This can be explained as a consequence of over-fitting of neural-network to training set. In this research, as a principle, the weight value, when the average error of valid set is the lowest, is selected as the final solution.

##### 2) Data Standardization

Usually statistics within a data set is not acquired under a same commensurability but by individual method and unit of measurement, which indicates that different input variables of BP-network may have unbalanced influences on target variables. The unbalancing situation among variables caused by disunified measurement is obviously irrational and it might waken some variables of great significance. In order to avoid any mistake caused, the following method of standard deviation (each variable is divided by the standard deviation of sample) is applied. The standard deviation of variable number  $k$  that is denoted as variable  $X_k$  is estimated in the following formula:

$$s_k = \left( \frac{1}{n} \sum_{i=1}^n (x_k(i) - m_k)^2 \right)^{\frac{1}{2}} \quad (3)$$

$m_k$ , denoting the average of  $X_k$ , is estimated through sample average

$$\bar{x}_k = \frac{1}{n} \sum_{i=1}^n x_k(i) \quad (4)$$

Ultimately the inaccuracy brought by disunified measurement is eliminated by calculating

$$x'_k = \frac{x_k}{s_k} \quad (5)$$

After the two steps above, BP-network training begins.

The training can be carried out by the Neural Network Function in SAS/EM.

## 5. SIMULATION ANALYSIS

Simulation data includes 5822 observation results gained per hour by per-existing enterprises, each of which contains 83 input variables and 1 target variable. 83 input variables are enterprise-related data, including the number of partner enterprises, communicative efficiency within partners, information-safety rate and product-purchasing rate, etc. The target variable denotes the possibility of the risk of product quality. The data set is divided randomly into a training set, which contains 70% (4075 pieces) of observation results and a valid set, which contains 30% (1747 pieces) of observation results. There are many methods for evaluating the model, such as error-classifying rate, average error, profits/loss, etc, but in regards to the nature of risks, wrong prediction of the possibility of a risk, and its deviant receive more attention. Consequently error-classifying rate and average error are chosen to be the evaluating measurement to BP network model.

BP network training is a repeating and continuously adjusting process, which needs several parameters to be

units in hidden hierarchy, learning rate and numbers of iteration. In these parameters, the initial value of weight almost have no effect on the training result. The numbers of iteration should be proper; too small the training will be not convergence, too big the training will last long time. However, the numbers of units in hidden hierarchy and learning rate effect the accuracy and process of training largely. Figure 2 and 3 show respectively the influence of them on average error in both training and valid set.

The numbers of units in hidden hierarchy is crucial to BP network training because it directly affects the quality of prediction. Insufficient units may result in divergence or dissatisfactory accuracy of prediction while too many units sharply increase training time and arouse more difficulties in learning process. As the training goes further, it is shown in Figure 2(a) that under the same parameters, the increasing number of units in hidden hierarchy results in a smaller model-predicted average error but too many units takes a much longer time for training. Also, the Figure 2(b) shows the numbers of units in hidden hierarchy should be proper. So, in general, 16 is chose as the numbers of units in hidden hierarchy when Figure 2 (a) and (b) is considered synthetically.

Figure 2 The influence of the numbers of units in hidden hierarchy on average error

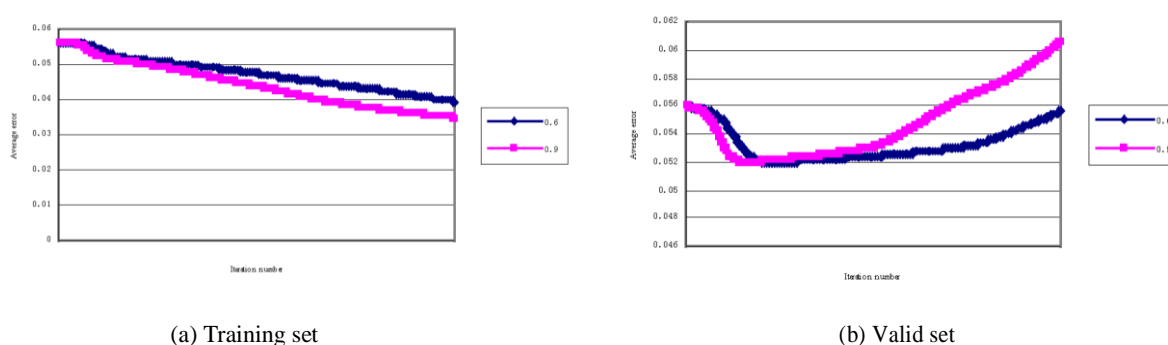

Figure 3 The influence of learning rate on average error

setting first: the initial value of weight, the number of

Figure 3 shows the influence of learning rate on the training process. Figure 3(a) shows that lower learning rate results in slower training but an excessive learning rate (bigger than 8) may make the training process swing among unsuitable solutions or even results in divergence. Figure 3(b) shows although the average error of the learning rate 0.6 is higher in training set, it is lower in valid set. Hence, 0.6 is chose for learning rate.

Figure 2(b) and 3(b) also show that the average error in valid set decrease first and then increase, which is the “Over-fitting” process. To avoid this, the weight of the smallest average error point in valid set is used as the final training result.

Figure 4 shows the training curve and valid curve

illustrating the changing average error in neural network training. The vertical line shows the smallest average error point in valid set, to which the weight corresponds is used as the ultimate result.

Based on the analysis above, the structure of BP-network model and parameters for training are determined as shown in Table 1.

Table 2 lists out the result of model evaluation. It shows that the average error and error-classifying rate are small enough in both training and valid set, which proves the model’s excellent ability in risk identification

Figure 4 BP training process

Table 1. Structure of BP network model and training parameters

Number of input hierarchic units	83
Number of hidden hierarchic units	16
Number of output hierarchic units	1
Activating function of hidden and output hierarchy	$f(x) = \frac{1}{1 + e^{-x}}$
Combination function between	$\sum_i w_{ij} o_i + q_j$
Learning rate	0.6

Valid set	0.0519343988	0.0595306239

## 6. CONCLUSIONS

It's a brand-new attempt to solve risk identification problem by BP network. Simulation results have proved the method's validity. Some excellent software for data mining also makes the application of this method possible. With an accurate identification of risks, enterprises are capable of taking more effective measures in their risk management.

## ABSTRACT

Employing IT as the key enable technology, virtual organization (VO) is primarily characterized as being a network of independent, geographically dispersed organizations (member organization) providing electronic services via Internet. To align these services effectively, one of the main challenges is to model cooperation in VO and provide correspondent management tools. Here we present a VOC (VO Structure-Organization Resource-Character) approach to model and run VO. VOC consists of three models. VO Structure model describes how VO functions in terms of VO Role (VR), Protocol; Organization Resource model describes potential service providers (potential member organization) capable participate VO. Character Model describes dynamic binding relationship between VO role and member organization. Following the VOC model, a platform supporting the design, administration, and running of VOC is given.

**Keywords:** Virtual Organization, VOC model, VO Structure Model, Organization Resource Model, Character Model

## 1. INTRODUCTION

A virtual organization (VO) is primarily characterized as being a network of independent, geographically dispersed organizations with a partial mission overlap<sup>[1,2]</sup>. Each VO is built to carry out some processes and achieve certain goals, and as the products and services provided by a virtual organization are dependent on innovation and are strongly customer-based, the organization structure must be adaptively dynamic. Within the network, all partners provide their own core competencies as deliverable services, and in a networked computational environment, some of these services are delivered in electronic form, for example, web services. To make a VO work flexibly and smoothly, a proper VO model and correspondent supportive running environment that can align these e-services are definitely necessary.

In this paper, we present a VOC (VO Structure-Organization Resource-Character) based approach to model and run VO. The VOC approach consists of a VOC model and correspondent supportive platform.

In section 2, we illustrate VOC model and some core processes, in section 3 a VOC-based VO management platform prototype is introduced and several correspondent core processes is then illustrated. Then we present a collaborative manufacturing example in section 5. Finally we conclude some characteristics of the VOC approach.

## 2. VOC MODEL

In a VO, each member organization (MO) has to assume

certain duties, deliver prescriptive services, join and leave VO dynamically. In VOC approach, we model the whole VO in several different models with each one focusing on different aspect of VO.

VOC model consists of three sub models:

- ò VO Structure Model (VSM)
- ò Organization Resource Model (ORM)
- ò Character Model (CM)

The VOC meta model is described in Figure 1.

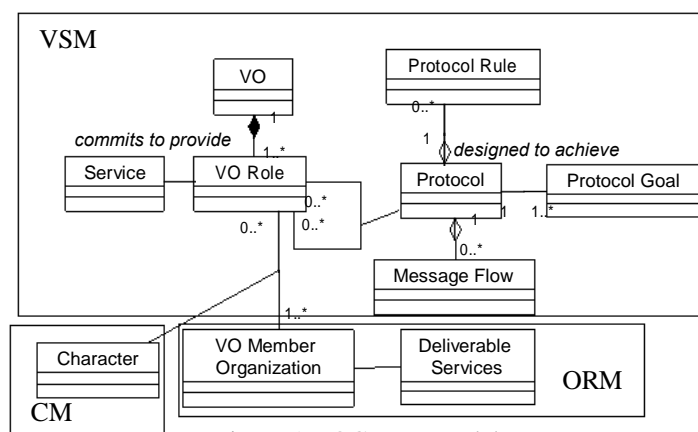

Figure 1 VOC meta model

### 2.1 VSM

The VO Structure model (VSM) describes VO structure in terms of VO Roles and Protocols. VO Role (VR) acts as a duty placeholder and commits to realize certain services in VO. VR will be dynamically assigned to MO

at VO design time and runtime (MO being the undertaker of VR). VR undertaker must realize the services VR commits to provide. VR cooperates with each other to achieve VO goals. The cooperation relationship between VR is modeled as Protocol. Protocol includes protocol rule and Message Flow. The former represents constraints that VR has to comply with. The latter illustrates message template and message sequence exchanged between protocol participants (VR). Protocol is instantiated as conversation which maintains the concrete context and threads participants will refer to frequently during cooperation.

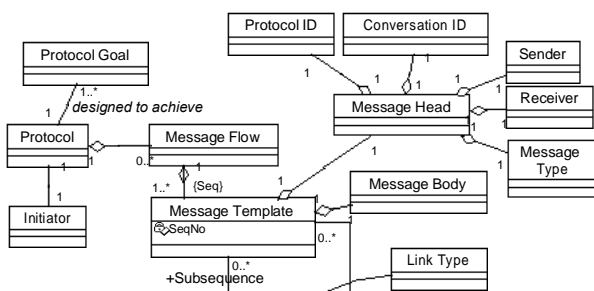

Figure 2 Message Flow

VR models static aspect of VO while Protocol models dynamic aspect. Each Protocol is designed to satisfy certain cooperation goals. For example, we can design a protocol based on Contract Net with its goal being task delegation. During runtime, VR undertaker can only choose from prescriptive protocols to cooperate with other VR, and follow exactly the Message Flow (Figure 2). Each protocol has an Initiator who is responsible for creating a protocol-based conversation. Each Message Template has a head and body. The Head includes message related protocol ID, conversation ID, sender VR, receiver VR and message type. The Body contains message content. Conversation participant must send message in according with the sequence and template specified in Message Flow to help each other indicate, understand, respond message quickly and properly.

## 2.2 ORM

Organization Resource Model (ORM) describes MO's capability and deliverable services. ORM of VO contains all potential MOs of a VO. Organization in ORM can be deputed VR dynamically by VO Administrator.

## 2.3 CM

Character Model (CM) is responsible for binding ORM and VSM. To make a VO functions as will, each VR has to be assigned to certain MO. We name this kind of 'Play' relationship between VR and MO as character. A MO can assume several characters at the same time.

## 3.VOC-BASED PLATFORM

Figure 3 VOC based Platform structure

Based on VOC model, we developed a VOC based platform prototype (Figure 3). The core VOC model element is realized as Java object running in classified pools: VSM Pool; Character Object Pool; MO Agent Pool. Each kind of pool is managed by a correspondent software component.

By using the platform, we can design and run VO. The platform includes a VOC Model DB, a VO Instance DB, and VO Tools.

### ð VOC Model DB

VOC Model DB stores all VOC model data, including VSM, ORM and CM. VOC model works just like a class in Object-Oriented technology. A running VO is an instance of a special VOC model and consists of different types of software objects (or components) living in correspondent object pools.

### ð VO Instance DB

VO Instance Db stores all VO instance related data such as VO start time, VO original VOC model, VO MO etc.. By providing VO Instance DB, we can adjust VO in a case-based approach and thus providing a flexible way of managing VO.

### ð VSM Mgr

VSM Mgr is responsible for VSM management, including VSM creating, saving and dynamic adjustment, VSM Object initiation and life cycle management. VSM Mgr is the manager of VSM pool. There are four types of object in VSM Pool:

#### V VO Object

A VO object is the controller of a running VO. When a VO is initiated the system will create a VO object and this VO object will be responsible for managing the whole life cycle of VO and create, manage, destroy other VSM object in this VO as needed.

#### V VR Object

Each VR in VSM will create a VR Object at VO runtime.

#### V Protocol Object & Conversation Object

Each protocol in VSM will create a Protocol Object at VO runtime. When a protocol-based interaction is initiated, a Conversation Object is created to manage it. Conversation Object acts as a communication channel between VO Object which can only send messages through the interface Conversation Object provided and in the protocol specified form and sequence. Conversation Object can get message and rule related information from Protocol Object at runtime. For there may be tens of thousands conversation being running at the same time, saving protocol related information in Protocol Object is wise choice to avoid frequent DB access.

#### ò ORM Mgr

ORM Mgr manages ORM, and can instantiate MO Agent Object (MAO) according to the registered MO in ORM. Any organization that wants to participate in the VO must be registered in ORM. There are two ways of registering MO: active way and passive way. In active way, organizations must register themselves in ORM by providing their own capacities and deliverable services information. In passive way, VO Administrator has to search above information and identify appropriate organizations, contracts with them and registers them manually in ORM. Each registered organization will get a reference (though Web Service) to a MAO which is created by ORM Mgr in MO Agent Pool. When a registered organization exits from ORM, the correspondent MAO will be terminated.

#### V MO Agent Pool

A MAO can only live in MO Agent Pool. Each MAO is just a proxy of registered MO in VOC Platform and is exposed to related MO as an accessible web services. MAO provides an effective way of communicating with MO and is independent from the internal realization structure of original MO. We also provide an interface for MAO so that it can interact with Character Object smoothly.

#### ò Character Binder

Character Binder manages the binding between MO and VR. A VO can not be instantiated until each VR has been assigned to a concrete MO. A MO-VR pair is represented as a character and instantiated as a Character Object (CO). Thus, within a VO, MO can cooperate with each other in this way: MO Æ MAO Æ CO Æ VR Object Æ Conversation

Object Æ MAO Æ MO. This indirect way of interaction may bring some efficiency problems but illustrate a flexible way of reconfiguration. By making all objects active in pool (RAM), we can alleviate the efficiency problem to some extent.

#### ò VO Admin Center

VO Admin Center is the center controller of the whole VOC-based platform. VO Administrator uses it to manage all VO running in the VOC-based Platform. VO Admin Center calls VSM Mgr, Character Binder, ORM Mgr to create, destroy, and adjust VOC model and instantiated VO as well.

### 3. VO CORE PROCESS

To build VO based on the platform in an effective way, we identified some core processes in constructing VOC model and running VO. These are processes the platform supports and each MO has to comply with. We illustrate several processes below:

#### ò MO Registering Process

MO can participate in special VO by first registering itself in VOC-based Platform and then get a MAO reference.

#### ò MO Terminating Process

MO can only terminate from running VO after issuing MO-TERMINATION message to all other VRs and complete works on hand. Thus other VRs won't send it any more messages after their completing to-be-terminated MO related cooperation work. The platform will then destroy related CO, MAO.

#### ò MO Entering VO Process

After a special MO is selected to assume a VR, it has to realize all services specified in VR specification. First, the platform will send the target MO a VR specification identifying all services and protocols MO has to realize in detail. Then MO must design and realize it, and then answer the platform with a SERVICE-READY message. Only after this process, the platform can confirm the VR-INSTANTIATION-READY status of VR.

#### ò VSM Instantiating and Terminating Process

The platform first checks all its VR to confirm all of them being in VR-INSTANTIATION\_READY status, and then creates the whole VO instance in this sequence: VO Object Æ VR Object Æ Character Object.

To terminate a exist VO instance, the platform first check all VR to confirm all MO has issuing MO-TERMINATION message and then destroy the whole VO instance in this sequence: Character Object Æ VR Object Æ VO Object.

### 4. SAMPLE APPLICATIONS

By referring a production process in an aeronautic assembly factory, we construct our sample application

to verify the effectiveness of the platform (See Figure 4). The product experience 2 stages before assembled. Due to the cost-reduction problem, the first two stages is outsourcing to two different factories. But the contractual manufacturer is not fixed to allow more flexibility to purchase lower cost and higher quality. And production stages will change from time to time due to technology development. That is to say, the production routine and contractor list is not static. Thus the factory has to issue production task and cooperate with contractual manufacturers in an unstable production net. A production-net-adaptive platform supporting collaborative production task allocation is helpful.

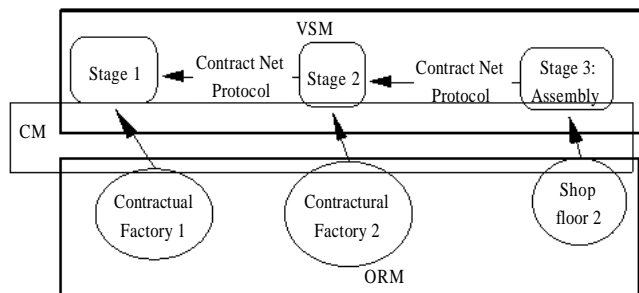

Figure 4 Collaborative Manufacturing Example

By applying VOC approach in this example, we can build Stage as VSM VR, and manufacturing contractor as MO, and the contractual manufacturing relationship as Character, thus we can adjust the collaborative relationship flexibly. Meantime, by designing proper VR Protocol suitable for production task allocation, we can change task allocation procedure as well.

## 5. CONCLUSIONS

The VOC based approach of managing VO has the characteristics as follows:

### V Reusable

We divide the whole VO into three models with each one focusing on different aspects of VO. VSM models the static structure and cooperation relationship between MO. ORM works as a resource pool while VO Administrator can choose from. Character Model connects VSM and ORM to form a concrete VO. Thus we can conclude the reusable issue into these three levels. In VSM level, a historical VO structure model can be a reusable unit. For example, we can elicit a proved effective VSM into enterprise knowledge base and turn it into the original reference model of an upcoming VO (like the case of section 5). In ORM level,

a MO is shared between different VO and can be assigned different VR from different VO at the same time. A MO's Character history can identify what kind of VR (protocols, services) it is most suitable for.

### V Reconfigurable

As MO cooperate with each other in an indirect way and the existence of VO Instance DB, VO Administrator can reconfigure the VO structure by adjusting VSM, ORM or CM. For example, you can change the cooperation constraints by applying different protocol between VR.

### V Model driven

Each VO is initiated and run based on the VOC model. You can influence the VO behavior by just adjusting VO case model stored in VO Instance DB.

### V Scalable

ORM works as a resource pool where all potential VO participants can enter and exit flexibly.

Future research will focus on dynamic VR delegation and dynamic VR selection.

### ABSTRACT

Virtual enterprise is based on the premise that work should be done where it can be done most optimally. In virtual enterprises, geographical boundaries merge seamlessly. It enables organisations to act in a way of flexibility and ability to adapt to rapid changes on the fly. However, different parties in a virtual enterprise must understand each other before they go further details in business. Ontologies are such kinds of ideal baselines to assist parties to communicate. One of the essential research issues with ontology is how to deal with changes during their evolving cycle. Therefore, ontology refinement is a crucial component in ontology evolution. This paper presents a taxonomy structure focusing on the is-a relations. In particular, the concept of closeness measurement is introduced based on the “distance” estimation. An extended cluster analysis process is provided. According to the algorithm presented, a new concept is generated according to its attributes. Additionally, the refinement mechanisms for primitive operations are proposed. Unlike some other ontology refinement mechanisms which leave ontology consistency checking to human users after modification, our method emphasises the importance of consistency checking by applying description logics which is demonstrated based on the proposed ontology.

**Keywords:** ontology evolution, virtual enterprises, clustering, description logic, consistency checking

### 1. INTRODUCTION

An ontology can be defined as *an explicit specification of conceptualisation* [6]. Currently, the use of ontology for different purposes such as Web applications, Web semantics, information systems, are intensively addressed. The ontology is important because it is the foundation for different organisations to understand each other within or across enterprises. Feasible ontologies in virtual enterprises (VEs) are especially important because of VE’s characteristics: VEs only exist for a short life span as a temporary network of geographically distributed partners that cooperatively work together to share skills, costs, profits, risks, and markets, and, at the same time, decrease the investment [3]. VEs are not rigid organisational structures within rigid frameworks, but rather, heterogeneous ensembles, continuously evolving over time [13]. For this reason, a complete ontology is essential for VE formation because of its pressing time requirement and heterogeneity. However, there indeed exist cases when some concepts/attributes and their relations are out of date or cannot be accessed through the current ontology. According to Stojanovic [14], there are seven different requirements demanding ontology evolution. In addition, a six-phase evolution process is addressed. Other researchers [12,14] also note that ontology development is a dynamic process starting with an initial rough ontology, which is revised, refined and filled with details on an ongoing basis. That is to say, ontology refinement is important and needs more efforts throughout its entire lifecycle. In VEs where different parties might work on an ontology collaboratively, dynamically refining the ontology is likely to be more important than that in any other places.

Intelligent software agents (agents hereafter) are a suitable means of representing the partners of a VE [5]. Agents act on behalf of the enterprises or organisations that collaborate among themselves to achieve a specific goal under assumptions that they are goal-oriented, commitment-based and able to share skills, cost, profits, risks and markets [12]. We assume agents who are likely to form a VE have similar but slightly differing ontologies rather than completely different ones. This is reasonable in the real world for different partners having something in common within the domain.

Some work has been performed on tackling ontology refinement. Noy’s work [10] talks about that both *merging* and *alignment* are two processes which are usually used to handle the ontology refinement. These two processes are illustrated in PROMPT [11], a semi-automatic approach to ontology merging and alignment where users’ intervention is required. In his book [8], Maedche mentions an essential part of ontology engineering ontology learning. The development of the taxonomic backbone of the ontology is also involved. The clustering analysis mainly discussed in natural language processing previously, has been highlighted from learning the taxonomic relation perspective.

Generally speaking, existing refining proposals fall into two categories. One is to investigate ontology dynamic changes and the corresponding management from the knowledge engineering perspective [1,4,8,14]. The other is from the context of plan execution [9]. However, in light of their proposed approaches, a new term’s relationships with existing concepts are specified/semi-specified by human users. By doing so they avoid indicating how they get to know the relations between con-

cepts. That is to say that they fail to address how they get to know the relations between new terms and the existing ones and whether the ontology is still consistent after some modifications.

To comply with the requirements, our main task will be on adjusting the proposed ontology structure to any changes of concepts and their relations while at the same time processing consistency checking with the source ontology. We use a statistics-based approach, especially the cluster analysis method first to obtain a corresponding classification of the terms (in the is-a concept hierarchy). Then we use description logics (DLs) [2,7] to check if the newly added concepts are consistent with the original ontology structure by considering their satisfiability and subsumption. The novel contribution of this paper is to provide a method that operates in a resilient manner in ontology refinement, and at meantime, consistency checking complying with the ontology evolution life cycle to guarantee that any application has a sound knowledge of the world.

We do not distinguish terms between parties, partners, participants and agents in this paper only if they would convey much more meaning in certain circumstance.

The rest of this paper is organised as follows. The next section first presents a taxonomy structure and then addresses the mapping between concept relations and distances. Section 3 proposes refinement mechanisms for the add and delete primitive operations. Section 4 discusses consistency checking of an ontology by using DLs. Section 5 illustrates our approach with an example. Finally, section 6 concludes our work.

## 2. CLUSTER ANALYSIS

Term *cluster analysis* [15] actually encompasses a number of different classification algorithms. Two things are worth noting here. One general question facing *cluster analysis* in many areas is how to *organise* observed data into meaningful structures—taxonomies. Another is a suitable algorithm for a specific question. In this paper, concepts are organised as the higher the level of concept aggregation the more abstract these concepts are in the respective class. We borrow term “distance” to show close/loose relations in the paper. In addition, we use the term “new cluster” to notate a new generated concept if needed in a dendrogram. It will be discussed in more detail in section 3.

### 2.1 Taxonomy Structure

A concept definition, along with its relations and others (if they exist), is more likely to be described in a taxonomy (the “is-a” hierarchy) structure. The most central relations are the is-a relation (concept—concept) and property-of relation (concept—attribute). Like in Figure 1, nodes in squares with capital letters such as *A*, *B*, *C*, *D*, *E*, and *F* are abstract concepts whereas other nodes

notated in circle with lowercases are concrete ones. The difference between an abstract concept and a concrete one lies in that the abstract one subsumes sub concepts. In this paper, concrete concepts are specified with primitive or common knowledge in terms of attributes and properties. For instance, in a general “transport” ontology which describes different transports such as “ship”, “airplane”, “bus”, and “train” etc. and their relationships, concepts like “ship”, “airplane”, “bus”, and “train” are abstract concepts, while “mph”, and “capacity” are concrete concepts to define the attributes of a specific transport. Clearly, concept *B* subsumes both *E* and *F*, whereas *B* is subsumed by another concept *A*. And lowercase *f* is a property-of concept *A*. Obviously, the higher the concept is, the more abstract it is. Ontology structure in this paper is described in the “is-a” hierarchical structure. And we will refer to Figure 1 again in subsequent sections. Understanding how a dendrogram is constructed, and how it should be interpreted, is helpful to understand ontology refinement by using clustering analysis. The next subsection will discuss Figure 1 in-depth from the cluster analysis perspective.

Fig. 1. Taxonomy structure of concepts

### 2.2 Mapping Concept Relations and Distances

Every concept, no matter it is a concrete or an abstract concept, has a set of attributes with different levels of granularity. Generally speaking, a concept can be expressed by a set of triples of (attribute, value, weight), namely  $A_{att} = \langle (a_1, v_1, w_1), (a_2, v_2, w_2), \dots, (a_m, v_m, w_m) \rangle$ , where  $a_j$  is an attribute and  $v_j$  is the corresponding value. Here  $w_j$  ( $j \in [1, m]$ ) is represented by a real number in range  $[0, 1]$  which is an estimation standing for to what extent an attribute getting a specific value (1 means matching perfectly, while others mean they can be approximately equal to those values). An instance such as (shape, circle, 0.8) means that a concept has attribute “shape” with value “circle”, but not a 100 percent circle, the closeness estimation is only 0.8 instead of 1.

In order to reduce redundancy, a value matrix (*VM* in short), a corresponding attribute vector (*AV*), and its corresponding weight matrix (*WM*, in which 0 means corresponding attribute is *N/A*) are introduced below. It is easy to get a triple mentioned above such as (shape, circle, 0.8).

$$\begin{array}{c}
 \begin{bmatrix} \text{shape} \\ \text{colour} \\ \text{L} \\ \text{size} \end{bmatrix} \\
 (VM)
 \end{array}
 \begin{array}{c}
 \begin{bmatrix} \text{circle} & \text{red} & \text{L} & \text{N/A} \\ \text{square} & \text{green} & \text{L} & \text{small} \\ \text{L} & \text{L} & \text{L} & \text{L} \\ \text{N/A} & \text{green} & \text{L} & \text{big} \end{bmatrix} \\
 (AV)
 \end{array}
 \begin{array}{c}
 \begin{bmatrix} 0.8 & 1 & \text{L} & 0 \\ 1 & 0.6 & \text{L} & 0.1 \\ \text{L} & \text{L} & \text{L} & \text{L} \\ 0 & 0.9 & \text{L} & 0.8 \end{bmatrix} \\
 (WM)
 \end{array}$$

It is clear that the concept similarity, which is based on

relevant matrixes and closeness measurement, determines the relations between the concepts. In terms of the closeness measurement, “distances” between the attributes will be calculated. Obviously, the smaller “distance” means much more similar than that of greater “distance”.

In order to calculate the distance, similarity matrixes (also symmetric matrixes, notated as  $SM_1, SM_2, SM_j, \dots, SM_m$  for simplicity), where  $SM_j$  corresponds to the  $j^{th}$  attribute in the  $AV$  vector and their different values, are provided. These matrixes show how close these values are (similarity closeness  $\in [0, 1]$ , in which 1 means perfectly matching, 0 means never matching, other value  $\in (0, 1)$  means approximate matching).

Let us recall all of them before we start to discuss our approaches. In order for agents to automatically refine their individual ontologies, firstly, a value matrix ( $VM$ ), a corresponding attribute vector ( $AV$ ), and its corresponding weight matrix ( $WM$ ) must provide. Moreover we suppose that similarity matrixes ( $SM_1, SM_2, SM_j, \dots, SM_m$ ) are available for the proposed ontology and their attributes. In addition, we always treat ontologies are consistent initially. Without this our consistency checking will make no sense.

### 3. REFINEMENT MECHANISMS

As indicated earlier, ontology evolves overtime in the real world. How to refine ontology on the fly needs to be handled properly. In this section, we consider two primitive operations, i.e. add and delete as the refinement mechanisms based on the ontology structure and cluster analysis discussed earlier in this paper.

#### 3.1 Add Operation

When we consider the add operation, generally there are two cases: (1) a new concept is subsumed by another concept; (2) a new cluster (concept) needs to be created in order to subsume a new concept. It is also possible that a new cluster may generate another bigger new cluster afterwards. Let us consider new concept  $X$  (only considering an abstract concept here) in Figure 2. In one case (on the left),  $X$  is subsumed by concept  $B$ , while in another case (on the right) shows that a new cluster  $Y$  (being subsumed by concept  $A$ ), is generated which subsumes both  $B$  and  $X$ .

Fig. 2. Two cases of adding operation

For the reason that the number of the attributes might vary from concept to concept, for simplicity, the biggest number will determine the cardinality of the  $VA$ . In this

case, there must be some empty elements in  $VM$ , here “ $N/A$ ” is used to notate no such a property in  $VM$ . Figure 3 is the flow chart to add a new concept through top-down in the hierarchy.

Fig. 3. Flow chart of adding a new concept

First of all, we assume that new concept  $X$  has the same attribute vector ( $AV$ ) as others do. Of course, some properties are “ $N/A$ ” under certain circumstance, so does the weight matrix ( $WM$ ) with corresponding 0’s value. Additionally,  $X$ ’s weight vector  $X_w$  and value vector  $X_v$  are also provided. The details are as follows.

#### Step 1: Function *sort WM*

It mainly deals with sorting weight matrix ( $WM$ ) by referring to  $X$ ’s 1’s distribution by referring to its weight vector  $X_w$  (each  $w_{Xj} \in [0, 1]$ ). The summary  $\sum_{j=1}^m w_{ij} \cdot w_{Xj}$ , where  $i \in [1, n], j \in [1, m], w_{ij} \in [0, 1]$ , corresponding to the element in  $WM$ ,  $w_{Xj} \in [0, 1]$ , corresponding to the element in  $X_w$  is filtered by a threshold ( $d_1$ ) which is given apriori.

- (1) The values that are less than the threshold are ignored.
- (2) If all values are less than the given value, the process leads to the *END* of the adding process. That is to say, the new concept  $X$  is irrelevant to the existing concept taxonomy structure.
- (3) Otherwise all selected vectors form a new weight matrix *New WM* and a new value matrix *New VM* respectively (only related concepts are left after this step).

#### Step 2: Function *calculate\_closeness*

As mentioned before (Section 2.2),  $SM_j$  ( $j \in [1, m]$ ) as a similarity matrix (it is symmetric) provides similarity measurements of different values upon a specific attribute. For example, an attribute “*shape*” has a matrix ( $SM_j$ ) to estimate to what extent the shape “circle” and “ellipse” can be regarded as similar to each other. Figure 4 gives a demonstration. For new concept  $X < w_{X1}, w_{X2}, \dots, w_{Xm} >$ , calculate  $\sum_{j=1}^m w_{Xj} \cdot s_j$

where  $s_j'$  coming from above  $SM_j$  ( $j \in [1, m]$ ) (Figure 4) based on the *New\_WM* (filtered).

Fig. 4. Similarity matrixes

#### Step 3: **Function** *sort\_result*

Sorting above values in the descending order and selecting candidates (notated as *Selected\_New\_WM*) whose summary values are greater than the threshold ( $d_2$ ). If there is no one with a sum value greater than  $d_2$ , go to step 5. Again, getting corresponding *Selecte\_New\_VM* as well.

#### Step 4: **Function** *generate\_new\_cluster*

(1) Appending new concept  $X$ 's weight vector  $X_w$  and value vector  $X_v$  to the *Selected\_New\_WM* and *Selected\_New\_VM* respectively.

(2) Selecting all attributes (mapping to  $AV$  and satisfying corresponding elements in *Selected\_New\_WM* which are greater than threshold  $d_3$ ) to form a *New\_AV*.

(3) Making an intersection to obtain how many attributes are involved (with a corresponding weight in *Selected\_New\_WM* which is greater than  $d_3$ ) if possible.

Otherwise go to step 5.

(4) Making an intersection to obtain what values are involved (with a corresponding weight in *Selected\_New\_WM* which is greater than  $d_3$ ) if possible.

Otherwise go to step 5.

(5) The newly generated cluster features with value vector  $Y_v$  and weight vector  $Y_w$  as well. It is worthy noting that the newly generated cluster features with 1's (if it has corresponding attribute) or 0's (no such property) rather than other values between (0, 1).

#### Step 5: **Function** *attach\_new\_concept*

Attaching the newly generated concept to the original structure, such as in Figure 2, new concept  $X$  (enclosed in a dotted line circle) is attached to original node  $B$  if there is no new cluster generated, on the contrary,  $Y$  should be attached to node  $A$  if new cluster  $Y$  is generated while the new concept  $X$  is added to the structure.

### 3.2 Delete Operation

As for deleting a concept from the structure, generally, it should be relatively easy if a simple case (without any sub concepts) is concerned (Figure 5). For other cases, sub concepts of the deleted concept (subgraph) will be attached to its parents (Figure 6).

(1) In Figure 5, suppose the deleted concept is  $t$  (on the left), just delete it (see the graph on the right as the result).

Fig. 5. Delete operation—case 1

(2) In Figure 6, suppose the deleted concept is  $Y$  (on the left) this time, all its ( $Y$ 's) sub concepts (both  $X$  and  $B$ ) will be attached to its parent  $A$  (see the graph on the right as the result).

Fig. 6. Delete operation—case 2

Functions such as *generated\_new\_cluster* and *attach\_new\_concept* are very useful to explain the add and delete operations. We believe more complex structure can also get some help from approaches here.

## 4. CONSISTENCY CHECKING

Different partners can contribute to the extension of an ontology. In addition, the same partner may revise the ontology from time to time. Therefore, ontology consistency checking is vital to any applications based on it. Description logics (DLs) as carefully selected parts of first order predicate logics are designed to be expressive enough to be useful for constructing and querying ontologies. Their inference engines are good at answering subsumption and satisfiability queries. In the paper, we use them to check consistency of refined ontology. The basic ideas look as follows.

Generally,  $C$  and  $D$  denote any concepts,  $R$  for the role name. The semantics is given by means of interpretation  $I$ . An interpretation is a pair of domain  $\Delta^I$  and interpretation function  $\cdot^I$ , namely  $I = (\Delta^I, \cdot^I)$ . With parts of constructors, interpretation  $I$  for concepts is defined in Table 1

Table 1. Parts of constructors of DLs

Constructor	Syntax	Semantics
Atomic role	$R$	$R^I \subseteq \Delta^I \times \Delta^I$
Conjunction (AND)	$C \sqcap D$	$C^I \sqcap D^I$
Disjunction (OR)	$C \sqcup D$	$C^I \sqcup D^I$
Negation (NOT)	$\neg C$	$\Delta^I \setminus C^I$

Existential restrict	$? R.C$	$\{x \mid \exists y. \langle x, y \rangle \in R^I \wedge y \in C^I\}$
Universal restrict	$\forall R.C$	$\{x \mid \forall y. \langle x, y \rangle \in R^I \Rightarrow y \in C^I\}$

In terms of ontology consistency checking, we have axioms like  $\mathcal{Q} D$  ( $C$  is subsumed by  $D$ , “?” notates subsumption relation in DLs) iff  $C \not\sqsubseteq D$ , that is to say  $\mathcal{Q} \neg D$  is not satisfiable (inconsistent). We use annotations like *property1*, *property2*, etc. to notate different attributes shown in Figure 1 by ignoring what it really means. Based on the DL model, the taxonomy structure (Figure 1) can be expressed more formally as:

$A \not\sqsubseteq B \not\sqsubseteq C \not\sqsubseteq D \not\sqsubseteq \text{property1.f}$   
 $B \not\sqsubseteq A$   
 $B \not\sqsubseteq E \not\sqsubseteq F$   
 $C \not\sqsubseteq A \not\sqsubseteq \text{property2.c} \not\sqsubseteq \text{property3.d}$   
 $D \not\sqsubseteq A \not\sqsubseteq \text{property3.d} \not\sqsubseteq \text{property4.e}$   
 $E \not\sqsubseteq B \not\sqsubseteq \text{property5.a} \not\sqsubseteq \text{property6.b}$   
 $F \not\sqsubseteq B \not\sqsubseteq \text{property6.b} \not\sqsubseteq \text{property2.c} \not\sqsubseteq \text{property7.g}$

For new concept  $X$  from Figure 5, it looks like:

$X \not\sqsubseteq B$   
 $X \not\sqsubseteq W \not\sqsubseteq \text{property7.t}$

The satisfiability and subsumption can be used during ontology construction to verify whether the ontology is consistent or not. We assume it is consistent initially. When the primitive operations have been processed, DL can answer the questions such as ‘is a concept consistent with the source ontology?’, and ‘Is this concept a part of another?’. For instance (Now look at the case that  $X$  is attached to  $B$ ),  $X \not\sqsubseteq \text{property1.f}$  is inconsistent because of  $X \not\sqsubseteq B$  (given condition),  $B \sqsubseteq A$  (already known condition) and which implies  $X \sqsubseteq A$ .  $X \not\sqsubseteq \text{property1.f}$  is not satisfiable because it contradicts with the reasoning result  $X \sqsubseteq A$  (*property1.f* is one of properties of concept  $A$  shown in Figure 1). As the above consistency checking is conducted according to Figure 1 which is platform- and description language-independent, it is promising to deal with ontology refinement in the is-a hierarchy in general.

## 5. EXAMPLE

A simple example below will show how a new node is added and a new node is generated by applying cluster analysis. In this example, we assume  $d_1$ ,  $d_2$ , and  $d_3$  (Figure 3) equal to zero. Euclidean distance, computed as:  $\text{distance}(x, y) = \sqrt{\sum_i (x_i - y_i)^2}$ , is used to measure “distance”, and the shortest distance in a Euclidean distance matrix will determine which pair of nodes will be fused to form a cluster. First we demonstrate a dendrogram construction through the example, then we con-

sider adding a new node to this hierarchical structure to refine it.

Now suppose there are 4 nodes  $V_1(2,3)$ ,  $V_2(5,1)$ ,  $V_3(4,4)$ ,  $V_4(1,2)$ . Their corresponding Euclidean distance matrix is shown in Figure 7.a. It shows that the most similar nodes are  $V_1$  and  $V_4$  (the value is 1.4). Then we get a new cluster  $V_{14}(1.5, 2.5)$ , a means of these two nodes is calculated for each dimension. That is to say, after  $V_1$  and  $V_4$  clustered, a new node  $V_{14}(1.5, 2.5)$  is generated. So now there are three nodes  $V_{14}(1.5, 2.5)$ ,  $V_2(5,1)$ ,  $V_3(4,4)$ . Repeat the above calculation, a revised distance matrix is shown in Figure 7.b. At this stage, the most similar nodes are  $V_{14}$  and  $V_3$  (the value is 2.9). Then we get a new cluster,  $V_{143}(3.5, 4.5)$ . Now there are two nodes,  $V_{143}(3.5, 4.5)$ ,  $V_2(5,1)$ . Again we get a revised distance matrix which is shown in Figure 7.c.

The whole process is summarised by a dendrogram as shown in Figure 8 (on the left). Suppose a new node notated as  $V_x(6,5)$  is going to be added. As we mentioned before, the entire process works in a top-down approach. The same is here. However, in this example, we only focus on nodes on the first level (the root level namely the top level normally is virtual item annotated as “ENTIRY” or “THING”. In real cases, the attribute matrix will determine to which level the algorithm is affected. The worst case is that all existing concepts will be taken into consideration), namely  $V_{143}(3.5, 4.5)$ ,  $V_2(5,1)$ . At this stage, calculations are between these three nodes. That is  $V_x(6,5)$ ,  $V_{143}(3.5, 4.5)$ , and  $V_2(5,1)$ . At the end, the distance matrix is shown in Figure 7.d. It is clear that the most similar pair is  $V_{143}$  and  $V_x$  (the value is 2.5). The revised dendrogram is shown in Figure 8 (on the right). New node  $V_x$  is added in and fused with  $V_{143}$  to form a cluster  $V_{x143}$  which can be regarded as a new generated concept in the ontology refinement process.

Fig 7. Euclidean distance matrixes

This example demonstrates our ontology refinement process, especially the add operation works well by taking attribute-value pair “distance” and clustering analysis. It is no doubt that in the real world, the refinement for ontology, which includes many concepts, is definitely more complicated than the example. However, the basic ideas and mechanisms to refine the ontology are quite similar to the method here.

Fig. 8 New cluster in dendrogram construction

## 6. CONCLUSIONS AND FUTURE WORK

In this paper, our general focus is on developing a new approach to deal with the refinement for ontology evolution in virtual enterprises. A novel clustering algorithm has been applied to classify new concepts. Unlike other methods in ontology refinement, our approaches can classify the new concepts automatically instead of specified or semi-specified manually. In addition, the primitive add and delete operations are provided. Furthermore, we have illustrated that consistency checking should be a crucial element within the ontology evolution life cycle to guarantee that any application has a sound knowledge of the world. The consistency checking of the concepts makes our approach in accordance with knowledge management requirements in preserving knowledge and sharing knowledge. In addition, we believe that clustering analysis is a promising way to knowledge acquisition and ontology management. Moreover, differentiating abstract concepts from concrete ones are useful when we address the hierarchical taxonomic structures.

There are many issues remaining as future work. The semantic meaning of new clustering cannot be fully achieved only through the vector descriptions. Moreover, deleting is not as easy as people first thought. Another aspect is the structure for ontology consistency checking. Consistency checking needs to be emphasised in ontology evolution by considering multiple users. In addition, it is nevertheless essential to address the attribute weighting issue not only in a deterministic environment but also in a non-deterministic environment.

## ACKNOWLEDGEMENT

Work reported in this paper is partly supported by Swinburne Vice Chancellor's Strategic Research Initiative Grant 2002-2004 for project "Internet-based e-business ventures".

### ABSTRACT

Virtual Enterprise is the potential mode of enterprise in the future. The risk management for virtual enterprise is the new research area recently. In virtual enterprise, the enterprise operation is always organized by project mode and there is always less historical data and there are many uncertain factors. Hence, in this paper, the fuzzy synthetic evaluation model for the risk evaluation of virtual enterprise is established focus on the project mode and uncertain characteristics of virtual enterprise. In the 5 levels model, the goal and sub-goal of the enterprise, the process of the project, as well as the risk event and risk factors are considered. The case study suggests that the method is useful.

**Keywords:** virtual enterprise, risk evaluation, fuzzy synthetic evaluation

### 1. INTRODUCTION

Risk Evaluation, a significant stage in risk management, is defined as a process in which the acceptance level of integrated enterprise risk is determined based on single-risk evaluation. Common evaluating methods include balance-point method, sensitive analysis and probability analysis, etc. [1-4], in which the simple relation between one kind of profit and its relevant parameter is discovered from a standpoint of profit then described mathematically or probabilistically. However, since an enterprise, especially a virtual enterprise is a complicated system consisting of a number of functional elements, its risks should be analyzed and evaluated from a systematic point of view so that the general objective of the system and functions of all parts can be managed and the relations in-between acknowledged. Only when the operating regularity of each kind of risk is studied can the integrated risk level be determined. Besides, since a virtual enterprise is a dynamic alliance [5-7] which exists temporally with the aims of grasping some new opportunity in the market, two main features of it is considered in this research. First, the operation of VE is always organized by project mode, so the integrated risk level is obtained based on the evaluation of each sub-procedure risk level in the analysis. Second, there is neither basic data nor objective probabilistic distribution for reference but personal experiences and subjective judgment, which is of great fuzziness. As a result, fuzzy method is proposed in our research. In this research, a risk evaluation model for virtual enterprises is established based on fuzzy mathematic theory from a systematic point of view and case study provided to prove its effectiveness.

### 2. FUZZY SYNTHETIC EVALUATION THEORY

Comparison is often needed for judging in productive operation, scientific researches and daily life. To

evaluate is easy if there is only one factor to be considered. However, it is always necessary to judge synthetically because there are always a number of attributive factors reflecting different characteristics, especially when dealing with complicated systems. If fuzzy features are also involved, it becomes a fuzzy synthetic evaluation problem[8-11].

#### 2.1 Single-level Fuzzy Synthetic Evaluation

The single-level synthetic evaluation is used when the factor to be considered is not too much. Four factors need to be considered in this process:

- 1) Factor set of all factors to consider in the synthetic evaluation, denoted by the set

$$U = \{u_1, u_2, \dots, u_m\} \quad (1)$$

- 2) Fuzzy subsets indicating importance levels of factors in the synthetic evaluation, denoted by

$$A = \frac{a_1}{u_1} + \frac{a_2}{u_2} + \dots + \frac{a_m}{u_m} \quad (2)$$

among which  $a_1, a_2, \dots, a_m$  represents importance levels of the corresponding factors.

- 3) Comment set of evaluation result, denoted by

$$V = \{v_1, v_2, \dots, v_m\} \quad (3)$$

- 4) Evaluating matrix of fuzzy relation between factor domain and comment domain, denoted by :

$$R = \begin{pmatrix} R_1 \\ R_2 \\ \vdots \\ R_m \end{pmatrix} = \begin{pmatrix} r_{11} & r_{12} & \dots & r_{1n} \\ r_{21} & r_{22} & \dots & r_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ r_{m1} & r_{m2} & \dots & r_{mn} \end{pmatrix} \quad (4)$$

where  $r_{ij}$  represents membership degree of object to be  $v_j$  from the standpoint of  $u_i$ .  $R_i$  represents the

mono-factor evaluation to  $u_i$ . It is a fuzzy subset of  $V$ .

The fuzzy matrix being compound-calculated, then:

$$A \circ R = B \quad (5)$$

or

$$(a_1, a_2, \dots, a_m) \circ \begin{pmatrix} r_{11} & r_{12} & \dots & r_{1n} \\ r_{21} & r_{22} & \dots & r_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ r_{m1} & r_{m2} & \dots & r_{mn} \end{pmatrix} = (b_1, b_2, \dots, b_n) \quad (6)$$

Let

$$B = (b_1, b_2, \dots, b_n) \quad (7)$$

$B$  is a fuzzy subset of comment domain  $V$ , indicating the membership degree of evaluated results to comment set, which is usually determined according to maximum membership degree principle.

A number of methods can be applied to compound calculation in fuzzy matrix, of which the two most commonly-used types are:

#### 1) Main-factor-determining type

$$b_j = \max[\min(a_1, r_{1j}), \min(a_2, r_{2j}), \dots, \min(a_n, r_{nj})] \quad (8)$$

It is best applied to the situation of which the optimum is determined by one optimal single factor.

#### 2) Weighted-mean-determining type

$$b_j = \sum_{i=1}^m a_i \cdot r_{ij} \quad (9)$$

It takes function of every factor in general evaluation into account, giving attention to the influence of each, which makes it the most suitable for situations that require integrated evaluative index.

The second type is used in our analysis.

### 2.2 Multi-level Fuzzy Synthetic Evaluation (MFSE)

A lot of factors should be considered in complicated problems and systems. These factors might belong to different categories and hierarchies, which are in need of a multi-level evaluation: firstly they are primarily and synthetically evaluated within lowest hierarchy; then a higher hierarchy synthetic evaluation is given based on the results of its prior step in lower hierarchy; and so on, till the evaluation of top hierarchy is gotten. This method can specify the status and functions of all factors in the general evaluation and adopt all information derived from the factors.

Let  $L$  be the level number of the MFSE model,  $l$  be the counter of level. The integrated level is on the level 0, the sub-goal is on the level 1, and so on. Let  $K_l$  be the factor number of level  $l$ ,  $k$  be the counter of factor number,  $a_k = (a_{k1}, a_{k2}, \dots, a_{kM})$  be the weight

vector of factors under factor  $k$  on level  $l$ ,  $M$  be the factor number under factor  $k$  on level  $l$ ,  $m$  be factor counter under factor  $k$  on level  $l$ ,  $V = (v_1, v_2, \dots, v_n)$  be the set of evaluation,  $b_k$  be the fuzzy evaluation of factor  $k$  on level  $l$ ,  $R_k$  be the fuzzy evaluation matrix composed of fuzzy evaluation of each factor under factor  $k$  on level  $l$ .

The steps of MFSE are as follows.

Step 1:  $l = L - 2$ ;  $k$  from 1 to  $K_l$ , determine  $R_k$  according to  $V$ , then:

$$b_k = a_k \circ R_k = (b_{k1}, b_{k2}, \dots, b_{kn}) \quad (k = 1, 2, \dots, K_l) \quad (10)$$

The synthetic evaluation of level  $l$  is finished and turns to step 2.

Step 2: If  $l = 0$  stop. Otherwise, let  $l = l - 1$  and turn to step 3.

Step 3: Let  $k$  from 1 to  $K_l$ , according to  $b_m = (b_{m1}, b_{m2}, \dots, b_{mn}) \quad (m = 1, 2, \dots, M)$ ,  $R_k$  is given as follows:

$$R_k = \begin{pmatrix} B_1 \\ B_2 \\ \vdots \\ B_M \end{pmatrix} = \begin{pmatrix} b_{11} & b_{12} & \dots & b_{1n} \\ b_{21} & b_{22} & \dots & b_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ b_{M1} & b_{M2} & \dots & b_{Mn} \end{pmatrix} \quad (11)$$

Then, according to equation (10) the synthetic evaluation of level  $l$  is finished, and turns to step 2.

### 3. FUZZY SYNTHETIC EVALUATION MODEL OF RISK FOR VIRTUAL ENTERPRISE

Risk evaluation is performed based on risk identification and risk estimation. Such information can be acquired in risk identification as:

- General Objective and sub-objectives, the contents of which do not overlap;
- Components or operation procedures of the enterprise, the contents of which do not overlap;
- Whether the procedures and the objectives are relevant;
- Every possible risk;

While risk estimation provides:

- Significance of each sub-objective and its weight;
- Importance of relevant procedures or components to the sub-objectives and their weights;
- Risk allocation, e.g., which procedure or component the risks affect, to which objective they are

related;

d) Significance of each risk and its weight;

e) Factor-factor relations within risks and the weights of factors;

f) Fuzzy description of risk factors.

Two factors are determining the significance of a risk: risk probability and risk lost. Criterion of assessment<sup>[3]</sup> is listed as follows for analyzing the two factors (see Table 1 and 2, from which a fuzzy description of risk factors can be derived.

Based on risk identification and estimation, considering the project organization mode and the uncertain characteristics of VE, the fuzzy synthetic evaluation

hierarchical model (FSEHM) of risk evaluation is given in Figure 1. In this FSEHM model, each process of the VE project is considered, as well as the fuzzy description of each risk factor.

In the FSEHM model, there are 5 levels from level 0 (top) to level 4 (bottom). The level 0 is the general object of VE to minimize risk. Table 3 provides the criterion for evaluating general objective. The level 1 is the sub-objectives the VE pursued, which are different for a special VE. The level 2 is the procedures, which are the activities in the VE project. The level 3 are the risk events, which will cause the risk in the procedures for different sub-objective. The level 4 are the risk factor of the risk event. As mentioned above, two risk factors, risk probability and risk loss, are considered for each risk event.

Table 1 Rank criterion for risk probability

Severity	Incidental possibility description	Criterion for evaluation
0	Nil	0%—5%
1	Slight	5%—15%
2	Lower	15%—25%
3	Lower	25%—40%
4	Mediat	40%—60%
5	A bit high	60%—75%
6	High	75%—85%
7	Higher	85%—95%
8	Highest	95%—100%

Table 2 Rank criterion for risk lost

Severity	Lost description	Criterion for Evaluation
0	Nil	No influence on producing system
1	Slight	Slight influence but almost no product demands reproduction.
2	Lower	Producing system influenced, part of products demand reproduction
3	Lower	Producing system is operatable with a deteriorating capacity. Half products demand reproduction.
4	Mediat	Operatable producing system with a sharply-decreasing capacity, majoroty of products demand reproduction
5	A bit high	Producing system operates abnormally, no significant segment paralysed, reparable
6	High	Producing system operates abnormally, significant segment paralysed, reparable
7	Higher	Producing system damaged severely, almost disrepairable
8	Highest	Producing system breaks down, disrepairable and may endanger operator's life

#### 4. CASE STUDY

The example involves the real life problem of an enterprise, which bid for a market opportunity for the manufacturing lamp. The project consists of 5 processes, the precedence relationship represented by the Activity-on-Arc mode is shown in Figure 2. The owner has the ability of design and core manufacturing, while the bulb manufacturing, cap manufacturing, and assembly processes are finished by partner.

The objective of the VE is to minimize the general risk; the sub-objectives are to minimize cost risk, coordination risk, the time risk and the quality risk respectively. The weight of each sub-objective to the subjective is shown in table 4. The weight (W) of each procedure (P) to sub-objective (S) is shown table 5. The risk events are shown in table 6. Their relationship to each procedure under a sub-objective and the weights to the corresponding procedure are show in table 7. The weight of probability and loss to each risk event is shown in Table 6. The fuzzy description of probability and loss for each risk event is show in Table 8.

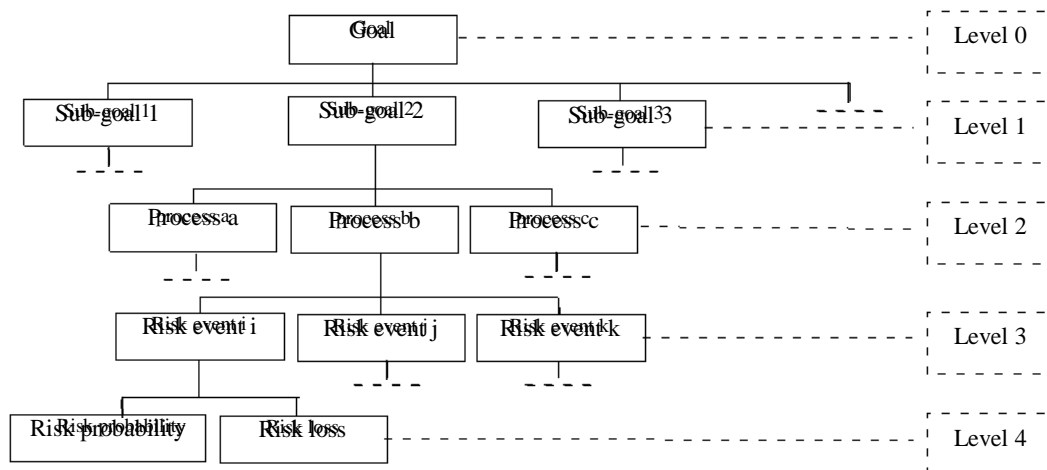

Figure 11 The hierarchical model for risk evaluation

Table 3 Integrated evaluation standard for risk level

Risk level	0	1	2	3	4	5	6	7	8
Description	Nil	Slight	Lower	Low	Mediate	A bit high	High	Higher	Highest

Figure 2 The network for the lamp manufacturing

Table 4 The weight of the sub-goals to the goal

Sub-goal	Cost	Coordination	Time	Quality
Weight	0.3	0.3	0.15	0.25

Table 5 The weight of the processes to the sub-goals

W \ S \ P	Process 1	Process 2	Process 3	Process 4	Process 5
Sub-goal1	0.5	0.3	0.05	0.15	0
Sub-goal2	0.2	0.5	0.1	0.1	0.1
Sub-goal3	0	0.2	0.3	0.3	0.2
Sub-goal4	0	0	0.4	0.6	0

Table 9 shows the result of risk evaluation for the VE. According to the principle of maximum membership and the method of fuzzy synthetic evaluation, the result of integrated risk evaluation is 0.234, indicating a grade 3 risk.

## 5. CONCLUSION

In accordance with project organization mode and the

great uncertainties and information fuzziness of virtual enterprise, a risk evaluation model is established in this paper based on procedures in project network and the theory of fuzzy synthetic evaluation, and the integrated consideration of influences of different factors. Examples have shown its simple, operability and charity for comprehension. The result reflects the integrated risk level effectively.

Table 6 The risk events and probability and loss weight of them

Risk event No.	Risk event	Risk probability	Risk loss
1	Design method	0.4	0.6
2	Designer's level	0.5	0.5
3	Delay of bulb	0.4	0.6
4	Bad rate of core	0.35	0.65
5	Delay of cap	0.5	0.5
6	Communication with partner	0.35	0.65
7	Selection of bulb partner	0.8	0.2
8	Contract award	0.15	0.85
9	Strategy of partner	0.25	0.75
10	Selection of cap partner	0.3	0.7
11	Selection of assembly partner	0.7	0.3
12	The experience of the designer	0.5	0.5
13	The complexity of the product	0.6	0.4
14	Contract management	0.8	0.2
15	The capability of the enterprise	0.3	0.7
16	The experience of the worker	0.7	0.3
17	The capability of assembly partner	0.5	0.5
18	The reputation of bulb partner	0.2	0.8
19	The reputation of cap partner	0.65	0.35
20	The reputation of assembly partner	0.5	0.5

### ABSTRACT

With the rapid development of internet and emerging of global economic, risk management for enterprise under EC (Electronic Commerce) environments has drawn attentions of many researchers. In this paper, the characteristics of risk for EC enterprise are analyzed. Further, focused on the project organization mode and the uncertain factor of the enterprise under EC, which are main different characteristics from the conventional enterprise, enterprise risk sorting, which is one of the key problems of risk management under EC environments, is studied by using fuzzy ISODATA cluster method based on fuzzy describing of risks. Case study suggests the effectiveness of the method.

**Keywords:** electronic commerce, risk management, risk sorting, fuzzy cluster

### 1. INTRODUCTION

As the developing of computer and communication technology and the forming of global market economy, internet-oriented EC (electronic commerce) has become a trend and a must for enterprise operation [1,2], which made enterprise management under EC environments a popular issue among the field of management [3-6]. Since there are more uncertainties and unstable factors in enterprise operation under EC environments, such as the dynamic nature of enterprise alliance in different districts, regions even nations, and the leading function of enterprise development caused by new technology progress, enterprises are facing a larger number of conspicuous risks and enterprise risk management, as a special kind of enterprise management, is becoming more significant.

Risk sorting, one of the fundamental works of risk management, aims at acquiring overall and profound knowledge of all kinds of risks after sorting the existed risks from different point of view and according to different criteria and therefore suggests a well-aimed management. Many researches has done about risk sorting [7], however, most of them are qualitative method [8,9], and the features of enterprise under EC are not considered. In this paper, we focus on the project organization mode and the uncertain factor of the enterprise under EC, which are main difference from the conventional enterprise. In the research risks are sorted by the sub-procedures of enterprise projects under EC environments. With the focus on the uncertain features of enterprise risks under EC environments, a fuzzy risk description mechanism is established and a fuzzy sorting is given to the risks by fuzzy ISODATA [10,11] cluster method, which providing a satisfactory preparation for risk evaluation and control.

### 2. FUZZY RISK DESCRIPTION MECHANISM

The risks to be sorted are denoted by set

$A = \{A_1, A_2, \dots, A_n\}$ , factor set to be considered by  $B = \{B_1, B_2, \dots, B_m\}$ .  $n$  represents the number of risks,  $m$  represents the number of evaluation factors, hence the descriptive vector of each risk  $A_i$  is:

$$X_i = (x_{i1}, x_{i2}, \dots, x_{im}) \quad (1)$$

where,  $x_{ij}$  is the evaluation of  $i$  risk by  $j$  factor.

Then,  $X_{m \times n} = \{X_1, X_2, \dots, X_n\}$  is the factor evaluation matrix.

Let  $C = \{C_1, C_2, \dots, C_c\}$  be the cluster set, which is sub-procedures of the enterprise project.  $c$  is the number of sorting, which is equal to the number of sub-procedures of the enterprise project. Let  $V_{c \times m}$  be a group of cluster central vector, and then  $V_h$  be cluster center for sort  $h$ .

The aim of risk sorting is to get the sorting matrix  $R_{c \times n}$  for common sorting and the fuzzy sorting matrix  $\tilde{R}_{c \times n}$  for fuzzy sorting, where,  $R \in M_c$

$$r_{hj} = \begin{cases} 1 & i \in \text{sort } h \\ 0 & i \notin \text{sort } h \end{cases} \quad (2)$$

And  $\tilde{R} \in M_{fc}$ ,  $M_{fc} = \{\tilde{R} \in V_{c \times n} | r_{hi} \in [0, 1], \forall h, i\}$ ;

$$\sum_{h=1}^c r_{hi} = 1, \forall i; \sum_{i=1}^n r_{hi} > 0, \forall h \quad (3)$$

### 3. FUZZY ISODATA CLUSTER ANALYSIS

Fuzzy ISODATA cluster is a fuzzy sorting method based on fuzzy descriptions [10,11].

The cluster criterion for common sorting aims at minimizing the object function:

$$J(R, V) = \sum_{i=1}^n \sum_{h=1}^c r_{hi} \|x_i - V_h\|^2 \quad (4)$$

where  $\|x_i - V_h\|$  represents the distance between sample  $x_i$  and cluster central vector  $V_h$ .

The sorting is to minimize the object function by determining an appropriate matrix  $R_{c \times n}$  and  $V_{c \times m}$ .

The cluster criterion for fuzzy sorting aims at minimizing the object function:

$$J(R, V) = \sum_{i=1}^n \sum_{h=1}^c (r_{hi})^q \|x_i - V_h\|^2 \quad (5)$$

where  $q$  is a parameter equals or greater than 1. If  $q=1$  and  $r_{hi} \in \{0, 1\}$ , function (5) transforms to a common sorting.

This criterion minimizes the object function by determining an appropriate matrix  $R_{c \times n}$  and  $V_{c \times m}$  group of cluster central vectors.

### 3.1 Fuzzy ISODATA Cluster Steps

1) Data normalization: using standardizing method

$$x'_{ik} = \frac{x_{ik} - \bar{x}_i}{\sigma_i} \quad (6)$$

In equation (6):

$$\bar{x}_i = \frac{1}{m} \sum_{k=1}^m x_{ik}, \sigma_i = \sqrt{\frac{1}{m-1} \sum_{k=1}^m (x_{ik} - \bar{x}_i)^2} \quad (7)$$

2) Determine the number of cluster  $c$ ,  $2 \leq c \leq n$ , and an initial fuzzy sorting matrix  $R^{(0)} \in M_{fc}$ , let  $l=0$ , go to 3).

3) Calculate the cluster central vector for  $R^{(l)}$ :

$$V^0 = (V_1^0, V_2^0, \dots, V_c^0)^T \quad (8)$$

In equation (8):

$$V_h^0 = \frac{\sum_{i=1}^n (r_{hi})^q x_i}{\sum_{i=1}^n (r_{hi})^q} \quad (9)$$

$q$  is a positive number greater than 1. Go to 4).

4) Modify fuzzy sorting matrix  $R^{(0)}$

$$r_{hi}^{(l+1)} = \frac{1}{\sum_{t=1}^c \left( \frac{\|x_i - V_h^0\|}{\|x_i - V_t^0\|} \right)^{\frac{1}{1-q}}}, \quad (\forall h, i) \quad (10)$$

Go to 5).

5) Compare  $R^{(l)}$  and  $R^{(l+1)}$ , if for the given error accuracy  $\varepsilon > 0$  have:

$$\max_i |r_{hi}^{(l+1)} - r_{hi}^{(l)}| \leq \varepsilon \quad (11)$$

$R^{(l+1)}$  and  $V^{(l)}$  are the results wanted. Stop iterating. Otherwise,  $l = l + 1$ , back to 3).

### 3.2 Evaluation of Fuzzy ISODATA Cluster

Sorting Coefficient Index (SCI) can be applied to the evaluation the results of the fuzzy cluster:

$$F_c(R) = \frac{1}{n} \sum_{i=1}^n \sum_{h=1}^c r_{hi}^2 \quad (12)$$

where  $R \in M_{fc}$ ,  $F_c(R) = 1$ .

Hence as  $F_c(R)$  approaches 1, fuzziness of the ultimate sorting decreases, which indicates a better outcome.

## 4. CASE STUDY

### 4.1 Case Description

Let set A, which denotes the risks to be sorted, be:

A = {demand risk, competition risk, overflow risk, market fluctuation risk, economic descent risk, financial risk, environmental risk, policy risk, quality risk, cost risk, time risk, technical risk, communicative risk, technical up-link risk, technical out-leak risk, data quality risk, information system security risk, organization and management risk, credit risk, mobility risk, excitation risk, strategic supply lost risk, investment hold-up risk, investment attainment risk}

It can be seen that  $n=24$ . Two situations are considered here, the number of sorting and factors for them are respectively:

$c_1 = 11, m = 40$  and  $c_2 = 17, m = 45$ .

### 4.2 Simulation Analysis

Two methods have been tried out here:

Method 1: Cluster on the basis of given initiative fuzzy sorting matrix  $R^{(0)}$ .

Method 2: Cluster on the basis of given fuzzy cluster unstable influence on cluster outcome. Therefore, the central vector  $V^{(0)}$ .

Number of sorting  $c$ , the initiative fuzzy sorting matrix  $R^{(0)}$ , error accuracy  $\epsilon$  and parameter  $q$  might affect the cluster results. So, the analyses of them are given in the following subsection.

#### (1) Influences of Different Methods on Cluster

Let error accuracy  $\epsilon = 0.00001$ , parameter  $q = 1.45$ . The clusters of the two methods are compared in Table1.

As in Table 1, method 1 shows a superior outcome to method 2 because it takes relative constraints into consideration when choosing the initiative fuzzy sorting matrix.

Table 1 Comparison of the two methods		
SCI	Method	
	No. of sorting	
		Method 1      Method 2
$c_1 = 11$		0.601126      0.243985
$c_2 = 17$		0.780527      0.101113

#### (2) Influences of Different Initiative Fuzzy Sorting Matrix on Cluster

Figure 1 shows the graphs of the SCI against evaluation of initiative sorting matrix (error accuracy  $\epsilon = 0.00001$ , parameter  $q = 1.45$ ).

In Figure 1, initiative sorting matrix shows a very

actual risks and their characteristics should be given major consideration when determine the initial fuzzy sorting matrix.

#### (3) Influence of Different Error Accuracy on Cluster

Figure 2 shows the curves of cluster outcome against error accuracy  $\epsilon$  (parameter  $q = 1.45$ ).

Figure 2 indicates that an error accuracy  $\epsilon$  of 0.01 or less than 0.01 leads to a satisfactory outcome. This complies with that rule that cluster outcome improves as the error accuracy increases while deteriorates as it decreases.

#### (4) Influence of Different Parameter $q$ on Cluster

The curves of cluster outcome against parameter  $q$  are represented by Figure 3.

It can be concluded from Figure 3 that an increasing parameter  $q$  deteriorates the cluster. The fuzziness of sorting becomes smaller as parameter  $q$  gets closer to 1. When  $q$  equals 1 the sorting becomes a solid sorting. When  $q$  increases the sorting becomes fuzzier, which leads to a less definite implication.  $q = 1.45$  is chosen according to the actual situation.

The analysis above also indicates that the numbers of sorting does not show an obvious influence on cluster outcome. Nevertheless, more operational time of the procedure is needed as it increases: when  $c = 11$ , the operational time is 3 seconds; when  $c = 17$ , it is 4 seconds.

(a)  $c=11$

(b)  $c=17$

Figure 1 Curves of cluster outcome against initiative sorting matrix

Figure 2 Curves of cluster outcome against error accuracy

Figure 3 Curves of cluster outcome against parameter

#### (5) Sorting Outcomes

According to the analysis from (1) to (4), the ultimate sorting outcomes are listed in Table 2 when the number of sorting  $c = 11$ , error accuracy  $\varepsilon = 0.00001$ , parameter  $q = 1.45$ , evaluation of estimate of initiative sorting matrix is 0.386458.

It can also be seen in Table 2 that the sorting matrix meets the 3 requirements of fuzzy space division  $M_{fc}$  throughout the iteration because the sample initiative sorting matrix has been normalized. It shows:

$$r_{hi} \in [0, 1], \forall h, i; \sum_{h=1}^c r_{hi} = 1, \forall i; \sum_{i=1}^n r_{hi} > 0, \forall h$$

Hence the model is proved correct and the sorting result complies with objective facts as in Table 2.

#### 5. CONCLUSION

In this research enterprise risk sorting – the key issue of enterprise risk management under EC environment – has been studied focus on the project organization mode and

uncertain factors of the enterprise under EC. A fuzzy description system to enterprise risk is established firstly in accordance with the uncertain features of enterprise risk under EC environments then enterprises risk sorted based on the method of fuzzy ISODATA cluster considering the project sub-procedures is present. The case study involved has analyzed influences of parameters on cluster outcomes, which proves the effectiveness of the method and its significant guidance for enterprise risk management.

## ABSTRACT

This paper has built a product model by UML and corresponding Product Schema. Then we have illuminated transmit mechanism of the product information by a dumbbell XML document. At last, we have pointed out the direction of the research. This research will provide a significative explore to the product data interchange between the members of virtual manufacturing enterprise in e-commerce environment.

**Keywords:** E-commerce, Product model, UML, XML

## 1. INTRODUCTION

Along with the rapid development of network technology, the e-commerce technology becomes increasingly ripe. The importance of the e-commerce has been recognized more and more and this kind of trade form has been accepted. Virtual manufacturing enterprise as the important user of e-commerce, comparing with the traditional manufacturing enterprise, has many merits such as sharing infrastructure, outstanding manpower, advanced technology resources, sharing the market risk and researching development cost, sharing market and customer etc. The product data exchange certainly must be carried among the members of virtual manufacturing enterprises in order to share product information. In collaborative design, the visualization technology is one of tools to realize the product data exchange, and can realize the some functions, such as the CAD's documents browsing, marking, reading etc.

At present, many visualization systems (Such as the wiseVIEW of SAMSUNG(SAMSUNG, 2004), the VOLO VIEW EXPRESS of AUTODESK (AUTODESK, 2003), The Browsing Tools of Tsinghua Ying Tai(Ying Tai,2004) etc.) all exist a common question to browse CAD's documents, which is that the documents can be opened by using the corresponding tool only when the documents must have been completely transmitted during document delivery. The more complicated the product increasingly become, the more corresponding huge the product data are also, once completely download will fairly cost time. Sometimes, we needn't to see whole details. When one small part of details of product has been modified, the whole product graphical documents needs to be transmitted again. So the limited network resource is wasted seriously.

## 2. PRODUCT MODEL WITH UML

Product has many features, such as geometry feature, material feature, manufacturing feature, assembly

feature, etc. The each feature has a corresponding class. This paper has built a product model with UML. This model has represented the detailed model structure, especially the geometry feature of product. Shown as the figure 1, the product class is the highest rank class in the model, has its own Product\_ID attribute and Product\_Name attribute. The material class, geometry class, manufacturing class and assembly class are the subclasses of product class. The product geometry feature is core feature and other features, it is very important to comprehensively and felicitously represent the product geometry feature..

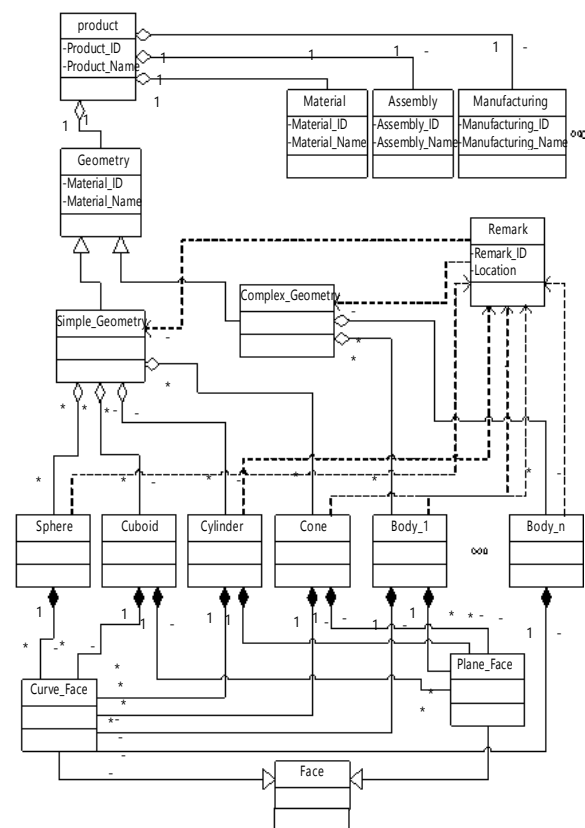

Fig.1 The Product Model

### 3. THE REPRESENTATION OF PRODUCT DOCUMENT WITH THE SCHEMA OF XML

Extensible Markup Language (XML) is a simple, very flexible text format derived from SGML. Originally designed to meet the challenges of large-scale electronic publishing, XML is also playing an increasingly important role in the exchange of a wide variety of data on the Web and elsewhere. XML has many merits, such as extendability, simpleness and ripeness. So this paper has put forward to a modeling method of the product graphical information based on XML to the virtual enterprises in the e-commerce environment.

Shown as the figure3, according to the Schema of XML(Schema,2003), the paper has described a product data model, including product geometry information and its remark information. Owing to the characteristic of XML itself, this model possesses very strong extensibility and still can add other product information except mentioned above the geometry information and the remark information, like the material information, the assembly information, the process information and manufacturing information etc.

Fig.2 The Product Schema

#### 4. THE EXCHANGE OF PRODUCT INFORMATION

XFI(XFI,2002) allows the exchange of specific information of interest without sending complete XML documents. The most important merit of XFI is to reduce the quantity of communication data and save cost of communication. According to the product Schema having been created in the second paragraph, we have built a simple dumbbell example to show the application of XFI in the data transmission. Then, we have defined the mechanism to create and transmit the product graphical documents and their attached remark. The Figure.3 is a example of a product XML document to describe a dumbbell.

```

<?xml version="1.0" encoding="utf-8"?>

<product_model
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://localhost:8080
Product.xsd" xmlns="http://localhost:8080/Product.xsd"
product_ID="P00001">
  <Geometry>
    <Simple_Geometry ID="S00001">
      <Sphere ID="Sp00001">
        <Sphere_center>
          <x>0</x>
          <y>0</y>
          <z>0</z>
        </Sphere_center>
        <Radius>1.0</Radius>
        <Color>red</Color>
      </Sphere>
      <Sphere ID="Sp00002">
        <Sphere_center>
          <x>4.0</x>
          <y>0.0</y>
          <z>0.0</z>
        </Sphere_center>
        <Radius>1.0</Radius>
        <Color>blue</Color>
      </Sphere>
      <Cylinder ID="C00001">
        <Cylinder_bottom_center>
          <x>0.0</x>
          <y>0.0</y>
          <z>0.0</z>
        </Cylinder_bottom_center>
        <Radius>1.0</Radius>
        <High>4.0</High>
        <Color>black</Color>
      </Cylinder>
    </Simple_Geometry>

```

```

    <Complex_Geometry/>
  </Geometry>
  <Remark remark_ID="R00001">
    <Title>Geometry Remark</Title>
    <Content>the radius is too thick!</Content>
    <Location>
      <x>2.0</x>
      <y>2.0</y>
      <z>2.0</z>
    </Location>

    <Correlative_entity_ID>P00001</Correlative_entity_ID>
  </Remark>
</product_model>

```

Fig.3 The dumbbell XML document according to the Product Schema

#### 4.1 The validity of the fragment in a product XML document

The fragment in a product XML document is a general term to refer to part of an XML document, plus possibly some extra information, that may be useful to use and interchange in the absence of the rest of the XML document. We can appoint the context information of a product graph documents fragment by transmitting the part information rather than the whole product graph documents. So we can achieve the aim to reduce the data transmission quantity.

A valid product XML fragment has a continuous test block according to XML specifications. The figure 4 shows some valid fragments.

- a. 0.5
- b. <Radius>0.5</Radius>
- c. <Content>the radius is too thick!</Content>
- d. <Location>
 <x>2.0</x>
 <y>2.0</y>
 <z>2.0</z>
 </Location>

Fig.4 Some valid product XML fragments

#### 4.2 The transmit mechanism of the product XML fragment

By the most important merit of XFI, we can build a mechanism to realize the aims to reduce the quantity of communication data .

