### ABSTRACT

How do we develop and sustain trust? What is the process for building trust between business partners in virtual environments? Is there a significant difference between the development and sustainability of trust online or offline? In this paper, we first introduce the concept of e-business and discuss the importance of trust for ensuring effective collaboration. Secondly, we discuss the relationships between e-collaboration and trust for managing e-business. Thirdly, we suggest a framework, which may help facilitate the development and sustainability of trust in an online environment. Finally, implications for the development and sustainability of trust online, which can be used to understand the interplay among technologies, e-business and collaboration is provided. We suggest that the implications of this study are three-fold: trustworthy relationships among business partners, effective sustainable collaboration, and optimal use of ICT for supporting e-business activities.

**Keywords:** Trust, Social exchange, Collaboration, e-Business

### 1. INTRODUCTION

In general, e-business refer to the use of Internet technologies for support activities such as buying, selling products and services, as well as collaboration with business partners. We first highlight that e-business is not a synonym for e-commerce. E-business refers to an organization's capability to electronically connect with their partners for exchanging values such as knowledge, products and services (Venkatraman and Henderson, 1998; Hackbarth and Kettinger, 2000; Fahey, et al., 2001; Flurry and Vicknair, 2001; and Davis and Ritsko, 2001). Exchanging values with business partners requires collaboration. Therefore, collaboration with business partners is increasingly seen as a critical aspect of e-business management (Davis and Ritsko, 2001; Sairamesh et al 2002; Lechner and Hummel, 2002; Alt and Fleisch, 2001). Hackbarth and Kettinger (2000) further highlight that e-business should address issues such as human performance within the organization and also in an inter-organizational network. Therefore, understanding the exchange relationships among buyer, suppliers and trading partners is seen central for e-business management (Markus et al 2000). We argue that the management of e-business requires understanding strategies for building effective collaboration, and ensuring the optimal use of Internet infrastructure for supporting the sharing of knowledge among buyers, suppliers and trading partners. We suggest that for an e-business to be successful, an effective collaboration must exist among different participating business partners. Therefore, the design of the e-business systems should be based on a framework, which facilitates the development and sustainability of collaboration among business partners.

We emphasize that collaboration is essentially a social phenomenon and is regarded as a complex issue. IT is there to support the flow of effective sharing only when the partners have adequate level of trust so that they can start to collaborate with each other. We suggest that a low level of trust may lead to a lower level of IT utilization for supporting collaboration and higher level of trust between business partners would lead to a higher level of collaboration so that the use and utility of IT can be maximized. So, why is collaboration a complex social phenomenon? How do we build an effective collaborative culture so that the use and utility of IT can be maximized? Here, we present a casual model, which can serve as a basis for the management of e-business activities and also to ensure the utilization of ICT for supporting the relationships among business partners. Discussions of the interrelationships of different variables and their dependency are presented in the forthcoming section.

The focus of this study is on understanding the relationships among the use of Internet technologies, the degree of collaboration and its social context for the management of e-business activities. In the next section, we suggest the importance of collaboration in managing e-business activities. We further discuss the complexity of collaboration and in particular, e-collaboration for managing e-business activities. We apply social exchange theory to develop an understanding of the phenomenon referred as social exchange on-line. Here, trust is considered to be the key antecedent and discussed in relation to supporting effective collaboration. We conclude that social exchange theory can be applied to further our understanding of how structure can be used in facilitating the development and sustainability of trust.

Finally, a framework for the development and sustainability of trust on-line is provided.

## 2. SUPPORTING COLLABORATION THROUGH ICT

Collaboration, in its traditional sense, is the collective interaction between multiple parties. Rapid advances in technology along with globalization provides opportunities and challenges for businesses to establish collaborative relationships with suppliers and customers so that they can enhance competitiveness and lower costs (Karsten, 1999). In e-business terms, collaboration connects all the parties involved in the process, which enables information-sharing. This facilitates structured and controlled interactions through proper channel-connectivity, electronic information and workflow. Connectivity provides the core network for interaction. These network systems not only eliminate regional, inter-departmental and intra-enterprise barriers, but they also bring together a network of people around specific processes. Collaboration tools such as the TeamSCOPE system trail is proven to be effective Team Software for a geographically dispersed collaborative project environment (Steinfeld et al., 1999). TeamSCOPE, a web-based trail system provides each team with a team-shared file repository, which makes it easy to users to store and exchange group-related files.

Once connectivity is established, the next major aspect is sharing information because electronic information acts as the lifeblood of collaboration in organization. For example, previous studies suggest that the collaborative culture is an essential prerequisite successful use of IT for supporting sharing (Orlikowski, 1993; Bowers, 1994; and Gallivan et al., 1993). We suggest that three core elements—connectivity, electronic information and workflow make e-business collaboration a very powerful way of bringing a group of people together to interact and communicate efficiently. In this regard, Vandenbosch and Ginzberg (1997) further suggest that organizations must first meet four basic conditions in order for the implementation of IT to support effective collaboration. The first is the organizational members need to collaborate. The second is the understanding of IT and its use in supporting collaboration. The third is the organizational support for the adoption, implementation, and continued use of the technology. The fourth is the organizational culture that supports collaboration.

The purpose of collaborative workspace is to provide a structure or framework, which allows its user to achieve and understand its purpose (Chin et al., 2002). In addition, it should support the users to adapt and follow conventions for its use. The behavior of a collaborative workspace must be controllable and support the orientation of the members in the workspace and in the cooperation process. We suggest that the development of collaborative workspace requires a high level of attention

to the basic principles of organizational design such as—(i) the connection between the design of e-business and the elements of the social world leads to effective collaboration; (ii) components must be designed in ways that work against the strong tendency towards entropy; and (iii) open access leads to higher collaboration. This can be supported by the case of combustion researchers collaborating over the Internet (see Pancerella et al., 1999) where effective collaboration was achieved through the application of principles of organizational design presented above. We suggest that the effective use of IT for supporting collaboration requires frameworks/models as a guiding principle so that individuals and groups in an organization or inter-organizational network can work effectively and efficiently. We discuss this further by focusing on two popular collaboration models—the *contract* model (Wachter and Reuter, 1992) and the *consortium* model (Kouramajian et al., 1995) and suggest a rich framework called *social exchange* perspective to further understand the social aspect related to effective collaboration for e-business activities.

Collaboration for information sharing and knowledge management is increasingly becoming possible through the introduction of network computing (Kouramajian et al. 1995). Kouramajian et al. (1995) further suggest that the *consortium* provides a flexible framework for defining collaborative transactions. Contrary to this, a *contract* model is designed to provide a programming environment for long-lived transactions between parties concerned (Wachter and Reuter, 1992). Studies suggest that interaction under the *contract* model is rather tightly constrained tightly to collaborative tools and may severely restrict collaboration among users (Wachter and Reuter, 1992; Kouramajian et al., 1995). The *consortium*, on the other hand, consists of both the structural and the behavioral models and provides a new way for collaborative interaction (for example, What You See Is What You Want-WYSIWY). The structural model is based on the assumption that a large collaborative task can involve multiple phases or sessions and different phases may have different participants. In addition, the behavioral model defines mechanisms for specific collaborative actions. Therefore, two main abstractions—sessions and transactions are integral parts of the consortium framework for supporting e-collaboration. Here, a session provides a convenient abstraction for a collective action. Further, an ordered set of sessions where the owner specifies the order is regarded as part of transactions.

However, these models do not provide an adequate background for understanding the implications of trust as a social factor for the effective utilization of IT in an e-collaborative environment. For example, work by Malone et al. (1987) and Clemons et al. (1993) focused primarily on IT as a means for reducing inter-organizational transaction cost, without taking social factors such as trust and its implications in reducing

transaction costs in inter-organizational systems (Kumar et al., 1998). In the information systems literature, the development and sustainability of trust for managing virtual collaborative relationship is increasingly seen important for ensuring the optimal use of IT for supporting e-business activities (Whittaker, 1996; Hoffman et al., 1999; Jones et al., 2000; Ratnasingham and Kumar, 2000; Ono et al., 2001; Nayak et al., 2001; Kasper-Fuehrer et al., 2001). Recent studies on the use of computer-mediated communication tools for supporting trust building in an on-line environment suggest that audio and video technologies have the potential to be as effective as face-to-face communication as long as the design of systems is guided by the social process in place (Bos et al., 2002). In line with these we suggest the following propositions:

*Proposition 1:*

Higher collaboration relates to optimal use of ICT for supporting e-business.

*Proposition 2:*

There is no direct relationship between the level of collaboration and level of ICT use for supporting e-business activities.

*Proposition 3:*

Sessions and transactions are directly related to higher level of collaboration.

### 3. UNDERSTANDING THE RELATIONSHIPS BETWEEN TRUST AND COLLABORATION

Hosmer (1995) suggests that trust deals with the expectation by one person, group, or firm of ethical behavior which is morally right decisions and actions based upon ethical principles of analysis on the part of the other person or part in an exchange. Therefore, ensuring successful business transactions and cooperative work requires a high level of attention to the development and sustainability of trust (Josang, 1996; Nelson and Coopridge, 1996; Sheppard and Tuchinsky, 1996; Swagerman et al., 2000; Wigand, 1978). Trust can also be based upon the rational appraisal of a partner's reliability and competence, and upon feelings of concern and attraction. These factors may help to reduce awkwardness, complexity and uncertainty in social interactions and therefore, make the collaboration effective.

A study by Ratnasingham and Kumar (2000) suggest that trust and interpersonal relationships are essential elements for understanding the role of communication media in collaborative work. Collaboration is seen as most effective and rewarding when the participants trust each other (Axelrod, 1997). We suggest that two types of activities--*cognitive and emotional* faculties must be established for developing trust. Cognitive-oriented activities may convey competence and reliability, and thereby increase confidence that a task will be

successfully completed. Emotion-oriented activities can create an emotional bond, and help decrease fears of exploitation and increase feelings of mutual support for building trust.