For example, we want to change the radius of the dumbbell' handle , we shouldn't need to transmit whole

dumbbell model data before getting to the part of interest. The goal of this paragraph is to define a way to enable processing of small parts of an product XML document without having to process everything up to the part in question. This can be done regardless of whether the parts are entities or not, and the parts can either be viewed immediately or accumulated for later use, assembly, or other processing.

The following content is the XML fragment document with the right fragment about the change of the dumbbell handle' radius.

```
<Radius>0.5</Radius>
```

And its context following shows as the figure 5:

```

<?xml version="1.0" encoding="UTF-8"?>
<f:fcs
xmlns:f="http://www.w3.org/2001/XML-fragment"
paraentref="http://localhost:8080/Product.xml"/>
<product_model>
  <Geometry>
    <Simple_Geometry>
      <Cylinder>
        <f:fragbody
fragbodyref="http://localhost:8080/dumbbell_radius.xml"/>
      </Cylinder>
    </Simple_Geometry>
  </Geometry>
</product_model>

```

Fig.5 The context of XML fragment about the radius of the dumbbell' handle

The context is information to describe the location of the original document fragment. The context include the URL of the original document, the father information of the fragment body, etc. For transmit the fragment information, we can transmit the fragment document and its context to the receiver. The receiver can insert the fragment to the correct location in the original document by the context. In this way, we have realized the transmit mechanism of the product XML fragment.

## 5. CONCLUSIONS AND FURTHER WORK

This paper has built a product model by UML and corresponding Product Schema. Then we have illuminated transmit mechanism of the product information by a dumbbell XML document. To realize the visualization mechanism, we want to use the Java3D technology. Java3D is a low level 3D scene-graph based graphics programming API for the java language.

Each of the members of virtual manufacturing enterprises in e-commerce can change CAD's documents of oneself into the product graphical document that this paper has built, and show the product graphical document by using the corresponding browsing tool, then achieve the purpose of low cost information sharing owing to the open character of XML. This research will provide a significative explore to the product data interchange between the members of virtual manufacturing enterprise in e-commerce environment.

### ABSTRACT

Risk management is important to the development of enterprise as well as social-economic prosperity. Virtual enterprise is the potential mode of future enterprise under electronic commerce environment and the risk management for it is a popular research area recently. Due to the complexity of its risk management a decision support system (DSS) with 3-bases-1-cell structure was designed. By coordinating data base, model base, algorithm base and dialogue cell, the functions of project management, risk identification, risk assessment, risk evaluation and risk programming was supported. The user-friendly system has such main characteristics as generality for verity virtual enterprise as well as different projects and the flexibility of model and algorithm, ensuring a standardized, scientific and informational risk management for virtual enterprises.

**Keywords:** virtual enterprise, risk management, decision support system, electronic commerce

### 1. INTRODUCTION

The subject of risk management has a history dating back to the 1950s. In the 70s it rapidly developed theoretically and practically and prevailed among developed countries [1-4]. With the formation of globalized market economy and emerging of electronic commerce, Virtual Enterprise (VE) has become a potential mode of enterprise development. Such a complicated environment requires effective production management as well as a complete and practical Decision Support System (DSS) for risk management to assist decision makers in making objective and correct decision.

Risk management is significant to the development of enterprise as well as social-economic prosperity. It is generally defined as an enterprise management which includes identification and assessment of every potential risk, as well as proper manipulation and solution, aiming at ensuring a safe enterprise operation with the lowest risk cost [5,6]. Trouble-free risk management relies on scientific strategies and its process consists of risk identification, risk assessment and risk evaluation sequentially and response-measure programming based on the first 3 steps so as to carry out effective risk manipulation and solution to unfavorable consequences. VEs are temporal virtual organizations for grasping some newly occurred opportunity [7,8]. It is always organized by project mode. The projects are different from each other for different VE. So, the risk management should be different accordingly. DSS of VE provides a functional support to risk identification, risk assessment, risk evaluation and risk programming for different projects in order to ensure a safe and effective operation for enterprises.

### 2. LOGICAL DESIGN FOR SYSTEMATIC STRUCTURE

Characteristically, project risk models differ when VEs are facing different opportunities, which require a flexible risk-describing function of the system. Similarly, the complexity of problems in a projects calls for flexible algorithmic solutions. Based on such requirements, a 3-base-1-cell logical structure [9] is established (see Figure 1), which consists a database, a model base, a algorithm base and a dialogue cell.

The logical structure of the system effectively carries out the 4 operational functions (risk identification, risk assessment, risk evaluation and risk programming) by constructing an operational environment of DSS for VE in the dialogue system on the informative basis of the 3 bases (database, model base and algorithm base) with the assistance of friendly man-machine interface and dialogues.

#### (1) Dialogue System

This is the component that users work with directly, the general frame of which is constructed according to the basic flow process of risk management. From a user's point of view, the frame presents itself as a master-control menu.

#### (2) Model Base

##### 1) Requirements of VE DSS to model base

Risk evaluation model is a multi-level synthetic evaluation model with a dendritic structure (see Figure 2).

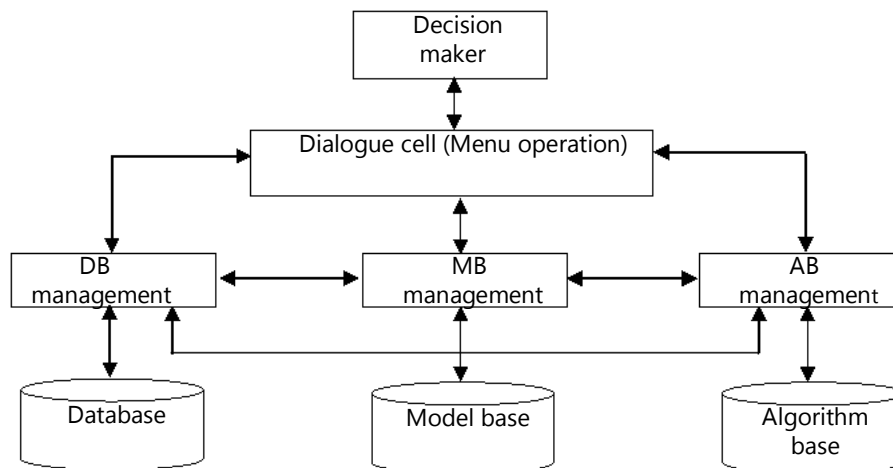

Figure1 The logic structure chart of the system

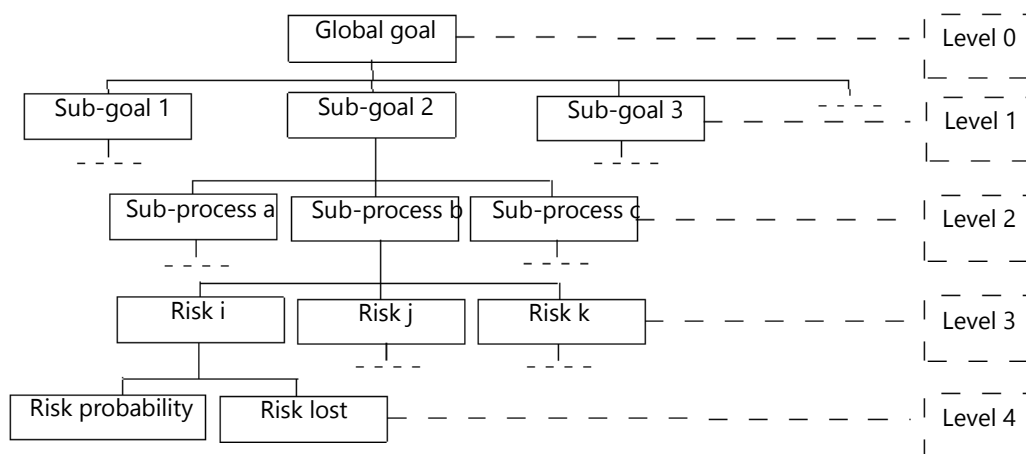

Figure 2 The hierarchic model for risk evaluation

When applied to risk management of different VE, the avoid the inconvenience of repetitive maintenances. model has the same levels but different numbers of node. Therefore a versatile structure of database is established according to the characteristics of the system. Consequently, managing system of model base should be able to establish a special model according to specific requirements of a project, which can be realized by achieving the followings:

#### ÅSeparating model from algorithm

Model must be separated from algorithm; otherwise the source program has to be modified so as to make algorithm adaptive to a changed model, which is impossible for the operators to do by themselves.

#### ÇAutomatic model generation

Unlike some DSS, system programmers cannot store some fixed models of DSS for VE in computers because the structure of the model is determined by a specific VE. Hence, it is necessary to build up a versatile system to assist users in establishing and storing a model structure according to his business.

#### ÉDatabase structure with adaptability to all models

Such a database structure should be established so as to modify itself, complying with a changing model base and

#### 2) Model base design

In this part, the core is how to store a model structure in computers. This research expresses the structure in a 3-level frame, which combines frame-knowledge and characteristics of database system and fully presents the external and internal features of the model, presenting a simple and straightforward visual illustration and proving the easiness of establishment.

In Frame level 1 store the model name, date of establishment and referential information etc., which are all external characteristics of the model.

Frame level 2 describes the internal characteristics of the model, mainly including the number of levels and nodes. Since 5 fixed levels are stored in the system, the number of nodes determines the main feature. The content consists of the name of model, level names, and the number of nodes in each level, etc.

Frame level 3 presents the physical mode of the model evaluation and risk programming. The foreign-key which describes and stores the physical data of the model. reference relations are shown in Figure 3.

Different model has different internal physical mode. Based on the characteristic that the synthetic evaluation reflects on each nodal point in this level, its content includes model name, level name, node name and the weight of the node etc.

### (3) Database

Database is an important component of DSS. In this system, 9 tables are designed based on the data of risk

### (4) Algorithm Base

This system provides the risk-programming model with two methods: genetic algorithm and Tabu search, which are stored in database system for users' options. Further the new algorithm can be added, and the exist algorithm can be deleted and modified by user according to practical needs, providing flexibility in algorithms.

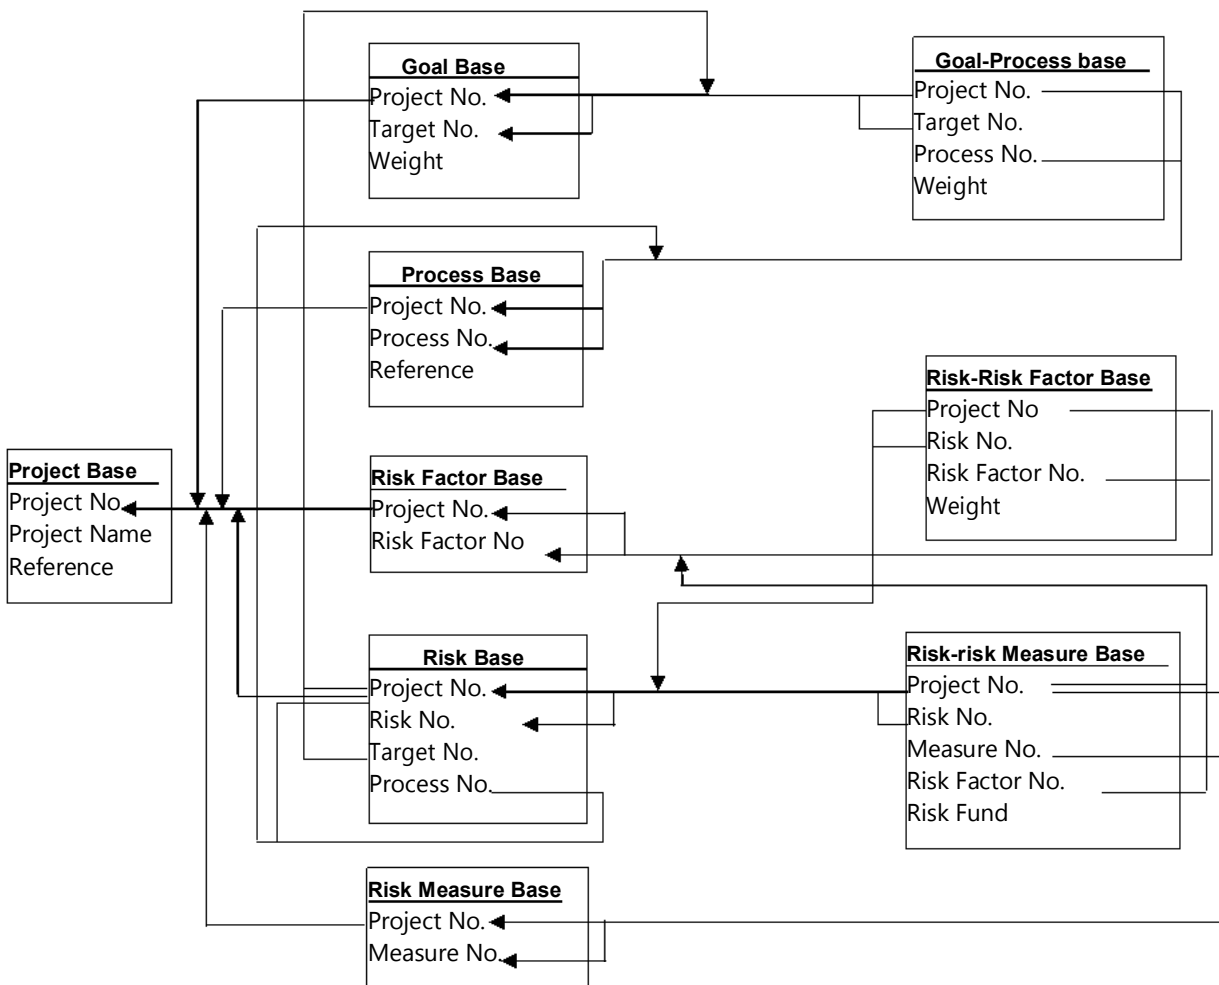

Figure 3 Relationship chart of foreign key

### 3. SYSTEM-FUNCTIONAL MODULES

In accordance with the demands of VE risk management, this decision support system can be functionally divided into 5 parts as follows:

(1) Project Management is an all-project-oriented management of VE, providing such projective functions as building, opening and deleting projects.

(2) Risk Identification is the first step of risk management. According to risk evaluation model, the managed content of this stage is the global goal, sub-goal, sub-processes, risks, risk localization, risk manipulation method etc. It also provides inputting, searching, sorting, inserting, modifying and saving functions for the data. This function corresponds with the establishment of frame level 1 and 2.

(3) Risk Assessment is a process in which the identified

risks are quantitatively estimated, including sub-goal weight assessment, sub-goal and sub-process relevant level assessment, relevant risk weight assessment, risk factor weight assessment and fuzzy description to pre-manipulation and after-manipulation risk factors. The module also provides inputting, searching, sorting, modifying and saving functions for the data. This function corresponds with the establishment of frame level 3.

- (4) Risk Evaluation calculates the general risk level according to risk evaluation model (Figure 2), where the risk evaluation is dealt from local (lowest level) to global system (level 0).
- (5) Risk Programming provides the optimized risk-manipulating strategies according to programming model. Such function is especially applied to algorithm base management and algorithmic operation.

#### 4. CONCLUSION

In this research, decision support system for VE under electronic commerce is designed. This user-friendly system has such main characteristics as generality for verity VE as well as different projects and the flexibility of model and algorithm. The system driven by general strategic goal of enterprise, assist the decision maker in establishing a standardized, scientific and informational risk management in an electronic commerce environment full of internal and external uncertainties.

# Virtual Manufacturing and Virtual Spaces

Mélissa Saadoun

INEDIT Institute, 24 rue du Panorama - 95800 Cergy St-Christophe, France  
msaadoun@aol.com

## ABSTRACT

This article presents news problems linked to the increasing use of **virtual spaces** in the building of new types of manufacturing what is currently called **Virtual Manufacturing (VM)**. VM has many consequences in the activity of industrial companies whatever be size, economic sector or geographical area. Particular attention is paid on virtual spaces, manufacturing and collaboration, skills matrix and manufacturability, the CAD and Virtual Prototyping case and, finally, the virtual partnerships or enterprise as a new type of organization.

**Keywords:** Virtual Enterprise, Virtual Manufacturing, Virtual Partnership, Virtual Prototyping, Virtual Space.

## 1. INTRODUCTION

Virtual Manufacturing (VM) can be defined as an integrated, synthetic manufacturing environment exercised to enhance all levels of decision and control. The vision of VM is to provide a capability to «Manufacture in the Computer». That means, VM will provide a modeling and simulation environment so powerful that the fabrication/assembly of any product, including the associated manufacturing processes, can be simulated in the computer.

It is then a manufacturing within a computer supported on the network, having a strong links with real or physical world of manufacturing (See Figure 1).

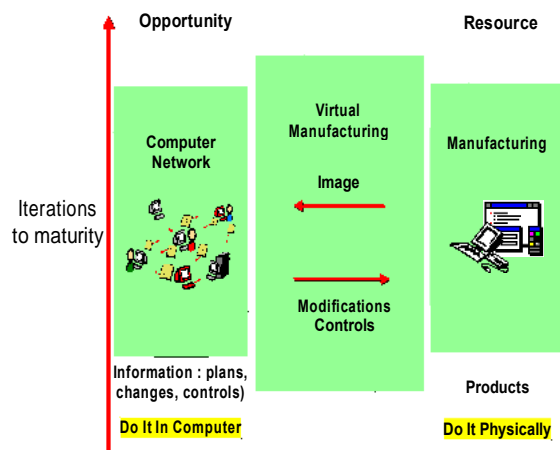

Fig.1. Virtual Manufacturing Vision

The main significant (semantics) of this definition are:

- *Synthetic or virtual working space*, mixing real and simulated objects, activities and environments of processes which supports the construction and use of distributed manufacturing simulations by synergistically providing a collection of analysis tools, simulation tools, implementation tools, control tools, models (product, process and resource), equipment, methodologies and organizational principles (culture) exercising, constructing and executing specific manufacturing

simulations using the environment.

- *Enhance*: increase the value, accuracy, validity levels: from product concept to disposal, from the shop floor to the executive suite, from factory equipment to the enterprise and beyond, from material transformation to knowledge transformation decision: understand the impact of change (visualize, organize, identify alternatives).
- *Control*: predictions effect actuality.

## 2. IMPACTS OF VM AND NEEDS

VM affect the all industrial company activities starting from the manner in which market signal are taken into account, its relations with customers and providers until its internal reorganization or reconfiguration. In particular here are concerned the impact on the company memory, capital investment, design of production; cost estimation, risk management, client interfaces, functionality interfaces, workshop. The needs for VM are:

- Technology and development for models and simulations.
- Virtual infrastructures.
- Tools for working in the virtual spaces such as, the CAD kernel.

The scope of VM ranges from workshop to company areas. To set up a theoretical approach of this phenomenon, we propose two cases : CAD and virtual prototyping. Both will evolve more in the area of the future workshop define under this : from the «virtualisation of the real to the realization of the virtual», characterizing the new productive reality.

## 3. SHARED SPACES AND COLLABORATION

One of the main problems with classical forms of collaboration: they are not able to capture the knowledge generated during the collaboration process. In reality, most of the collaboration process are ad-hoc process addressed to search solutions to different emerging problems but without an infrastructure that support this process. In that case the available knowledge, generated by collaborations, is used only one time and, probably,

lost for ever [1].

We must create simple models to capture this knowledge and avoid dissipating the expertise created by collaboration [2]. Collaboration is essentially based on knowledge interaction between complementary expertise, but for becoming reality there should be a common understanding allowing creating new concepts. One of these new concepts is that of the virtual spaces. Virtual spaces have a particular nature in which problems such as communication coordination or synchronisation are among the most relevant [3].

The distributed and shared infrastructure is composed of virtual spaces constituted of virtual reality models that could be manipulated by complementary expertise's of trading partners. Those virtual creations and manipulations by multidisciplinary teams enable people to reach a common understanding and to elaborate shared concepts in a better and faster way than any long discussion during meetings. Virtual spaces shared by disciplines provide a collective sense of identity and fundamental purpose as requested by the knowledge-creating company. One practical problem is to identify the rationale of any interaction need and interdependencies between entities manipulated by complementary disciplines and, to be able to manage the consistency of generated constraints. The virtual project office example of virtual shared space will be demonstrated in the, where several industrial trading partners forming a consortium will use the virtual project office as a distributed infrastructure (see Figure 2).

**Fig.2. Example of virtual shared space : the virtual project office (Source EPICE ESPRIT project)**

Expected virtual project office services to be distributed to the trading partners include the following:

- Work breakdown structure (WBS) and organization breakdown structure (OBS) management on the Web.
- Workflow management and tasks coordination.
- Requirements and constraints consistency management.
- Project progress monitoring.
- Configuration and data management.

#### 4. VM INFORMATION BY INTERNET: THE CASE OF CAD DATA

HTML documents can be useful to send some kind VM information, transmitting design and manufacturability data to Web navigators from remote sites. Examples of this include STEP files, CAD models and textual data such as results of design or fabricability or information based on manufacturing catalog. One limit to a fluent data transmission is the large bandwidth at a given moment. For example, if we want to have a view of CAD image with a Web navigator, we need several minutes of transmission and interpretation. So the interactive operations (such as rotation of one CAD model) become impossible in a real time.

For some types of VM data, it is possible to get a larger bandwidth for transmitting data as bitmapped images but using VRML (Virtual Reality Modeling Language). One other solution of the congestion problem is to transmit only the specific code for programs to be executed in local sites. Any code must be involved but it is better to use a code written in a specific language for that purposes such as HotJava or Telescript. They are written for exchanging software components over the network. At the arrival site, it run programs and enable users to interact each other. Using these generic tools, one can compose interactive programs containing several types of documents. The navigator HotJava permit to interact dynamically without congesting the network with additionnal traffic. To do it, HotJava adds a new type of markup, the HTML APP, where APP means «applet», a program wrote in Java language and running using HotJava which can link dynamically a Java code from the host and execute on the local machine.

Linked to these tools, there are the development environments of applications. These tools are used to build packaged software modules «add on» which will be coupled with other tools. In CAD soft market, examples include Pro/Develop from Pro/Engineer, GRIP from EDS/Unigraphics, the Development Language (MDL) of Bentley Systems. They can be used to create software modules of network to share, execute or buy on the network starting from a simple CAD environment.

On the implementation side (Figure 3), the Internet and Web-related technologies are used through Intranet (Internet tools used on an enterprise private network) and Extranet (Internet tools used on a trading partners private network). Otherwise, encryption systems and large bandwidth on the Internet must allow trading partners to avoid the use of a costly private network. The security aspect should not be underestimated as it was rated as the second greatest challenge in implementing collaboration between trading partners.

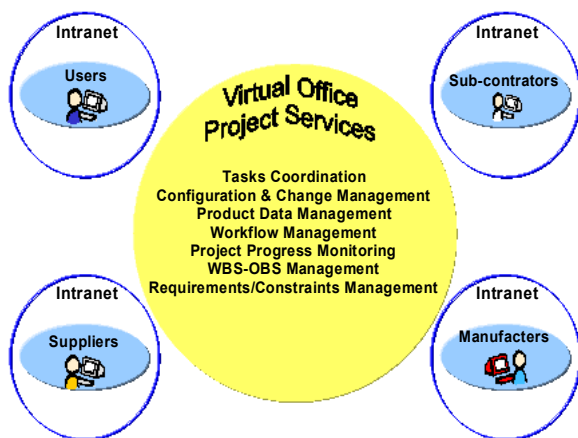

Fig.3. Example of a virtual shared space implementation

### 5. VM: THE CASE OF VIRTUAL PROTOTYPING

Virtual prototyping models offer an entirely new perspective in particular for the Internet trading partners and provide a strong sense of reality and the means to test the model of a product through meaningful interaction. All-digital prototypes resemble their physical counterparts as closely as possible in terms of visual three-dimensional images, behavioral, haptic, and auditory characteristics.

An Internet virtual salesroom concept is needed to be based on a virtual three-dimensional photo realistic salesroom environment featuring a selection of virtual product models (Figure 4). A particular enabling technology, virtual prototyping, in the context of consumer electronics and telecommunications industries is addressed (in Nokia case). Virtual prototyping is the application of advanced modeling and simulation techniques, user interface techniques and virtual reality techniques to support electronic commerce for customers and also business-to-business electronic commerce in the value chain that is product design, manufacturing, and sales [4].

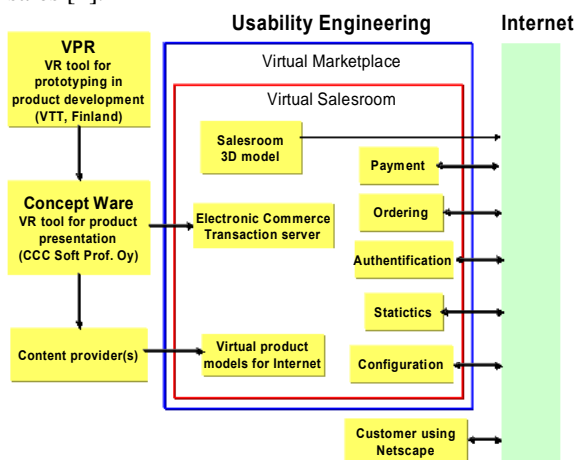

Fig.4. the proposed concept for Internet electronic commerce utilizing digital virtual product models in marketing and sales

Virtual prototyping means the process of using virtual prototypes instead of or in combination with physical prototypes, for innovating, testing and evaluating of specific characteristics of a candidate design. The following aspects are dominant:

- Functionality, created virtually, clearly defined and realistically simulated (for example product functionality and dynamic behavior).
- Human Interaction: the human functions involved must be realistically simulated, or the human must be included in the simulation (that is real-time operator-in-the-loop simulation).
- Environment: an off-line (non-real-time) computer simulation of the functions can be carried out, or a combination of computer (non-real-time) and hardware-in-the-loop (real-time) simulation can be carried out.

In virtual prototyping, a virtual world comprises both the VR model of a product under development (that is virtual prototype), and the model of the product's target environment, called virtual target environment [5]. Virtual worlds, the VR models, are highly advanced human-computer interfaces based on virtual reality techniques, providing a strong intuitive sense of reality and the means to change the world through meaningful interaction. Virtual worlds may include various levels of reality, thus enabling us to concentrate on any desired aspects of the product.

The most elementary interaction interfaces can be a keyboard and a mouse with a conventional window-based two-dimensional user interface. A more sophisticated virtual prototyping environment with a 3D user interface may include, for example a head mounted display, a 3D position and orientation tracking device, and auditory and haptic feedback devices. The type of representation in a virtual prototyping environment may be spatial,  $n$ -dimensional with abstract information spaces, or various combinations of video, natural and computer-generated images. During the development process, a virtual world can be seen as a model that best matches reality.

A necessary aspect of the full exploitation of the results of virtual prototyping is the requirement for the communication of the results to the interested parties. These may include persons taking part in actual product development - digital signal processing designers, software and hardware designers, and mechanical designers - or people involved in the sales and marketing of the product - marketing and sales representatives, wholesale and retail representatives, and of course customers. Quite often these persons may be quite widely geographically distributed, so solutions based on utilizing communication networks are needed.

The Internet is a viable medium for communicating of the results of virtual prototyping to parties in distributed concurrent product development. Enterprise benefits arise from the potential of the Web as a distribution channel, a

medium for marketing communications, and a market in and of itself [6]. Customer benefits arise primarily from the structural characteristics of the medium and include availability of information, provision of search mechanisms, and on-line product trial, all of which can lead to reduced uncertainty in the purchase decision. It is especially the last one where virtual prototyping would seem a superior technology.

An opportunity arises when the offering is differentiated by elements such as convenience through direct electronic distribution of software, or enjoyment through a visually appealing and exciting Web site. A visually appealing photorealistic operational virtual 3D prototype of a product would certainly fall in the same category. As evidence that this kind of behavior is already happening on the Web, consumers indicated that price was the least important product attribute when making on-line purchases [7].

## 6. MANUFACTURABILITY AND MATRIX OF COMPETENCIES

Industrial companies must have a virtual presentation of its kernel competencies using, for example, appropriated Internet servers as brokers of these competencies. Each company has their own competency portfolio, develop and enrich it continuously, and supplying then virtually. At this point, Manufacturability Analysis is an essential step in defining VM. This is a measure of the effort required to manufacture the part according to the design specifications (estimate the manufacturing time and cost). Given a computerized representation of the design (i.e. a solid model) and a set of manufacturing resources, the automated manufacturability analysis problem can be defined as follows: Determine whether or not the design attributes (e.g., shape, dimensions, tolerances, surface finishes) can be achieved. Two alternatives appears:

- The design is found to be manufacturable, then determine a manufacturability rating, to reflect the ease (or difficulty) with which the design can be manufactured.
- The design is not manufacturable, then identify the design attributes that pose manufacturability problems.

A VM tool, operating across the Internet, systematically generates redesign suggestions to improve the manufacturability of product designs while still satisfying the design's functional requirements. Linked to the Manufacturability Analysis, there is a Manufacturing Resource Matrix. In this case the system uses a tool for identification of potential participants for supplying manufacturing parts of virtual enterprise. It identifies industrial who are able to manufacture automatically a part and have the corresponding capacity to do it. Finally, we have the Parts Characterization Matrix, an other VM tools, which must operate automatically across the distributed manufacturing network.

## 7. VIRTUAL PARTNERSHIPS & ENTERPRISES

VM as a powerful capability would take into account all of the variables in the production environment from shop floor processes to enterprise transactions. In other words, VM will accommodate the visualization of interacting production processes, process planning, scheduling, assembly planning, logistics from the line to the enterprise, and related impacting processes such as accounting, purchasing and management.

VM is linked to the Virtual Prototyping, the Virtual CAD and Virtual CAM made most of the time by simulation [8]. But these technical solutions need to be completed by a special attention on people working on. The first problem here is the building of the appropriated engineering teams. The second problem is that of the building of virtual partnerships forming Virtual Enterprises (VE). In both cases the manufacturability and skill matrix are the essential constituents. The constitution of VE, for example, needs an electronic presentation and qualification partners. Here's intervene virtual spaces because all this process exists only in that space.

**Fig.5. VM related notions**

But an other double challenge is appearing: to use some techniques of virtual reality to build, evaluate and test VE, and to combine it with the ad hoc techniques developed within the framework of VE building such as, for example, the VE algebras that we can produce according to every project. We think VE exist only by project [3]. New research problems emerges, one of them being that considering communities as a virtual reality entities. The separated fields must be then integrated, creating a virtual lifecycle. *Figure 5* illustrates de relations between all these notions.

## PERSPECTIVES

In the short term, the most promising fields for applying VM by Internet can fill the next criteria: to be operational on Internet, every user interaction with a remote server must respect this rule: do not use the tool frequently and

do not need of a large bandwidth. It is better to have a tool serving a large group of users because this eliminate the need for doing copies of tools to the local site users. Having this criteria in mind, we can propose as potential candidate for VM by Internet the data CAD translation, the distributed manufacturing and the design of production systems. Starting from these cases, we can build different levels of scenarios for using VM techniques by Internet.

### ABSTRACT

The Application Service Provider (ASP) model is a widely adopted business model for communities of buyers and sellers to conduct commerce over the Internet in a virtually integrated environment. However, there are limitations imposed by the ASP model. This paper discusses how an alternative combination of peer-to-peer and web services technologies can provide a suitable, low-cost IT infrastructure that could potentially overcome these limitations and enable trading partners in a community to achieve virtual integration. Such an alternative infrastructure would allow trading partners to improve upon their resource utilisation for IT and, instead, focus on their core businesses, discover new business opportunities and form new partnerships dynamically as and when needed, in a loosely-coupled manner.

**Keywords:** collaborative commerce, distributed trusted network community, peer-to-peer, virtual integration, web services.

### 1. INTRODUCTION

The current economy faces two key challenges, namely the market challenges and catching up with the rapid advancement of information and communication technologies (ICT). The market challenges are attributed to factors such as the shift from a PUSH<sup>1</sup> to a PULL<sup>2</sup> economy, shorter time-to-market, erosion of product loyalty, internationalisation and globalisation, and decentralisation of manufacturing activities [2][3][4]. The other great challenge relates to making sense of rapidly evolving ICT, attributed to the fusion of computer and communication technologies, the advent of the Internet and the wide adoption of open and de-facto standards, such as XML, Java™, TCP/IP and HTTP.

Due to these challenges, businesses from various industry sectors have gradually migrated away from their traditional way of conducting business such as the use of the telephone, fax machine, and postal mail, to conducting their transactions over the Internet. For instance, trading partners in the high-tech manufacturing industries are moving away from the rigid, heavyweight, and tightly-coupled EDI interfaces to the XML-based RosettaNet® [10] business-to-business (B2B) standard, to conduct e-business over the Internet.

### 2. THE RISE OF THE NEW DIGITAL ECONOMY

Technology has revolutionised the way of doing business

over the Internet. Fingar [1] described that technology and business move abreast of one another. Based on the changes in information technology, the timeline of business technology is divided into 6 stages. We are now entering the ubiquitous computing realm which focuses on Internet-based collaborative computing. The B2B interaction will be increasingly be digitised and migrated to cyberspace.

The new digital economy has transformed the business world from the traditional, linear value chain model to a centralised value network model. Figure 1 illustrates how information and product are passed within the traditional linear value chain model. The main drawback of this model is that the visibility of information is tier-dependent. Information is not properly shared between the parties upstream and downstream of the value chain. Even if information is shared, the information systems tend to be rigidly-configured, tightly-integrated, proprietary, non-reusable and unportable, often requiring high infrastructural set-up and maintenance costs. The chain, and hence the information systems to be used, tends to be dominated by the chain master.

Figure 1 Traditional Linear Value Chain

Figure 2 illustrates a centralised value network where partners form a trusted network community to conduct collaborative commerce via a hub-and-spoke e-marketplace that facilitates the business processes. For example, Covinsit's [2] e-marketplace model transforms the linear chain into a far more efficient network model that facilitates information sharing within the community. However, the infrastructural cost is still substantially

<sup>1</sup> In a PUSH economy, there is more demand than supply. The producer or manufacturer pushes out their products to the consumer.

<sup>2</sup> In a PULL economy, there is more supply than demand. The consumer dictates the kind of products to be produced.

high, and information systems remain tightly integrated and proprietary. Furthermore, the interconnectivity within the community is static in nature.

**Figure 2 Centralised Value Network Model**

In this model, the application service provider has to bear the full cost of the infrastructure that needs to be put in place to provide the service to the community. The cost of enterprise application integration (EAI) to the partners' back-end systems will be high as well, if they choose to have it. The interconnectivity within the community is static because it has to be pre-determined.

### 3. THE VIRTUAL COMMUNITY

Figure 3 shows an example of the complex, interwoven digital commerce connectivity among different clusters of value network communities (VNCs) that is beginning to emerge. This is a decentralised VNC model. The clusters of VNCs give rise to the dynamic nature of the digital economy. Some of the key characteristics of the digital economy are described as follows:

- each VNC consists of both supply and demand chains that form a value chain driving from customer demand to the delivery of the final product to the customer
- one VNC competes with another VNC
- a trading partner of a community can be a partner of another community
- each trading partner focuses on its core competencies

The success of a VNC requires the sharing of information, business processes and other resources among partners upstream and downstream of the individual value chains. It is therefore vital that partners in the community are virtually integrated with one another. Competing in the digital economy is neither just about technology nor just about business. It is about getting all the value chain partners to work together seamlessly, collaboratively, securely, dynamically as a digital commerce community over cyberspace, and hence, the formation of "Virtual Enterprises". In this context, the "virtual enterprise" comprises all trading partners, customers and suppliers working together as ONE single, extended entity.

**Figure 3 Decentralised VNC**

### 4. CURRENT CHALLENGES

For enterprises, both large and small, to function as a member of a VNC, they are confronted with a number of business and technical challenges. The business challenges include:

- Ability to re-configure itself rapidly
- Lack of common standards in digital commerce exchange
- Ability to handle a diverse, de-centralised and dynamic collaborative environment
- Ability to provide visibility of timely business information

The technical challenges faced relate to making sense of the diversity of technologies and the multitude of applications being used by the members of the community, including

- Diverse IT applications for Enterprise Resource Planning (ERP), Customer Relationship Management (CRM), Supply Chain Management (SCM), Product Design Management (PDM) and other customised applications.
- Diverse programming languages used for the implementation of IT applications.
- Diverse operating system and middleware platforms.
- Diverse networks types and topologies.

The key challenge is, therefore, to connect the islands of technologies and applications for information visibility and the formation of dynamic B2B relationships and connectivity for the network community.

### 5. VIRTUAL INTEGRATION INFRASTRUCTURE & FRAMEWORK

Reddy [4] defines virtual integration as being based on the enterprise infrastructure that provides the necessary mechanism for integrating a broad range of forward and backward activities within the value chain, including interaction with trading partners, industry networks, customers, and other maintenance and commodity suppliers. The virtual integration IT infrastructure would then consist of a collection of systems that create an Internet-based marketplace for buyers and sellers to transact in a VNC. Such an infrastructure should enable efficient sharing of information and resources as well as

seamless collaboration of trading partners with one another.

It is observed that three major factors need to be considered to achieve virtual integration for a VNC of trading partners, and they are:

- (1) A good IT framework that is able to support e-services, connectivity, interoperability, security, standardisation of business dictionary, inter-enterprise business process, scalability, reliability and flexibility.
- (2) A suitable business model for deploying the IT framework.
- (3) Commitment from top management.

Obviously, satisfying the first factor would put an organisation at an economic advantage as it would have a comprehensive IT framework to conduct on-line business with partners in the VNC. However, not all partners will have the luxury of owning such a framework because of the high cost of investment. There is, therefore, a need for a cost-effective IT infrastructure that can serve as the necessary framework for partners in a VNC to collaborate seamlessly over the Internet, which is proposed in the ensuing sections of this paper.

It is equally important for a company to have full commitment from the top management to ensure streamlining of the company's Internet strategy with its business strategy. Leading strategy experts Robert and Racine [4] proposed a comprehensive framework that connects a company's Internet strategy with the company's business strategy.

## 6. COMMON E-BUSINESS COMPUTING MODELS

The widely used computing models used to conduct e-business over the Internet are summarised as follows:

- *The centralised web-based architecture* model provides all on-line business applications for a trading partner community at a central location. A central web server is responsible for handling incoming user requests. Upon receiving a request, the web server gathers data from back-end applications, processes the data based on the appropriate business logic and responds to the user with the required information. In this model, the application can be custom-built or procured, and hosted within the trading partner company's premises. This is an attractive solution if the cost of IT investment is not a constraint of the company because it allows for total control and customisation of the application. However, it requires a substantial level of manpower resources to coordinate and execute implementation strategies, as well as maintain and update the systems.
- *Application Service Providers (ASPs)* offer an alternative solution to the centralised web-based model. ASPs essentially put their applications up for "rent" via the Internet to companies that need them. It is a cost-effective model for companies that have limited IT budget and resources. By paying for the use of such

remotely hosted applications, rather than procuring or developing, and maintaining them in-house, the total cost of ownership for a company could be substantially reduced. The ASP provides the majority of the IT infrastructure and manages the hardware and software upgrades. Such a model enables trading partner companies to "try out" newer technologies at lower costs, as there would not be a need for an upfront investment on hardware and software. However, the ASP would need to have a substantial client base to sustain its high set-up cost, operations cost and maintenance cost, and a typically high service availability rate.

The use of the Internet for e-Commerce has, to date, largely been based on the centralised, multi-tier computing model, such as the two described above. Typically, the functionality of such systems is broken up into three separate tiers, namely, the presentation, business logic and the data source tiers. Such a model may not fit well in the new era of digital commerce due to the complex business interfaces among trading partners. It also does not facilitate information to be shared easily among the VNC due to the complexity involved in B2B integration and the diverse technologies and information systems used by individual partner companies.

## 7. IMPACT OF PEER-TO-PEER ARCHITECTURE (P2P)

What is *peer-to-peer*? Briefly, it is an architecture model for that can be used to better utilise resources that are connected to a network, such as the Internet. It facilitates the sharing of data, computational resources and services by computers and devices residing on the network.

The main characteristics of P2P are outlined as follows:

- Peers understand both *requests* and *responses*.
- A peer can either act as a *client* or a *server*. It is a client when making a request and a server when responding to one.
- Peers are interconnected with one another via a network, such as the Internet.
- There is no single point of failure.
- Information and resources remain at the edge of the network.

The P2P architecture abstracts traditional, hierarchical networks into a set of nodes that are interlinked based on a set of well-defined rules that provide increased flexibility and mitigates traditional bottlenecks and points of failure. Presently, P2P networks are largely server-mediated. Each network contains both peers and a handful of central servers. These servers are responsible for maintaining a registry of the peers on the network so that they can locate one another. Multiple instances of these servers are usually present for the purpose of ensuring performance and providing redundancy in the event of failure of one or more servers.

In the dynamic digital economy, collaborative product commerce in a VNC is approaching that of a tier-less model. Transactions are being carried out between partner endpoints at the edge of the network community. Each partner endpoint can perform a dual role, one of being a commerce services *provider* as well as commerce services *consumer*. This relates well with the P2P computing model where clients can be servers and servers can also be clients.

From this close correlation between the characteristics of the VNC and those of the P2P computing architecture, it is apparent that the latter would potentially be a good fit for the former. Moreover, P2P overcomes the limitations of the centralised-server computing model by allowing trading partners to provide information services directly to one another. An example of the P2P computing model is Gnutella [7], an open, decentralised network that uses P2P technology for file sharing over the network. Figure 4 illustrates how Gnutella works.

Figure 4 Gnutella Network

When My Company searches for inventory information located in Company B, the search is transmitted to everyone connected in the Gnutella network horizon. Although My Company is not directly connected to Company B, as long as the latter has allowed all partners in the community to view its inventory information, the former will be able to access it through one of the peers that is connected to the latter. Common characteristics of such a network are:

- Any peer can *publish* any information one wishes to share in the network.
- Any peer can *discover* new information in the network.
- Any peer can *consume* the required searched result.
- Any peer can be an information *provider* as well as an information *consumer*.
- New peers can easily *connect* to the network.

P2P technology is an ideal candidate to model the real-world dynamic connectivity required of the virtual integration among partners in a VNC. Each peer in the VNC represents a company that provides its core business functions as e-Services for its partners within the community to consume.

Mirroring the characteristics of the P2P network architecture, the key benefits of a P2P-enabled collaboration community are:

- Each partner in the community can be a service provider as well as a consumer.
- The ability to publish new information to the community as and when it is available.
- The ability to discover and consume new information introduced in the community.
- The ability to rapidly integrate the trading partners in the community.

However, there is a drawback imposed by the existing P2P architecture in that although new information being published to the network can be automatically discovered and consumed, the same cannot be said of services. When a new service has been published to the community, each peer would have to be notified and reconfigured for it to be able to consume the new service. There is no standardised way of describing services and how a peer can be configured to consume new services. One way to resolve this is to leverage Web Services technology to enhance the P2P architecture.

## 8. WEB SERVICES

Web Services are software components that are programmatically accessible as services over the Internet. The platform- and language-independent interfaces of Web Services allow for easy integration of diverse applications residing on heterogeneous systems. Web Services focus on moving data around using XML [6] to keep inter-application communication loosely-coupled. The publication, discovery and invocation of Web Services over the Internet make use of the following open standards:

- **Web Service Description Language (WSDL)** [8] – a standard that describes a Web Service type and its interfaces.
- **Universal Description, Discovery and Integration (UDDI)** [9] – a standard mechanism for the registration and discovery of Web Services.
- **SOAP (formerly an acronym for Simple Object Access Protocol)** [7] – a standard messaging protocol for Web Services.
- **Extensible Markup Language (XML)** [6] – defines the structured data to be interchanged among applications.

Web Services and P2P complement each other to provide an infrastructure to support the virtual integration of partners within a VNC to enhance their collaborative commerce activities. Figure 5 depicts the conceptual roles and operations of peers in a Web Services-based environment. It illustrates the way Web Services and P2P work side-by-side to complement each other.

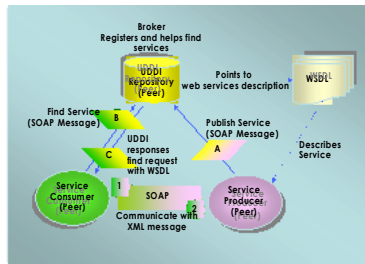

Figure 5 Marrying Web Services & P2P

There are three basic roles. They are the service *provider*, the service *consumer*, and the service *broker*. The service provider makes available the service contract and registers (A) the service with a service registry. A service consumer queries the registry, which serves as the broker, and finds (B) a compatible service. The service registry gives the service consumer directions on where to the service is located and its relevant contract (C). The service consumer uses the contract obtained to bind ((1) and (2)) the client to the service.

The service provider can be a service consumer, and vice versa (for example, in the case of service aggregators). The service registry's responsibility is to maintain a central repository or directory of information on services that have been published for consumption.

## 9. BENEFITS OF COMBINING WEB SERVICES AND P2P

The use of Web Services and P2P technologies for virtual integration will give rise to the following potential benefits:

- As it is a distributed architecture, the cost is shared among the partners of the VNC, each bearing a fraction of the infrastructure cost. This is in contrast to the centralised web-based architecture where a single party bears the cost and controls the applications that serves the community.
- VNC members can concentrate on providing core business functions as web services for partners to discover and consume, as and when needed.
- VNC members can dynamically discover, establish and conclude short-term trading partnerships without substantial integration overheads.
- VNC members have the flexibility to add new services or update existing services as and when needed, at the edge of the network without affecting other peers.
- The VNC can share resources, for example, by not duplicating existing services that are already being offered by a member.
- VNC members own their business data and maintain their own applications. There is no concern of data privacy as opposed to that of a centralised approach.
- By allowing the community as a whole to better utilise and manage its resources, it is able to achieve better efficiencies to compete with rival communities.
- Information can be pushed as well as pulled, on-demand when required.

- Scalability is enhanced for the VNC as a whole, and single points of failure and other performance-related issues are reduced.

## 10. CONCLUSION

The combination of Web Services and P2P provides an ideal platform for the virtual integration of partners in a VNC. Using such a platform, individual trading partners have the freedom to make and break short-term partnerships without having to incur large overheads required in integrating with each partner they collaborate with. Data and services provided within the community are always up-to-date as they are put out by the members themselves instead of a central service provider. Data privacy concerns are also eliminated with each member of the community hosting its own data and services instead of making use of a centralised service provider. Performance issues are mitigated by the distributed nature of the services, resulting in a more efficient VNC as a whole.

## 11. FUTURE RESEARCH

Despite all the benefits described earlier, there remain a number of gaps to be filled before the full benefits of virtual integration can be realised. They include:

- The definition of an inter-enterprise public business processes standard. This to ensure a common set of business dialogues for business process integration between partners in a community.
- The definition of standard business and technical dictionaries to be used for terminologies to be exchanged in documents and messages in business transactions over the network. This is to ensure that a common business language is used between trading partners for on-line B2B transactions.
- The definition of an architectural layer for business process management (or BPM) that enables the orchestration of business processes across the various stages of the life cycle of a project.

### ABSTRACT

Davis's Technology Acceptance Model (TAM) suggests that perceived ease of use and perceived usefulness can predict user behavior and acceptance when using information technology. In this study we use it as a tool for evaluating the acceptance and usage for mobile commerce by employing data collected from 205 students selected proportionally from nine universities located at Taipei City. The results show that perceived ease of use and perceived usefulness are the fundamental determinants of user acceptance and have positive impact. They demonstrate positive impacts on attitude to use and behavioral intention to use. In addition, the attitude toward using m-commerce has a partial mediating effect on behavioral intention to use. Behavioral intention to use exerts a positive, though lesser, impact on actual use of m-commerce.

**Keywords:** Technology Acceptance Model, M-commerce, Confirmatory Factor Analysis, Regression Analysis, partial mediating effect.

### 1. INTRODUCTION

Digital mobile phone has improved the defects of analogue mobile phone, and brought mobile communication into a digital era. Governments of many countries have released their telecom policies for new dealers to invest in the market so as to compete with each other and cause the telecom fee to reduce. In the meantime, emulation among the dealers will bring innovations of communicative semi-conductor technique. As a result, the "used to be" heavy mobile phone now turns into portable and light personal stuff, which makes the mobile communication service grow rapidly.

Ever since the "i-Mode" service promoted by NTT DoCoMo, all global wireless dealers pay great attention to this emerging commerce, and start to run a similar business model which leads to a trend for crashing in the wireless network. With the vast application of Wireless Application Protocol (WAP), the promotion of GPRS communication service, and various newly promoted wireless terminal equipments (such as Smart Phone, Wireless PDA etc.), the integration of wireless communication and network will quicken the grand opportunities.

The technology acceptance model (TAM) proposed by Davis (1989) has been widely applied and empirically tested in the adoption or acceptance of information technology (IT) to explain end-users' acceptance

behavior. The technology such as e-mail and graphics, word process, voice mail were tested with TAM to explain the users' acceptance behavior. However, a meta-analysis of empirical findings indicates that the relationship between ease of use and acceptance is weak and the relationships in the model may be moderated by

a third variable such as gender, culture (Ma and Liu, 2004). In this study, we use m-commerce technology to test if the relationships in the TAM still validate.

### 2. LITERATURE REVIEW

#### 2.1 Technology Acceptance Model

Davis (1986) used belief-attitude-intention-behavior relationship of TRA (Theory of Reasoned Action) to develop TAM to model user acceptance of IT, as shown in Figure 1. This model provides a theoretical foundation to understand how external variables influence the user's inner beliefs in a technology, and then predict his/her behavior, which in turn affect the use of technology. The purpose of TAM is to provide an explanation toward the acceptance of technology which explains user's behavior on accepting new IT, and analyze the factors that influence their attitude toward using new IT. The design of the constructs used in TAM is both valid and reliable, and has been discussed, experimented, and amended by many scholars. So the same constructs could be adopted even though the technologies to be studied are different. (Adams et al., 1992; Taylor and Todd, 1995; Mathieson and Chin, 2001).

Figure 1 Technology acceptance model  
(Davis et al., 1989)

## 2.2 Mobile Commerce

Durlacher (1999) figured mobile commerce (m-commerce) as a vast area of activity comprised of transactions with monetary value conducted via wireless network. Other scholars like Skiba et al. (2000) defined m-commerce as transactions using a wireless device either in word or speech that result in the transfer of value in exchange for information, services, or goods. Jiang (2001) mentioned that m-commerce is the transactions conducted by terminal equipment, such as PDA, and SmartPhone etc, and the services should be paid. The related services and application include the downloading of music and picture, mobile monetary control, and mobile advertising.

From the above definitions, we can find that the divarication for the definition of m-commerce is whether monetary transactions should be included. The definition by Skiba et al. (2000) will be adopted as the foundation for this study, which referred m-commerce to transactions using a wireless device either in word or speech that result in the transfer of value in exchange for information, services, or goods.

The definition for m-commerce by Skiba et al. (2000) is not restrained for monetary service only. Therefore, the formation of m-commerce will depend upon the match of software and hardware. According to the framework proposed by Varshney and Vetter (2002), the formation of m-commerce is divided into two main sections, application, and development and supply. For development and supply, there are three categories: the supplier of service, the supplier that provides content, and the developer of application framework. Therefore, there are four levels for application, infrastructure for wireless network, intermediary software, device, and the application of m-commerce. This framework provides the m-commerce not only a direction but also a reference for standard allocation before investing in m-commerce.

## 3. RESEARCH MODEL AND HYPOTHESES

This study adopts the extended structural definition of TAM proposed by Davis et al. (1989), without considering external variables, as shown in Figure 2.

Figure 2 Research framework

## 3.1 Measures

In this study we used five questionnaire items to describe the construct of perceived usefulness and four items for perceived ease of use, which were adapted from Davis (1989) and Moore and Benbasat (1991) and measured on a five-point Likert scale with anchors ranging from strongly agree (1) to strongly disagree(5).

Attitude toward using m-commerce were indicated by four items adapted from Ajzen and Fishbein (1980), Malhotra and Galletta (1999) and measured on a five-point Likert scale; behavioral intention to use by two items adapted from Ajzen and Fishbein (1980), Davis (1989) on a five-point Likert scale.

As for the actual use of m-commerce it was defined as the frequency used per week (Malhotra and Galletta, 1999; Igarria et al., 1997).

## 3.2 Research Hypotheses

The research hypotheses for this research were made according to the structural theory of TAM proposed by Davis et al. (1989).

H1: Perceived ease of use will have a positive effect on perceived usefulness.

H2: Perceived usefulness will have a positive effect on attitude toward using m-commerce.

H3: Perceived ease of use will have a positive effect on attitude toward using m-commerce.

H4: Perceived usefulness will have a positive effect on behavioral intention toward using m-commerce.

H5: The attitude toward using m-commerce will have a positive effect on behavioral intention of use.

H6: The behavioral intention to use will have a positive effect on actual use of m-commerce

## 3.3 Data Collection

According to the ten years information communication technology research for university students made by Macleod et al. (2002), the percentages of students that were expected to use information communication technology frequently increased from 15%~30% to 65%, and the percentages of emphasize on self-use also increased from 20%~35% to 73%, which showed that most students had more desire to use information communication technology. According to the 2004 Taiwan Internet and Broadbar Usage Survey published by TWNIC, as of the end of January 2004, they are 12.64 millions Internet users in Taiwan and the number of broadband Internet users are 9.03 millions and about 81.55% with age of 21~25 (TWNIC, 2004). Since almost of those users are college students, they can be formed the sampling units. However, due to the limited resources, we decided to collected data from the students studied at nine universities located in Taipei City. We planned to select a sample from each university with

sample size proportional to its size. So 500 questionnaires were delivered with 205 usable copies returned including 95 female and 110 male.

### 3.4 Analytical Procedure

In this study we used Cronbach's  $\alpha$  with the cut-off of 0.7 (Nunnally, 1994) to assess the reliability of each construct. Exploratory factor analysis using principle component analysis with varimax rotation and confirmatory factor analysis were employed to assess construct validity and unidimensionality. The former is to investigate if the number of factors extracted is the exact number of constructs determined prior to the analysis and the later to assess construct validity and unidimensionality.

The Correlation analysis and multiple regression analysis were used to test the relationships among the scales or constructs and the effects on dependent variables. The causal direct, indirect, and total effects between the exogenous and endogenous variables can be calculated by using structural equation modeling (SEM).

## 4. DATA ANALYSIS

### 4.1 Reliability and Validity Analysis

The Cronbach's  $\alpha$  coefficients for perceived usefulness, perceived ease of use, attitude toward using m-commerce, behavioral intention to use m-commerce, are 0.8969, 0.8028, 0.9216, and 0.7562 respectively. All those Cronbach's  $\alpha$ 's are above the cut-off of 0.70. The reliability of each construct is acceptable.

Exploratory factor analysis for the items of perceived usefulness and perceived ease of use reveals that the items produce two proposed factors with total variance explained 68.7% and the individual items are loaded with loadings above 0.7 on their appropriate factors as intended. The items for attitude toward using m-commerce, behavioral intention to use reveals and actual use produce three proposed factors with total variance explained 83.9% and all loadings above 0.78. The results of confirmatory factor analysis also show the consistency with the findings in exploratory factor analysis. The validity and unidimensionality for the constructs of both perceived ease of use and perceived usefulness are supported. The validity and unidimensionality for the constructs for attitude toward use, intention of use, and actual use are also supported.

### 4.2 Correlation Analysis

The averaged item scores are used as a measure of their posited construct. The correlation matrix for the constructs used in the model are shown in Table 1. It indicates that the correlation between each pair of constructs is statistically significant at the 0.05 level, except the pair of behavioral intention to use (*intention*)

m-commerce and actual use (*action*) of m-commerce (marginal significance,  $p$ -value=0.061). Independent variables, perceived usefulness (*use*) and perceived ease of use (*ease*) show significantly positive correlation with attitude toward use (*attitude*), 0.656 ( $p=0.000$ ) and 0.543 ( $p=0.000$ ) respectively, and with behavioral intention toward use, 0.527 ( $p=0.000$ ) and 0.457 ( $p=0.000$ ) respectively, at  $\alpha=0.01$ . The correlation coefficient between perceived usefulness and perceived ease of use (0.477) is significantly positive at  $\alpha=0.01$ . The correlation coefficient between attitude toward use and behavioral intention to use (0.591) is significantly positive at  $\alpha=0.01$ .

Table 1 The correlation analysis of variables

	<i>use</i>	<i>ease</i>	<i>attitude</i>	<i>intention</i>	<i>action</i>
<i>use</i> Sig.	1 .				
<i>ease</i> Sig.	.477** .000	1 .			
<i>attitude</i> Sig.	.656** .000	.543** .000	1 .		
<i>intention</i> Sig.	.527** .000	.457** .000	.591** .000	1 .

### 4.3 Hypotheses Testing

In correlation analysis the correlation coefficient between perceived ease of use and behavioral intention to use (0.457) is significant with  $p$ -value=0.000. Regress behavioral intention toward use on perceived usefulness, perceived ease of use and the attitude toward using m-commerce with stepwise method. The results, as presented in Table 2, show that the three independent variables are all significant in predicting the dependent variable with standard beta coefficients in the regression equation,  $b_{Attitude}=0.368$ ,  $b_{Use}=0.211$ ,  $b_{Ease}=0.157$ . The total variance of intention toward use can be explained 0.391 (adjusted  $R^2$ ) by perceived usefulness, perceived ease of use and attitude toward use

Table 2 Stepwise regression analysis

Order	R	A- $R^2$	$\Delta$ A- $R^2$	Std. $\beta$	$\Delta$ F	Sig.
1. <i>attitude</i>	0.591	0.346	0.346	.368*	109.058	0.000
2. <i>use</i>	0.619	0.377	0.031	.211*	11.141	0.001
3. <i>ease</i>	0.633	0.391	0.014	.157*	5.581	0.019

Dependent variable: *intention* (Behavioral intention to use)

\*significant at  $\alpha=0.05$ , A-  $R^2$ : Adjusted  $R^2$ .

In order to test the hypotheses we established the related regression models as presented in Table 3. All models are significant at  $\alpha=0.05$ , except the model  $action=intention$ , significant at  $\alpha=0.10$ .

Table 3 Regression analysis

Model	Variable	$\beta$	Std. $\beta$	A- $R^2$	Sig.
use=ease	Constant	2.131		0.224	0.000**
	<i>ease</i>	0.448	0.477		
attitude= Use+Ease	Constant	0.479		0.494	0.000**
	<i>use</i>	0.597	0.514		
	<i>ease</i>	0.324	0.297		0.000**
intention= use+attitude	Constant	0.985		0.377	0.001**
	<i>use</i>	0.295	0.244		
	<i>attitude</i>	0.448	0.431		0.000**
action=intention	Constant	1.673		0.012	0.061*
	<i>intention</i>	0.153	0.131		

Table 4 shows that the results of the six hypotheses testing in this research, which indicates that all research hypotheses are supported by data.

Table 4 The results of research hypotheses testing

Item	Hypotheses	Result
H1	Perceived ease of use positively influences perceived usefulness.	supported
H2	Perceived usefulness positively influences attitude toward using m-commerce.	supported
H3	Perceived ease of use positively influences attitude toward using m-commerce.	supported
H4	Perceived usefulness positively influence behavioral intention toward using m-commerce.	supported
H5	The attitude toward use positively influences on behavioral intention toward using m-commerce.	supported
H6	The intention toward use positively influences actual use of m-commerce.	supported

The causal direct, indirect, and total effects between the exogenous and endogenous variables were calculated by using SEM. As can be seen in Table 5, all the effects are statistically significant at or above the 90% confidence level. For example, the total and indirect effects of perceived ease of use on attitude toward use are .543 (t value=8.48) and .246(t value=5.72), respectively. The direct effects presented in Table 5b can be shown in TAM diagram as in figure 3.

Table 5 Total effects, direct effects, and indirect effects

a. Standardized total effects (t value)

	<i>ease</i>	<i>use</i>	<i>attitude</i>	<i>intention</i>
<i>use</i>	.477 (6.91)	.000	.000	.000
<i>attitude</i>	.543 (8.48)	.514 (6.76)	.000	.000
<i>intention</i>	.350 (5.47)	.466 (7.17)	.431 (5.32)	.000
<i>action</i>	.046 (1.70)	.061 (1.79)	.057 (1.78)	.131 (1.93)

b. Standardized direct effects (t value)

	<i>ease</i>	<i>use</i>	<i>attitude</i>	<i>intention</i>
<i>use</i>	.477 (6.91)	.000	.000	.000
<i>attitude</i>	.297 (4.24)	.514 (6.76)	.000	.000
<i>intention</i>	.000	.244 (2.77)	.431 (5.32)	.000
<i>action</i>	.000	.000	.000	.131

	<i>ease</i>	<i>use</i>	<i>attitude</i>	<i>intention</i>
				(1.93)

c. Standardized indirect effects (t value)

	<i>ease</i>	<i>use</i>	<i>attitude</i>	<i>intention</i>
<i>use</i>	.000	.000	.000	.000
<i>attitude</i>	.246 (5.72)	.000	.000	.000
<i>intention</i>	.350 (5.47)	.222 (4.35)	.000	.000
<i>action</i>	.046 (1.70)	.061 (1.79)	.057 (1.78)	.000

The t values >1.66, 1.98, and 2.35 are considered to be significant at the 0.10, 0.05, and 0.01 levels, respectively.

Figure 3 The causal direct effects between constructs

## 5. CONCLUSIONS AND SUGGESTIONS

A number of hypothesized relationships in Davis's TAM with different IT, i.e. m-commerce, were tested based on a sample of 205 college students. The results of our study generally confirm the Davis's findings. The relationships between perceived ease to use and perceived usefulness, and between perceived usefulness and attitude toward use are strong. The relationships between perceived ease to use and attitude toward use is also strong, while weak reported by Ma and Liu(2004). We found from regression analysis that behavioral intention to use can be predicted by perceived usefulness and attitude toward use.

Although we did not proposed a formal hypothesis about the mediating effect of attitude toward use, we added one more regression model,

$$intention = .400 use + .266 ease,$$

p values=.000 for beta testing,

with two models, that is,  $attitude = .514 use + .297 ease$ , p values=.000, from Table 3, and  $intention = .211 use + .157 ease + .368 attitude$ , p values< .050, from Table 2. By mediating effect test (Baron and Kenny, 1986) the beta coefficient of *use* decreases from .400 to .211 when adding *attitude* toward use into the regression model, which demonstrates that attitude toward use has a partial mediating effect on behavioral intention to use. However, the effect of behavioral intention to use on actual use is marginally significant (p=0.061).

In this survey one question about the most common used

m-commerce service, it is the message-sending, the most typical service provided. About the service the users of m-commerce expect most is the improvement of entertainment service, followed by global positioning, financial service, and general information. The above information implies the trend that the users may gradually accept more m-commerce services and use them.

That the effect of behavioral intention to use on actual use is statistically marginal significance may imply that there are some important variables omitted, such as the service charge, the security of the system, and the problem of on-line quality, when users considering taking action to use.

Because m-commerce is expected to have a prosperous market for service providers, they should realize user's behavior in the market and manage potential user's requirements for it. Potential user's attitude toward using m-commerce and the factors that influence their intention to use should be realized and emphasized in order to develop proper marketing strategies for the use of m-commerce.

## ABSTRACT

Most of existing mobile services were designed based on the client/server architecture. Those mobile services neither paid much attention to mobile users' interactions with their environments nor considered the cooperation efforts between the mobile users in a dynamic peer group. In this paper, the notion of ambient e-services is defined to identify a new scope of mobile e-services. The notable features of ambient e-services are the exhilarated linkage based on social context and significantly rapid growth of connections. We also present an ambient e-service framework that characterizes ambient e-services with three dimensions (value stack, environment stack and technology stack). We exemplify several ambient e-service applications, which rest on the mobile peer-to-peer technology and ambient context aware sensors environments. Ambient e-services make a mobile user not only connect to dynamic ambient environments but also build channels that connect with other mobile users in the nearby surrounding environment, capitalizing dynamic environmental values as well as dynamic social values. Lastly, we identify for ambient e-services certain important issues worthy of future intensive research.

**Keywords:** Ambient e-Services, Mobile commerce, Context awareness, Social context, Mobile Peer-to-Peer

## 1. INTRODUCTION

Mobile commerce promises to deliver the real potential of Internet for commercial purposes to a significantly expanded market of existing and new users. A four-level integrated mobile commerce framework was proposed in [1], which discussed how to successfully define, architect, and implement the necessary hardware/software infrastructures in support of mobile commerce. However, the applications mentioned in [1] were grounded in the client/server architecture where the only interactions involved are between a services provider and a mobile user. Mobile users were standalone due to the lack of technology functions and communication channels that enabled mobile users to interact with each other; interactions or cooperation between mobile users were not considered as an important issue in mobile service scenarios. Consequently, the collected value attained from the mobile users of a peer group (or multiple peer groups) cannot be produced.

Fortunately, the latest Peer-to-Peer (P2P) technology (e.g., JXTA) makes it possible for individual mobile peers communicate with each other and wirelessly exchange their own information under sensors-enabled environments. One may notice that P2P computing has increasingly emerged at the forefront of Internet computing. The cooperative computing and resource sharing has been around for quite a while [2]. The collaborative interactions between mobile users bring mobile commerce into a new paradigm. Accordingly, a new framework of mobile applications should be investigated, considering dynamic environments and collected efforts of mobile users.

The ambient intelligence refers to the vision that technologies become invisible, embedded in our natural surroundings, present whenever we need them, enabled by simple and effortless interactions attuned to all our senses,

adaptive to users and context and autonomous acting [8].

In other words, ambient intelligence is to embed information representation in everyday objects and the physical environment becomes an interface to digital information. In this paper, we embrace this vision into mobile e-services built with the Mobile-P2P technology, unfolding the notion of ambient e-services.

Moreover, Location-based services (LBS) employ knowledge of the user's location to enable the provision of new or enhanced services to a user via a wireless handheld device (e.g. mobile phones, PDAs). Wireless e-services can be potentially very personal, timely and relevant, or even integrated with other services in a near-seamless way [4]. Within ambient environments, wireless handheld devices are very personal to a user and carried by the person; the context of the user (e.g., time and place) can be measured and interpreted; services can be provided at the point of need; and applications can be highly interactive, portable and engaging.

However, some people may wonder if current sensor networks can replace ambient e-services. Wireless Integrated Network Sensors (WINS) provide distributed network and Internet access to sensors, controls, and processors that are deeply embedded in equipment, facilities, and the environment. However, in sensor network environment, peers within the range may not know who others peers are (i.e., social context is confidential and presumed to be retained privately). But ambient e-services are capable of leveraging peers' private social context or past interactive experience, diversifying the potential opportunities of the dynamic collected efforts. There exists something about ambient environments that the sensors network cannot accomplish. The social connections based on the context aware environment provide a trustworthy linkage on the strength of the social networks and keep sensitive data from others. The social

contexts accordingly must be retained in the personal devices. Otherwise, sensitive data kept in a central server will make user loath to participate in such services. Compare with the client/server architecture, the P2P design makes the connection numbers in a significantly rapid progression growth especially in an open space. Those are two distinguished characteristics that make the P2P design more appropriate than client/service architecture in ambient e-services.

This paper does not intend to offer fixed answers about how ambient e-service application systems should be designed in the future. Instead, it aims to motivate a new direction of research, which addresses challenges and research questions that arise when we take a system-oriented but high-level view of ambient e-services. We are interested in examining those novel applications and technologies that constitute the frontier of the ambient e-services.

The ambient e-service is a new thinking. To ward off ambient e-services framework limited to those scenarios we provided, we deploy the presentation of the paper in a top down structure. In section 2, we propose the ambient e-service framework that represents the ambient applications in three dimensions. Section 3 illustrates several key ambient e-service scenarios and their basic interaction architectures. Then we discuss those issues arise in ambient e-services in section 4. Finally, in section 5 we describe some conclusion remarks and future research topics.

## 2. AMBIENT E-SERVICES FRAMEWORK

In this section, we present an ambient e-service framework (as shown as Figure 1), identifying some possible deliverables (values) of ambient e-services and addressing the technologies required to support the applications of ambient e-services. The framework is composed of three dimensions, the value stack, the environment stack and the technology stack. The descriptions of the stacks will be detailed in the following subsections.

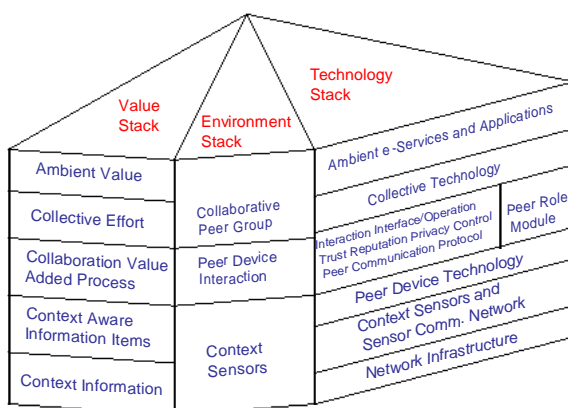

Figure 1. Ambient e-Service framework

### 2.1 Value Stack

The ambient value stack comprises five layers indicating the supporting value layers for ambient e-services

(deliverables of higher levels requiring the provision of deliverables of lower levels). The basic layer is the "Context Information", which is attained from the ambient sensor environments. A mobile user can interact with the environments (e.g., entering a room) and the context sensors then communicate with the device the user carries (e.g., informing the user of his/her location). Comparing the user's profile, the second layer "Context aware Information Items" send to the user information items that matches his/her preferences.

The information items received from the environments may be useful to the user, but sometimes some of the information items may be irrelevant. With the communication ability, a mobile peer can collaborate with another mobile peer and exchange carried information items stored in their mobile devices. Through these collaboration interactions, it may be the case that there is someone whose information items are valuable to me and thus I can exchange or trade with them with a micro payment or a barter process. This is called "Collaboration Value Added Process".

Not only communicating with only one peer, a peer can also interact with a peer group of multiple peers. Aiming at the same goal or interests, a peer group can collect their abilities to accomplish the goal that is impossible for a single peer to reach. Therefore, "Collective Effort" represents the power of a peer group (or multiple peer groups). The ambient value subsequently refers to the collective efforts, which include the peers' interactions and peer groups' interactions.

### 2.2 Environment Stack

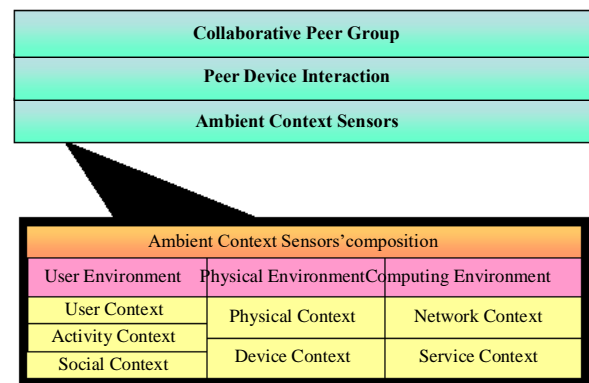

Figure 2. Ambient environment stack

The environment stack consists of three layers indicating the supporting environment layers for ambient e-services (environments of higher levels comprising those of the lower levels). The sketched stack diagram is shown in Figure 2.

The "Ambient Context Sensors" is the bottom layer, which include three categories of environments. Schilit, Adams & Want claim that the important aspects of context are: where the user is, who the user is with, and what resources are nearby. [12]

The user environment includes the user context, the activity context and the social context. The user environment represents the profile of a user, such as peer identification, where the user is, who the user is, the user's preference, their privacy concern, their social situation and relations with others, etc. The physical environment includes the physical context and the device context. The physical environment refers to things like temperature, noise and lighting level and device context. The computing environment includes the network context and the services context. The computing environment represents the network connectivity, available processors, cost of computing, bandwidth and available nearby services, etc.

The layer "Peer Device Interaction" represents environments (featuring peer-to-peer interactions) in which mobile users may exchange their experience and trade attained information items with nearby peers. The "Peer Device Interaction" layer rests on the "Ambient Context Sensors" layer; that is, all peers' information items originally come from the interaction with the dynamic environments of the bottom layer.

The top layer of the environment stack represents environments featuring peer groups' interactions and collaboration. Peer group can collect all peers' power for certain objectives (e.g., collective buy, forming a task-oriented workforce group, etc.).

### 2.3 Technology Stack

Network infrastructure is the fundamental of all ambient technology stacks. The wired and wireless hybrid network infrastructure provides the basic communication infrastructure for context sensors and peer devices. Above the network infrastructure layer, context sensors and sensor communication can interact with the surrounding peers. Peer devices function on top of the sensor communication network and the mobile device's hardware, operation systems and software platforms.

The layer above the peer device technology layer has two folds: (1) For peers to interact with each other, a peer communication protocol is required (similar to that in web services). (2) In ambient environments peers may just know nearby peers for quite a short period of time. How can a peer trust the nearby peers? Is it possible to build a reputation system for the aforementioned situation so that it is feasible to trust unfamiliar peers? Similarly, privacy control should be addressed in ambient e-services. Resting on trust, reputation and privacy control as the communication basics, mobile users can engage ambient interactions to handle some operations between peers. These operations are the likes of "discovery", "request", "respond", "bargain", "transact" and "delivery".

Since a mobile user plays different roles in different interactions, the peer role module can be applied to the peer in response to the dynamic roles rendered. Mobile users, who have the information items required by other users, play the seller role by applying the seller module. The surrounding peers (who have attained various kinds of information) then can play as the broker role by applying the broker module. Mobile users, who need the information

from others, apply the buyer module and play the buyer role (who can trade or barter with other mobile users).

Beyond the peer to peer interactions, peer group collective effort is the communal power of peers. Collaborative technologies that support peer and peer groups to work together underlie the key character of ambient power. Based on the collective technology, ambient e-services can be unfolded in various applications, which we will discuss in the next section.

### 3. AMBIENT E-SERVICE APPLICATIONS

It will be useful, to begin with, making a distinction between two kinds of ambient e-Services. One is for the distributed trading; another is for the distributed collaboration. Please note that the social context and the rapid growth of connections are the major incentives of applying the ambient e-service design. The two characteristics are not mutually exclusive; of course, one scenario may apply both of the ambient characteristics.

This section aims to identify several important ambient e-service application scenarios presuming ambient environments of mobile commerce are provided. Without loss of generality, the physical context of location is referenced and considered in the ambient environments addressed in the following scenarios, naturally relating to the LBS research. As mentioned in Section 1, ambient e-services aim to identify a new scope of mobile e-services mainly addressing dynamic collected efforts between mobile users (enabled by M-P2P) and dynamic interactions with ambient environments (envisioned by LBS).

Since LBS was categorized into four major types (transaction services, information services, navigation and tracking services and safety services [3]), we accordingly exemplify some scenarios reflecting the LBS types as well as exhibiting dynamic collected efforts based on M-P2P.

We introduce an ambient shopping mall scenario to be a representative of ambient transaction services. The shopping mall scenario can easily be modified to act as ambient safety services. The information items distribution cooperation scenario then is considered as an exemplar of ambient information services. The cooperative peer group scenario then can be instantiated into ambient navigation and tracking services. As to the ambient location information acquisition scenario, it can be considered as an instance of ambient transaction services, ambient information services or ambient navigation and tracking services.

These applications differ from the past mobile e-services in addressing dynamic collected efforts between mobile users and dynamic interactions with ambient environments. The collective efforts of mobile users are not possible in the primal mobile services framework that deploys the services with the client/server architecture. Moreover, mobile devices in ambient e-services applications are very personal to the users, and thus the social contexts retained in the personal devices (e.g., the social relationships in the vicinity) can unfold the e-services of high complexity and security than that of no social contexts in sensor networks.

E-services with the social context environment render ambient e-services capable of providing the most appropriate collaborative power for mobile users anywhere whenever needed.

In the following subsections, each scenario will be detailed in terms of its motivation and promised value and the interaction structure.

### 3.1 Ambient Shopping Mall Scenario

In Figure 3, a picturesque view of the ambient shopping mall scenario is presented. In a shopping mall (fully equipped with wireless network infrastructures), information items (e.g., advertisement or sales promotion information) can be broadcast to passing-by peers with Info\_BC\_Station. This means the attained information items of a peer vary based on the peer's interactions with the shopping mall ambient environments.

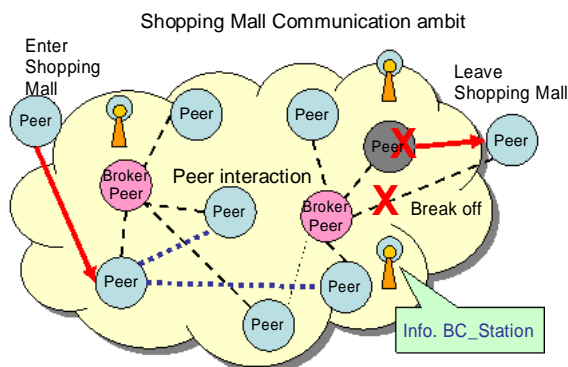

Figure 3. Ambient shopping mail scenario

The ambient e-service addressed in this scenario will be delineated for the case of new customers of high buyer perishability (entering the shopping mall and being in a rush to buy certain items without the knowledge of where to buy and how to buy cheap given relevant sales promotion). Those new customer peers carrying mobile devices can communicate with nearby peers when they just enter the shopping mall.

In such scenario, the goal of ambient shopping mall e-service is to provide a new channel for customers to get needed information. The assumption of this scenario is that the contents of information items kept in peers are different from one another based on their membership status. Mobile users will receive the information items based on their user context such as their preferences or membership data. Those members with higher loyalty points will get a higher discount e-coupon. This would encourage customers to join the membership program.