Recent studies on interorganizational networks, virtual organizations and the long-term sustainability of virtual collaboration suggest that trust is critical so that the IT infrastructure can be leveraged optimally to support the exchange among business partners (Josang, 1996; Whittaker, 1996; Bandow, 1998; Staples and Ratnasingham, 1998; Karahannas and Jones, 1999; Ratnasingham and Kumar, 2000; McKinght et al. 2000; Kasper-Fuehrer et al., 2001; Nayak et al., 2001; Ono et al., 2001; Bos et al., 2002; Gefen, 2002). We argue here that the development and sustainability of trust in an on-line or virtual environment requires an understanding of the social exchange systems in which individuals, groups or organizations operate. This is important as effective collaboration is seen to be largely dependent on the trust relations among different interest groups (Abdul-Rahman and Hailes, 1997).

It is therefore suggested that there is a direct relationship between the success of e-business and the embedded social exchange systems under which individuals, groups or organizations operate. We argue that this social exchange system helps building a collaborative and sharing culture in organizations. Chadwick-Jones (1976) also suggests that the level of social exchange is dependent on trust. Blau (1964) highlights that distrust is expected in economic relations but have a negative impact on social behavior. Thibaut and Kelley (1959) and Blau (1964) further suggest that building trust is a gradual process, which requires a cumulative commitment to a relationship. For example, the Prisoner's Dilemma game illustrates the problems associated with building trust. In this game, the participants are given choices between only two alternatives—(i) sharing the outcomes equally with another person or (ii) try to maximize his/her own gains at the expense of the other. On the basis of the aforementioned discussion, we suggest the following propositions related to collaboration and trust:

*Proposition 4:*

Higher levels of trust lead to higher collaboration among business partners.

*Proposition 5:*

Lack of trust or, conversely, higher levels of distrust lead to a lower level of collaboration among business partners.

*Proposition 6:*

High competency and reliability of business partners lead to high degree of trust.

*Proposition 7:*

There is no direct relationship between the level of competency and reliability of business partner for developing the level of trust.

Therefore, common business goals or a shared vision is considered to be a prerequisite for ensuring the optimal use of IT systems for supporting information exchange and knowledge sharing among business partners in an inter-organizational network (Wigand et al., 1997; Wigand, 1977; Scott and Lane, 2000). We suggest that the social exchange perspective presented below provides a useful mechanism for understanding the complex process of building trust such that higher collaboration among business partners may be achieved. Moreover, embedded in the social exchange perspective is a social control mechanisms that mutually regulates exploitive and opportunistic behavior (such as suggested in the Prisoner's Dilemma discussion above). This may in fact reduce uncertainty by guarding against opportunistic behavior among participating members (Fichman, 1997; Wicks et al., 1999; Grambowski and Roberts, 1999).

It follows then to ask, how do we build and sustain trust through social exchange? It is evident from the previous studies on ICT, trust and collaboration that understanding social exchange systems is a powerful mechanism for developing an understanding of the development and sustainability of trust among the business partners. Bandow (1998) suggests the importance for exploring strategies for developing trust in virtual environment, which is now a reality due to increasing use of IT in the work place. This deserves careful attention as IT may be used to allow or support work in separate locations, the relationships with others in their groups are not the same due to the reduced or non existent of face-to-face contact. A recent empirical study of the effectiveness of computer mediated communication channels of trust development suggest that video and audio conferencing groups are nearly as good as face-to-face (Bos et al., 2002). However, the use of IT such as video and audio for building trust is considered to be a slower progress towards a full cooperation and vulnerable to opportunistic behavior (Das and Teng, 1998).

#### 4. TRUST THROUGH SOCIAL EXCHANGE

Rapoport and Guyer (1966) suggest seventy-eight forms of two-person games where the mixed-motive can be the impediments for building trust. This Prisoner's Dilemma design originated from the anecdote about the two persons arrested on suspicion of committing a crime (Chadwick-Jones, 1976). Here, two suspects are taken into custody and separated with an assumption that they are guilty of a specific crime (Luce and Raiffa, 1957). However, the district attorney does not have enough evidence against the suspects so that they can be convicted at a trial. Therefore, the district attorney suggests two alternatives to each prisoner—(i) to confess to the crime or (ii) not to confess. Table 1 provides an example of the Prisoner's Dilemma game. It is suggested in the dilemma matrix presented below that the first entry in each cell below represents the choice (and payoff) for

Prisoner A and the second entry represents the outcome for Prisoner B.

		Prisoner B
Prisoner A	Not Confess	Not Confess C, C 1 year, 1 year (Cooperate, Cooperate)
	Confess	Confess C, D 9 years, 2 months (Sucker, Temptation)
Prisoner A	Not Confess	D, C 2 months, 9 years (Temptation, Sucker)
	Confess	D, D 6 years, 6 years (Defect, Defect)

**Table 1. An example of the Prisoner's Dilemma game**  
(Chadwick-Jones, 1976)

Therefore, both A and B receive one year of imprisonment in the cooperation cell and in the joint defection option both receive several years. However, in the temptation cell, Prisoner A gets off with only two months, whereas Prisoner B refusing to confess, receives the worst type of sentence (the sucker option). In this game, the player A and B may decide to cooperate or may decide to go for 'temptation cell' for gaining more for one. An intention to gain more for one may lead to 'defecting' from the cooperative option to a competitive one. The danger behind moving from cooperation to competition is the loss of trust, which may lead to distrust between A or B. We suggest that the higher the level of distrust between individuals or parties, the lesser the level of collaboration. It is also suggested in the social psychology literature that the higher-level distrust may lead to defensive behavior and both parties may lose sustainable collaboration (Chadwick-Jones, 1976).

We suggest that understanding the dynamics of reciprocity and imbalance is important for the trust building process, which in fact would ensure higher levels of collaboration. Blau (1964) was interested in understanding the complexity of attracting individuals to a relationship and suggested that one may be attracted by intrinsic or by extrinsic benefits. Table 2 below provides an illustration of Blau's (1964) view of relationship formation. Here, a distinction between reciprocal and unilateral transactions is drawn. Blau (1964) further argued that the distinction between reciprocal and unilateral transactions suggest a dynamic force, which transforms a social process simple into an increasingly complex one.

For example, intrinsic rewards such as love in a reciprocal relationship may suggest mutual attraction and the extrinsic rewards such as advice in carrying out a task or a reciprocal relationship may suggest exchange between individuals or parties involved. Blau (1964) further highlights that the exchange of extrinsic benefits helps sustain the major intrinsic rewards when an association is intrinsically rewarding. Similarly, one-sided attachment is established when intrinsic benefits are part of unilateral relationships. However, in the case

of unilateral extrinsic benefits, power is established because those who cannot reciprocate in kind are obligated to comply with the other person's wishes (Chadwick-Jones, 1976). In line with this, we suggest the following proposition:

*Proposition 8:*

Trust building is dependent on the dynamics of reciprocity and imbalance between business partners.

	Intrinsic	Extrinsic
Reciprocal	Mutual attraction	Exchange
Unilateral	One-sided attachment	Power

**Table 2. Illustration of a two-dimensional distinction among transactions**

From another point of view, norms or agreements are important in trust-building processes as they help avoid uncertainty (Chadwick-Jones, 1976). For example, the study of kingship relations suggest that interpersonal trust reduces one principle source of uncertainty in actual social situations (Anderson, 1971). Anderson (1971) argues that uncertainty in social relationships influences someone to be calculative and also to seek shorter-term returns. The study of kingship relation suggested by Anderson (1971) is based primarily on two assumptions—(i) calculative behavior leads to increased variability in behavior within business partners under the extreme uncertainty in social or kingship relations; and (ii) arrival of calculative orientations in a community may lead to termination of exchange which requires high levels of trust. It is further suggested that the general norms of kingship behavior will be a reality only where communities are highly homogeneous and stable (Anderson, 1971).

Therefore, it may be concluded that social exchange theory is based on the assumption that in order for exchanges of goods and behaviors to take place in an organization, there is a joint activity or transaction, which would involve two or more actors when each of them has something the other would value (Thibault and Kelley, 1959; Homans, 1961; Emerson, 1972). Here, the assumption made is that actors face substantial degrees of uncertainty and ambiguity about what the potential partner value, the utility of different exchanges to them and what exchanges are been made among others in the exchange network (Molm and Cook, 1995). Social exchange theory primarily deals with how actors react to these uncertainties and ambiguities, in which the actors based their expectations of rewards, cost and punishments. Likewise, the actors also use this information to anticipate their future exchanges in terms of the rewards, cost and punishments.

In addition, this theory highlights the importance of cost and rewards in the formation of social relationship. According to Thibault and Kelley (1959), exchange theory is based on the exchange of rewards and costs to quantify the values of outcomes from different situations for an individual. People strive to minimize costs and maximize rewards and then base the likeliness of developing a relationship with someone on the perceived possible outcomes. For example, when a person perceives a greater outcome from another person, he or she intends to disclose or share the knowledge greater and thus develops a closer relationship with that person. Another important aspect of this theory is that people will establish a reciprocal relationship among themselves once these two main elements—cost and rewards are fulfilled. We discuss the implications of this study in the next section.

## 5. IMPLICATIONS FOR MANAGING E-BUSINESS

The implications of this study are three-fold—trustworthy relationships among business partners, effective sustainable collaboration, and optimal use of ICT for supporting e-business activities.

### 5.1 Trustworthy relationships among business partners

Here, trustworthy relationships refer to non-symmetrical or unidirectional and conditionally transitive agreements between parties. Trust relations may be divided into two categories (Abdul-Rahman and Hailes, 1997)—*direct trust relationship* and *recommender trust relationship*. For example, there is a *direct trust relation* if person A trusts person B. However, if person B trusts person A to give recommendations about other persons' trustworthiness, then there is a *recommender trust relationship* between person A and person B. For the case of virtual networks, the opportunities for face-to-face interactions to facilitate this is minimal. Therefore, the virtual environment constitutes a special case of network organizations and is characterized by lateral rather than vertical relationships (Snow et al., 1992; Bleecker, 1994; Semich, 1994; Garreth, 1998 and Wigand et al., 1997). Kasper-Fuehrer et al., (2001) suggests that authority is clearly defined by the hierarchical structure in the organizational design, along with organization charts and formalized procedures in vertical relationships. However, this hierarchical coordination and control mechanisms is lacking in a network organization. Therefore, trust may act as a substitute for control in a network or lateral relationship organizations (Sheppard and Tuchinsky, 1996; Handy, 1995; Jones and Bowie, 1998).