All mobile peers have their temporary peer ID number, preference, context data, transaction history and the information attained information items. Peers can do basic operations such as bargain and payment. Mobile peers can apply different role modules to do specific operations. There are the buyer module, the seller module and the broker module for mobile peers.

When a peer applies the seller module, it can respond a buyer's product discovery operation. If a seller peer has the information items that the buyer required, the seller then responds the buyer's request and starts a bargain operation with the buyer peer. After the payment process, the seller delivers the information items to the buyer. The operations performed by the buyer module are complementary to those performed by the seller module. But the buyer module has been designed not only to handle the transactions with seller module, but also to request the package service from the broker module.

The broker module is applied to those peers who will stay in the mall for a long time and own much complete information items. The broker module is designed for peers serving as service providers. The broker module has the 'generate' package, which can generate services of producing information items of the buyer's interests and preference. Package templates are used for the broker module to produce a service package in an easy way. Also, the broker module has the same ability as the seller module that can deliver the products.

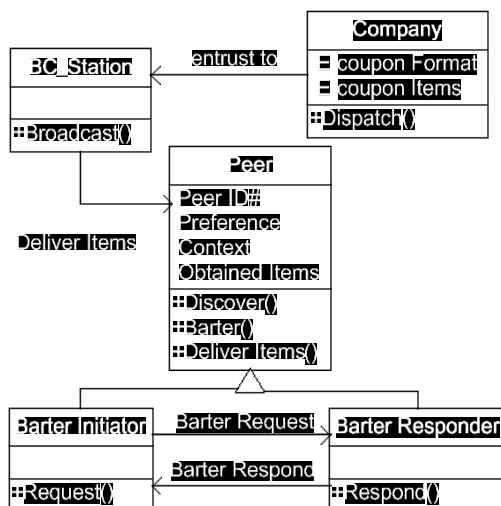

Although the effective reach is one of the shopping mall's goals. If the contents of information items are the same for everyone, both client/server and P2P designs can pass the items to the public but in different ways. However, mass broadcast like spam mails will annoy customers and thus be reluctant to join this shopping program, attaining the contrary results. When considering user differentiation, content differentiation will be in relation to user profiles and to ambient context sensors in the environment stack (that subsequently will involve social context and correlate to the privacy concerns of the customers). Those concerns make the P2P design is more applicable than the client/server architecture.

A UML class diagram is depicted (as shown in Figure 4) represents the relationships between the different modules as well as the peer module basic functions.

ambient e-service based on a mobile advertising infrastructure. Distributor companies can broadcast shops' advertisement items (e.g., e-coupons) through an ambient advertising infrastructure, which dispatches advertisement items relevance to their preferences to proximate users. In this scenario, e-coupons are considered as valuable information items. When a mobile user passes through a shop and wants to buy certain products but is short of the relevant e-coupons, the mobile peer can probe the surrounding environment to see if there are some nearby peers that own the desired e-coupons.

The P2P design combined with social awareness will make the connections not only in a rapid growth but also with persuasiveness, being more powerful than the client/server design. Moreover, as mentioned in Section 3.1 e-coupons become a valuable information item if the contents of information items are different. In this business model, mobile users can exchange their e-coupons, get some financial benefit, and be attracted to join the program so as to create a large scale of the participants. That is a win-win situation is created for both customers and the shops.

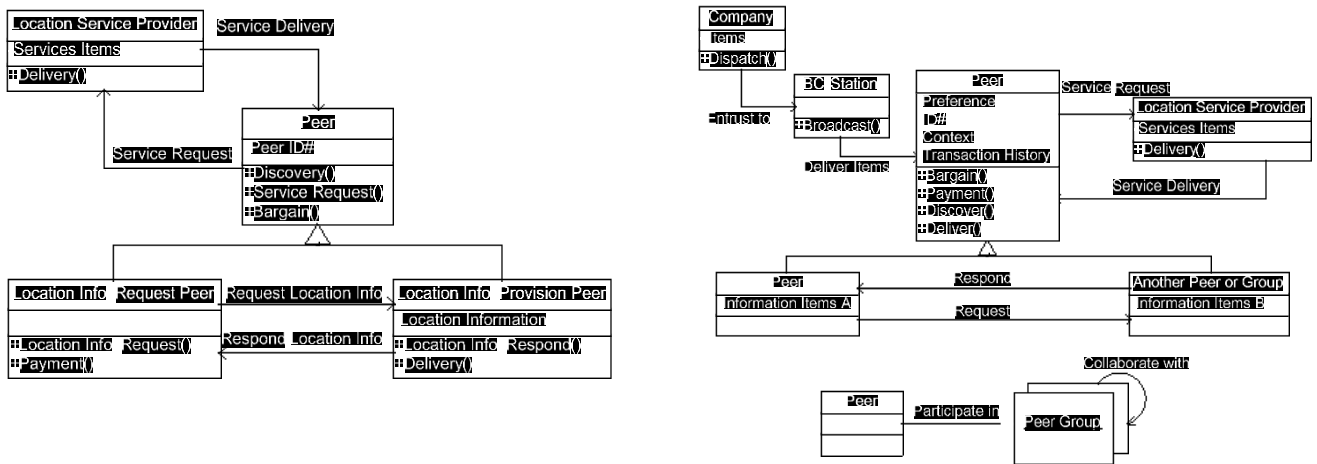

Figure 8. Cooperative peer group scenario

### 3.5 Ambient e-services Infrastructure

#### 4.1 Trust, Reputation and Privacy Issues

Ambient e-services rest the focus on the interactions and collective efforts of the surrounding environments and nearby participating peers. However, in the ambient environments of ad-hoc networks, peers are not familiar with others. Not like the fixed Internet environment, there are no permanent databases of historical data that can be analyzed in the ambient environments. Accordingly, there exist no mechanisms for peers to trust each other in the ad-hoc network domain. However, before cooperating with other peers, peers need to guard themselves and seek who can be trusted based on the peers' reputations.

Privacy may have different meanings and significance to different mobile users. Privacy must be considered together with all other requirements-functionality, usability, performance, costs, security, and so on [6]. The privacy issue is not only important in the fixed Internet environment, but is even more important in the ambient environments.

The privacy concern is the barriers for mobile users join ambient e-services. When users are not feel safety for their sensitive data, they may not participant in such e-services. However, the more participants, the power of ambient e-services will provide. The social effort appears only when the number of the connections reaches above a certain threshold. This is the central problem for developing ambient e-services. Therefore, it is interesting to identify the privacy requirements for ambient e-services. Having decided the privacy issue for ambient e-services application, the interaction between reputation data and trust mechanism become meaningful. The semantic interactions of privacy, reputation and trust are depicted in Figure 11.

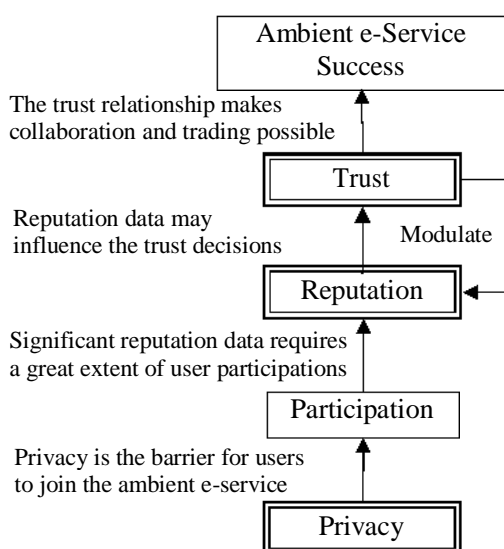

Figure 11. Semantic interactions of Privacy, Reputation and Trust

Many distributed trust management systems have been studied [5, 7, 9]. In a distributed trust system, reputation

information is scattered among parties in the system. For instance, a distributed trust and reputation management framework for e-services was proposed to solve the trust issues in a distributed environment, a distributed broker-based architecture which gather enough information to make a confident judgment of the trustworthiness [5]. Nevertheless, this solution is so designed with the client/server architecture that the brokers and the users live with the fixed Internet. Although this system like the ambient framework, use the collective efforts of the broker peers to build up the trust and reputation management system. However, this may work in the fixed Internet; but it is not suitable for the ambient e-services environments. The rationale is two-fold.

First, peers in ambient environment form a dynamic organization structure. Not like in the fixed Internet environment, peers do not have permanent ID in the ambient environments. A peer enters an ambient environment ambit and gets a temporary peer ID with the technology of mobile identity management [10]. Lack of permanent identification ID, the trust and reputation data cannot be tracked as the framework mentioned. Accordingly, unlike the fixed Internet environment the trust and reputation information cannot be retained. Second, an ambient environment's setting is different from the fixed Internet. In the fixed Internet environment, all brokers can communicate with each other. But in ambient environments, due to peer connections are in a limited range, peers may only connect to the surrounding peers. That makes the framework not applicable to the ambient e-services environments.

In short, there exist distributed trust and reputation systems to provide methods for collecting participators' reputation information for e-services. Unfortunately, it does not suit for the ambient e-services environments due to the difference in environment architectures and design ideas. These challenges are still awaiting future research to counteract.

#### 4.2 Social Issues and Economic Issues

With the advent development of trust, reputation and privacy control for safety of ambient e-services, the relevant social issues and economic issues can be subsequently investigated.

The ambient e-services will develop certain revolutionary business models, which definitely needs to be paid attention in this new ambient era. User interface and the usability of the ambient e-services are quite different from the primal mobile commerce that should also be concerned as a vital social issue awaiting future studies. Not only technical problems being barriers to ambient e-services implementation, the legal issues are also troublesome. How to protect intellectual property in the ambient e-services [11]? How to treat the ambient e-service taxation?

Regarding the economics issues, one of the most important issues is the pricing utility issue. The ambient e-services require several kinds of supporting infrastructures, such as sensor networks, wired/wireless network infrastructures, broadcast stations and the e-service application providers.

The ambient value is delivered with the combined efforts of the supporting infrastructures. Accordingly, how to price ambient e-services and how to divide the revenue between the infrastructure providers will become an important issue.

In certain ambient e-service scenarios, the pricing issue is regarded as the major problem. For example, in the ambient shopping mall scenario, a buyer peer requests information packages from a broker peer. How the broker peer price the service package for different buyer peers is an important issue. Based on the buyer's anxiousness and preference, the broker can provide the buyer several packages of services in different prices. The buyer can also bargain with different brokers before concluding a transaction. In the information items distribution cooperation scenario, mobile users may exchange their information items using the barter mechanism. When bartering with other peers, how to evaluate the value of certain information items and how to make a fair-trade agreement are also belonging to the pricing utility issue. Even for the ambient location information acquisition scenario, the mobile users who own the location information can be treated as sellers holding information valuable to nearby mobile users (who want to engage location-based services but do not have the ability to know the location information). Mobile users with the location information can also price the information items based on buyer's preference and anxiousness.

Besides the pricing issue for the ambient interactions, the issue also occurs to the network infrastructure utility rates rendered for ambient e-services providers.

In cases that the infrastructures are built by governments, different networking enterprises and different service providers, different vertical or horizontal relationships result in different pricing and revenue sharing strategies. In short, how to price the e-services and how to divide the revenues of e-services will unfold as an important problem when the ambient e-services industry forms. Accordingly, the pricing utility issue of ambient e-services is a major economic issue worthy of future intense research.

## 5. CONCLUSIONS AND FURTHER RESEARCH

In this paper, the notion of ambient e-services is defined to identify a new scope of mobile e-services, addressing dynamic collected efforts between mobile users (enabled by M-P2P), dynamic interactions with ambient environments (envisioned by LBS), and the moment of value (empowered by wireless technologies).

Ambient e-Services applications can be divided into two types. One is for the distributed trading; another is for the distributed collaboration. However, social context and significant rapid growth of connections enable by P2P are the two major incentives for applying ambient e-service to such revolutionary business models.

The paper also presents an ambient e-services framework characterizing three supporting stacks. The ambient value stack describes the value process in ambient environments. The ambient technology stack identifies the technology

process to ensure connectivity and security in ambient interactions and cooperation between peers and then realize powerful collective efforts. The environment stack then represents the ambient basics for the collaborations.

We also exemplify several ambient e-service applications. Those applications differ from existing mobile e-services (grounded on client/server design) in terms of the focus of the dynamic interactions between peers in dynamic ambient e-service environments.

Finally, we identify a few future important research issues as follows: (a) trust, reputation and privacy control in ambient e-services environments, (b) pricing utility issues such as how to price the e-services and how to divide the revenues between the ambient e-services infrastructure providers (c) new business model in ambient e-service environments, (d) the taxation problem for ambient e-services (e) the intellectual property rights issues. Many of the traditional issues (such as QoS, fault tolerance, etc.) are also need to be revisited now that suitable solutions for the ambient e-service environments are desired.

## ABSTRACT

As mobile market grows more and more fast, the mobile contents market, especially music contents for mobile phones have record remarkable growth. In spite of this rapid growth, mobile web users experience high levels of frustration to search the desired music. And new musics are very profitable to the content providers, but the existing CF system can't recommend them. To solve this problem, we propose an extended CF system to reflect the user's real preference by representing users in the feature space. We represent the musics using the music's content based acoustic feature like timbral, MFCCs, rhythmic, and pitch contents in multi-dimensional feature space, and then select a neighborhood with distance based function. And for new music recommendation, we match the new music with other users' preference. To verify the performance of the proposed system, the simulation imitating the real user's decision-making and context in conducted. Through comparison with the pure CF, we validate our system's performance

**Keywords:** collaborative filtering, recommender system, mobile commerce, music information retrieval

## 1. INTRODUCTION

With the popularity of the mobile device, technologies and applications, the mobile contents market grows very rapidly. In mobile web environment the multimedia contents like musics, character images, and pictures are the most popular contents, and especially the music contents take a very large portion among them [7]. Although the popularity of the multimedia contents increases very fast, many users frustrate to search the music which they really want because of mobile phone's limitations like the small LCD, tiny keypad, and low memory and music's unique character. Music is hard to explain its feature like tempo, pitch, beat and other spectral features; therefore many users have to search for the desired music by scanning the offered music list one by one or keyword directly. For reducing mobile users' searching efforts and time, contents providers would adopt a recommender system.

Collaborative filtering (CF) is known as the most successful system in recommender systems. But the CF system results in many problems because of its input data representation. The general CF system uses a user-item binary matrix; therefore it is hard to find the real neighbors.

And in mobile environment new musics are very frequently supplied, and their purchasing ratio is considerably high, however existing CF systems can't recommend new musics. A new music doesn't be purchased by anyone, it can't have any ratings.

In this paper we propose the system which can solve these problems. This system extracts the music's various content-based acoustic features like MFCC, tempo, beat, pitch, and then represents these musics in a

multi-dimensional feature space. As doing this, we can identify the neighbors who are really similar to the target. And we can recommend new musics by giving a virtual rating to them in the feature space. This paper describes how can solve these problems in mobile web environment.

The rest of the paper is organized as follows: Section 2 reviews the related work on CF system and music information retrieval. Section 3 gives a brief overview of the proposed system. Section 4 presents the detail recommendation procedure. Section 5 describes the experimental design and evaluations for system. Finally, Section 6 provides our conclusions.

## 2. RELATED WORK

### 2.1 Collaborative Filtering

Collaborative filtering (CF) is the most familiar, most widely implemented and most mature of the technologies in recommender system [1]. It is defined as one which makes recommendations by finding correlations among users of a recommender system [8]. The goal of CF system is to suggest items for a target user based on the user's previous preference and the opinions of other like-minded users. But the CF system has many problems like sparsity, and scalability problem, but these problems have been explored in [2,6,10,11].

Beyond these problems the CF system has a radical problem related its input data representation. The CF system uses a user profile which is composed with  $m$  user's ratings about  $n$  items, and is represented by the  $m \times n$  user-item binary matrix. When a user has purchased a music, a general CF system gives a rating to the music. This causes that the system is hard to identify

user's real neighbors because it uses only common musics for forming the target user's neighborhood. Therefore it is possible that someone whose preference is similar to the target user's preference didn't purchase common musics.

Figure 1. CF system in feature space

Figure 1 shows an existing CF system's problems. Generally the existing CF system selects user A as the target user's neighbor because he purchased the common music. But user A's preference is quite different from target user's preference when their preferred musics represent in feature space. In Figure 1, user B and user C are more similar to the target user rather than user A. Moreover the system can't find hidden neighbors such as user C as the target user's neighbor.

And the CF system has the new-item ramp up problem. The new item ramp up problem is the most difficult and unsolved problem in the CF system. In the mobile web environment, new musics are very frequently provided, their purchasing ratio is very high, and many contents providers try to find out this problem. But the existing CF system can't recommend the new music.

In Section 4 we describe how to solve the problems related the input data representation and new item ramp-up problem.

## 2.2 Music Information Retrieval

As the popularity of digital music has been increasing, efficient and accurate automatic music information processing will be an extremely important issue, and many systems try to classify the music genre, and describe the music contents automatically. Many researches have suggested the automatic music classification methods, especially music feature representation. Many different features can be used for music classification, e.g., content-based acoustic features including tonality, pitch, and beat.

The content-based acoustic features are classified into timbral features, rhythmic content features, and pitch content features. Timbral features are mostly originated

from traditional speech recognition techniques. Typical timbral features include Spectral Centroid, Spectral Rolloff, Spectral Flux, Energy, Zero Crossing, Mel-Frequency Cepstral Coefficients (MFCCs) [9].

Rhythmic content features constrain information about the regularity of the rhythm, the beat and tempo information [9]. Pitch content features deals with the frequency information of the music bands and are obtained using various pitch detection techniques.

## 3. OVERALL PROCESS

We design to deal with the problems of the CF system's input data representation and a new music recommendation on the mobile web. The system follows a general CF process, and is added a new music recommendation module.

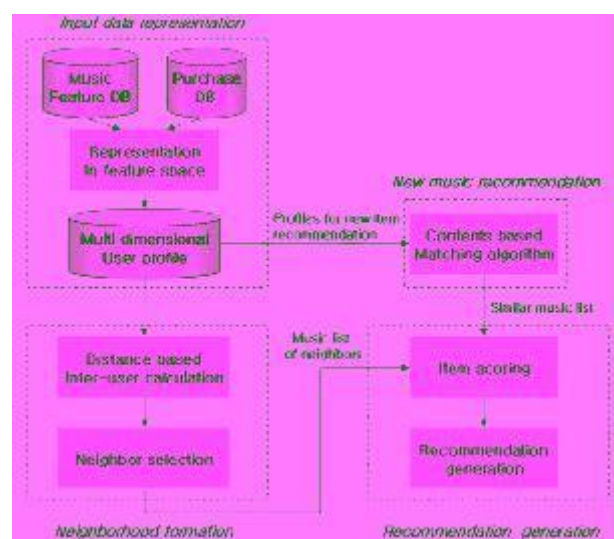

Figure 2. The overall process

*The input data representation module* creates a user profile using the music feature database and purchase database. The Music feature database is organized with the features like timbral, MFCC, rhythmic, and pitch features, which are extracted by the MARSYAS system [12]. The Purchase database is organized with the individual user's purchasing or pre-listening histories. Using this module, the system reflects the individual user's preference, can represent each user as a point in the multi-dimensional feature space.

*The neighborhood formation module* selects the target user's neighbors. The existing CF systems calculate the inter-user correlation by the Cosine formulation or Pearson Coefficient; however this way is hard to identify the neighbors who are really close to the target user as described Section 2.1. Therefore this module calculates the distance between the target user and other users to identify his real neighbors, and forms his neighborhood. Finally it gathers neighbors' purchasing or pre-listening musics, and gives the list of these musics to the recommendation generation module.

The recommendation generation module creates a recommendation list for the target user. This module scores the musics which neighbors purchased or pre-listened. As many neighbors purchase or pre-listen, this score increase.

The new music recommendation module solves the new item ramp-up. This module finds the most similar music by the content-based matching algorithm, and generates a similar music list, and gives it to the recommendation generation module.

#### 4. RECOMMENDATION PROCEDURE

##### 4.1 User Profile Creation

A user profile, which is the key component for CF system, includes information about user's preferences on music. This module is organized by two phases, the first phase is the extraction music's features, and second phase is the construction of user's preferred music set.

###### Phase 1: The extraction music's features

For extracting the music's features, we use the described features in section 2.2. For getting these features, we use the MARSYAS system [10]. This system extracts the timbral, MFCCs, rhythmic, and pitch content features. The timbral features consist of average spectral centroid, average spectral rolloff, average spectral flux, energy, and zerocrossing. MFCC features consist of the mean or each of the first five MFCC coefficients over the frames. The rhythmic features consist of six features from the rhythm histogram. Pitch features are five features from the pitch histograms.

The system extracts the whole music's features, represents the individual musics in the multi-dimensional feature space as a point.

###### Phase 2: The construction of user's preferred music set

The general CF system uses the user-item binary matrix, but we use the user's preferred music set as the user profile. In the mobile environment users could do actions like purchasing, pre-listening or giving up buying a music. We set a rating about user's action assuming that these actions reflect user's preference about the music. Therefore we define a rating about user's action.

If user 'a' has purchased music 'x', it could be given a rating ' $R_a^x$ '. We define the ' $R_a^x$ ' as the following:

$$R_a^x = \begin{cases} 1.0 & \text{If user 'a' has purchased music x} \\ 0.5 & \text{If user 'a' has pre-listened music x} \\ 0 & \text{If user 'a' has done any action to music x} \end{cases} \quad (1)$$

With the music which user 'a' has done any actions to and its ratings, the system composes the individual user's

preferred music set. We defined user a's preferred music set as the following:

$$\text{Preferred music set} = \{(x_1, R_a^{x_1}), \dots, (x_{N_a}, R_a^{x_{N_a}})\} \quad (2)$$

$N_a$  is the number of the music whose  $R_a^x$  is non zero, and  $x_i$  is the music which user 'a' purchased or pre-listened.

The illustration of the preferred music set is showed in Figure 3.

Figure 3. User's preferred music set

In Figure 3, user 'A', 'B', and 'C' are represented in the 2-dimensional feature space. The system represents all of the musics in this space, and binds the purchased and pre-listened musics as user's preferred music set by a dotted line. As shown in Figure 3, the user A's preferred music set includes 7 musics, and consists of 2 purchased musics and 5 pre-listened musics, which reflect his preference. User B and C's preferred music set also are composed by this way.

As doing this way, the user profile is composed by the whole users' preferred music sets.

##### 4.2 Neighborhood Formation

Because whole users and musics are represented in multi-dimensional feature space, the system can find the target user's neighbors with distance based inter-user similarity calculation. If a user is close to the target user in this space, he could have a similar preference the target user's one. To calculate the distance between users, we assume that a user's preferred music set is a cluster.

There are many inter-cluster distance function, and the favorite function is the Centroid Euclidean distance function. This function is very simple and easy to calculate, but it works well in a condition that each cluster is fairly distributed and its form is a circle. However the individual users' preference isn't same and their distributions are difference from each other in shown Figure 3. Therefore we use the Average

Inter-Cluster distance function [3] which the distance function considering the variance of two clusters, and we modify this function a little as the following:

$$d(a, b) = \frac{\sum_{y=1}^{N_a} \sum_{x=1}^{N_b} \sqrt{\frac{\sum_{i=1}^N (R_a^x \cdot F_x^i - R_b^y \cdot F_y^i)^2}{N}}}{N_a \cdot N_b} \quad (3)$$

Where  $d(a, b)$  is the distance function between user  $a$  and  $b$ ,  $N$  is the number of features.  $N_a$  and  $N_b$  is the number of user  $a$ 's and user  $b$ 's preferred musics, respectively.

$R_a^x$  and  $R_b^y$  is the rating about music  $x$  by user ' $a$ ' and about music  $y$  by user ' $b$ ', respectively.  $F_x^i$  and  $F_y^i$  is the value of  $i$ th feature of music  $x$  and music ' $y$ ', respectively.

We sort the neighbors ascendingly according to the distance value, and then select the  $L$  neighbors. Finally we determine the neighborhood set  $H$  for target user  $c$ , and  $H = \{h_1, h_2, \dots, h_L\}$  such that  $c \notin H$ .

### 4.3 Recommendation Generation

The proposed system generates a list of  $n$  musics,  $R = \{r_1, r_2, \dots, r_n\}$  such that  $r_i \notin \{\text{the music that the target user } c \text{ has already purchased}\}$ .  $PLS(c, x)$  denotes the Purchase Likelihood Score of the target customer  $c$  on music  $x$ , and is computed as the following:

$$PLS(c, x) = \frac{\sum_{a \in H} (R_a^x - \bar{R}_a) \times \text{sim}(c, a)}{\sum_{a \in H} \text{sim}(c, a)} \quad (4)$$

Where  $\bar{R}_a$  is the user  $a$ 's average rating,  $u, w$  are the other users included the neighborhood set  $H$ . Because we use the distance function, we have to covert these distance values into similarity values, and normalize them.  $\text{sim}(c, a)$  function denotes the similarity between target user  $c$  and user  $a$ , and it is computed as the following:

$$\text{sim}(c, a) = \frac{\text{Max}_{u, w \in H} [d(u, w)] - d(c, a)}{\text{Max}_{u, w \in H} [d(u, w)] - \text{Min}_{u, w \in H} [d(u, w)]} \quad (5)$$

### 4.4 New Music Recommendation

In mobile web environment, new musics are frequently provided and their purchasing ratio is very high, but the existing CF system can't recommend new musics. The general CF systems use the common items to find neighbors. Therefore they can't recommend musics that anyone didn't have been purchased. New musics can't be purchased by anyone, therefore they don't have ratings. If a new music has a rating, it could be recommended. To solve this problem we give a virtual rating to the new music.

*Phase 1: Determination of new musics recommendation*

New music also has the above mentioned features, which can be extracted. The proposed system extract new musics' features by the same way described in Section 4.1, and represent the musics in multi-dimensional feature space. Although new music can't have any ratings, it could be included in any user's preferred music set. Therefore we define a condition to determine new music's recommendation, as the following:

$$\begin{aligned} &\text{If } x_{\text{new}} \in a \text{'s preferred music set} \\ &\text{then } x_{\text{new}} \text{ is recommended} \end{aligned} \quad (6)$$

Where  $x_{\text{new}}$  is a new music,  $a \in H$ ,  $H = \{c, h_1, h_2, \dots, h_L\}$ , and preferred music set is defined in (2). Why target user  $c$  is included in the neighborhood set  $H$  is that the new item doesn't purchased by target user, and the system have to reflect the target user's preference as much as possible.

The target user's preferred music set reflects his preference, therefore a new music comes in the target user's preferred music set or his neighbor's one, it would be preferred by them. The illustration of this is showed in Figure 4.

Figure 4. New music recommendation

Case 1, 2, and 3 are new musics and represented in the feature space. As shown Figure 4, case 1 and 2 can be recommended because they are satisfied the condition, but case 3 isn't. Therefore the system determines to recommend the case 1 and 2.

*Phase 2: Finding the most similar music*

We determine whether to recommend the new music or not, but it still doesn't have a rating. To give a virtual rating to the new music, the system searches for the most similar music where it is included. If music  $x$  and  $y$  in the same user's preferred music set are very similar, they would be given the very similar rating by that user. Most similar music is founded as the follows:

$$\min_{y \in a} \{d(x, y)\} = \sqrt{\frac{\sum_{i=1}^N (x_{\text{new}}^i - y^i)^2}{N}} \quad (7)$$

Where  $x_{new}^i$  and  $y^i$  is the  $i$ th feature value of new music  $x_{new}$  and music  $y$  included user  $a$ 's preferred music set, respectively.

The illustration of this is showed in Figure 4. As shown in phase 1, the case 1 and 2 can be recommended, but we see the case 2. The case 2's most similar music is the music A, and its rating value is 1.0. Therefore the case 2 is given the rating 1.0.

Through this way new music can have a rating, with this rating the system calculates new item's PLS value. Therefore we generate a recommendation list with combination of old musics and new musics.

## 5. EXPERIMENT EVALUATION

### 5.1 Experiment Design

For the purpose of the performance evaluation of the proposed system, we developed a simulation program imitating the real user's decision-making and context in conducted. And we use two databases for our experiment. The first dataset contains features of 500 songs which are the most popular songs in mobile environment. The second dataset contains 1000 users' utility. We assume that the individual user's preference is different from each other, and they have their own utilities. Therefore we create utility functions for 1000 users.

Because the CF system has to start with a few transactions, we make the initial transactions. This is conducted by user's utility, and transactions organized by three purchase and five pre-listened transactions. With these transactions, we conduct the initial experiment.

For the new music recommendation, we offer the 100 new musics to the system, conduct the second experiment. We give the new music with no ratings to the system, evaluate the system's performance.

### 5.2 Evaluation

To evaluate our system, we use two matrix widely used in the information retrieval community namely recall and precision. Each matrix is defined as the following:

$$\text{Recall} = \frac{\text{Purchased musics}}{\text{all recommended musics}}$$

$$\text{Precision} = \frac{\text{Recommended musics}}{\text{all purchased musics}}$$

However these two measures is often conflicting in nature. Then we use the standard F1 metric that gives equal weight to them both and is computed as the following:

$$F1 = \frac{2 \cdot \text{Recall} \cdot \text{Precision}}{\text{Recall} + \text{Precision}}$$

We compute F1 for each individual user and calculate the average value to user as our matrix.

## 6. CONCLUSION

Because of an information overflow for multimedia contents like music, character images, and movie, mobile users need recommendation systems. Especially, music is the most popular contents in the mobile contents market, but there are few music recommender systems to aid mobile users to search musics which they really want. The CF system is known to be useful, but it is inadequate for the multimedia contents. Moreover CF system can't recommend the new item which is very frequently supplied and most contents providers want to sell out. We proposed the extended CF system which can solve these problems in the feature space and verify our system's performance.

## An Overview of the Impact of National Culture on the Adoption of Mobile Commerce

Nasrin Rahmati

School of Business Systems, Faculty of Information Technology, Monash University, Wellington Road, Clayton, Victoria 3800, Australia

### ABSTRACT

The predictions that mobile technologies would greatly benefit both firms and individuals have now come under increasing scrutiny. Some of the authors suggest that the industry must move beyond “nice-to-have” services and devise new “must-have” services that positively affect people’s lives (Jarvenpaa, et al. 2003). Others believe that mobile commerce is facing many obstacles as an emerging market, this is particularly so in some countries such as United States (Venkatesh et al, 2003). This study provides a brief overview of the literature on the impact of national culture on the adoption of mobile commerce. The study focuses on Singapore, Japan, UK and Germany.

**Keywords:** Mobile Commerce, Mobile payment, National Culture

### 1. INTRODUCTION

This study follows the suggestion made by Malone (2001). He suggests that academic Information Systems researchers accelerate the rate at which businesses learn from each other's experiments. The IS researchers observe the experiments, gather and analyse data in systematic and interesting ways and disseminate the lessons to anyone who wants to listen. Mobile commerce is distributed computing that involves elements whose location changes in the course of computing (Samaras, 2002). The opportunities associated with mobile commerce are the ability to compute, to do commerce and access information from anywhere and at any time. Payment over mobile networks, while bearing some relation to fixed-line eCommerce, will be very different. Firstly, mobile devices are unlikely to support traditional online shopping, such as buying a book or piece of furniture, even if higher speed mobile networks are available.

The mobile environment is, however, ideally suited for payments for digital content, and for payments that use the device as a secure, mobile payment instrument. Unlike eCommerce, mobile commerce is inherently global given the popularity of mobile phones in every major market worldwide.

It has been suggested by many authors (eg, Khalifa and Cheng, 2002) that mobile commerce is the next big wave of business. It is also suggested that given the already high mobile phone penetration the rapid growth of mobile commerce is assured. It is generally agreed that mobile phones have offered great convenience, but they lack the screen space and bandwidth available in traditional desktop computers. Although several technologies such as WAP/WML, Palm.Net, and HDML, have been developed specifically for mobile devices, it is agreed that there is no successful and dominant technology for displaying Web pages over mobile devices (Urbaczewski, et al, 2002).

Figure 1: Cellphones and PCs in 2002 from “The Diffusions of Mobile Data Applications” by Elizabeth Fife and Francis Pereira

Figure 1 shows the difference between PC and Cellphones adoption in different countries. It is also suggested that although the use of mobile data applications has grown across the world, the adoption rates of these applications and services has been very uneven across countries. Figure 2 shows the different growth rates in adoption of PC and Cellphones by different countries.

Many of the standards designed to transfer information from one terminal to a mobile device (most notably with SMS, a fairly mature technology based on text messages of 160 characters or less), can also originate with a mobile device. Some of these technologies are

more developed than others, and some cultures and nations use these technologies more widely than others. Table 1 shows the relative penetration of SMS messaging in different nations (see Table 1).

It is important to capture the influence of the national environment, as contrary to early predictions, mobile commerce has not been adopted similarly by different nations. It has been suggested that those with well-developed infrastructures, resources and skills have gained the initial advantage (eg, Brown et al. 2004). In December 2000, Germans sent 1.8 billion SMS messages and Britons sent 803 million messages, both up about 50% from the levels listed in the table.

Figure 2: PCs, and growth rates of PC and Cellphones penetration (2000-2002) from “The Diffusions of Mobile Data Applications” by Elizabeth Fife and Francis Pereira

Nation	Population (millions) (June 2000)	Mobile Users (millions)	SMS sent per month (millions)	SMS/mobile user/ month
Australia	18.6	8.1	30 (3/2000)	3.7
Finland	5.2	3.4	175	51.47
Germany	82	28.2	1000	35.46
Norway	4.5	2.9	150	51.72
Philippines	73	4.1 (6/2000)	540 (12/2000)	131.7
Sweden	8.8	5.4	175	32.41
UK	59	28.3	400	14.13
USA	280	134 (7/2000)	20 (3/2000)	0.15

Table 1: Penetration of SMS in everyday life (Urbaczewski, et al. 2002)

SMS accounts for 12 percent of European mobile operators' revenues. According to Forrester, 156 million SMS messages are sent in Europe every month. Nearly 90 percent of these messages are person-to-person (P2P) traffic. Application-to-person (A2P) traffic, such as weather reports sent by SMS, accounts for 11 percent of traffic. Forrester predicted SMS revenues to account for 47 percent of total messaging revenues in 2007. Multimedia messaging (MMS) will

account for 32 percent, Instant Messaging (IM), 10 percent, Mobile Email, 9 percent, and Enhanced Message Service (EMS), 3 percent. Forrester also forecasted that SMS traffic will rise to 11.5 billion messages per month in 2004. Still why is short message service (SMS) messaging so popular in Europe but barely used in the US? The use of SMS has been relatively low in the United States, as compared to Asia and Europe, where, in Europe alone, it is a \$14

billion dollar market. Of the estimated 576 million people reported to be using SMS, 256 million are in the Asia-Pacific Region and 196 million are in Europe. One of the crucial differences between European and

American companies, according to a survey conducted by Protogeris (2002) was the payment system for on-line sales.

Figure 3: Payment systems for online sales a comparison between businesses from EU and US

Lee et al. (2002) used values as the core concept of culture in their comparative cultural study on the adoption of mobile commerce by Japan and Korea. The authors focused on values as the core concept of culture to address the impact of values on people behaviour and the attitudes which in turn affect the ways people behave in their lives (also cited in Geertz, 1973; Straub et al. 2002, Trompenaars and Hampden-Turner, 1993).

Xu et al. (2004) include different factors under Technology, Organizational and Environmental Contexts, to compare the ecommerce adopting countries with non-adopters. At technology level they are concerned with 1- technology readiness- which refers to technology infrastructure and IT human resources. 2- technology integration- which refers to the extent of inter-connection among IT systems and databases within and beyond firm boundaries. At the organizational level they are concerned with 1- firm size- which refers to the number of employees in the organization, 2- global scope and 3- managerial obstacles. Under the Environmental Context they look at competition intensity and regulatory environment. The present study examines Hofstede's work on national culture. Then using the culture level factors provided by his study compares the use of mobile commerce in Singapore, Japan, UK and Germany.

## 2. DIFFERENT APPROACHES TO CULTURAL STUDIES

There are different approaches to study the national culture impact on mobile commerce in different countries. Lee et al. (2002) on the basis of the findings of previous research on values (eg, Sweeney and Soutar, 2001, Sheth et al., 1991) suggest four dimensions of values. Their suggested dimensions are

Functional Values; Emotional Values; Social Values and Monetary Values. They use this four sub-value structure to interpret the different usage patterns of mobile internet users in Korea and Japan. Their findings indicate a significant difference between Korean and Japanese users in terms of the suggested dimensions of value structure.

Markus and Soh (2002) argue that although effects of national culture are an important line of research on global information management, the researchers should not lose sight of structural conditions related to ecommerce. They suggest structural conditions as physical, social and economic conditions that shape ecommerce activity.

Different models have been suggested for the adoption of any new technology, eg mobile commerce technologies. One of the suggested models is suggested by Xu et al (2004). To study the contextual factors that influence the innovation process they use earlier work by Tornatzky and Fleischer (1990) and suggest three aspects of a firm's context that influences the process by which it adopts and implements technological innovations: 1-Technological Context (both internal and external technologies with impact on the company). 2- Organizational context (eg, size, scope, managerial structure, etc). 3- Environmental context (eg, industry, competitors, government, etc). There are also suggestions regarding the combinations of many factors such as National Culture, Infrastructure and Access Costs on the adoption of mobile commerce in different parts of the world (Heales, 2004).

### 2.1 Hofstede's Framework On Culture

Hofstede identified five different variables in the study of culture, namely power distance, uncertainty avoidance, individualism, masculinity and long-term

orientation. Each of the five concepts of culture is defined as follows:

- Power distance: the degree in which members of a society accept that power is unfairly distributed (Teng, Calhoun, Cheon, Raeburn and Wong, 1999). Hofstede believes that High Power distance at work place means that subordinates expect to be told what to do (Hofstede, 1980).
- Uncertainty avoidance: the extent to which people in a society are unnerved by the unknown and ambiguity, thus leading them to look for conformity (Teng, et.al., 1999). Hofstede (1980) suggests that societies with high uncertainty avoidance need written or unwritten rules. They need formalization and standardization.
- Individualism: the degree in which a society believes that individuals should take care of themselves and their family as opposed to collectivism, whereby there is absolute loyalty towards a larger group (Teng, et.al., 1999). According to Hofstede (1980) in a collectivist society relationship prevails over task and values standards differ for in-group and out-groups.
- Masculinity: the extent in which a society adopts a competitive and assertive nature, constantly striving to achieve success over others as opposed to femininity where members of a society care for everyone and cherish relationships with others (Teng, et.al., 1999)
- Long-term orientation: the extent in which a society embraces tradition and values long-term commitments. A high long-term orientation society is said to be more resistant to change. A low long-term orientation society is one where traditions are not

generally observed and thus are more receptive to change (International Business Centre, 2003)

Heales (2004) only uses Uncertainty Avoidance, Performance Orientation (Javadian, 2001) and Future Orientation (Kluckhohn and Strodtbeck, 1961). Performance orientation is the degree to which a society encourages and rewards group members for performance improvement and excellence. Singapore, Hong Kong and New Zealand score the highest, Russia, Argentina and Greece the lowest, whereas Australia has a medium performance Orientation. Future Orientation is the extent to which a society encourages and rewards future-oriented behaviours such as planning and investing in future. Countries with high future orientation include Singapore, Switzerland and Netherlands.

### 3. A CROSS-CULTURAL REVIEW

Using Hofstede's cultural framework above, four different countries will be examined to determine whether cultural differences in European and Asian countries will have an impact on the adoption of mobile payment applications. In this research, Germany, Britain, Singapore and Japan are used as case studies since mobile payments have been widely established in these countries. Tables will be used to summarise the various findings.

Judging from table 2 below, it appears that both regions although have different power distance indexes; both are receptive to mobile technologies.

JAPAN	SINGAPORE	GERMANY	BRITAIN
Medium power distance score = 54	High power distance score = 74	Low power distance score = 35	Low power distance score = 35
Mobile phone used as a tool to reflect social status (Barnes & Huff, 2003) This can have beneficial impact on the adoption of mobile payment.	Strong government policies imposed to ensure smooth and controlled adoption into the global networked economy (Warshauer 2001).	Mobile phone is not a status symbol (Hofvenschiold, 2003)	Mobile phone is not a status symbol (Hofvenschiold, 2003)

Table 2: Power Distance Between The East And West

However, it seems that there are some social pressure in adopting mobile technology in Asian countries, but this is absent in European countries. This is in agreement with the findings of Hofstede study. He

believed that in High power distance nations the adoption of the technology, if encouraged by the government or the superiors have a positive impact on the adoption by the members of the society.

JAPAN	SINGAPORE	GERMANY	BRITAIN
High uncertainty avoidance score= 92	Low uncertainty avoidance score= 8	High uncertainty avoidance score = 65	Low uncertainty avoidance score= 35
Japanese people are used to having innovative entertainment devices being developed regularly. Thus there is not much uncertainty about Imode (Barnes & Huff, 2003)	The adoption process of mobile payment technologies is controlled and regulated by government organisation (IDA, 2003) Thus eliminating uncertainty.	Mobile applications in Germany are popular, but not as much interest as Japan  The reason being personal information security is a major concern for Germans (Martin, 2003)	More tolerant to innovative ideas, yet not capable of attaining full-scale implementations due to considerable demand for detail and timeliness (Hofstede, 1997)  Mobile payment still not widely used as compared to Japan

Table 3: Uncertainty Avoidance between East and West

Based on table 4, Asian countries are more collectivist as compared to European countries. Societies with low individualism believe in 'learn how to do' and 'learning is for the young'. This can mean that the younger generation are expected to adopt the new technology faster than the older generation. On the

other hand in countries with high individualism, there is a belief about 'permanent education'. This combined with the 'self-interest' should serve as a positive impact on the adoption of the mobile commerce by different generations alike.

JAPAN	SINGAPORE	GERMANY	BRITAIN
Medium individualism score= 46	Low individualism score= 20	High individualism score= 67	High individualism score= 89
Main application of Imode is E-mail. (Mizukoshi, Okino & Tardy, 2001). Thus suggesting keeping in touch is important to the Japanese	Increased in work hours and mobility in society resulted in mobile phones being commonly used to keep in contact with family (Burgess, 2004)	Paybox, a mobile payment application Imode is more popular than Imode. (Pousttchi & Zenker, 2003). Thus suggesting personal convenience is more important.	Mobile entertainment and small payments like M-pay and M-live are most popular mobile applications (Shannon, 2003). Thus suggesting personal convenience is more important.

Table 4: Individualism between East and West

It appears that there are some conflicting findings into whether masculinity can affect the rate of mobile payment adoption in countries of different regions. This is because in Western countries where masculinity is high, people do not necessary use the mobile phone as a tool to achieve competitiveness. On the other

hand, people in Eastern countries such as Japan, a highly masculine society, tend to use the mobile phone to gain a competitive edge. Therefore, it should be noted that masculinity does not necessary influence the rate of adoption of mobile payments in western countries as it does to eastern countries.

JAPAN	SINGAPORE	GERMANY	BRITAIN
High masculinity score= 95	Medium masculinity score= 48	High masculinity score= 66	High masculinity score= 66
Need to read important e-mails and news anytime anywhere to be competitive (Fife & Pereira, 2003).	Mobile payment applications mainly used for making payments such as paying for car parking (IDA, 2003). Thus suggesting personal convenience than competitiveness	Relatively low interest for Imode in Germany as compared to Paybox, which is used for making mobile payments, attracted more users (Pousttchi & Zenker, 2003). Thus suggesting personal convenience than competitiveness	Mobile entertainment and small payments like M-pay and M-live are most popular mobile applications (Shannon, 2003). Thus suggesting personal convenience than competitiveness.

Table 5: Masculinity between East and West

JAPAN	SINGAPORE	GERMANY	BRITAIN
High long term orientation score= 80	Medium long term orientation score= 48	Low long term orientation score= 31	Low long term orientation score= 25
Imode is locally developed and proved very popular. No foreign mobile commerce application in Japanese market as yet.	A few locally developed mobile payment applications with foreign company collaborations  Government regulates the rate of adoption (IDA, 2003)	A few locally developed and foreign mobile payment applications available on the German market.	A few locally developed and foreign mobile payment applications available on the British market

Table 6: Long term Orientation between East and West

As can be seen from table 5, it can be concluded that in eastern countries, although have differing long-term orientation indexes; the people are generally more receptive of locally developed mobile payment technologies which is developed over time, for example iMode. Western countries on the other hand, have a number of local and foreign mobile payment applications being successfully implemented into the market.

addition to examining the impact of national culture on the adoption of mobile commerce one should not lose sight of physical, social and economic arrangements that shape ecommerce business models and influence individual use of these technologies. The next step would be to develop a mobile commerce adoption model by individual users considering different factors including national culture, economic, social, geographic and technological infrastructure.

The above review suggests that culture is a complex notion which is best assessed in terms of multiple dimensions. Markus and Soh (2002) suggested that in

## ABSTRACT

Mobile phones adoption and diffusion is a practical issue that has significant implications for e-commerce and m-commerce development. Examining the adoption of mobile phones from the well-developed theoretical foundation of innovation diffusion theory may clarify some significant factors that affect the adoption decision. Moreover, with the understanding of the influence sources of mobile phones adoption, the businesses can evaluate the number of mobile devices that can support the mobile commerce, plan the wireless capacity, formulate mobile commercial strategies, design more sophisticated applications, and launch more innovative wireless services.

In this research, we explore the sources of influence in the adoption of mobile phones in Taiwan, which mobile phone penetration ranks No.1 worldwide. We test adoption and diffusion pattern using three classical models: internal influence, external influence, and mixed influence models. Our findings suggest that mixed influence is the dominant influence factor in the diffusion of mobile phones. That is, the decision to become a new adopter of mobile phones is mainly determined by the positive influence of existing adopters and mass media channels.

**Keywords:** Innovation, Diffusion, Mobile Phone

## 1. INTRODUCTON

Explosive growth of the mobile phones over the past decade has greatly increased interest in its potential use of mobile commerce, especially as a vehicle for transactions. Plenty of mobile phones have provided consumers to perform various mobile commerce-related tasks without regarding to time and location. Therefore, tracking the adoption and diffusion pattern of mobile phones from the well-developed theoretical foundation of innovation diffusion theory is an increasingly important task, especially for mobile commerce planners. Examining the adoption of mobile phones from the well-developed theoretical foundation of innovation diffusion theory may clarify some significant factors that affect the adoption decision. With the understanding of the influence sources of mobile phones adoption and tracking the diffusion process, the businesses can evaluate the number of mobile devices that can support the mobile commerce's future use, plan the wireless capacity, formulate mobile commercial strategies, design more sophisticated applications, and launch more innovative wireless services.

Several behavioral models, such as Technology Acceptance Model, Theory of Reasoned Action, and Theory of Planned Behavior, for explaining and predicting the adoption and usage of technology have been proposed in the information systems literature. These studies primarily focused on surveys of individuals' perceptions but do not explore the sources of influence in the adoption of innovation within a social system. In this paper, we investigate the adoption process of mobile phones in Taiwan, which mobile phone penetration ranks No.1 worldwide, with

well-developed theoretical foundation of innovation diffusion theory. By means of the mathematical diffusion models, the process by which the innovation (mobile phones) is communicated through certain channels over time among the members of a social system can be analyzed. Three classical diffusion models [Loh et. al., 1992; Venkatrman, 1994; Hu et al., 1997], external influence model, internal influence model, and mixed influence model, are applied to depict the successive increase in the number of mobile phone adopters over time. The validation consequences will show us which factors influence the speed and specific course of mobile phone diffusion processes and may clarify some significant factors that affect the adoption decision. The research results will also allow us to have better understanding of the mobile phone growth, explore the sources of influence in the adoption of mobile phones, and illustrate possible implications on mobile commerce.

The rest of the paper is organized as follows: Firstly, we would like to briefly outline the current status of mobile communications in Taiwan. Then we will review the literature related to diffusion of innovation theory. Secondly, we would like to discuss the classical mathematical models of the diffusion of an innovation as developed by Mahajan and Peterson [1978, 1979, 1985]. At length, we will present the research results with longitudinal statistics and discuss their implications.

## 2. RESERARCH BACKGROUND

### 2.1. Mobile Phone Telephony

A mobile phone is a portable telephone which receives or

sends messages through base station network. Each base station overlaps other stations and has a range of 6-9 kilometers. Most people use the term “cellular phones” to mean all mobile phones using cellular technology, including GSM (Global System for Mobiles), CDMA (Code Division Multiple Access), DECT (Digital Enhanced Cordless Telecommunications), and traditional analog mobile technology. In a mobile phone network, users can roam with their mobile device and be handed off from one base station to the other. Mobile phones not only support voice calls, but send and receive data such as text, pictures, and short messages. Newer models also allow for accessing WAP (Wireless Application Protocol) services, have a built-in digital camera, and have some applications and entertainment programs integrated into them. At the present, mobile phones are changing to include the ability to access the World Wide Web and providing e-mail capability. They offer full Internet access using technologies such as GPRS (General Packet Radio Service).

## 2.2. The Status of Mobile Communications in Taiwan

The past decade has seen tremendous growth in the mobile sector in Taiwan. According to ITU (International Telecommunication Union) World Telecommunication Indicator Database, the number of mobile phone subscribers makes Taiwan to take the top seat in Asian mobile phone penetration ranking in 2000 and the 1st place in worldwide level in June of 2002. Relatively cheap rates, variety services, and aggressive operator subsidization programs have all contributed to Taiwan's mobile growth. With a population of about 23m, Taiwan is one of Asia's most dynamic markets. Figure 1 portrays the critical events and historical growth trend of mobile phone subscribers in Taiwan.

The high growth rate also means that service providers are facing a quickly maturing market. Despite aggressive marketing campaigns, operators are discovering that the pace of growth cannot be maintained. The market is quickly shifting from one focused on customer acquisition to one that is examining how to increase revenue with new service. The operators in Taiwan have begun to concentrate on improving earning ability base on its existing customer. At the present, the mobile commerce, mobile internet, short message service, WAP service, entertainment programs, and data/value-added services have been regarded as the major revenue sources of Taiwan's mobile phone operators. For example, data/value-added services usages last year grew 426% and 284% respectively. Moreover, personalization, such as interchangeable covers and user defined ring tones, has also helped in the uptake by the teen's market.

## 2.3. Diffusion of Innovation Theory and Diffusion Models

The diffusion of innovation theory provides an

explanation of how innovations diffuse through a social system. Diffusion is defined as the process by which an innovation is communicated through certain channels over a period of time among the members of a social system [Rogers, 1995]. Four key elements determine the characteristics of diffusion process of an innovation: innovation, time, social system, and communication channels. Rogers [1995] describe innovation as “any idea, object or practice that is perceived as new by the members of a social system... Time relates to the rate at which the innovation is diffused or the relative speed with which it is adopted by members of the social system... Social system consists of individuals, organizations, or agency ... are potential adopters of innovation... Communication channels are means by which information is transmitted to or within the social system”. As described above, communication channels have a significant effect on the diffusion pattern. Bass [1969] has categorized communication channels as either mass media messages or interpersonal communication channels. Mass media employ radio, television, newspapers, or other channels which enable a source of one or a few members within a social system to reach an audience of many. In contrast, interpersonal communication channels transmit an innovation to members within a social system via face to face communication between two or more individuals [Rogers, 1995]. Traditionally, the distribution of adopters over time is expected to be a bell-shaped curve. Adopters can be categorized into five categories by the different standard deviation from the mean: innovators, early adopters, early majority, late majority and laggards [Rogers, 1995].

Figure 1. Historical Growth Rates

Since diffusion is the adopting process of the users among a social system, diffusion pattern, a line that is often a nonlinear curve, can describe the successive increase in the number of adopters or adopting units over time. Diffusion models are mathematical models that can be applied to depict the diffusion pattern, predict future distribution of an innovative technology, illustrate possible effect of a policy, or marketing of a new product. Mahajan and Peterson [1985] indicated three general

diffusion models: the external influence model, internal influence model and the mixed influence model. External influence model means the diffusion rate is affected by the mass media. The coefficient of diffusion is a constant, and the diffusion model was expressed as equation (1). Internal influence model hypothesize that the diffusion rate is affected by the interpersonal communication. Earlier adopters influenced the later adopters. The coefficient of diffusion is a function of the cumulative number of adopters, and the diffusion model was expressed as the equation (2). Mix influence model, equation (3), combined the effect of external and internal influence. All three general diffusion models are in the following:

$$N(t) = m(1 - \exp(-pt)) \quad \text{---- (1)}$$

$$N(t) = \frac{m}{1 + \frac{m - m_0}{m_0} \exp(-qmt)} \quad \text{---- (2)}$$

$$N(t) = \frac{m - \frac{p(m - m_0)}{p + qm_0} \exp(-(p + qm)t)}{1 + \frac{q(m - m_0)}{p + qm_0} \exp(-(p + qm)t)} \quad \text{---- (3)}$$

Where:  $N(t)$  is the cumulative number of adopters,

$$N(t) = \int_{t_0}^t n(t) dt;$$

$N(t=t_0) = m_0$ , the initial number of adopters in a social system;

$\frac{dN(t)}{dt}$  = diffusion rate at time  $t$ ;

$m$  = total number of potential adopters in a social system.

In addition to three classical diffusion models, a rich body of studies adopt Exponential model to fit the diffusion pattern. Gurbaxani [1990] describes that an S-curve specification can be approximated by an exponential curve and characterized by a constant ratio of change when an innovation is in its early stages. Moreover, parameters of the diffusion models can be estimated in nonlinear estimation procedures [Srinivasan, 1986] or maximum likelihood estimation procedures [Schmittlein, 1982].

Diffusion models are built under some kind of patterns rather than random process. Therefore, it is necessary to verify the distribution of diffusion patterns after calculating the parameters. Mahajan et al. [1988] propose the White-Noise model, equation (4), to be the null hypothesis in order to test the validity of diffusion model. It means that diffusion model is useful when it can explain better than the White-Noise model on the innovation adoption process.

$$X(t) = x(t-1) + e(t) \quad \text{---- (4)}$$

Where:  $x(t)$  is the number of adopters at time  $t$ ;

$e(t)$  is assumed to be  $N(0, s^2)$

We adopt J-test [Davidson and Mackinnon, 1981] to test each influence model against White-Noise model, because White-Noise model is suitable for linear

problems and J-test was designed to test the specification of an econometric model in the presence of an alternative model that purport to explain the same phenomenon.

## 2.4. Studies of Innovation Diffusion

A rich body of studies has discussed innovation diffusion. For instance, Chaddha and Chitgopekar [1971] used a logistic formulation in estimating the demand for Bell System residence main telephones over the period 1966-1991. Wang and Kettinger [1995] applied a logistic model to survey the diffusion of number of subscribers and number of cell sites in the United States. The data they used covered the period from December 1984 to June 1994. The result shows that the logistic fit for number of cellular subscribers and the number of subscribers starts flattening out in year 2015 with 78,242,205 subscribers. The logistic model fit for number of cells as for the subscribers. The model also points out that a saturation point is reached at year 2020, with 33,248 cell sites.

Since the Internet is an example of a technology cluster innovation [Prescott, 1996], the prior researchers have done many investigations related to Internet diffusion. For example, Goodman et al. [1994] argued that most of the barriers to the wider distribution of networking tend to fall into three categories: government relative policies, technical impediments, and cultural factors. In addition to qualitative discussions, the quantitative methodology-mathematical diffusion models- are adopted to track the diffusion process of Internet hosts. For example, Gurbaxani [1990] found the pattern of diffusion in the case of BITNET is S-shaped and is consistent with a logistic curve, which describes a symmetrical growth process. Rai et al. [1998] adopted logistic, Gompertz and exponential models to forecast future development of Internet. They used nonlinear regression with data from August 1981 to January 1994 to estimate parameters for each of the three models. The result shows that the Exponential model provided a better fit than others in the initial growth stage of Internet. Moreover, Kauffman and Techatassanasoontorn [2004] used a modified Bass model and a coupled-hazard survival model to test the effects of country environmental factors, digital and analog wireless phone industry environmental factors, and technology policy factors on the speed of diffusion. They found that multiple standards and high prices slow down the digital wireless phone diffusion process from the Introduction state to the Partial Diffusion state. Competition in both analog and digital wireless phone industry also shapes the growth of digital wireless phone diffusion.

## 3. MODEL EXAMINATION

Mobile phone is an innovation of communication technology for people to communicate with each other. Therefore the number of mobile phone subscribers is influenced by both the number of existing subscribers

and the number of potential future subscribers. This section would explore the sources of influence in the adoption of mobile phones in Taiwan. We will test adoption and diffusion pattern of source influence using three classical models: internal influence, external influence, and mixed influence models.

### 3.1 Data

In order to estimate the parameters of diffusion model, we collected longitudinal statistics of mobile phone subscribers from 1989 to 2004 in Taiwan. The data source is ITU World Telecommunication Indicator Database. Table 1 shows the historical data of mobile phone subscribers in Taiwan. We use the data between 1989 and 2001 to estimate the parameters of three classical models and the data between 2002 and 2004 for checking sum of squares of the difference.

Table 1. The Historical Data of Mobile phone Subscribers in Taiwan

Year	Number of Subscribers	Year	Number of Subscribers
1989	37,000	1997	1,492,000
1990	83,000	1998	4,727,000
1991	197,000	1999	11,541,000
1992	385,000	2000	17,874,000
1993	539,000	2001	21,633,000
1994	584,000	2002	23,905,000
1995	772,000	2003	25,090,000
1996	970,000	2004	25,207,000

### 3.2. Testing Methods

In this section, we conduct two types of statistic tests to determine which model best fits the observations of mobile diffusion. Firstly, we estimate the model parameters of all three diffusion models with the nonlinear least squares regression method. Then we determine the true model among the three alternatives using the J-test. Finally we calculate the sum of the squares of the difference between predictive value and actual subscriber numbers.

NLIN, a nonlinear regression procedure of the SAS software package, is used to estimate the parameters in the three diffusion models. Table 2 summarizes the parameter estimation and the model fit for the three models. As Table 2 illustrates, the internal model has an adjusted  $R^2$  of 0.9833 which is the proportion of variance explained by this model. The mixed model has an adjusted  $R^2$  of 0.9800 and the external model just has an adjusted  $R^2$  of 0.6687. That is, the adjusted  $R^2$  of internal model is almost exactly the same as the adjusted  $R^2$  of mixed model. Both of them are significantly higher than the  $R^2$ -adjusted value of

external model. Thus, the overall predictive fit of external model is the worst.

Table 2. Parameter Estimation and Model Fit

Parameter	Internal Influence	Mixed Influence	External Influence
m	47,433	35,134	266,620
$m_0$	37	37	37
p		6.54E-21	0.0038
q	1.2433E-05	1.73683E-05	
$R^2$	<b>0.9833</b>	<b>0.9800</b>	<b>0.6687</b>
NOTE: 1.Unit: 1,000 subscribers			

After the model parameters are estimated, the J-test is conducted to use each model in turn as the null hypothesis and the rest as the alternative hypotheses. Table 3 presents the results of comparisons of the alternative specifications with the White-Noise model with the J-test.

Table 3 J-test Model Comparisons: t Values with Probabilities

Null Model	Alternative Models		
	Internal Influence	Mixed Influence	External Influence
White Noise			
t statistic	8.3669	7.8965	0.7924
p-value	0.0000****	0.0000****	0.4449
**** p<0.001			

As table 3 shows, the J-test result rejects the null hypothesis that the adoption pattern of mobile phone is a random process. The alternative models can reject the White-Noise model at the significance level of  $p < 0.001$  or better. Thus we come to a conclusion that the diffusion of mobile phones is not a random process. However, table 3 also indicates that the J-test result can't reject the null hypothesis while alternative model is external-influence. That is, the external model is not suitable for predicting the diffusion process of mobile phones. This also confirms the parameter estimation and model fit results described in Table 2. Accordingly, we don't analyze the external model any more in next section.

### 3.3. Best Model and Discussions

Figure 2 presents the curve of actual numbers of mobile phone subscribers and model forecasts. In order to examine the predictive validity of internal model and mixed model, we calculate the sum of squares of the differences between actual and predicted number of subscribers with the data from 2002 to 2004.

Table 4 summarizes the actual and predicted number of subscribers and sum of squares error for each model. As table 4 shows, the mixed model performs better than another one. Our research result clearly indicates that the mixed model best describes the diffusion process of mobile phones adoption. That is, the mixed influence is the dominant influence factor in the diffusion of mobile phones adoption. Hence, the decision to become a new adopter of mobile phones is mainly determined both by the positive influence of existing adopters and mass media messages. Therefore, mass media play a critical role in the earlier diffusion stage. These mass media publicize the advantage about using mobile phones widely in several years ago. However, the effect of mass media is not the only outstanding factor in the adoption process.

Figure 2. Actual Numbers of Mobile phone Subscribers V.S. Model Forecasts

Mahajan and Peterson [1985; p.18] noted that the internal influence perspective is “most appropriate when an innovation is ... socially visible, and not adopting it places social system members at a disadvantage”. With the rapid development of mobile technology, the mobile phone offers services independent of time and space. These benefits are perceived by users and are communicated to potential adopters. Even individuals will ask their friends, colleagues, or staffs to adopt mobile phones for communicating to each others more efficient. Besides, many individuals adopted mobile phones for the purpose of imitation. Factors which may motivate people to imitate buying mobile phones vary. For instance, factors considered in prior researches include perceptions that a user who adopts the mobile phone will be taken professional image, that a mobile phone makes me feel efficient, that it makes the user appear contemporary, dynamic and innovative.

Table 4. Model Forecasts vs. Actual Number of Subscribers

Year	Actual Subscribers	Internal Influence	Mixed Influence
1989	37	37	37
1990	83	67	68

1991	197	120	125
1992	385	216	230
1993	539	389	420
1994	584	696	766
1995	772	1,241	1,384
1996	970	2,192	2,467
1997	1,492	3,811	4,288
1998	4,727	6,457	7,159
1999	11,541	10,496	11,251
2000	17,874	16,072	16,317
2001	21,633	22,783	21,601
2002	23,905	29,647	26,213
2003	25,090	35,593	29,652
2004	25,207	36,024	29,883
Sum of squares of the difference		260,291,062	48,003,684

Furthermore, the pre-adopters may require friends of their social network to use mobile phones, especially the mobile phone has become a popular communication tool for most people. This is a strongly relationship for communication mechanisms where the value of the mobile phones increase with an increase in the number of users it connects. The mobile phone adoption is communicated among the members within the social system via interpersonal channels.

#### 4. CONCLUSION

Mobile phone is one of the most important innovations over the last decade of the 20th century: with which communications become available anytime and any place. Accessibility, convenience, localization, and confidence make mobile services so unique. Mobility changes not only the life style of people but the enterprise's business model. Who, then, pushes the growth of the mobile phones? Our study addresses this issue with the diffusion of innovation perspective. The research results show that mixed model, which assumes that the decision to become a new adopter is mainly determined by the positive influence of existing adopters and mass media channels, has better predictive validity. This leads us to conclude that it is the combined effects of external media, interpersonal pressure, and internal communications at the personal level that significantly influence the decision to adopt mobile phones. Moreover, network externalities might also offer a good explanation [Gurbaxani, 1990]. That is to say, the value of the mobile phones increases with an increase in the number of users it connects. Another explanation is that imitation within social system is a very popular phenomenon. The potential adopters perceive the value from early adopters and then decide to buy mobile

phones. While this study provides empirical result of diffusion process of mobile phones adoptions in Taiwan, future research can examine diffusion models with different country's data or apply the different model to have better understanding of mobile phones diffusion.

# Explaining Intent of Adoption of Wireless Internet Services by Business Executives: The Case of Paris Airports' Hotspots

Madeleine Besson, Olivier Epinette, Olivier Segard, Pierre Vialle

Institut National des Télécommunications, Evry, 91011, France  
{Madeleine Besson, Olivier Epinette, Olivier Segard, Pierre Vialle}@int-evry.fr

## ABSTRACT

According to most industry experts and researchers, wireless Internet access is seen as a promising market for mobile users in locations such as airports and other public venues [1]. According to the Gartner Group, 6,000 wireless Internet hotspots were installed in the world in 2002, 57% in Northern America and 14% in Europe. 15,000 hotspots should have been implemented in Europe by 2000, used by 11 million regular users and 12 million occasional users. Airports, because of the high density of travellers and the relatively long waiting times involved, are considered as key hotspot locations. Yet, consumption of such services is still lagging behind suppliers' expectations. Why, and whether, consumers will use wireless Internet still remains unclear. This paper aims to contribute to answer both questions by defining a framework explaining the intent of use by consumers. To this end, we carried out market research, focused on executives attending public venues where wireless Internet services can be proposed. In this paper we first define the specific features of the wireless Internet access for airports. We then propose a framework explaining the intent to use wireless Internet services.

**Keywords:** e-business, m-business, product adoption, telecommunications, mobile Internet, wireless Internet

## INTRODUCTION

Understanding and anticipating potential consumer behaviour is critical for suppliers of new high technology services. However, this is a particularly difficult exercise because of factors such as the complexity of the products involved, the presence of interdependencies, the low or non-existing consumer experience, or the high incertitude of the impact of innovations.

More specifically, consumer behaviour concerning wireless Internet services in public venues is hard to understand for the following reasons. First, these services can be used by a large variety of travelling professionals, even if senior executives currently constitute the main target of hotspots. Second, adoption and usage are dependent both on the decision of the individual users, and of the company employing them. Third, from the individual user's perspective, there is no clear border between professional and more personal expectations. Family, entertainment and business topics must be equally considered. Fourth, a multitude of companies can coexist on a hotspot, as in the case of an airport. So, the spectrum of localised mobile Internet services, which can be proposed, is broad. Fifth, the adoption and consumption of such services are subject to network externalities: consumption in one hotspot is dependent on consumption in other geographical areas. Finally, beyond the services to be provided, the physical characteristics of the hotspot could have an influence on the consumption experience.

To explore this complex consumption situation, we conducted a survey in co-operation with the state-owned organisation which manages the main airports near Paris.

From this survey, we present, in the second part of this paper, a framework aiming at explaining the intent to use wireless Internet services. We begin with the context of the survey.

## 1. THE CONTEXT: WIRELESS INTERNET HOTSPOTS IN AIRPORTS

The research<sup>1</sup> was conducted in the main airports near Paris, in order to analyse the intent to use Wireless Fidelity (Wi-Fi) services in these hotspots, the provision of which began in the year 2003.

An airport covers different activities and geographic zones. Several activities can be carried out on an airport platform, such as transport, control, cleaning, maintenance, or passenger care. Geographically, these activities broadly relate to three zones on the airport area: tarmac (services concerning aeroplanes), air terminals (services for passengers on site) and airport periphery (activities benefiting from close location to the airport, such as hotels or offices). Finally, three categories of people can be found on an airport site: employees of businesses and administrations located on the airport platform, passengers, and employees from outside firms on short duty at the airport (for example for repair activities). In this study, we focus on business travellers that have been identified as the main market target by ADP, the organisation managing the various airports around Paris.

<sup>1</sup> This research is drawn from a broader research project called ERACE, including also an inter-organisational component [3].

The study relates to a hotspot service in the main airports of Paris, using a Wireless Local Area Network (WLAN) technology. WLAN is a short-range, broadband data communication system using radio waves [2]. Various standards coexist, but the 802.11b standard, defined by the Institute of Electrical and Electronics Engineers (IEEE) tends to be dominant. It allows a theoretical flow of 11 Mb/s in the frequency band of the 2.4 GHz, on a distance of up to several hundred meters. The IEEE 802.11b standard is more popular under the name of Wi-Fi. The deployment of a Wi-Fi network is relatively easy and it offers a much higher level of flexibility than fixed networks. The number of accesses can be increased without needing to re-dimension the network, as would be the case with fixed networks. This system allows some limited mobility inside one cell, but contrary to cellular networks such as GSM networks, does not allow roaming between cells without service interruption. Such networks can be accessed by different types of terminals equipped with Wi-Fi chips, such as mobile phones, Personal Digital Assistant (PDA), or laptop computers.

There are three possible uses of Wi-Fi. The first is private use, either for a home network, or for a company Local Area Network (LAN). The second is community networks, usually in rural areas. The third is hotspots in public venues such as coffee shops, hotels, railway stations or airports.

A Wi-Fi network can give access to the following services:

- Internet access: including surfing, messaging and Virtual Private network services allowing access to Intranet,
- Localised information services: reception of "push" information, such as infrastructure usage information and schedules (transport hotspots), or commercial information (for example from nearby shops),
- Multimedia services, such as movies or music. As the available bandwidth is shared between current users, a large number of users can result in unacceptable download time.

As users of a particular hotspot may be customers of another hotspot, or of a mobile operator, the establishment of roaming agreements is necessary. Basically, a roaming agreement ensures that a customer of network A is able to use the service provided by network B, while being billed by network A, with some mechanism of revenue sharing between the two networks. Therefore, users can pay for service usage in three different ways. They can be billed by the hotspot manager, either directly through payment by credit card,

or indirectly with prepaid cards that can be bought in the airport's newspaper shops. They can also be billed on their mobile phone account, as most mobile operators offer subscription schemes bundling General Packet Radio Service (GPRS) cellular services with Wi-Fi services.

## 2. THE FRAMEWORK: FACTORS EXPLAINING INTENT TO USE

To explore this complex subject, we made a qualitative study, and not a quantitative research, which would be limited to quantifying traditional uses, and might not take into account all the richness of the consumption experience in a hotspot, and of the psychosocial context. The qualitative study is based on twenty-four interviews with medium and senior executives. From our preliminary results, we were able to conceive a simple framework aiming at explaining the intent of adoption and use of wireless Internet services. This framework specifically concerns an airport environment, but can easily be adapted to other types of public hotspots.

The sampling frame was made up of several lists of business schools' alumni. People were selected in order to ensure the strongest variety of the points of view on our study subject. The selection was operated starting from two variables that could discriminate the answers: the function in the company and the degree of mobility. After having contacted further these two hundred people, we were able to carry out twenty-seven interviews. Three could not be used because of bad audio recording quality.

To collect information, individual in-depth interviews were carried out. They are appropriate for collecting information concerning perception and behaviour. The interviewed person expressed himself freely, but within the framework of the topics suggested by the guideline. The former is composed of three parts. The first part makes it possible for the person interviewed to evacuate the stereotypes concerning the Internet and to centre on the current uses. The second part centres the discussion on travel and the situations of waiting able to occur on this occasion. The last part proposes to imagine the mobile Internet services able to be offered.

Four categories of factors emerge from our qualitative analysis, namely individual characteristics and experience of business travellers, the policy of their organisation concerning Information and Communications Technology (I&CT), situational factors relative to the hotspot, and service availability inside and outside the hotspot (table 1).

Table 1. Factors explaining intent to use Wireless Internet in an airport

<i>Factors</i>	<i>Explanations</i>
<i>Individual characteristics and experience</i>	
Position	Managers with higher positions are more likely to be equipped, but less likely to use
Function	Mobile communications are more crucial for some functions (e.g. sales, technical support)
Age	Older people are less likely to use
Sex	Men more likely to use than women
Personality	Desire to keep in touch, need for anticipation and reassurance
Experience	Experience in using the Internet and mobile devices (learning effect, familiarity), related to personal interest, technical functions, sector of industry
User status	Effect of positive/negative experience on general attitude towards computing and Wi-Fi Wi-Fi user in other contexts
<i>Organisation policy</i>	
Attitude towards I&CT	Strategic resource or cost to minimise
Equipment and access policy	Influence equipment
Service policy	Policy to spur or restrict usage
Security policy	May lead to restrict availability of remote access to IS
<i>Situational factors</i>	
Perceived available time	The more perceived available time, the more usage
Travel characteristics	The type of travel, in terms of duration, destination, transit, determines the available time. A low level of organisation induces need for information and transaction
Physical environment	Privacy, comfort, noise level, availability of sockets
<i>Service availability</i>	
At hotspot	Attractiveness and width of services available influence usage
At other hotspots	The more hotspots, the more adoption and incentive to use (network externalities)
At company premises	Availability of company WLAN induces adoption and propensity to use
Roaming availability	Reduce transaction costs, induce spontaneity of usage

## 2.1 Individual characteristics and experience

Various factors seem to have an influence on the propensity to use wireless Internet in a hotspot: hierarchical position, function, age, sex, personality, experience and user status.

The hierarchical position plays an ambiguous role. On the one hand people with a higher position are more likely to be equipped with terminals by their organisation, and particularly with PDAs. On the other hand, their comments suggest that travel time is often perceived as an opportunity to read, think and relax, rather than dealing with a computing device.

The function in the organisation also has an influence on intended usage. First, for some functions, such as sales or technical support, communicating in situations of mobility can be critical. People carrying on such functions are therefore more likely to be equipped, to be experienced in communicating while being mobile, and to have urgent needs in a hotspot. In general, executives working in technical functions or in the I&CT sector are more experienced in using computing devices and therefore more likely to use Wi-Fi services.

Age can have a low influence on usage, as propensity to use seems to decrease with age.

Men exhibit a higher propensity to use wireless Internet than women. One explanation could be that laptop computers and their connection do not appear practical.

PDAs are considered as an interesting alternative, but are still not perceived as user friendly enough by women.

Some personality features seem to influence usage, and particularly one characteristic that we call "need for reassurance". Even when the trip is organised in advance, some respondents expressed the need to connect to the Internet in order to check information or to be able to deal with unexpected events, concerning, for example, a hotel or car reservation. The role of "orientation towards communicating with others" can be ambiguous. On the one hand, such people can be expected to communicate electronically, on the one hand they may prefer to communicate directly, for example, with their neighbour. The latter case seems to be more likely.

Experience plays a role through two distinct but related aspects. The first concerns the accumulated experience, and hence familiarity and skills with the use of computing and telecommunications products and services. The more experienced the user, the higher the propensity to use other products and services such as wireless Internet. This is apparent, as explained before, through the type of function (e.g. technical), or the sector of industry. The second concerns the positive or negative attitude generated by former experience. Interestingly enough, some respondents having tested Wi-Fi in another context (WLAN) had a negative attitude due to the problems they encountered.

User status: being already a Wi-Fi user in other hotspots naturally leads to an increase in the propensity to use it in an airport.

## 2.2 Organisation policy concerning Information & Communications Technology

For business travellers the policy of their company or organisation concerning I&CT can have a decisive impact on the availability of equipment and of usage. In [5] and [6], we identified that the adoption behaviour for new I&CT products and services was strongly dependent on the way these investments and expenses were considered, and that Information Technology (IT) managers found it difficult to assess the return on investment for this type of project. The attitude towards I&CT investment and expenses broadly oscillates between two extreme positions. One possible attitude is to consider I&CT as a strategic investment (at least for a given number of projects), whose benefits are localised outside the IT function, such as improving internal and external co-ordination, reducing time to market, or increasing customer satisfaction. Another attitude is to treat these resources as a cost to be minimised, according to the available budget. In this case, investments will be considered if benefits are localised inside the IT function, such as a lower cost per bit, or lower maintenance cost.

The attitude towards I&CT will impact on the equipment and access policy (deciding who will be equipped with a terminal equipment and allowed to access a service), as well as the service policy, such as the range of services available.

Another critical point is the security policy of the IT department. A tight security policy may lead IT departments to restrict remote access to their Information System, in order to avoid malevolent intrusions (for example by hackers). IT departments may be even more cautious in the case of Wi-Fi access, as intrusion is easier to achieve for radio links than for fixed lines. An intruder could pretend to be another user for the server, or alternatively appear as the server to a user.

## 2.3 Situational factors

The main influencing factors are the perceived available time, the travel characteristics, and the characteristics of the physical environment. The perceived available time is relative in two aspects: the user personality (e.g. tolerance of inactivity), and the competing entertainment or other activities at hand.

Travel characteristics, in terms of duration, destination and transit time, have an influence on both time available and need for communication and information. For example, a passenger transiting between two intercontinental flights would have a high need to keep informed about his family or his business, and would also have enough time available for it. A low level of

pre-organisation of travel should also induce stronger needs for communicating, for example in order to confirm a reservation, or to get additional tourist information.

Consumption of Wi-Fi services should also depend on the physical environment. This refers to ambience factors such as benefiting from a comfortable enough environment, in terms of furniture, silence, and isolation from other people. It also refers to more critical issues such as the availability of sockets for terminal equipment to be plugged in to. These factors appear to be critical and also difficult to provide, as the organisation of space in an airport is strongly determined by considerations of security, passenger management, and scarcity of available space.

## 2.4 Service availability

The expected consumption will be dependent on the availability of attractive services both inside and outside the hotspot considered. Service expectations are rather standard and mainly concern e-mail and Internet access. For PDA users, the provision of information in a suitable format is required. In terms of content, respondents seem to focus more on travel related information. "Push" information, for example to keep informed about accurate boarding and departure time, also raised interest. We did not identify much attraction towards multimedia services, such as downloading movies<sup>2</sup>.

Expected consumption is also related to service availability outside the hotspot considered, through the number of other hotspots, and/or the existence of WLANs in the organisation employing travellers. This is a typical example of network externalities where the utility of a service is dependent on the availability of complementary products and services [4]. In fact it is unlikely that potential users would adopt Wi-Fi specifically in the case of the Paris airports. We would expect a two-stage decision process: first a decision to adopt Wireless Internet at a general level, or in a company WLAN, and then to use it in the airport under a given number of conditions. Multi-usage means the existence of roaming agreements between the various hotspot owners and mobile operators, including the possibility to be billed by one's usual provider.

## CONCLUSION

We proposed a framework explaining the use of wireless Internet services by individual characteristics, company policy, usage situation, service availability and travel characteristics.

<sup>2</sup> However, this may result from a possible bias in the interviews, as we felt that respondents were rather reluctant to mention entertainment while talking about professional travel.

A first key result of our research is the importance of the consumption situation, such as the availability of electrical connectors, a comfortable environment, or the perception of the serviceable time. The provision of localised services and of a related physical environment seems to be able to trigger the consumption of wireless Internet services on hotspots.

A second key result is that focusing only on the individual's needs and expectations, a traditional characteristic of consumer marketing, is not sufficient in order to understand the product's potential for adoption. The individual adoption behaviour will be obviously influenced by the company's computer policy, such as the terminal equipment policy, the security policy or the services provided by the organisation.

A third key result consists of the confirmation of the importance of network effects. The consumption of services in a specific hotspot is dependent on the consumption in other places, related to geographical range of availability of similar services, as well as the provision of adequate billing solutions.

The next step of our work is to use the framework to develop a set of hypotheses to be tested with a quantitative study.

## Extracting Requirements for Ubiquitous Computing Technology-based IS Using Factor Analysis

Natalia Em, Euiho Suh, Keedong Yoo

Dept. of I.E., Pohang University of Science and Technology, 790-784, Republic of Korea  
{natalia, ehsuh, kdy}@postech.ac.kr

### ABSTRACT

The paper describes a methodology for extracting the requirements for ubiquitous computing technology-based information system (IS) using factor analysis. The early idea of ubiquitous computing was articulated by Mark Weiser in 1988 and since then has been constantly developed. However, so far there was no any or few research on application of ubiquitous computing to IS. Prior to the development of a ubiquitous computing-based IS model necessary requirements are to be identified. To derive the requirements we refer to conventional research on ubiquitous computing, ubiquitous service and ubiquitous environment, and hence, to their characteristics. Having specified those requirements using factor analysis technique it will be easier to develop a consistent ubiquitous computing-based IS.

**Key words:** ubiquitous computing, information system (IS), factor analysis.

### 1. INTRODUCTION

In this paper we attempt to develop a methodology in order to identify the requirements for ubiquitous computing-based IS with the help of data analysis. Numerous projects and research were done in the field of ubiquitous computing, service and environment since the first attempts to identify ubiquitous computing concept have been undertaken by Mark Weiser. Conventional research can be categorized into four main areas: U-Device, U-Environment, U-Media and U-People [14]. With ubiquitous computing advent research was mainly focused on creating a proper hardware such as active badges, beacons, smart tags (U-Device). Meanwhile, other explorations were undertaken in developing ubiquitous computing technology-enabled environments, so called “smart environments” (U-Environment). Yet, U-Media area has not progressed as much because of “users’ often conservative attitude toward new media, as well as the technical complexity in fitting the new types of media to users” [15]. Despite some technical complexity, researches concentrated on the development of new concepts of interface patterns for users with disabilities are conducted in U-People field.

However, only few works have been carried out towards the connection of the notions of ubiquitous computing and IS so far. One can try to develop a model of IS based on ubiquitous computing technology. Still, before one does this, the requirements for such a model are to be defined. Otherwise, ignoring the requirements can lead to development of an inconsistent model.

In order to derive the requirements specific for the development of ubiquitous computing-based IS related

literature, namely, conventional literature on ubiquitous computing must be examined. Having reviewed the literature we then outline certain characteristics and

features that are intrinsic to ubiquitous computing. Out of the multiple characteristics it becomes possible to determine particular keywords that can serve as a platform for formulating necessary requirements for ubiquitous computing-based IS.

For obtaining the requirements a formal tool should be used. Factor analysis is one of them since it is a statistical tool that is determined to reduce the number of variables as well as to detect structure in the relationships between variables.

The remainder of the paper is organized as follows. Section 2 reveals related works. Section 3 is dedicated to the methodology. Finally, section 4 concludes the paper with summary and future work.

### 2. RELATED RESEARCH

#### 2.1 Ubiquitous Computing

The concept of ubiquitous computing was first proposed by Mark Weiser in early 1990s. In his early works he describes ubiquitous computing or “Ubicomp” as a way to augment computer usage by “making many computers available throughout the physical environment, but making them effectively invisible to the user” [12, 13]. The technology requirements comprise three aspects: cheap, low-powered computers with convenient displays, a network that unites them as well as software systems implementing ubiquitous applications [14].

Hence, multiple issues have arisen with the advent of ubiquitous computing, particularly related with the development of proper hardware and devices, software and applications, environment, etc. Beader et al. [2] in their research investigate the usage of mobile location aware systems equipped with Badge based location and environment sensors where they tried to overcome the

deficiencies connected with environment awareness. Xerox PARC carried out explorations of the capabilities of mobile computers in an office setting which have resulted in the development of PARCTAB system prototype [11]. Narumi et al. [9] pose the technology requirements for ubiquitous environment and describe Fujitsu's real-time communicator ubiquitous middleware. Meanwhile, the FUSE (Future Ubiquitous Service Environment) group's focus is software architectures for ubiquitous service environments designing as well as privacy and context sensitivity [8]. Epp [5] stresses privacy and authenticated identity issues within ubiquitous environment. Burrell et al. [3] discuss the design and development of Semaphore, a contextually aware application for use in wireless networked environments.

## 2.2 Ubiquitous IS

As it was mentioned above, only few explorations have been done in this direction. However, we give a brief description of more or less corresponding works. "Docodemo-Display" is one of them and is a recently developed ubiquitous IS. It is a display-centric communication system, which is portable, interactive, and collaborative [10]. The goal of "Docodemo-Display" System is to increase the value of the place with helping to form local communities at that place. Another research is by Balke et al. [1]. In their work "A Situation-aware Mobile Traffic Information System" they present a prototype of traffic IS offering advanced personalized route planning, including added service like traffic jam alerting by means of SMS.

## 2.3 Factor analysis and Its Applications

Factor analysis is a branch of applied mathematics [6] and is generally referred to as a statistical tool for reduction of the number of variables and structure detection in the relationships between variables. First applied in psychology this method quickly became popular in other fields like economics, medicine, sociology, etc. as they often need to outline dominating factors out of huge volumes of variables they have to operate with.

One of the conventional works using factor analysis describes the application of the latter to tests on Cheshire cheese [7]. The study reveals the relationships between a number of rheological experiments and essential subjective judgments on cheese. Another research applies factor analysis to psychological diagnostics [4] and particularly to the development of psychological tests and models such as the Cattell 16 Personal Factors model.

Numerous studies in various fields using factor analysis can be found. However, no studies seem to be carried out towards extracting the requirements for ubiquitous computing technology-based IS using factor analysis.

## 3. METHODOLOGY

Owing to well-developed concept we find factor analysis applicable to extracting essential requirements for ubiquitous computing-based IS. However, due to impossibility to collect data necessary for conducting empirical tests in a short period of time we describe only a methodology that comprises several stages (Figure 1). The first stage considers reviewing conventional literature in ubiquitous computing, services or environment fields and deriving specific features and characteristics. Next, on stage two we create a questionnaire for the experts in the related fields. The questionnaire will include the list of the derived features and characteristics that must be evaluated by the experts in terms of their significance. Having done this, we will get a data sample. The data will perform experts' estimations of the characteristics in scores. Having obtained the essential data we then apply factor analysis on stage three and extract dominating factors. Eventually, on stage four, relying on the results of factor analysis we formulate the requirements for ubiquitous computing-based IS.

Figure 1. Methodology of extracting the requirements to ubiquitous computing-based IS.

## 4. SUMMARY AND FUTURE WORK

The fact that very few works can be found on application of ubiquitous computing to IS and, therefore, the requirements for such an IS are not clearly articulated, makes this paper unique for it aims to

extract and classify those requirements. In this paper we delineate a general methodology of extracting the requirements using such a common statistical tool as factor analysis.

The future work within the research will lie in applying the described methodology to practice. Probably the most time-consuming stage will be collecting necessary data as it requires direct participation of respondents. However, having done this, it will be possible to acquire significant results which, in turn, will make a valuable contribution in ubiquitous computing-base IS development.

## IEEE 802.20 Based Broadband Railroad Digital Network – The Infrastructure for M-Commerce on the Train

Fumin Zou<sup>1</sup>, Xinhua Jiang<sup>2</sup>, Zhangxi Lin<sup>3\*</sup>

<sup>1</sup> Information College, Central-South University, Changsha 410075, China,

<sup>2</sup> Fujian University of Technology, Fuzhou, 350014, China,

<sup>1</sup>xhj@mail.csu.edu.cn,<sup>2</sup>zlin@ba.ttu.edu,<sup>3</sup>fmzou@fjut.edu.cn

### ABSTRACT

The broadband wireless access is emerging as a promising technology to meet the ever-increasing demand of M-commerce on the train. The traditional railroad communication system (RCS) is not only in charge of the traditional train scheduling, but also offers broadband WLAN services to passengers and provides the network platform to the intelligent railroad information system. This imposes a major challenge on the capability of the RCS in response to the increasing application requirements, particularly, the one for ubiquitous Internet access. To take the advantage of the rapid evolving mobile communication technology, this paper proposes an IEEE 802.20 based broadband railroad digital network, namely BRDN, for the next generation RCS. The paper further presents the scenario how BRDN operates and identifies the IP mobility as the major technical issue to be solved for BRDN. The predictability of mobile IP for the train-based applications will ease the difficulties in implementing BRDN. With the availability of IP standard for the next generation Internet - IPv6, BRDN will eventually become a reality.

**Keywords:** M-commerce; Broadband wireless network; Railroad Communication; Mobile IP

### 1. INTRODUCTION

With the advancement of information technology, M-commerce is undergoing a rapidly growth and exerting significant impacts on the economy. According to Finfacts' report based on several sources [8], the percentage of Internet users who use the wireless access grow from 16% in 2001 to 41.5% in 2004 (eMarketer, <http://www.emarketer.com/>). This figure will continue to get as high as 56.8% in 2007 with the total number Internet users almost tripled from that in 2001. In 2002, although only 2% of Internet users were using the "mobile cash" but 44% intended to use it later (ATKEARNEY, <http://www.atkearney.com/>). IDC (<http://www.idc.com/>) predicted that during 2001 to 2007, the M-commerce revenue in the US will grow from \$127 million to \$58.4 billion – more than 400 times.

Known as "wireless E-commerce", M-commerce generally refers to the use of wireless devices, such as mobile phones, to conduct electronic business transactions [17]. There are five value-added attributes of M-commerce to regular E-commerce [9][20]:

- Ubiquity: Available at any time and any location.
- Convenience: Convenient for users to operate.
- Instant Connectivity: Easily connect to the target.
- Personalization: Allows for preparation for personalized information.
- Location: Location-specific information and products.

As one of the most important scenarios of M-commerce, Internet access from trains has become an outstanding M-commerce issue among others. It is predicted that in the next five years, 625 million people will be traveling on Wi-Fi enabled trains around the world each year [3][5]. By 2008, train passengers will be spending 420 million dollars per year on in-transit wireless LAN hotspot services. Passengers in the train typically will stay a few hours to a few days in a small area that is like a mobile office more comfortable than staying in other moving vehicles. Thus, M-commerce allows passengers to conduct their business via the Internet. The key for the train-based M-commerce is the Internet access underpinned by mobile communications technology.

This paper is intended to propose the IEEE 802.20 based Broadband Railway Digital Network (BRDN), the wireless network infrastructure for the next generation railway communication system (RCS) based on the latest mobile broadband Internet access technology. The remaining part of this paper is organized as follows: Section 2 summarizes the status of RCS; Section 3 introduces the IEEE 802.20 standard; Section 4 presents a framework of BRDN based on IEEE 802.20; Section 5 discusses the key technical problems in implementing BRDN; finally, Section 6 concludes the paper.

### 2. THE EVOLUTION OF RAILROAD COMMUNICATION SYSTEM

\* Primarily affiliated to Texas Tech University, USA

The traditional railroad communication system plays an important role in train distributing and programming, and inter-section wireless communication. At the same time, it is responsible for the railroad application data transmissions, such as train serial numbering, wind pressure remote sensing and railroad alarm messaging. As the intelligent railroad information system is highly regarded as the future value-added service on RCS, the limited data transmission capability of the traditional RCS is apparently the bottleneck for an advanced railroad information system. As ubiquitous Internet access becomes the trend, RCS should not only support the operation management of the railway system, but should also offer the Internet services to support M-commerce on the train.

The evolution of RCS relies on the advancement of the mobile communication technology (MCT). Historically, each new generation of MCT has refueled the RCS with the revolutionary improvement. As illustrated in Figure 1, MCT has led RCS's evolution with each innovative generation (the thin line represents the history of MCT, and the bold line indicates the following development step of RCS).

Figure 1. The development of MCT boosts the RCS's advance

In the last two decades, MCT has experienced rapid development, from the first generation (1G) to the third generation (3G) in technology, and achieved great commercial success. At the same time, RCS has evolved from analog communication system based on UIC751-3 protocol into the narrowband digital communication system based on 2G technology. The typical 2G technologies include GSM-R (UIC), iDEN (Motorola) and TETRA (ETSI), etc. The TETRA version 2 in planning by China's MoR possesses some 2.5G features [23]. Furthermore, the GT800 system developed by China's Huawei adopts the 3G technology (TD-SCDMA) and has been tested [10].

Now, the 4G technology based on IEEE 802.20 is rising on the horizon [2]. The basic idea of 4G is to merge the narrowband circuit-switching cellular phone technology with the broadband packet-switching technology. The IEEE 802.20 standard under discussion supports various vehicular mobility that classes up to 250 Km/h in a wide

area network environment with spectral efficiencies, low latency, high transmission rate, and QoS. Its goal is to enable worldwide deployment of affordable, ubiquitous, always-on and interoperable multi-vendor mobile broadband wireless access networks that meet the needs of business and residential end user markets. Although IEEE 802.20 demonstrates the promising future of mobile application, the narrow band digital mobile communication systems, such as GSM-R, TETRA, etc, are still the mostly available choice for RCS [7][21][24], only meeting the basic requirement for the operation of the railroad system. Even the 2.5G and 3G based RCSs, which are still under improvement, cannot satisfy the passengers' high demand for Internet access for M-commerce. This is mainly because it can only provide a peak bit rate up to 144Kbps when the mobile node is moving at a high speed. According to the status of RCS, it is a necessity to adopt the more advanced mobile communication technology.

### 3. IEEE 802.20 – THE KEY TECHNOLOGY FOR BRDN

Since July 1999, the IEEE 802.16 Working Group on Broadband Wireless Access (<http://grouper.ieee.org/groups/802/16/>) has been openly developing voluntary consensus standards for Wireless Metropolitan Area Networks with global applicability. Addressing the demand for broadband access to buildings, IEEE 802.16 provides solutions that are more economical than wired-line alternatives. The standards set the stage for a revolution in reliable, high-speed network access in the "last mile" of Internet by homes and enterprises [13]. On December<sup>th</sup> 12 2002, the IEEE Standards Board approved the establishment of IEEE 802.20 Mobile Broadband Wireless Access (MBWA) Working Group (<http://grouper.ieee.org/groups/802/20/>). It described the scope of IEEE 802.20 as:

*Specification of physical and medium access control layers of an air interface for interoperable mobile broadband wireless access systems, operating in licensed bands below 3.5 GHz, optimized for IP-data transport, with peak data rates per user in excess of 1 Mbps. It supports various vehicular mobility classes up to 250 Km/h in a MAN environment and targets spectral efficiencies, sustained user data rates and numbers of active users that are all significantly higher than achieved by existing mobile systems.*

According to the above scope, the basic features of IEEE 802.20 include compatibility, coexistence, distinct identity, technology feasibility, and economic feasibility [11].

According to the MBWA announcement, IEEE 802.20 is aimed at mobile communication, and its data rate can reach more than 2Mbps in high speed mobile application. IEEE 802.20 is the first real broadband wireless network standard that dedicatedly supports the mobility of network. A comparison between IEEE

802.20 and others mobile techniques for traditional RCS are shown in Table 1 [10][12][13][23].

Table 1 : IEEE 802.20 vs. Other Mobile Techniques used by Traditional RCS

Characteristics	GSM-R	TETRA version 2	GT800 (3G)	IEEE 802.20
Data rate	2.4-28.8Kbps	96-384Kbps	2Mbps, < 144Kbps in high speed	16Mbps, > 2Mbps at the speed of 250mk/h
Latency	About 1000ms	About 500ms	About 250ms	About 30ms
Spectral efficiency	200KHz/8channel	25KHz/4channel	About 0.2b/s/Hz/cell	> 1b/s/Hz/cell
Cell radius	5~10 Km	10~15 Km	2~5 Km	> 15 Km
Spectrum	Licensed bands 876-880/921-925MHz	Licensed bands 806-821/851-866Mhz	Licensed bands below 2.7GHz	Licensed bands below 3.5GHz
Switching method	Circuit	Circuit	Circuit/Packet	Packet

#### 4. THE FRAMEWORK OF BRDN

In this section, we construct a framework for the BRDN underpinned by two wireless network standards - the IEEE 802.20 wireless WAN (WWAN) on ground and the IEEE 802.11x WLAN on train.

##### 4.1 The Configuration

Figure 2 illustrates a configuration for a mobile network on the train implemented. A WLAN is deployed in a train with a typical configuration: The Ethernet (IEEE 802.3) cable is wired through all carriages via MVB (Multi Vehicle Bus); in each carriage, Wi-Fi access points are deployed with complete coverage of the area,

and are hooked up to the Ethernet; end users access this WLAN via their mobile devices, such as notebook computer, PDA, mobile IP phone, etc. An IEEE 802.20 client interfaced to the Ethernet via a router connects the WLAN to the base stations of IEEE 802.20 on the ground, which jointly offer the transparent services on the physical layer and data link layer between the Internet and the mobiles nodes.

Because of the availability of NAT (Network Address Translate) technology, the whole network on train may only need a single IP address. A DHCP server can automatically assign each mobile node of the network on the train a dynamic IP address.

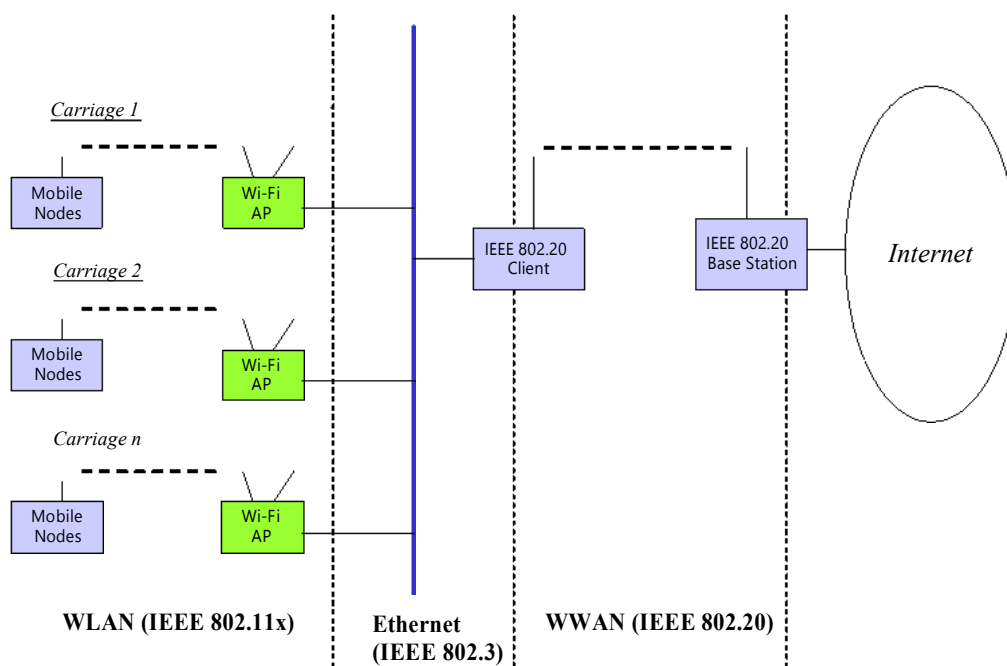

Figure 2. The Configuration of BRDN

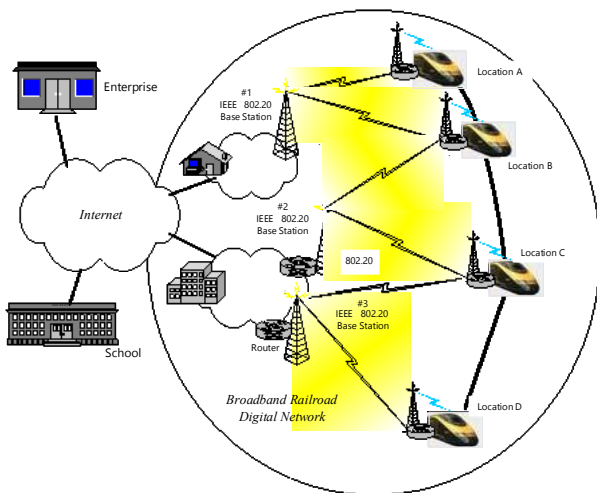

The interconnection scheme of WWAN between the stations are still. As we discussed in Section 3, IEEE 802.20 is supposed to be the best choice for its high-speed mobility support, with high data rate, spectral efficiency and low latency.

The train-based IEEE 802.20 mobile client as a whole is on moving when the train is in operation, switching from one network to another over time (about 10-30 minutes at the regular moving speed). Section 5 will discuss the mobile IP problem - how the train-based client remains reachable from the ground stations, while moving around in the Internet quickly, regardless of its current point of attachment to the Internet.

According the above configuration, the proposed BRDN will adopt IEEE 802.20 and 802.11x standards to implement the function of physical layer and data link layer. The physical layer provides the air interface of wireless network, and the data link layer offers reliable data frame transmissions between neighboring hosts, by use of the bit transmission function provided by physical layer.

#### 4.2 The Operation Scenario

The working scenario of BRDN is shown in Figure 3. When a train departs from location A, the #1 base station provides the Internet connection to the train via #1's network. When the train approaches location B, it will contact both #1 base station and #2 base station at the border because there is a coverage overlapping between the two base stations. After the IEEE 802.20 client on train switches the connection from #1 base station to #2 base station, #2's network starts to provide the path to the Internet, and the network connection handover is complete. The network handovers happens in the same way when the train arrives at location C and

location D.

Figure 3. The operation scenario of BRDN

### 5. MOBILE IPV6 - THE KEY ISSUE IN BRDN IMPLEMENTATION

Broadband wireless network has generally raised a number of research issues aiming at the requirements from the mobile applications. Although many have

proposed various resolutions for these issues, for example, mobile IP telephony, more effort has to be input to find the better ones that will eventually lead to commercialization. In the context of railroad based mobile applications, the same problems exist as in other mobile IP applications, but there is a possibility that the problems in railroad based mobile applications can be solved by alternative approaches with better outcomes because of the specialty of the application environment. This section briefly covers two most outstanding topics: IP mobility in BRDN, and VoIP for BRDN.

Mobile IP introduced a solution of bi-address, with a long-term IP address on a home network (HN) and a "care-of address" (COA) when away from its home network. This home address (HA) is administered in the same way as a "permanent" IP address is provided to a stationary host. The COA is associated with the mobile node (MN) and reflects the mobile node's current point of attachment. Every time when MN handover to a foreign network, mobile IP requires it to bind its COA to Home Agent (HA) [14][15]. If MN is moved far away to HA, the latency caused by handover will be long, and will lose the packets sent to MN, and the network performance will decline seriously. This Seamless Handover question has attracted wide attentions. Many researchers have put forward their proposal [1][16][18][23]. Much of them are based on mobility detection, and some are based on mobility predictive. But, because of the complexity of mobile node's moving, both the mobility detection and predictive are hardly implemented.

The IEEE 802.20 mobile client on train is always on moving along with train, switched from one network to another at a fixed trajectory, particularly, the period of handover can be predicted by the train schedule [22]. Based on these premises, BRDN adopts a Predictive Pre-Handover (PPH) algorithm. PPH is based on the highly predictive of train's moving from one network to the neighboring network. Not only the arriving time, but also the ID and router's address of the next network are predictable. It adopts many effective methods such as actively mobility detecting, pre-registering and pre-transmitting and storage. The flow of PPH algorithm illustrated as below:

- 1) Initialization: Create the entry for each network handover and get the predictive handover table according to the train's schedule.
- 2) Handover predict: BRDN predicts the next network's ID, router's address and arrive time  $t_p$  according to the handover table.
- 3) BRDN creates the frequency of detection and detects the foreign network actively.
- 4) Pre-registering: BRDN implements the preparations for registering, such as authorization and authentication.
- 5) Pre-transmitting and storage: According to the result of step 3 and  $t_p$ , BRDN copies the

communication data to the router of the network which about to handover.

- 6) BRDN triggers the handover process when it detected that the quality of the new network's signal is better than that of the former.
- 7) If there has any data missed, auto-transmit from the router's storage, and BRDN amends the predictive handover table according the result of this handover.

Internet, which can overcome the many known weaknesses of IPv4. With its 128 bits IP address IPv6 has realized the Stateless Address Auto-configuration (SAAC) [19]. Applied to the BRDN, IPv6 is able to configure each communication node on a train automatically with a unique global IP address freely. That implies that besides current IPv4 based dynamic IP assigning, IPv6 has the potential to provide a better solution. The operation for mobile IPv6 is shown in Figure 4.

IPv6 is presently the IP standard for the next generation

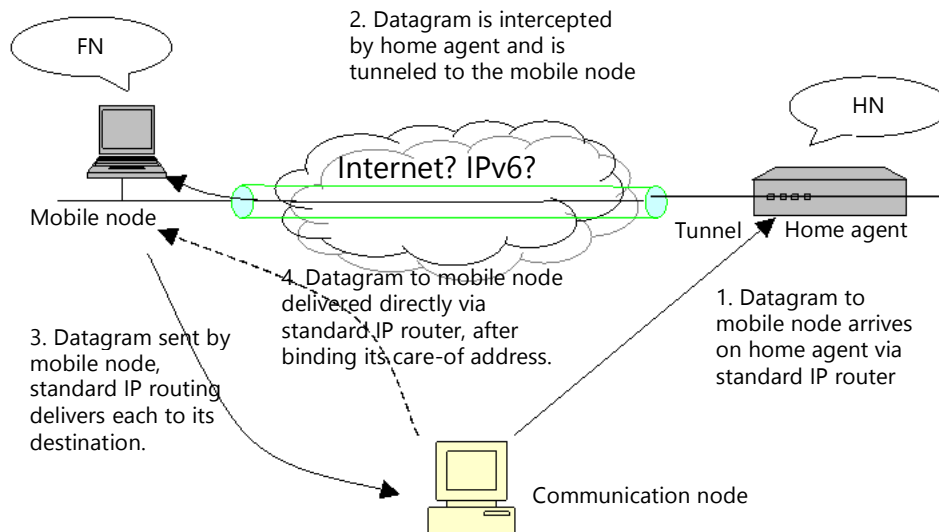

Figure 4. The operation of mobile IPv6

In a hybrid scheme, the WLAN on trains may still use mobile IPv4, which has been well explored recently, while the main connection to the Internet will be IPv6-based in order to support better IP mobility by taking the advantage of IPv6. A gateway between the WLAN and the IEEE 802.20 based WWAN will take care of the IP address translation.

Voice communication is a fundamental service demanded for RCS. In particularly, unless RBDN realizes the priority management, urgent call support, broadcast, multicast and quick establishment for call question, the RBDN based on IEEE802.20 can implement in rail-transit. VoIP application based on IEEE802.11x has been mature and deployed [4][6], which is the technology we introduced in the above sections.

## 5. SUMMARY

To extend M-commerce, the next generation RCS is a necessity for the advanced mobile network infrastructure. This paper presents current status of MCT and RCS, and introduces the latest mobile broadband wireless access technology IEEE 802.20. Although the standard of IEEE 802.20 is still under discussion and to be launched in 2005, its current specification has shown its promising potential in the

near future in supporting the ubiquity of M-commerce. We further compared IEEE 802.20's technology advantage with other RCS solutions, and identified that constructing the BRDN based on IEEE 802.20 standard is not only feasible, but also urgent. This paper further brought forward a configuration for RBDN, with the considerations in the required features of next generation RCS and the technology advantages of IEEE 802.20. We also discussed the mobile IP problem for BRDN – the key issue in implementing the next generation RCS, covering the predictive mobility management for mobile IP and VoIP over RBDN.

## ABSTRACT

This paper addresses mobile service pricing and affordability issues in China. Taking history as a mirror, it shows individual tariffs existed at the dawn of telephony. A vision of future mobile services with individual tariffs is formalized which will suit specially well the culture of communities rooted in Chinese traditions. An analysis of current tariff conditions in China shows community-based individual tariffs will speed up the diffusion of mobile services to the majority of populations and benefit both economically and sociologically the development in China

**Keywords:** Individual Telecommunications Tariffs, Wireless Services, Wireless Communities, Telecommunication History

## 1. INTRODUCTION

The focus of this paper is on pricing and affordability of mobile services, addressing especially factors essential to a sustainable adoption of wireless communication in China. Taking a historical perspective around the world, it shows first that telecommunication services started in the 1880's with prices set for each user individually; an analysis of current situation in mobile communications especially in China is followed by a vista of the situation in approx. year 2030 (Section 2); it then presents (Section 3) a visionary version of mobile user pricing suiting especially well the Chinese culture of communities and the service dependencies therein (礼尚往来). The paper concludes in Section 4 with the suggestions that the adequacy of individual tariffs inside Chinese communities, further compounded with growing service creation skills, will fuel a fast improving affordability and use of mobile services.

The economic theory of pricing has traditionally been derived for physical goods, and from different angles:

1. either from a static equilibrium between supply and demand [1], including auction;
2. or taking in consideration ranked preferences for individual price formation [2];
3. or reflecting price dynamics with endogenous fluctuations due to market restructuring [3].

Most traditional telecommunication pricing schemes have been variants of the above, assuming limited capacity in either bandwidth or transmission capacity. These two assumptions have been made largely erroneous with the advent first of fiber optic transmission, and next of advanced radio coding/modulation/spectrum usage techniques.

Unfortunately, in general only little has been published around service pricing and affordability for end users,

which furthermore takes social networks into account, as in this paper.

## 2. THE HISTORY, PRESENT AND FUTURE OF WIRELESS SERVICE TRAFFIC AND AFFORDABILITY

This section is successively addressing the telephony usage and pricing in general in the 1880's, thereafter the current situation in China for wireless communications, and proposes finally a vision about wireless service pricing in e.g. the 2030's. (Date picked randomly to reflect the social and technology legacy and adoption curves.)

### 2.1 Users, Demand and Supply in the 1880's

At the dawn of the telephony services history, there were individual tariffs! The telephone was patented by Alexander Graham Bell in 1876. For quite some years, and in some markets, it served mainly some high level civil servants and privileged people (trade, news), and was the symbol of wealth and social rank. Telephone subscribers were not designated by a number, but by their name; picking up the phone would get the operator, who would then ring and connect the desired party by a polite support staff protocol.

As a luxury service at that time, the demand for telephony was limited (lack of network capacity effect). Phone calls were mainly local, with national and international calls a rare phenomenon except in some key cities. The demand patterns by called party, between office and home, or between national parties and international parties, were by and large not analyzed, as their influence on telephone company tariffs was minimal. Each individual was eventually satisfied, or not, in a binary way with whatever the telephone companies offered (since the person was rich or the services were paid by the government). The individual

demands were price insensitive, which resulted in an inelastic demand curve as shown in Figure 1.

Regarding the supply of telephony services, there were in general only geographically limited pure monopolies, and the capacity in each country was dominated by two or three local companies able to invest in interconnections.

Figure 1: Service demands at the dawn of telephony. A, B, C represents the individual demands, which were limited and price insensitive. The average telephony demand curve at the dawn of telephony is also shown in the bold curve, which is inelastic. All voice calls here are assumed for the same destination/distance.

From the very beginning, although the reduced sets of telephone users and suppliers were restricted, charging patterns diverged very early between flat rates and individual usage-based rates. Numbers of call attempts, physical destination and the duration were manually recorded – but the pricing of the calls was a matter between the telephone company sales person and the service customer (who was then not a subscriber); usage, rank, fame, location were all taken into account, and the settlement was done by a bank note or cash. In some countries, an annual contract fee was charged, while others started with flat rates for a fixed number of calls (not even based on duration or distance).

**Case 1:** In Sweden, year 1881, the city of Gävle called for bids to supply a local telephone system. The Bell Company in Stockholm offered to install and operate a system for SEK 200 per user per year (2004 value = SEK 9102)<sup>1</sup>, based on a minimum of fifty five-year user contracts. The local enterprise Ericsson offered SEK 275 per user (2004 value = SEK 12514) and thereafter to operate it for SEK 56 (2004 value = SEK 2458) per user per year<sup>2</sup>. The rate of annual operation cost, to Gross National Product (GNP) of SEK 310/capita in 1881<sup>3</sup>, is 18%.

<sup>1</sup> "Consumer Price Index," Statistics Sweden, 2004.

<sup>2</sup> "Lars Magnus Ericsson - A brief biography," Telefonaktiebolaget LM Ericsson. Available: [http://www.ericsson.com/about/compfacts/history/lars\\_magnus\\_ericsson/company\\_born.shtml](http://www.ericsson.com/about/compfacts/history/lars_magnus_ericsson/company_born.shtml).

<sup>3</sup> "The gross domestic product of Sweden and its composition 1861-1955.", Östen Johansson.

**Case 2:** In Los Angeles (U.S.A), in 1888 the common policy of the telephone company was high-quality service and high costs. "The minimum flat rate in central Los Angeles in 1888, for example, was USD 4 per month (2004 value = USD 80.37)<sup>4</sup> plus two cents a connection after the fortieth call (2004 value = USD 0.40). This rate equaled about 10% of the average nonfarm employee's wages" [4]. At the time, the penetration rate of telephone in the U.S is 1.08%<sup>5</sup>.

In all cases, the supply was scarce and inelastic to prices, as there was no choice, nor competitive mechanisms. And, although prices were fixed individually or bundled into packages with fixed numbers of calls, they were extremely high, which resulted in the exclusion of the majority of population from accessing the services due to unaffordability.

## 2.2 Current Situation for Mobile Communications and Especially in Relation to China

The worldwide GSM mobile phone users reached 1 billion in February 2004, almost one sixth of the world's population<sup>6</sup>; besides other mobile communications standards also have user and subscriber bases adding up to that number, for a worldwide grand total of approximately 1.4 Billion (1,340,667.7) at the end of 2003<sup>7</sup>.

In China, the first public mobile operator (China Telecom) started its services in 1987 under heavy government involvement and as a state-owned enterprise, with 700 subscribers. With a fierce growth, in October 2003, the number of mobile users exceeds the number of fixed telephone users<sup>8</sup>. By the end of 2003, the overall penetration rate among the total population was approximately 20.9%. There were approximately 290.31 million mobile users at the end of March 2004, with a growth of 60 millions of users per year, according to MII statistics<sup>9</sup>.

In China, mobile tariffs, as part of the telecommunication tariffs, are guided by "Regulations of the People's Republic of China on Telecommunications"[5]. A Telecommunications Law is supposed to be promulgated in 2005. Tariffs are divided into three categories:

1. Government-set tariffs;

<sup>4</sup> "Consumer Price Indexes," Bureau of Labor Statistics, U.S. Department of Labor, 2004.

<sup>5</sup> "Penetration rate of Consumer Technologies (1876-present)", FCC, U.S.A

<sup>6</sup> "GSM: the business of a billion people." Cannes: GSM Association Press Release, 2004.

<sup>7</sup> "World Telecommunication Indicators - Basic indicators," ITU, 2003. Available: [http://www.itu.int/ITU-D/ict/statistics/at\\_glance/basic03.pdf](http://www.itu.int/ITU-D/ict/statistics/at_glance/basic03.pdf)

<sup>8</sup> "Telecommunication Industry Monthly Statistics, October 2003," Ministry of Information Industry, China.

<sup>9</sup> "Telecommunication Industry Indicator, 1<sup>st</sup> quarter 2004," Ministry of Information Industry, China.

2. Government-guided tariffs;
3. Market-based tariffs.

Basic mobile services (voice call, roaming, and long distance call) can follow either government-set tariffs, government-guided tariffs or market-based tariffs. Value-added mobile services (call forward, line identification, SMS, etc) can follow government-guided tariffs or market-based tariffs. When there is intensive competition, the tariffs can be set based on the market mechanism. "State-aid" operators are entitled to set price fluctuating within 10% of the government-set tariffs. There are two dominant mobile operators (China Mobile and China Unicom), plus two minor ones.

The current mobile tariffs are based on a regulation issued in 1994 by the former Ministry of Posts and Telecommunications. Postpaid users pay a monthly subscription fee of CNY 50 and the tariff is CNY 0.40/minute for local calls, CNY 0.60/minute when roaming. Prepaid users do not pay the monthly subscription fee, and the corresponding tariffs are CNY 0.60/minute for local calls and CNY 0.80/minute when roaming.

Table1: Ratio of ARPU to disposable income.

	Urban usage	Rural usage
Weighted ARPU (CNY)/month	129.93	56.38
Disposable income (CNY/year)	8472	2622
(Weighted ARPU)*12/ Disposable income	18.40%	26%

We approximate urban users to be the postpaid users, and rural users to be the prepaid users. The weighted ARPU is the average revenue per user, weighted within each population category (urban/postpaid, rural/prepaid) by weight equal to market share applied to published ARPU of two large mobile operators: China mobile and China Unicom.

Due to high income disparity in China today, the ratio of the ARPU<sup>10</sup> to disposable income urban and rural<sup>11</sup> (see table 1) reminds closely of the situation in the 1880's described above in Section 2.1, with a ratio of 18.40% and 26% respectively. The overall average ARPU is CNY 76.3/month (2003). The ratio of the overall average mobile voice usage cost per year, to Chinese GDP per inhabitant CNY 9025 (2003) is of 10.14 %. Whereas the overall mobile penetration rate in China among the total population was approximately 20.9% at the end of 2003, with high usage subscribers representing an estimated 20% of the subscriber base, or

<sup>10</sup> The ARPU data are acquired from the 2003 annual results of China Mobile (Hong Kong) limited and 2003 annual results of China Unicom Limited.

<sup>11</sup> "Statistical Communiqué on the 2003 National Economic and Social development," National Bureau of Statistics of China.

4.2% of the population. For all practical matters, high volume users (privates or enterprises) still largely negotiate their rates. Meanwhile, the majority of the population (79%) still can not afford the expense on wireless communications, reminding of the situation depicted in Section 2.1.

Although the regulatory situation has obviously evolved rapidly, in purely economic terms, demand and supply are not yet happening on an equal-access basis and the suppliers are closer to an oligopolistic behavior than to a pure competitive one, partly due to the government directives.

### 2.3 A Vision of the Tariffing Situation in Approx. Year 2030 ("The Bright Future")

Twenty years from now on, advanced personal communication technologies enable people to stay connected anytime, anywhere with access network alternatives. Users' devices can seamlessly roam between PAN, WLAN, WAN, with new services yet unknown. With a penetration rate of wireless devices of over 100 percent over the entire population in most countries, how mobile services are provided will be quite different from now.

While connectivity is the most cherished property as in year 2000 (see [6]), the key values of mobile service in the 2030's will be totally different. By a combination of a large number of users, technology improvements, and operator productivity gains, the pure transport and access tariffs for wireless will have plummeted to very low values. Content-based service will generate certain revenue. Content exists in two variants:

1. "static", from data warehouses with only slow modifications;
2. "dynamic", from real-time information sensors and other sources, including user-originated content.

By profiling and data mining, besides personalization selections, the service operators will know in real time much more about users than now. However, in an age with information "overload", static content has no commercial value except for those with copyright of the creators, or information access provisions. Advertisement will generate some revenue for service providers, but it will probably not be sufficient to support a whole mobile communication industry living from the "law of large numbers" and from very low tariffs. User driven service personalization will enhance some tariffs, but the cost of provisioning of such services will offset revenue gains.

Mirroring the early trend in video/broadcasting industries for dynamic content, the relative share in tariff bundles of the intellectual property right owner will be larger; the multiplication of dynamic content channels will add to tariff bundles price pressure.

Consequently by say 2030, the true value of wireless services lies in the interactions, where the services are formed as a result of multiparty interactions. These interactions can be divided into three categories:

1. Community based human-to-human interactions;
2. Cluster based machine-to-machine interactions;
3. Human-to-machine interactions.

In this paper, we focus on the first category. Sociologist Barry Wellman [7] had defined communities as: "Networks of interpersonal ties that provide sociability, support, information, a sense of belonging, and social identity." We assume that all the members of such a community rely amongst other communication mechanisms, on the usage of mobile technology in the 2030's.

Because of their business, sociological or process-linked nature, the communities mentioned above rely on a membership fee (in kind or in money, eventually free) and on managed access privileges, akin operators customer care administration, but in diverse forms and with more freedom in the organization thereof. More precisely, belonging to community requires an identity and membership for a user in order to receive services. The community provides collectively information, know-how, and services to members through interactions and access to static or dynamic content. The access to the services inside a community is based on prices and based on competition, or possibly quasi real-time spot service prices. There are also prices for community peering arrangements, or community-to-community interactions, but these may be on a flat basis once a service-level agreement has been enacted between them. One key driver of these communities is obviously the affordability in economic terms, and the obligation in social terms, to join one or several communities. Section 3 explains in more detail the cost the revenue formation justifying this affordability.

The above analysis leads directly to pointing at the future potential of individual tariffs between now and the 2030's, although these would obviously be provided in a completely different way to the 1880's in terms of user population, technologies and management processes.

In China, the traditional "families" and groups culture (人以群分) leads to more diverse communities. In addition to business, occupations and hobbies, communities are often formed under a same origin, or under a same dialect [8]. The above pricing settlement arrangements suit especially well the various communities. Take the example of a family-based community: the flat rate will be very low (close to zero), similarly within a rural village. But the differences lie in the fact that in a formally organized community, "such as in a village", affordability will be higher as set

largely by users themselves in view of their social, economic and information needs, which may result in non-zero membership fees.

### 3. INDIVIDUAL TARIFFS

#### 3.1 Definition of Individual Tariffs for a Set of Communication Services

"Individual tariff" means that each individual sets a tariff for himself/herself for a specific set of services provided by the community, whether this service is user-defined or community-defined. Even if that individual belongs, say to an enterprise, the members of the enterprise may have different individual tariffs, simply because their service demand and content flow (contributions and receipts) are different. Even, different users of the identical service (if any such exists) may value and price it differently as they decide to belong to different communities as their choices.

In the definition above each community ends up supplying a number of services of which only some are initiated by consensus at community level or by the service manager. A community does not need to own part or the entire fixed and wireless transmission infrastructure, which can be sourced competitively from an infrastructure owner.

The above definition says nothing about the service provisioning duration the community commits to its members, or which communities commit to between themselves. Duration of the service will be one attribute in the multi-attribute service demand from the user in a community; e.g. sporadic uses are possible, just as are long term ones, but the difference with today is that they can be different and user-specific.

The above definition says nothing either about the transparency of prices and pricing provisions. More precisely, the information disclosure rules are of three types at least, with one between the member and his community (especially if this is managed formally), one within a community, and the last one between communities. These information disclosure rules may lead to price equalization but this effect is twice limited in that it can only happen for the same service, while each community member will have a different service profile.

Very importantly, per this definition, when the end user requests a certain service from a community, he/she is also responsible for the existence and survival of the community through contributions (money, but also information, knowledge). The individual will take and share the risk if the service is underfunded and ceases to exist. So, if the user appreciates the service, he/she may end up paying slightly more than other members, or even than users of the same service in other communities, to ensure the existence of the service. The

person can also consider paying an insurance premium to the community to cover against the risk of service loss.

By paying an individually negotiated premium, which can be a very small amount of money, the user maintains his access to services, but also by mutualising this risk, he contributes to the survival of the community [9].

There are several countries where some operators are on an experimental basis, or publicly, having individual tariffs which are not just options inside or outside a wireless “subscription plan/bundle”: Estonia, Norway and South Africa. In first two cases, it is part of business model and last one as part of policy to balance with disposable income (“universal service provisioning”).

### 3.2 Business Model of a Community

The income of a community will be made up of a combination of:

1. the member fee (once per year);
2. the competitive specific service usage revenues within the community;
3. service usage revenues generated from non-members;
4. the possible premium income from members who select to cover themselves against specific service disruption;
5. flat fees from other communities;
6. and, last but not least, contributions in kind (work, information, know-how, knowledge, innovation) by members.

On the cost side, they include:

1. costs of managing community memberships; but this cost does not bear marketing and publicity costs, so it will be far less than with today’s public operators;
2. investments in infrastructures and possibly service access devices;
3. partial service creation expenses, possibly shared with community users or other communities;
4. service provisioning and operations expenses, with in some cases community members being member-employees;
5. flat fees to other communities;
6. and, last but not least, intellectual property right expense from service creation and innovation, and from access to information or knowledge shared in the community.

We estimate that the community management overhead share will be 25%, the community service creation share 60% and the transport plus access share (to infrastructure owner) will be 15% of the total costs.

### 3.3 The Demand Analysis

The total demand will be large, as people can

personalize their services according to their needs, and furthermore because community proliferation may multiply the effect. Compared to the situation with generic public services in limited number, used by very many, communities offer viable alternatives in terms of revenue and demand. The reason is that within a community, the above two multiplicity factors are replaced by four:

1. number of community members;
2. overlapped sub-communities that share some common interests but have some interests and service demands different from others;
3. number of specific services for a sub-community;
4. number of common services to all members in the community.

These four distributions allow to replace flat rates for all, by individual tariffs, subject to the condition that each community has detailed network management and monitoring tools to be able in real-time as well over membership durations to quantify equilibrium break-even tariffs (see [10]). People will pay the amount of money, and put in their individual contributions, exactly according to how they value the personalized service bundles offered or requested by them. This results in price insensitive individual demands. Although for each specific service, the preference from each user will be different, but the average demand across large number of user again leads to a price inelastic demand curve (see Figure 2); in this way, we are back in history (see Figure 1). However, the new demand curve is much more to the right of in absolute value in the “number of service requests” axis and much lower in the price axis.

Figure 2: Service demand for one specific service “S” at 2030’s.

A, B and C represent individual A’s service profile: (S, A1, A2, etc), individual B’s service profile: (S, B1, B2, etc) and individual C’s service profile: (S, C1, C2, etc).

The average demand for service “S” is shown in the bold curve. Note there is a “service proliferation effect” driving the curve slope.

Case 3: A good example of community services are from the largest Chinese game community “Lian Zhong” (联众世界 [www.ourgame.com](http://www.ourgame.com)). It offers

online and mobile gaming, which include board games, card games and arcade games. It has over 130 million members, including 1 million paid members. Member fees are CNY 35 (90 days) or CNY 120 (1 year). However, membership days can be traded into credits which can be spent in the games. (E.g. 10 days of membership for 300 credits.) Paid members can, among other services, buy credits, have privilege joining and selecting the games, set up their sub-communities and can enter the "hall of fame" based on their scores and credits. Normal members can access common game services, with limited capability; they can not buy credits but have to earn them in the games. There are over 3600 sub-communities which are formed under different basis. An average sub-community has 600 members, and over 20% are paid members. Besides the common services, members in each sub-community can have their own specific services. Generally, each sub-community offers 2-3 specific services, like monthly training or tournaments but tailored to their favorite games and within a closed community. Currently, the access to services offered by sub-communities is free.

### 3.4 The Supply Analysis

The supply of services will be abundant, and the price will be low, driven not only by the deregulation of telecommunication services and technology advances, but above all by the freedom to define, request and bear a share of the risk around service creation. In the Chinese case, and maybe others, additional factors are the traditions within a community and their closed nature.

Still backbone transmission will be essential, as will be different authentication/roaming/settlement functions, but it remains to be seen if traditional operators born in mindset in the 1880's (analog voice) or 2000's (wireless) can offer competitive services in flexibility, price, quality and scalability to what some larger communities may do themselves. Do not forget that due to exploding traffic demand, and competition driven by many community-clients, the revenue from pure transport or access will become minimal compared to the added value of personalized services.

### 4. CONCLUSION: INDIVIDUAL TARIFFS IN CHINA?

The above analysis and evolution is highly relevant to the cultural, technical and sociological evolution in China—it shows a pattern in China today as to mobile adoption and affordability similar to the early days in the 1880's for fixed telephony on the user side.

A graduate adoption of community-based individual tariffs, first on connectivity, then on content, and finally

on interactions, will speed up the diffusion of mobile services for the majority of population in China. While various demands are met individually by user-set affordability, China can avoid the competitive model between large operators offering reduced set of standardized services and at the same time obtain a sustainable development in economic aspect.

On the other hand, the importance of individual and community pricing scheme is furthermore compounded by the importance in China of regional dialect and regional traditions as well as community demographics.

Community-based individual tariffs can be fueled by the very fast adoption of new technologies (WLAN etc.), and cultural linked services (e.g. mobile gaming). Furthermore, the skills base in software for service creation is a pre-requisite, the very presence of which in China may further accelerate this evolution by community based service needs.

However, the vision of individual tariffs envisioned here is not implemented in China, nor yet supported by regulatory policies. A balance has to be found between the emergence of communities, government policies and the opening up of Chinese communication market.

## ABSTRACT

Most of the CSCW innovations related to mobile technologies are at the research stage and have been launched commercially, as they are developed within labs and lack direct practical relevance. This paper reports the findings of a case study on real-world companies operating in the fine-paper supply chain and places emphasis on the requirements for supporting mobility within specific collaborative settings. A mobile web-based system for managing customer complaints in a collaborative group work environment is described, which we have designed and developed for the fine-paper industrial setting. The benefits - including stronger customer relationships, lower operating costs and better use of human resources - are available to any complex customer care activity that follows activity-centered collaboration and seizes the initiative via a web-based system with mobile access.

**Keywords:** collaboration, mobile system, complaint handling, paper industry

## 1. INTRODUCTION

The ever-increasing spread of mobile communications, rapid development of sophisticated smart phones and forthcoming future of IP convergence make it possible to adapt computer-supported cooperative work (CSCW) applications to mobile devices. Our motive for this study is twofold. We are witnessing the emergence of networked organizations that are based on flexible business processes and rely upon the dynamic work of teams that temporally coalesce. Increasing business velocity and mobility require collaborative applications and systems in B2B settings. One of the most time-sensitive fields in every business operation is internal and external customer service. Therefore major software providers, vendors and consulting companies offer various mobile deployment options for their CRM products [16]. Despite the contribution of such systems to supporting remote activities, these solutions are unwieldy and mobility in collaboration is often overlooked. Secondly, we aim to address an issue that has recently emerged within CSCW and still received relatively little attention – the requirements and conditions to support mobility in B2B collaborative activities. A growing number of studies exist on mobility in collaboration that offer findings about the actualities of mobile work in general and characterize the problems of mobile work [1, 11, 6, 15]. However, only a few of them have presented actual prototypes for mobile CSCW, featured them in empirical studies of work and communication [13, 3, 7, 12] and provided enough evidence of the implications for supporting mobility and enhancing collaborative work in corporate settings. As a number of authors have commented, activity-centered research on collaborative work is now beginning to emerge [8, 10]. This paper is based on the latter concept and presents a mobile collaborative system that places a strong emphasis on the requirements for supporting

mobility within specific collaborative settings. We report on studies of communication and collaboration in a vertical corporate market of the fine-paper industry, and discuss the implications of the horizontal mobile solutions for supporting collaborative work in the complaints handling process and more generally enhancing customer relationships.

## 2. CRITICAL INCIDENTS IN THE FINE-PAPER SUPPLY CHAIN

The case study reported here centers on three real-world companies, participating in the supply chain for high-quality fine paper. It aims to reveal the general condition of customer care that are specific to the fine-paper industry and focus on what is needed to improve the handling of complaints via a CSCW system. The fine-paper business within the pulp & paper industry produces a multitude of paper-based products. The industry is complex and depends on good customer relations with a great variety of players, ranging from paper mills and printers to retailers and consumers. A successful commercial publication is a sum of elements: content, layout, illustrations, font and, often very crucially, the paper and print quality. Despite the complexity, there are some key elements to becoming more successful on the market. In the fine-paper supply chain you need your customers' business. Most customers today want more flexible service concepts and more transparency in the supply chain and are willing to work more closely in production planning, logistics, etc. to get that. In the fine-paper industry, there is a lot of talk about customer service focus within manufacturing settings, but surprisingly few companies have envisioned where to start from and how to accomplish this. Our case is no exception, and critical incidents are often overlooked. Critical incidents related to fine-paper products consist of feedback and claims, which together

are referred to as complaints. There is no room for setting up a call center, since to resolve the conflict requires group decision-making and follows complex checkup procedures on the part of the technical customer service (TCS) working at the mill and of the personnel maintaining the printing machines at the customer site. Besides being a complex activity that requires group decision-making, coordination and information sharing, handling complaints related to fine-paper products is also a seasonal activity, which puts additional pressure from time to time on both customers and TCS. Another factor is related to the timeliness of the product to the end user, i.e. the consumer. Moreover, to keep abreast of market demands, printing houses aim to incorporate state-of-the-art technology. In the era of the mobile internet, this means customers in the fine-paper industry will be equipped with modern and efficient terminals, will submit their complaints and questions to the paper mills and expect to be answered promptly. In concluding this section, we stress that handling complaints in the fine-paper supply chain is a complex, group-work activity that under seasonal time pressure requires a high degree of collaboration.

### 3. RESOLVING CRITICAL INCIDENTS WITH TRADITIONAL IS TECHNOLOGY

Design, development and implementation of collaborative systems imply an understanding of group processes, i.e. the essence of collaborative work. Before describing a suggested collaborative system for complaint handling, let us have a look at the existing communication and work structures of complaint handling.

#### 3.1 Customer Service Tools for Handling Complaints

In traditional markets such as fine-paper products, customer complaints are considered an important source of information regarding areas of customer satisfaction and profitability. A recent study that examined complaints data [4] found that more customer dissatisfaction was generated by problems with customer service centers than by product failure. However, the first difficulty arises in the context of the fine-paper industry: what communication channels are most beneficial when trying to serve customers fast, individually and successfully? In the past few years online customer service has been receiving more attention, as the Internet has become a powerful tool for strengthening relationships between firms and their customers [17]. Recently, one of the paper mills' priorities has been to provide more online service for corporate customers. The paper-producing company has upgraded and improved its website. The new site offers a frequently asked questions (FAQ) section, and interactive discussion forum and a promotional goods section with marketing materials online. The FAQ page of an Internet producer's site provides answers to questions that are asked by customers on a regular basis. The disadvantage, however,

is just as clear: auto responders are standardized and can therefore not be called a customized service. When customers ask questions they will not be satisfied with a "canned" answer. Especially in complex processes, business customers want to communicate with humans. Auto responders can never be a substitute for a personalized answer and can therefore only be a subordinate part of a functioning customer care system.

While some researchers identify e-mail as one of the most pervasive collaborative technologies in organizations [18], others regard it as one of the worst communication media because of information overload and the interruption to work [9]. Even if the former can be proved, it does not seem to be an appropriate solution for handling complaints in the fine-paper supply chain. Failure to treat customer questions fast will result in dissatisfied customers and poor perception of the company. A rather popular customer care tool in the paper industry is an auto e-mail responder which is widely used especially when the technical customer service personnel is not available on line. The auto responder sends out a standardized reply to every incoming e-mail before any human looks at it. This means that one aspect of the customer relationship concept, instant customer care, is fulfilled. However in most cases the customer realizes that the service center on the supplier's side is a "dead end" providing usual apologies for a personnel being out of the office. Despite the modernization efforts and introduction of online customer service tools, there is a strong preference for face-to-face (F-to-F) interaction channels among technical service employees and management. "When we see people face to face, we really invest in the relationship", says a technical service manager at a paper mill. These moments of physical co-presence and F-to-F conversation are crucial to patterns of social life, but emphasis on meeting and thus the related delay in response time arising out of different modes and form of travel, as well as related traveling expenses may negatively contribute to the customer relationship. Many alternatives to traditional face-to-face interactions now exist without the need to travel to a common location. Mobile technology is the most efficient communication medium so far: it is real time, always and everywhere with the user, fast and easy to use, and customer service can indeed be reinforced by the mobile use of Web technology. When it comes to collaboration, 'togetherness' implies that group work takes place through the same artifacts. For certain processes in the supply chain, such as handling complaints, the cooperation takes place mainly through complex communication and understanding. This suggests that an interactive and efficient medium that enables instant information delivery, easy access to that information flow and sharing among participants should be considered an appropriate communication artifact for resolving industrial complaints. However, the picture becomes even more complicated in our case, as both tasks of complaint handling and individual difference

factors affect the way groups use the medium of their choice available to them.

### 3.2 The Study

In the case study reported here we have focused on developing new IS solutions and used constructive research methods based on action research methodology. Multiple data sources provided more accurate evidence of the complexity of the process. In our data collection effort, we used F-to-F interviews and documentary materials as the primary source of data. We conducted private interviews with each of the 10 focus group members from the paper producing company, customer printing houses and wholesaler. The official documents we received (a standard flow diagram and summaries of complaints handled in the year 2003) gave us a picture of how the complaints had been handled by the paper-producing company. As an independent external facilitator of the process, the author of this study conducted a series of expert surveys to enable customers, service technicians and management at the mill to provide data for defining problems and opportunity situations regarding customer service. Responses were obtained from 16 experts. Fragmentation of working time, information flow and working space were used as measures to uncover shortcomings within the existing process and potential areas for improvement, where combination of mobile and web technology served as an enabler. Data collecting process, covering the stages of feasibility and development through to preliminary experiment, took a period of one and a half years.

### 3.3 Dimensions of Work and Resulting Requirements

One of the motives for using collaboration systems is that CSCW is more effective and efficient than traditional forms of teamwork. A group of team members has more information and possesses more knowledge than any individual member alone. Therefore groups are better than individuals at understanding problems, in noticing errors; as a result, more alternatives are generated for problem solving. A key concept of Systems Theory [4] can be applied in the complex industry of fine-paper products: the effectiveness of group work in resolving complaints and the quality of the corrective actions suggested can be larger than the sum of what is produced by an independent individual. But incomplete access to information can hamper successful completion of the group work. The group process can be time-consuming, costly and might even jeopardize good customer relations without appropriate coordination to integrate participants' contribution in solving critical incidents. Co-location, temporality and contextuality are not mentioned in the literature as variables of groupness, but they are one of the most essential characteristics of individual work. If not taken seriously enough, these dimensions of individual work may constitute barriers to group collaboration.

**Spatiality.** The existing complaints handling process suffers from coordination difficulties when the process actors are working remotely. These people are located at different offices across the continent and use various technological artifacts to communicate. But not all the actors have the same intensity and scope of mobility. Technical managers at the paper-producing company are key decision-makers in solving complaint-related problems, but they are highly mobile and work at least twice a week away from desktop computers. Engineers, on the other hand, are involved in routine work on the mill premises, which is characterized as micro mobility. These people are most often overloaded with customer's questions, are heavily involved in the communication process and need a good visual interface when describing laboratory results to the customers. Effective customer response should be immediate. No matter how mobile and where the customers are, they expect to have problem solutions on-line (PC and/or mobile device) and in real time. Wireless has value for managers on the move, whereas high-resolution desktop computers are mandatory for engineers.

**Temporality.** Systems such as electronic mail or mobile phone calls may have several advantages; they are likely to be a burden in the complex group work activity of handling complaints. The above systems are very intrusive by their very nature, especially in communication-intensive environments when people have to work under the pressure of time. E-mail is an asynchronous medium, but imposes information overload with risk of being unable to keep track of how the handling of the complaint is progressing. Another problem is related to telephone calls. While it is an extremely flexible medium, producing lots of unstructured and codified information, it also requires the user to do a lot of work by manually retransmitting that semi-structured information to the relevant team member. Knowledge workers in the paper-manufacturing company spent 15-30% of their day searching for information and lose about 6 working hours altogether per complaint because of interruptions to their work. People often became frustrated because they were unable to get to things via a single access point, as necessary information was often spread across different actors and communicated via multiple devices. Electronic media may lead to new patterns of communication, encouraging people to collaborate at the point of need with certain team members, perceiving each other's actions instantly but asynchronously.

**Fragmentation of information.** In our study the notion of information fragmentation refers to what and how activity relevant information is communicated, shared and stored by the group members. Variety in the communication medium used makes the information flow process slow and inefficient (knowledge workers spend a lot of time on requesting and providing information manually, a lot of copy/paste work is involved). The system fails to integrate and structure the

incoming information from the customers and leaves it optional for the customers to enter. This also makes it more difficult to perform statistical analysis of annual complaints and identify the various problems associated with it.

We mentioned earlier that collaboration implies that the object of work should be common to the actors, i.e. by having access to a common artifact. In our case this means that information should be shared. This raises the question of what type of information and how it should be shared in order to support effective communication and shared understanding between actors. We believe that structured information, visible flow and sharing constitute a first underlying requirement here.

#### 4. SYSTEM TO SUPPORT ACTIVITY-CENTERED COLLABORATION IN COMPLAINT HANDLING

##### 4.1 Activity-Centered Collaboration

Malone [14] suggests that, in general, organizational technologies consist of production and coordination technologies that have implications for different processes. Complaints are regarded as service messages and clearly form part of management processes; they can therefore be enhanced by improved availability and communication of information. Work redesign can be based on the "object-oriented" modeling techniques discussed by Crowston et al. [5], where information flow can be streamlined by new technologies to provide necessary coordination among group members. In their recent study, Geyer and colleagues [10] introduced the notion of "object-centric sharing", where users collaborate in a lightweight manner, by aggregating and organizing different shared artifacts into larger collaborative activities with dynamic membership, hierarchical object relationships, and enable both real time and asynchronous communication. The "shared objects" paradigm of collaboration-aware content is very similar to Dourish's [8] notion of "placeless" documents, which define a set of people who are allowed to access the information, indicate who is currently looking at the content and allow broadcasting of data to members of the object. In our case, different actors involved in resolving the same complaint could use the data stored in one centralized data base and share a common virtual work environment accessible via different interfaces, rather than each having partial information or passing information among themselves. It is also argued that IT plays an important role in recent attempts to focus on core activities of reengineered business processes. The organization should be less centered on the process actors, and more on the activities they have to perform. The emergence of mobile communication technologies provides the relevant support for flexible forms of organization and temporal group work in producing a service. Systems for activity-centered collaboration which could also incorporate mobile technologies would appear to correspond and facilitate new forms of

customer service, offering the kind of support for all geographically dispersed group members.

##### 4.2 Web-based System with Mobile Access

Nowadays the term IP technology convergence is quite popularly used. By this is meant a certain kind of fusion or close interaction of the Internet and mobile phone networks. This wireless access to the digital content of the Internet via mobile devices, including mobile phones, smart phones, PDA's, handheld computers (communicators) and portable PCs (laptops) is understood as the *mobile Internet*. From the convergence of Internet-based systems and mobile computing technologies, the term mobile Internet systems was derived, which is sometimes replaced by mobile web-based applications or M-commerce. Let us describe the architecture of the proposed complaints handling system with mobile functionality (see Figure 1). A web-based system is primarily built for a PC and GPRS-enabled smart phone, but is written with generic code and will in fact work on all html\xhtml-supporting devices.

Figure 1. Architecture of the proposed system

**Customer/Admin UI.** The customer/administrator uses a web browser on a computer or a phone to access our system. The browser of a mobile device does not have to support xhtml, but it must support html. It means that we use html (html4-strict) instead of xhtml both for the PC and the phones. Since xhtml is easier to implement than html, it is usually the case that a smart phone browser that supports html also supports xhtml.

**Servlet/interface.** The interface between the browser and our system is based on servlet middleware or Java servlets and uses a template system, named "Velocity", to create the actual interface.

**J2EE.** The servlets use an abstraction layer that we have created and named "Knowledge Base", which accesses the J2EE-based core of the system. This is the application core, which is where all business logic is handled.

**Application database.** The application core stores all data in a database. All access to the database goes through an abstraction layer, which makes it possible to change the database to another brand without having to recompile the application.

The web-based complaints handling system can be accessed via a mobile device and the Internet accompanies its user everywhere, regardless of the type of device used. The system can work on any html/xhtml-supporting mobile device, but the Nokia 6600 was chosen for its reliability, faster navigation and cost efficiency compared with alternative smart phones. In a final product the web-interface and mobility feature should be integrated on top of the existing corporate ERP system.

### 4.3 New Communication Structures and Implications

The main users of the application will be key customers (resellers, purchasers, printing managers, plant manager) and paper-mill employees involved in the complaints process at the mills (engineer and manager of Technical Customer Service Center (TCS), director of TCS, logistics manager, production and operations managers, mill management and sales office personnel.

**The main features** of the proposed complaints handling system are traceability and structured information. Traceability will allow the user of the application to track the progress of complaints handling activities in real time, the ability to access and update the complaint file – a self-documenting and self-reporting common most important document within a system – via a PC or any other mobile device. When somebody is working on something with the complaint, the customer as well as other colleagues can see it. The principal value for the customer will be the transparency of the handling process, which is critical to them - the ability to track the complaint in real time and to have control over the process from the date the complaint was instigated.

Figure 2. Traceability feature and system's visual outlook on PC and smart phone

Another important advantage of the web-based system is to have very structured initial information coming from customers. This also makes them think about the reasons before claiming and include additional info at the very beginning. A customer in an ideal case will create a complaint file at the very beginning of problem recognition, and should provide as much information as possible about the problem. The user will have the option of choosing a complaint type and filling in the required information fields, according to the reason for the complaint. In addition, we aim to ease the job of TCS at

the mill too. The system incorporates instantaneity and supports automatic notification; thus participants perceive each other's actions with no perceptible delay. Each group member is instantly notified by the system when a certain activity is finished or new questions arise. Depending on the work mobility, user may select whether he or she wants to receive e-mail notification or an SMS.

**Usage scenarios.** There are two scenarios for the modernized complaint system. In the best-scenario case, we have a direct link between a customer who files the complaint and the TCS (manager & engineer) at the mill. The second scenario is more applicable abroad only if language constraints do not allow the customer to send a complaint directly to the mill. In this case a sales office should register the complaint on the web during a phone call with the customer. A password will be required to log into the web-based system, so paper-mill employees working with complaints will know who the customer is. A self-documenting and self-reporting complaint file might include auto alerts in the form of an SMS or e-mail for actors performing at the end of the process, e.g. operations and productions managers, logistics managers, etc. At the end of the complaints handling process, the auto summary of the complaint file will generate a PDF file, and will allow the use of the well-structured information for various statistical analyses (beyond the current way of monitoring the success rate of complaint reply and closing time).

Referring to Figure 2, it is important to note, that the "visual outlook" on the smart-phones will be simplified, as usability of such mobile phones is limited and requires much more relevant and precise information than on a PC. We believe a smart phone serves merely as an additional tool and is not a replacement for a PC. It is meant to be used for information tracking, other checkups and decisions when a user cannot access the PC. Having the smart phone on hand, a user would simply be able to use the system when a PC is not an option. A PC/Laptop is also supposed to be the primary tool for customers filing complaints. However, they will also have the choice of making the best use of smart phones when checking the status of very urgent complaints.

### 5. CONCLUSIONS AND FURTHER RESEARCH

We have entered the field of research into what business currently needs and what consulting companies do not take seriously. In this paper we have described a mobile web-based collaborative system that we have designed and developed for managing complaints in the collaborative group-work environment of the fine-paper industry. The benefits - including stronger customer relationships, lower operating costs and better use of human resources - are available to any complex customer service activity that uses collaborative group work and seizes the initiative via an activity-centered collaborative system with mobile access.

First of all, collaborative customer service reduces costs while solving problems related to spatiality, temporality of working time and fragmentation of information. The math is simple. Just compare the cost of receiving and responding to several hundred phone calls and e-mails to the cost of sending a single, well-crafted message to a targeted audience. Secondly, a collaborative and always accessible system allows TCS to support more customers and resolve more complaints with existing staffing levels. With automated proactive service mechanisms carrying more of the burden, TCS no longer has to grow in proportion to demand. A well-structured and transparent way for handling routine issues also frees TSC staff to focus on more complex and/or urgent problems that truly warrant their personal attention and knowledge workers' skills. As a result, instant and transparent way of handling critical incidents is a key to a long-term customer relationship based on trust, customer empowerment and smooth service experience.

Despite the obvious positive effect of using an activity-centered collaborative system for handling complaints, various barriers do exist to its widespread adoption and use. The client of a new system is the worker at customer service and only indirectly the organization. A successful design is one that increases the group members' satisfaction and improves their attitudes towards work. The major barrier to introducing a state-of-the-art technology in an organization is the learning effort required: this is why we need "usable" systems and devices. On the other hand, people are likely to learn how to use new technology if they find it useful. Our future studies will focus on evaluating the usability of the working prototype in field experiments, depending on the type of devices adopted by different team members. This form of evaluation is needed to develop the system further and to make sure it is usable and easy to use.

## ABSTRACT

In spite of the rapid growth of mobile multimedia contents market, most of the customers experience inconvenience, lengthy search processes and frustration in searching for the specific multimedia contents they want. These difficulties are attributable to the current mobile Internet service method based on inefficient sequential search. To overcome these difficulties, this paper proposes a MOBILE COntents Recommender System for Movie (MOBICORS-Movie), which is designed to reduce customers' search efforts in finding desired movies on the mobile Internet. MOBICORS-Movie consists of three agents: CF (Collaborative Filtering), CBIR (Content-Based Information Retrieval) and RF (Relevance Feedback). These agents collaborate each other to support a customer in finding a desired movie by generating personalized recommendations of movies. To verify the performance of MOBICORS-Movie, the simulation-based experiments were conducted. The experiment results show that MOBICORS-Movie significantly reduces the customer's search effort and can be a realistic solution for movie recommendation in the mobile Internet environment.

**Keywords:** mobile commerce, recommender, collaborative filtering, agent, relevance feedback

## 1. INTRODUCTION

As mobile Internet technology becomes more increasingly applicable, the mobile multimedia contents market has recorded remarkable growth. In spite of this rapid growth, however, most of the customers experience inconvenience, lengthy search processes and frustration in searching for the specific multimedia contents they want [3]. These difficulties are attributable to the current mobile Internet service method based on inefficient sequential search:

1 When customers log on to the mobile Internet site using a mobile phone, they are presented with the best-seller list or a list of multimedia contents in sequence of most recent introduction.

1 Customer pages through the list and selects an entry to check out its contents hoping that the contents will be what he or she wants.

1 If the customer likes the contents, he or she may make a purchase. Otherwise, the customer repeats the same steps until the customer either has stumbled over the right one or decides to give up.

Using current service method, the expected number of contents the customer views before he or she hits the desired movie far exceeds the acceptable level. Inconvenience, lengthy search processes, and frustration make customers easily annoyed by the amount of irrelevant and uninteresting information they have to filter out. During a search, as more time is consumed, frustration builds with the result that the purchase conversion rate drops. To make search processes more acceptable, a more efficient searching aid that suggests only the movies meeting the individual customer's preference is needed. This paper proposes a MOBILE COntents Recommender System for Movie

(MOBICORS-Movie), which is designed to reduce customers' search efforts in finding desired movies on the mobile Internet. The system combines two of the most popular information filtering techniques: Collaborative Filtering (CF) and Content-Based Information Retrieval (CBIR).

MOBICORS-Movie consists of three agents: CF, CBIR and RF (Relevance Feedback). These agents collaborate each other to support a customer in finding a desired movie by generating personalized recommendations of movies.

The simulation-based experiments were conducted to verify the performance of MOBICORS-Movie. The experiment results show that MOBICORS-Movie significantly reduces the customer's search effort, so it can be a realistic solution for multimedia contents recommendation in the mobile Internet environment. We believe that deployment of MOBICORS-Movie offers the following benefits to both consumers and suppliers of mobile multimedia contents:

1 Customers can purchase mobile contents with much less search effort and much lower connection time to the mobile Internet, because they can much more easily find desired mobile contents.

1 Mobile contents providers can improve the profitability of their business because lower customer frustration in finding desired contents increases revenue through an improved purchase conversion rate.

## 2. EXISTING TECHNIQUES

### 2.1 Collaborative Filtering

The recommender system is one of possible solutions to

searching for individually preferred contents from a large-contents database. A recommender system is defined as a system that assists customers in finding the items they would like to purchase. One of the most successful recommendation techniques is Collaborative Filtering (CF) [7,8], which has been widely used in a number of different applications.

Collaborative filtering is an information filtering technique that depends on human beings' evaluations of items. It is an attempt to automate the "word of mouth" recommendations that we receive on a daily basis from our family, friends, and colleagues. It identifies customers whose tastes are similar to those of a given customer and it recommends items those customers have liked in the past. In general, CF-based recommender systems make recommendations according to the following steps [4,7]: (1) A customer provides the system with preference ratings on items that may be used to build a customer profile. (2) The system applies statistical or machine learning techniques to find a set of customers, known as neighbors, who had in the past exhibited similar behaviors (i.e., either they had purchased a similar set of items or they had given the set similar ratings). A neighborhood is formed based on the degree of similarity between a target customer and other customers. (3) Once a neighborhood is formed for a target customer, the system generates a set of items that the target customer is most likely to purchase by analyzing the items in which neighbors have shown an interest (*top-n recommendation*).

Although the CF is the most successful recommendation technique, it suffers from two major shortcomings. First, when there is a shortage of ratings, CF suffers from a sparsity problem [1,2,4,7]. Most similarity measures used in CF work properly only when there exists an acceptable level of ratings across customers in common. An increase in the number of customers and items worsens the sparsity problem, because the likelihood of different customers rating common items decreases. Such sparsity in ratings makes the formation of neighborhoods inaccurate, thereby resulting in poor recommendations. Next, CF suffers from a new item problem [1,5]. Since CF recommends an item based on customers' ratings on the item, it does not recommend a newly introduced item until some ratings of the item become available. The new item problem becomes even worse when the turnover rate of items is high. The Third issue is related to *scalability* [4,7]. Recommender systems for mobile customers have to deal with large amount of multimedia contents and millions of customers. Because these systems usually handle very high-dimensional profiles to form the neighborhood, the nearest neighbor algorithm is often very time-consuming and scales poorly in practice.

## 2.2 Contents-based Information Retrieval

Content-based information retrieval represents a movie

as a point in the multi-dimensional feature space and performs similarity-based retrieval using its contents-based keywords. In CBIR, customer describes movies using a query that is a set of example keywords. A query is internally represented as multiple points (i.e. query points) that have keywords of example movies. In general, CBIR systems retrieve movies according to the following steps [3,9]: (1) A system presents a query to the customer via the results of collaborative filtering as a request for desired movies. (2) The system searches for movies similar to the query. The similarity between a movie in the database and a query is calculated using the distance between corresponding points in the feature space. (3) The movies with the highest degree of similarity are retrieved and recommended to the customer.

In spite of the virtues of CBIR in retrieving movies similar to a query, CBIR rarely brings a customer to the desired movies immediately. The reason for this is that any combination of example movies may not precisely represent the movies that a customer desires. For a system to handle this gap properly, it needs the ability to learn about what movie the customer really wants through iterative interactions. The customer's current preference on the presented movies needs to be fed back so that CBIR can learn from this preference to retrieve, in the next iteration, movies more similar to the one customer really wants. This learning process, the *relevance feedback*, is an essential mechanism for a faster search of desired movies. The degree of preference of a movie in MOBICORS-Movie is expressed in three-level (e.g. *preferred*, *neutral*, *unpreferred*) weights. We will refer to a set of preferred movies as a *preferred set*. The movies in the preferred set are used for query refinement for the purpose of learning customer's current preference. And relevance feedback is performed using Rocchio's algorithm [6].

## 3. MOBICORS-Movie

### 3.1 Recommendation Procedure

MOBICORS-Movie is designed to reduce customers' search efforts in finding desired movies on the mobile Internet. The system consists of three agents: CF, CBIR and RF (Relevance Feedback). These agents collaborate each other to support a customer in finding a desired movie by generating personalized recommendations of movies. Figure 1 shows the recommendation procedure of MOBICORS-Movie.

First, an initial recommended movie list is generated by CF agent and shown up to the mobile customer. A customer selects one of the recommended movies using just a movie title. Then the customer sees the detailed information of selected movie, such as brief introduction of the movie, director, actors, actress, and so on. If he/she buys the movie, then he/she can watch the movie by mobile phone after payment process. If the customer

replied as “unpreferred”, the recommended movie list generated by CF agent except the selected movie is shown up to the mobile customer. If the customer doesn’t buy the movie but replied as “preferred”, CBIR agent and RF agent search for similar

movie(s). Then the customer sees the detailed information of selected movie. The procedure is terminated until the customer buys the movie or disconnects the searching process.