### 5.2 Effective Sustainable Collaboration

The authors emphasize that the arguments for a social exchange perspective presented in the previous section provides valuable insights about the trust building

process for the sustainability of virtual network relationships. We argue that this perspective of e-business management is important in order for exchanges of goods and behaviors to take place in an organization. This would also encourage joint activity or transaction, which would involve two or more actors when each of them has something the other would value (Thibault and Kelley, 1959; Homans, 1961; Emerson, 1972). However, it is important to note that actors face substantial degrees of uncertainty and ambiguity about what the potential partner value, the utility of different exchanges to them and what exchanges are being made between others in the exchange network (Molm and Cook, 1995). We conclude that social exchange theory (Chadwick-Jones, 1976) is a powerful mechanism for understanding the relationship building process as it primarily deals with how actors react to these uncertainties and ambiguities, in which the actors based their expectations of rewards, costs and punishments and also to anticipate their future exchanges.

### 5.3 ICT Use for Supporting e-Business

How may a higher level of trust help sustain higher levels of collaboration among business partners? We suggest that higher levels of trust among parties may be achieved by the norms or agreements as they help reduce uncertainty (Anderson, 1971; Chadwick-Jones, 1976) and help establish common business goals or shared business vision among parties involved (Wigand et al., 1997; Scott and Lane, 2000). Studies suggest that this shared vision helps in understanding each member's role, identification of groups, determination of critical behaviors such as willingness to cooperate with others, and also willingness to engage in mutual goal setting, so that higher levels of collaboration may be achieved among partners (Albert and Whetton, 1985; Wiesenfeld et al., 1998). Therefore, establishing group identity, awareness of mutual needs and expectations, and clarification of tasks and responsibilities is a necessary prerequisite for building trust and also to promote collaboration (Anderson, 1971; Kasper-Fuehrer et al. 2001). We further suggest that the use and utility of ICT may be optimal for supporting e-business activities once these necessary prerequisites are used to promote collaborative culture during the design phase of business systems (Gallivan et al., 1993; Orlikowski, 1993; Bowers, 1994).

## 6. CONCLUSION

We utilized social exchange theory to explore the underlying relationships among ICT, trust, and collaboration as a means to advance our understanding of the management of e-business activities. We have argued three important factors so that ICT may be effectively used to support collaboration and suggested sets of propositions. Firstly, we suggest that the successful integration of this architecture for a network organization is largely dependent on the establishment of a shared

business vision. This would help build trust among business partners so that a higher level of e-collaboration may be achieved. Secondly, we suggest that social factors such as trust are a key element for ensuring the optimal use of ICT so that higher levels of collaboration can be achieved among business partners. Thirdly, we introduce the game-theoretic approach of the *Prisoner's Dilemma* to argue that distrust among business partners is the result of the adverse consequences of calculative and opportunistic behavior. We conclude that this distrust among business partners may lead to the termination of exchanges and impede the possibility of e-collaboration.

### ABSTRACT

This paper analyses several security systems and aggregates their characteristics supporting trust. These characteristics are then matched with e-business models to try and identify the most suitable security system for each model. This is preliminary work undertaken to establish appropriate trust models in the e-commerce environment. The models discussed in this paper are hypothetical.

**Keywords:** electronic commerce, public key infrastructure, trust, trust model

### 1. INTRODUCTION

The Internet is the largest global network supporting e-business models, B2B (business-to-business), B2C (business-to-consumer), C2C (consumer-to-consumer), or G2C (government-to-consumer) e-commerce. E-businesses use the Internet to provide product information, online catalogue, electronic transactions, business exchanges, e-negotiations, e-procurement, and online services (e.g. e-government, e-banking and e-insurance) to customers and business partners. New and evolving technologies can be combined with the Internet to enhanced business services. Business organizations around the world are capitalising on the Internet to expand business to organizations and customers to greater geographic regions. Turban et al. [27] emphasise that the benefits of e-businesses include reduced costs, automated and integrated business processes, quick retrieval and dissemination of information, better information management methods, and efficient transactions. In the B2B e-commerce, e-procurement is an important application enabling organisations to reduce purchasing administrative costs by a substantial amount. In the B2C, e-business consumers have the advantage of a 24 by 7 shopfront, access to e-banking and e-government services. [27]. The SMEs (Small and Medium Enterprises) are also capitalising on the Internet to compete with larger businesses.

Although security technologies available off the shelf, these are not always sufficient to prevent the Internet from various kinds of attacks (virus, information access, worms, etc.), an important barrier to e-commerce has been a lack of trust by the Internet users to complete a transaction. Trust has been found to be a crucial factor for e-commerce success [20] due to uncertainty and risk in its nature. As e-commerce environment becomes more uncertain because Internet users are separate from each other by space (e.g. distance between countries) and time (e.g. delayed response on the Internet), the need for trust is very critical [10, 20].

This paper introduces and discusses trust models suitable for different e-business models (e.g. B2C, B2B, B2E, and G2G). These models were developed by analysing the trust mechanisms from several existing trust models, including ITU-T Recommendation X.509 [1], PEM (Privacy Enhanced Mail) [13], PGP (Pretty Good Privacy) [2], PEMToolKit [3], ICE-TEL (Interworking public key Certification infrastructure for Eurpoe) [6], SDSI (Simple Distributed Security Infrastructure) [23], SPKI (Simple Public Key Infrastructure) [8], NPPI (Nested certificate based PKI) [17], and Solar Trust Model [7]. Note that SDSI and SPKI has been merged and become one trust model as the version 2 of SDSI/SPKI recommendations were published in 1997, due to the similarity of these two models. These eight trust models are PKI (Public Key Infrastructure) -based models from either international security standards for IT (Information Technology), purposed models in published paper, or existing models that have been successfully deployed in several business applications.

### 2. TRUST

Technology trust has been studied for at least half a century. These studies have included meanings [19], characteristics [20], calculation of trustworthiness [18], and the relationships between trust and other factors, such as risk, uncertainty, and confidence [14, 16, 24, 26, 28]. The impact of trust on the human society, business and commercial partners, organisations, and teamwork has also been investigated. Regrettably, to date there is no satisfactory explanation of the nature of trust or its relationship to these entities [24]. As a result, the meanings and characteristics of trust in many technical applications are still imprecise. McKnight and Chervany [20] identified sixteen distinctive categories of trust characteristic definitions (competent, expert, dynamic, predicabile, good and moral, good will, benevolent and caring, responsive, honest, credible, reliable, dependable, open, careful and safe, shared understanding, and personally attractive) grouped into five major categories of competence, predicability, benevolence, integrity, and other. Their findings demonstrated that trust is a

relationship that can be seen and used from several perspectives. In this paper, trust refers to one's belief of others in terms of competence, predicability, benevolence, or integrity in the e-commerce environment.

### 3. TRUST IN E-COMMERCE

The reason why trust has become a very important issue in e-commerce is that the environment and digital processes (e.g. electronic transactions) of e-commerce contain very high risk factors, such as impersonation, fraud, security, privacy, dishonest people, page-jacking, and parallel webs [5, 14, 16, 20, 25, 26]. Hoffman, Novak, and Peralta are of the opinion that almost 95 percent of online users decline to provide personal information on web sites due to a lack of trust [12]. They also suggest that 69 percent of online users did not provide information on web sites because the sites did not provide any information on how the data would be used. Ponemon Institute (<http://www.ponemon.org>) and TRUSTe (<http://www.truste.com>) reported that 76 percent of Internet users are concerned about "identity theft" if their personal information were leaked to unauthorised individuals or organisations [11]. Grazioli and Jarvenpaa emphasise that there are approximately 25 million pages, or 2 percent of the total number of pages on the Internet supporting fraud, called "page-jacking"[10].

Trust is important wherever risk, uncertainty, or interdependence exists [20]. Without trust, e-commerce will not be a success [26]. It is one of the most desired qualities in any close relationship. It is indispensable in social relationships, which may lead to significant benefits especially in business relationships [14]. Trust reduces complexity in human society [16]. Similarly, it is a bridge for both a seller and a buyer to cross over uncertainty in the e-commerce environment. Trust problems affect family relationships, business transactions, and client/professional interactions [28]. A buyer wants to buy a quality product with a reasonable price while a seller wants to sell a product and to be well known in the marketplace. In fact, a buyer could be a fraudster or a seller could sell a non-qualified product - or nothing at all in the e-commerce environment.

Before e-commerce had been established, there was only one type of commerce called "brick-and-mortar commerce." In the marketplace, products could be seen, touched, and tested at the point of sale. Tan and Thoen [26] suggest that it is difficult to increase the trust of online users in e-commerce as compared to brick-and-mortar commerce because buyers and sellers cannot see each other and someone could impersonate somebody else, either known or non-existent. This makes trust in the online environment very vulnerable. E-commerce is known for receiving payment and not sending the product to the buyer. This occurred with eBay many

times. Auction fraud had increased from 106 cases in 1997 to 25,000 cases in 2001 [22].

Another type of risk perceived by the online shopper is losing control over the situation and/or not being familiar with this kind of technology. "Social uncertainty" exists when the seller has an incentive to act in a way that imposes cost or harm on the buyer, and the buyer does not have enough information to predict the behaviour of the seller [10].

### 4. EVOLUTION OF TRUST MODELS

In 1976, Diffie and Hellman [8] introduced the PKCS (Public Key Cryptosystem), which is a cryptography method, a central authority or public file to support e-mail security. This scheme reduced the risk of key management, which is a method of managing a key pair that consists of a public key and a private key. However, with this method, an impersonation was still possible because no one could ensure that the public key that online users obtained from the trusted public directory really belonged to the claimed entity.

In 1978, Kohnfelder invented the idea of a digital certificate [15]. It was a mechanism designed to link the public key, which is a tool to encrypt a plain message and can be opened by the owner of that key, to a given identity, and signed by a trusted entity such as TTP (Trusted Third Party). Depending on the method of encryption used, the digital certificate could be almost unforgeable, or take a long time to be deciphered. This method solved the impersonation issue previously mentioned and improved the performance of key management for the TTP [8].

In 1988, the CCITT (Comité Consultatif Internationale de Telegraphie et Telephonie), which is now known as the ITU (International Telecommunication Union), published CCITT Recommendation X.509. Part of X.509 was to define and standardise a global, distributed database of named entities, such as people, computers, printers, etc. It also could be described as an online telephone book. However, the plan was not a success because the idea of using a single global name in the world that had countless number of entities was unlikely to be true [8].

In 1989, PEM (Privacy Enhanced Mail) attempted to implement the X.509 standard by the IETF (Internet Engineering Task Force). However, it was delayed due to the long time spent on deploying its infrastructure, including IPRA (Internet Policy Registration Authority), PCA (Policy Certificate Authority), and CA (Certificate Authority) [6].

In 1991, Zimmermann [2] introduced new secure-communication software known as PGP (Pretty Good Privacy). The structure of PGP was different from X.509 and PEM. Unlike PEM that had to wait for the

establishment of a single global root and a hierarchy of CAs, PGP allowed a digital certificate to be signed by anyone, and could contain multiple digital signatures. This approach enabled several virtual communities to be quickly established and grown due to the “Six Degrees of Separation” theory, which describes how someone can connect to anyone in the world through the chain of intermediaries containing not more than six people [4], and was well known as the “web of trust” model.

In 1992, the NSF (National Science Foundation) enabled commercial companies to conduct business transactions securely over the Internet. With the establishment of this large global network, many companies lodged business online. However, the Internet was not suited for a commercial environment and was not developed with security in mind [14]. It was meant for sharing information in plain text format.

## 5. TRUST MODEL ISSUES

A trust model should be able to support trust relationships that are required by users and online businesses, and to provide control mechanisms that allow them to establish and enhance trust. Therefore, it is important to understand the characteristics and needs of target community and users, and to create and embed these characteristics into a trust model [6]. The framework of a trust model is an important factor to determine how the model will be used and whether it is suitable for the target virtual community. The framework of a trust model in this paper refers to trust mechanisms to manage trust relationships between buyers, sellers, suppliers and other relevant parties. If the target community is a small group of casual end-users but a trust model uses a very strict security policy, then model deployment, user registration, and cross certification will be very difficult and slow to manage. This happened with PEM that contains very strict security policy and requires deploying several central authorities before any user is able to communicate with each other securely. On the other hand, if the target community is made up of a large number of end-users and CAs but the trust model lacks a standard security policy, then that virtual community will not be able to function successfully. PGP can be associated with this characteristic because it contains no standard security policy, and therefore, it is not easily scalable when hundreds of thousands of users are involved [6].

Although a trust model is not only a security system [14, 16], in this paper, it is based on the analysis of PKI-based security systems. Security system in e-commerce is different from security in traditional networks. There are four major security issues in e-commerce [25]:

- Authentication – communicating parties must be certain of each other’s identity and/or credentials;
- Confidentiality – data must not be visible to eavesdroppers;

- Integrity – communicating parties must know when data has been tampered with; and
- Non-repudiation – it must be possible to prove that a transaction has taken place.

However, Skevington [25] argued that this approach is inadequate in the open and distributed environment of the Internet. Trust must be embedded into infrastructure, data, and user identity.

## 6. RESEARCH METHODOLOGY

The research discussed in this paper was inspired by a lack research on trust mechanisms illustrating how trust models perform or apply to e-commerce business models. It is based on a document analysis methodology. The findings in this paper were compiled using a categorical aggregation analytic strategy. Categorical aggregation is the process of piecing together bits of information gathered regarding an issue and organising it into an orderly research interpretation [29]. Each of these categories is further broken down into nominal attributes (non-numeric and unordered elements) using both homogeneous and heterogeneous decomposition methods. Goldstein and Roth [9] stated that there are two types of decomposition. Homogeneous decomposition is to use the same attribute to repeatedly partition a group by choosing more narrow ranges of the attribute’s values. Heterogeneous decomposition, on the other hand, is to use different attribute to decompose sets for successive partitions.

## 7. FINDINGS

An analysis of eight trust models chosen for this research revealed that some of the findings are common to all while some are quite different. Trust models examined in the research are all PKI-based. The research found that there are 25 trust mechanisms in the chosen trust models. Although the value or importance of trust mechanisms were not identified, these trust mechanisms were ranked based on the opinions of [2, 3, 6-8, 17, 21, 23] who previously stated in their works, the commonality of trust models, and the effect of these mechanisms on communities when attributes were changed. In this paper, an attribute is a sub-category of a trust mechanism. Table 1, which is presented at the conference, shows trust mechanisms and their attributes in the trust models commonly used. The horizontal top column shows the name of each trust model. The vertical left-most column lists trust mechanisms. Each trust model uses different attributes to create. Some trust models support more attributes than others. This illustrates that they are more flexible than other models. However, it does not mean that they can support more kinds of e-commerce models. An appropriate combination of trust mechanisms is crucial in order to develop a trust model suitable for each kind of e-commerce models.

## 8. TRUST MODELS

In order to determine the most appropriate trust model for an e-business model, trust mechanisms are matched with the interaction between participants. The behaviour of a trust model may affect how users interact with each other, what kind of information (e.g. user's identity, security policy) is available, how information can be validated or delivered, what kind of environment is used (e.g. user-friendly interface, control mechanisms), and for which e-commerce model is suitable. Trust mechanisms are used to assist in the development of the framework of a trust model for each e-commerce model.

In this section, seven conceptual trust models are discussed. These models were developed from 25 trust mechanisms presented in Table 1. The combinations of attributes of trust mechanisms are based on the application and the type of network in which the hypothetical e-commerce model operates. The models are discussed from the smallest community containing the simplest trust relationships (e.g. relationships between friends, family, relatives, and team-mates), to the largest community containing very complex trust and several kinds of trust relationships (e.g. relationships between business partners, companies, government, organisations). The model starts from the simplest trust relationships or close relationships.

### 8.1 Close-Relationship Trust Model (B2E, B2C)

The simplest human society starts from close relationships that are established directly between relevant parties (PGP Corporation 2003). It contains the highest level of trust because members in this community know each other very well. It also needs the least secure environment, which makes this trust model very simple, compared to other sample trust models in this section. Figure 1, which is presented at the conference, illustrates a small group of end-users that have agreed to establish an internal network with a convenient communication method based on an adequate security system.

This type of trust model could be used for private trust relationships such as friends, members in the family, relatives, colleagues, or a group of people that know each other well, and this makes the community small. Thus, there is no need for any formal proof signed by some trustworthy entities. It may not need a strict security policy unless there is some very sensitive information that needs to be shared among a few exclusive members in the same community. In the e-commerce context, it may apply to a small B2C enterprise that contains single security domain or B2E (Business-to-Employee) e-commerce, an Ethernet, or the requirement of establishing a secure communication channel (e.g. e-mail).

Members in this small community are assumed to be familiar with each other and do not need a central authority because it is a close domain. Therefore, the structure is anarchy, growth is organic, trust management is decentralised, and trust relationships are managed by a trusted entity. There is no standard security policy and trust transitivity in this model because members do not need to contact people in other communities. From Table 1, it can be said that PGP is most suitable for this e-business model.

### 8.2 Casual Trust Model (B2C, B2B)

A casual trust model in this paper refers to the illustration in Figure 2 (presented at the conference) when:

- Users need to contact other users, who are members in different security domains;
- Users need to create a central authority for enabling a standard security policy for user authorisation system; and/or
- Users need to strengthen the security level throughout their community.

With any of these reasons, a security policy must be standardised and this means that a community needs to establish a central authority. In this paper, a central authority is a person who is responsible for validating the identity of members, signing digital certificates, creating security policy, issuing cross certificates, and maintaining the network. Thus, this trust model is suitable for a medium enterprise that contains a few different security domains. In B2B e-commerce, two companies need to establish security communication channels between several security domains (e.g. sending or sharing sensitive information between two companies). In B2C e-commerce, a customer needs to do business with a company.

Members in this community need to contact people in other communities, presumably in an e-commerce environment containing a few companies and customers. Security policy is needed to properly standardised in order to enable cross certification, which is a task done by a central authority. Therefore, the structure is both hierarchy and anarchy, growth is both scalable and organic, trust management is both centralised and decentralised, trust relationships are established by either a trusted entity or a trusted path. These cover security policy and trust transitivity. From Table 1, it can be said that ICE-TEL is the most suitable for this e-business model.

### 8.3 Community Trust Model (B2C, B2B, G2C, G2G)

A community trust model is used when:

- Users need to establish proper formal small communities on the Internet;
- Organisations need to set up a trustworthy network for secure communication; or

- Companies want to create their communities in order to deploy an e-commerce environment and applications. In this model, there would be more than one type of trust relationship because it is an open community, which anyone could join in. This does not limit them to only a close-relationship as it does in the trust models previously discussed. Possible types of trust relationships may include close relationship, acquaintance, friends, family, colleagues, co-workers, customers, business partners and other distant relationships (e.g. third parties). An appropriate set of security policies is needed in order to prevent hackers and malicious attacks. This trust model is suitable for an open community where there are several kinds of companies and organisations in the same environment, e.g. B2B or G2G exchanges of goods between large and small organizations or suppliers and distributors, or B2C or G2C e-commerce where customers need to filter unrelated companies and measure the trustworthiness of related companies.