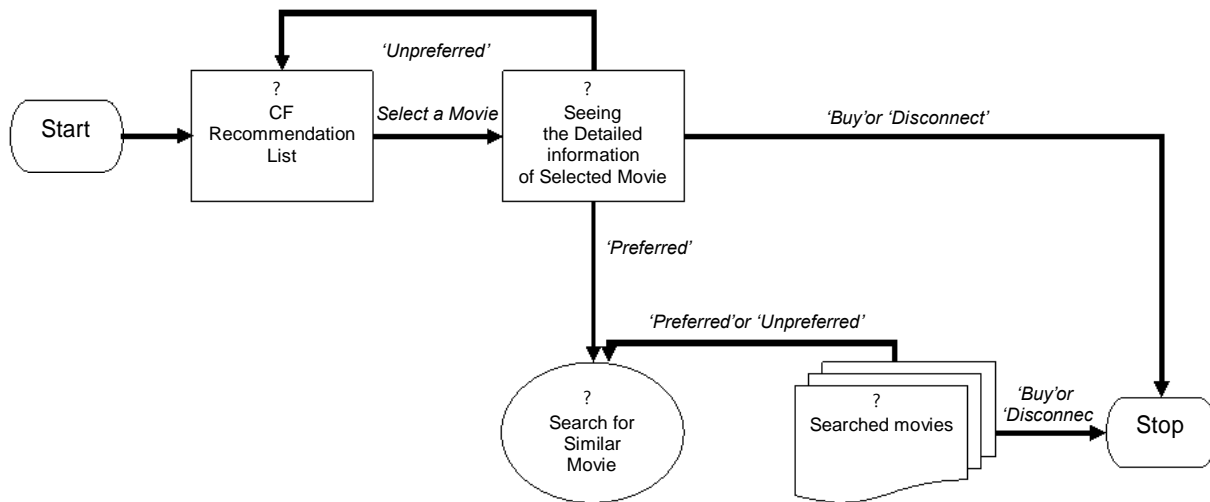

Figure 1. The procedure of MOBICORS-Movie

### 3.2 System Architecture

The architecture of MOBICORS-Movie is shown at Figure 2.

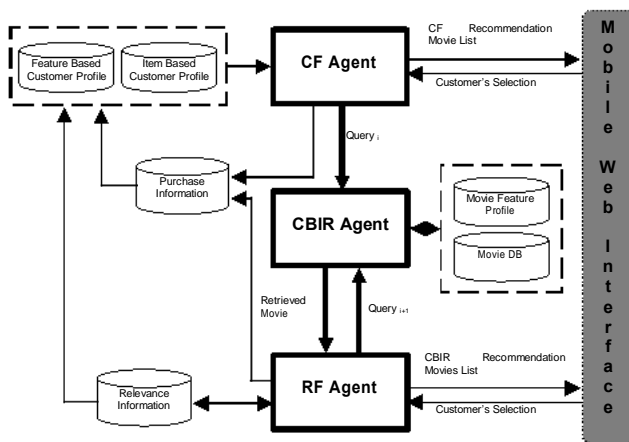

Figure 2. The architecture of MOBICORS-Movie

The CF agent generates a list of recommended movies and provides an initial movie to the CBIR agent. This agent creates the customer profile using purchase and preference information to identify neighbors and generate recommendations. When the CF-generated recommendation list is presented, a customer skims through the list to see if there are any movies of interest. Then, the customer selects an entry to view the movie.

After viewing, the customer may decide to purchase the movie or decide whether to use the movie as a query for content-based search of similar movies or to go back to the CF-generated recommendation list.

When the customer decides to use the viewed movie as a starting query for further search, the viewed movie is passed to the CBIR agent as an initial query, and the agent retrieves movies based on similarity between the query and other movies in the database. For all movies in the database, this agent calculates the similarities from the query and generates a list of the most similar movies as recommendations. It then passes the retrieved movies to the RF agent. RF agent presents the retrieved movies to the customer one by one, and interactively elicits the user’s preference judgment on the presented movies.

At any point in this presentation session, the customer may decide to buy a movie or decide to quit. After all of preference judgment, either preferred or unpreferred, are made, the RF agent updates the preference information and purchase databases with all the fed back preference and/or purchase information respectively for later use by the CF agent when the customer revisits the site. If all of presented movies are marked as unpreferred, the search session returns to the CF-generated recommendation list. Otherwise, the RF agent learns the customer’s current preference using his/her preference judgment, formulates the new query, and passes the query to the CBIR agent for the next iteration of retrieval.

### 3.3 Profile Management

**Movie Profile:** A movie profile includes information about the characteristics of movies. A movie profile is represented by matrix  $V=(v_{jk})$ , where  $j$  and  $k$  implies  $j$ th movie and  $k$ th keyword. If  $j$ th movie contains  $k$ th keyword, the value of  $v_{jk}$  is 1, otherwise it is 0. For example, the number of movies is 7, and that of keywords is 6, an example of movie profiles is represented as Table 1.

Table 1. A Movie Profile

	Betrayal	Crime	Cult-favorite	Drama	Police	Twist-in-the-end
Godfather	1	1	0	1	1	1
Pulp Fiction	0	1	1	1	0	0
Reservoir Dogs	0	1	1	0	1	1
Fight Club	0	1	1	1	0	1
Fargo	0	1	1	0	1	0
Psycho	0	0	1	0	1	1
Goodfellas	1	1	0	1	1	0

**Feature-based Customer Profile:** A feature-based customer profile represents customer's preference on keywords. It is composed of customer-keyword matrix  $F = (f_{ik})$ , where  $f_k$  implies the preference degree of  $i$ th customer on  $k$ th keyword. For example, the number of customers is 4, and that of keywords is 6, an example of feature-based customer profiles is represented as Table 2.

Table 2. A Feature-based Customer Profile

	Betrayal	Crime	Cult-favorite	Drama	Police	Twist-in-the-end
Kim	5	10	0	5	-10	0
Cho	10	5	-5	5	5	10
Kang	5	15	5	10	-5	0
Lee	0	10	0	10	0	-5

**Item-based Customer Profile:** An item-based customer profile represents customer's preference on movies. It is composed of customer-movie matrix  $P = (p_{ij})$ , where  $p_{ij}$  implies the preference degree of  $i$ th customer on  $j$ th movie. For example, the number of customers is 4, and that of movies is 7, an example of item-based customer profile is represented as Table 3..

An item-based customer profile includes information about customer's preferences on movies. Generation of CF recommendations depends totally on item-based customer profile. MOBICORS-Movie builds the item-based customer profile using purchase records and fed-back binary preference information, either preferred or unpreferred.

Table 3. An Item-based Customer Profile

	Godfather	Pulp Fiction	Reservoir Dogs	Fight Club	Fargo	Psycho	Goodfellas
Kim	5	15	0	15	0	-10	5

Cho	15	-5	5	5	-5	0	10
Kang	15	10	15	15	15	0	5
Lee	10	5	5	10	5	-5	5

The profile is updated as the following equation:

$$p_{ij} = \begin{cases} +2 & \text{if customer } i \text{ has purchased movie } j \\ +1 & \text{if customer } i \text{ has marked movie } j \text{ as preferred} \\ -1 & \text{if customer } i \text{ has marked movie } j \text{ as unpreferred} \\ 0 & \text{if customer } i \text{ has not seen movie } j \end{cases}$$

Note that the brief introduction of movie that customer viewed from CF recommendation list and decided to use or not to use as an initial query for CBIR is counted as a preferred or unpreferred movie, respectively. As shown in above equation, the cells of the rating matrix have four possible different values. We place the highest ratings on the previously purchased movies, because they should reflect the customer's taste the most strongly. The movies marked as preferred or unpreferred are represented in ratings of half the magnitude of the purchased ones with an opposite sign. Assigning -1 to unpreferred images gives a better chance to unseen movies over unpreferred ones in generating recommendations. Please note that further research work is necessary to justify heuristic choice of values used for preference ratings, since their relative sizes in magnitude could affect recommendations of CF.

The ratings in customer profile are constantly replaced with newly obtained purchase and preference information to dynamically reflect customer's most recent preference. This is significantly different from the customer profiles used in traditional CF techniques [7,8].

## 4. EXPERIMENTAL EVALUATION

### 4.1 Experiment

For the purpose of the performance evaluation of MOBICORS-Movie, we developed a Web-based application system running on a PC with exactly the same user interfaces as the mobile phone-based MOBICORS-Movie system. Using the system, we carried out the experiments with the intent of answering three major questions:

- (1) How much performance improvement does MOBICORS-Movie deliver as his/her search and purchase information in customer profile is accumulated?
- (2) How does the number of movies CBIR agent search affect the performance of MOBICORS-Movie?
- (3) How much performance improvement does MOBICORS-Movie deliver compared to other recommender systems in mobile phone environment?

For the experiments, the 250 movies from IMDB(www.imdb.com) were used. MOBICORS-Movie used the top 100 keywords sorted by frequency from

IMDB. Virtually generated 1000 mobile Web customers are participated in the experiment. They are set to purchase 5 movies randomly, and their initial purchase information is stored as an initial feature based customer profile and item based customer profile.

For performance evaluation of MOBICORS-Movie, a metric *views-per-success* (*vps*), defined as the number of movies viewed by a customer before he/she purchases a movie in a search session, was devised. The *vps* measures the amount of effort a customer takes per successful search [3].

## 4.2 Results and discussion

The quality of recommendations of CF is known to vary by the size of the neighborhood [4,7]. The neighborhood size yielding optimal performance depends on customer profile, whose contents change all the time. For this reason, comparison between optimal performances of different periods requires increasing number of additional experiments to calculate the optimal neighborhood for every period. However, considering the burden of participants in the experiment, we used the optimal neighborhood size of the first period and fixed the neighborhood size for the rest of the experiment. According to Figure 4, the optimal neighborhood size was determined to be 40. For the rest of the experiment, we fixed the neighborhood size at 40.

Figure 3. Average *vps* over diverse neighborhood sizes

To answer the question 1 and 2, we observed the variation in *vps* over periods and *n*, number of nearest neighbor movies retrieved in CBIR. This is observed as a decreasing curve in Figure 4, which shows the overall performance of MOBICORS-Movie in terms of *vps* vs. period for five different values of *n*.

As periods move on, more rating information becomes available and the customer profile with more ratings makes neighborhood formation more accurate, thereby improving the quality of CF recommendations. Figure 4 indicates that the variation in *vps* by *n* is significant. Furthermore, it is observed as the difference in *vps* by values of *n* especially in early periods, and as the diminishing trend of difference in *vps* over periods in

Figure 4.

Figure 4. Overall performance of MOBICORS-Movie

Furthermore, as the value of *n* becomes from 2 to 6, the performance becomes better, but the value of *n* goes over 6, the performance becomes worse. In general, sparsity level of customer profile and heterogeneity in customers' buying behaviors are the most important factors influencing the effectiveness of CF [2,3,4]. In cases with high level of either sparsity or heterogeneity, CF's performance is poor, thus we select optimal value of *n*. The value of *n* can be selected considering other factors such as customer's burden of feedback in CBIR or the firm's marketing strategy toward the diversity in recommended movies.

To answer the question 3, the performance of MOBICORS-Movie is compared to those of two other recommender systems, the best-seller-based system (Bestseller) and a typical CF-based recommender system (pure-CF), whose procedure is identical to that of CF-based recommendation of MOBICORS-Movie except that, in building a customer profile, it uses purchase information only.

As compared in Figure 5, the *vps* of MOBICORS-Movie is about 60% and 72% lower, at 40 periods, than that of the pure-CF and best-seller-based systems respectively. In other periods, the performance gap between MOBICORS-Movie and other techniques is higher. Figure 5 also shows that the rates of improvement in *vps* over the 10 periods (i.e. learning speed of the system) of MOBICORS-Movie, pure-CF and best-seller-based systems are 50%, 68% and 55% respectively. These results show that, of the three systems evaluated, MOBICORS-Movie offers not only the lowest *vps* but also the most robust performance over 10 periods. The superior performance of MOBICORS-Movie over the pure-CF results from MOBICORS-Movie's accelerated learning of customer preference from additional preference rating information fed back from CBIR. This evidences that MOBICORS-Movie, as intended, successfully overcomes the sparsity problem of CF.

Figure 5. Comparison of MOBICORS-Movie and Other Recommendation Techniques

## 5. CONCLUSION

It is devised a recommender system, MOBICORS-Movie, to address the real problems encountered in movie watching services in the mobile Web environment. The system combines two techniques from different research domains: recommender system and information retrieval. By employing two techniques, MOBICORS-Movie generates recommendations with the following characteristics: (1) MOBICORS-Movie recommends movies by reflecting the opinions of other customers with similar tastes. (2) MOBICORS-Movie recommends movies with similar keyword features to the ones the customer currently prefers. (3) MOBICORS-Movie recommends movies by learning the customer's preference adaptively via feedback on recommended movies.

To verify the performance of MOBICORS-Movie, the simulation experiments were conducted. From the experiment result, we can conclude that MOBICORS-Movie is a viable solution to the problems currently encountered in movie watching on the mobile Web, and that it can be expected to reduce the search effort, thereby increasing the purchase conversion rate. Use of MOBICORS-Movie offers the following benefits to both consumers and suppliers of mobile contents: (1) Customers can purchase contents with much less search effort and much lower connection time to the mobile Web, because they can much more easily find desired mobile contents. (2) Mobile contents providers can improve the profitability of their businesses because

lower customer frustration in finding desired contents increases revenue through an improved purchase conversion rate.

With the rapid growth of the mobile Web service, the mobile Web-based recommender system for other types of multimedia contents, such as music on demand (MOD) will continue to be an area of research interest in the future.

## Mobile Payment System with Privacy Protection

Kuenliang Sue, Wanpu Hsieh

Department of Information Management, National Central University, Chung-Li, 320, Taiwan, China  
{klsue, im880703}@mgt.ncu.edu.tw

### ABSTRACT

Trade security is the main point of the payment system. The system should fit the security issues such as confidentiality, authentication, and non-repudiation. However, the privacy problem seems to be ignored. This article proposes a new structure to improve the privacy of mobile payment system when consumers buy something via mobile device. The new system needs to fit three points: familiarity, privacy, and non-repudiation.

**Keywords:** mobile payment, non-repudiation, privacy, mobile commerce

### 1. INTRODUCTION

The trade behaviors are changing gradually because of the rise of mobile commerce. In the past trade activity, people needed to bring a lot of cash by themselves. Gradually, the applications of the plastic currency grow, people reduce the times using cash. Then, the appearance of e-commerce, the trade is no longer confined to face-to-face. The trade no longer needs to stay in one regular place. However, some problems still exist. Although plastic currency is convenient, people need to take a lot of cards with themselves. Even the trade of e-commerce can be remote, the security and convenience are still insufficient. Fortunately, mobile payment can change the predicament. People do not need to bring many cards because the tool of the trade is the mobile communication device that we can find easily on our person. Convenience of the trade increases greatly. The trade activity can be processed in any time, at any where, and with any people. Nevertheless, due to the congenital defect of the mobile device, it is unable to carry on the complicated security mechanism. The security problem is the key point in mobile payment system. Figure 1 shows the traditional payment model of credit card. This is the payment model of e-commerce, too. With this model, we can understand the trade activity in the past.

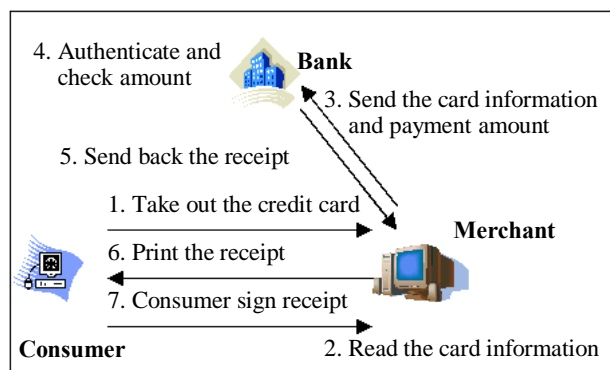

Figure 1. Traditional credit card payment model

Step 1, consumers take out the credit card to begin the

trade. Step 2, the merchant uses a card reader to read the credit card information of consumer. Step 3, merchant sends the credit card information to the bank. Step 4, the bank authenticates the consumer and checks amount to finish the payment. Step 5, the bank sends the receipt back to confirm the trade. Step 6, after the merchant receives the receipt, merchant will print out the trade receipt to do a confirmed by consumers. Step 7, consumers need to sign and confirm on the receipt. After finishing those steps, trade behavior by using credit card completes.

Although using plastic currency is very general for people nowadays, it seems that the whole procedures do not pay enough attention to the security issues. Potentially, one can pretend himself is someone else and forge a trade by using other people's credit card number. The similar situations also happen on the network. Except for worrying about the criminal gang to record the number of the card, consumers also need to believe the merchant very much and think that the merchant will not steal the personal information of the consumer. Because we must transfer the personal credit card to the merchant to help us read the information and finish the trade procedure. Although we can use receipts to confirm whether the amount of money of consumption and goods have mistakes or not, the important private information like trade account may be recoded and collected during the step of reading the card. Hence, the evil-minded merchant can use the information, forge into consumers and consumers are unable to be aware of it.

In order to remedy these known defects, this article proposes an improved architecture and meets the following demands. First, follow the past trade habits of the consumer, but change the paying device into the mobile community device or other hand-hold community device. Secondly, strengthen privacy protection and disable the merchant to learn account information and accumulate shopping habits of the consumers. Also, the telecommunication operator (operator) is unable to know what the user bought. Last, offer the non-repudiation trade security.

## 2. RELATED WORKS

This section will review the related works of mobile payment system. In wireless mobile payment system the greatest challenge is the security threat. The study of Welch and Lathroped [1] divided these attacks into seven kinds as shown in Table 1. Except for unauthorized Access and Replay, others are set up on the basis of collecting and analyzing the package. Moreover, the Session High-Jacking attack could take the session instead of the user.

Table 1. The attack of wireless security

Traffic Analysis	Analyze the transmitting flow in the network
Passive Eavesdropping	Collect and analyze the network package to understand its content
Active Eavesdropping	Attract the destination to sending the specific package voluntarily to collect and succeed in analyzing packages
Unauthorized Access	The abnormal authorizes
Man-in-the-middle	Steal a glance or modifies the package that destination send
Session High-Jacking	Get involved and replace the session of the destination
Replay	Repeat sending the used package

Hence, wireless network also need to consider several important issues in the network security, such as confidentiality, authentication, authorization, integrity, non-repudiation. The best solution relies on encryption and the authentication mechanisms. Encryption mechanisms can offer the confidentiality and integrity. Authentication mechanisms can offer authentication, authorization, non-repudiation. In addition, the personal privacy of the consumer, e.g. shopping habits, is important security issues, too.

In order to apply mobile payment to the commercial trade, several trade systems considering about security issues are proposed. The research of Soliman and Omari [2] propose a dynamic encryption mechanism, the encryption key does not need regular storing in user's device, but produce the encryption key dynamically to avoid the encryption key lost or stolen. This system adopts symmetrical encryption to maintain confidentiality of consumer's trade and the encryption key exchange mechanism is also proposed to overcome the problem about losing encryption key. Later, Kungpisan, Srinivasan, and Le propose an encryption key management mechanism [3] to improve the

symmetrical encryption problem that may be lost of key if the encryption key does not change. Maybe this kind of systems can protect confidentiality, but the importance of non-repudiation is not mentioned.

In the model of the trade, non-repudiation is a very important security mechanism. All of the symmetrical encryption systems are unable to offer non-repudiation. Thus, Fourati, Ayed, Kamoun, and Benzekri propose a research that hope to take SET [4] mechanism to provide non-repudiation and personal privacy [5]. After consider the operation ability of mobile device, take the authentication mechanism of the part of SET, and combine WTLS/TLS [6] [7] to build a non-repudiation system which mixes the advantage of the two. Except for adopting the method like this, there are also systems introducing the mechanism of digital signature to improve performance. Such as the research of Herzberg, it adopts the digital signature mechanism of DSA [8] to satisfy non-repudiation.

In addition, the privacy of consumer also needs protection in the trade. The research of Sue adopts user identity (UID) to replace the cell-phone number [9] when the trade message transmitted to the merchant. Because consumers' user identity is regular, merchants probably collect customer's private information, such as habit about consumption. If the UID is not always the same, consumer's privacy can be protected. Based on the similar concept, Rubin and Wright [10] propose the variation code method in the payment system of the wired network. It utilizes random codes to prevent consumers' credit card number from spreading in the network. Combine the UID [9] and variation code methods [10] for wireless applications, the merchant probably can not accumulate consumers' shopping habit.

However, this method needs to assistance of the operator. Hence the operator has an opportunity to accumulate consumers' shopping habit. The main reason of the problem lies in the structural design. The mobile payment model is often modified by e-commerce payment model. Only the trade equipment of the front-ends is changed. No matter which payment model is adopted, the account numbers of the trade should pass to the merchant. Consumers will lose the privacy, such as shopping habits.

## 3. A NOVEL MOBILE PAYMENT SYSTEM

This article proposes a novel model to reduce the security risk of the credit card payment and provide privacy protection in mobile payment. The proposed system will employ mobile equipment as the front-end traded device and the trade information will not be transmitted via any merchants. Hence, the system is able to protect the security of the trade account. The structure of the system is shown as Figure 2.

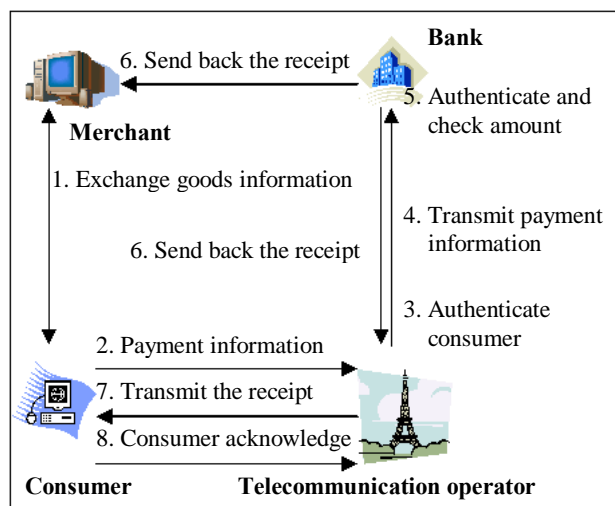

Figure 2. Structure of Payment System

### 3.1 Structure of Payment System

In order to exchange the trade message with consumer's mobile equipment directly, the trade structure demands some techniques to support, such as the Bluetooth interface. The interface is better an independent set to disable merchant from acquiring consumers' information, such as cell-phone number or account number. The banks in such system need to connect with the operators to deliver trade information to the users of the mobile payment system. In addition, consumers' mobile equipment needs the memory devices to store private key because this article applies consumers' private key to do digital signature to maintain non-repudiation. However, the signature algorithm is part of asymmetrical algorithms, several researches point out that the asymmetrical algorithms is more complicated than the symmetrical algorithms. Hence, we can select an asymmetrical algorithm to minimize the burden of mobile device when implementing the proposed payment system. According to the comparison [11] shown in table 2, the RSA algorithm is adopted to do digital signature.

Table 2. Digital signature perform comparison sheet[11]

Signature	Verifiable Encryption	
	#exponentiations	Size (bytes)
<b>RSA</b>	<b>7.5</b>	<b>400</b>
Gennaro et al	7.5	400
GramerShoup	8.7	544
GQ	10.5	544
Schnorr	8.3	388
ElGamal	8.5	388
DSA	11.6	484

In addition, we can adopt shorter private key on the mobile device to reduce the computation load and request the telecommunication operator to employ other

complicated digital signature algorithm for security after confirming users because the telecommunication operator has no restriction on computation. If consumers lose the mobile device, they just need to notify the operator stopping the service of the cell-phone. The forgers will be unable to pass the second layer authentication mechanism, and obtain the digital signature of the telecommunication operator. It can protect both the banks and consumers.

### 3.2 Procedure of Payment System

In this section, the trading procedures of the proposed system will be introduced. Table 3 defines the code to help readers understand.

Table 3. Code contrast

Name	Code
Merchant	Merchant
Consumer	Consumer
Telecommunication operator	Operator
Bank	Bank
Hash function	Hash
Item identity	Item_id
Item price	Item_price
Merchant identity	Merchant_id
Trade identity	Trade_id
Message Authentication Code	MAC
Cell-phone number	PhoneNum
Digital signature of Consumer	Sign_U
Digital signature of operator	Sign_O
Digital signature of the bank	Sign_B
Digital signature text of Consumer	Text_Usign
Digital signature text of Operator	Text_Osign
Digital signature text of the bank	Text_Bsign

The payment system has 8 steps. The motion of each step and content of each message will be introduced below

Step 1, (Item\_id, Item\_price, Merchant\_id, Trade\_id) + MAC

Consumers communicate with the trade system of the merchant and get the trade message from it via the bluetooth interference. In order to prevent the trade information from being modified, the merchant will use hash function to product message digest, such as MD5 [12] or SHA-1 [13]. The detailed composition of message is shown in Figure 3.

Hash

Figure 3. Trade procedure - Step 1

Step 2,  $\text{Sign}_U(\text{Trade\_id}, \text{MAC}) + \text{PhoneNum}$

Figure 4. Trade procedure - Step 2

Consumers' mobile device will receive the trade message from the trade system of the merchant. Then consumer takes out the trade identity and MAC, and signs to respond the trade. Transmit the message to the telecommunication operator by GPRS or other wireless technology. The content of message is shown Figure 4. To prevent the operator and the bank from knowing the detailed content of the items that consumers bought, only the trade identity is transmitted.

Step 3, Authenticate consumer

When the operator receives the message that consumers transmitted, the operator will do the GSM authentication method to confirm the user identity of the mobile device.

Step 4,  $\text{Sign}_O(\text{Sign}_U(\text{Trade\_id}, \text{MAC}), \text{PhoneNum})$

Figure 5. Trade procedure - Step 4

If consumers pass authentication, the operator will do digital signature to show the responsibility. In order to strengthen the non-repudiation, the operator can adopt more complicated digital signature algorithm. The content of the whole digital signature are shown in Figure 5. Later, transmit the message to the bank.

Step 5, Authentication and payment inside the bank

When the bank receives messages from the operator, the bank will verify operator and consumers by the digital signature of them respectively. Then, the bank confirms consumer's available amount and pays the money.

Step 6,  $\text{Sign}_B(\text{Trade\_id}, \text{MAC})$

Figure 6. Trade procedure - Step 6

After finishing the payment, the bank produces the receipt of the trade and adds the digital signature to show the responsibility. The content of receipt is shown in Figure 6.

Step 7, (Text \_ Bsign)

This procedure only passes the receipt that is come from the bank. The operator does not need to add any digital signatures on the receipt because mobile device will need more complex computation if there are more digital signatures. In addition, the content of receipt is just trade identity, has no safety consider.

Step 8, consumers acknowledge the operator.

Step 8 is to ensure that consumers have already the receipt, but it is not the essential procedure. Such procedure can be omitted to simplify the procedure of the system and payment check can be done by the bank monthly.

Here showing some expected goals which this article tries to satisfy. First is familiarity. Although consumers have more one action, it can protect the individual privacy of consumer. Actually, the action is equivalent to the consumer signature in the past. Furthermore, such action can be simplified by software design, the consumer just need to press the next button when mobile device receives the trade message. Second is that the privacy of consumers is protected. The merchant only participates in Step 1 and Step 6 (Figure 2). These two procedures transmit the receipt and the trade message which include item identity, item price, and trade identity. The merchant are unable to know the account that consumers use for trade, and even can not accumulate shopping habit of consumers because consumers do not transmit the user identity or the cell-phone number to the merchant. As in the aspect of the operator and the bank, because consumers just transmit the trade identity in Step 2 (Figure 2), the operator and bank are unable to know what consumers buy and accumulate consumers' shopping habit. Hence, consumer's privacy of shopping habit and trade account

can be protected. Third is the non-repudiation. Three digital signatures of the consumer, the bank, and the operator are used in this system and represent non-repudiation of three participants. Consumers' digital signature makes consumers unable to deny the trade. Digital signature of the operator makes the operator can not deny ever passing the trade messages from authenticated consumers to the bank. Digital signature of the bank makes the bank can not deny approving the payment.

#### 4. EVALUATION OF SYSTEM SECURITY

This section analyzes the system structure and system procedure to evaluate the system if fit the request of security. Evaluation will follow three aspects: bank, merchant, and consumer.

##### 4.1 Confidentiality

Confidentiality is usually done by encryption, but this system does not apply the encryption algorithm. Here is another opinion of the confidentiality in trade. Because the message which is transmitted by consumers in the network has important information inside, such as bank account of consumers, trade items information. The confidentiality protects the message not to be watched. If the information does not be transmitted in the network or the message transmitted in the network does not include such important information. Then, encryption may not be necessary, and indirectly satisfy the confidentiality.

##### 4.2 Integrity

Integrity is designed to protect the merchant. Because the merchant only participates in the beginning step 1 and the step 6 of the trade procedure shown in figure 2. The merchant may be afraid that the price of the items or the items identity will be changed. Let the merchant add MAC which is made by hash function on the transmission message. In after procedure among transmission, the MAC needs to be transmitted without changed until the message transmitted back to the place of merchant.

##### 4.3 Authentication

The Authentication has difference opinion because of the participant. From the view of the consumers, consumers add digital signature on the transmitted message to the bank, in order to confirm that no other people can start the trade request without consumer's permission. According to the digital signature added by the bank consumers can also authentication the bank. From the view of the bank, confirm the trade is authorized by consumers using the digital signing of consumers. From the view of the merchant, because the received receipt has digital signature of bank, the merchant can confirm the bank had already paid the

amount.

#### 4.4 Non-Repudiation

The non-repudiation also finishes through the mechanism of digital signature. By digital signature, consumers can't deny the trade, the operator can't deny authentication consumers and pass trade request made by consumers. The bank can't deny finishing consumers' payment. The trade is invalid unless there is assurance of digital signature.

#### 4.5 Privacy

The protection of privacy is the key of this article. About trade account which includes the credit card number and bank account, the merchant has no way to receive trade account because trade message is transmitted by consumers. In addition, the consumer is authenticated by using digital signature, and trade account of consumers is never transmitted in the network. About shopping habit, the transmitted message in the network only has the trade identity and MAC, the bank and operator only know the identity without meaning. Therefore, the system can protect privacy of consumers.

#### 5. CONCLUSION

The proposed system in this article puts emphasis on three parts, familiarity, privacy, and non-repudiation. First, the trade behavior does not change very much. Instead of using credit card, consumers use the mobile device with them to do trade activity. Hence, consumer will just perceive the change of trade device. The mobile device, e.g. handset, is familiar to consumers. Secondly, consumer's privacy can also be protected. The merchant, operator, and bank can't accumulate shopping habit of consumers. Third, the proposed system using digital signature to protected the trade non-repudiation. Table 4 shows the comparison of relevant payment system research in the past.

Table 4. Systematic comparison of payment

	Encryption system	Digital signature system	Account protected system	The proposed system
Confidentiality	◎	◎	◎	◎
Non-repudiation	×	◎	×	◎
Account protect	×	×	◎	◎
Trade privacy	×	×	×	◎

(◎: Offer, ×: Does not offer)

The proposed mobile payment system satisfies not only the payment security and non-repudiation requirement in the traditional electronic trade but also the protection of consumer's privacy which is paid attention gradually now. In this system, the merchant, operator, and bank

can't accumulate shopping habit of consumers.

Perhaps someone will query that this model needs consumers to transmit trade message to the operator and this step will increase the transmission burden of the network. In fact, under the primitive transmission structure, consumers must transmit the trade message to the merchant. In our design, the message is just transmitted to operator instead. Hence, the change will not increase the transmission burden of the network.

### ABSTRACT

This paper is designed to investigate physicians' opinions regarding an SMS professional medical news service in the Finnish health-care sector. A survey using SMS mobile technology was conducted on March 5, 2003. 259 out of 685 responded within 2 days, and 90% came within 6 hours after the survey was sent out. The response rate was 38%. Findings from this simple SMS survey showed that physicians had positive perceptions of the SMS news service. Nearly 60% of the respondents have used the service. Some of the answers included spontaneous feedback about the service, which revealed valuable comments and suggestions regarding the further improvement of the service. The SMS survey as a new data collection method needs academic attention. Future research is briefly discussed.

**Keywords:** SMS medical news service, physicians' acceptance, SMS survey, time-saving, cost-effective

### 1. INTRODUCTION

Mobile commerce (m-commerce) has been an important research focus in recent years. Generally, m-commerce is defined as the extension of electronic commerce (e-commerce) from wired to wireless computers and telecommunications, and from fixed locations to anytime, anywhere and anyone [17], i.e., the use of mobile technologies and devices to provide, sell and buy convenient, personalized, and location-based services.

Text-based technology or Short Messaging Service (SMS) is one of the underlying technology platforms for m-commerce. In a comparison with wireless web-based technologies, i.e., another m-commerce platform, SMS has a simple user interface and is supported by most mobile phones. Recent years have seen the adoption of SMS worldwide in many commerce sectors, e.g., news, weather forecasting, retail, entertainment etc. It is also considered to be the most convenient and cheap communication technology used by normal consumers [23].

The rapid diffusion of SMS has also inspired some applications in the health care industry, for example, SMS professional medical news service. Medical knowledge is changing constantly. It is not easy for physicians to keep their knowledge and information up to date to help in their patient care and patient management efficiently on the one hand, and to maintain the level of their professional competence on the other [16]. An SMS professional medical news service might help physicians keep their knowledge up to date and to provide some hints of recent medical development trends and new discoveries. The objective of this paper is to investigate physicians' acceptance of

an available SMS professional medical news service that is currently implemented in the Finnish health care sector. First, we present the theoretical background underlying the study. We describe the mobile service in detail in section 3. In section 4, we present the study context and the method we used for data collection. In section 5, the results are reported. Discussions and conclusions are at the end.

### 2. PHYSICIANS ADOPTION OF TECHNOLOGY

Users' perceptions of and intentions to adopt information system (IS) and the rate of diffusion and penetration of technology within and across organizations are two important foci in IS research [e.g., 22]. They are understood to represent or stand for the essential aspect, property or value of the information technology [21]. It is generally accepted that the usage of information systems at work could increase employees' productivity in their working time, and improve individual and organization performance. System usage is an important dimension to measure IS success [9] [10]. In particular, physicians adoption of IS in the health care is aimed to improve the health quality of the human beings. In the past several decades, the conclusions of many studies based on different theoretical approaches and research methods, have approved and confirmed that usefulness of a supportive medical IS is very important in influencing a physician's decision making of using it. For examples, Chau and Hu [6] [7] based on classical IS adoption models [e.g., 8, 20] and collected data from a self-administered questionnaire to investigate physicians' adoption behavior of technology. They found that usefulness is a single factor determines a physician's adoption of telemedicine technology. They argued that

physicians are professionals and might exhibit considerable differences in general competence, adaptability to new technologies, intellectual and cognitive capacity and the nature of their work. Therefore, the ease of use of the technology might weaken as the competency of the user increases. Jayasuriya [15] conducted his research in a similar style. He indicated, health professionals were willing to use technology in their jobs when they perceived it to be useful for their performance. But the study results from Han et al., [14] presented that in the early stage of using mobile technology, ease of use still has strong effects on a physician's behavior intention towards the technology. Many studies were conducted by utilizing qualitative methodologies revealed similar results. For instances, Mayer and Piterman [18] studied the attitudes of Australian general practitioners to evidence-based medicine by using a focus group method. They concluded that physicians' acceptability was influenced by relevance (usefulness) to general practice, as well as the local contextual and patients factors. By using a prototype simulation study 1 week in a hospital in Germany, Ammenwerth et al. [1] successfully found out that in order to meet the diverse requirements of different professional groups, the developer needs to design "multi-device mobile computer architecture". Therefore, the usefulness of the mobile information and communication system in clinical routine is more likely to be improved.

Obviously, researchers have adapted different methods to study physicians' adoption of technology. The selection of different research methods is incumbent of individual IS researcher depending on the problem he or she aims to solve. As suggested by Moody and Buist [19], the real question is not whether the research method is appropriate *per se*, but whether it is appropriate to answer the question being asked.

### 3. MOBILE SERVICES AND THE SMS PROFESSIONAL MEDIAL NEWS SERVICE

Carlsson and Walden [3, 4, and 5] provided a conceptual framework for mobile services from three perspectives: the customer, the producer and management. Mobile services viewed from different perspectives have different distinguishing elements. These embedded elements actually describe what the mobile services will be. Here we only focus on the customer perspective. From this perspective, mobile services are durable technological products and technology-based services where repeat purchases are sparked off by an increase in user-perceived functionality. Seen from the perspective, the necessary distinguishing elements of mobile services are:

- 1) Flexibility, mobile services should be available anywhere, at anytime and anyhow;
- 2) Value adding, mobile services should improve productivity, they should be adaptive

to localization and they should be sensitive to customer personalization ;

- 3) A mobile technology basis, mobile services should use innovative and distinguishing features of mobile technology to enhance the quality of life (e.g. messaging, entertainment, education, information, privacy, etc)

These elements are key factors to ensure the quality and possible success of mobile services.

Duodecim Publishers Ltd. owned by the Finnish Medical Society Duodecim, has developed and provided the SMS professional medical news service (interchangeably referred to as the SMS news service or the service in the paper) to physicians currently involved in the Finnish health care sector, including hospitals, health care centers and private doctors etc. The news team at Duodecim Publishers Ltd maintains the service. The physicians subscribe the service to a specific number. After the service is issued, the physicians will get one piece of news per day. Currently, they do not need to pay for the service because of the support of Pfizer Finland Ltd.

Due to the limitations of SMS technology, the service does not include any pictures. A strong message from the developer mentions that the adoption of Multi-Media-Message (MMS) is a must in the near future. The pictures might be included as well.

### 4. STUDY CONTEXT AND DATA COLLECTION

The Finnish Medical Society Duodecim is a leading medical knowledge and information provider in Finland. It has placed much effort into improving the quality of medical knowledge. It has also adapted new technologies to distribute that knowledge to physicians, for instance, CD-ROM, Intranet, the Internet and wireless technology [11, 12, and 13]. The SMS professional medical news service started in 2002.

In order to investigate the physicians' acceptance and their feedback of the service, a survey was conducted on March 5, 2003. The survey was sent to the target group (685 physicians, among those, 259 subscribers to the service) as an SMS message, and the answers were gathered via the same media.

Concerning the limitations of SMS technology, the survey had only one question, i.e., "how do you perceive the SMS medical news service by Duodecim?" with three pre-defined answer alternatives, they were:

- a) "The service is really good and useful."
- b) "It is ok, but needs to be improved."
- c) "I haven't subscribed to the service."

The question was sent out on March 5, 2003 at 12:52. Totally 259 answers out of 685 were received within 2

days, a response rate of 38%. Two responses were excluded from the data analysis due to empty replies. In case of the 259 have subscribed to the service, the response rate from the subscribers was extremely good, over 50%. Some of the answers included spontaneous feedback about the service, which was very valuable. The majority of answers (>90%) were gathered within 6 hours of sending out the question. Before mid-night of March 5, we got 243 answers, only sixteen was sent back on March 6.

## 5. RESULTS

We did a basic summary report of our data. Since some answers provided feedback about the services other than our pre-defined alternatives, we consider those responses as D. Results are summarized in Figure 1.

Figure 1 Survey results

Of 257 usable answers, thirty-one percent (n=79) perceived that the service was really good and useful. Seventy three, i.e., 28% thought improvement of the services was necessary. Thirty-three percent of the physicians had not yet subscribed to the service. We got 22 extra answers that were not covered by our pre-defined answers, which we counted as D. Below we present the details of the feedback spontaneously provided with the three alternatives and other comments categorized as D.

### I Arguments with A

Physicians who replied with the A alternative really liked the service and thought it was very useful for their work. They also showed a positive future intention towards the service. Such as a physician wrote,

*"[The service] is very useful and I would like to receive the messages in the future..."*

Besides acknowledging the usefulness of the SMS news service, physicians are still expecting information from traditional channels, a physician replied,

*"The messages are excellence for me and I would be happy to receive other news letters as well."*

### I Arguments with B

Most of those who selected B did not specify very much about how to develop the system. Several physicians did give suggestions. A physician mentioned that

*"Occasionally one gets news from a short message. [It is] a different picture of the matter compared with the original text [e.g., newspapers]."*

This message indicated that, as an emerging information distribution channel, mobile SMS was expected to be compatible with other traditional media, such as the texts published in newspapers or on the Internet. On the other hand, physicians also welcomed the SMS news, *"I have during weekdays several times had the time to read the same news on the Internet, but it's good to have repetitions"*.

Three physicians suggested that the SMS news might include more extensive sources or specialized fields.

*"... [the news might come] along with Internet references or more extensive sources"*

*"...Develop the messages for specialized fields, i.e. information to the correct address..."*

*"... More accurate sources of references could make it easier to find the article (e.g., about the disadvantage of epilepsy medication)"*

Those suggestions shed light on how to improve the content of the services. The reference sources are quite demanding that help physicians go further to check the latest medical information. Physicians also need information from their specialized fields that are better suited to meet their personal requirements on specific knowledge they want to acquire.

Some physicians have pointed out that the SMS news should be longer, the shortness of SMS was considered a drawback. Comments came like,

*"The messages could be even longer"*.

*"Apparently the shortness of SMS causes limitations"*

### I Arguments with C

The feedback came with alternative C provided our several reasons why physicians did not subscribe to the services. The first and obvious reason was they didn't need the SMS news service, e.g,

*"Not in use and not needed"*

*"Not in use and I don't want it."*

The second reason was some physicians still stick to other distribution channels, such as newspapers or the Internet

*"I haven't followed the text message news. I read newspapers."*

*"It is easier to read from the internet"*

The third reason was that technical problems hindered physicians' usage of the SMS news service. Complaints came like,

*"I have not received any news even though I have subscribed";*

*"I have tried to get the service without success..."*

*"Not in use since I don't know how..."*

The fourth reason was due to the small screen of the mobile device, *"I would prefer to read them as emails due to the small screen of my mobile phone...probably better with the communicator."* The size of the screen is not comparable with PC-based media apparently. Some physicians also lacked the time to subscribe to the service, *"I'm in principle interested, but haven't had time to pick up the instructions"*. Physicians are usually very busy. Lack of time is frequently cited as a reason for them not adopting new information systems [2].

Besides those negative comments, we also found positive intentions from some non-adopters. Such as,

*"I will activate"*

*"I would like to have in use..."*

*"Reading news as SMS can in principle be feasible".*

#### 1 Arguments collected from D

A deep analysis of the feedback we classed as D was conducted as well. We found out that there were three main strong suggestions from the physicians.

1) The service still had some bugs, problems with receiving and opening the service were common complaints. For examples,

*"None of the text message news that I ordered have been activated, so I have not received any news for the time beings";*

*"I have not received any news even though I got the confirmation of order";*

*"For some reason, I have not received news for a long time";*

*"I did according to instructions, didn't receive messages";*

*"How is it activated?"*

These messages indicated that the developer and the service content provider have to pay much attention to the technical problems associated with the service. The growing complaints of the difficulties in activating and receiving the service might become a severe barrier for physicians to continue their adoption of it.

2) The current length of the message (160-200 characters) was considered both a limitation and an advantage. We got free-form feedback like,

*"160 characters is quite limited amount. But on the other hand, one doesn't bother to read too long stories""During office hours short and concise..."*

Obviously the limited length has made the news concise. Physicians might save their time for reading the news in a busy working day.

3) The news service is quite general; more categories of specialties and more in-depth news are required. For example,

*"Seems like a good idea, personally, I would like to choose those fields that interest me"*

*"I would wish for more information about urology..."*

These messages revealed that physicians demand more services that meet their "personal" needs. The current service is targeted to all physicians as one uniform group. The developer has to take "personalization" into consideration for the further improvement of the service.

## 6. DISCUSSION AND CONCLUSION

This paper is intended to investigate physicians' acceptance and opinions regarding the SMS professional medical news service in the Finnish health-care sector. The findings from this simple SMS survey showed that physicians had positive perceptions of the service. Those responses located in the alternatives of A and B indicated that, generally, the ones (31%) who were happy with the service really liked it, and an almost equal amount, i.e., 28% thought the service should be improved. The total answers that went to A and B reached 59%, nearly 60%. In general, the SMS professional medical news service is useful. User adoption theories assert that usefulness is the main driver of individual adoption of a specific information technology. The perceptions of usefulness of the SMS medical news by physicians demonstrate strong possibilities of continuous usage in the future.

Arguments came with pre-defined alternatives and those categorized as D overlapped in some cases. In brief, they highlighted several important issues concerning the improvement of the service in the future. Firstly, technical problems have to be solved immediately. It constitutes a barrier to physicians' usage of the service continuously, or hinders their subscriptions. Possible guidance on how to open and use the service should be improved as well. Ease of use is always considered a crucial driver of the success of information system implementation. Mobile technology is not an exception [14]. Secondly, the length limitation of SMS technology has made not only the news concise, which considered a time-saving way to read it, but also made it impossible to include more information in one message. With the development and diffusion of MMS,

technically the news items could easily be made longer. Thirdly, "personalization" is demanded by the physicians. The general topics adapted in the current service did not take use of the advantages of mobile technology, i.e. personalized services to mobile users. Therefore, it might undermine the value added by the SMS medical news service. Personalized service for the physicians' news needs will enhance their knowledge what is highly relevant to their specialties, and provide the information that they desire most. Fourthly, as an emerging technology, SMS is competing with traditional channels of distributing medical news. The traditional channels, e.g., newspapers and the Internet, have dominated information delivery for a long time. Currently, SMS is a complementary channel, but far from the dominating one. A good thing is that it is warmly welcomed by most of the physicians. It has strong growth potentials in the future. It comparatively adds more value to physicians' work in terms of flexibility and personalization or localization.

Nearly one third of the respondents had not yet subscribed to the SMS professional news service. Attention has to be paid to the reasons why they did not subscribe to the services, in order to increase the diffusion speed. Compared with the aforementioned important issues for the improvement of the service, we find that strong effort of improvement might remove the negative "reasons" that impede some physicians' subscription to the service.

The results of the paper were from an SMS survey. It is a new data collection method which is time-saving and cost effective. We got 38% responses within 2 days, and 90% came within 6 hours after the survey was sent out. This new survey method needs our attention. It is a method welcomed by practitioners. The simple survey provided the answers in a very short time. The service developer and content providers received "instant" results that help them investigate the problems and find solutions almost at the same time. The SMS survey does not like traditional surveys that usually take months or years; it is a new attempt to do the survey in hours or days with aid from new mobile technology. It also reduces the cost of the survey. Mail surveys are usually very expensive, as are Internet surveys that have a monthly fee. The main weakness of the SMS survey is obviously its length limitation; we can not have many questions in the survey. But it helps us to concentrate on the most important message that the practitioners want to know immediately. Such instant feedback might represent high business value for practitioners.

In the future, as MMS is on its way to replacing the current SMS, technically, it is easy to overcome this limitation, and we might include more and longer questions in a MMS survey. With the support from

Pfizer Finland Ltd., such a survey is planned to be conducted at the autumn in 2004.

## ACKNOWLEDGMENT

Our warmest thanks go to Pfizer Finland Ltd. for its support for conducting the survey. The first author also would like to reserve thanks to Ms Stina Störling-Sarkkila for her support in translating the Finnish data into English.

## ABSTRACT

Due to the advent of the Internet, electronic business transactions have exploded around the globe. Along with the Internet, wireless technology has exponentially developed as well. Today, new technologies that allow mobile (cellular) phones and other handheld devices to access the Internet have made wireless business transactions possible. This phenomenon is known as mobile commerce or M-Commerce. It has been predicted that the number of mobile phones connected to the mobile Internet will exceed the number of Internet-connected PCs before 2007. The mobile phone will therefore become the most prevalent device for accessing the Internet. Several industry analysts predict that M-commerce will constitute a multibillion dollar business by 2005. However, M-Commerce brings new challenges in providing information security as information travels through multiple networks often across wireless links. What must be done to secure financial transactions via mobile commerce? Generally speaking, M-Commerce creates more security concerns than traditional E-Commerce. In this paper, security measures in M-Commerce, wireless security, and the application of cryptography for key generation, authentication, digital signature and digital certificate are discussed.

**Key words:** M-Commerce, wireless security, elliptic curve cryptography, WLAN security, Bluetooth

## 1. INTRODUCTION

Mobile commerce, commonly known as M-Commerce, 'is concerned with the use, application and integration of wireless telecommunication technologies and wireless devices', such as Internet-enabled mobile phones, personal digital assistants (PDA), palmtops, laptops, and pagers, commonly known as handheld wireless devices (HWD). The discipline of M-Commerce includes reference to the infrastructures and electronic technologies necessary for wireless data and information transfer in the form of text, graphics, voice, and video. M-Commerce is a subset of electronic commerce where the Internet-enabled HWDs and wireless networking environment are necessary to provide 'location independent connectivity'. It is predicted that M-Commerce services would be the next biggest growth area in the telecommunications market, representing the fusion of two of the current consumer technologies: wireless communications and E-Commerce [7].

Mobile communications is now considered a relatively mature technology with the transition from second to third generation (3G) wireless technology and with its high consumer acceptance. 3G wireless technology provides a variety of services and capabilities in addition to voice communication, such as multimedia data transfer, video streaming, video telephony, and full Internet access. 3G mobile phones provide high-speed data transfer and are designed to support large numbers of users more efficiently allowing for future expansion in user capacity. This technology was first introduced in Japan in 2001 and then spread in Europe and USA in

2002. In Japan mobile commerce has been a huge success, accounting for over \$400 million in revenues each year [8]. In 2003, there were about 800 million Web-enabled cellular phones in use worldwide. By 2004, the worldwide number of Web-enabled mobile phones is projected to rise to one billion. The M-Commerce market may rise to \$200 billion by 2004 (Gartner Group). It has been predicted that the number of mobile phones connected to the mobile Internet will exceed the number of Internet-connected PCs before 2007. The mobile phone will therefore become the most prevalent device for accessing the Internet and M-Commerce. Several industry analysts predict that mobile commerce will constitute a multibillion dollar business by 2005. However, once again, the question of security arises. What must be done to secure financial transactions via mobile commerce? Secure mobile commerce will be a key area within the expanding functionality of mobile phones. Generally speaking, M-Commerce creates more security concerns than traditional E-Commerce.

## 2. APPLICATIONS OF M-COMMERCE

There is a wide variety of applications of M-Commerce. For example, Smart cards with an embedded integrated microchip can be used as prepaid phone cards, ATM cards, or public transportation cards. They can be biometrically enhanced to include voice recognition, iris and face scans, and finger print authentication. In France, some 35 million Smart cards are in circulation and every year they process over three billion transactions [4]. Wireless banking refers to purchasing over Internet-enabled HWDs like wireless application protocol (WAP)

phones or PDAs. Interactive TV is enhanced TV where additional content is added to an existing broadcast format that the viewer can query, request or even interact live with the program. It has reserved channels and bandwidth for data applications such as weather, news, games, or commerce. It also offers services like Video on Demand (VOD) or Personal Video Recording (PVR). Companies are providing facilities to track stocks on HWDs. Aspiro, a Swedish company, allow its customers to check stock prices or look at their portfolios and even trade using WAP phones or PDAs. Accessing information using WAP mobile phones and PDAs is significantly becoming popular for business-to-business (B2B) and business-to-consumer (B2C) applications. Mobile and wireless technologies have been an integral part of defense and military ever since these technologies were available. In light of growing concern with cyberterrorism, security has undoubtedly become the single most important issue because many U.S. intelligence services use mobile technologies and wireless networks for communication and commerce.

### 3. M-COMMERCE SECURITY CONCERNS

M-Commerce is bringing together two technologies, wireless communication and traditional E-Commerce, with a history of security problems. Coupled with the convergence of voice and data communications, interconnection with external data networks and issues surrounding the transactions themselves, the potential risks are very high [7]. There are three basic security components in M-Commerce: (a) *Transaction*: protecting the transaction parties and their data by providing an acceptable level of security, (b) *Information*: protecting valuable and sensitive information about customers, and (c) *Infrastructure*: protecting the network infrastructure from attack.

Mobile 3D is Visa International's new global secure specification that is expected to ensure the security of Internet payments made over mobile devices [14]. It was developed in conjunction with some 15 industries, including Ericsson, Motorola, and Oracle Mobile, and was launched in September 2001. It extends payment authentication initiatives into M-Commerce, enabling the Visa card issuers to validate the identity of their cardholders in real time, ensures that payment data sent over open networks is not compromised and allows consumers to actively protect their Visa accounts from unauthorized use, and supports global interoperability, enabling consumers to have a consistent and seamless experience regardless of the method or device being used to access the Internet. A number of Visa M-Commerce programs are currently underway worldwide to test the validity of M-Commerce payment solutions and raise consumers awareness. In Asia, Visa has partnered with Hutchison Telecommunications and Dao Heng Bank to develop a mobile payment service using Mobile 3D Secure. In Europe, Visa has made a strategic alliance with Omnitel Vodafone, while in the US, Visa and Sprint

are working together to help facilitate secure mobile payments.

A satisfactory level of security is required for the successful deployment of HWDs. To a certain extent, it seems reasonable to utilize solutions used for the wired environment in the case of the wireless environment. However, this approach is not always feasible because of the differences between the wired and wireless environments. For example, because of the hardware limitations of the HWDs, no large routing tables can be maintained on these devices, thus increasing the risk of a denial-of-service attack. Furthermore, wireless communications make physical eavesdropping almost undetectable [10]. Similar to wired communication, wireless communication also needs three basic security requirements: (i) confidentiality- information is disclosed only to legitimate entities or processes, (ii) integrity- unauthorized modification of information is prevented, and (iii) availability- authorized entities can access a service provided they have appropriate privileges. The mechanisms suitable to the HWD are discussed here.

M-Commerce needs several layers of security: (i) device security, (ii) language security, (iii) wireless security, and (iv) cryptographic security.

#### 3.1 Device Security

Within the design of mobile devices, there are a number of high quality security features. The most important of these are: (i) a built-in password mechanism which will lock after several mistyped attempts and (ii) an industry approved, tamper-proof smart card, known as Subscriber Identification Module (SIM) card.

The SIM card and the mobile device are always stored together and the device is an every day utility object that is easily lost or stolen. Time-out and key-locks are often not used on phones. This means that as long as the phone remains turned on the strong password system will be bypassed. All WAP data, in some popular handsets, is stored in the phone's memory, not in the SIM; this will include login and password information. These features certainly diminish the security of the mobile phone. The SIM card used in mobile devices are *de facto* micro-processor and they can be used to facilitate mobile commerce. Gemplus SIM cards features a digital signature and public key encryption [11] and the technology is embedded in the card. In May 1999, Motorola, jointly with Identix, a biometrics company, developed fingerprint scanning devices, called the DFR 300 that is 4.5 millimeters thick [2]. This scanning device can now be incorporated into the HWDs.

#### 3.2 Language Security

If special purpose M-Commerce software, such as a stock trading application, is to be deployed on mobile

devices, then Java is the recommended language to be used as the deployment language on the HWDs. By using Java, the amount of software that needs to be changed in order to adopt the application to various mobile platforms is minimized. Feasible Java execution environments are available for PDAs, Smart phones, Communicators (such as Symbian), laptops, and other platforms. Maffeis [6] also recommended using server side Java technology, such as the Jave-2 Enterprise Edition (J2EE) platform, in the data center. This allows for shorter time-to-market and avoids vendor lock-in.

### 3.3 Wireless Security

#### 3.3.1 WAP Security

WAP (Wireless Applications Protocol) is 'an open, global specification that empowers mobile users with wireless devices to easily access and interact with information and services instantly.' WAP is currently the only publicly available solution for wireless communication and enables M-Commerce where Internet data moves to and from wireless devices. WAP-enabled phones can access interactive services such as information, location-based services, corporate information and interactive entertainment. WAP is targeted at various types of HWD and Bluetooth enabled mobile phones.

WAP 1.x security uses the Wireless Transport Layer Security (WTLS) protocol. This protocol is the WAP equivalent of Secure Socket Layer (SSL) and it provides authentication, encryption and integrity services. WTLS has three levels, all have privacy and integrity: (i) *Class-I* has no authentication (anonymous), (ii) *Class-II* has server authentication only, and (iii) *Class-III* has both client and server authentication. WTLS supports some familiar algorithms like Diffie-Hellman, RC5, SHA-1, and IDEA. It also supports some trusted methods like DES and 3DES, but it does not support Blowfish and PGP [9].

Since Web- and WAP-based protocols are not directly interoperable, a component known as the WAP gateway is needed in order to translate Web-based protocols to and from WAP-based protocols. The WAP gateway is a software that runs on the computer of the Mobile Service Provider (MSP). Thus sensitive information is translated into original unencrypted form at the WAP gateway [5]. This problem is known as WAP gap.

Public key cryptography (PKC) is used to exchange a symmetric or private key using certificate and then all transmission is encrypted. A short key size of 40 bits is used because of power limitation. A tamper-proof component, known as WIM (Wireless Identity Module) is designed as part of the WAP architecture to store private data, such as key pairs, certificates, and PIN numbers within the mobile device. In practice, a WIM is implemented using a smart card. Wireless Markup

Language (WML) is used in WAP 1.x technology. Figure 1 shows WAP gap model.

Figure 1 WAP Gap Model (not a full end-to-end security)

WAP 2.0 security uses TLS (Transportation Layer Security) instead of WTLS due to requiring end-to-end security with all IP based technology in order to overcome the WAP gateway security breaches. It is a Public Key Infrastructure (PKI) enabling protocol that provides the services such as authentication by using digital signatures and public key certificates, confidentiality by encrypting data, etc. This protocol uses RSA, RC4, 3DES, and SHA-1 algorithms for encryption. Wireless PKI (WPKI) is released for the first time. Figure 2 shows the WAP proxy model.

Figure 2 WAP Proxy Model (end-to-end security)

#### 3.3.2 PKI/WPKI

PKI systems and WTLS are at the heart of today's mobile security technology. In a WAP environment WTLS must be translated at the WAP gateway into SSL, the Internet standard. A PKI is a set of policies, processors, software, hardware, and technologies that use PKC and certificate management to secure communication [18]. PKI's trusted services enable the secure transfer of information and supports a wide variety of M-Commerce applications. PKI must ensure the following: (i) confidentiality, achieved by cryptography, (ii) authentication, achieved by digital certificates, (iii) integrity, achieved by digital signatures, and (iv) nonrepudiation, achieved by digital signatures and certificates.

PKI consists of the following components: (i) Certificate Authority (CA)- responsible for issuing and revoking certificates, (ii) Registration Authority (RA)- binding

between public key and the identities of their holders, (iii) Certificate Holders- people, machine or soft-ware agents that have been issued with certificates and can use them to sign digital documents, (iv) Verification Authority (VA, Clients)- validate digital signatures and their certificates from a known public key of a trusted CA, and (v) Repositories- stores that make available certificates.

WPKI is an optimized extension of traditional PKI for the wireless environment. 'WPKI encompasses the necessary cryptographic technology and a set of security management standards that are widely recognized and accepted for meeting the security needs of M-Commerce' [18]. WPKI applications have to work in an environment with less powerful CPUs, less memory, restricted power consumption, and smaller displays. WPKI solutions are likely to employ "network agents" that take care of some of these tasks. The HWD must at least be able to perform a digital signature function to permit the establishment of a WPKI. Network agents can perform all other WPKI-related tasks such as validation, archiving or certificate delivery. Figure 3 shows a schematic diagram of WPKI.

Figure 3 Wireless PKI

The private keys are stored in WIM or SWIM. Two main components of WPKI are the PKC and the key certification management. In order to perform globally, worldwide PKI legislation is required.

A number of companies, including Entrust, Certicom, RSA Security, VeriSign, and Baltimore, have announced solutions enabling the use of PKI software in a wireless environment. The biggest challenge in implementing a PKI solution for wireless deployment lies in the devices themselves. With limited bandwidth and low power, a small screen and no keyboard, the average mobile device presents a number of unique problems. Certicom developed Elliptical Curve Cryptography (ECC) that reduced the key size from RSA's 1024 bits to as few as 56 bits and made handling certificates a lot easier for low-bandwidth and low-power devices [2]. This technique can process a digital signature in a second compared to the RSA technique, which takes almost 15 seconds to process a digital signature on a Palm device. Both Nokia and Ericsson have been supporting server certificates since the middle of 2000.

### 3.4 Wireless LAN (WLAN) Security

#### 3.4.1 IEEE 802.11b

The WLAN standard IEEE 802.11b provides a mechanism for authentication and encryption. It provides a maximum of 11 Mbps wireless Ethernet connections using the band at 2.4 GHz. 802.11b security features consists of security framework called Wired Equivalent Privacy (WEP). WEP is based on RC4, a symmetric stream cipher. It has a pseudo-random number generator, whose output is XORed to the data. WEP can use 40 or 128 bits key size. However, using a 128 bits key size, 802.11b throughput drops much due to heavy calculations. In August 2001, RC4 was announced to be broken and can be cracked in less than half an hour. Consequently, WEP can be broken. WEP with 40 bits key size can be broken in real time.

#### 3.4.2 Bluetooth

Bluetooth technology, developed by Ericsson in 1998, is used to connect different HWDs and provides a method for authenticating devices. Device authentication is provided using a shared secret between the two devices. The common shared secret is called a *link key*, generated from PIN. This link key is established in a special communication session called *pairing*. All paired devices share a common link key. There are two types of link keys: (i) *unit keys* and (ii) *combination keys* [17]. The link key is a 128-bit random number.

A device using a unit key uses the same secret for *all* of its connections. Unit keys are appropriate for devices with limited memory or a limited user interface. During the pairing procedure the unit key is encrypted and transferred to the other unit. Only one of the two paired units is allowed to use a unit key. Combination keys are link keys that are unique to a particular pair of devices and they are only used to protect the communication between these two devices. Clearly a device that uses a unit key is not as secure as a device that uses a combination key. Since a unit key is common to all devices with which the device has been paired, all such devices have knowledge of the unit key. Consequently they are able to eavesdrop on any traffic based on this key.

In every Bluetooth device, there are four entities used for maintaining the security at the link level: (i) the Bluetooth device has an IEEE defined 48-bit unique address, (ii) a private authentication key which is a 128-bit random number, (iii) a 8-128 bit long private encryption key, and (iv) a random number, which is frequently a changing 128-bit number that is made by the Bluetooth device itself [12]. The security algorithms of Bluetooth are considered strong. Bluetooth standard does not use the RC4 cipher; rather it uses the E1, a modified block cipher SAFER+. No practical direct attack has been reported.

#### 4. CRYPTOGRAPHY

The two types of cryptography currently available are (a) symmetric or secret-key and (b) asymmetric or public key cryptography (PKC). In secret-key cryptography, two devices must share their secret key in order to communicate securely. Thus two concerns arise: how to exchange the secret key securely; and if  $n$  HWDs must communicate with each other, a total number of  $O(n^2)$  secret keys must be exchanged. The management of such a number of secret keys should consider the scalability issues.

In PKC, both the above problems are solved since two parties in the communication do not require exchanging any secret keys. According to this consideration, PKC seems to be the ideal candidate to enforce confidentiality. Cryptographic techniques already exist to protect data transmission over the Internet. The *de facto* cryptographic algorithm for digital signatures and for encryption of secret keys is the RSA PKC. For electronic commerce, it is a highly secure technique. Although RSA is highly secure and widely used, there are some potential problems with its use in M-Commerce: (i) in RSA the key size is large which requires a significant amount of memory for storage, (ii) decryption time increases rapidly as the key size increases, and (iii) key generation is complex and time consuming. Memory constrained devices cannot easily generate RSA keys and therefore may need to have keys generated by another system. Moreover, the computations needed to encrypt and decrypt messages using RSA is overwhelming compared to secret key cryptography.

##### 4.1 Elliptic Curve Cryptography (ECC)

What is really needed is a public key algorithm that achieves a high level of security using short keys. Algorithms based on mathematical objects known as elliptic curves offer interesting possibilities [1]. Elliptic curve discrete logarithm problems (ECDLP) is defined as “give a base point  $P$  and the  $kP$  lying on the curve, find the value of  $k$ ”. From cryptographic point of view, a new cryptographic system needs to be defined based on elliptic curves. Any standard system that relies on the discrete logarithm problem has a direct analogy based on the ECDLP. For example, Elliptic Curve Digital Signature Algorithm (ECDSA) has already been standardized. Diffie-Hellman key exchange can be easily implemented in an elliptic curve system.

Certicom promotes the use of ECC, as well as its mobile Virtual Private Network (VPN) client, and a client, which bring sophisticated security functionality to resource-constrained devices. WPKECC is recognized as the most optimized and therefore the best suited for supporting security in the wireless environment. The key for digital signature in ECC is 163 bits as compared to 1024 bits in other signature schemes. However, good

elliptic curves must be carefully chosen, otherwise it might be prone to various attacks. ECC is small, efficient and requires low power. Table 1 shows key sizes for ECC and RSA.

**Table 1 EEC Key Size compared to RSA**

ECC Key Size (bits)	Traditional RSA Key Size (bits)	Key Size Ratio
109	512	1:5
131	768	1:6
163	1,024	1:6
283	3,072	1:11
409	7,680	1:19
571	15,360	1:27

Recently, ECC has been deployed on Smartcards without coprocessors [16]. Weimerskirch *et al* [15] implemented ECC on a Palm OS device. Their study showed that the normal transaction, such as a key exchange or signature verification, can be done in less than 2.4 seconds while signature generation can be done in less than 0.9 seconds. Table 2 shows the three major industry standard PKC systems that can be considered secure, efficient, and commercially available [13].

**Table 2 Three Major Industry-Standard PKC**

PKC	Mathematical Problem	Algorithm
Integer factorization	Given a number $n$ , find its prime factors	RSA, Rabin-Williams
Discrete logarithm	Given a prime $n$ , and numbers $g$ and $h$ , find $x$ such that $h = g^x \bmod n$	ElGamal, Diffie-Hellman, DSA
EC discrete logarithm	Given an elliptic curve $E$ and points $P$ and $Q$ on $E$ , find $x$ such that $Q = xP$	EC-Diffie-Hellman, ECDSA

##### 4.2 Problems with Elliptic Curve System

The true difficulty of the ECDLP is not yet fully understood [1]. Recent research has shown that some elliptic curves that were believed suitable for ECC are, in fact, not appropriate. For example, if the order of the base point  $P$  is equal to the prime number  $p$  then it turns out that the ECDLP can be solved efficiently. Such curves are known as anomalous curves. For a given curve and base point, it is trivial to generate public and private keys (the private key is simply a random integer  $k$  and the public key is the point  $kP$  on the curve). However, it is an extremely difficult problem to generate a suitable curve and base point in the first place.

The main problem is how to count the number of points on the curve. Having done this, it is then necessary to select a suitable base point  $P$ , which must have a large order to ensure the difficulty of the ECDLP. But the order of  $P$  must divide the number of points on the curve.

Having found the number of points on the curve, it is quite likely that a suitable base point cannot be found. Users may use random curves or special curve generating soft-ware, such as the "Elliptic Curve Generation Bureau" created by Zaxus.

In April 2000, the French National Institute for Research in Computer Science and Control announced that the 109-bit ECC key was cracked in a four-month brute-force effort using 9,500 computers by 1300 volunteers from 40 countries [3]. The amount of work required was about 50 times that required to solve a 512-bit RSA cryptosystem. The NIST has endorsed 163-bit ECC and WAP standards to be used in HWDs.

### 4.3 Digital Certificates and Digital Signature

In a PKC, a message is encrypted using a public key and is decrypted using a secret key. However, there is no inherent way of knowing the person who has the corresponding secret key. This is where the idea of certificates arises. Certificates confirm that the public key given in the certificate belongs to a private key held by the legitimate person, not by an imposter. To trust a certificate means to trust the party who issued the certificate, not the person for whom the certificate is issued. To protect a certificate from being modified one uses digital signatures. The message can only be created from the ciphertext by the private key holder. This provides authorization and non-repudiation. That is the basis for digital signature.

How to protect private keys? The private key is stored in a Smart card, where all crypto operations with it are performed. The Smart card access gets restricted by the use of a PIN. The place where a user's private credentials are stored is called Personal Security Environment (PSE).

## 5. CONCLUSION

M-Commerce security is a very crucial issue that needs further research to introduce efficient and effective solutions. In this article, various security concerns were expounded. ECC certainly appears to provide a viable alternative to RSA. There are potential advantages, especially when used in devices with limited processing capability and memory. Typical applications include M-Commerce using handheld wireless devices. There are, however, some problems and issues that are inhibiting the widespread adoption of ECC. These include (i) the real security of such systems is still not well understood, (ii) difficulty of generating suitable curves, and (iii) relatively slow signature verification. Time will tell its future.

# Simulating Collaborative Mobile Services – An Approach to Evaluate a New Location Enabling Service

Peter Dornbusch, Florian Fuchs, Martin Huber

Center for Digital Technology and Management (CDTM), Technical University Munich,  
Arcisstr. 21, 80333 Munich, Germany  
{Peter.Dornbusch, Florian.Fuchs, Martin.Huber}@cdtm.de

## ABSTRACT

Although enthusiasm for the “killer-application” in the mobile sector has decreased, location based services still seem to be valuable mobile services. Today’s location based services are mostly forced to use the proprietary location information provided by mobile network operators. The approach that is discussed here depicts a way of locating a mobile client independently from certain network operators and in heterogeneous networks. The Location Trader system collects and provides location information for users and providers of location based services. The accumulated interaction of each user of the user community enables to generate reliable location information in the Location Trader database. This paper prepares the groundwork for modeling the core principles of unintended value co-production with the Location Trader System. We intend to focus our analysis on the Location Trader System resp. Services, as the phenomenon of value co-production is widespread because of low coordination costs for integration and transactions enabled by immateriality and potential automation of business and transaction processes. The focus of this paper is the simulation of the user integration based on the theoretical basis.

**Keywords:** Location Aware, User Integration, Collaborative, Mobile Service

## 1. INTRODUCTION

Location-based services are considered by many as the next generation of mobile services with a huge potential: Allied Business Intelligence, for example, predicts that the market for location-based services will grow from one billion US dollars in 2000 to about 40 billion dollars in 2006.

Currently the development of such services, however, is severely impeded by the lack of an open, network-crossing positioning platform: Only splintered solutions are available for particular networks and the various operators of these networks are eager to defend their positioning monopoly.

In a novel approach the Location Trader system aims to overcome this situation and to establish a generic positioning platform that fosters the development of innovative and diverse location-based services.

The Location Trader approach is based on the integration of service users in the creation of the positioning service. It has first been introduced by Dornbusch and Huber in [1].

The Location Trader system constitutes a virtual link between service users, service providers and developers in a complex network constellation of these economic actors. This property together with the fact that the service is build up in cooperation with users poses several challenges for the successful launch and operation of such a system.

We identify two key properties of the Location Trader concept:

- Quality of service and therefore the value of the positioning platform increases with the number of people involved, and
- The system relies completely on volunteer contributions by its users.

In this paper we use the Location Trader system as a case study for analyzing unintended value co-production both qualitatively and quantitatively. We first introduce the relevant economic literature in section 2. In section 3 we apply these theories to the Location Trader concept. Section 4 models the concept quantitatively in a computer simulation and analyzes the results. The findings are summarized with a conclusion in section 5.

## 2. VALUE CO-PRODUCTION VIA USER INTEGRATION

Value co-production is different from the traditional view of value creation as a value chain [2]. Value co-production adds a new dynamic to the producer/customer relationship by engaging customers directly in the production or distribution of value [3][6]. Some researchers have given an even broader definition as “value co-creation by two or more actors, with and for each other, with and for yet other actors”[4].

Value co-production exhibits the following characteristics: Value is created more and more synchronously, it is created more interactively and it is created involving more actors. This has been enabled by recent technical breakthroughs and social innovations.

From a more implementation-oriented perspective, value co-production requires motivating customers as well as monitoring and managing the process of co-production. There are three generic ways of integrating the customer in the creation of value [5]:

- *Innovation* which describes an intended, innovative and creative contribution like generating new service ideas
- *Substitution* where a certain activity that used to be carried out by a service provider is now carried out by the customer, representing an intended but not innovative way of value creation
- *Variation* which describes a non-intended, non-creative and non-innovative contribution. “The value of a single customer activity is so small that the customer is not able to exploit his contribution and only the aggregation of many single parts by the service provider allows realizing the value”[5]

Some research has also been done on the potential of co-created value over time. For this Huber and Sandner have investigated *variation* as the special case of value co-creation where actors unintentionally and probably even unconsciously participate in value production [5]. This *non-intended value co-production* is made possible by the automation of certain business processes and the immateriality of the generated value, namely information.

A service based on variation usually exhibits feedback effects as contributions by users are aggregated over time and used to refine the service. Considering this feedback loop for the analysis of the service potential over time suggests the following three-phase model:

- **Build-up of service:** The initial service potential is low and will be build up over time through user input
- **Stable system:** User input and potential loss are balanced so that the system remains stable without the input from the service provider
- **Skimming of potential:** The user-created potential can be skimmed by the service provider

### 3. QUALITATIVE ANALYSIS OF VALUE CO-PRODUCTION WITH THE LOCATION TRADER

The economic ecosystem of the Location Trader concept involves two economic actors around the Location Trader positioning platform (see Figure 1): *Service providers*, who base their location-based services on the Location Trader positioning platform; *service users*, who access these services and contribute their current locations if necessary.

By design the Location Trader system relies on contributions by service users: They are the ones disclosing their current location when their current position –in the case of cellular networks the current

network cell –is not known to the system yet. This way they contribute to building up the location data pool and –together with all others service user –co-create value for all involved parties by improving the quality of the positioning service.

**Figure 1: Economic ecosystem of the Location Trader approach**

Co-creation in the case of Location Trader is enabled by cellular communications technology and the Internet in connection with the fact that the created value is immaterial information which can be transmitted and processed very cost-efficiently using these technologies.

The Location Trader approach exhibits the properties of value co-production, especially through value being created synchronously and involving all service users at the same time. This suggests modeling the value creation process as a value constellation rather than as a value chain where management has to focus on managing the interactions within this constellation.

Analyzing this value creation constellation from an implementation point of view suggests considering the following *risks*: Privacy concerns of service users may prevent them from contributing to the system. When they feed the data pool with location information they effectively disclose their current location. As they are requesting a location-based service this is actually required and will be plausible to them. However, as the system stores this information in the data pool, service users may be concerned that this information is used to track or trace back their movements. It needs to be credibly assured that the information they contribute is stored anonymously and therefore cannot be associated with their identity at any point of time.

Legal risks play a minor role in the co-creation process of Location Trader as the contribution process is well defined and the contributed information is always mere location information. However, it has to be ensured that intellectual property issues are considered.

The main *challenges* for co-creation in the context of Location Trader are goal divergence, effort and equity returns.

Both service users (as the value co-creators) and the positioning platform have different goals: Service users want to receive information or services based on their current location; the positioning platform wants users to access services and disclose their current location in

order to feed the location data pool. Nevertheless both goals can be combined and jointly satisfied with the Location Trader co-creation process where contributions are only required if nobody else has made a contribution yet.

Crucial for motivating users to contribute is to minimize the effort of contribution: Contribution in the case of the Location Trader co-creation process is a very structured and invariable task that can be highly automated. As most users are naturally used to disclosing their current location when requesting a location-based service they do not even perceive an additional effort. In fact, each user's average effort is reduced as contributions do not have to be made every time, but will automatically be reused in the future. There is a greater effort on the side of the positioning service to enable the co-creation of value through service users, but this effort has to be accepted as it constitutes the core of the whole concept. Interrelated with these two challenges is the issue of equity of returns. The return to each service user for the disclosure of their current location is the provision with a location-based service. It has to be ensured that the value of these services is perceived equitable to effort by each service user.

Applying *best practices* of value co-creation to the Location Trader concept yields the following insights: The objective of co-creation in the case of Location Trader is clearly defined: Service users disclose their current location so that the positioning platform can associate this location with the user's current positioning in a cellular network and can reuse this information in the future for positioning services. So co-creation takes place at the production stage. It also takes place at the maintenance stage once there is sufficient data available and further contribution are just used to refine the data pool and keep it up to date.

This implies that within the Location Trader ecosystem only service users can be selected as co-creators. It may make sense to further segment this group in order to select those of them who are most likely to contribute frequently.

The different rights of the involved parties need to be considered: Service users have the right of privacy and that their contributions are not associated with their identities. The positioning platform has the right of storing and using the contributed information.

Expectations of both involved parties need to be explicitly managed: Service users should expect that they are provided with a location-based service, but may sometimes have to disclose their current location. This will be the case more and more rarely in the future. Vice versa the positioning platform can expect every user to disclose the current location when it is required.

The channel that the positioning service can use to monitor and control user contributions is the list of incoming locations. They should be checked for plausibility before they are added to the core data pool.

Service users need to be enabled to contribute by providing them with the required Location Trader Client Applications and by making the contribution process as easy and self-explanatory as possible.

The users' incentives to contribute need to be explicitly communicated and managed. There is the immediate incentive of being provided with a location-based service that otherwise would not be available. However, there are also more indirect incentives such as the idea of the Location Trader platform as an independent, open source-like data pool where contributors can identify themselves with this vision. A competitive and signaling incentive can be created by allowing the association of a particular network cell with the nickname of the user who first "discovered" and contributed the cell to the data pool. Other incentives can be thought of.

An important aspect of value co-creation in the case of Location Trader is that it takes place automatically and not necessarily intentionally: The basic co-creation process is automated and users need to be involved only if their current location is not known to the system yet. Only then they become aware that they need to submit information in order to be provided with a location-based service. However, they are not necessarily aware that this information will also be reused at a later stage and therefore they are not aware that they are actually co-creating value. This kind of integration is denoted as *variation* as it is non-intended, non-creative and non-innovative.