A number of e-commerce organisations are large and contain different sizes of companies and businesses. Members in this community need a more sophisticated trust model for trust management. A suitable structure for this will be both hierarchy and anarchy, scalable and organic growth with trust management both centralised and decentralised. From Table 1, it can be said that ICE-TEL is suitable for this e-business model.

#### **8.4 Community with Casual Trust Model (B2C, B2B, G2C, G2G)**

This model has the same characteristics as the community trust model with an extra environment for users to create their own private communities. It is actually a casual community inside the community trust model. This means that this trust model contains a community trust model as a primary model, and a casual trust model, as a secondary trust model. Therefore, users can create casual communities, and save time and bandwidth requirements in the process of verifying identities. This model is suitable for a larger scale community compared to the previous models. For example, a virtual community where there are several companies, governments, and users in the same environment; it will incorporate central system administration domain, and share sensitive information between several member companies in the same department that contains members from different companies or organisations. Another example is that a large company that contains several large divisions or sub-companies, and wants to create a new special division that contains a few selected members from different divisions.

For this, bottom-up virtual society establishment, which is a unique feature of PEMToolKit, is chosen. From

Table 1, it can be said that ICE-TEL is the most suitable for this e-business models.

#### **8.5 Organisational Trust Model (G2G)**

An organisational model is to be used for a large organisation having a solid structure that is unlikely to be changed, or a community that contains very sensitive information and needs very secure communication channels. One of the most suitable business models is G2G (Government-to-Government). Hence, it is crucial to not only to increase trust but also reduce risk in a community. Members in this community need a very secure and solid model. Trust relationships established by users are not allowed in order to minimise risk. In fact, this community seeks more security rather than trust. From Table 1, it can be said that X.509 is the most suitable for this e-business model.

#### **8.6 Popularity-based Trust Model (C2C, P2P)**

This model is based on the popularity of each user. It may be used with a measurement of trustworthiness of users in some closed communities, such as an online auction, bookshop, or e-commerce company search engine. For example, it would be better if an online auction could provide trustworthy information about buyers or sellers before transactions have been processed. The trustworthiness value would be determined by how many digital signatures have been signed on the digital certificate of the target and who signs those digital signatures.

In this model, if a member registers online, then a central authority would not sign on a digital certificate because it is too difficult to trust and verify all information provided digitally from a faceless member. However, if a member registers at a physical office, then a central authority would verify proof of identity (e.g. driving license, social security number, passport or other personal id cards). A central authority would then help one to generate a key pair with a digital certificate signed by a central authority. This process is long but it counterbalances the problem of new members having no trustworthiness information. The local business registrar should be responsible for this task, as all companies must be registered with the government organisations before commencing any business. However, a central authority could revoke the digital signature for any member if there is any suspicion. Therefore, trust relationships in this trust model would be changed dynamically by comparison with other trust models. This trust model is suitable for a large community that contains members with the same level of authorisation and needs the value of trustworthiness or background information of users in order to decide which one is trustworthy enough to do the business. One of the suitable business models using popularity-based trust model is C2C (Consumer-to-Consumer), P2P (Peer-to-Peer) or auction-based e-commerce environment.

Figure 7, which is presented at the conference, illustrates how this model is superior to other models previously discussed in this section. Members in this closed community need a dynamic and flexible trust relationship. Therefore, structure is anarchy, growth is organic, and trust management is decentralised. From Table 1, it can be said that PGP is the most suitable for this e-business model.

### 8.7 Integrated Trust Model

This trust model is the combination of casual, community, organisational, and popularity-based trust models. It is a trust model, which could support different kinds of trust relationships in the same or across communities. This trust model is suitable for a very large and complex community that contains many relationships. In addition, both central authorities and end-users are included. End-users are also able to create their own communities in order to create either open or closed communities. In fact, this model will be used when all models above have been already deployed and users need to standardise or unify their communities in order to establish secure communication channels conveniently. Suitable e-business models that can use this model are B2C, B2B, G2C, and G2G when calculation of trustworthiness is important.

An integrated trust model firstly uses a hierarchical structure as a backbone in order to properly define and distribute a set of security policies for different security domains. If a community is very large and contains different types of members, then an IPRA (Internet Policy Registration Authority) and PCAs (Policy Certificate Authorities) may be needed. The part involving an IPRA to a CA is an organisational trust model, and the part involving a CA to an end-user is a community trust model. From Table 1, it can be said that ICE-TEL is most suitable for this e-business model.

## 9. CONCLUSION

In this paper, a first attempt has been made to match appropriate trust models to e-commerce models for managing trust. Further work will be done to prove the discussion in this paper.

### ABSTRACT

This paper reports and summarises the important findings of a study into the factors that influence the adoption and diffusion of knowledge management systems (KMSs) in Australian organizations. The implications for managerial practices are discussed. The future research directions are also presented.

**Keywords:** Research Summary, Managerial Implications

### 1. INTRODUCTION

There has been a major shift towards a knowledge economy over the past decade. Coupled with extreme competition, shorter product life-cycles, and rapid development in technology, organizations are paying more attention to safeguarding their knowledge-based assets. Knowledge is now considered the most important organizational asset for obtaining sustainable competitive advantage (Wiig, 1997). Organizations are paying more attention to organizational knowledge and KM. They are looking at ways to maximize their knowledge-based assets for the purpose of staying ahead of the competition. Although knowledge and knowledge management (KM) are not new concepts, knowledge management systems (KMSs), which involve the application of IT systems and other organizational resources to manage knowledge strategically in a more effective and systematic way (Alavi & Leidner, 1999), are a relatively recent phenomenon. While a KMS (or some version of it) is widely applied in organizations, the topic has not been well explored by researchers and scholars in an empirical way. There is a scarcity of empirical studies of KMSs, especially in the area of their adoption and diffusion. This paper reports the findings of an Australian study of KMS adoption and diffusion in organizations. This study was done in a comprehensive manner and findings have been reported elsewhere on different aspects of the study (Quaddus, Xu & Wood, 2002; Quaddus and Xu, 2002; Quaddus and Xu, 2003; Xu, Quaddus & Wood, 2001). This paper presents a summary of the findings and articulates the managerial implications of them.

The paper is organized as follows. The capstone summary of the study findings is presented in section 2. Section 3 presents the comprehensive managerial implications of the results. The conclusions and future directions are presented in section 4.

### 2. CAPSTONE SUMMARY OF THE STUDY FINDINGS

This research attempts to get answers for the research question: What are the factors that influence the adoption and diffusion of knowledge management systems (KMSs) in Australian organizations? In doing so it identifies the factors affecting the diffusion of KMSs based on selected Australian companies at both the organizational level (identifying what causes organizations to adopt and implement a KMS) and the individual level (identifying what causes individuals/end users to accept or reject a KMS). The study also focuses on identifying the relationships between the external influences, the perceptions of the KMS, and the diffusion of KMSs in Australian organizations to answer the second research question: What must be done for the successful diffusion of a KMS? The research proposes and examines a model of KMS adoption and diffusion developed from both the literature review and practical field studies. The details of the study can be found in Xu, Quaddus & Wood, 2001; Quaddus, Xu & Wood, 2002; Quaddus & Xu, 2002; Quaddus & Xu, 2003; and Xu, 2003. The research has resulted in a number of findings to explain the adoption and diffusion of KMSs in organizations:

1. Perceived usefulness has a positive relationship with an organization embarking on a KMS. Perceived user-friendliness has a significant effect on the initiation of a KMS indirectly through perceived usefulness. Perceived usefulness is the primary driver of an organization's interest in seeking a KMS to manage its knowledge in a better and more effective way.
2. People's decision to accept and use a KMS is directly determined by perceived user-friendliness and perceived voluntariness jointly. Meanwhile, perceived usefulness also has a significant effect on people's decision to use the system. But user-friendliness has the greatest total effects on an individual's intention to use the system, followed by perceived usefulness, and then perceived voluntariness.

3. The impact of individual differences and task complexity on the organization's decision about KMS adoption and diffusion is mediated by the perceived usefulness.
4. The influence of individual differences and task complexity on people's use of a KMS is mediated by the perceived usefulness.
5. The KMS diffusion process consists of six stages: initiation, adoption, pilot implementation, organic growth, organizational implementation, and diffusion/sustained use of KMS.

The details of the results can be found in Xu, Quaddus & Wood, 2001; Quaddus, Xu & Wood, 2002; Quaddus & Xu, 2002; Quaddus & Xu, 2003; and Xu, 2003.

### 3. MANAGERIAL IMPLICATIONS

The results of this study have significant implications for managerial practices. The managerial implications arising from this study are discussed from various perspectives:

- ◇ The need for a KMS
- ◇ Approach to implementing a KMS
- ◇ Cost of a KMS
- ◇ The comprehensive model of KMS adoption and diffusion
- ◇ Significant factors of KMS adoption and diffusion
- ◇ End-user focus and involving people in the KMS
- ◇ Organizational adjustment to embrace the KMS
- ◇ Role of top management in KMS implementation
- ◇ Technology for the KMS
- ◇ Suggestions for KMS adoption and diffusion

#### *The Need for a KMS*

It is necessary for organizations to adopt and implement a KMS to survive competition and gain competitive advantage in the knowledge economy. Organizations need better control of the knowledge they already have. Many organizations do not know what they have. KMSs have the ability to make an organization better and help individuals do their jobs better. A KMS can make a contribution in the following areas (see Quaddus & Xu, 2002):

- § Help decision-makers cope with challenges and problems.
- § Make people more effective in their jobs.
- § Inspire people to become more creative in their jobs.
- § Make organizations more productive.
- § Cut operating costs and time for production and product development by avoiding the need to reinvent the wheel.
- § Increase people's knowledge and enlarge their knowledge base.
- § Avoid repeating the same mistakes.

- § Provide better service to customers.