Theory suggests that the potential of a service with these properties will follow a pattern of three phases over time: A buildup phase where initial potential is low and increased over time through user integration. A stability phase where the service remains stable just based on user contribution. Finally a skimming phase in which the service provider can skim the co-created value.

This section has applied the theoretical basis on value co-creation as presented in the previous section to the Location Trader system. It has pointed out risks, challenges and implications based on best-practices. Finally, it presented a three-phase model of the potential of the service over time.

#### 4. QUANTITATIVE COMPUTER SIMULATION OF VALUE CO-PRODUCTION WITH THE LOCATION TRADER

In addition to the theoretical and qualitative analysis of the Location Trader system in the previous section, this section presents a more quantitative analysis based on a

computer simulation as a second approach to understanding the system's mechanics.

The simulation models the service usage behavior of a certain number of Location Trader users within a certain area and over a certain period of time. It takes into account several factors such as contribution of locations, individual satisfaction and completeness of the data pool. By varying initial settings and comparing the effects on the resulting simulations, the importance of particular factors is determined.

It is important to bear in mind that all conclusions are based on an idealized model of the real world and cannot be taken for granted. Nevertheless they can help to identify general interdependencies and trends. Furthermore the simulation should serve as an interactive model for playing around and experimenting.

#### 4.1 Model

The model of the Location Trader system assumes a certain number of users in a certain quadratic area. This area is partitioned in equal-sized squares where each square represents an idealized network cell in a cellular network. Every user is unambiguously located within one of these network cells, however, as in real life one cell can accommodate several users.

Each user in the model has the properties requests, contributions, satisfaction and frustrations. *Requests* counts for each user how frequently the user requested a services. *Contributions* represents the number of locations that the user contributed to the data pool. *Satisfaction* measures the satisfaction of each user by incrementing the current value each time the user requested a service and was automatically provided with the service without the need of contribution. *Frustrations*, on the contrary, counts the situations when a user requested a service and had to provide the current location manually.

Each cell has the property *locations* which counts how many locations have been mapped to the cell's cell ID. If a cell is mapped to at least one location the model assumes that a service request in this cell can be satisfied.

When the simulation is started, each user acts autonomously, but everybody follows the same rules: First, the user roams around, which may or may not result in changing the network cell. Second, the user may or may not request a service which will either satisfy the user, if at least one location has already been mapped to the current cell, or will frustrate the user and cause the user to contribute the current location to the data pool. If the discrepancy between *satisfaction* (successful request of services) and *frustrations* (need to manually contribute the current location) grows too far, a user may be disappointed and stop using the system.

On the other hand, if *satisfaction* exceeds *frustrations* by a certain value, the user starts using the system more frequently and may even recruit new users to the system. Finally, after all users are done, a random network cell may be removed from the data pool to simulate changes in the network infrastructure.

The environment and exact behavior of the users is determined by several initial settings and also randomized between certain boundaries.

The cellular network environment is modeled by the radius of each cell and the number of hours after which the data pool is degenerated to simulate a change in the network infrastructure. In addition, the initial number of users, who will be randomly distributed over the network, can be set.

The behavior of the users is mainly influenced by the average number of times per week that they request a service (*usage*) and by their *mobility* that influences how frequently they move to another cell. Of course, this depends also on the radius of the cells.

In addition, it can be set how many more frustrations than satisfactions a user can stand before abandoning the system (*discouragement threshold*). The *recruitment threshold* determines how many more satisfactions than frustrations a user has to experience in order to start recruiting new users. The probability of a successful recruitment can be set, too.

Finally, it can be varied how frequently the systems asks the user to contribute the current location although the data pool already contains a location for the current cell (*redundant location request*). This is to maintain the integrity of the data pool and also to increase positioning quality.

#### 4.2 Implementation

The previously described model was implemented using the software StarLogo 2.0<sup>1</sup> by the Media Lab at the Massachusetts Institute of Technology (see Figure 2 for a screenshot). StarLogo is a programmable modeling environment designed to help modeling and exploring the workings of decentralized systems, such as bird flocks, traffic jams, and market economies. It is available free of charge for download.

StarLogo is an extension of the Logo programming language and adopts Logo's terminology of autonomous *turtles* living on *patches* and an *observer* observing and controlling what happens.

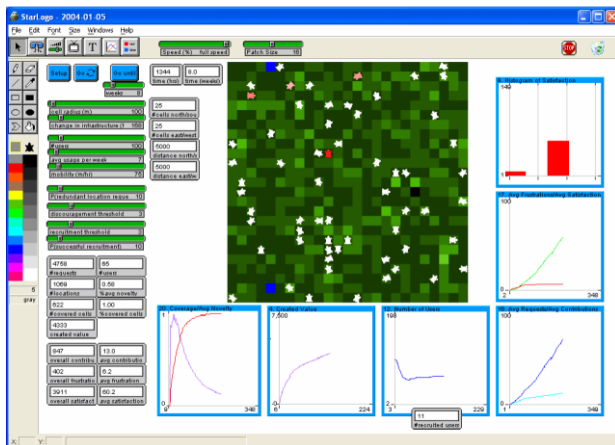

In the implementation turtles represent service users and patches represent networks cells. The observer controls the overall simulation flow and provides a global clock.

<sup>1</sup> StarLogo website: <http://education.mit.edu/starlogo/>

The simulation is partitioned in discrete steps where each step represents one hour of simulated time. In each step each turtle completes one sequence of roaming and then probably requesting a service.

The parameters described as the initial settings for the model are implemented as *Sliders* on the simulation area and can be adjusted by the user. Service users/turtles and network cells/patches are visualized on the so called *Graphics Canvas*. The color of the patches is scaled between black and light green where the level of green indicates the number of locations mapped to a patch. The color of the turtles is scaled between dark red and white where the brightness indicates the level of satisfaction of a turtle.

So called *Monitors* display indicative figures such as the total number of requests, users and contributed locations. Furthermore the completeness of the data pool is measured as the percentage of cells that are mapped to at least one location. A fictive value of the current data pool is calculated by valuing the first location for each patch with a value of 5, the second location with a value of 3, the third with a value of 2 and the fourth with a value of 1. Finally, overall and average value for each user's contributions, satisfaction and frustrations are indicated.

**Figure 2: Computer simulation of the Location Trader concept in StarLogo**

The temporal development of some of these figures is visualized in small *Graphs*. (Note that these Graphs can only use running time as their axis in x direction in contrast to simulated time.)

Three *Buttons* allow controlling the simulation: Setup resets and initializes the simulation with the current parameters. Go starts the simulations and runs it until the button is pressed again. Go until starts the simulation and runs until the simulated time has reached the predefined number of weeks.

### 4.3 Simulations

As a structured approach to simulation, two scenarios

and a set of basic initial settings have been chosen. They serve as a basis for comparison with simulations where selected parameters have been varied.

The two scenarios are an urban and a rural scenario. The urban scenario tries to model an urban environment where there are smaller and more network cells in a certain area. Based on reported average cell sizes the cell radius has been set to 100 meters with 25 times 25 cells. The resulting area of 5 times 5 kilometers approximates the area covered by the city of Munich.

The rural scenario is modeled after a rural environment where the radius of a cell can be several kilometers. Here a cell radius of 3000 meters has been chosen and the covered area is 15 times 15 kilometers.

The following basic initial settings have been chosen: The number of users has been set to 100. This seems to be a reasonable number that should be possible to reach with a concentrated effort at the university, the CDTM community and word-of-mouth propaganda. The average usage of Location Trader-based services has been set to 7 times a week which corresponds to 1 usage per day. This is a reasonable number, especially when motivation and curiosity are still high in the beginning. The average mobility of users has been set to 75 meters per hour which means that users move at most 75 meters per hour on average. This setting takes into account that most people spend several hours a day in the same building, where only few cell changes occur, but sometimes cover longer distances, for example during lunch break or in the morning and in the evening. Finally, the system has been set to require the user to contribute the current location redundantly in 10 percent of the cases where a location has already been mapped to the cell. It is assumed that a user accepts three cases more in which the current location has to be provided manually than cases in which a service is provided automatically. And it has been estimated that a user has to have been satisfied by the system three times more than being disappointed in order to start recruiting new users.

Based on these basic initial settings several simulations have been run. A comparison of the results of simulations with the same initial settings has shown that outcomes are converging and are therefore representative for the selected initial settings.

### 4.4 Evaluation

In 20 different simulation setups five basic initial settings, as explained in the previous section, have been varied along a single dimension each time in order to single out and identify their effects on the simulation outcome. Both urban and the rural scenario were considered. The simulation was run for a simulation time period of 8 weeks to allow a comprehensive overview of the launch period.

The five settings that were varied are: the initial number of users, frequency of usage, mobility of the users, the users' discouragement threshold and the redundancy of contribution (the percentage of cases in which a user is required to provide the current location although at least on location information is already available). All these settings were both halved and doubled one after the other and the effects on the simulation outcome were examined.

The examination was based on the value of nine indicative figures at the end of the simulation: the completeness of the data pool, the total created value based on the valuation as described in 0, the number of users, the total numbers of requests and contributions and the users' average number of requests, average number of contributions, average satisfaction and average frustration.

#### 4.5 Urban Scenario

The outcomes for the urban scenario suggest the following interdependencies (see also Table 1): Both the initial number of users and the frequency of usage seem to have the greatest effect on the completeness of the data pool. While an almost complete coverage is achieved in almost all cases after at least 8 weeks, these two factors speed up the process. They also increase the total created value and the overall number of requests and contributions. The initial number of users has an even higher impact on the latter two, whereas the frequency of usage increases the average number of requests per user. This is understandable as both factors have a direct effect on the number of locations contributed to the system and therefore have a direct impact on the quality of service and the satisfaction of users. Frequent usage further pushes average satisfaction which can be explained with the more frequent satisfaction that users experience. On the other hand, a greater initial number of users helps to extremely decrease average frustration as the disappointment of having to provide the current location manually is spread across more people.

In fact, the initial number of users is mission critical as in all simulations for the urban scenario a great loss of users occurs in the beginning. If the initial number of users is too low (less than 75 in the simulation) the initial great loss may even be unrecoverable and the system may fail completely. (The user loss is due to the frequent frustrations that user experience with a not-yet-complete data pool in the beginning.) On the other hand, the higher the initial number of users is, the more users the system will have in the future. In fact, this seems to be a super-proportional relation.

Surprisingly, user mobility as an indicator for the spatial distribution of service usage has very little effect on any

of the indicative figures. It seems that a high number of users already provides sufficient spatial distribution.

The discouragement threshold proves to be another mission critical factor. Simulations show that users must accept at least two frustrations more than satisfactions before abandoning the system to keep the system running. Otherwise the number of users drops dramatically and the system fails. In the simulation a discouragement threshold of three is sufficient. A higher threshold has only a moderate positive effect on the number of users and requests.

Requiring the user to redundantly provide the current location has an interesting effect on several factors. Of course, it increases the average number of contributions per user and maintains the quality of the data pool. On the other hand it decreases average satisfaction and therefore the number of users. But this is only true for redundancy rates of more than 20% in the simulation. Below this value these negative effects are negligible, but improvements in completeness and quality of the data pool are still gained. A moderate rate of redundancy does therefore make sense.

In conclusion in the urban scenario the initial number of users and frequency of usage are the most effective levers on the number of service requests and the future number of users. The initial number of users is mission critical, but at the same time most effective for increasing the number of users. There needs to be a certain level of resistance of users against frustrations in the beginning. Redundant manual contributions seem to be acceptable to users within certain boundaries.

#### 4.6 Comparison to Rural Scenario

The basic observations for the urban scenario proved to be true for the rural scenario, too. However, there are some important differences that will be pointed out in the following.

First of all, simulations for the rural scenario never failed: Initial number of users and their discouragement threshold are not as mission critical as in the urban environment. In fact, in the rural scenario there is basically no loss of users in the beginning, which is very much in contrast to the urban scenario. On the other hand, a high initial number of users does not have a significant impact on the number of users in the future. This can be explained with the fact that users in the rural scenario only infrequently change network cells due to the size of the cells. This prevents them from frequent frustrations by the system, but at the same time does not make them enthusiastic enough to attract new users. In addition, it generally slows down the build-up and completion of the data pool.

**Table 1: Simulation outcomes for the urban scenario**

Effect of higher ... on ...	Number of users	Frequency of usage	Mobility of users	Discour. Thresh.	Redund. of contrib.
Completeness of data pool	proportional	super-prop.	insignificant	insignificant	insignificant
Created value	sub-prop.	sub-prop.	insignificant	insignificant	insignificant
Number of users	super-prop.	sub-prop.	insignificant	sub-prop.	insignificant
Total number requests	super-prop.	proportional	insignificant	sub-prop.	insignificant
Total contributions	super-prop.	proportional	insignificant	sub-prop.	insignificant
Average requests	insignificant	proportional	insignificant	insignificant	insignificant
Average contributions	insignificant	sub-prop.	insignificant	insignificant	proportional
Average satisfaction	insignificant	super-prop.	insignificant	insignificant	insignificant
Average frustration	invers Prop.	insignificant	insignificant	insignificant	insignificant

As users usually stay close to their home cell, the system does not require a comprehensive data pool to provide them with satisfying services. This decreases the importance of the discouragement threshold in the rural scenario. The negative effects of requiring redundant contribution are also reduced. However, due to the size of network cells in the rural scenario, positioning accuracy in general is dramatically lower which affects the overall value of services to users.

All in all, general trends and interdependencies are the same for both the urban and rural scenario. However, the rural scenario is less prone to failure, but at the same time provides lower quality of service due to lower positioning accuracy.

## 5. CONCLUSION

Value co-creation takes place between service users and the positioning platform. The major risk involved with this is that privacy concerns of service users may prevent them from contributing to the system. It has therefore to be credibly assured that the location information cannot be associated with their identity at any point of time. The Location Trader approach naturally ensures that the goals of both parties are satisfied in the co-creation process: the positioning platform improves its data pool and service users are provided with a location-based service. Requiring a contribution only if necessary further reduces the effort of co-creation. In order to ensure equity of returns, the quality of the offered services has to be guaranteed. For encouraging service users to contribute their expectations have to be managed and they have to understand why they sometimes have to disclose their location. A major incentive will be to fascinate them for and make them identify themselves with this

independent and open source-like approach. Still, contributions have to be checked for intentionally corrupt information. Finally, as the co-creation process is nearly completely automated, some users may not even perceive it as such.

For quantitative analysis the service usage behavior of a certain number of Location Trader users within a certain area and over a certain period of time was modeled in an idealized computer simulation.

The model takes into account environmental factors such as network cell size and initial number of users as well as individual factors such as frequency of usage, number of requests, number of contributions, each user's satisfaction level, frustration level and tolerance towards frustration before abandoning the system.

By systematically varying certain initial settings, their effect on the outcome of the simulation can be observed. Each simulation was run for both an urban and a rural scenario.

The basic observations are the same for both scenarios: Initial number of users and frequency of usage have the greatest effect on build-up speed and the future number of users. Users have to tolerate a certain number of frustrations in the beginning when required to manually provide their location. However, a certain level of redundancy in requiring contribution is acceptable. In contrast to the rural scenario, the urban scenario may fail if the initial number of users or their tolerance towards frustration is too low. However, positioning accuracy is significantly lower in the rural scenario due to the greater size of network cells.

### ABSTRACT

The paper aims at assessing how can location based mobile support systems support salespersons' CRM efforts when they are operating within a highly mobile work environment. The paper is structured as follows. In the first section the paper conceptualises key properties of location based mobile support systems. It then introduces the dual role of salespeople in CRM through a brief literature review. A fourth section suggests potential mobile location services and applications that can support salespersons in performing effectively their everyday CRM tasks and links such applications to the determinant of salespersons' performance. The papers concludes with some remarks and suggests some areas of further research

**KeyWords:** *Mobile location technologies, Customer relationship management, Salespersons tasks, salespersons performance, Personalisation.*

### 1. INTRODUCTION

Effective customer relationship management (CRM) has emerged as a strategic imperative for companies in virtually every business. The rapid rates at which innovations can be made and copied have made product advantages brief (Shoemaker, 2001). However, as Day (2001) observed, because nurturing customer loyalty is usually resource intensive, long term and difficult to manage, loyalty relations can provide a durable competitive advantage.

Today many companies are trying to move closer to their customers by capturing the available wealth of internal and external data to better understand their customer needs, preferences and profitability and then leverage that knowledge in every customer contact. Recent studies show that the movement to CRM is gaining momentum. One study by IDC Group forecasts that the worldwide market for CRM products and services would top US \$ 125 billion while a survey of more than 1500 companies by the Data Warehousing Institute in 2000 found that 91 percent either have or plan to deploy CRM solution in the near future (Goodhue et al. 2002). The impetus for this interest in CRM came from Reichheld, who demonstrated a dramatic increase in profits from small increases in customer retention rates. His study showed that as little as a 5 percent increase in retention had impacts as high as 95 percent in the net present value delivered by customers.

Salespersons play a dual role in CRM. On one hand, forging close relationships between firms begin with the initial contact by a salesperson (Levitt, 1993) who serves as a boundary spanner between the selling firm and the customer. For some customers the salesperson is virtually synonymous with the firm (Crosby et al., 1990; Czeipeil, 1990). On the other hand salespersons possess

valuable source of market information that is frequently needed in strategic planning and CRM programs. However crucial marketing information still remains locked in the heads of salespersons in the form of tacit knowledge. Converting tacit dispersed information possessed by salespersons into explicit knowledge that can be used to better satisfying customer is still a challenge for a number of companies (Choo 1996).

The advent of access to services through mobile and wireless devices has resulted in a fast growing of a number of mobile applications and services. Mobile (or wireless) applications, despite being different in their nature, they share a common characteristic that distinguishes them from their wire-line counterpart: They put the user at the centre of information and communication through the provision of location specific information, personalization, immediacy, and service availability (Durlacher, 2001). These characteristics would enable the development of innovative mobile applications to support firms' salespersons in developing and nurturing committed customer relationships. How and which mobile applications can support these frontline ambassadors in their CRM related tasks are key questions facing a number of stakeholders including sale managers today.

The purpose of this paper is to assess how can location based mobile support systems support salespersons' CRM efforts when they are operating within a highly mobile work environment.

The remainder of the paper is structured as follows. Next the paper conceptualises key properties of location based mobile support systems. It then introduces the dual role of salespeople in CRM through a brief literature review. A fourth section suggests potential mobile location services and applications that can support salespersons in performing effectively their everyday CRM tasks and

links such applications to the determinant of salespersons' performance. The paper concludes with some remarks and suggests some areas of further research.

## **2. KEY PROPERTIES OF LOCATION BASED MOBILE SUPPORT SYSTEMS**

### **2.1 Personalisation**

Personalisation in information systems is about adapting content and services based upon the user's interests, preferences, and behaviour, allowing further optimisation, which results in an optimal experience for the user, targeting the goal of the user (Setten, 2003). One key enabler of providing personalised services to users is ensuring the adaptivity of the system. System adaptivity is the process in which a system adjusts itself based upon some form of model of the user's needs. Location awareness can be a key feature in updating the mobile user's model based on the system's awareness of the user's current spatial context. Information about the user's current geographical position when combined with other elements such as the user's daily schedule of activities, or her predefined preferences in terms of content or interests would enable the service provider to proactively deliver a meaningful mobile support which is based on a continuous update of the user's changing spatial environment. For instance, within the sales force work environment, the service provider can deliver, based on the awareness of the salesperson's geographical position and her predefined preferences about the information she wishes to receive, a personalised support that has the potential to add value within the spatial context where the salesperson is located. Also the support can be delivered in the form that matches the requirements of the salesperson work context (i.e. face to face meeting with a client, in the train or in restaurant). For instance, the service provider can push an alert to the salesperson's smart phone in the form of text message if the salesperson is in face-to-face meeting and thus enabling him/her to read the alert and potentially exploit it during his/her interaction with the client.

### **2.2 Relevance**

Knowledge of the user's spatial position can be a key element in providing relevant support to him/her. Awareness of the user's geographical position can provide a good filtering mechanism in terms of determining how relevant is the intended mobile support given the user's current geographical location. This has the potential of reducing the functional deficiency associated with information overload, where the amount of information the individual client side user encounters extends her cognitive processing capacity (Ljungberg and Sorensen 2000). For instance, combining the knowledge of the salesperson's current geographical location with her calendar of daily activities can provide the service provider with insights that the salesperson is

about to meet the client X whose address matches the geographical position where she is located. Then the service provider can push to the sales person relevant information that fit him/her predefined preferences about that client that he/she could use during the sales interaction.

### **2.3 Convenience**

The ability of the service provider to know the geographical position of the mobile user can make it faster and simpler for such user to be provided with the targeted support she needs. Indeed it will suffice the mobile user to notify its request to the service provider to get the service he/she is seeking as the service provider can know where the user is located. Indeed, the user's request can be automatically completed by the current location (i.e. if the user asks about the restaurant nearby, the system can infer from the user's geographic position what nearby means and select such restaurants that are in the area (BenMoussa, 2004).

### **2.4 Timeliness**

Another key characteristic of location-based mobile support is the timeliness of the support that service providers can provide users with, based on the knowledge of their locations. The timeliness of location-based mobile support refers to the ability of the service provider to provide the user with support at the moment of value. The moment of value can be defined as "the moment when I a service provider can do something for you where you are and regardless of where I am or what time it is" (Keen, 2001).

### **2.5 Proactiveness**

Another key property of location based mobile support system is the ability of the service provider to proactively enable the user to react to changing trends in the environment. Based on the user's situational context and changing environment, the service provider delivers content without receiving a request from him/her. Providing a proactive support to users can be of great importance in terms of saving time (i.e. alerts about traffic jam), tapping an opportunity (i.e. notifications about nearby tradeshow) or avoiding relationship-damaging problems (i.e. getting in time to a meeting with a new client thanks to the road instruction delivered by the service provider).

## **3. THE DUAL ROLE OF SALESPERSONS IN CRM**

Evidence indicates that salespeople play a central role in the evolution of quality business relationships (Crosby et al, 1990; Dwyer et al., 1987). According to Kotler (1994), personal selling is evolving towards the salesperson as "relational manager" who is able to build strong ties with important customers. Further, Swan and Nolan (1985) contend that firms are seeking out relationships with

their customers and that salespeople are important in helping to build these relationships. One reason for the critical nature of a salesperson's role in developing quality relationship between their firm and the customer lies in the salesperson's ability to develop strong lines of communication with the customer. In addition to their role as relationship-builders, salespeople serve as CRM-enablers through the wealth of market information that they possess and which can serve as a basis in developing effective CRM programs. The following discusses such a dual role of salespersons in CRM.

### 3.1 The Salesperson as Relationship-Builder

In the marketplace, salespersons often perform a vital boundary-spanning role that links their firm to customers. For some customers the salesperson is virtually synonymous with the firm (Crosby et al., 1990; Czeipeil, 1990). Research on buyer-seller relationships suggests that a firm's salespeople are uniquely positioned to address several issues related to quality relationship building. Through their interaction with buyers, salespeople can increase the customer's confidence in the supplier. This helps reduce uncertainty and increase trust (Moorman et al, 1992). The relationship-builder role of salespersons is critical throughout the relationship evolution process.

### 3.2 The Salesperson as CRM-Enabler

The salesperson's role as CRM-enabler stems from the knowledge he/she possesses about the marketplace and which can serve as a valuable input in feeding customer information system for CRM. Marketing scholars have indeed advocated that business salespeople be incorporated into firm's formal marketing information systems for almost 40 years (Webster 1965). For instance klompaker (1980) stated, "Salespeople are used because they possess a great deal of information about the market". To leave this rich source of information untapped would be fool-hardy"(Evans et al, 1985).

## 4. LOCATION BASED MOBILE APPLICATIONS TO SUPORT SALESPERSONS CRM EFFORTS

After discussing the key properties of location based mobile support and the dual role of salespersons in CRM, the paper now presents potential mobile location applications and services (MLS) to support salespersons tasks for better performance. The paper categorises such mobile location applications and services as the adaptive, the proactive, the locative and the disseminative. The paper shows how each category of such mobile location based applications can support salesperson CRM tasks and enhance their overall performance through its impact on a number of mediator variables that constitute salespersons' performance determinants. Indeed, several authors (Mooney et al. 1996; Huber, 1990; Davenport 1999) have proposed that in order to uncover the added value mechanisms and the impact of information

technology on productivity, studies should include intermediate benefits of information technology. For instance according to the theory of the effects of advanced information technology (Huber's 1990), the benefits in individual and organizational effectiveness occur" indirectly "through the positive impact the technology has on information and communication processes. Figure 1 depicts a model linking location-based mobile support system with salespersons' performance.

### 4.1 Adaptive MLS

Location based mobile adaptive applications are aimed at supporting situations where the salesperson is engaged in the interaction with her client and needs useful information about the client so that she can practice adaptive selling. Salespeople's adaptive selling is one of the main determinants of their performance (Weitz et al, 1986; Sipro and Weitz 1990; Sujun 1986). Indeed the process of selling requires that the salesperson matches the customer's needs with the available range of products. The process of adaptive selling involves two stages. In the first stage, the salesperson uses the available information to form impressions about the customer and in the next stage she formulates a sales strategy that maximizes the fit between the customer preferences and the company's offerings. Through the practice of adaptive selling, salespeople exploit the unique opportunities of personal selling. However it has been shown that adaptive selling can be improved by providing salespeople with the necessary market information and resources such that they can link insights from other sales situations to the customer contacts in which they are currently engaged (Weitz et al.1986). For instance, the market intelligence department can push, based on knowledge of the salesperson's location, an alert about a new discount policy released by the company's main competitor related to the product she is selling to her client. The salesperson can then read the alert and prepares suitable arguments should the client raises issues associated with new competitor's discount policy. Likewise, the salesperson can receive, based on her location, real time notifications about the business of the customer she is visiting and use such information in tailoring her proposal to the customer.

Location based adaptive applications can also support salespersons in altering their sales call schedule based on alerts about her customers changing orders and profitability as well as competitors' move, so that they can target their relationship efforts on the most profitable customers. For instance the market research department may push an alert to the salespersons that one of her customers, which is located in the nearby has just cancelled an important order. Such alerts would enable the salesperson to adjust her sales visits schedule so that she can devote more efforts to react to the potential account loss.

## 4.2 Proactive MLS

Proactive MLS enable salespersons to continuously search for market opportunities and experiment with potential responses to changing environment. (Venkatraman, 1989).

An indicative example of proactive location based mobile applications include notifications, based on the salesperson's geographical position, about sales leads which are located in the nearby. For instance, the market research department can push alerts about trade shows in the area where the salesperson is located. Similarly, telemarketing support centre can provide real time alerts to the salesperson about high -quality leads that are in the same area where the salesperson is located. Depending on the quality of the lead (that is, sales versus no sales) and the salesperson's sales calls schedule, the salesperson can accept or deny making face-to-face sales visit to the sales call identified by the telemarketing support centre. If the salesperson accepts to make the sales visit then additional information from the marketing research department can be pushed to his/her mobile terminal about the lead including a rebuttal to prepare him/her for question that the prospect may raise (BenMoussa 2004). Furthermore, proactive MLS may include location based intelligent alerts that would enable the salesperson to respond proactively to the competitors' alerts threatening her accounts.

Another indicative example of proactive MLS is notifications about traffic conditions (i.e. traffic congestion or a road blocking accident together with alternative routes).

Proactive MLS may include also notifications pushed by the different functions within the salesperson's organization. For instance the customer service department can alert the salesperson that the order of a customer located in the same geographical area where the salesperson is may experience a delay in delivery. This would enable the salesperson to contact the customer and proactively suggest alternative solutions. Similarly, the account department may send a notification to the salesperson that the client she is about to meet has not yet paid her invoice so that the salesperson can tackle the invoice payment within her interaction with the customer.

Proactive MLS would enhance the salesperson ability to focus her efforts on value adding activities such as maintaining quality relationship with her customer. In addition proactive MLS have the potential to enhance the salesperson customer orientation, which is a key determinant of salespersons performance. Support for the use of customer oriented selling is provided by the contention that customer orientation is an important characteristic of high performers (Kelly 1992, Bragg, 1986, Mackay 1988; Peterson 1988). For instance according to MacKay (1988) "best" salespeople are

genuinely interested in their customers and that sales representatives sell to people not to computers. Likewise Peterson (1988) contends that successful salespeople work to satisfy the needs of the customers

## 4.3 Locative MLS

Locative MLS are aimed at empowering the salesperson to deal customer requests and problems. The purpose is to shorten the time it takes to address customer problems and concerns. Indicative examples of locative MLS may include product tracking applications, customer support staff locator applications colleagues' locator, and entertaining areas for clients (BenMoussa, 2004). Product tracking applications consist of enabling salespersons, irrespective of their locations, to track the delivery status of products ordered by customers, either by connecting wirelessly to smart tags incorporated in the products or through receiving location based alerts about the order status of clients situated in the same geographical location where the salesperson is located. This would enhance their ability to answer rapidly, accurately and irrespective of their locations to customer order related inquiries, which their customer orientation. Furthermore, receiving location based alert about customers' orders status would enable salespersons to react to eventual shipment problems that may result in a delivery delay to customers.

Customer support staff locator applications would enable salespersons to locate the nearest customer support staff in order to address a client's problem. The salesperson can send a request to locate customer support staff, display their locations on a map and forward the client's request for service to the nearest field worker. Upon receiving confirmation to perform the service by the field worker, the salesperson can then be able to provide his/her client with accurate personnel arrival time. Dispatching the nearest customer support field employee has the potential to reduce the time needed in providing support to customers, which would enhance the customer's perception of the salesperson's empathy.

Colleagues locator applications would support the situations where the salesperson need to collaborate with her colleagues in order to deal with a complex sales problem. The salesperson can then identify the colleagues who are in the same geographic position as her and checks whether they are available for a meeting or a conference call.

## 4.4 Disseminative MLS

The disseminative MLS support the situation where the salesperson wants to alert her colleagues about a market opportunity and /or potential threats within the colleague's sales area. The salesperson can use the geographical position of her colleague as a filtering mechanism to assess the potential impact of the alert in terms of information overload. For instance the

salesperson can uncover a competitor's deficiency in the sales area of her colleague. The salesperson can then based on her colleague's geographical position and her calls agenda assess whether or not the insight she uncovers may help her colleague in practicing adaptive selling with the client she is visiting. Therefore the salesperson may either push directly the notification to her colleague or elect to submit the alert to the corporate customer database for subsequent forwarding to her colleague.

Disseminative MLS have the potential to exploit the wealth of information the salesperson possess as a result of their daily interactions in the market place. In addition, disseminative MLS provide salespersons with a tool that has the potential of enhancing collaboration among them despite their constant move. Furthermore, enabling salespersons to disseminate the market insight just after it occurs (i.e. after the sales interaction) would enhance their accuracy. The importance of accurate customer knowledge to salespersons performance is intuitive. If salespersons' perceptions are inaccurate, it can adversely affect customer relationship building at least in two ways. First inaccuracy in assessing customer requirements by the salesperson will negatively affect both relationships

building and corporate profitability particularly in industries where sales persons are given the latitude in tailor prices and services to individual customers. Second, the use of inaccurate salespersons' insight in the company's planning process including CRM programs will adversely affect the quality of these plans (Lambert et al.1990).

## 5. CONCLUSION

The paper explored the area of location based mobile support systems within the context of salespersons' CRM efforts, when they are operating within a mobile work setting. More specifically the paper discussed the unique role of salespersons as both an enabler and facilitator of CRM. The paper also suggests potential location based applications to support salespersons in their CRM efforts and linked them to the determinants of salespersons performance. Future research would involve issues associated with the acceptance by salespersons of location based mobile application and services so that they could integrate them into their everyday work life and take benefits from their full potential.

# Technology Attribute-Diffusion Pattern Nexus: Evidence from the Early Experiences of 3G Mobile Communications

Nir Kshetri

University of North Carolina at Greensboro, NC 27402-6165, U.S.A  
nbkshetr@uncg.edu

## ABSTRACT

The diffusion patterns of 3G cellular technologies indicate that the reality is not matching the optimistic estimates of various consulting firms regarding the size of the network. What factors influence the diffusion of rapidly developing network goods? This paper draws upon innovation diffusion literature and the early experiences of 3G mobile technologies to examine the influence of supply-side factors on the 3G diffusion trajectory. We also propose a model that classifies various 3G related attributes in terms of their influence on present utility vs. expected future utility and the mechanism of influence: via 3G device vs. via 3G network. The central argument of this paper is that while the breadth of offers has been wider in 3G compared to lower generation cellular technologies, there has been digression rather than progress on some dimensions (e.g., bulky 3G handsets, very short battery lives, small geographical coverage, and lower network externality effects). The problems are compounded by the lack of strategic pricing and industry-regulator coordinations.

**Keywords:** 3G mobile communications, diffusion, supply-side, technology attributes, upgradability, utility of network goods

## 1. INTRODUCTION

The diffusion patterns of 3G cellular technologies indicate that the reality is not matching the optimistic estimates of various consulting firms. The early experience in Europe and Asia-Pacific indicates dismal consumer response to 3G mobile communications. For instance, Hutchison 3G (H3G), which launched 3G services in the UK and Italy in March 2003, had set a target of target of 1 million subscribers in each country by December 2003. The company achieved only 30% of its target in Italy and 21% in U.K. by that time (Table 1).

This paper draws upon innovation diffusion literature and the early experiences in Europe and Asia to explore the connection between attributes of a technology and its diffusion pattern. Although we focus on 3G, the issues examined in this paper have broad implications technology marketers.

## 2. SUPPLY SIDE OF TECHNOLOGY DIFFUSION: RELEVANT THEORIES

The existing literature indicates that supply side factors that influence diffusion of network goods include price, breadth and depth of technology products, complexity, positioning, government-supplier coordination and modularity and upgradability, degree of supply abundance and expected size of the network (Table 2). It should, however, be noted that these factors are not necessarily orthogonal. In the case of network goods such as 3G mobile communications, some of these

factors are more relevant to the device whereas others are more relevant to the network. These attributes can also have differential impact on the perception of present utility and expected future utility. Table 3 classifies the attributes in two dimensions: device specific vs. network specific and present utility vs. expected future utility.

The demand for a network good is a function of the expected size of the network (Katz and Shapiro 1994). Too small new market may result in the failure of a new technology (Lin 2003). The expected size of the network is a function of various factors including price of the technology product, quality, degree of compatibility with previous generations of technologies, and upgradability.

Suppliers can modify product characteristics and price structure to fit the needs of a market segment (Robertson and Gatignon 1986). The price of a technology influences consumers' adoption timing (Kamakura and Balasubramanian 1988) and the rate of adoption (Jain and Rao 1990) at the micro-level and for a network good, the demand and the market potential (Kalish and Lilien 1986; Katz and Shapiro 1994) at the macro-level. Since the network externality is positively related to the network size, the number of users has a higher significance than the intensity of use for network goods. For networks that require two part fees, a reduction of the fixed component is thus a more appropriate way to stimulate the growth of the network than a reduction in variable costs (Perrot 1995).

**Table 1: 3G Mobile networks in selected economies**

	Hong Kong	Japan	Italy	U.K.
Launched in	January, 2004	September 2001	March 2003	March 2003
Service provider(s) and technology	H3G (W-CDMA)	DoCoMo (W-CDMA) KDDI (CDMA)	H3G (W-CDMA)	H3G (W-CDMA)
Number of subscribers (Date)	3,000 (February 1, 2004)	DoCoMo: 2 million (January, 2004) KDDI: 13 million (October 2003)	210,000 (December 2003)	300,000 (January 2004)
ARPU		US\$77.8 (October-December 2001)	Euro 79 (2003)	

Mason's (1990) study, on the other hand, provided empirical support that product attributes and not cost affect the adoption decision. For rapidly developing technologies such as mobile phones, modularity and upgradability have a strong impact on the diffusion pattern. Rosenberg (1982) found that if a technology is upgradable, it allows a firm to offer product innovations continually that users can integrate into their current product configuration. He argues that users will be reluctant to purchase products that cannot be upgraded and rapid technological change further

increases the reluctance since their investments become obsolete under such conditions (Rosenberg 1982). Upgradability is found to be one of the major factors that influence the selection of a desktop computer. PC buyers are concerned about the possibility of upgrading the processor, adding the memory, availability of drive bays for additional hard drives (Grier and Bryant 1998). Product standardization and modular upgradability also affect and are affected by network externality and compatibility requirements (Kotabe et al. 1996).

**Table 2: Supply side factors influencing the diffusion of network goods**

Factor	Impact on innovation diffusion	The case of 3G
Expected size of network (NS)	Influence network externality effects	<ul style="list-style-type: none"> <li>• Incompatibility with lower generation phones and PCs.</li> <li>• Too small coverage in some countries</li> </ul>
Modularity and Upgradability (MU) Price (PR)	Allows users to integrate innovations continually Influences: <ul style="list-style-type: none"> <li>• Adoption timing</li> <li>• Rate of adoption</li> <li>• Market potential</li> </ul>	Cellular technologies lack consumer-level upgradability <ul style="list-style-type: none"> <li>• Higher prices. Suppliers focused more on reducing variables prices (VPR).</li> </ul>
Number of versions/standards (NV)	Multiple versions/standards increase complexity	Uncertain standards and complexities of 3G applications
Degree of supply-abundance (SA) Depth and breadth (DB) Industry-government coordination (IG)	Slow growing and fast declining diffusion pattern under supply restriction. Increase choice and value Inadequate coordination leads to failure.	Shortage of 3G handsets  3G has a wide breadth of uses <ul style="list-style-type: none"> <li>• Market fragmentation</li> <li>• Supply-side crowd</li> <li>• Unrealistic expectations of governments</li> </ul> H3G's confused positioning
Communication/promotion (CP) Other characteristics (OC)	Positioning influences attractiveness.	Size, battery life, reliability of devices and network, etc. H3G's confused positioning
Communication/promotion (CP) Other characteristics (OC)	Positioning influences attractiveness.	Size, battery life, reliability of devices and network, etc.

Modular upgradability and its benefits are also illustrated by Sun's SPARCstation 10 series. SPARCstation enables users to increase system performance by plugging in faster microprocessors and memory modules as they become available. SPARCstation 10 series can also be upgraded easily to multiple processing and other future technologies. The SPARCstation 10 provided integrated services digital

network (ISDN) capabilities as a built-in feature. Moreover, SPARC modules and bus architecture can accommodate advances in microprocessors technology. Sun also offered "no penalty upgrades" to its users--the price of an upgrade plus user investment in an existing system would be equal to the price of a new system (Garud and Kumaraswamy 1993).

Inadequate coordination among firms and governments is another source of failure of a new technology (Lin 2003). The failure will also imply the inappropriateness of the industrial policy to other firms and they can avoid that failure by not following the policy (Lin 2003). The diffusion pattern of telecom-related products is also a function of the focus of national industrial and technological policies on fostering and strengthening this sector (Beise 2001, p. 263).

The degree of supply-abundance also influences the shape of diffusion curves. For instance, Simon and Sebastian (1987) found that a diffusion curve exhibits slow growing and fast declining (that is, negatively skewed) pattern under conditions of supply restriction.

Past research has also found that variety and uncertainty of multiple versions increase complexity (Frizelle 1998). A technology's possibility of forking into numerous versions increases the uncertainty. For instance, UNIX in the 1970s was broken into several proprietary formats (Kogut and Metiu 2001), which increased its complexity.

In the case of radical innovations, firms with greater depth and breadth in their product portfolio tend to be more successful (Sorescu et al. 2003). Broader and deeper product portfolio increases consumer choice and hence value of technologies offered by a company. For instance, breadth of product line is found to be positively related to consumers' workstation purchase decisions (Kaplan 1991).

Suppliers can also influence the adoption rate of a product by communicating ideas through advertising and promotion (Narasimhan and Mendez 2001; Rogers 1995) and setting fashions (Abrahamson 1996). Like all other products underpositioning, overpositioning, confused positioning and doubtful positioning (Kotler 2003, p. 311) will slow down the adoption rate.

**Table 3: A two-dimensional representation of supply side factors influencing 3G diffusion**

	<i>Present Utility</i>	<i>Expected Future Utility</i>
<i>Device Specific</i>	PR, DB, CP, NV, OC (Size, battery life, reliability of device, etc.).	MU, NV, FPR, OC (Size, battery life, reliability of device, etc.).
<i>Network Specific</i>	PR, DB, CP, OC (e.g., reliability of network).	NS, FPR, OC (e.g., reliability of network).

### 3. SUPPLY-SIDE FACTORS INFLUENCING THE DIFFUSION OF 3G MOBILE COMMUNICATIONS

3G cellular technologies are characterized by different types of network externality compared to lower generations. Whereas second generation (2G) phones could communicate with first generation (1G) phones

as well as with fixed phones, this is not the case with 3G phones. Only 3G devices can exploit combined voice/picture capabilities of 3G networks and lower generation mobile phones and many PCs could be excluded from such application networks (Lehrer et al. 2002). Limited geographical coverage in most countries has exacerbated the problem. Lack of coverage hindered the initial success of FOMA in Japan, NTT DoCoMo's 3G service launched in October 2001. In Italy and the U.K., H3G's coverage started with half the population (Norton, Leslie P 2002). Even by the early 2004, H3G offered 3G services to only 55% of the Italian population (Taaffe 2004).

In a survey conducted by *ChangeWave Alliance*, the Number 1 concern about 3G services of 18% of the respondents was too expensive services and that of another 4% was too expensive handsets. Consider the prices of 3G handsets. In Korea, SK Telecom and KTF had set the price of 3G handsets from US\$581-\$830 in 2003 (Business CustomWire, December 28, 2003). In U.K., immediately after the launch of 3G services, H3G had to reduce the price of its handsets by half to pounds 199 which was still much higher compared with the "free" phones offered by 2G operators to those signing up to their monthly plans (Economist.com 2003).

Not only the fixed costs but also variables costs of 3G are expensive. Higher average revenue per user (ARPU) of 3G services reflects unattractive variable costs. In Italy, for instance, ARPU from 3G services was Euro 79 per month in 2003 which compares with 2G ARPU of euro27 in Europe (Taaffe 2004). In Japan, NTT DoCoMo reported that the mean 3G revenue per user in April – June, 2002 was \$65.43 a month (Georgi 2002). In July 2003, 3's UK customers spent an average of £45 a month -much higher than its rivals' £25-£35 (Payton and Bowen 2003).

In an attempt to make 3G services more attractive, the operators have reduced variables costs for some attributes. In U.K. a new tariff introduced by Hutchison 3G in June 2003, offered subscribers 500 minutes for \$40 per month, which compares with the plans of the incumbent 2G operators which averages \$72 for 400 minutes (The Economist, September 20, 2003). In Hong Kong, Hutchison offers three basic service plans to customers at monthly charges of US\$34 (Business CustomWire, January 19, 2004). To stimulate 2G consumers to sign up, NTT DoCoMo cut 3G fees by up to 55% for existing subscribers (Kakenaka 2002).

The wide breadth of uses of 3G has not translated into improvement on each dimension. In the *ChangeWave Alliance* survey, 4% respondents were concerned about current technology's capability to carry high-quality calls (Business CustomWire, November 19, 2003). Subscribers complain of lost calls, bulky handsets that

were awkward to handle and inadequate battery life. In Italy, 15% of early customers took their handsets back (Payton and Bowen 2003).

H3G's pre-launch brand-building campaign, designed to "cultivate curiosity" could not achieve its goal (Payton and Bowen 2003). Hutchison also made too many claims and too frequent change of the positioning of its brand, resulting in confused positioning. Hutchison, for instance, first launched a huge advertising campaign promoting the video capabilities and high-speed internet access of 3G handsets. In September 2003, Hutchison started promoting its 3G services as the cheapest ways to make voice calls instead of touting advanced features such as videoconferencing and Web-browsing (The Economist, September 20, 2003, Ramstad et al. 2003). In fact, the killer application of 3G has become voice communications (Payton and Bowen 2003).

In the ChangeWave Alliance survey, the number 1 concern about 3G services of 17% of the respondents was the reliability of technology and equipment (Business CustomWire, November 19, 2003). Many 3G subscribers are reported to carry their 2G handsets as back-ups. Hutchison 3G mobile in Australia received several complaints of calls dropping out not being able to deliver video and Internet service on the 3G handsets (Business CustomWire, December 28, 2003).

The slow growing diffusion pattern of 3G is can also be attributed to the shortage of 3G ready handsets (Business CustomWire, December 2, 2003). Hutchison also failed to launch the pre-pay service due the lack of suitable handsets. Vendors like Nokia, Motorola, and Ericsson could not ease the supply-side bottlenecks to ensure the availability 3G ready handsets for W-CDMA services. Even 2.5G handsets were seriously delayed by Nokia (Reinhardt et al. 2001).

Many operators around the world enjoy supplier-level upgradability in the cellular network. Economies with CDMA-based 2G networks such as South Korea, Brazil, India and Mexico can easily upgrade to 3G in the form of CDMA2000 (The Economist 2002). Thanks to its CDMA-based 2G standard, South Korea was able to launch the 3G network as early as in 2000. Consumer benefit of the supplier-level upgradability in the cellular network, however, has been minimal. Consumers, for instance, are required to buy a new handset for 3G services. 2G handsets thus cannot be upgraded. There is thus no "no penalty upgrades" (Garud and Kumaraswamy 1993) in cellular networks.

In the 3G mobile industry, there seems to be the lack of proper coordination among governments and mobile players. First, the lack of coordination resulted in market fragmentation. The European Commission for instance, allowed individual governments to make their own decision on 3G spectrum. Such move converted

otherwise homogeneous European cellular market into different licensing regimes, networks and services (Wallage 2000).

Second, cellular operators got into heavy debt because of expensive 3G licenses postponed 3G investments. For instance, Vodafone paid about £ 15 billion to acquire 3G mobile licenses in the U.K., Germany, Italy, Holland and Spain, which doubled its debt level to GBP 13.2 billion in November from GBP 6.64 billion in March 2000 (Naik 2000). Many operators asked governments to ease various requirements and reduce costs (Latour 2002). A petition signed by 2000 European businessmen in April 2001 asked governments in Germany, the U.K. Italy and other countries to return 3G auction proceeds to operators and conduct new auctions (Ryan 2001).

Third, the lack of government-industry coordination also resulted in supply-side crowd in the 3G industry. For instance, consider the European 3G cellular market. In September 2002, Germany had four 3G competitors, the U.K. had six, the Netherlands, Sweden, Finland and Italy each had five, and Spain had four (Latour and Delaney 2002).

These problems are compounded by a lack of policies to foster 3G sector and unrealistic expectations from national governments. For instance, Hutchison faced problem in getting the building permits needed to set up base stations for 3G in Sweden. The Swedish government also specified the requirement of 3G coverage of 99.9% of the Swedish population (Latour 2002).

### ABSTRACT

Traditionally, the document was recorded on the papers and signed by related personnel to differentiate the responsibility. As the technology of communication is evolved quickly, it makes people connect each other by many different ways. Now, the e-document can be transferred on the network and e-signed with proper tools. However, it still needs people to stay in front of desktop to send and receive e-document. In this paper, we propose a way to send and receive the urgent e-document with cellular phone. For the sake of safety and non-repudiation, the users need to e-sign the document after receiving and before sending our e-document using the embedded wireless identity module (WIM) inside the SIM cards. The use of WIM in the SIM card to sign e-document can make the signing process more secure and reduce the possibility of argument. A prototype of this system was implemented. As can be imagined, the system will provide convenience and security for top managers to handle urgent events and e-document on the move.

**Keywords:** Smart card, wireless identify module (WIM), electronic document (e-document), mobile office

### 1. INTRODUCTION

The computers and networks give lots of convenience to us. We can process our e-document very quickly no matter where we are as long as we have the access of Internet. Now, it is convenient to use desktops to get the access of Internet. However, many top managers need to travel very often to handle the remote business. If the notebook is not suitable to be carried with in the long trip and the manager needs to handle the urgent document on the move, the cellular phone or personal digital assistant (PDA) could be a convenient tool to take the initial step. For the consideration of safety and non-repudiation, the proposed system was designed to allow the mobile manager to handle e-document using digital signature through the mechanism of WIM inside the SIM card. The smart card is used to prevent from intrusion by hackers and to show the users' identification to e-document servers. The benefits of using a smart card include [1] :

- | increased security,
- | potential user mobility, and
- | sequential access to one machine by multiple users.

In 1997, an industry organization named the WAP Forum was founded to develop technical standards to bridge the gap between the mobile and Internet networks. The development of WAP brought the wireless world closer to the Internet through a set of specifications utilizing technologies that enhance the experience of wireless users [14]. The first draft of

specifications was published in February 1998. The subsequent release of WAP 2.0 with additional features allows WAP to support improvements in wireless devices and Internet content technologies [14]. WAP can be used to define both communication protocols and application environments. The protocol optimizes the standard Web protocols for use in the low bandwidth, high latency conditions prevalent in wireless networks. Various enhancements to the session, transaction, security, and transport layers make HTTP (Hypertext Transfer Protocol) functionality better suited to the wireless network environment [20]. WAP security functionality includes the Wireless Transport Layer Security (WTLS) and application level security [12]. The WTLS has three classifications of security and provides different functionality as presented in Figure 1.

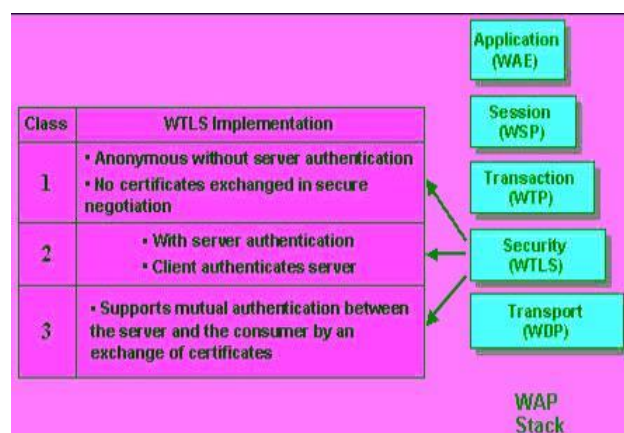

Figure 1. The Security Classification of WTLS [13]

<sup>\*</sup> Corresponding Author

For optimal security, some parts of related functionality need to be performed by a tamper-resistant device [12], especially for level 3 of WTLS. The Wireless Identity Module (WIM) is one of the WAP security function. The WIM is used to perform Wireless Transport Layer Security (WTLS) and application level security functions, and especially to store and process information needed for user identification and authentication [12]. The smart card is the best tamper-resistant equipment. So, our design is to use a cellular phone to provide the better mobility, and the digital signature and mutual authentication will be done by using the WIM embedded in the SIM card. This is the so-called SWIM card. Using the SWIM card to compute the digital signature and authenticate client and server, it can provide the security, mobility and also non-repudiation for e-document transactions.

## 2. RELATED TECHNOLOGY

### 2.1 SMART CARD

There are two kinds of smart cards. One is storage card and the other is processor card. People are already accustomed to some applications where a smart card is used just to store data, such as telephone cards and health insurance cards. Currently, the most popular application for processor cards is the SIM card within cellular phone [11]. There are many kinds of applications, which are related to the smart cards. Table 1 presents these applications.

Table 1. The Market Share of the Smart Card [16]

Domain Market	Market Share
Financial Services	16%
Government	13%
Communications	12%
Healthcare	11%
Retail	9%
Transport	8%
Services	7%
Education	7%
Insurance	6%
Utilities	6%
Manufacturing	4%

Because the smart card is a tamper-resistant device, it is widely used for authentication, making payments, or issuing digital signatures. The smart card can protect from physical attack and provide mechanisms against light or abnormal voltage detection, so the security of embedded data is ensured through the use of various coding techniques [11].

To exchange data between the smart card and the terminal, APDUs (Application Protocol Data Units) should be used [9]. The APDU denotes an internationally standardized data unit in the application layer [9]. Table 2 is the format of the command APDU and table 3 is the format of the response APDU.

Table 2. Structure of Command APDU [2, 9, 12]

Mandatory Header				Optional body		
CLA	INS	P1	P2	Lc	Data field	Le

Table 3. Structure of Response APDU [2, 9, 12]

Optional body		Mandatory Trailer	
Data field		SW1	SW2

A command APDU, which is sent by the card reader to the smart card, is composed of a header and a body. The header consists of the four elements [2][9]:

- u CLA (class of instruction): the class byte is used to identity applications and their specific command sets.
- u INS (instruction code): which encodes the actual command.

- u P1、P2 (parameters 1、2): these two bytes are primarily used to provide more information about the command selected by the instruction byte.

The section following the header is the body, which can be dispensed with except for a length specification. The elements of the body are described as follow [2][9]:

- u Lc: Lc is the length of the data section sent to the card.

- u Data field: contains the data associated with the command that are sent to the card.

- u Le: it specifies the length of the data section to be sent back from the card.

The response APDU, which is sent by the smart card in reply to a command APDU, consists of an optional body and a mandatory trailer, as shown in Table 3. The length of the data field may be zero, regardless of the value specified in the command APDU [9]. SW1 and SW2 are the status words to encode the response to the command [2].

### 2.2 ELECTRONIC OFFICIAL DOCUMENT

There are many disadvantages of manipulations of traditional official document. It may take much of time to deliver the official document and it may be also difficult to reserve the physical document or retrieve it. So our government planed to computerize the official document system and deliver the official document on the Internet since 1993. The electronic document use XML (eXtensible Markup Language) as the national standards. Through the usage of the XML, electronic official document can be exchanged automatically and it is also very easy to be retrieved and maintained. The following Figure 2 describes the infrastructure of e-document exchange. First, the sender should build the official document via XML standard and then use the

digital certificate to confirm the sender's identification. Finally, the sender should e-sign the official document by smart card and then transmit the electronic document to the receiver. After getting the document, the receiver should check the sender's identification and signature and then process the document.

Figure 2. The Integrated Service of the E-Document Exchange

### 3. SYSTEM ARCHITECTURE

Throughout the usage of the cellular phone, we can utilize the WIM inside the SIM card to verify user's identification and issue digital signature to make the mobile office possible. The Figure 3 presents the system architecture and all functions of WIM are illustrated in Figure 4.

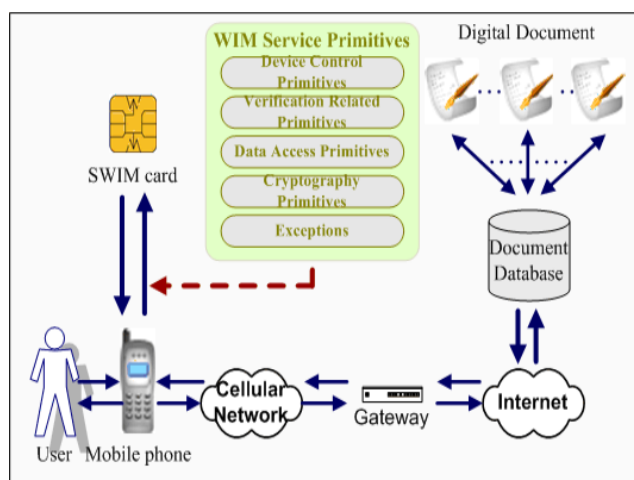

Figure 3. The system Architecture

The WIM contains five categories of service primitives, which are data control primitives, verification related primitives, data access primitives, cryptography primitives and exception [12].

#### u Device Control Primitives

There are two components in the device control primitives, one is WIM-OpenService and the other is WIM-CloseService. The WIM-OpenService can be used to open a logical channel and the WIM-CloseService can be used to close it.

#### u Verification Related Primitives

The verification process is based on a reference data (PIN) stored in the card. A user must be able to verify his/her identity by presenting the verification data.

#### u Data Access Primitives

These primitives can be used to search and access the data in the card.

#### u Cryptography Primitive

These components can be used to compute digital signature, verify signature, derive master secret, etc.

#### u Exception

This primitive is used to warn the user when the system goes wrong.

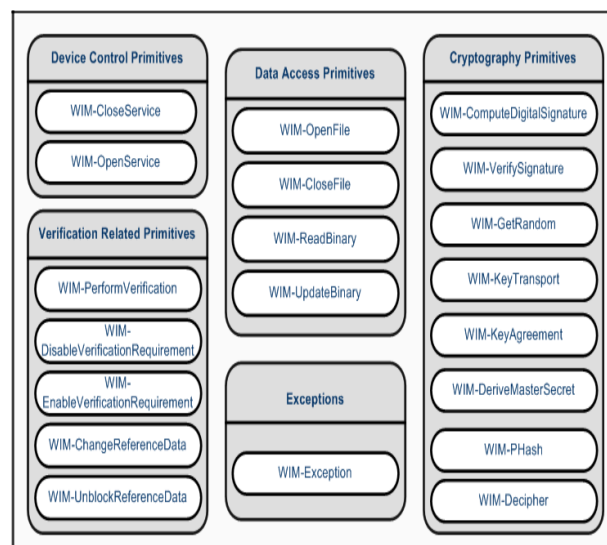

Figure 4. The Service Primitives of WIM [14]

We implement an interface on the mobile phone to communicate with the SWIM card and to access each service primitives. The user can verify his/her identity by entering the Personal Identification Number (PIN) and the SWIM card will return the verification status through the interface as shown in Figure 5. If he/she enters the wrong PIN more than three times, the SWIM card will be blocked and the original PIN will become useless. Only the issuing center can unblock this card [9]. This function can protect the SWIM card against possible unauthorized usage.

Figure 5. User's Verification

Before computing the digital signature, a Management Security Environment-Restore (MSE-Restore) command should be issued. A Security Environment (SE) is a logical container of a set of fully specified security mechanisms, which are available for reference

in security related commands. Each SE specifies references to the cryptographic algorithms to be executed, the modes of operation, the keys to be used and any additional data needed by a security mechanism [12]. After storing the SE, we should use MSE-SET command to set the location of key of the current SE. Figure 6 illustrates the procedure of computing digital signature.

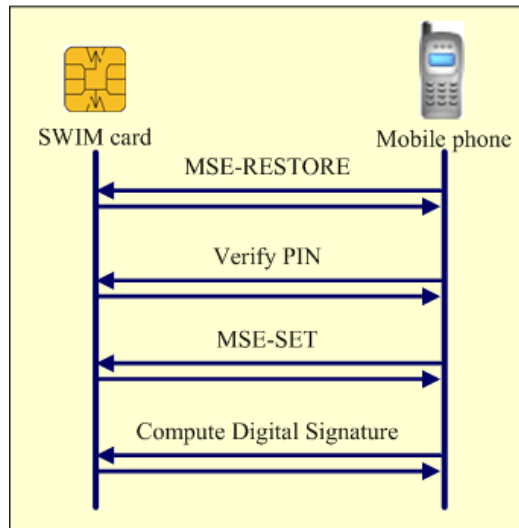

Figure 6. Procedure of Computing Digital Signature [14]

Please set the paper size as A4 (29.7cm\*21cm). Leave 2.5cm margins at both the top and the bottom of the page, 2cm on both right and left sides. Please write your paper using MS-Word. The Word of Microsoft's office 97 and 2000 is strongly preferred. If you write the paper by using other versions' Word, please give clear indication of what version of Word you use when you submit the paper by email.

#### 4. PROTOTYPE

The system has two parts, which are the web server and the mobile client. We build the electronic documents with web interface on the server and communicate with SWIM card on mobile client. Therefore we can e-sign the remote digital documents on the web server through the WIM modules in the SWIM card.

Microsoft windows 2000 was chose as the development platform and the JSP (Java Server Pages) and Tomcat 5.0 had been used to implement the website. The development of the mobile client is based on J2ME. First, the user has to login the website of the official document. After the user login, he/she can fill out the electronic form of official document as shown in Figure 7.

Figure 7. Electronic Official Document

Figure 8. Compute Digital Signature

After filling out the form, the user will select the button to compute the digital signature as shown in Figure 8. First, the SHA-1 (Secure Hash Algorithm) is used to compute the digest of official document. Then the web server will transfer this hash value to the mobile client and the mobile phone will invoke the related service primitive to compute the digital signature. If needed, the user can also verify the digital signature through the SWIM card and the card will return the verify status as shown in Figures 9 and 10.

Figure 9. Verify Signature

Figure 10. The Screen of Verify Status

When the user receives the electronic official document, he/she can read and e-sign the receipt as shown in Figures 11 and 12. Therefore the sender of official document knows that his/her document arrives intact.

Figure 11. The letter of receiver

Figure 12. Signing the document while receiving

## 5. SECURITY ANALYSIS

The security of this system is based on the secure mechanism of the SWIM. We will examine the system security based on the information security

standards- ISO/IEC 10181 [4], which are defined by International Organization for Standardization (ISO) and International Electrotechnical Commission. The ISO/IEC 10181 information security standard can be divided into four part, they are Confidentiality, Authentication, Integrity and Non-repudiation. We will ignore the confidentiality because we assume the document is not confidential.

### u Authentication

Authentication means that the individual is who he or she claims to be. Our system uses SWIM card to authenticate the user. The user should enter his/her PIN code in order to authenticate himself/herself. If the card owner entered the wrong PIN code more than three times, the SWIM card will be blocked and the original PIN code will also be useless.

### u Integrity

The system should prevent the modification of document when it is transmitted. Our system keeps the digest in the web server. If these digests are not consistent then server will ask the mobile client to send it again.

### u Non-repudiation

Non-repudiation means that the sender of official document can't deny ever transmitting this document and the receiver can't deny ever getting it. We use the digital signature to prevent the sender or receiver from repudiating their transaction.

## 6. VARIABLES AND EQUATIONS

In this paper, we propose the system of electronic official document, which can be processed via the cellular phone. In the future, the 3G communication network will provide higher data rate, then the capability of processing multimedia document can be embedded in our system. By adopting the mobility of cellular phones and high data transfer rate, we will go one-step further to the ideal mobile office.

## **The Quest for Mobility: Designing Enterprise Application Framework for M-Business Practices**

**Chianhsueng Chao**

Department of Information Management, National University of Kaohsiung,  
Kaohsiung, Taiwan, China  
cchao@nuk.edu.tw

### **ABSTRACT**

With the advent of the “road warrior,” a growing part of the workforce is mobile and using all sorts of mobile devices to stay in touch and transact business. As the global economy shifts toward the mobile economy, enterprises need to be progressively more flexible and globalize. Mobile businesses open up new opportunities for innovative enterprises and give them new means of communications with customers and employees. In a changing business landscape, mobile business addresses new customer channels and integration challenges. The current transformation is simply the movement of e-business to a mobile environment. It is still a developing concept as are the business models that support it. The usefulness of the mobile channels will be largely driven by new enterprise applications that enhance the overall customer values. This paper provides a broad discussion on the movement of mobile integration strategies. Several issues will be addressed, such as value chain, the data access of mobile computing, m-business application framework, and the future development of mobile computing. All of these efforts attempt to provide an overview and schematics for the integration of modern e-business application strategies into future m-business practices. This paper will show that any proposed system or strategy must recognize the primary value and mechanism of how people “work,” and technological solutions must be devised in order to facilitate people who conduct business. With mobile technologies, enterprise applications will go beyond the four walls of organizations to a workforce on the move.

### **1. THE PARADIGM SHIFT**

The challenge of global marketplace and new emerging technologies are the driving forces for enterprise to optimize their business strategies and operations frequently. Customer preferences and needs change constantly, resulting in pressingly intense competitions. Time sensitive real-time transaction is becoming the common denominator for successful businesses. Information also needed to be available to anyone from anywhere at anytime. There are challenges along the path of business evolutions, however, the innovated enterprises seize every opportunity to reinvent themselves in order to fit into the global spectrum of business. The Internet is bringing profound impact to the business world and has enabled a new way of conducting commerce. To compete in the emerging digital economy, enterprise need to change their business models, rethink the way they work and forge new relationships with their trading partners and customers.

Today, mobile businesses open up new opportunities for innovated enterprises and give them new means of communications with inside/outside stakeholders. In a changing business landscape, mobile business addresses new customer channels and integration challenges. The e-business comes a long way from hype to mature. The mobile solutions will build on the top of the existing e-business investments. The m-business is facilitated by the integration of the Internet, e-business, and the wireless world where customers can go online with any device at anytime from anywhere. Enterprises focus on

how to use mobile technology to provide customers with rich service experiences and greater satisfactions. This is a more real picture about business, because business opportunities occur in anywhere at anytime. To embrace this big vision, a new value chain is emerging which focuses on the mobile devices, access methodology, and enterprise contents. Mobile applications are beginning to play a central role in enabling real-time supply chain. Enterprise must design a mobile application framework for both customers and their suppliers. The usefulness of the mobile channels will be largely driven by new enterprise applications that enhance the overall customer values. Seeing m-business processes in terms of a net value added chain is a good approach for visualizing current and future competitive advantages. The creation of these values depends on the enterprise's ability to coordinate and link those internal/external activities efficiently.

### **2. THE WIRELESS LANDSCAPE**

The m-business is facilitated by the integration of the Internet, e-business, and the wireless world where people can go online with any device at anytime from anywhere [1]. All mobile workforce demands mobile computing and access to e-commerce resources regardless of the medium used to gain access. However, to create multi-channel and multi-technology solutions in a fast-moving and technologically indefinite mobile environment is difficult and extremely risky. A number of mobile devices, closed networks, disparate carrier/server systems, protocols, and solutions characterize today's

wireless landscape. Currently, accessing the web through a wireless device is different than accessing the web through wired connections. The fastest way to access the Internet on the move is through the IEEE 802.11b (Wi-Fi) standard. Overall, 802.11 (Wi-Fi) in its various forms (a, b, e and g) has emerged as the winner in wireless LAN technology [2]. However, the problem with wireless LAN-based access is that the access points or base stations have a very short range, which means they're restricted to a few "hotspots," such as hotels, conference centers, and airport. The situation gets more complex when the wireless LAN is mobile.

## 2.1 The Wireless-to-Wired Network Infrastructure

The development of the cellular network not only enabled the advancement of mobile communications but

also provided the playgrounds for mobile commerce. The term cellular comes from the honeycomb shape of an area into which a covered region is divided. Cells are base stations transmitting over small geographic areas. A frequency spectrum is divided into blocks of frequencies and those blocks are assigned to the cells. As a mobile unit passes from one cell site to the next, the call is handed off from one transceiver to another. When the service area grows with more users, the approach is to split an area into smaller ones. In this way, the urban centers can be split into as many areas as necessary to provide service in heavy traffic regions. Therefore, less expensive cells are then deployed to cover the remote rural areas. The base station (BS) host several telecommunication equipment at the transmit/receive antenna's base, the center of a cell.

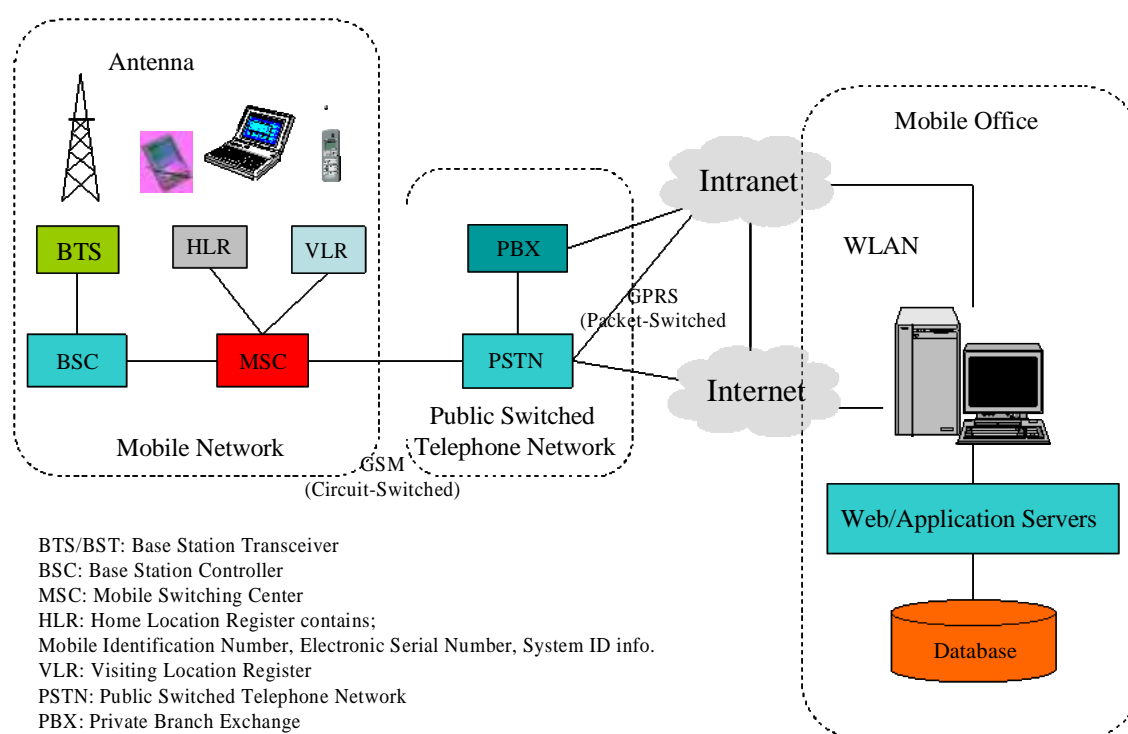

Figure 1 The Wireless-Wired Landscape

The base station in Figure 1 consists of two major electronic units known as the base station transceiver (BST) and the base station controller (BSC). The BSTs are full-duplex transmitter and receiver units (transceivers) that signal to the mobile units and receive signals from them. The BST serves one cell in the cellular network and contains one or more transceivers. The BSC controls the transmission and reception of signals of the BST and switches calls between the BST and mobile units. The BS is also responsible for administration, call processing, maintenance, handoff, and audio signal compression and decompression as directed by the mobile switching center (MSC). Each BS is controlled by the MSC. The BS is connected to the MSC using voice trunks and data links. The MSC serves

as a central coordinator and controller for the cellular system and is also an interface between the wireless and wired infrastructure. The MSC is connected to the Public Switched Telephone Network (PSTN) using voice trunks and data links. The MSC can be considered the same as a landline-switching center in the central office (CO) with the enhanced capability to track each mobile unit. A system identification number (SID) is used to identify whether a person is roaming or in the home (home SID) area. If a person makes a call within the home area, then the MSC serving the call is considered the home MSC. If the person is roaming outside the home area, then the MSC serving the call is known as the serving MSC. In that case, the SID of the MSC is known as serving SID.

In addition, there are Home Location Register (HLR) and Visiting Location Register (VLR) databases owned and maintained by the service providers that keep track of subscriber's information. In this way, the mobile users can get on the Internet using technologies, such as Wideband Code Division Multiple Access (WCDMA), which is usually referred to as 3G.

The fourth-generation (4G) cellular services intend to provide mobile data rates of 100Mbps or more. This 4G is an entirely packet-switched network that all network elements are digital with higher bandwidths to provide multimedia services at lower cost. In 4G mobile IP, each cell phone is assigned a permanent "home" IP address, along with a "care-of" address that represents its actual location. When a computer somewhere on the Internet wants to communicate with the cell phone, it first sends a packet to the phone's home address. A directory server on the home network forwards this to the care-of address via a tunnel, as in regular mobile IP. The directory server also sends a message to the computer informing it of the correct care-of address, so future packets can be sent directly. This should enable TCP sessions and HTTP downloads to keep going as users move between different types of networks. The ultimate 4G would be full on-demand capability, Wi-Fi to WAN roaming, and have it as a true IP network. Currently, the Japanese government required all of Japan's ISPs to support IPv6 by 2006, to coincide with the launch of 4G. Countries in Europe and Asia are considering similar regulatory action. NTT DoCoMo (provides i-mode service) also hopes that true mobile broadband will enable them to replace fixed access entirely, and they plan to have a 4G system operational by 2006.

### 3. DEFINING MOBILE MARKET VALUE

Whenever a technological innovation is introduced, it brings both new business opportunities and new challenges to enterprises. As the global economy shifts toward the mobile economy, enterprises need to be progressively more flexible and globalize. The mobile business strategies will focus on what "value" might be created for the enterprises in the marketplace.

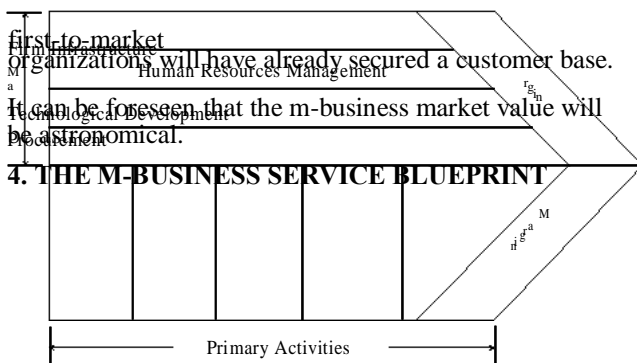

Figure 2 Porter's Value Chain

To gain competitiveness and create values, the enterprise should target on redesigning their core business processes in response to key competitive factors. These competitive factors can be derived from the Porter's value chain [3]. The value chain divides the organization into a set of generic functional areas, which can be further divided into a series of value activities. In the value chain, there are two distinct types of functional area: primary and support (Figure 2). Primary activities are concerned with the direct flow of production (such as inbound logistics, operations, outbound logistics, marketing, sales, and service), whereas support activities (firm infrastructure, human resource management, technology, and procurement) support the primary activities and each other. Starting with its generic value chain categories, a firm can subdivide into discrete activities, categorizing those activities that contribute best to its competitive advantage. Porter's version of supply chain management is called a value chain because it focuses on value. The value is measured by the amount customers are willing to pay for an organization's product or service. Primary and support activities are called value activities, and an enterprise will be profitable as long as it creates more value than the cost of performing its value activities [4]. In this way, a value chain is defined and a better organizational structure and business process can be created around those value activities that can most improve an organization's competitive advantage [5].

Porter also recognized linkages outside the enterprise, as they relate to the customer's perception of value. This provides the possibility that one value chain could be linked to another value chain, because one business partner could be the other's customer. This interconnected value chain system can act as a supply chain that encompasses the modern business world, and participating organizations can readily extend their technologies to their partners. The "extended enterprise" aspect enables supply chain integration, more effective outsourcing, and self-service solutions for both internal and external stakeholders [5]. The usefulness of the mobile channels will be largely driven by new enterprise applications that enhance the overall customer values. A business that creates m-business applications can benefit from the first-to-market advantage. As the wireless Internet continues to expand,

As mentioned before, seeing m-business processes in terms of a net value added chain is also an approach for visualizing current and identifying future competitive advantages. In short, the creation of these values depends on the enterprise's ability to link and coordinate these internal/external activities efficiently [3]. This

interconnected value chain system can act like a supply chain that encompass the modern business world, and participating organizations can readily extend their technologies to their partners. The m-business supply chain practices are just like e-business supply chain practices with the exception of mobility. This is a more real picture about business, because business opportunities occur in anywhere at anytime.

With the convergence of B2B, B2C, SCM, CRM, ERP, Business Intelligence, and real-time relationship management, the personalization of customer information is now possible. The IP convergence strategy will provide a solution that joins the two worlds of voice communications (telephony) and data traffic together. Technologies, such as interactive voice response (IVR), computer telephony integration (CTI), are beneficial to selling chain management. The fully interactive nature of the Internet changes everything in the world of self-service. The blending of Sales Force Automation (SFA) with customer self-service brings new business opportunities. Relevant information and intelligence support processes all can be aligned and implemented in real-time at anywhere. The application and technological framework of m-business to facilitate

these highly interactive communications will be illustrated in the following section. This framework extends existing business applications such as ERP, CRM, and mobile workforce applications to wireless devices.

## 5. THE M-BUSINESS SYSTEM ARCHITECTURE

In today's m-business, competing for mobility requires either aligning one's strategy to what the enterprise agility or developing mobile computing capabilities to support a desired supply chain strategy. Mobile business systems must to address the strategic visions of enterprise. A successful mobile business application framework for enterprises should link supply chain management, relationship management, and knowledge management to function in an adaptive way and continue to thrive in the m-business era. The design of a m-business system needs to focus on collaboration. In the m-business system architecture, several dedicated servers and databases are required, because enterprise must capture and retain in a central/distributed data repository the data and information that employees need (Figure 3).