#### *Approach to a KMS*

A KMS is a broad way or approach to deal with the management of both tacit and explicit knowledge. This notion is supported by the majority of the survey respondents (see Quaddus & Xu, 2002). Many organizations do not have a KMS even though they have a number of systems that are consistent with a KMS. But they have not put the whole package together. A KMS consists of a number of elements, such as structure, culture, job descriptions, information technology (IT), processes, procedures, etc. A KMS is also a multi-process. It actually touches every part of the business and everything the organization does. At the same time, IT can be an important enabler to support KM in various ways. The KMS is a much broader subject than IT. It is a way, mechanism and structure to manage organizational knowledge. Organizations should focus on building a knowledge-sharing culture and structure as well as people's capabilities before they adopt or build a system.

The first necessary and important step for setting up an effective KMS is to review the way an organization operates and determine the easiest method of collecting and transferring the important types of knowledge, which will provide competitive advantage (Mazzei, 2000). The organization should understand what knowledge means to its business and find out what the potential impact of the knowledge will be. It has to identify what might be worth doing and where the leverage points might be. For example, the most important knowledge domains identified in this study were knowledge of customer services, knowledge of strategic planning, knowledge of marketing sales, knowledge of competition (see Quaddus & Xu, 2002), which implies that when an organization is developing its KMS, it should include this knowledge into its KMS and provide cost-effective access to these knowledge areas. Furthermore, the cost-benefit analysis of a KMS can also be linked to organizational performance in the corresponding perspectives, such as customer satisfaction, business strategy development, product development and innovation, time to market, product promotion, market share, competitive positioning, and so on (Alavi & Leidner, 1999). The results of this study suggest that a KMS has the capability to provide both external knowledge (such as customer information, competitive information, market information, business partner information, and supplier information) and internal knowledge (such as operations information, human resources information, financial and accounting information) to people. That will help them figure out how to structure, allocate responsibilities and draw the process through the business. The first thing in KM is addressing the different areas of knowledge content and business processes relating to knowledge that are critical to the business. Then the organization should

adjust its business processes and organizational structure accordingly to embrace the KMS.

#### *Cost of a KMS*

In the survey, the respondents reported the total cost of KMSs in their organizations up to the time the questionnaire was answered as ranging from less than AUST\$100,000 to more than AUST\$1,000,000 (see Quaddus & Xu 2002). However, these figures should be interpreted with caution since there are difficulties in accounting for building, operating and maintaining a KMS, and also in measuring the system benefits (Sarvary, 1999). Before organizations put KMSs into place, they have to look at their corporate infrastructure (Brooking, 1999). Corporate infrastructure includes a broad range of infrastructure assets, such as management philosophy, corporate culture, management and business processes, financial relationships, methodologies, and IT systems (Brooking, 1999). The investment on a KMS should cover both technological infrastructure (i.e., KMS technologies – both hardware and software, MIS department, etc) and organizational infrastructure (i.e., user training, rewards for knowledge sharing, changing organizational culture, structure, etc).

#### *A Comprehensive Model of KMS Adoption and Diffusion*

This research presents a practical model of KMS diffusion. All the factors/sub-factors and variables have been obtained from the literature and the real world. A close examination of the model reveals that all the factors/sub-factors ultimately lead to sustained use of a KMS. Companies planning to embark on a KMS can consider the variables of the model (see Xu, Quaddus & Wood, 2001) as criteria for the successful diffusion of a KMS. It must be noted that not all the criteria of the comprehensive model will be applicable to all companies. A careful analysis is first needed to select the appropriate criteria for a company. A multiple-criteria modelling approach can then be undertaken to assess the suitability of the company for KMS adoption and diffusion. A similar modelling approach can also be undertaken to find the type of KMS suitable for a company (Quaddus & Achjari, 2001).

As per the factors and variables in the model, an organization can predict whether the system will be suitable for the organization and be accepted by the users when it is embarking on a KMS. The factors and variables in the model will also help the organization to diagnose the possible reasons for unsuccessful implementation and diffusion, and take corrective action to increase the acceptability among the end users and integrate the KMS into its business processes for the purpose of maximizing business performance and optimizing business impact.

#### *Significant Factors of KMS Adoption and Diffusion*

This research identifies three of the most significant perception-related variables in the KMS adoption/diffusion process, namely usefulness, user-friendliness and voluntariness of a KMS. The implication is that any KMS has to be extremely user-friendly for any level of users to use it effectively; it has to be useful for the task and a policy must be implemented to facilitate the voluntary use of the KMS. It is noted that any kind of norm (pressure) creation is unlikely to make it grow effectively within the organization.

The results show perceived user-friendliness has more influence on people's use and continued use of a KMS than perceived usefulness, and suggest that an organization should advocate the user-friendliness/ease of use of the KMS when it promotes and implements a KMS. Meanwhile, when the organization is deciding to embark on a KMS, it should pay more attention to the benefits the system can bring to the organization rather than spending too much time on looking for, or designing, a user-friendly system. It should be understood that the ultimate purpose of the KMS is to improve the performance of the organization and individuals. No amount of user-friendliness can substitute for the usefulness/benefits of a system (see Xu 2003).

All the hypotheses related to the sequence of the KMS diffusion process (see Quaddus & Xu, 2003) were found to be significant. This is an important and significant finding. It clearly demonstrates how KMS adoption and diffusion should be planned in Australian organizations. A well-planned sequence must be adopted for the effective adoption and diffusion of KMSs.

#### *End-user Focus and Involving People in the KMS*

An organization should build or adopt a KMS, which is user-focused and can bring benefits to everyone in the organization. If individuals do not commit to and support the KMS, it will never happen. Organizations should adopt and implement a user-friendly KMS, otherwise people may not use it even though it is useful. Organizations should only establish a KMS that people want to use. They should shift their attention from the hardware and software perspectives of a KMS, and pay more heed to the effects of people problems and motivational problems (Huber, 2001). If user-centered principles are followed, the required KM activities will automatically be identified as the KM project proceeds (Robertson, 2002). It will be of greater value for everyone in the organization if people shared their knowledge. And everyone can enjoy the benefits of sharing knowledge and using the KMS.

When an organization is embarking on a KMS, it should encourage people's involvement in the system and local ownership of the system, which will have an impact on people's decision to accept and use the system. Users

are both beneficiaries of, and contributors to, the KMS (Alavi & Leidner, 1999); as a result, people must be involved in KMS development and maintenance. In other words, people should be invited to participate in KMS activities all the time and right from the beginning.

At the same time, the organization should ensure that everyone understands that an important part of their working life is to learn as much as possible, contribute knowledge to the system, and participate in the dissemination of knowledge (Pan & Scarbrough, 1998). Also, the organization should motivate and reward early adopters of the KMS. By doing so, the critical mass of KMS use can be achieved, and more people will be willing to share their knowledge and make a contribution to the system (Bansler & Havn, 2002). But the positive incentive scheme aimed at encouraging people's use of, and contribution to, the system should be carefully monitored since an overemphasis on rewarded behaviour may induce people to focus on quantity rather than quality of knowledge submission to the system (Bansler & Havn, 2002).

It is seen that, in the KMS adoption/diffusion process, individual factors/differences of end users and task complexity are the significant factors influencing the perceived usefulness of a KMS (see Quaddus & Xu, 2002). This provides an interesting challenge for would-be adopters of KMSs in Australian organizations. Top-level executives of these organizations should plan carefully as their support does not guarantee a positive influence on the usefulness of a KMS. They must look deeply into the task factors and the end users to see if they are conducive to KMS use. Prior to introducing a KMS into the organization, top management should ensure that: (1) people are involved in the KMS adoption and implementation, (2) people have the experience/skills to use computer systems (both software and hardware), (3) people understand what knowledge the organization has and where and how to locate it, (4) people have time to document what they have done, and are encouraged to try new things. The organization should also examine task complexity by looking at a number of multidisciplinary complex projects, the amount of knowledge required for the business to grow, and the need to effectively track and reapply past best practice.

The mediating effects of perceived usefulness between external variables and KMS adoption/diffusion (see Quaddus & Xu 2002) suggest that organizations probably should put more emphasis on shaping and forming the perceived benefits/usefulness. The organization's effort of implementing a KMS might be more fruitful when management's attention focuses on the development of perceptions of usefulness of the KMS rather than implementation issues. Successful implementation will take place if the formation of perceptions is properly handled (Agarwal & Prasad, 1999).

At the meant time, the significant and positive impact of people's perceptions of voluntary use (i.e., the extent of KMS use to perform the tasks required by management and the extent of KMS use required in their job description) on the organic growth of KMS use (see Quaddus & Xu, 2002) indicates that, management pressure may not make people use the KMS. They have to educate and persuade people to use the system. They have to create an environment in which people feel comfortable and willing to use the system.

#### *Organizational Adjustment to Embrace the KMS*

The organization should have a KM strategy, otherwise its KM activities will be somewhat ad hoc. Effective KM practices start with a KM strategy. The KM strategy is the vision for an organization's effort in managing knowledge.

An important factor in ensuring the success of a KMS is to identify the business processes of most value to the organization. An integration of the KMS and business processes can help demonstrate how shared knowledge can generate immediate and highly visible returns to both individuals and the organization as a whole (Mazzie, 2000). The KMS must acknowledge an organization's business and business processes since the ultimate purpose of the system is to bring benefits to the organization and improve its performance.

Organizational culture is the set of values, beliefs, norms, and expectations that are widely held in an organization (Huber, 2001). In order to successfully implement a KMS, an organization should work on building a knowledge-sharing and pro-KM culture as well as an organizational structure. The organization should have a culture in which everyone is prepared to share knowledge and knowledge sharing is rewarded. In other words, an organizational culture in which seeking, sharing, and applying knowledge is the norm in the context of a KMS (Huber, 2001). Changing the existing culture and people's work habits is the first hurdle for most KM programs (McDermott, 1999). Chase (1997), Zyngier (2002), The Conference Board (1997), The Delphi Group (1997), and others state that the lack of a knowledge-sharing culture is the biggest obstacle to KM.