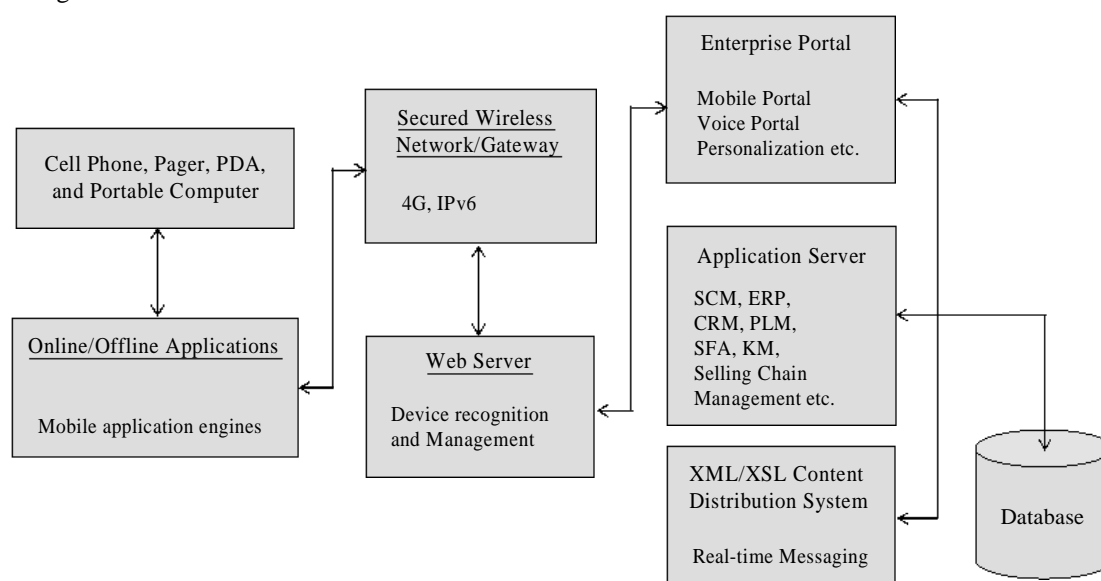

Figure 3 M-Business Application Framework

A selling chain management suite for customer care applications enables new kinds of interactions, new kinds of information, and comprehensive access to all customers and enterprise portals. This customer care can foster joint problem-solving, and convenient self-service. Given the information customers need in the purchasing process. The reasons to stress on 4G and include in this framework are (a) it has wider bandwidths, higher bit rates, (b) it support interactive multimedia services, teleconferencing, wireless Internet, etc., and (c) the global mobility and service portability. For knowledge

management issues, the architecture of IT in the knowledge management system is concerned with organizing and analyzing information in an enterprise's database so this knowledge can be readily available throughout an enterprise. A central/distributed data repository that provides/captures the data and information for employees and executive decision-making is also very important in a knowledge management system. The database system is the driver that consolidates and directs the overall resources of the supply chain to the most mission-critical business

activities. As a result, an m-business supply chain solution must provide supports for the capture and communication of customer demand, as well as enable this demand to automatically trigger business events and initiate process workflow. Transcoding contents and developing enterprise applications to work across several mobile devices and browsers seem to be a complex problem. The key is to focus on the lowest common denominator: the XML (eXtensible Markup Language) and XSL(eXtensible Style sheet Language). The XML supports for developing mobile applications running on multiple devices and platforms [6]. Databases are also working with XML-structured data and tabular relational data. The ability to translate standard HTML/XML content into the various flavors of wireless content is based on the way that the XML/XSL standards operate. Because of these standards, XML is able to function as a meta language, flexible enough to recreate other markup languages and use them as subsets. Technologies such as Java Server Pages (JSP) and Active Server Pages (ASP) are also being extended to support multimode clients. Figure 4 and Figure 5 illustrate some examples of transcoding systems and applications. Enterprises that provide HTML to wireless transcoding solutions translate standard content into XML that reflects all of the information flow and logic of the transcoded content, and by browser detection determines for each mobile user which subset of XML to translate content into [7]. Thus we see that a robust and active transcoding system goes a long way toward reducing complexity and maintaining consistency throughout the enterprise across multiple clients. Effective m-business supply chain solution will need to deliver an accurate and common view of customer demand data as well as any subsequent events, plans, or other business data. This new supply chain framework will offer virtually unlimited business opportunities in the alignment of technologies and processes. A well-designed and well-integrated supply chain for m-business will improve upon existing cost-responsive processes, and have organizational agility in the event of change.

## 6. CONCLUSION

The emerging mobile technologies with Internet capabilities that connect numerous devices and information portals represent a new phase in enabling intelligent mobile workforces. Multi-channel and multi-technology strategies represent the next frontier. Mobile business addresses new customer channels and integration challenges. Being the central platform for mobile applications, the next generation Internet must provide an infrastructure that allows data transfer to be fast and more cost-efficient. The mobile Internet will open an important new channel for commerce. With mobile technologies, enterprise applications will go beyond the four walls of organizations to a workforce on the move. Employees will be able to access the company's mission-critical enterprise applications, such

as enterprise resource planning (ERP), customer relationship management (CRM), and supply chain management (SCM). This open enterprise is also extended to suppliers and trading partners so that when customers get in contact with the resources of an enterprise, they also touch upon the resources of the value chain. The usefulness of the mobile channel will be largely driven by these enterprise applications that enhance the overall customer values. With self-service applications in hand, customers will be able to touch the resource of an enterprise. It is the customers who drive the entire value chain (or supply chain), determining what is to be produced, when, and at what price. They will be able to interact with the entire business ecosystem and not just individual enterprise.

Content in XML can use XSL style sheets to dynamically render the content into:

- HTML for Desktop and PDA
- HDML or WML for mobile devices
- Specific XML for B-to-B

tjycwang@vip.sina.com

### ABSTRACT

The "mobile e-business" is a business activity derived out by the concept of the "e-business", which can finish the specific commercial service function through mobile devices, such as cell-phone, PDA, etc, with the marketing purpose of achieving products and service. Mobile e-business is gradually known by kinds of enterprises, and successively put into practice among them. This paper sets out from analyzing the prospect of mobile e-business and current situation of small and medium-sized enterprise of our country, proposes the technology, implementation means, mode of the mobile e-business for the small and medium-sized enterprise, and compared with the application mode of the large-scale company with its one's own characteristic.

**Keywords:** the mobile e-business, the small and medium-sized enterprise, implements, mode

### 1. THE PROSPECT OF THE MOBILE E-BUSINESS

As far back as 2000, the mobile e-business once becomes the focus that everybody looks forward to it. A global investigation indicates, saying 61% of those who are investigated all have their heart filled with hopes: in the near future, they can regard the wireless device as an ordinary payment tool. Analysts who engaged in this investigation predict the mobile commercial market can reach 100 billion dollars in the whole world in 2003. Though the present situation is not optimistic, the rapid development of the mobile e-business need not be queried<sup>[1]</sup>.

According to the news of "net of PC World", a market survey report of Frost&Sullivan's company shows that, Because of the emerge of a large amount of portable equipment such as cellular telephone, PDA, etc, the mobile e-business after more than two years quiet, will develop at a full speed over the next several years. It is predicted, the market of mobile e-business will reach 25 billion dollars by 2006, which share will account for about 15% of the global online trade market.

Nearly there are 250 million cellular telephone users at present in China, and added about 4 million pre month; the market penetrance is 15%, which is relatively at low levels. It proves that a sizable potentials market still remain to be explored. It is estimated that by 2010, the cellular telephone will exceeds 540 million users, the popularity will reach 40%; In 2002, the value-added telecom service "short message" created over 30 billion. During the Spring Festival of 2003, the user of China Unicom and China Mobile delivers 7 billion pieces of SMS news altogether<sup>[2]</sup>.

Therefore, to develop the mobile e-business, expand the products and service in the mobile field that the

enterprise utilized, raising the income based on mobile service, is a piece of forward position for the enterprise's development, which will bring the enormous profit space for the enterprise.

### 2. THE NECESSITY THAT THE SMALLAND MEDIUM-SIZED ENTERPRISE DEVELOPS THE E-BUSINESS

Headings are numbered and capitalized. All major headings are centered in bold in 10 fonts. Do not put a period after the text of the heading. Leave one line above a major heading, and one line clear below before the start of the next paragraph or second-level heading.

As the elementary cell of national economy, the quantity small and medium-sized enterprise in our country exceeds 99% of all the enterprises, Small and medium-sized industrial enterprise account the 60% of total gross output value, the sales income accounts for 57% of total value. So, to some extent, the level of the informationization of small and medium-sized enterprise has reflected the current situation of the informationization of enterprise in China. Their demand for informationization represents an important respect of information-based market demand of Chinese enterprise too<sup>[3]</sup>.

Seen from resource of the hardware, CCID investigation has shown, in the enterprise of our country, the having rates of the desktop, printer are nearly 100%, and the having rate of the server exceeds 50% too. According to the statistics of New network ChinaDNS, now, the enterprise which participates in the e-business is only 22.3%, and among them, the incidence of net inquiring reaches 72.9%, issuing the information on the net reaches 71.4%, which are relatively high, but it isn't universally applied in supplying chain integrating, net paying, distribution channel, etc. Among them, Web

sites which have online-paying system are less than 1/3, and web sites which carry on e-business are 1/7.

According to a large amount of data above, the Informationization level of the small and medium-sized enterprise of our country remains to be strengthen, The level that the enterprise uses the e-business still needs to be improved further. The enterprise utilizes the advanced means of mobile network, extend the concept of the e-business to all kinds of terminal stations, which will make enterprise as closer to customers as possible, make the customers know the enterprise and its products, make the enterprise be in the front row throughout in the fierce market competition, be keeping vigorous.

### 3. THE APPLICATION KINDS OF THE MOBILE BUSINESS

At present, the enterprise implementing the mobile e-business is to carry on the commercial activity on the basis of mobile device which the user already adopted generally. According to large amount of data of cell-phone application and other mobile devices which are developing and popular, we can fulfill the mobile e-business on the basis of following several kinds of popular technology:

#### 3.1 WAP

WAP is one of the key technologies of developing the mobile e-business. Through WAP, the cell-phone can conveniently and swiftly insert Internet whenever and wherever possible, really realizing the mobile e-business not restrained by time and region. WAP is a kind of communication protocol, it offers a set of open, unified technological platforms, the user can visit and obtain Internet or network information and various kinds of services inside the enterprise expressed with unified content very relaxed while using mobile devices. It defines one a suit of the interfaces of software and hardware. People can use cellular telephone receive and dispatch E-mail and surf Internet as using their computer. Besides, WAP has offered a kind of applicative development and running environment and it also support the most popular embedded operating system at present.

WAP can support the most wireless devices used at present, on the transmitting network, WAP support kinds of mobile networks now, for instance GSMs, CDMA, PHSS, etc. It also support the coming third generation of mobile communication systems. Now, many telecommunications companies have put out many kinds of WAP products already, including WAP gateway, instruments for applicative development and WAP cell-phone which offer the users the services such as online information, ticket ordering, mobile bank, games, shopping and so on.

#### 3.2 GPRS

GPRS break through GSM offer thinking that circuit

exchange fix type by network, divide into groups and exchange mode introduce and get GSM network. It through increasing corresponding function entity and stand and go on transformations come and realize and divide into groups and exchange systematically to existing base only, Thus improve the utilization ratio of resources. GPRS set up and join fast, suitable for and convey little data quantity businesses or convey heavy data quantity businesses frequently. GPRS technology can offer the speed of data which is up to 115 Kbit/secs for moving the user, because GPRS exchanges because of dividing into groups, so users can keep the online forever.

#### 3.3 The close quarter transmitting technology

Close quarter transmit technology that we say, mainly means infrared transmitting technology, "Bluetooth"(Bluetooth), 802.11, RFID (Frequency Identification of Radio) and remote control, etc. But relatively successful ones at present are the infrared ray technology and Bluetooth technology. Infrared ray, Bluetooth, compare to 802.11 technologies have some advantages: low costs, extensively use on the terminal stations like cell-phone, etc., correctly transmitting which reduces the danger of intercepting information, and it is difficult to be interfered by the external world in addition<sup>[4]</sup>. Because of seeing the market prospects, Visa International, KDDI, UC Card, Toyota Finance to test the infrared ray payment business.

"Bluetooth" is as another kind of communication technology which is low cost, low power, small circle. It can make the equipment carry on communication in the short distance without the line cable. For example, we can use the cellular telephone to pay in front of the dispenser. It is the key technology of realizing the wireless electronic wallet. "Bluetooth" supports 64 kb/s transition and data transmission, whose transition distance is 10 - 100 ms with the network principle of "the principal and subordinate network".

#### 3.4 other developing Technology

At present, the movable IP technology and the moving localization systematic technology grow vigorously, especially the moving localization system. It can offer the business based on position, for instance it can offer the information, such as local news, weather and hotel, etc. to the tourist and company staff who going out to handle official business. This technology will bring the enormous opportunity for the development of tourist industry, retail business, entertainments and catering trade, etc.

### 4. IMPLEMENTATION MODE AND THE WAY OF THE MOBILE E-BUSINESS

Because of its own characteristic, there will be very different for the small and medium-sized enterprise

using the technology of mobile e-business to realize the mobile operation when compared to the large-scale enterprise.

First of all, on the inputting of the hardware, large-scale enterprises has much fund to buy the large-scale SP platform, the hardware such as equipment of server that can offer mobile service, while it is impossible for small and medium-sized enterprise. But they have their own advantages: setting up one's own hardware system offering mobile service, conditionally choosing one or several ordinary servers, making which to be the special-purpose server with GSM, GPRS communication equipment offering mobile service again. It can save the enormous expenses which buys SP's platform, In addition, several small and medium-sized enterprises can buy a SP platform together. So long as they add their distinguishing codes, they can realize one's own business when the system running; Or they can rent SP's platform to test or expand the mobile business of the company, Thus in case of achieving the goal of using mobile service, the input and the cost are reduced.

Secondly, on the development of the mobile business, the large-scale company can organize its own specialized development group to carry on the technological development., while the small and medium-sized enterprise can set up the software system which suit one's own scale of company by buying the shaping software the developed interface and module to carry on the secondary development through the software company. Compared with systems of the large-scale company, this method has the characteristic with low cost, high flexibility, spread the operation advantages and gain the customer quickly.

The third, on commercial operation, because of the scale, the large-scale company will put into a lot of manpower, material resources, and carry on advertising to run and maintain it. Because the systems of small and medium-sized enterprise are based on jointly, rented SP platform and ordinary servers, the expenses of running and maintaining are relatively low. When offering the service, the flexibility should be stronger than that in the large-scale company, However, at the same time, small and medium-sized enterprise can apply the system to handle the daily official business reliably to in itself, which realize purpose on "one a suit of systems plant and use more" raising the systematic frequency of utilization to the maximum extent to improve the efficiency of market expanding and inside management of the enterprise.

The fourth, on proportion between inputting and outputting, because of the large input on the mobile business, large-scale companies have to obtain the income from heavy popularity which forming a large scale. Small and medium-sized enterprise has high flexibilities for investing less. If it offers the suitable services meeting the user's needs, it will get good income even it is small. Though this kind of income may be lower than incomes of the large-scale company, it is relatively considerable to its input.

## 5. THE SUMMARY

The development of the mobile e-business is a inexorable trend, though it experiences the twist and turn. How to seize the opportunity and how to open up a suitable soil to grow up for the small and medium-sized enterprise in our country is the key to be strong. According to the existed mobile application level, there are 4~5 kinds of relatively ripen technology which can be used into the real mobile e-business business. The question while the small and medium-sized enterprise taking the road to mobile e-business must be noticed are as the following: to summarize the characteristic and advantage of small and medium-sized enterprise, to take different strategy from the large-scale enterprise, to draw the successful experiences of the mobile e-businesses from domestic and international case, to pay attention to the flexibility of mode and implement, to reduce the cost of investment and accelerate to obtain incomes.

## ABSTRACT

Mobile commerce is heading for advanced fourth generation (4G) mobile systems. However, rapid development of ubiquitous computing technology can implement and complement the 4G mobile systems. It enables anticipation that ubiquitous computing technology creates the new commerce, so called ubiquitous commerce. This paper analyzes the characteristics of mobile commerce service and ubiquitous computing service, and then extracts the core requirements for ubiquitous commerce. Moreover, this paper suggests technical requirements for the ubiquitous commerce. These requirements can lead the development of technology for the future and suggest the milestone that mobile commerce in present heads for.

**Keywords :** Mobile Commerce, Ubiquitous Computing Technology, Ubiquitous Commerce

## 1. INTRODUCTION

In the past few years, by technology advance, especially Information technology, mobile commerce has been marked as a new paradigm that is the next stage after electronic commerce and electronic business. However, appearing of new technology and increasing of customer needs promote development of highly advanced technology, and it presignifies another revolutionary paradigm shift. In this situation, it is valuable work that prospects the future about mobile commerce.

Generally, mobile commerce and mobile business are used reciprocally and mobile commerce is defined as any transaction with a monetary value - either direct or indirect - that is conducted over a wireless telecommunication network[3,19]. Mobile commerce is continuously prevailing and its market size is magnifying daily. Industry forecast statistics predict exponential growth in this sector

- International wireless data market is expected grow from 170 million to more than 1.3 billion subscribers between 2000-2004, equipping themselves with 1.5 billion wireless-capable handsets and other internet appliances by end 2004  
(Source : Cahners Instat Group)
- Wireless internet users in the Asia-Pacific region alone will rise ten-fold from 20 to 216.3 million between 2000-2007 (Source : Strategis Group)

Growth of market and increase of customer needs lead the technological advance, and it accelerates translation of fourth generation(4G) mobile systems from third generation(3G) mobile systems[5,23]. 4G mobile systems are project to solve still-remaining problems of 3G systems as to the perspectives of network and device, these technologies share common characteristics with

ubiquitous computing technology that has been rapidly developing recently[6,9]. Furthermore, ubiquitous computing technology aims at highly advanced technology surpassing the existing mobile commerce technology[4]. It enables anticipation that ubiquitous computing technology not only evolves the existing mobile commerce but also creates the new commerce. In other words, we can predict new paradigm shift confidently that converts mobile commerce into a new commerce, so called ubiquitous commerce.

Based on this assumption, this paper will extract the essential requirements for ubiquitous commerce in order to progress from existing mobile commerce. So, in section 2, we analyze the characteristics of mobile commerce service and ubiquitous computing service by studying related work. Section 3 shows the essential requirements for ubiquitous commerce and the technical demands for achieving each requirement.

## 2. LITERATURE REVIEW

### 2.1 Characteristics of mobile commerce service

There are many studies on mobile commerce. Table 1 shows the summary of these researches.

<Table 1> Studies of mobile commerce service characteristics

Author	Characteristics
Tsalgatidou And Pitoura (2001)	<b>Terminal</b> : small size keypad and screen, small resources including memory and disk capacity, reliance on the finite energy provided by batteries. (disadvantage) <b>Wireless network</b> : bandwidth restriction

	and network topology, variant bandwidth and burst traffic (disadvantage) <b>Usability</b> :location awareness, adaptivity, ubiquity, personalization, broadcasting (advantage)[19]
<b>Camponove And Pigneur (2003)</b>	<b>Mobility</b> : freedom of movement, ubiquity, localization, reachability, convenience, instant connectivity, personalization (advantage) device limitation, bandwidth limitation, expensive cost (disadvantage) <b>Network effects</b> : positive external effect <b>Exclusive control over important asset</b> : exclusive control over important assets exclusive control of MNO(Mobile Network Operator)[3]
<b>Kim et al. (2003)</b>	<b>Efficiency</b> : instant clearance, mobility, instant reaction <b>Effectiveness</b> : instant satisfaction of demand, usage of location information, personalized service[8]

Analyzing these characteristics synthetically, characteristics of mobile commerce service are derived from not characteristics of commerce itself, but technological features, especially handheld device and wireless network. Therefore, these characteristics can be represented in two criteria, mobility and connectivity, in terms of handheld device and wireless network[13].

Mobility means freedom of movement and is relevant to 'place' concept. In mobility perspective, it brings a number of unique benefits of mobile commerce[3]. Ubiquity is the most obvious advantage of a wireless terminal. A mobile terminal can fulfill the need both for real-time information and for communication anywhere, independent of the user's location[11]. Portability means that user can easily carry around mobile terminals. The smaller and lighter the devices are, the more portable they are[19]. Convenience is an attribute that characterizes a mobile terminal. Devices store data, are always at hand and are increasingly easy to use[11]. On the other hand, connectivity means overcoming of available time limitation and is relevant to 'time' concept. In the view of connectivity, mobile commerce serves instant connectable service. Instant connectivity means that it will be easier and faster to access information on the web anytime[11]. Combinations of mobility and connectivity provide rich characteristics for mobile commerce service. Reachability is important for many people who want to be in touch and be available to other people. With a mobile terminal a user can be contacted anywhere anytime. Localization of services and applications will add significant value to mobile devices. Knowing where the user is physically located at any particular moment will be the key to

offering relevant services that will drive users towards transacting on the network[11].

These characteristics are unique features of mobile commerce service. They are extracted by considering technological perspectives, such as device and network. Table 2 shows the summary of these characteristics.

<Table 2> Characteristics of mobile commerce service

<b>Mobility</b>	<b>Connectivity</b>
<b>Portability</b> Carrying the mobile device easily[19] <b>Ubiquity</b> The possibility of using services anywhere, independent of user's location[11] <b>Convenience</b> Mobile devices are always at hand[11]	<b>Instant connectivity</b> Easy and fast access information on the web anytime[11]
<b>Location awareness</b> User's location information can be exploit to offer location-based relevant services[11] <b>Reachability</b> User can be reached anywhere anytime[11]	

## 2.2 Characteristics of ubiquitous computing service

Mark Weiser stated that the most profound technologies are those that disappear and they weave themselves into the fabric of everyday life until they are indistinguishable from it[4]. Sakamura Ken in Japan emphasized ubiquitous network, and IBM suggested pervasive computing concept corresponding to ubiquitous computing. Like this, characteristics of ubiquitous computing technology are arguable and it's difficult to define the characteristics of ubiquitous computing exactly. However, opinions that ubiquitous computing technology will change not only the existing commerce but also all around environments drastically are converged[4]. At this point of view, such a forecasting becomes a good evidence of possibility that ubiquitous computing technology will evolve the mobile commerce technology and create the new paradigm of commerce. Many researchers predict an advent of new commerce, which is called ubiquitous commerce. Generally, ubiquitous commerce is defined as convergence of electronic commerce and mobile commerce, etc.[6]. The realm of ubiquitous commerce, previously isolated and intentional actions become automatic and even invisible, where commercial interaction in every physical and digital sphere will be ever-present. In a ubiquitous commerce environment, objects are always on, always aware, and always proactive by ubiquitous computing technologies[14].

Since Mark Weiser suggested the characteristics of ubiquitous computing in 1991, many researchers have added and developed the characteristics of ubiquitous commerce services. Yoo et al.(2004) suggested 6 characteristics of ubiquitous commerce service; Embeddedness, Mobility, Nomadicity, Proactiveness, Invisibility and Portability[24]. Table 3 shows these characteristics.

<Table 3> Characteristics of ubiquitous computing service, Yoo et al.(2004)

Characteristics	Description
<b>Embeddedness</b>	small intelligent devices are embedded in the physical world and connected to the fixed and/or wireless network
<b>Mobility</b>	client devices must be operated under the mobile and flexible network infrastructure
<b>Nomadicity</b>	the system provides a rich set of computing and communication capabilities and services to nomads as they move from place to place in a way that is transparent, integrated, convenient, and adaptive
<b>Proactiveness</b>	the system needs to be self-triggered to capture a priori what its users want to increase the service quality
<b>Invisibility</b>	to be as unobtrusive as possible, enable the user to put as little data as possible
<b>Portability</b>	providing services with hands-free or at least one-handed light device

### 2.3 Technical approach of 4G mobile systems and ubiquitous computing technology

As we have referred before, mobile commerce aims at fourth generation(4G) mobile systems[5,23]. Generally, 4G mobile systems should provide various multimedia services, ubiquitous services and extended service through seamless global roaming[7]. According to ITU-R WP8F's vision and objective of 4G, 4G mobile systems have characteristics of ubiquitous & seamless connection, high data rate, openness, and network convergence. 4G mobile systems have to solve these problems concretely [5,7].

- Average 200 Mbps high data rate
- More 10 times increasing capacity than 3G
- 3~6 GHz broad bandwidth
- QoS problem

#### •Mobility management

Table 4 shows hot technology issues to solve existing problems of 3G mobile systems.

<Table 4> Core technology for 4G mobile systems

Technologies	Description
<b>MIMO (Multi-Input, Multi-Output)</b>	<ul style="list-style-type: none"> <li>- Both the transmitter and receiver use multiple antenna elements, or antenna arrays</li> <li>- Help mitigate channel impairments and help reduce interference, thus yielding better error rate performance to support an increased number of users</li> </ul>
<b>UWB (Ultra Wide Band)</b>	<ul style="list-style-type: none"> <li>- Transmit and receive over a wide range of frequencies supporting a variety of radio standards used around the world</li> <li>- Can be used in a broad array of applications ranging from voice and data communication to high - performance radar systems</li> </ul>
<b>SDR (Software Defined Radio)</b>	<ul style="list-style-type: none"> <li>- Performed by software residing in high-speed digital processors</li> <li>- The radios can consequently be easily reprogrammed to transmit and receive over a wide range of frequencies supporting a variety of radio standards used around the world</li> </ul>

Ubiquitous computing technology can solve and complement these problems that 4G mobile systems pursue. Table 5 shows element technology of ubiquitous computing.

<Table 5> Technology classification table of ubiquitous network project in Japan

Technical type	Technology
<b>Ubiquitous system technology</b>	Flexible personalized system tech. Mobility control tech. Advanced location awareness tech. Profile portability tech. Advanced sensing system tech. Data-grid tech. Ubiquitous address operation management system tech. Architecture tech. Real-time OS tech.
<b>Network technology</b>	Seamless network access tech. Photonic network tech. Full IPv6 network tech. High capacity wireless tech. Zero administration tech. Network QoS tech. Distributed network tech.

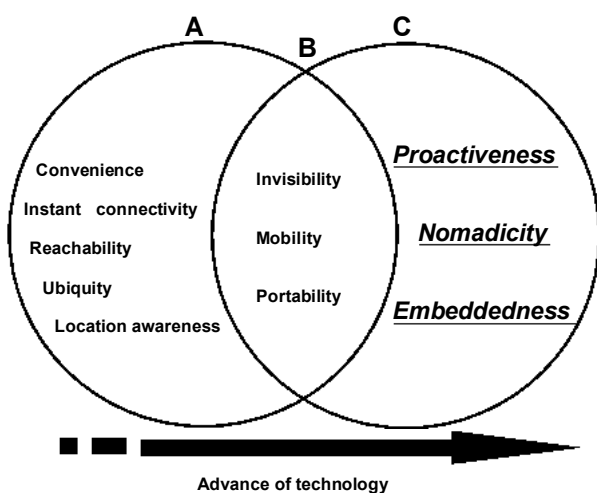

<b>Application technology</b>	Intelligent contents tech. Transcoding tech. U-agent tech. Optimistic and inference engine tech.
<b>Appliance technology</b>	MEMS Advanced electric power tech. Micro interface tech.
<b>Platform technology</b>	IC card certification tech. Personal certification tech. DRM tech. Optimistic security system tech.

### 3. ESSENTIAL REQUIREMENT FOR UBIQUITOUS COMMERCE

#### 3.1 Technical relativity

Considering the aims of 4G mobile systems and the technology of ubiquitous computing, Ubiquitous computing technology can not only solve the limitation of 3G mobile systems but also includes core technology for 4G mobile systems. For example data rate and capacity problems can be solved by network technology of ubiquitous computing. Additionally, fatal limitation of mobile commerce, especially small keypad and screen or computing capacity, can be overcome by using platform and appliance technology. Moreover, the core technologies for 4G mobile systems, such as MIMO, UWB and SDR, are included in ubiquitous computing technology ; ubiquitous system technology, network technology and application technology.

Then, what is the requirements for ubiquitous commerce? We can extract these requirements by comparing characteristics of mobile commerce service and ubiquitous commerce service. Figure 1 shows relativity of each characteristics.

<Figure 1> Ubiquitous commerce requirements diagram

Part A is the characteristics of mobile commerce service only. These characteristics are already developed. Part B is the shared-region of mobile and ubiquitous commerce and these characteristics are under development. Part C is the unique region of ubiquitous service only. This region is not developed yet and is an important part we have to focus on. Therefore, elements in part C become essential requirements for ubiquitous commerce.

#### 3.2 Nomadicity

Nomadicity means advanced network technology. The system needs to provide a rich set of computing and communication capabilities and services to nomads as they move from place to place in a way that is transparent, integrated, convenient and adaptive[24]. To accomplish this requirement, following technical demands must be developed.

##### •Ubiquitous system technology

Real-time O/S technology, Mobility control technology, Advanced location awareness technology

##### •Network technology

Seamless network access technology, Full IPv6 network technology, Network QoS technology

#### 3.3 Embeddedness

Small intelligent devices are embedded in the physical world and connected to the fixed and/or wireless network[24]. In other words, small device disappeared and user can be freed from the device. Embeddedness can create new business model. Health care toilet of Matsushita Electric Industrial Co. in Japan is a good example. Following technical demands must be developed.

&lt;Table 6&gt; Technical demands of each requirement

	Nomadicity	Embeddedness	Proactiveness
Ubiquitous system technology	Real-time O/S tech. Mobility control tech. Advanced location awareness tech.	Advanced sensing system tech.	Advanced sensing system tech.
Network technology	Seamless network access tech. Full IPv6 network tech. Network QoS tech.		Network QoS tech.
Application technology			U-agent tech. Optimistic inference engine tech.
Appliance technology		MEMS Advanced electric power tech.	Micro interface tech.

#### •Ubiquitous system technology

Micro sensing system technology

#### •Appliance technology

MEMS(Micro Electro Mechanical System),  
Advanced electric power technology

### 3.4 Proactiveness

The system needs to be self-triggered to capture a priori what its users want to increase the service quality[24]. Proactiveness has the same meaning as context awareness. Context is defined as any information that can be used to characterize the situation of an entity[16]. Context awareness is a very important concept of ubiquitous computing. Without context awareness, there's no ubiquitous commerce[15]. Yoo et al.(2004) emphasized the importance of context awareness[24]. Proactiveness needs mixed-application of various advanced technology because of technical complexity.

#### •Ubiquitous system technology

Advanced sensing system technology

#### •Network technology

Network QoS technology

#### •Appliance technology

Micro interface technology

#### •Application technology

U-agent technology, Optimistic and inference engine technology

### 4. CONCLUSION AND FUTUREWORK

In present, mobile commerce is heading for advanced 4G mobile systems. But specific technical element of 4G mobile systems can be implemented and complemented by ubiquitous computing technology that is under development. Furthermore, ubiquitous computing technology will create new paradigm of commerce, so called ubiquitous commerce. Based on this assumption, this paper analyzed the characteristics of mobile commerce service and ubiquitous commerce service and extracted the requirements for ubiquitous commerce, which are Embeddedness, Nomadicity and Proactiveness. Finally, we suggested core technical demands.

This paper depends on uncertain future technology heavily. This is a fatal limitation of this paper. Therefore, we must study more cases of mobile commerce and ubiquitous computing technology, and for credibility of the requirements, there is a need to carry out case study and apply reliable methodology such as survey and factor analysis. In spite of this limitation, requirements extracted in this paper can suggest milestone that existing mobile commerce goes for, and we can expect the development of technology.

## User-Centered Guidelines for Design of Mobile Applications

Xiaowen Fang, Susy Chan, Jacek Brzezinski, Shuang Xu, Jean Lam

School of Computer Science, Telecommunications, and Information Systems, DePaul University,  
243 South Wabash Avenue, Chicago, IL 60604, USA  
{xfang, schan, jbrzezinski, sxu}@cti.depaul.edu, jeanlam@us.ibm.com

### ABSTRACT

In this study, interviews were conducted to derive user-centered guidelines for the interface design of mobile applications. These guidelines cover general design issues in input, display, navigation, and feedback. They address five out of seven elements that describe effective mobile commerce interface design proposed by Lee and Benbasat [7]. Compared to guidelines obtained in prior studies, the guidelines derived from this study are user-centered and can be applied to multiple form factors. The comparison between e-commerce and mobile commerce design guidelines suggests that the mobile context plays the most important role in designing mobile commerce interfaces.

**Keywords:** mobile commerce, design guidelines, usability, human-computer interaction

### 1. INTRODUCTION

The convergence of mobile Internet and wireless communication technology has promised users anytime, anywhere access to information for work and personal communications. However, many technology constraints such as small screen size hinder such access through a mobile device. In order to provide truly ubiquitous access to information, design guidelines addressing potential usability problems on mobile devices are essential.

Usability studies on mobile applications have focused on addressing the interface design constraints imposed by a bandwidth limitation and small screen size of handheld devices. Along this line, researchers have proposed several design guidelines for Wireless Application Protocol (WAP) phone applications. Ramsay and Nielsen [8] suggested that many WAP usability problems echoed problems identified during the early stages of Web site development for desktop computers, and could be alleviated by applying good user interface design. Such design guidelines for WAP applications may include: (1) short links, (2) backward navigation on every card, (3) a minimal level of menu hierarchy, and (4) headlines for each card [5]. Similar design guidelines, validated in a separate usability study of WAP phones [2], include: (1) direct, simple access to focused valuable content, (2) simple hierarchies, (3) reducing the amount of vertical scrolling, and (4) reducing the number of keystrokes. These studies focused solely on WAP phones.

Diverse form factors offer different functionalities and have separate interface requirements. Chan et al. [4] systematically reviewed 10 wireless Web sites – ranging from travel, financial services, retail, news, and Internet portals – across three form factors: wireless Palm, WAP phones, and Pocket PCs. They found that user tasks for the wireless sites were designed with steps similar to the wired e-commerce sites and geared primarily for

experienced users. Many usability problems, such as long downloads and broken connections, information overload, and excessive horizontal and vertical scrolling, are common to all three form factors. Based on this study, interface design flaws are platform independent, but the more limitations are imposed on the form factors, the more acute the design problems become. These researchers recommend eight guidelines: (1) avoid scrolling, (2) use a flat hierarchy, (3) design a navigation system consistent with a regular Web browser, (4) include a back button, (5) provide a history list, (6) provide indication of signal strength, (7) reduce user's memory load, and (8) limit the search scope to improve search efficiency. Furthermore, Chan and Fang [3] indicated that limited bandwidth and multiple form factors posed constraints for user interface design in terms of the amount and format of content presentation, navigation, and site structure.

Lee and Benbasat [7] proposed a reference framework for designing m-commerce interfaces. This framework consists of seven design elements: context, content, community, customization, communication, connection, and commerce. Venkatesh, Ramesh, and Massey [10] assessed usability guidelines for Web and wireless sites and found that ease of use was significantly more important in wireless contexts. Tarasewich [9] has also suggested that context plays an important role in the design of mobile commerce applications. Furthermore, design guidelines and usability methods that work with wired systems do not necessarily work with mobile systems.

However, the design guidelines developed so far have two major shortcomings: 1) Some guidelines may be only applicable to WAP applications; and 2) Some guidelines were derived from expert opinions without real user input. In order to develop user driven design guidelines that are applicable to a broad range of form factors, a study was undertaken as discussed below. In this study, participants were asked to use one of three

types of handheld devices: WAP phone, Palm Pilot, and Pocket PC. Their experience and opinions were elicited through interviews.

## 2. METHOD

A wireless web site that provided the function of making an advising appointment was developed on three platforms: Palm, WAP phone and Pocket PC. Similar to the regular web site of School of Computer Science, Telecommunications and Information Systems at DePaul University, these wireless versions of a desktop application allow students to make advising appointments with faculty members. Fig. 1 shows sample screen shots of this Web site on the three platforms. Thirty-seven students from DePaul University participated in the experiment. A pre-experiment questionnaire was used to collect background information on the participants. Questions were asked regarding their familiarity with the functionality of the regular web site and their experience with WAP phone, Pocket PC, Palm, and other wireless devices. Among these participants, some had used handheld devices before, while others had not. Most of them had used the advising appointment application on the regular web site before the experiment.

**Fig. 1.** Sample screens of the experiment Web sites

Nineteen participants were assigned to perform tasks on Palm, nine participants on WAP phone, and nine participants on Pocket PC. Participants were asked to make appointments with their faculty advisors using the handheld device. While the participant was performing the task, the experimenter sat aside, observed the participant's performance, and took notes about any unusual events such as mistakes, comments, and complaints. Each participant's online activities were also recorded into a log file by a server-side program. Upon completion of the task, each participant answered questions during an exit interview as to what they liked or disliked about using the handheld device and about the appointment application.

During the interview, if the participant used any ambiguous terms, follow-up questions were asked for clarification. Each interview took about 45 minutes. All

interviews were tape-recorded and transcribed. Based on the transcribed comments, we distilled findings that were independent of the advising application through the follow process:

- Useful comments were extracted from the transcripts and rephrased to reflect similar comments based on authors' professional judgment.
- Each new comment was assigned a unique number and marked with its recurring frequency in the participant's commentary.
- A list of comments for each participant was created.
- Another list was constructed to combine comments from all the participants. Similar or identical comments were consolidated and listed as one.
- Comments were further summarized into categories.

From these findings, we derived user-centered design guidelines as discussed below.

## 3. USER-CENTERED DESIGN GUIDELINES

Table 1 presents 18 most important design guidelines derived from this study. These design guidelines address users' concerns from the following four aspects of a mobile application: input, display, navigation, and feedback. Because these design guidelines reflect users' response to mobile applications, the findings could be extremely valuable to developers of mobile applications.

The reference framework for mobile commerce interfaces proposed by Lee and Benbasat [7] was used to analyze these design guidelines. As shown in Table 1, the design guidelines from our study address five of the seven design elements for mobile commerce interface design: context, content, customization, communication, and commerce.

Context captures how Web sites are developed, consisting of functionality and aesthetics [7]. Design guidelines concerning navigation of a wireless Web site address this element. Given the mobile setting, navigation functions must be designed to accommodate the context.

Content focuses on what a site presents, comprising the offering, appeal, multimedia mix, and content type [7]. This study indicates that large amount of graphics is not suitable due to the small screen of handheld devices and security information must be presented.

Customization refers to a site's ability to tailor itself or to be tailored by users [7]. Customization reduces information load by filtering unnecessary information. This is consistent with the results from this study. One of the guidelines states that short and concise information display is preferred.

**Table 1.** User-centered design guidelines for mobile applications

Category	Design Guidelines	Interface Design Elements
Input	<ul style="list-style-type: none"> <li>• Input on handheld devices must be minimized</li> <li>• Graffiti is preferred by users. It is faster but less accurate compared to soft keyboard.</li> </ul>	Communication
Display	<ul style="list-style-type: none"> <li>• Short and concise displays are preferred on handheld devices. A large amount of graphic and audio/video information is not suitable for handheld devices.</li> <li>• Features indicating security protection must be prominent on handheld devices.</li> <li>• Products that do not have to be graphically represented such as books and audio CDs are more suitable for online shopping on handheld devices.</li> <li>• Widely-accepted short names are appropriate for the items in a drop-down menu.</li> </ul>	Content / Customization  Content / Commerce  Commerce  Content
Navigation	<ul style="list-style-type: none"> <li>• Wireless Web sites must be consistent with regular Web sites.</li> <li>• Exit from an application on handheld devices must be visible.</li> <li>• A hierarchical information structure is helpful and preferred.</li> <li>• A history list is important in the navigation process.</li> <li>• Buttons and menus must be presented on the top of a Web page on handheld devices.</li> <li>• Icons with descriptive and accurate labels are preferred.</li> <li>• Hyperlinks and buttons must be prominent.</li> <li>• Scrolling should be avoided if possible. If scrolling cannot be avoided, use “page-up” and “page-down” type scrolling.</li> <li>• Buttons must be clearly separated from each other.</li> <li>• Access to action buttons in a form should not be obscured by scrolling.</li> <li>• Scrolling in a drop-down menu must be avoided. Items in a drop-down menu should be sorted.</li> </ul>	Context
Feedback	<ul style="list-style-type: none"> <li>• For successful submissions or tasks involving multiple steps (pages), confirmation is necessary.</li> </ul>	Communication

Communication is defined as dialogue between sites and users: broadcast, interactive, and hybrid [7]. The design guidelines from our study indicate that during the interaction between sites and users, information input on handheld devices must be minimized and feedback must be provided.

Commerce is concerned with interfaces related to sales of goods and product services [7]. It was found in our study that features indicating security protection must be prominent. It was also found that the so called “low touch” products like books or audio CDs do not require graphic display and are more suitable for online shopping using handheld devices.

Some of the most important findings are further discussed in the following sections.

### 3.1 Text entry

Text entry on the handheld devices is inconvenient due to lack of efficient input methods. About 90% of the participants brought up this issue. The findings of our study suggest:

- Text entry or typing must be minimized. Users don't like to enter long texts regardless of the input methods: graffiti, soft keyboard, or keypad. No matter which input method is used, it usually takes

significantly more effort to type texts on handheld devices than on regular PCs.

- Graffiti is preferred by experienced users because it is faster than soft keyboard. However, it takes users more time to learn graffiti and graffiti is usually less accurate than soft keyboard. Novice users prefer soft keyboard.

### 3.2 Information display

Information overloading and over-crowded screens are the problems most commonly shared by regular Web applications and mobile applications. However, these problems become more severe for mobile applications because of two factors: the small screen size of handheld devices and the user's mobility. Our study has identified the following unique requirements:

- Short and concise output is preferred. To minimize excessive amount of text information, widely-accepted short names can be used in the display.
- In general, users like graphical icons and buttons but a large amount of graphical and audio/video information is not suitable for handheld devices.
- Scrolling should be avoided if possible. Scrolling is significantly more difficult on handheld devices than on PC computers. Horizontal scrolling is more confusing than vertical scrolling.

- Action buttons or links such as “Submit” and “Search” should not be separated from the input text boxes. Due to the small screen, users are often confused by the separation when trying to figure out how to submit the form.
- Products that do not require graphic display such as books and CDs are more suitable for online shopping on handheld devices. For this type of products, users are not concerned about the graphical details, which cannot be displayed clearly on handheld devices.

### 3.3 Security

Security has been a major concern in e-commerce. It becomes an even more sensitive issue for mobile applications due to doubts about the security and reliability of wireless connections. About 40% of the participants of this study expressed their concern regarding security with mobile applications. They frequently mentioned that they were not willing to commit online transactions on a handheld device because they worried about the security and reliability of the wireless connection. For mobile applications that involve any online transaction, security assurance is important.

### 3.3 Tasks

Tasks that can be performed on handheld devices are different from what can be executed on PC computers. As suggested by Anckar and D’Incau [1], mobile applications must address the following five most common mobile values: (1) time-critical needs and arrangement; (2) spontaneous needs and decisions, such as auction, email, and news; (3) entertainment needs; (4) efficiency needs and ambitions; and (5) mobility related needs. In a separate study, Xu, Fang, Chan, and Brzezinski [11] identified five factors contributing to user’s preference of tasks to be performed on handheld devices: perceived usefulness, perceived ease of use, perceived playfulness, complexity, and perceived security. The following users’ responses are consistent with these two studies:

- Users would like to perform tasks that will meet their mobile needs such as sending/receiving emails, and checking flight status.
- Users would like to see an easy and friendly user interface with considerations of all the constraints imposed by handheld devices and mobility.
- Users would like to use handheld devices to entertain themselves in their free time.
- Users would like to perform simple tasks.
- Users are concerned about the security of online transactions.

## 4. DISCUSSION

Usability for regular e-commerce Web sites has received a lot of attention in both academia and industry. In this

section, we will compare design guidelines for e-commerce and mobile commerce and discuss what is most important to mobile commerce users.

Fang and Salvendy [6] conducted a series of interviews to derive customer-driven rules for the design of e-commerce Web sites. Their study captured a broad range of e-commerce Web sites and tasks, and developed the following design guidelines:

- Web page should be clean and not cluttered with text and graphics.
- The width of a page should be less than the width of the browser window to avoid horizontal scrolling.
- Text on the links or buttons should be self-explained and descriptive.
- When linking to another product related Web site, link to the exact product page instead of the homepage of that site.
- Categorize products in a way that is meaningful to regular customers.
- The depth of the categories should be no more than 3.
- Present accurate, consistent, and detailed descriptions of products.
- Provide accurate and full pictures of products.
- Present the size of products in a measurable and comparable way.
- Present the inventory information of a product in the beginning.
- Present products in a table with enough information to make a purchasing decision such as prices and features for easy comparison.
- Present related charges up front and in an accurate way.
- Same products should be presented in the same page, same position.
- Products shouldn’t be removed from the page because of out-of-stock.
- In the shopping cart page, provide a link that directs the customer back to the page he/she left for continuing the shopping.
- Only ask for necessary and meaning information such as name and address. No marketing questions.
- Allow customers to browse the site without logging in.
- Provide a 1-800 number for customers to call.
- Clearly state the return policy in a prominent place.

A comparison between design guidelines for e-commerce sites and mobile commerce sites reveals the following:

- Both e-commerce and mobile commerce sites share some common design guidelines such as avoiding horizontal scrolling and labeling buttons and links clearly.

- Most e-commerce design guidelines are concerned with offering specific and accurate information.
- Most mobile commerce design guidelines are concerned with design constraints imposed by mobile context such as device limitations and user's mobility. Mobile users can only input and view very limited amount of information on handheld devices under mobile conditions. Design of mobile applications must satisfy user's needs and desires.

Findings from the current study are consistent with prior research findings. Mobile context was identified as the most important factor in designing mobile commerce interfaces in two separate studies [9] [10].

## 5. CONCLUSIONS

In this study, user-centered guidelines for design of mobile applications were developed. These guidelines cover general design issues for input, display, navigation, and feedback. They address five out of seven elements for effective mobile commerce interface design proposed by Lee and Benbasat [7]. Compared to guidelines derived from prior studies, these guidelines are user-centered and can be apply to multiple form factors. The comparison between e-commerce and mobile commerce design guidelines suggest that mobile context plays the most important role in designing mobile commerce interfaces. However, more studies are needed in the future to address the technical constraints imposed on interface design for mobile devices.

### ABSTRACT

Mobile commerce is increasingly perceived as a powerful lever to foster growth of local economy and an opportunity to generate revenue. However, both the literature and empirical evidence have revealed that there exist perils hidden in decision-making by mobile commerce advocates. A system dynamics (SD) approach is used in this article to analyze how factors will influence the process of mobile commerce diffusion. In this paper, mobile commerce market formation is studied as a social economic system, which is dynamic and whose states change continuously. The model-building process incorporates a wide variety of sources of knowledge ranging from system thinking, through international marketing and management science, to system dynamics. The resulting simulation models are developed upon the mental models of a group of experts and available information from written documents, web forum, and online workshops. A simulation model is empirically established and simulated for the Chinese market. The model development and related analysis provides a typical example in using system dynamics to understand the process of mobile commerce diffusion and decision-making.

**Keywords:** mobile commerce, electronic commerce, system dynamics, innovation diffusion, simulation, modeling

### 1. INTRODUCTION

The fact that m-commerce is developed and rooted in Western countries makes m-commerce implementations more Western-oriented. Most of the m-commerce services are created to meet the requirements of the pre-existing infrastructures and environments of developed economies. This situation will make developed markets and emerging markets totally different in evaluating the market potential. Is there a generic model that is globally applicable in simulating each of the existing developed or emerging markets? System thinking and system dynamics are relevant methods in achieving this purpose. In order to accurately reflect m-commerce market, it is necessary to put mobile commerce diffusion under system thinking [1-3], in which the mobile commerce market is regarded as a complex system and the relationship between its existing structure and the behavior will be explored in a dynamic situation. Efforts in this area are likely to help entrepreneurs in learning the mobile commerce market and understanding opportunities and pitfalls related to m-commerce decision-making.

In order to explore the mobile commerce market, we developed a system-learning framework. In the real world, there are two categories of mobile commerce markets. One is called the existing mobile commerce market, or similar market like mobile communication market, which already exists in some developed countries. The application of mobile communication service and mobile commerce service in these countries provides important empirical evidence to explore new emerging markets. Another category is the emerging mobile commerce market in developing countries. Because mobile commerce in emerging area is still in its

infancy, the market is in a dynamic state. The structure is still unknown. Large-scale experiments about the system are inevitable if there is no other method available. In fact, any controlled experiments about a countrywide dynamic market may turn out to be expensive and unrealistic. Whereas developing virtual world model to simulate the real world and doing experiments on the computer-based model is more cost effective and operative. As Sterman [4] points out, a virtual world model provides low-cost experimentation for learning complex system without the limitation of time and space. This paper is aimed at introducing the modeling of the virtual world.

System thinking and system dynamics are effective tools to explore the world. Information collected from the real world will be analyzed and synthesized using system thinking [2, 5], system dynamics [6-11] and innovation diffusion theories [12, 13]. Group experts' opinion is solicited to enforce the modeling process. A model is finally developed with main feedback loops and logical and mathematical relationship coupling the key variables. Since the research is still in progress, the empirically developed model will be further tested using the data collected from existing markets. After testing, the model will be applied to other existing and emerging markets.

Our research framework is divided into the four stages: stage 1, analysis of mobile telecommunications industry, management science, control theory, computer simulation and Delphi surveys, aimed to establish theory and to build qualitative System Dynamics (SD) models; stage 2, development of a generic SD simulation model based on the insights from stage 1; stage 3, collection of several secondary data and primary data in existing

market, aimed to calibrate, validate the model developed in the previous stage; stage 4, scenario analysis and corresponding strategy design in any target market.

Up to now, stages 1 to stage 2 have been finished and a SD model has been built. This article aims to outline the findings generated so far from the research. In order to provide a clear outline for the paper, the main critical loop and stock and flow analysis of m-commerce diffusion is initially outlined. Then, modeling analysis is presented. Such an analysis aims to depict the main forces controlling the flow rates associated with local policies and other participants' strategies [5-7]. Finally, the main research findings and implications for further research are summarized.

## 2. MODEL DEVELOPMENT

Mobile commerce diffusion can be considered as a technological innovation. The diffusion and adoption of new ideas and new products often follows S-shaped growth patterns [4]. The problem is to identify what the positive feedback that generate the initial exponential growth of a successful mobile commerce diffusion are and what the negative feedback that limits the growth are and, to what degree, any endogenous or exogenous variables will influence the growth both in magnitude and speed of reaching an equilibrium.

### 2.1 Main Causal Loop and Stock Flow

The system boundary of the research refers to any mobile commerce market covering a geographical country or region, in which a certain number of populations reside. The number of people in the population fluctuates with the variation of net increase rate (birth rate minus death rate), which is controlled by local population policy through adjusting birth rate. In the population pool, a proportion of the population has the Capability to use a mobile terminal (hereafter refers to mobile phone) because their income and knowledge make them eligible to consume the mobile phone service although they may have not taken the service. This part of the population is called capable population. From the capable population, some of them, who have adopted the mobile phone services, are called mobile terminal users. In the emerging mobile commerce market, the 3G licenses are not issued yet (3G refers to the third generation of telecommunication networks). It means up to now there is no actual mobile commerce user but the mobile terminal users are the potential ones. As long as there is a demand from the market, mobile terminal manufacturers will replace ordinary mobile terminals with mobile terminals with mobile commerce capability, over which commerce services will be conducted. Then the mobile terminal users will gradually consume the mobile commerce services and become actual mobile commerce users.

Figures 1 and 2 illustrate the causal loop diagram and stock flow diagram identified for the main system. To visualize it, imagine the whole market system is like a water irrigation system with the population as the source at the top; the flow starts at Potential Capable Population, passing through Potential Mobile Terminal Users, and returns back to Potential Capable Population. The process forms a typical closed causal loop. As illustrated in Figure 1, the Actual Mobile Commerce Users come from Actual Mobile Terminal Users, the Actual Mobile Terminal Users from the Actual Capable Population, and the Actual Capable Population from the population reservoir in the origin. The clockwise closed loop starting from the Potential Capable Population through the Potential Mobile Terminal Users to the Potential Mobile Commerce Users illustrates the evolution, development and formation of mobile commerce diffusion. It is along this critical process that the research starts to explore the system structure and discover the market behavior over time both in the short term and in the long term.

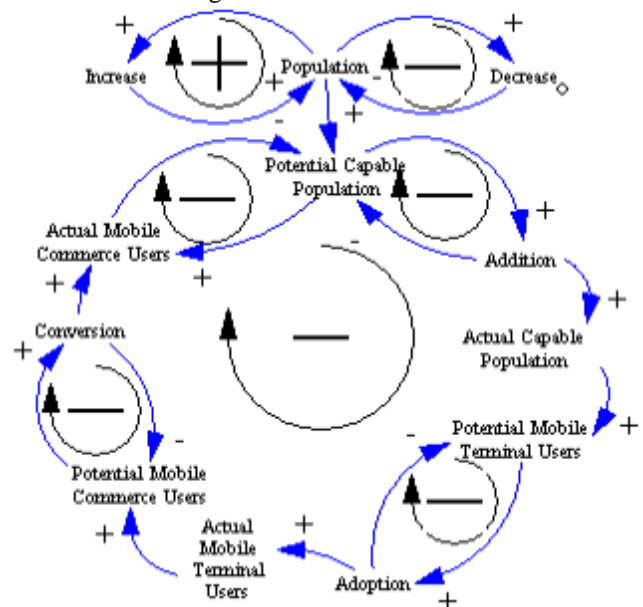

Figure 1 Causal loop diagrams in main system

Figure 2: Stock and flow diagram in main system

The whole system includes one big closed feedback loop and four semi closed feedback loops (excluding the population loop). There are two fundamental loops that

affect the number of Mobile Commerce Users. One is the clockwise loop from the Potential Capable Population through the Potential Mobile Terminal users and the Potential Mobile Commerce Users back to the Potential Capable Population. In this loop, starting from the Potential Capable Population in a clockwise direction, an increase in value of each variable will result in the increase in value of the next variable except that an increase in Actual Mobile Commerce Users will reduce the level of Potential Capable Population. Thus, the loop constitutes a negative loop (in Figure 1, B, short for balancing, is used to denote a negative loop; R, short for reinforcing, is used to indicate a positive loop). Another important loop is the semi loop directly linking the Potential Capable Population and the Actual Mobile Commerce Users. An increase of the Potential Capable Population will increase the value of the Actual Mobile Commerce Users, but, on the contrary, an increase of the Actual Mobile Commerce Users will decrease the value of the Potential Capable Population. This semi loop is also a typical negative loop. The combination of these two fundamental loops determines the state of the Actual Mobile Commerce Users. With these loops combined with variables, a variety of behavior patterns are possible [7]. In this research, the big negative loop, as well as any semi negative loop, generates flows that add to each level downstream to the Actual Mobile Commerce Users and tries to generate goal-seeking behavior. It is the goal and its development that the research tries to seek.

Another important loop (stock) that is the beginning of the main stream at the top of Figures 1 and 2 is related with the population state. The population is normally regarded as an exogenous factor and defined as a constant. In this research, the population is presumably regarded as an endogenous factor because population policy is widely manipulated as a tool to change long-term conditions in most of the populous developing countries. For example, family planning is used as a leverage to control the population birth rate. The population in the system is the only source of the Potential Capable Population, which is the starting point of the flow generated in the main loop, so the fluctuation in the population will inevitably vary the flow in the main loop.

## 2.2. Simulation Model

A generic model, developed using the PowerSim software package, focuses on the adoption and diffusion of mobile commerce service. The factors that influence the change rate in each level are derived from the related theory and experts' opinion. This section examines the assumptions and equations contained in each level. In the future, more field survey will be done and more current data collected to consolidate the robustness of the model. The simulation covers a time span of 50 years and takes each year as time step. Next we will explain how to formulate the relationships among

factors and level and then articulate them logically and mathematically.

### Population development sub model

The first sub model is the population development model. The factors that influence the level of population are shown in Figure 3. Population in the system is increased with the inflow of birth and decreased with the outflow of death and mortality. Fractional Birth Rate and Population determine the amount of Increase. The Fractional Birth Rate is further decided by the fraction of couples who are in the age of first time bearing child but never gave birth to any child before, the age at which the couple can be allowed to bear first child and the number of children that the couple can give birth to during the period of bearing age. Decrease presumably depends on the life expectancy in the country under investigation. The equations adopted in the sub model are listed as follows:

- (1)  $\text{Population} = \text{Increase} - \text{Decrease}$
- (2)  $\text{Increase} = \text{Fractional Birth Rate} \times \text{Population}$
- (3)  $\text{Fractional Birth Rate} = \text{Fraction of First Child Bearing Age Couple} \times \text{First Child Bearing Age} \times \text{Number of Birth for One Couple}$
- (4)  $\text{Decrease} = \text{Population} / \text{Average Lifetime}$

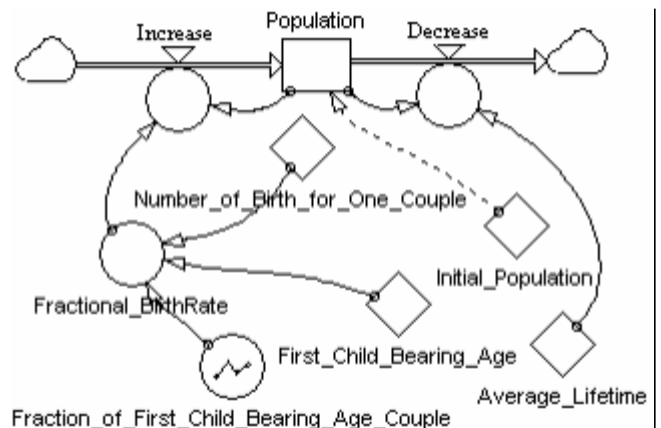

Figure 3: Population development sub model

### Capable population conversion sub model

The second sub model is the model for determining the level of the capable population. The population is classified into two categories. One is the capable population which is an independent economic entity in the society and to whom mobile terminals are useful. Another part is the potential capable population who is a dependent economic entity and to whom a mobile terminal is temporarily useless. For example, young people under eighteen years old are typical potential capable population but not of the actual capable population. When they grow up they become members of the capable population. Elderly people over a certain age are presumably regarded as persons who will never use mobile terminals. Elderly people will be excluded from the initial value of the Capable Population. As depicted in Figure 4, the Historical Birth controls the addition to the Capable Population. After eighteen years,

the addition to the Capable Population is the today's Increase, an 18-year delay of Increase. To simplify our simulation, we choose eighteen year as time span for the first simulation. After the first simulation, we get the data about Increase. After we feedback the data to Historical Addition, we can get another 18 year simulation. As long as the simulation is needed, theoretically, the time span for Historical Addition can extend to any time period. Analyzing the historical birth number of the previous eighteen years and directly drawing a curve between birth and year can determine the addition rate. It is easily realized through lookup functions in the simulation, which allows manually inputting the collected data or directly importing data from other applications.

**Figure 4: Capable population conversion sub model**

### Mobile terminal user addition sub model

The third sub model is the model for determining the level of mobile terminal users, i.e. modeling the addition of mobile terminal users in the mobile terminal market. We assume that personal income influences the addition of mobile terminal users. With the improvement of living standards brought by economy development, more and more people can afford to buy mobile terminals. Every year, a certain number of persons become actual mobile terminal users. In developing countries, there exists a great gap in the economic environment between urban and rural areas, so the addition is assumed to be different under rural and urban contexts. The concept of urbanization is introduced.

**Figure 5: Mobile terminal addition sub model**

As illustrated in Figure 5, Addition is determined by Rural Addition Rate, Urban Addition Rate and Urban Fraction. Urban Fraction is also a dependent variable

that depends on the urbanization pace in the region. The key equations in this level are expressed as follows:

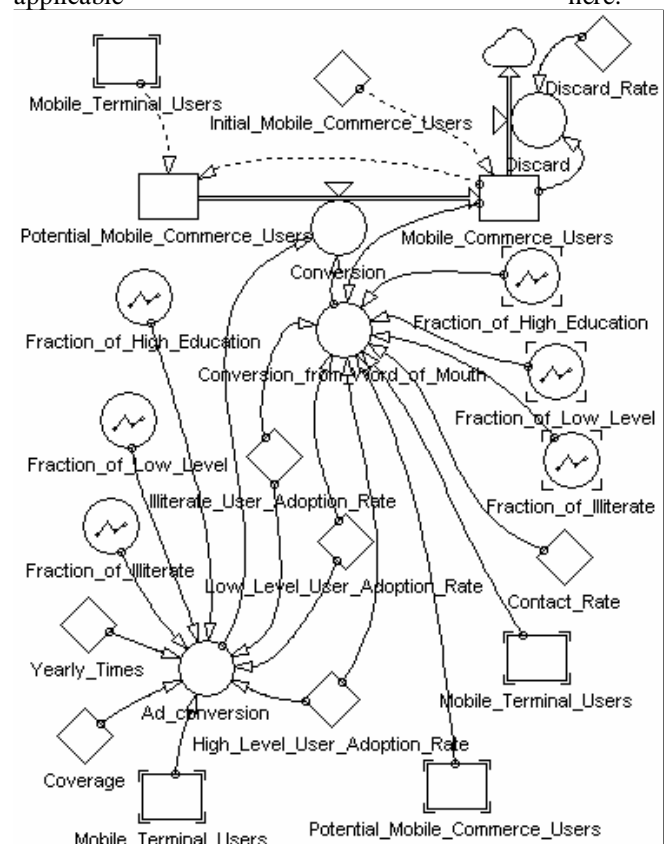

(1) Addition = (Rural Addition Rate x Rural Fraction + Urban Addition Rate x Urban Fraction) x Potential Mobile Terminal Users.

(2) Rural Fraction=1 - Urban Fraction

(3) Urban Fraction=Initial Urban Fraction x (1+Urbanization Rate).

### Mobile commerce user conversion sub model

The final sub model is the model for determining the level of mobile commerce users, i.e. modeling the conversion of mobile commerce users or the diffusion of mobile commerce service in the mobile commerce market. Because mobile commerce service is a technological innovation, Bass diffusion theory [14] is applicable here.

**Figure 6: Mobile commerce user conversion sub model**

The sub model in Figure 6 illustrates the factors that directly affect the conversion. The influences mainly come from the scale and intensity of information disseminations about mobile commerce among target users and the education level of recipients. The information propagation refers to advertising and “word of mouth”. Based on the education level, mobile terminal users are classified in three groups. One is called illiterate who have received no education at all. Another one is defined as low level education users who

have finished the primary or secondary or equivalent education, and the other one is called high level education users who have achieved tertiary or tertiary-above education. Because they have different education background, they take different attitudes toward mobile commerce services. Their attitudes are reflected on their adoption rate.

The equations used in the model are listed as follows:

(1) Conversion = Ad conversion + Conversion from Word of Mouth - Discard

(2) Ad conversion = (Fraction of High Education x High Level User Adoption Rate + Fraction of Low Level x Low Level User Adoption Rate + Fraction of Illiterate x Illiterate User Adoption Rate) x Mobile Terminal Users x Coverage x Yearly Times

(3) Conversion from Word of Mouth = (Fraction of High Education x High Level User Adoption Rate + Fraction of Low Level x Low Level User Adoption Rate + Fraction of Illiterate x Illiterate User Adoption Rate) x Potential Mobile Commerce Users x Mobile Commerce Users/Mobile Terminal Users

(4) Discard = Mobile Commerce Users x Discard Rate

On the aspect of advertisement, the times and coverage area is controlled by mobile commerce providers. Every advertisement covers a certain number of populations, which consists of persons with three different education backgrounds. Advertising will induce a number of potential mobile commerce users to adopt the new service and become an actual mobile commerce user. Each kind of person with specified education background has its own fraction in target population and conversion rate. The total effect from advertisement is calculated using equation (2).

Another aspect is direct contact, also called demonstration effect or "band wagon". The process is visualized as someone in the Potential Mobile Commerce Users group being converted into an Actual Mobile Commerce Users. The two groups of people communicate and make contact with one another. When they make contact, there is some chance that the comments of the person who is a member of the Actual Mobile Commerce Users group will cause the person who is in the Potential Mobile Commerce Users group to adopt the service. The model shown in Figure 6 assumes that for each such contact between a person in the Actual Mobile Commerce Users and a person in the Potential Mobile Commerce Users there will be a number of conversions. This conversion is called conversion from word of mouth. As illustrated in equation (3), the number of conversion in a year will be equal to the sum of contributions from each category of potential mobile commerce users with different educational background. The conversion of each category user is equal to the specified adoption rate times the specified fraction in the Potential Mobile Commerce Users groups, times the product of Actual

Mobile Commerce Users and Potential Mobile Commerce Use, and times the Contact Rate.

Another important outflow in this level is Discard, which is shown in Figure 6 as a sink. Because mobile commerce is still in its infancy, there inevitably exist a lot of issues such as ease of use, security, usability, technological obsolescence etc, which bring discard and reduce the level of actual mobile commerce users. As expressed in equation (4), Discard is the product of discard rate and actual mobile commerce users. In reality, the discard rate may be very high at the beginning of conversion. As time elapses, the discard rate will decrease.

### Mobile commerce diffusion model

The main model can be obtained by articulating the relationships among levels. Population equals potential capable population plus actual capable population. The actual capable population is the sum of potential mobile terminal users and actual mobile terminal users. Actual mobile terminal user involves potential mobile commerce users and actual mobile commerce users. Each level in the upper stream provides information to the next level.

## 3. SIMULATION AND FINDINGS

We collected preliminary data for the Chinese market available from the Chinese Statistics Bureau and the United Nations database. Wherever data was not available, we used common sense to arrive at some reasonable values. The results of a simulation run of a typical scenario with a time span of 50 years are shown in Figure 7 and compared in Figure 8.

The first graph in Figure 7 shows the population level, which grows very fast in the first 10 years. The level then reaches a peak of 1.5 billions after 10 years. Afterwards it starts to decline and eventually drops down to the initial level of 1.3 billions. The second graph shows the capable population level, which grows linearly from the initial amount of 600 millions to 1 billion in 50 years time. The third graph shows the mobile terminal users level which increases from the initial amount of 200 millions to 570 millions. During this period the market of mobile terminal users displays a goal-seeking behavior to reach a goal (arbitrarily set at 570 millions in the simulation run). The fourth graph at the bottom shows the level of conversion of potential mobile commerce users to actual mobile commerce users. This follows a quasi S-shaped pattern. In the first 30 years, the number of actual mobile commerce users will reach a maximum of 200 millions. The whole process will experience three stages. The first stage (market introduction) starts at the beginning of the simulation period and ends where the curve starts to take off. During this phase, which lasts for 15 years, development is slow as the number of actual mobile

commerce users is less than 30 millions. The second stage (market growth) covers the period from the time the exponential development starts to the time it starts to level off. This phase lasts for another 15 years. In this phase, the number of actual mobile commerce users skyrockets from an initial amount of 30 millions to 200 millions at the end. The increase is initially exponential and then changes to a goal-seeking pattern. In the final stage (market maturity), the dynamic market, after booming in stage two, reaches a new equilibrium. The amount of actual mobile commerce users is stabilized and remains at a high level.

Figure 7: Key levels change in the system

Figure 8: Contrast of the key level development in China

#### 4. CONCLUSION

We have proposed a system dynamics model of mobile commerce diffusion and used preliminary data from the Chinese market to perform some simulation runs. Our intention is not to forecast the number of mobile commerce users in the future. Rather, our purpose is to discover the factors that influence the development of mobile commerce and their inter-relationships. This will undoubtedly help in decision-making processes such as exploring the effects of different policies and strategies to achieve certain goals (e.g. a targeted number of users, etc.) under different scenarios. The model is still under development and we need to collect more data from the Chinese market (telephone interview, questionnaire survey, etc.) to improve it. We are also considering conducting a Delphi survey for the purpose of validating the model. Experts will be recruited from China and their feedback on the model sought.

### ABSTRACT

Global economy has formed a huge challenge to the trust of traditional business. It's a important problem of all enterprise how to build a effective trust institution in the new economy. The rapid development of E-business is bringing a turning point of trust institution. In traditional trust institution, trust means that principal controls the agent in fact. The evolution of trust institution was closely related to the development of technology because of control. This paper presents, with the innovation of technology and system, precondition of trust through the method of controlling has already been out of the existence. The development of E-business will have influence on the evolution of trust institution, Advantages of E-business can promote monitor from man-made to market-made, from control to competition. It will build an effectual trust institution.

**Keywords:** trust, control, competition, E-Business, advertising game

### 1. INTRODUCTION

Global economy has formed a huge challenge to the trust of traditional business. It's an important problem of all enterprise how to build an effective trust institution in the new economy. The rapid development of E-business is bringing a turning point of trust institution.

### 2. THE PROBLEM AND CHALLENGE

#### 2.1 The traditional trust

Trust is a definite expectation of other's action (Gambetta, 1988) as well as an active ability that engage oneself to accept the many social institution (Zucker, 1986). Trust is necessary to reduce transaction cost, and help business organizations operate better (Miles & Snow, 1992). Trust becomes a pivotal factor of the thought and philosophy of management (Miles & Greed, 1995). Trust is rooting in three patterns: process based trust, character based trust, and institution based trust (Zucker, 1986). Institution, especial comparability and reciprocal experience decide the trust (Arrow, 1984). Trust was a situation that we relied on others; it meant dependence together with risk. Because calculativeness is ubiquitous (Williamson, 1998), the trust of coming from dependence means that principal controls the agent in fact. Trust is derived from distrust. The premise of trust is the exchange of direct interaction and sensing knowledge. So some scholars think that management is one art of control (Putti & Weihrich & Koontz, 1998).

#### 2.2 Trust and technology

The evolution of trust institution is closely related to the development of technology because of control (Kipnis, 1991). The development of technology is divided into three stages: skills based technology, which corresponding to the era of producing by hand; the routine technology, which corresponding to the era of

producing by machines; informational technology, which corresponding to the era of producing by intelligence (Faunce, 1981). The principal cannot only simply rely on the agent's moral because of the complicated technology. The dependence is more displayed that whether the agent can better deal with the technology, at this moment, the need of agent's skills and moral improved highly. It was more difficult to control than before. Further more the way that technology used make the implied terms of traditional trust out of existing, more and more trades based on multi-region and provisional colony were substituted trades of self-region and steady colony (Kipnis, 1994), codified knowledge which is gradually replacing the sensual knowledge is becoming basis of the trade (Masahiko Aoki, 2001).

### 3. TRUST IN E-BUSINESS: AN ADVERTISING GAME MODEL

Because the traditional trust institution has relied on strong ethical hypothesis, it can be described as a game model. Players have all or part knowledge of the game structure. The trust institution is a common strategy choice of players, and it can be self-enforcing. We will analyze the trust institution by an advertising game model that is reformed by Spence's job market model (Spence, 1974).

#### 3.1 Advertising game model

Because of asymmetric information, bargainors know the quality level of their goods, buyers don't. But the information of quality can be transferred to buyers by advertising. According to Spence-Mirrlees condition (Spence & Mirrlees, 1974), there are different costs of advertising between different quality. The cost of advertising is inverse ratio of quality. The efficiency improvement of different quality is different.

Thinking of a buyer and a bargainer. Quality has two estates: if  $\theta = 1$ , the quality is low, if  $\theta = 2$ , the quality is high. The bargainer is clear of the real value of  $\theta$ , but the knowledge of the buyer is only the probabilities of quality. Let the probability is  $p$ :  $p(\theta = 1) = p(\theta = 2) = 1/2$ . Before contracting, the bargainer will select advertising level. Let the level is  $s$ :  $s \in \{0, 1\}$ ,  $s = 0$  means advertising,  $s = 1$  means no advertising. The cost of advertising is  $C(s, \theta) = s/\theta$ . After advertising is observed, the buyer will decide the price  $w(s)$ . The bargainer will choose whether receiving the price or not. If being received, the buyer has an expected value:  $v = \theta$  (it is a hypothesis that advertising isn't influence of value), the bargainer's expected utility is  $U(s, \theta) = w - s/\theta$ . The buyer's expected utility is  $\pi(s, \theta) = \theta - w(s)$ . Otherwise,  $U = \pi \equiv 0$ . At one time, it is a hypothesis that there is a complete market, so when the market has an equilibrium, price will be equal to expected value and the buyer's expected utility is 0.

### 3.2 The game of trust in control

The analysis of this game model has two angle of view: symmetric and asymmetric information games. By symmetric information, advertising needs many costs but has no value. So whether high with low of the quality, bargainer will choose  $s = 0$ , the price of low quality is  $w(\theta = 1) = 1$ , the price of high quality is  $w(\theta = 2) = 2$ . There is trust institution in the market this time. But this Pareto dominance equilibrium will not exist in asymmetric information games. If the buyer doesn't know  $\theta$ , his expected value will be  $v = 0.5 \times 1 + 0.5 \times 2 = 1.5$ , the competition of players will have a result in  $w = 1.5$ . But, when the advertising can transfer quality signal to buyers,  $w = 1.5$  would not able to be Nash equilibrium (Zhang, 1996).

Traditional trust institution is built by a hypothesis of symmetric information games. Besides of a strong common share of the institution, it also needs a small self-region market. Along with the development of technology, the bound of market is more and more expanding. The hypothesis of traditional trust institution is removing from the fact. For obtaining the symmetric information, many other forcing controls are necessary, such as quality standard, understanding of craftworks and abilities, etc. In fact, the trust has been equal to the control. The essence of "dependence and control" has brought high cost, and can't meet the demand of trust in the times of global economy. The principal cannot far directly control the behavior of the agents because of his bounded rationality. Controlling has sharpened the contradiction between the principal and agent.

### 3.3 The game of trust in competition

Though the traditional business environment has stronger regional characteristics, the conditions of the hypothesis of the trust are easier to realize, the controlling, as a kind of ways to form trust, can work in a certain extent. With the innovation of technology (modern manufacturing, modern transportation and modern information) and system (the freedom of trade), the modern economy becomes globally day by day, precondition of trust through the method of controlling has already been out of the existence. Under this environment, the agent who is prone to calculativeness will not promise openly, so the effective trade can only be realized on terms that the trust is restrained from reliably supporting (Williamson, 1998). As the important displaying form of the technology at the third stage, E-business is not only the handed technology, but also is the main means to change the environment. The development of E-business will have influence on the evolution of trust institution.

In E-Business, by the regional difference of culture and moral, the belief of traditional trust institution will not be more and more common shared. Because of the asymmetric information of quality, buyers can only observe  $s$  not  $\theta$ , so the price will only be decided by  $s$ . Let  $\mu(\theta = 1 | s)$  is the buyer's posterior probability of low quality when he has observed  $s$  that the bargainer selected. Perfect Bayesian equilibrium means: (1) the bargainer selected  $s(\theta)$ , (2) the buyer knows  $\mu(\theta = 1 | s)$  and decides  $w(s)$  by the " $s$ " that he has observed. The result is: ① by  $w(s)$ ,  $s(\theta)$  is the best choice of the bargainer when quality is  $\theta$ ; ② by  $s(\theta)$ ,  $\mu(\theta = 1 | s)$  is accordant to Bayesian ruler,  $w(s)$  is the best choice of the buyer.

The equilibrium may be pooling or separating. First, pooling equilibrium (PE) means the bargainer selected same advertising in different qualities and won same price. By  $s(\theta) \equiv 0$ ,

$$(PE): \begin{cases} s(\theta = 1) = s(\theta = 2) = 0 \\ w(0) = w(1) = 1.5 \\ \mu(\theta = 1 | s = 0) = 0.5 \\ \mu(\theta = 1 | s = 1) = 0.5 \end{cases} \quad (1)$$

It means no advertising of any qualities is Pareto dominance equilibrium. The buyer considers there is no quality signal in advertising, so the price is equal to the expected utility. Because of the buyer's Pareto dominance equilibrium is  $w \equiv 1.5$ ,  $C(1, \theta) > 0$ , so  $s(\theta) = 1$  is impossible, the bargainer's Pareto dominance equilibrium is no advertising ( $s(\theta) = 0$ ) (Zhang, 1996).

Because we assume the buyer will not rework his prior probability when he finds  $s(\theta) = 1$ , (PE) is Pareto

dominance equilibrium. The invariable prior probability in advertising game demands players have share-beliefs of sensual knowledge and codified knowledge, by all appearances, it could not come to existence in global economy and E-business. If the buyer's posterior probability is  $\mu(\theta=1 | s=1) = 0$ , it means the quality advertised must be high, the (PE) will not come into existence. For by  $\mu(\theta=1 | s=1) = 0$ , when the bargainer's choice is  $s(\theta) = 1$ , the buyer's choice will be  $w(1) = 2$ . The high quality will select advertising,  $U(s=1, \theta=2) = 2 - 1/2 = 1.5$ . No advertising is poor,  $U(s=0, \theta=2) = 1 - 0 = 1$ , so we will have the separating equilibrium (SE):

$$(SE): \begin{cases} s(\theta=1) = 0, s(\theta=2) = 1 \\ w(0) = 1, w(1) = 2 \\ \mu(\theta=1 | s=0) = 1 \\ \mu(\theta=1 | s=1) = 0 \end{cases} \quad (2)$$

(SE) is perfect Bayesian equilibrium. When the buyer has selected the posterior probability and the price, if  $U(s=1, \theta=2) = 1.5 > U(s=0, \theta=2) = 1$ , the quality is high, the best strategy is advertising; if  $U(s=0, \theta=1) = 1 \geq U(s=1, \theta=1) = 1$ , the best strategy is no advertising when the quality is low. Otherwise, by the bargainer's choice, the buyer's posterior probability is based on Bayesian ruler, so the price strategy is Pareto dominance, and other (SE) isn't being (Zhang, 1996).

#### 4. CONCLUSIONS

The advertising level is a signal in (SE) which transfers information of quality to buyers. Spence-Mirrlees condition is the precondition of this game equilibrium. When the same advertising is selected, the cost of high quality is lesser than low quality, the high quality will have enough incentive to separate itself from others by advertising. Otherwise, for winning same price, the low quality will have enough incentive to simulate the high quality by same advertising strategy. Thus the buyer will not believe the advertising as a quality signal. It will bring on market failure if there is not enough quality information in other ways. The trust isn't being. So we will see the conclusions as follows:

1. In global economy and E-business, because of scarcity of sensual knowledge, the condition of strong ethical hypothesis in traditional trust institution is not being. The new trust's game model should be more and more based on "an invisible hand" (Smith, 1776). The ethical hypothesis is feeble.