KM involves breaking down barriers. Hence, organizations should not operate in a silo structure. The ideal structure for knowledge sharing and effective KM is the matrix structure and team-based approach, in which the teams work across the organization. The KMS has to comply with the organizational structure. If an organization really practices KM, it should continually make adjustments to the organizational structure to facilitate the process.

Structure also influences the use of a KMS. The way an organization is structured in terms of lines of

responsibilities and accountabilities will reinforce the use of the KMS. Probably the most difficult thing for any organization's implementation of KMS is to set up the structure and build enough definition into it so people can retrieve what they want while allowing flexibility. The organization should encourage the practice of knowledge sharing through the linking of 'communities of practice' (i.e., people who perform similar tasks and functions but who are geographically dispersed), which can result in the organization's use of employees' expertise to maximize efficient product and service delivery (Mazzei, 2000).

#### *Role of Top Management in KMS Implementation*

At the same time, top management should take the initiative and express strong support for the KMS by appointing KM positions and allocating a KMS budget. Even though some rigor in implementing the KMS may be helpful, management should focus on persuasion and education.

Top management's role in implementation and diffusion of the KMS lies in creating an environment in which people feel comfortable and are willing to use the system. Although management can provide leadership in KM, the management on its own may not always be sufficient to stimulate and sustain effective KM practices.

In order to make the transferring/sharing of knowledge a common practice in the organization, management has to ensure the implementation of policies and reward systems to encourage knowledge sharing. Management should also lead the knowledge sharing practices by setting a good example themselves. They must become users of the KMS.

Training can enhance the use of a KMS through building up people's competence and confidence to try and adopt it. Training will help end users overcome the fear of complexity of the KMS. Although in-class training can provide people with certain skills and knowledge (explicit knowledge), tacit knowledge is developed through hands on practices.

#### *Technology for a KMS*

An integrated, integrative, and adequate technology infrastructure is a key driver for KMSs. KM is not new to organizations. For example, organizations have been practising knowledge coding and transferring, such as employee training and development programs, organizational policies, routines, procedures, reports, and manuals, for many years (Gottschalk, 1999). What is new and exciting in KM is the potential use of information technologies (e.g., internet, intranet, data warehouses, search engines and tools, among many others) to help an organization in managing knowledge in a more systematic and effective way (Gottschalk,

1999; Alavi & Leidner, 1999). In other words, the key elements of a KMS, such as people and expertise, already exist; there is a need of good KM technology to do it in a smart way (Phillips Fox, 1998). Clearly, the current rapid development in technologies has empowered the opportunities for knowledge sharing and combination (Nahapiet & Ghoshal, 1998).

The various KMS technologies and applications can be classified into three categories: database and database management systems, communication and messaging, and browsing and retrieval (Alavi & Leidner, 1999). Some of the common functions of KMS technologies and tools are (1) organizing and sharing/transferring of internal benchmarks/best practices, (2) constructing corporate knowledge directories, such as corporate yellow pages, people information archives, etc., (3) creating knowledge networks and knowledge maps; among many others (Alavi & Leidner, 2001). This study found that the top 10 most widely used KMS technologies were (in order): e-mail and communication systems, internet, databases, intranet, document management systems, customer management systems, video conference, online discussion forum, workflow systems, data warehousing/mining, and search and retrieval tools (see Quaddus & Xu, 2002).

In some organizations IT leads KM, and in others it facilitates KM. The best way is for IT to facilitate KM, and not be KM. Most organizations are not in the IT business and do not exist for IT. Technology only puts different components of the system together. There is no doubt that KMSs need technology since it can provide assistance and facilitation in various dimensions of the KM process, namely: knowledge capture and documentation, knowledge storage, knowledge sharing and access, knowledge reuse and application. Technology can make a KMS happen.

#### *Suggestions for KMS adoption and diffusion*

Finally, based on the KMS adoption and diffusion model, which has been proved to be valid and significant, this research offers some suggestions to assist in the implementation of a KMS in organizations:

- q Top-level executives of would-be adopters (organizations) of a KMS should plan carefully as their support does not guarantee a positive influence on the usefulness of the KMS. They must look deeply into the task factors and the end users to see if these factors are conducive to KMS use.
- q The KMS system has to be extremely user-friendly. For any level of user to use it effectively, it has to be useful for the task to be dealt with and a policy must be implemented for the system to be used on a voluntary basis. Any kind of norm (pressure) creation is unlikely to make it grow effectively within the organization.

q A well-planned sequence of KMS adoption and diffusion has been mentioned in Quaddus and Xu (2003), but is reintroduced here since we feel it is essential to the success of KMSs in organizations.

- ⇒ Research the organization's challenges and people's needs regarding knowledge, i.e., identify the important knowledge domains for the organization.
- ⇒ Search for suitable applications for the KMS.
- ⇒ Develop a KMS plan/strategy.
- ⇒ Allocate a budget for the KMS.
- ⇒ Appoint a knowledge manager or a chief knowledge officer.
- ⇒ Build up/set up the KMS.
- ⇒ Test the KMS through pilot implementation on a limited basis in the organization and optimize the system according to feedback.
- ⇒ Work on the organizational culture and structure to facilitate implementation of the KMS.
- ⇒ Persuade and educate people to use the KMS.
- ⇒ Provide people with continuous training and support to encourage their use of the KMS.
- ⇒ Encourage people to go through a process of self-learning.
- ⇒ Implement the KMS throughout the organization.
- ⇒ Cut off people's old means of accessing knowledge.
- ⇒ Develop an organizational-wide interest in using the KMS.
- ⇒ Monitor people's use of the KMS.
- ⇒ Keep providing the knowledge people want in the KMS.
- ⇒ Promote best practice.
- ⇒ Develop and encourage people's sustained use of the KMS.
- ⇒ Make using the KMS a part of the organization's business.

#### 4. CONCLUSIONS AND FUTURE RESEARCH DIRECTIONS

The results of this research can help organizations that are currently practising KM or are planning to embark on a KMS, by enhancing their understanding of a KMS and providing them with a checklist of the important variables in the KMS adoption and diffusion model with which to do an internal audit to find out how they fare in terms of these variables. The results of this research also provide guidelines on successfully implementing KMSs in organizations. Meanwhile, even though this research was conducted in Australian organizations, its results will apply to different organizations in various countries across the globe because of its generic approach.

An interesting future study could be looking at the differentiation among the types of KMS adopters. According to Rogers' (1995) theory of innovation diffusion, there are five types of adopters. The first to

adopt a KMS are the innovators, who adopt it because of its intrinsic values, including perceived user-friendliness/perceived ease of use. Later, the early adopters adopt it since it is able to provide competitive advantage. Only then the early majority adopt it for pragmatic reasons, such as return-on-investment, cost and benefit. They are followed by the late adopters and conservatives, who wait until the KMS is very well established. Most adopt a new IT for the sake of its extrinsic value, such as perceived usefulness (Moore, 1991). At the mean time, the results of this study were obtained from large Australian organizations. The validity of generalizing these results to other countries or small firms is yet to be determined. Furthermore, this study only reflects and measures a snapshot situation of KMS adoption and diffusion at a particular point in time. Future research could do longitudinal studies to have a better understanding of the process of KMS adoption and diffusion.

## ABSTRACT

A well-functioning Knowledge Management is a competitive advantage for enterprises that act in co-operative and distributed networks with knowledge intensive production processes. A Knowledge Management approach that integrates both, hard factors (e.g., Information Technology) and soft factors (e.g., cultural aspects) for distributed and dynamic entrepreneurial (inter-organisational) networks is currently missing. This paper presents research findings of a project that is developing a methodology to support a service provider responsible for the KM within distributed entrepreneurial networks.

**Keywords:** Knowledge Management, Knowledge Networks, Inter-organisational Networked Businesses, Collaborative Networks

## 1. MOTIVATION AND RESEARCH RATIONALE

In recent years two major trends could be observed in the sector of manufacturing enterprises. On the one hand, the companies concentrate more and more on their core competencies, while on the other hand knowledge is increasingly recognized as a success factor in the tough competition of the global market arena [17] [18].

As a result of the concentration on core competencies, peripheral functions are abandoned and taken over by external partners [11]. This trend leads to a higher productivity and flexibility of the companies' core businesses, but also increases the interaction between different business units [18]. While this gives much more flexibility to the production process as a whole, it also bears the challenge of handling these interactions efficiently.

Knowledge, on the other hand, has been accepted as a crucial factor in business life [13]. Many companies have therefore focused on Knowledge Management (KM) and hence implemented KM solutions [2]. However, such implementations are usually focused on internal, enterprise specific applications and are mainly technology driven [9] [12] [13] [14]. They are therefore suitable only to a very limited extent to support companies in order to face the challenges of KM in distributed business networks.

In addition, different goals, ethic values and cultures as well as a lack of trust inhibit the exploitation of the potentials of networked knowledge [4][6][10]. Appropriate models and methods and in particular a methodology for KM in distributed and globally

dispersed entrepreneurial networks are lacking [6] [16] [19].

Thus, the idea behind our research is that, in order to build up and maintain co-operation and establish knowledge transfer in business networks, the companies involved require external support. Networked enterprises have to be taught how KM along complex and networked value chains can be accomplished. An external knowledge manager who acts as an intermediary in the network and represents a neutral trust centre can analyse applicable tools and critical success factors for KM in networks.

The presented research project integrates both, new Information and Communication Technology (ICT) driven organisational concepts and human-oriented approaches with KM methodologies and instruments, in order to implement an innovative KM Service Provider for distributed networks.

## 2. A METHODOLOGY TO DESIGN KM WITHIN INTER-ORGANISATIONAL NETWORKS

A methodology to support the design of KM within inter-organisational networks is supposed to fulfil two essential requirements. On the one side it has to describe how KM in the considered network is structured and with which instruments the handling of knowledge can be organised in the network. On the other side, it has to describe how KM has to be implemented in the network, i.e. the methodology has to support the KM-deployment along the complete KM life cycle.