2. In E-Business, Spence-Mirrlees condition makes it clear that the system assuring of real advertising is necessary. If the discount factor  $\delta > 0$ , players will have enough incentive to tell the truth in infinitely repeated games (Rasmusen, 1994). It is necessary to

build and improve the stable common E-Business market by strong legal system. The third party will regulate players' actions in market, such as quality, reality of advertising, etc. The certification authorities and the continuous open newsreel of business can make the cost is too expensive to lie.

3. If the bargainers' quality information can help buyers purchase properly, advertising can improve the effect of resource allocation. By taking the advantages of E-business that can help to share the mass codified knowledge, purchase and supply on-line can bring an effect of vendue. The good-right order can translate from traditional mode such as prior plan, unite control, posterior mediation, into the mode of contract that based on real product (Masahiko Aoki, 2001). Lesser asymmetry and uncertainty information will make enough incentive of the bargainer to improve quality. At one time, opening competition can promote monitor from man-made to market-made by the endogenous punishment mechanism by constantly repeated games. It is from control to competition.

## Negative Reputation Rate as the Signal of Risk in Online Consumer-to-Consumer Transactions

### ABSTRACT

Previous online reputation research has been focused on the effects of positive and negative reputations on trust formation, trading price, and probability of sale. We propose that negative feedback rate (NFR) is the most important indicator of the risk of buying from a seller online. This proposition has been supported by an empirical study based on data collected from eBay.com. We found that the 6-month NFR in the current period predicts much better the future risk measured by the NFR in the next 6-month period than did net reputation score and negative reputation score. A seller's life-long negative score in fact was not significant in predicting the future risk. In addition, a seller's age in the market was found to have similar predicting power on risk as did net reputation score.

**Keywords:** Reputation; Electronic commerce; Risk; C2C auction

### 1. INTRODUCTION

The prevailing online reputation systems, which provide trust-building mechanisms and assurance services on eBay, Yahoo auction, Amazon and many other online auction marketplaces, have contributed significantly to the success of the consumer-to-consumer (C2C) electronic commerce. The online reputation systems allow traders to leave each other a positive, negative or neutral rating after a transaction is finished. The scores are then added up as quantitative indicators of traders' reputation records which are available to future traders. In addition, traders can leave brief comments on their transactions or trading partners for further references.

The effectiveness of online reputation systems in the C2C auction market has triggered wide interests from the research community. According to the synthesis by Dellarocas [4], although some have investigated the effect on the probability of selling products [2], empirical studies on online reputation are unanimously focused on the effect of seller's feedbacks on item prices. However, because of the diverse nature of research design, such as different types and categories of items being investigated, different measures of reputation, different data collection processes, and different sample sizes, no consistent findings were found across these studies [13]. Positive feedback might or might not increase price or probability of sale, and the same applies to negative feedback and net reputation score, as Resnick et al. [13] summarize from 16 research reports. Whereas, accumulated positive and negative scores, as well as negative scores from a period of time, were found to be the most influencing

components of seller's reputation on buyer behavior.

On the other hand, some research has investigated the effect of risk or perceived risk on online trading and the adoption of trusted third party services (e.g., Antony et al. [1]; Hu et al. 2001 [7]). Perceived risk was identified as an important determinant of purchasing items and adopting trusted third parties' services in the electronic market. Further, perceived risk is subject to change with regard to each trading partner's online reputation.

The basic reputation indicators that can be obtained from a C2C online reputation system include positive score, negative score, and neutral score (less often used). Based on these three basic scores, three combination scores can be derived: the *total reputation score* which is the sum of positive, negative and neutral scores, the *net reputation score* which is the difference of positive score and negative score accumulated from the ratings from unique traders, and the *negative feedback rate* which is the ratio of negative score and the total reputation score. Presently, a majority of reported research uses positive, negative, and net reputation scores as the indicators of online reputation, but NFR has not been touched yet.

How do these reputation scores reflect the risk of trading with a seller? To our knowledge, little research has answered this question. So far, majority research effort is in the effect of reputation on trust, but not aimed at the measure of the risk in the C2C online transactions. The main research idea in this paper is described in Figure 1. In the dotted box of the figure is a typical model used in trust related research (see [8]),

\* Also an adjunct professor, Fujian University of Technology, Fuzhou, China

where perceived risk is investigated. However, the perceived risk does not necessarily match the real risk in the future, because online traders' behavior could be irrational. Therefore, this paper is intended to investigate the relationship between reputation indicators and the risk. We propose that a seller's negative feedback rate (NFR) is the most important indicator for predicting the risk of buying from him. Based on data collected from eBay, we conducted an empirical study. The result supported our proposition.

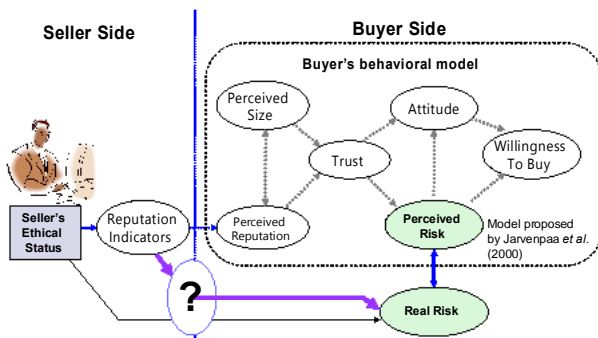

Figure 1: A conceptual model of the research

## 2. THEORETICAL BACKGROUND

### 2.1 Reputation

In the traditional reputation literature, reputation is generally defined as the consistency of an entity's behavior over a certain period of time [3][5][14]. It is a record of the history of an entity's interactions with others. Thus, reputation building is not a one-time effort but is based on the sum of all the past behaviors of the entity.

Reputation can be positive or negative. A positive reputation manifests all the favorable assessment of an entity, while a negative reputation shows the unfavorable aspects of the entity. Because the potential sacrifice associated with a negative or bad reputation is very high, an entity with a positive reputation is predicted to behave consistently in a favorable manner in the future. In buyer-seller relationships, the seller's reputation has a positive effect on buyer's trust in the seller and buyer's long-term orientation with the seller [6].

In electronic commerce research, Internet buyers are found to favor web sites that sell familiar products manufactured by familiar merchants [12]. The reputation of an online store is positively associated with an online consumer's trust in the store [8]. Further, research has shown that the negative reputation has much more effect than the positive reputation on buyers' trust because the negative reputation is the repeatedly appearance of a seller's unfavorable behavior that is highly associated with the potential trading risk in the future (See the review from Dellarocas [4] and Resnick et al. [13]).

### 2.2 Risk

According to classical decision theory, risk is "the variance of the probability distribution of possible gains and losses associated with a particular alternative" ([11], pp.1404). The definition is too abstract for the traders in the C2C auction market to understand. Following MacCrimmon and Wehrung [10], risk is defined as the chance or probability of loss. We thus define the potential risk of trading with a seller to be the probability of leaving the seller a negative feedback. Although the reputation system provides detailed comments about the negative reputation, a potential buyer may not have the resources (cognitive, motivational, or other external resources) to search the entire archive and find out the exact reasons for the negative comments. Further, risk is also associated with the significance of loss [11], e.g., how much a buyer can lose because of fraud.

### 2.3 The rationale of the research

In this research we focus on how online negative reputation can indicate the real risk in a future online transaction. This issue is represented by the question mark in Figure 1. Normally, a reputation system does not provide a direct causal link between the historical negative feedbacks and the information about the auctioned item, so that a buyer could not easily figure out the probability of future loss. Hence, we argue that a potential buyer will rely on the summarized reputation information in a seller's profile to judge the risk level of trading with the seller. The definition we have provided implies that risk is in the form of probability rather than a quantitative number representing the value of the loss. In the C2C online auction context, previous research has used negative feedback scores to measure risk. This measure is not accurate, because a negative feedback score does not reflect the probability of getting negative feedback in the future. The right measure of such risk should be a number signaling the probability of unpleasant consequences from the transaction with the involved seller. Thus, both the number of negative feedbacks the seller has received in a period of time and the total number of transactions in the same period of time should be considered together. We realize that there are several different types of NFRs, e.g., lifetime NFR and NFRs during different time periods. They are applicable to the same risk analysis purpose depending on different timeframes and accuracies. In the later discussion, we refer NFR as the NFR calculated from reputation scores in a 6-month period from now on.

## 3. AN EMPIRICAL STUDY

In this section, we report an empirical study based on data collected from eBay.com. The purpose of the empirical study is twofold. First, we aim to reveal the nature of the negative feedbacks through a content analysis of the feedback comments. We have not seen

any effort of analyzing the diverse contents of the reputation feedbacks. Second, we want to justify the predictive power of different reputation scores on the risk in the transactions with unknown sellers through a longitudinal study, using reputation score data collected at two time points.

### 3.1 Study 1 - Content Analysis of Negative Feedback Comments

For the content analysis, we randomly collected 216 unique sellers with negative reputation scores. We searched these 216 seller's transactional history archived on eBay.com. We randomly selected one piece of feedback comment associated with a negative rating to the seller.

As each online negative feedback may link to different stories and signal different types of perceived risks, such as financial losses, undesired low quality, and unsatisfied service, it is necessary to look into negative complaints in order to reveal their nature. We are interested in why buyers are unhappy with sellers and how buyers attribute those complaints.

The authors of this paper worked as independent coders of the feedback comments. After finishing coding two coders compared the results and resolved the differences and discrepancies with a detailed discussion. The reliability of inter-coders was 0.90.

The coding was focused on three basic questions: What are the causes of negative feedback, merchandize or service? Who are responsible for the negative feedback, the seller, the buyer, or the third party? Is the negative feedback resolvable?

Figure 2: Causes of complaints

### Results and Implications

The results of the coding on the three questions are shown in Figure 2-4 and Table 1. The three findings are discussed as follows:

*Not every complaint is related to a merchandise problem*

Figure 2 indicates that about two thirds of negative comments are complaints against merchandise problems. More than 30% complaints are related to seller services,

such as “shipped to wrong address”, “item received more than a month”, or “never response to my email”. Apparently these complaints are not related to any fraud, but reflect buyers’ unpleasant experience. Thus, this type of risk is about unsatisfactory transaction that every buyer wants to avoid.

*According to the responses from the seller, the buyer could be the number one trouble maker followed by the seller and the third party.*

There are many attribution errors in the negative feedbacks left by the buyer. According to Table 1, more than one third of complaints are because of the buyer. Typically, an inexperienced buyer may not understand the information of the auctioned item well and does not follow the way as an experienced buyer does. This is particularly remarkable in the complaints about the merchandise. Although this is not the kind of the risk in the traditional sense, the over reaction of a buyer may incur the retaliation of the annoyed seller returning with a negative rating. So the backfiring from the seller or uncomfortable feeling of the regrettable outcome is the risk the buyer may face under this situation.

Table 1. The liable agents to the complaints

Complained issues	Seller	Buyer	3rd party	Others
Merchandise	18.49%	38.36%	15.07%	28.08%
Service	12.12%	28.79%	19.70%	39.39%
Overall	16.20%	36.11%	16.20%	31.49%

In addition, about one sixth of the complaints are related to the third party who provides delivery services, contracted packing services, or original product supply (Figure 3). Although this also has nothing to do with fraud, it is one kind of risks that a buyer may encounter. As shown in Table 1, sellers are responsible for less than half of the complaints as buyers are.

Figure 3: The composition of liable agents

*More than 40% of the complaints are resolvable or have been resolved at the moment they are made.*

Figure 4 shows that more than half of the complaints can be classified as disputes. Sellers are responsible for almost half of complaints (47.95%) to merchandises. Less than one fifth (18.49%) of the complaints against the merchandise has caused sellers’ harsh responses and

ended unpleasantly. Practically, when a seller has responded to a buyer's complaint regarding the merchandise and a dispute is incurred, it becomes difficult to justify whether the case is a fraud or not. From a prospective buyer's angle, this is an undesirable situation and must be avoided.

Figure 4: The resolvability of negative comments

### 3.2 Study 2 - Predictors of NFR

For the longitudinal analysis, we followed the data collection procedure reported in Lin et al. [9]. We first

collected 2,000 seller's reputation data in March 2003. Six months later, we repeated the data collection using the same 2,000 seller IDs. 174 sellers IDs were no longer active in the second round collection because these sellers have quitted the account, leaving 1,826 useful observations in the study.

### Results

We tested how well the reputation indicators observed in the current 6-month period ( $t_0$ ), i.e., NFR, net reputation score, accumulated negative feedback, and age, can predict an individual seller's NFR in the next 6-month period ( $t_1$ ). We used stepwise regression to examine the correlation of the NFR in the next period to different reputation indicators. The results from the Tobit regression model and the OLS model are summarized in Table 2. Tobit regression model was used because the dependent variable NFR at the second point ( $t_1$ ) was censored with a lot of 0's. In general, the regression results from the two models are consistent.

**Table 2:** Regression analysis of predictors of NFR in the next 6-month period  
Dependent: NFR( $t_1$ )

Tobit Model	Ln(NFR( $t_0$ ))	Age	Ln(Net( $t_0$ ))	Ln( Neg( $t_0$ ))	N	Log Likelihood
Model 1	0.87				1826	-640.40

### Implications

*Seller's current NFR is the most significant variable for predicting the NFR in the next period*

The most important predictor of future risk is the NFR in the current 6-month period, which explains the highest percentage of the variance of the next period

NFR ( $R^2$  is about 59% from the OLS regression) among the four independent variables. This means that the NFR is the best among all four variable in predicting the risk of trading with an unknown seller in the C2C online auction market. The positive relationship suggests that the higher the NFR from the current period, the higher the NFR in the next period. The contribution of the other three variables in explaining the risk level is

marginal because their presence has little effect on the goodness of fit (for example, 63% vs. 59% of  $R^2$  in the OLS regression, or -640 vs. -627 of logarithmic likelihood in the Tobit regression).

*Net reputation score is negatively correlated to seller's NFR in the next period*

The relationship between net reputation score and NFR is significantly negative, suggesting that the higher the net reputation score, the lower the NFR in the next period. This finding is consistent with the findings reported in previous literature, in which net reputation score has a significant effect on trust and price premium. Therefore, our study suggests that net reputation is also a significant predictor for the trading risk with a specific seller. However, the explanatory power of net reputation score ( $R^2$  is about 24% in the OLS regression) is not as strong as NFR.

An explanation to the discrepancy of the effect of net reputation score is that when the net reputation score is high, the variance of NFR is low, because sellers with high net reputation scores tend to have high transaction volumes and their NFRs are relatively stable. The sellers with low net reputation score typically have lower transaction volume, and the variance of their NFRs is higher. Therefore, the NFR is more sensitive to the range of net reputation scores.

*Seller's age matters in predicting NFR*

The age of a seller also provides the similar explanatory power in predicting NFR ( $R^2$  is about 13% in the OLS regression) as the net reputation score. This implies that the longer a seller stays on the market, the lower the NFR. Therefore, like net reputation score, a seller's age can be another important measure of his experience and tenure in the market. According to Lin et al. [9], in the context of market structure research, online reputation as the tangible asset for online traders reflect their capacity as virtual firms in the electronic market. Based on this, our study is the first one that has found that age is an effective measure of a seller's capacity in doing business on the market.

*A seller's total negative score accumulated in his business life cycle has no effect on NFR*

Unlike previous studies who have found significant effects of negative feedback on person's trust and price, this study did not find significant effect of negative reputation score on the next period NFR ( $p>0.05$ ). This suggests that without considering the total number of transactions from which the negative reputation score are generated, the risk in a trading cannot be predicted accurately. Negative reputation score, an absolute number rather than a relative number, cannot tell exactly whether it is likely to have an unpleasant outcome in the transaction with a seller. The previously reported significance of negative reputation score on traders'

behavior was only the implication of their irrationality.

According to the above findings, the maturity of a seller, signaled by his age and net reputation score, is important for estimating the risk level in transacting with him. We can refer to this as the "learning effect." The learning effect was also found from the negative relationship between transaction volume and negative rate ( $\beta=-0.0002$ ,  $p<0.001$   $R^2=0.10$ ). The higher the number of transactions, the lower the NFR. Although an individual may maximize his effort to conduct a good business, his behavior is relatively consistent. If he has got higher NFR in the past, he is more likely to get higher NFR in the future. This implies that even though a trader changes his ID or identities on eBay, if he has got a high NFR, he is still likely to get the same level of NFR under a new ID, because his ability of doing business behind the pseudonym is unimproved. At the same time, the costs of switching ID and building new reputation may be high, which suggests to the sellers: *Do not change your ID when you have a high NFR. It does not work.*

#### 4. CONCLUSIONS

In this paper, we analyzed the negative feedbacks by coding the textual complaint data and examined the determinants of future NFR with the historical reputation scores. We made two clear contributions to the research on C2C auction market. First, we revealed the diverse nature of negative reputation. Several important findings were derived from analyzing the content of the negative feedback comments. Second, we proposed to use NFR to measure the potential risk in trading with an unknown seller in the electronic market. The results of the empirical study could provide guidelines for the future buyers to do business online. The findings also have important implications for the design of reputation systems. Online companies are encouraged to report NFR as a measure of reputation of traders. We have noticed that since 2004 eBay.com has started to provide positive feedback rate on its online reputation forum (see Appendix). We reason that the positive feedback rate (PFR) might work as an incentive for sellers to maintain their reputation and promote the effectiveness of eBays' feedback forum. However, PFR is not as straightforward as NFR as an indicator of the risk, although rational buyers can derive NFR from PFR. If eBay.com can further show the positive feedback rate during a period of one month and 6-month, the figures will be more informative and valuable.

## Recent Trend of Ratings Business in Japan and Improving Proposal for Ratings Forecasting Model

Sakamaki, Yoshikazu

Department of Value and Decision Science Tokyo Institute of Technology Tokyo, 1528550, Japan  
megacity@f3.dion.ne.jp

### ABSTRACT

The change of economic circumstances in recent years has increased the gaps of credibility among firms, and the necessity to measure the credibility adequately is an important ever-increasing factor. As the result, it is essential for banks to assess the rating evaluation of borrowers appropriately in order to measure the amount of credit risk. This paper reviews preceding studies regarding model building that enables us to explain or forecast the ratings of firms issued from credit-assessment agencies. The paper then explains the features of the ordered logit model in detail that is nowadays used as a ratings evaluation model throughout the world.

Finally, some defect points of these preceding models are pointed out and the improved ordered logit model on the non-compensatory rule that enables to compensate these defect points is proposed. In addition, the appropriateness of the proposed model is verified based on the actual rating data for the companies.

### 1 INTRODUCTION

Banks are incorporating credit risk evaluation, as it is a very important procedure to measure the level of default probability from the point of macroscopic portfolio strategy. On the other hand, it forms the foundation of a rating system that is nowadays used for self-assessment of major banks and the new BIS Accord in financial administration.

In Japan, financial institutes that pledge to drive credit risk control forward also measure the VaR of the holding portfolio regularly and hence, the management policy is checked up based on it. However, as we verify the element of risk factors in more detail, the evaluation of individual borrowers becomes considerably important. Unless a certain level of fairness or objectivity is compensated when banking facilities evaluate the individual borrowers, it inevitably becomes difficult to decide the organic management policy based on the result of it. That means it plays a very important role in the concept of credit risk control.

When banking institutes calculate the risk-based necessary net asset in proportion to credit risk, they need to know the trend of rating change of each borrower in advance. At that time, a new BIS Accord admits two types of evaluation methods. One method is the standard method where banking institutes can use the ratings of external credit-assessment agencies, whilst the other one is an internal method in which banking institutes can use the ratings that is calculated based on its proprietary system developed by themselves.

With regards to the internal rating method, after the collapse of the 90's bubble economy, as the spread of self-assessment and discussion of a new BIS Accord, it is becoming clear that banking institutes are recognizing the internal rating system as the basic information for credit risk control.

And it becomes essential for a banking institute to assess the rating evaluation of borrowers appropriately in order to measure the amount of credit risk. Therefore, this paper introduces some preceding studies regarding model building that allows the ratings of firms issued from credit-assessment agencies to be explained or forecasted. The paper then explains the features of the ordered logit model in detail that is nowadays used as ratings evaluation model throughout the world.

Moreover, discrepancies in these models are highlighted and an improved ordered logit model is proposed that compensates for these weak points.

### 2 RELATED WORKS EXPLANATION OF RATINGS MODEL IN THE PRECEDING STUDY

The statistical approach for the rating of firms originated in the 1970's. In the initial study, a linear regression model was mainly used for ratings forecasting. The development of a rating model was then devised by Kaplan and Urwitz (1979). They highlighted the flawed issues contained in the preceding models based on regression analysis or discriminant analysis, and proposed an improved ratings model based on the ordered probit model for the first time. The model developed by them was very sophisticated and they succeeded to hit the rating of 44 among 64 firms without failing and moreover, even the result of ratings of the firms that could not be predicted correctly could be put at least within just one rating before/behind the correct rating.

Here, the ordered logit model is briefly explained and the ordered probit model that is nowadays used widely as ratings forecasting throughout the world is presented. At first, the ordered logit model is built by expanding the normal binominal logit model based on the explanatory variables that classifies the sample data into one of the plural statuses. It can then be used to analyze which

of the statuses the sample data can be classified only when the statuses are ordered.

Here,  $x_m$  represents the  $m^{\text{th}}$  ( $m=1,2,\dots,M$ ) explanatory variable of firm  $i$  ( $i=1,2,\dots,I$ ) and  $\beta_m$  represents the estimation parameter for  $x_{im}$ . Furthermore, we assume that financial health without an error term is given by the summation of the weighted explanatory variables. That is, we define financial health of firm  $i$  by

$$z_i = \sum_{m=1}^M \beta_m x_{im} \quad (1)$$

and with the latent variable  $z_i$  defined in equation (1), financial health that contains an error term is given by

$$Z_i = z_i + e_i \quad (2)$$

Moreover, we define the threshold by which the ranking of each firm is decided as

$$-\infty = t_0 > t_1 > t_2 > \dots > t_k > \dots > t_K = \infty \quad (3)$$

Supposing the probability of firm  $i$  classified in rank  $s_k$  can be defined as  $p_{ik}$  and distribution function of the error term  $e_i$  as  $F$ , we can define  $p_{ik}$  by

$$p_{ik} = F(\tau_{k-1} - z_i) - F(\tau_k - z_i) \quad (4)$$

Here,  $z_i$  is the financial health as defined in equation (1). Moreover, paying attention to the condition of  $F(\infty) = 1$ ,  $F(-\infty) = 0$ , we can obtain an ordered logit model if we assume logistic distribution for the distribution function  $F$ , and an ordered probit model if we assume normal distribution for  $F$ .

Based on equation (3) and (4),  $p_{ik}$  in the ordered logit model can be expressed by

$$p_{ik} = \frac{1}{1 + \exp(z_k - \tau_{i-1})} - \frac{1}{1 + \exp(z_k - \tau_i)} \quad (5)$$

On the other hand, under the condition that

$$-\infty = \tau_{-1} < (\tau_0 = 0) < \tau_1 < \tau_2 < \dots < \tau_i < \dots < \tau_{I-1} = \infty$$

rating probability  $p_{ik}$  in the ordered probit model can be expressed by

$$p_{ik} = \Phi(\tau_{i-1} - \sum_{m=1}^M \beta_m x_{km}) - \Phi(\tau_{i-2} - \sum_{m=1}^M \beta_m x_{km}) \quad (6)$$

Here,  $\Phi$  represents the cumulative distribution function of normal distribution.

Parameter estimation for these models is done as follows. That is, if we assume that the probability of firm  $i$  belonging to status  $s_k$  as  $p_{ik}$ , the likelihood function regarding parameter vector  $\beta$  and threshold vector  $t$  can be defined by

In this model, we assume statistical independence in financial health of each firm. Here  $d_{ik} = 1$  if the financial health of  $i^{\text{th}}$  firm belongs to  $s_k$  and  $d_{ik} = 0$  if the financial health of  $i^{\text{th}}$  firm does not belong to  $s_k$ . Moreover, the log-likelihood function can be defined as equation (7), and parameter vector  $\beta$  and  $t$  that maximizes equation (11) is estimated.

$$l(\beta, t | x) = \prod_{i=1}^I \prod_{k=1}^K \delta_{ik} \log p_{ik} \quad (7)$$

In a preceding study, Nakayama and Moridaira (1998) studied the verification of parameter estimation accuracy between the ordered logit and ordered probit models, and showed that there are no significant differences of parameter estimation accuracy between the models. On the other hand, Kobayashi (2001) proposes original statistical criteria from his own point of view and verifies that the ordered probit model can be altered as the extreme limit of multivariate probit model.

### 3 IMPROVEMENT PROPOSAL OF THE TRADITIONAL RATINGS MODEL

As mentioned in Chapter.2, the ordered probit/logit model is built as an expansion of the binominal logit model for classifying sample data into one of the plural statuses. These models are very useful when a certain order is given to the statuses, and it is shown in the preceding studies that these models are possible to be applied in many academic case studies. (For example, when analysts forecast the ratings of firms, credit risk and debt etc.,)

However, the ordered probit model is generally very difficult to use because of statistical reasons. Therefore, the ordered logit model is used mainly in an actual business. In this paper, we focus on the ordered logit model.

The ordered logit model is based on the scores calculated from the summation of weighted variables (linear regression analysis). That is, linearly linked variables are comprehensively evaluated and the rating in which sample data belongs to can be decided. In this sense, this type of model is built on compensatory rule. This type of model can therefore be termed as an "ordered logit model on compensatory rule" in order to distinguish it from our model.

If, in this type of model, a certain explanatory variable happens to take a huge value, the calculated probability can become far from the realistic financial health, and sample data is classified into an extremely superior/inferior rating group.

On the other hand, Katahira *et al.* (1998) have reported a very interesting study in the field of marketing research. In their study, a consumers' choice behavior model is built with the assumption that consumers make a choice behavior based on the compensatory rule. However, as we can see in such a choice behavior, no matter how cheap the merchandise is, consumers do never accept it, unless the quality satisfies a certain criteria. Consumers therefore exhibit behavior based on the non-compensatory rule throughout a variety of occasions.

Concerning this point, Dawes and Corrigan (1974), and Jhonson and Meyer (1984) have shown that under a cer-

tain condition, we can approximate a choice model on the non-compensatory rule by that on the compensatory rule. However, as pointed out in the preceding study where consumers exhibit a choice behavior based on the non-compensatory rule (Bettman and Jacoby (1976), Payne and Ragsdale (1978)), we can not approximate a choice behavior model on the non-compensatory rule by that on the compensatory rule, if a very strong negative correlation between arbitrary two variables exists (Jhonson, Meyer and Ghose (1989)).

To overcome such an issue, we will apply the concept of the choice model on the non-compensatory rule to the traditional ordered logit model. Considering the ratings forecasting model of firms, in many cases, variables used as risk factors in the model like capital adequacy ratio and interest-bearing debt have a very strong correlation with each other. Moreover, considering the relationship between the rating of firms and risk factors, there is a tendency that most of the values of risk factors go up or down according to the rating of firm changes. Taking these points into consideration, it seems to be more realistic to apply a rating forecasting model on the non-compensatory rule in which rating changes only when all or most of the risk factors considered in the model goes up/down simultaneously, rather than to apply the model based on the compensatory rule.

>From the study based on the Katahira model, Sakamaki (2003) uses the publicly disclosed financial data of firms and shows that the logit model based on the non-compensatory rule can forecast the default probability more accurately than the normal linearly linked logit model based on the compensatory rule.

When examining the preceding literature, especially in studies where a strongly negative correlation between two explanatory variables exists, it can be thought that it is very meaningful to build a statistical model on the non-compensatory rule rather than the linear model on the compensatory rule. So in this paper, taking these points into consideration, the improved ordered logit model is proposed based on the non-compensatory rule as is shown below.

Here, two types of ordered logit models are proposed based on the non-compensatory rule.

#### [Conjunctive Type]

In this model, it is assumed that the rating change happens only when all of the risk factors used in the model shift simultaneously to the direction of changing the ratings.

$$\begin{aligned}
 p_{ik} &= p_{ik}(\tau_{mk-1} - x_{im} > \varepsilon \geq \tau_{mk} - x_{im}, \forall m) \\
 &= \prod_{m=1}^M p_{ik}(\tau_{mk-1} - x_{im} > \varepsilon \geq \tau_{mk} - x_{im}) \\
 &= \prod_{m=1}^M \left\{ \left( \frac{1}{1 + \exp(\beta_m(x_{im} - \tau_{mk-1}))} \right) - \left( \frac{1}{1 + \exp(\beta_m(x_{im} - \tau_{mk}))} \right) \right\} \quad (8)
 \end{aligned}$$

#### [Disjunctive Type]

In this model, it is assumed that the rating change happens when some of the risk factors shift to the direction of changing the ratings.

$$\begin{aligned}
 p_{ik} &= p_{ik}(\exists m, \tau_{mk-1} - x_{im} > \varepsilon \geq \tau_{mk} - x_{im}) \\
 &= 1 - \prod_{m=1}^M p_{ik}(\tau_{mk-1} - x_{im} > \varepsilon \geq \tau_{mk} - x_{im}, \forall m) \\
 &= 1 - \prod_{m=1}^M \left( 1 - \left\{ \left( \frac{1}{1 + \exp(\beta_m(x_{im} - \tau_{mk-1}))} \right) - \left( \frac{1}{1 + \exp(\beta_m(x_{im} - \tau_{mk}))} \right) \right\} \right) \quad (9)
 \end{aligned}$$

Here,  $x_m$  represents the  $m^{\text{th}}$  ( $m=1,2,\dots,M$ ) explanatory variable of the firm  $i$  ( $i=1,2,\dots,I$ ).  $\beta_m$  represents the estimation parameter and  $\tau_{mk}$  represents the threshold parameter that decides the ratings of each firm in explanatory variable  $x_{im}$ . This type of model is termed the "Ordered Logit model On Non-Compensatory Rule" in order to identify it with the normal ordered logit model. Parameter estimation for these models is done as follows. That is, if we assume that the probability of firm  $i$  belonging to status  $s_k$  as  $p_{ik}$ , the likelihood function regarding parameter vector  $\mathbf{B}$  and threshold vector  $\mathbf{t}$  can be defined by

$$L(\mathbf{Bt} | \mathbf{x}) = \prod_{i=1}^I \prod_{k=1}^K p_{ik}^{\delta_{ik}} \quad (10).$$

We assume statistical independence in financial health of each firm. Here  $\delta_{ik} = 1$  if the financial health of  $i^{\text{th}}$  firm belongs to  $s_k$  and  $\delta_{ik} = 0$  if the financial health of  $i^{\text{th}}$  firm does not belong to  $s_k$ .

Moreover, the log-likelihood function can be defined as equation (11), and parameter vector  $\mathbf{B}$  and  $\mathbf{t}$  that maximizes equation (11) is estimated.

$$l(\mathbf{Bt} | \mathbf{x}) = \prod_{i=1}^I \prod_{k=1}^K \delta_{ik} \log p_{ik} \quad (11)$$

Additionally, in the next chapter, applying publicly disclosed financial data to our model verifies the appropriateness of the model. Moreover, we show the proposed model is superior to the preceding ordered logit model from the view of fitness degree and forecasting power.

## 4 MODEL VALIDATION

In this chapter, actual data is applied to the model proposed and verifies the appropriateness of the model. The verification data used was publicly disclosed financial data issued from Rating and Investment Inc.

### 4-1. Outline of verification data

#### 1) Account settlement Term

Rating data that is evaluated and published based on the account settlement data from Apr.,2000 to Mar.,2001

#### 2) Data volume: 652 firms

(Financial data in which missing data does not contain. Moreover, in this study, the power industry is omitted because the relationship of actual management and financial health is very different with that of normal firms)

#### 3) Financial ratio used in the model

Based on the business experience, the following six indexes that can affect the ratings of firms materially are used in the model.

1. log-transformed net asset
2. total capitalization ratio
3. ratio of fixed assets to long-term capital
4. capital adequacy ratio
5. retained earnings ratio
6. dead capacity ratio

### 4-2 Parameter estimation

Based on this data, parameters of the three types of models, ordered logit model based on the non-compensatory rule (conjunctive/disjunctive type), and the normal ordered logit model are estimated by maximum likelihood estimation.

Generally, the fitness of the model on the training data set is fine, but the most important question is how the model works in out-of-sample data. This is known as generalization, and there are several modeling strategies available to address it. Since the training data set is all the modeler has to work with, strategies to address generalization involve splitting the sample into sub-samples.

The simplest way to split samples is to use two sub-samples randomly selected from the full training data set. The first sub-sample is used as the actual training data set. The second sub-sample, called the *holdout* sample, is not used in the initial estimation, but later, to test the performance of the estimated model. Similar performance on both the training data set and the holdout sample is an indication that the model will perform at about the same level. If the performance of the model deteriorates

substantially on the holdout sample, the model is sensitive to specific aspects of the two sets. Such specifics could include a set of unusual observations, referred to as outliers, which are more prevalent in some data sets. Clusters of observations that show a particular set of relationships that are not always found could also cause performance differences. In estimating parameters, we have chosen 60% of the sample data at random and used for in-sample-data, and 40% for out-of-sample data.

Here, in this study, the classification of ratings is simplified based on Table 1 because there are very few number of firms classified in rating AAA, and we have to consider too many rating patterns if so-called 'notch' described by positive/negative sign is considered in the model.

**Table 1. Definition of ratings used in our study**

R&I Rating	Rating in this study	R&I Rating	Rating in this study
AAA AA+ AA AA-	Over AA	BB+ BB BB- B+ B B- Under CCC	Under BB
A+ A A-	A		
BBB+ BBB BBB-	BBB		

**Table 2. The number of firms contained in each rating**

RATINGS	Number of firms	Ratio
AA	77	11.81%
A	201	30.83%
BBB	269	41.26%
BB	105	16.10%
Total	652	100. 00%

In this study, the parameters are estimated in each model by the best-subset selection method because it is very difficult to find the optimum combination and significant parameters effectively based on the normal variable choice method such as a stepwise algorithm. In the process of parameter estimation, twenty combinations of the initial value are generated for each parameter and the parameters are estimated by the maximum likelihood estimation method based on the initial value. In addition, the combination of parameters that minimizes the AIC and log-likelihood value are adopted as an optimum solution in each model.

The result of parameter estimation is shown in Table 3.

Table 3. Results of parameter estimates

Parameter	Normal Ordered Logit Model	t-value	Non-Compensatory Model (Conjunctive)	t-value	Non-Compensatory Model (Disjunctive)	t-value
$\beta_a$	1.782606	(16.145115)	2.304864	(10.782407)	3.102075	(7.513552)
$\beta_b$	1.703725	(1.500131)	-	-	-	-
$\beta_c$	-1.558375	(-3.405277)	-	-	-	-
$\beta_d$	-2.992869	(-2.756496)	-	-	-	-
$\beta_e$	8.349215	(8.041677)	11.123563	(10.072548)	20.005778	(8.599619)
$\beta_f$	-1.109246	(-4.757166)	-	-	-	-
$T_{aa}$	35.050708	(15.748833)				
$T_a$	31.355626	(14.957315)				
$T_{bbb}$	27.365669	(13.782615)				
$T_{a_{aa}}$			19.151688	(12.323935)	20.204592	(7.714131)
$T_{a_a}$			17.046034	(11.015636)	18.804618	(7.528707)
$T_{a_{bbb}}$			16.399593	(10.097468)	16.709588	(7.489304)
$T_{e_{aa}}$			0.650819	(7.241521)	1.064664	(0.022608)
$T_{e_a}$			0.478657	(9.869452)	0.187891	(7.278373)
$T_{e_{bbb}}$			0.066425	(0.851711)	0.042501	(3.267568)
Log-Likelihood	-494.490689		-467.330704		-543.979679	
AIC	1006.981379		950.661409		1103.959358	
Hitting ratio	65.48%		68.87%		59.82%	

Note: Based on the estimated parameters, the probability of a firm belonging to each rating is forecasted. If the result of forecasting and the actual rating corresponds perfectly, we regard that as a successful forecast.

The meaning of suffix  $x$  in  $\beta_x$  is and  $T_{x,y}$  is as follows.  $a$ -> log-transformed net asset,  $b$ -> total capitalization ratio,  $c$ -> ratio of fixed assets to long-term capital,  $d$ -> capital adequacy ratio,  $e$ -> retained earnings ratio,  $f$ -> dead capacity ratio, and suffix  $y$  in  $T_{x,y}$  means ratings.

## 5 RESULTS AND DISCUSSION

### 5.1 Findings

The statistical models studied in the preceding study, especially the ordered logit model has been used in the academic field of credit ratings, consumer's choice behavior etc., as a way to classify sample data into one of the ordered plural statuses. Preceding models are built based on a so-called linearly linked ordered logit model based on the compensatory rule, in which weighted explanatory variables used in the model are linearly linked. As mentioned in the preceding chapter, in the linear model based on the compensatory rule, if there exists a very serious relationship between two particular variables such as capital adequacy ratio and interest-bearing debt, the forecasting power decreases. Moreover, it is likely to happen that if one of the risk factors used in the model has extremely large/small values, a wrong rating evaluation inconsistent with the actual management status will be given to the firms.

Paying attention to each risk factor in the preceding model, it was difficult to know the threshold value among the ratings by each factor. Considering these points, an ordered logit model is proposed based on the

non-compensatory rule in order to overcome these issues in this paper, and the appropriateness of the model is verified by applying actual data to it.

It can be shown that new model proposed in this study can improve all of the log-likelihood, AIC criteria, and the hitting ratio of rating forecasting compared with the ordered logit model. Moreover, regarding the risk factor used in the model, we used all of the risk factors available in the model to optimize the fitness in the preceding model. Whilst on the other hand, it could be shown that we could get a higher fitting degree by using only two kinds of risk factors in the proposed model. The reason for this can be thought to be that in the preceding model, many kinds of risk factors that have a strong correlation to each other are contained in the model. This brings an adverse affect to the model, which as a result, leads to a declined forecasting power.

Furthermore, the result of parameter estimation is considered. Comparing the result of parameters estimated in each model, whilst regarding the identical parameter, the size of each parameter seems to vary among the models. However, the positive/negative sign of the identical parameter matches perfectly. It can therefore be assumed that the parameter estimation was performed accurately.

## 5-2 Future Investigations

Finally, there are issues of this study that require improvement for future work. Generally, when we estimate the parameters in the normal logit model, we can estimate the parameters effectively by using a parameter estimation algorithm such as a stepwise method. However, in this proposed model, the following point still remains where we have to assume two kinds of parameters for one explanatory variable, so that it is impossible to apply the normal stepwise algorithm to the non-compensatory type of model.

This study has adopted the best-subset selection method as the parameter estimation algorithm. However, this method does not always choose the optimal combination patterns of parameters of the model. Moreover, the number of combination patterns of variables increases rapidly and the length of time needed to find the optimum value of the parameters increases as the number of variables used in the model increases.

Regarding our model on the non-compensatory rule, applicability of the model is reported to be very various in the preceding study. For example, it can be used not only for ratings model but also for consumer's choice behavior model in marketing research and traveler's decision making for transformation method in social engineering science, and so on. Academic fields to which statistical model on non-compensatory rule can be applied, should spread rapidly in the near future. Variable choice algorithms such as stepwise, backward, and forward methods are proposed in the study of a linear model based on the compensatory rule. We expect the same type of variable choice algorithm that enables the analysts to use the model easily should be developed in the future.

## Security Alert Management in E-Business Networks

Allan Lam, Pradeep K. Ray

School of Information Systems, Technology and Management,  
University of New South Wales, Sydney, Australia  
p.ray@unsw.edu.au

### ABSTRACT

Security management has become a major concern in today's e-business systems due to ever-increasing attacks on enterprise servers. This has led to the increasing sophistication of network security tools and systems in e-business networks that involve a number of organizational entities cooperating over computer communication networks. Many large organizations are outsourcing the management of e-business networks. This paper examines the problem of security management in the context of an Management Service Provider (an organization that provides remote management of e-business networks). Existing security tools (e.g., Intrusion Detection Systems (IDS)) assist us in detecting attempts by unauthorized users to get access to networked information resources. However, the management of IDSs offers some interesting challenges (e.g., false alerts). This paper presents a policy-based management framework to solve this problem.

**Keywords:** Outsourced IT management, IDS Alerts, Management Service Provider

### 1. INTRODUCTION

E-business systems allow organizations to focus on their core strengths, while outsourcing many aspects of the business to business partners in a value chain. For example, many e-businesses now outsource the management of their IT networks to specialist organizations [7]. The increasing ferocity of cyber-attacks is making organizations think seriously of more and more sophisticated security management solutions. Organizations now have firewalls, anti-virus, authentication, and Intrusion Detection Systems (IDS). However, many of these facilities are either unused, or under-utilised due to problems, such as false alarms in IDS [1]. This paper presents a security management strategy for large e-business networks from the perspective of outsourced management.

The paper is organized as follows. The Section 2 starts with a background of current intrusion detection systems and the need for frequent management interventions. This is followed in Section 3 by our proposed architecture for Security Alert Management (based on management policies) that helps reduce frequent false alarms. Section 4 presents a case study of the implementation of this architecture in a large organization providing management services to e-business networks in the Asia-Pacific region. Finally, Section 5 concludes the paper.

### 2. BACKGROUND

Many network security technologies require regular human intervention in order to receive the best protection. Consider firewalls and intrusion-detection systems (IDSs). Typically, these devices are setup so that they log information to a database. It is then up to the security engineer to analyse these logs and to identify network attacks or suspicious behaviour if, or

while, they are occurring. Unfortunately, this can be very time consuming.

Logs are generated and typically contain information for the following three events:

A packet that is allowed to pass through a firewall.

A packet that is blocked (denied access) at a firewall.

A packet that satisfies one of the signatures in the IDS database.

Thresholding rules are then applied to the above events to generate security alerts. Unfortunately, because they work on data from firewalls and IDSs, they also inherit the major problem with them, e.g., the generation of numerous false positives [2].

This research reported in this paper aims to develop a framework whereby security alerts, in particular false or routine alerts, can be analysed and responded to automatically, saving precious employee time and the employer's money. Routine alerts are those that we wish to appear but which we do not want to analyse. False and routine alerts are composed of many events. Our proposed framework is called Security Alert Management System (SAMS). This is a Policy-based management framework as discussed in [4], [5] and [6].

### 3. SECURITY ALERT MANAGEMENT SYSTEM (SAMS)

SAMS uses the term policy to refer to a particular rule that defines a false or routine alert. Every policy is instantiated from a policy type. A policy type represents a set of policies that possess a similar underlying idea/pattern. For example, consider the following policy types:

- If pattern A appears at least Z% of the time in the alert, then acknowledge this false/routine alert.
- If pattern A appears at least Z% of the time in the

alert, AND if a pattern B appears at least Y% of the time in the alert, then acknowledge this false/routine alert.

Figure 1: SAMS framework

The above policy types can be used to instantiate the following policies:

- If the source IP address 127.0.0.1 appears 90% of the time in the alert, then acknowledge this false/routine alert.
- If the source IP address 127.0.0.1 appears 40% of the time in the alert, AND the destination IP address 234.22.12.120, then acknowledge this false/routine alert.

The policy types then really have no constraints, other than their realisation into code, which will be discussed later.

### 3.1 SAMS Framework

The framework presented in Figure 3 provides a design for the development of a system that analyses security alerts. It is called the Security Alert Management System (SAMS) framework. At a high level of detail, SAMS will wait for an event or trigger to start the alert analysis process. Once this event has been received, the alerts are retrieved from an alerts store. Each alert is then analysed with its corresponding policy, which is determined by the domain that the alert belongs to. Each policy will determine whether or not the alert is a false alert or a routine alert. The policy will also determine what action to carry out based on that analysis.

The simple framework of SAMS reflects the nature of the problem, which is to analyse and respond to security alerts. However, its simplicity hides the powerful inner workings of the policies. The more verbose or complex your false or routine alerts, the more complicated your policies become. As shown in Figure 1, the framework is made up of three main components, the Policy Enforcement System (PES), the Policy Database and the Security Policy Manager (SPM). These will be described in the following three sections.

### 3.2 Policy Enforcement System (PES)

The PES does three things, as shown in Figure 2 with a

triangle:

A) Intercept an event/trigger. This event/trigger can be a mouse click or a timed event and invokes the PES process.

B) When the PES is invoked, alerts are read from whatever format that they are stored as.

C) Each alert, based on its domain is then compared to its corresponding policies found in the policy database. If a policy is found that matches the alert then the action for that alert is automatically carried out.

Figure 2: PES process

The PES 'waits' for the event/trigger to start the process. Upon receiving this, it will 'fetch alerts' from the alerts store. Finally, it will 'get the policies' for this alert from the policy database. The policies that it retrieves are based on the alert domain. The policies are compared to the alerts and if one is found to "match", then the appropriate 'actions' are carried out. The last step is actually a little more involved, which will now be discussed. Recall from the beginning of section 3 that we wish to define different policy types. Each policy type will define a false or routine alert. The PES will actually store the policy type definition, represented as 'Policy Type A' and 'Policy Type B' in the above diagram. The policy database will then store the particulars for the policy type definitions. For example, the PES may have the following as 'Policy Type A':

If pattern A appears at least Z% of the time in the alert, then acknowledge this false/routine alert.

The policy database may then have a table such as the following:

alert_domain	pattern_A	percentage_Z
1	Shellcode.*	90

So if an alert that belongs to the alert\_domain 1 is encountered, then the corresponding pattern (Shellcode.\*) and percentage (90) will be replaced in the policy type. Encountering such an alert will apply this policy to it:

If pattern Shellcode.\* appears at least 90% of the time in the alert, then acknowledge this false/routine alert.

If the alert satisfies this policy, then it will be

acknowledged. Note that the pattern supports regular expressions. By separating the policy type and its specific details, we allow a policy to be applied to various domains and alerts, without producing repetitive policies. As the policy types need to be coded, this also reduces code redundancy.

In summary, the PES has been designed so that it stores the programming logic to analyse alerts. It in fact contains the skeleton of the logic. The remainder of the programming logic is obtained from the policy database. The reason for this separation is that many alerts have similar analysis. For example, many alerts are analysed based on what event occurs the most often. So, instead of replicating the code for this analysis across all domains, we can save disk space and redundancy by storing only the skeleton of the code and storing the finer details in the database. Creating new policy types therefore involve coding them into the PES.

PES is the only component that integrates with a current thresholding system.

### 3.3 Policy Database

This represents the database of policies. As described in the previous section, it will store the details of the policies in a policy table. Each domain is also represented in the Policy Database. This only makes sense since it is natural and easy to link domains with their particular policies via table joins. A schema such as the following can be employed for security alert management systems developed from SAMS (Figure 3).

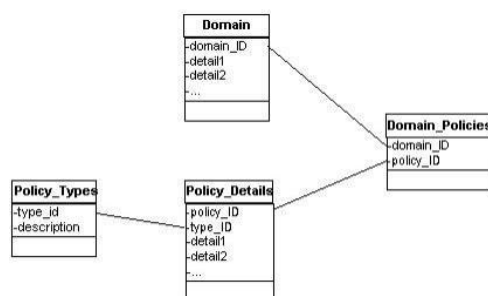

Figure 3: Policy Database schema

The table Domain will contain information about that particular domain. Policy\_Details will contain information about all policies that have been created for the system and Domain\_Policies is a lookup table matching the policies to the particular domains. So to retrieve the details for a particular policy the following query might be performed:

```
select p.detail1, p.detail2 from domain_policies d,
policy_details p where d.domain_ID=1 and
d.policy_ID=p.policy_ID.
```

The attributes returned from the above query can then be substituted into the policy type definition defined in

the PES. The Policy\_Types table helps with this task by associating a policy instance in the table Policy\_Details to the policy type definition in the PES.

### 3.4 Security Policy Manager

The SPM is the GUI management tool that will allow you to manage the Policy Database. It will allow you to enable, disable or edit policies for your defined domains. The SPM will present the information from the database in an easy to read format allowing rapid creation of the policies.

As discussed in the beginning of section , policies are instantiated from policy types. Hence, when we enable a policy, we are actually creating an instance of a policy type. Every instance is created by inserting the details for the policy into the policy database, discussed in the previous section. The policy created is then applied to a selected domain.

When we disable a policy, we are actually removing an instance of the policy from the policy database. This involves removing various rows from the policy database to remove both the policy instance and its association with a particular domain. Note that when we disable a policy, we do not actually remove the policy type definition from the PES. We are only removing an instance of it, which is defined in the policy database.

Editing a policy allows us to edit the details of a policy instance. For example, consider the following policy: If pattern Shellcode.\* appears at least 90% of the time in the alert, then acknowledge this false/routine alert. The user could modify this policy by changing the pattern or changing the percentage value. Note also that editing a policy does not edit the policy type definition. Editing a policy only edits a policy instance. Editing a policy will perform a database 'update' query on the policy\_details table.

Note that whenever a new policy type is created in the PES, the SPM must also be updated so that it recognises it. The SPM must be updated so that one can enable, disable and edit policies based on the new policy type.

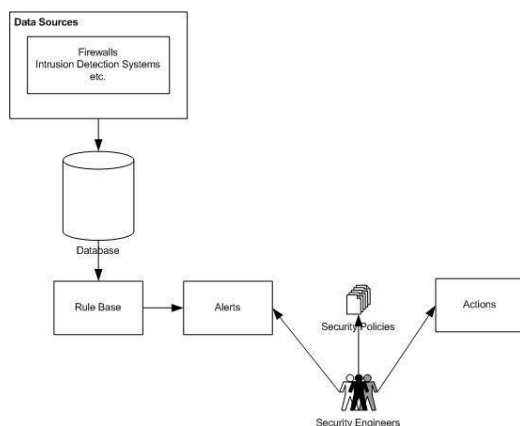

## 4. CASE STUDY

This section will use the SAMS framework to develop a working system. The system will be used on a thresholding system already in place at a company X. The company has asked its name to be withheld. The company is a leading IP networking and communications solutions provider in the Asia-Pacific region.

Of interest to this paper is the organisation's security division. The security engineers, among other tasks,

monitor the alerts from various firewalls and IDSs for various customers. The security division has implemented a thresholding system, which analyses events from firewalls and IDSs and based on predefined thresholding levels will generate alerts. These alerts are displayed to security engineers via an internal intranet web page.

The SAMS framework helps design a system that automatically acknowledges false and routine alerts produced from the thresholding system. According to the engineer, on average it takes one minute to analyse one security alert. On an average day for the organisation's security division, they receive 300 alerts. This means that every day, 300 minutes is used to analyse false alerts. If there are 230 working days per year, that equates to 1150 hours or 143 working days that are spent on analysing alerts.

**Figure 4: Current security architecture of company X**

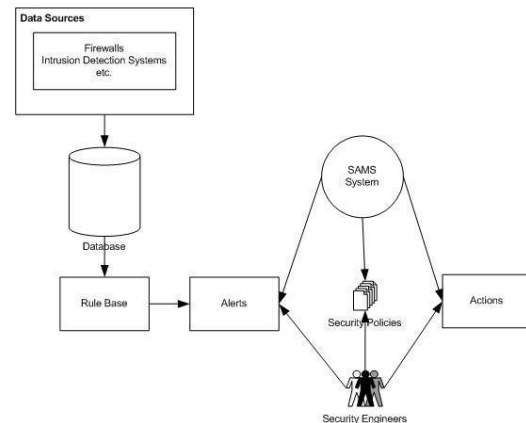

#### 4.1 Current Security Architecture

Before we design a SAMS system, we must first analyse the current architecture to see where it fits in. The following diagram shows the current data flow of the organisation's security division:

The data sources log their events to a PostgreSQL database. The thresholding system rule base then generates the alerts. Security engineers will analyse these alerts and perform the required actions. As indicated Figure 4, the security engineers are actually using policies when they are analysing the alerts. That is, the security engineers are applying certain rules for the analysis that they carry out.

#### 4.2 Design

This Section presents the design of the proposed system based on SAMS (Figure 5). However, we first need to identify how our alerts are being stored.

**Figure 5: Proposed SAMS Architecture**

The PES will therefore perform a similar task. It will read in the alerts from a HTML file and in the case of the organization's thresholding system, the alerts are stored as HTML files. Security engineers analyze alerts by entering an intranet web site. This web site provides the alerts and the events that make up in the alerts in a tabular format. It is then up to the security engineer to analyze these and acknowledge that they have been analysed. PES will only acknowledge the alerts if the policies in its database match the alerts.

The next step is to identify the domains. In the case of thresholding system, these will be the customers. Since the organisation manages customer networks, it is only logical that we distribute policies according to this domain. The existing database already has this information in a table called 'customers'. The schema for this table is as follows:

```
customers(id, name, fullname, heat_id,
gnc_name, speech_name)
```

Hence for our SAMS system we will need to create these tables:

```
policy_details(policy_id, description, ...)
cust_policies(cust_id, policy_id)
policy_types(type_id, description)
```

The full schema of policy\_details will be worked out later.

Our final step is to develop the SPM. Because the existing thresholding system is web-based, the SPM designed here will also be web-based. Similarly, because the existing thresholding system is developed in Perl, our SAMS system will also be developed in Perl.

#### 4.3 Implementation

After discussion with the organisation's security staff, it was determined that the main policy type that should be created first, was one that specified a pattern that was most prevalent. That is, in the analysis of every alert, false and routine alerts tended to have a pattern whereby certain elements would be repeated. As an example of such an alert, refer to the following that has been used throughout this report:

- If pattern Shellcode.\* appears at least 90% of the

time in the alert, then acknowledge this false/routine alert.

This is the first policy type that was coded into PES and which the SPM will recognise. Hence, after this decision was made, the schema for the table `policy_details` is as follows:

`policy_details(policy_id, devicetype_id, type_id, details)`

The important attributes are described here:

- `type_id`: this is a foreign key to the `policy_types` table and associates a policy with its policy type.
- `details`: this will be a string that contains the details for a policy. Since we are implementing the above policy type, this string will contain the pattern to look out for and the percentage that this pattern appears in the alert. More precisely, it will contain what specific details of an alert contain the pattern, what the pattern is and the percentage value.

When the user is creating a policy, they must first select which components of an alert make up the “key”. The key is a combination of the attributes in the above table that the policy type definition will concentrate on when it is analysing it.

The SPM was then designed so that it could properly manipulate the policy database. As mentioned, all development work for this system was done in Perl. The existing thresholding system was developed in Perl, so for compatibility issues, it was logical to select this as the development technology.

#### 4.4 Results

A successful SAMS system was developed on the development network. The following table shows how many alerts could have been automatically acknowledged if the SAMS system was put into production.

Time (for 26 November 2003)	Number of alerts that could have been automatically acknowledged
00:00 to 01:00	6
01:00 to 02:00	3
02:00 to 03:00	3
03:00 to 04:00	3

This is but a four-hour sample of the number of alerts that could have been automatically acknowledged. It would equate to 15 minutes of saved alert analysis time. For another random sample:

Time (for 27 November 2003)	Number of alerts that could have been automatically acknowledged
13:00 to 14:00	7
14:00 to 15:00	9
15:00 to 16:00	5
16:00 to 17:00	6

The above would have saved 27 minutes of alert time. These alerts are all based on the same policy type specified in the previous section. Due to the nature of networks it is hard to predict how many alerts on average could be automatically acknowledged with this policy type. But it is clear from the above samples that significant time can in fact be saved.

Future work will involve the creation of policy chains, introduction of policy priorities and the development of a policy type creator, since with the current framework, it is quite cumbersome to add other policy types. Also it is necessary to integrate the SAMS framework with the network and systems management framework [3].

#### 5. CONCLUSION

In this paper, we have proposed a new framework, called SAMS, for the analysis of security alerts in e-business networks. This framework incorporates foundational concepts in policy-based management to solve the problem of false alerts that threatens to render many security tools (e.g., intrusion detection systems) useless.

The framework that is proposed in this paper is free from many constraints on the policy definitions, unlike in the case of existing management policy frameworks. In fact, policies defined in this framework are constrained by the author’s ability to code them. This is hopefully a first step towards a framework that may become universally used in any system that generates alerts.

The time and money wasted in analysing false and routine alerts is great as proven by our case study figures. A system developed from SAMS can also be viewed as an “engineer-in-a-box”. Because the security engineer is telling the SAMS system what constitutes false/routine alerts, the system is really acting like a security engineer. As a consequence, if the security engineer decides to leave the organization for which he/she works, then the knowledge base of the engineer will be retained.

Such policy-based management frameworks are likely to be used more increasingly for security management in future.

### ABSTRACT

Researchers and academics from diverse disciplines have highlighted the role of 'trust' for establishing and strengthening existing relationships between individuals and organisations in the commercial and the social context. Various models have been proposed which aim to identify both the antecedents and outcomes of trust displayed towards e-commerce Web sites. Increased trust is generally shown to increase positive user attitude, which in turn is believed to increase the intention to buy. Studies have shown the antecedents of trust include variables such as the perceived reputation and size of the vendor organisation. The current paper investigates the role of trust on e-consumers from a cultural perspective. Religious sub-cultures have been targeted as the main study area for this paper's research investigation. Participants recruited from Christian, Muslim and other faiths were asked to interact with online bookstores that identified with a Christian, Muslim or Neutral orientation. Neutral Web sites were those sites classified as devoid of any religious marketing, branding and logos. Trust and attitudes towards the Web sites were measured and this data was used to test the hypothesis that same-religion sites would be found more trustworthy and appealing than other religion or neutral sites. This hypothesis was partially supported, but only for the Muslim participants. It was found that the Muslim group expressed significantly more trust in the Muslim site compared to the Christian site. They also expressed significantly more positive attitudes towards the Muslim online bookstore than the other two sites. The implications of these results for theories of web based trust and attitude are discussed along with the practical implications of the findings.

**Keywords:** Web-based Trust, Web-based Attitude, Culture, Religion

### 1. INTRODUCTION

The continuous growth in internet shopping has incited researchers to investigate the various factors that influence consumer purchase decisions in the web context. Trust is one of the variables which is receiving considerable attention. The lack of trust was often cited as the significant barrier to engage in e-commerce transactions [6,8]. Studies such as Jarvenpaa et al (2000) substantiate the supposition that there is a relationship between trust in an online store and willingness to buy. Other studies have also suggested a number of HCI and organizational factors that could contribute to increased trust in a Web site [6,16,18]. This paper considers the nature of the relationship between culture and trust in the e-commerce context. It asks whether a consumer's cultural affiliation can itself act as an antecedent to trust. The main theme of this study tests the hypothesis that participants will trust and like an e-commerce site affiliated to their own religion more than one affiliated to a different religion or to no religion.

### 2. TRUST IN THE E-COMMERCE CONTEXT

Definitions of trust vary from one context to another. Husted (1989) argues that trust is complicated due to the wide spectrum of approaches that define and describe it.

In general the concept of trust involves a relationship between the trustor and the trustee [12]. A precondition for trust to manifest and become a relevant concept is the presence of risk or uncertainties in a potential decision [10]. Internet purchasing certainly meets this criterion since all transactions in e-Commerce are dealt with remotely. Our research involves studying trust from a one-to-many relationships perspective (for example between an individual and an organisation) since it is this type of trust which an individual consumer holds in a Web-based retail organisation. In recent years a number of researchers have begun to investigate the role of consumer trust in e-commerce purchase decision making and several models have been developed [6,16,19,31]. In such models trust is generally seen as a factor which can affect a consumer's willingness to buy [31]. Jarvenpaa et al (2000) also proposes that this relationship is mediated by attitude (a positive relationship) and risk perception (a negative relationship). An empirical study carried out in a number of different countries corroborates this model [15]. Some researchers focused on identifying the antecedents of trust in e-commerce stores. Kim and Moon (1998) provide empirical results which suggest that the visual components of a Web site (such as color and graphics) can be manipulated to induce trust in Web visitors [18]. Egger's (2002) Model of Trust for

Electronic Commerce (MoTEC) suggests that pre-purchase knowledge (including store reputation), interface properties and informational content (for instance information provided by the store about their policies/guarantees) are all trust-instigating factors [6].

### 3. TRUST AND CULTURE

There are several reasons to assume that culture may be an important factor in on-line trust. Some studies found the ingrained cultural values that form an essential part of the cultural heritage of a person to be influential in evoking an individual's trust [9, 29]. In general, trust in its cultural context is credited with being the social 'glue' for sustaining bonds between members of cultural groups [32,33]. Individuals are more likely to perceive members outside their social circles as more untrustworthy than their in-group members [2].

In a collectivist culture, an individual is regarded as a part of the group that s/he affiliates [9]. Collectivists' behaviour is usually regulated by group norms. Credit or blame is a 'group' responsibility and strong distinctions are made between in-group and out-group members. This is in contrast to individualist cultures where the distinction between in-group and out-group members often overlaps or is altogether non-existent [36]. Further, collectivists value homogeneity within in-groups [32]. Thus, they are more willing to trust individuals and sub-groups within the same culture (in-group trust). In this research, we have chosen to explore the role of membership in a collectivist culture in the formation of trust in online stores. As has been mentioned earlier, members of a collectivist culture assign a higher level of trust to others from the same in-group than to those from outside. The question we address is whether this effect also applies to interactions with an interface, particularly a Web-based electronic commerce interface. In order to explore the proposed relationship between trust and culture, we needed to identify participants from collectivist cultures and have chosen religious identification to classify our cultural in-groups (religious sub-cultures). According to Iannaccone (1995), Islam, Judaism and Christianity share the traits of a collectivist culture. Devout followers of such religions are expected to abide by the rules set by their religious doctrines, for example, being strictly committed to the religious practices and membership of the group [13,27,28]. Membership of a collectivist religion thus provides a good example of where in-group trust should be present. We have selected the collectivist religions of Christianity and Islam in our research. Using two collectivist religions enables us to test the generalizability of any effects found.

#### 3.1 Research hypotheses

On the basis of the discussion above we propose the following research hypotheses:

*H1: Members of a collectivist religion will trust a same-religion web-site more than a neutral web-site or other religion web-site.*

This hypothesis can be rephrased more specifically according to the religious groups used in this study, thus:

*H1a: Members of the Muslim religion will trust a Muslim web-site more than a neutral web-site or other religion web-site.*

*H1b: Members of the Christian religion will trust a Christian web-site more than a neutral web-site or other religion web-site.*

*H2: Members of a collectivist religion will express more positive attitudes towards a same-religion web-site than a neutral web-site or other religion web-site.*

Again this hypothesis can be rephrased more specifically as:

*H2a: Members of the Muslim religion will express more positive attitudes towards a Muslim web-site than a neutral web-site or other religion web-site.*

*H2b: Members of the Christian religion will express more positive attitudes towards a Christian web-site than a neutral web-site or other religion web-site.*

Note that H2 follows from H1, since theories of trust suggest that trust is related to attitude. The following sections describe the research which was followed in order to investigate these hypotheses. Note that the scope of this research is confined to initial trust attitude formation.

### 4. EMPIRICAL WORK

An empirical study with 91 participants was conducted to explore the relationship between religious identification and trust in on-line stores. The experimental task involved participants interacting with religious or neutral e-commerce book stores. Questionnaire responses were used to measure the main dependent variables of web-based trust and web-based attitude. A separate questionnaire was used to measure demographic characteristics of the sample together with the extent of their religious affiliation and web experience.

#### 4.1 Construct measurement

A number of measures were developed and used in this research. Where measures were developed from scratch, we followed the procedure recommended by DeVellis (1991) and Bearden and Netemeyer (1999) for the development of psychological and latent construct measures which involved piloting an initial 'pool' of items drawn from the literature that are meant to represent the constructs. The Likert and categorical scaling procedures were used for developing the constituent items of the constructs following the guidelines provided by Zikmund (1977). To counter for

the response set of acquiescence, we reversed the Likert scale rating and the direction of the wording of some items [5]. The resulting items were tested in a pilot trial (involving 50 participants) and some items were reworded to remove ambiguities identified during this trial. It had been argued that the convergent loadings of items on a separate factor is a trait of construct validity [1,5] and that in general, factors extracted from a factor

analysis are assumed to represent the validity of the underlying latent constructs being investigated in a research study [5]. We have therefore performed a factor analysis on the constituent items representing the different constructs to see if they are valid. Cronbach's Alpha is used as a measure of the internal consistency of each scale used. A Cronbach's Alpha values of 0.80 or more are generally required for widely used scales [14]

**TABLE 1.** Characteristics of the sample cross-tabulated against religion (N = 91).

	Christian (%)	Muslim (%)	Others (%)	Total within Sample (%)
<b>Gender</b>				
Male	62	79	50	65.9
Female	38	21	50	34
<b>Ethnicity</b>				
Arab	0	29	0	12.1
Asian (Other)	3	8	17	8.8
Bangladeshi	0	3	0	1.1
Black African	3	3	0	2.2
Caucasian	3	0	0	1.1
Chinese	0	0	25	6.6
European/White	83	8	21	35.2
Hispanic	3	0	0	1.1
Indian	0	3	34	9.9
Kurdish	0	3	0	1.1
Mauritian	3	0	0	1.1
Pakistani	0	39	0	16.5
Persian	0	5	0	2.2
Srilankan	0	0	4	1.1
<b>Usage of Internet</b>				
< 6 months	0	0	0	0
1 year	10	3	4	5.5
2-3 years	28	39	30	33
> 3 years	62	58	68	61.6

#### 4.1.1 Dependent variables

Measures of web-based trust and web-based attitude were developed following the procedure described above. Several literature sources from different disciplines were consulted in the development of the constituent items of web-based trust [3,4,7,17,21,23,25,34] and Web-based attitude [11,22,24]. Following the pilot study a final version of the questionnaire was produced with items representing 'web-based trust', 'web-based attitude' and the 'intention to buy' from an online store.

The web-based trust (Cronbach's Alpha = 0.88) and web-based attitude (Cronbach's Alpha = 0.93) constructs were both reliable. The Intention-to-buy

loaded on the web-based attitude factor and was therefore included within this general attitude measure. There was a significant correlation ( $p < 0.05$ ) between the scores on the measures of web-based trust and web-based attitude which lends ground to models that posit on-line trust to be an antecedent to attitude and willingness to buy [16].

#### 4.1.2 Demographic variables

Several categorical demographic measures were used including one for the independent variable of religious identification (Christian, Muslim, none-or-other), as well as gender and ethnicity. In addition a number of demographic scales were used or developed to measure variables that might be expected to be important in the interpretation of the results (e.g. experience in using computers and the internet). We also wanted to establish the extent to which culture affects their general purchasing habits specifically the extent to which participants were inclined to buy from vendors within their own religious group. To measure this construct we adapted the pre-existing consumer ethnocentrism scale or 'CETSCALE' [26] so that it referred to religion rather than ethnicity. We refer to our new measure as the consumer religio-centrism scale (RELSCALE). The validity of the scales was checked through factor analysis and after some modifications the religious commitment scale (Cronbach's Alpha = 0.92) and the RELSCALE (Cronbach's alpha = 0.86) were both found to be reliable.

**TABLE 2:** Mean scores on the religious commitment scale and consumer religio-centrism scale.

Religious identification	Religious Commitment Mean (standard deviation)	Consumer Religio-Centrism Mean (standard deviation)
Christian	2.72 (0.88)	1.39 (0.52)
Muslim	4.11 (0.58)	2.83 (0.77)
None-or-Other Religion	2.15 (0.80)	1.40 (0.42)

## 4.2 Method

### 4.2.1 Experimental design

A pseudo-experimental approach was used in the empirical study. A 3 x 3 mixed-factorial design was used. The naturally occurring variable of religious identification of the participants was used as the between subjects independent variable with three levels: Christian, Muslim and None-or-Other. The religious affiliation displayed by an e-commerce web site was used as the within-subjects independent variable, again with above three levels. The dependent variables were web-based trust and web-based attitude.

We decided to use online bookstores as our 'testbed' sites since this category of purchase has been the focus of a number of other studies [15]. We were also able to find web sites within this category which were clearly affiliated to particular religions. The use of real web sites increases the ecological validity of the results.

Our hypotheses were directly tested through the inclusion of the Christian and Muslim groups of participants. However, since we were not able to control for all of the features of the web sites used, we also included a control group of participants, not affiliated to either of the target religions. This allowed us a means to check for the role of extraneous (non-cultural) variables. If the pattern of responses for all three groups across the three web sites were similar it would suggest that the results could be explained by non-cultural factors alone. If they vary by religious identification for the religious groups, and this pattern differs from that observed for the non-affiliated participants, we have stronger grounds for attributing the findings to the effects of culture.

### 4.2.2 Participants

Participants in this study were recruited from within the student population at Brunel University, West London, UK. This population was chosen since it is culturally diverse and generally experienced in using the web.

Ninety one participants took part in the study. Among them, 29 were categorised as Christian, 38 as Muslim and 24 as None-or-Other religion. Their demographic characteristics and web experience are summarised in Table 1 (see previous page).

The data indicate that the majority of participants within all religious categories are experienced web users.

However, there are large gender differences between the religious groups; nearly 80% of the Muslim sample are male compared to 62% in the Christian sample and 50% in the no-or-other religion group.

Mean scores on the religious commitment scale and consumer religio-centrism scale are shown in Table 2. The Muslim participants in our sample appear to be more strongly committed to their religion than the participants in the other groups, they also appear to be more consumer religio-centric than participants in the other groups. These differences were tested using the Krustal-Wallis test (this non-parametric alternative to one-way ANOVA was used since the assumption of homogeneity of variance was not met for these data sets). It was found that religious commitment varied with religious identification in our sample (Chi-Square(2) = 52.2,  $p < 0.001$ ). Post hoc Mann Whitney tests confirmed that there are significant differences between the Muslim participants and Christian participants ( $U=111$ ,  $p < 0.001$ ), and between the Muslim and the None-or-Other religion participants ( $U=24.5$ ,  $p < 0.001$ ). There was also a significant difference between the Christian and the None-or-Other participants ( $U=222.5$ ,  $p < 0.05$ ). It was also found that consumer religio-centrism varies with religious identification in our sample (Chi-Square(2)=51.7,  $p < 0.001$ ). The significant differences are between the Muslim participants and Christian participants ( $U=69.5$ ,  $p < 0.001$ ), and between the Muslim and the None-or-Other religion participants ( $U=49.5$ ,  $p < 0.001$ ).

### 4.2.3 Procedure and experimental tasks

All experimental tasks during this study were performed in a laboratory at Brunel University to control for any effects due to physical location. Each participant interacted with three Web sites; a same-religion site, a different-religion site and a neutral site. The neutral site in both cases was [www.bol.com](http://www.bol.com). The same-religion site for the Muslim participants was [www.dar-us-salam.com](http://www.dar-us-salam.com) (the other-religion site for Christian participants); for Christian participants the same-religion site was [www.christianbooks.com](http://www.christianbooks.com) (the other-religion site for the Muslim participants). They were asked to explore each web site for approximately 20 minutes before filling out a questionnaire based on their experience of it. Following completion of this part of the study, participants were asked to complete the demographic questionnaire.

### 4.3 Results

#### 4.3.1 Results for web-based trust

The mean ratings of Web-based trust for each site by each group of participants are summarised in Table 3. A 3 x 3 mixed-factorial analysis of covariance was performed on ratings of web-based trust (see Table 4). The within-subjects independent variable consisted of displayed religion of the web-site. The between-subjects independent variable was religious identification of the participant. Gender was used as a covariate to remove effects due to the uneven distribution of gender of the sample. Analyses were performed by SPSS using type III adjustment for unequal sample size. After adjustments by the covariate, a significant multivariate main effect was observed with  $F(2, 86) = 3.67, p < 0.05$ . There was also a significant interaction effect with religious identification of the participant ( $F(4, 86) =$

5.15,  $p < 0.05$ ). A test of the within-subjects effects showed a significant main effect of site religion ( $F(1, 87) = 6.75, p < 0.05$ ) and a significant interaction effect between site religion and religious identification ( $F(2, 87) = 6.0, p < 0.05$ ). There were no significant between-subjects effects. Planned comparisons were conducted for the Muslim and Christian portion of the sample to test Hypotheses H1a and H2b that in-group members of a religion will trust their own religion Web-site more than a neutral or other religion web-site. It was found that the Muslim participants did express significantly more trust in the Muslim book site compared to the Christian book site ( $t(37) = -2.74, p < 0.05$ ), however there was no significant difference between the mean trust rating for the Muslim site and the Neutral site. No significant differences were found in the Christian sub-sample so we cannot reject the null hypothesis.

TABLE 3: Mean ratings of web-based trust.

Participant religious identification	Site Religion:		
	Christian	Muslim	Neutral
Christian	3.49 (s.d. 1.04)	3.21 (s.d. 1.03)	3.49 (s.d. 0.86)
Muslim	3.18 (s.d. 0.88)	3.62 (s.d. 0.78)	3.39 (s.d. 0.80)
None-or-Other	3.44 (s.d. 0.75)	3.06 (s.d. 0.54)	3.60 (s.d. 0.85)

TABLE 4: Analysis of covariance of web-based trust.

Source	Sum of Squares	df	Mean Square	F	Sig.
Site religion	8.572	1	8.572	16.906	$p < 0.001$
Site religion x gender	3.112	1	3.112	6.138	n.s.
Site religion x religious identification	42.309	2	21.154	41.721	$p < 0.001$
Error (site)	44.113	87	0.507		

#### 4.3.2 Results for web-based attitude

The mean ratings of Web-based attitude for each site by each group of participants are summarised in Table 5. A 3 x 3 mixed-factorial analysis of covariance was performed on ratings of attitude toward the web sites (see Table 6). The within-subjects independent variable consisted of displayed religion of the web-site. The between-subjects independent variable was religious identification of the participant. The covariate was gender. Analyses were again performed using type III adjustment for unequal sample size. After adjustments by the covariate, a significant multivariate main effect was observed with  $F(2, 86) = 10.65, p < 0.001$ . There

was also a significant interaction effect with religious identification of the participant ( $F(4, 86) = 5.65, p < 0.001$ ). A test of the within-subjects effects showed a significant main effect of site religion ( $F(1, 87) = 13.57, p < 0.001$ ) and a significant interaction effect between site religion and religious identification ( $F(2, 87) = 11.64, p < 0.001$ ). There were no significant between-subjects effects. Within-subjects planned comparisons were conducted with the Muslim and Christian portion of the sample to test hypothesis H2a and H2b that in-group members of a religion would express more positive attitude towards their own religion site compared to another religion site or a neutral site. It was found that the Muslim participants did express

significantly more positive attitudes towards the Muslim site compared to either the Christian site ( $t(37) = -7.752$ ,  $p < 0.001$ ) or the Neutral site ( $t(37) = -2.13$ ,  $p < 0.05$ ).

For the Christian portion, a significant difference was found between attitude towards the Christian site and the Neutral site, but this was in the opposite direction to that predicted, with the neutral site being preferred over the Christian site ( $t(28) = -4.37$ ,  $p < 0.001$ ). No significant difference was found between attitude towards the Christian and the Muslim sites.

## 5. DISCUSSION AND CONCLUSIONS

The global nature of the internet allows e-commerce stores to market around the world. Within this context it is important for web retailers to understand how aspects of their sites may help to engender trust and positive attitude within members of particular cultural groups. The current paper has explored the role which consumer cultural identification plays in the initial formation of trust and attitude towards Web-based stores which display culture-specific characteristics.

The main contribution of this paper is to show that trust and attitude in a web-based retailer can vary with culture, at least as represented by affiliation to a religion. Within one collectivist culture, identification with the Muslim religion, we have shown that in-group trust effects can transfer to the web context. Muslims in our study were found to be more trusting of a Muslim site compared to a Christian site (though not compared to the Neutral site). Muslim participants also liked the Muslim site more than the neutral and the Christian site. Since the attitude construct used in this study is closely related to willingness to buy, this finding suggests that this group would be more likely to buy from the Muslim site than the other two sites tested.

However, the hypothesised relationship between trust and religious identification was not supported by the Christian participants. The Christian portion liked the neutral site better than the Christian site. Overall the pattern of responses given by the Christians was similar to those given by the None-or-Other religion group. This could imply that Christians do not use religious distinctions in forming their initial trust and attitude towards a web site. In the absence of culture effects we would expect large and reputable stores (such as Bol.com) to be trusted and liked better by participants [15].

The lack of predicted effects with the Christian sample calls into question the generalisability of the findings with the Muslim sample to other collectivist religions. However, a potential explanation for the different results between the Christian and Muslim samples can be attributed to the scores of these two groups on the religious commitment scale which differed significantly, so may be the Christians in our sample were not

“devout” Christians. Interestingly the Muslim and Christian participants also differed significantly in terms of how much they said religion affected their general purchasing decisions (as measured by the RELSCALE). This supports the idea that the effects we have observed in our experiment may demonstrate a transfer of in-group attitudes from the general to the web context.

### 5.1 Limitations and future work

There are a number of limitations that were identified during the course of this research study. One prominent issue was that we have assumed the existence of homogeneity within the religious groups. However, both Christianity and Islam have experienced profound schisms that resulted in the inception of several religious factions such as Roman Catholics and Eastern Orthodox in Christianity, and the Sunni and Shia sects in Islam [9]; Future work could address this issue by concentrating on specific religious sects, though the practical applicability of such research might be limited. Other avenues for future research include investigating online religious trust relationships for religious subgroups in (1) individualistic societies (e.g. US) and (2) in situations of high-risk purchase decisions (e.g. books) versus low-risk purchase decisions (e.g. cars) [20].