In analogy with the „Aachen PPS Model“ [15], we structured the methodology into a description and a procedure model. In the *description model* all relevant

elements to design and configure KM in business networks as well as their mutual relationships are described. In the *procedure model* it is explained how and in which phases KM can be implemented in the considered network. Within the methodology, also the interrelations between the two models have to be highlighted.

### 3. DESCRIPTION MODEL

The description model has four elements, which represent the relevant views for the service provider within the design of KM, namely: KM-tasks, Network, Design Areas, KM-Methods and Instruments. As shown in Figure 1, the different views are strictly mutually interrelated.

Figure 1: The elements of the description model

#### 3.1 KM-Tasks

The KM-tasks that have to be dealt with are of the most different kinds [4] [6] [14] [16]. We distinguish between direct and indirect KM-tasks.

*Direct KM-tasks* involve directly the KM of the network; their fulfillment is of great influence on the whole KM process. To the direct KM-task group belong: a) definition of knowledge objectives, b) identification of knowledge, c) acquisition of knowledge, d) development of knowledge, e) distribution of knowledge, f) deployment of knowledge, and g) preservation of knowledge.

On the other hand, *indirect KM-tasks* involve functions that deal indirectly with the KM of the network, but which are nonetheless of great relevance within the conceptual design and implementation of KM within the network. Indirect KM-tasks are: a) KM-controlling, b) management of KM-infrastructure (e.g. IT), c) personnel management, d) fostering / cultivation of knowledge culture and KM-vision, and e) management of knowledge structure.

All such tasks have to be taken into consideration while analysing the existing KM and especially in the following phase, in which the new KM-approaches are modelled and appropriate instruments are selected.

#### 3.2 Network

Distributed entrepreneurial inter-organisational networks can be described according to a variety of characteristics, which have an even wider range of potential expressions [9] [12] [17] [18]. In order to structure the field, a set of clusters of network characteristics was identified: a) *network size and demography* (e.g. number of partners, number of active partners, size of partner enterprises, number of active individuals); b) *legal, contractual and financial characteristics* (e.g. network borders, kind of commitment, funding); c) *economic characteristics* (e.g. position within the value chain of the partners, competitive relations among the partners, industrial sector, network reach); d) *temporal characteristics* (e.g. development phase of the network, time frame of planned cooperation); e) *characteristics related to the network organisation* (e.g. coordination, organisational structure, organisational forms within the network); f) *characteristics related to the management of information and knowledge within the network* (e.g. type of information exchange, type of communication, KM objectives, KM phase).

Clearly, the clusters are open and can be amended with new characteristics and expressions. Based upon all the identified characteristics and related sets of possible specifications a standardized framework for network analysis has been developed.

#### 3.3 Design Areas

The different design areas of KM within inter-organisational networks are presented within the description model of KM within distributed intra-organisational and inter-organisational networks [7] [8]. The four core elements of the Knowledge Management of organisational networks are: Network Knowledge, KM-Processes, KM-Resources and KM-Culture of the network (see also Figure 2).

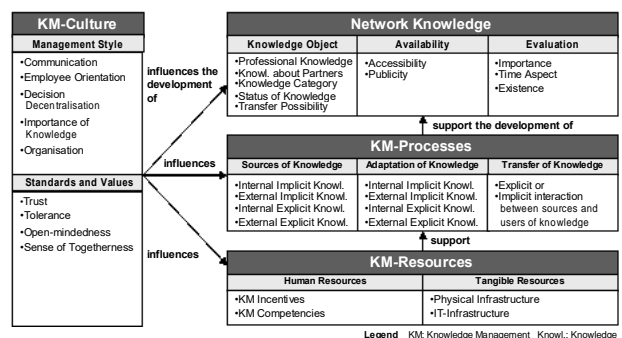

Figure 2: Design areas of KM

Starting point is the actual *knowledge within the network*: Its potential is the reason behind all KM activities. The network knowledge appears in different types of knowledge with specific attributes. It can be retrieved from different sources, and differs according to its accessibility [12] [20].

To realise the potential of Network Knowledge certain *KM processes* are necessary [12] [20]. They can be classified in processes needed to retrieve knowledge, to change knowledge and to pass on knowledge.

Such processes again rely on *appropriate resources* – both human and tangible. For example, employees need certain competencies to be able to carry out KM processes, but they also need the corresponding physical and IT infrastructure to fulfil their tasks [3] [5] [10].

These three areas are all influenced by a fourth one: the *KM culture of the network*. Cultural aspects can enhance an open knowledge transfer or inhibit a positive attitude towards sharing knowledge [1]. Thus a detailed consideration of the management style as well as the standards and values within the network is very important. Different aspects have to be examined in this context: communication, employee orientation, decision decentralisation, importance of knowledge, trust and tolerance etc.

Based upon all the attributes and related sets of possible specifications for each of the four areas an appropriate standardized framework for the analysis of the current KM within distributed Networks has been developed. This analysis framework consists of questionnaires, guidelines for interviews, screen-plays for workshops and tools for each area of the Knowledge Model to help the Knowledge Manager during the analysis of the existing KM in the network. The analysis framework was validated in four networks of industrial partners within the consortium.

### 3.4 KM-Methods and Instruments

The KM methods and Instruments are of the most different kinds [2] [4] [6] [7] [13] [19]. A vast number of KM-methods and instruments was collected and hence classified according to *a) related KM-Tasks, b) KM-design area of action, c) related form of knowledge representation, d) classification of method typology* (technological, organisational, personnel methods and instruments, see also Figure 3).

IT-Instruments for KM	Organisational Methods and Instruments for KM	Personnel Methods and Instruments for KM
<ul style="list-style-type: none"> <li>Knowledge Portals</li> <li>Document Management Systems</li> <li>Groupware Systems</li> <li>Data Warehouse Systems</li> <li>E-Learning-Systems</li> <li>Information Retrieval Systems</li> <li>Intelligent Agent Systems</li> <li>Filter Systems</li> <li>Workflow Management Systems</li> <li>...</li> </ul>	<ul style="list-style-type: none"> <li>Company Vision</li> <li>Knowledge Map</li> <li>Experience Exchange Circle</li> <li>Competence Network</li> <li>Experience Documentation</li> <li>Job Rotation</li> <li>Job Enrichment</li> <li>Job Enlargement</li> <li>Information Mapping</li> <li>...</li> </ul>	<ul style="list-style-type: none"> <li>Coaching/ Mentoring</li> <li>Network for New Employees</li> <li>Learning Coach</li> <li>Interview Techniques</li> <li>Creativity Techniques</li> <li>Shadowing</li> <li>Story Telling</li> <li>Seminars</li> <li>...</li> </ul>

Legend: KM: Knowledge Management

Figure 3: Classification of KM-Methods according to their typology

Hence they have been structured into a tool map, which is currently being implemented into a software tool.

## 4. PROCEDURE MODEL

The procedure model for the deployment of KM within entrepreneurial networks has six phases, which are namely: Initialisation, Analysis, Conceptual Design, Implementation, Operational Management, and Termination.

Figure 4 shows the rough structure of the procedure model for the service deployment. Clearly, the task of the Service Provider for KM within a distributed network accompanies the whole lifecycle of KM within the network.

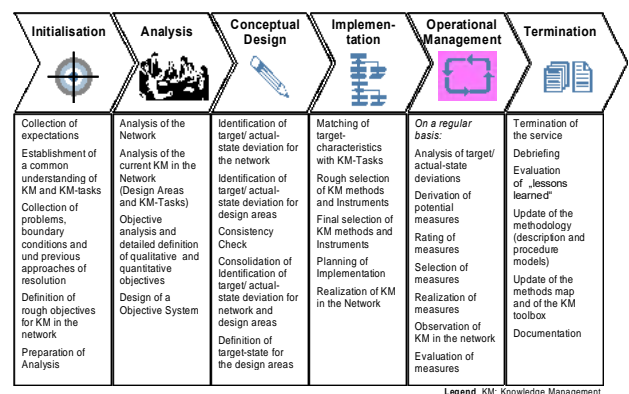

Figure 4: Phases of the procedure model

### 4.1 Initialisation

In the first phase, the initialisation, the Service Provider has to trigger the whole KM project within the involved inter-organisational network. After the collection of expectations of the different stakeholders, a common understanding of KM and KM-tasks within the considered network has to be established. Hence, current problems, boundary conditions and previous approaches of resolution of the KM issue in the considered network have to be collected, in order to be able to define rough objectives for KM in the network as well as the related evaluation criteria. Eventually, all the collected data and information have to be analysed and structured in order to prepare the following phase of analysis.

### 4.2 Analysis

In this phase the relevant elements of KM in the network have to be thoroughly analysed, in order to define a concrete basis for the conceptual design of the striven KM approach. In particular, a detailed analysis both of the Network and of the practiced KM in the Network (in particular with the help of the views “Network”, “Design Areas” and “KM-Tasks”) has to be conducted. Thus, within an analysis of KM objectives of the network, a set of detailed qualitative and quantitative objectives have to be defined in order to structure an objective system for the KM of the network. Eventually, appropriate evaluation criteria have to be defined.

### 4.3 Conceptual Design

Within this phase, the striven KM approach within the network has to be designed conceptually. First of all, the target/ actual-state deviation for the network as well as for the KM design areas has to be identified. Hence, such deviations have to be compared and, if necessary, harmonized in order to assure consistency between the network and the design areas. Eventually, after a consolidation of target/ actual-state deviation for network and design areas, a target state for the design areas can be derived.

### 4.4 Implementation

Within the implementation phase, with the help of the appropriate KM methods and instruments, the KM has to be implemented within the whole network. After a matching of the target states of the design areas with the related KM-Tasks, an initial rough selection of KM Methods and Instruments with the help of the tool map will be undergone. Thus, from all the methods and instruments potentially suitable for the considered network, a final, more restricted tool set will be selected. With this information the KM implementation will be hence planned and eventually realized.

### 4.5 Operational Management

The KM has to be then operationally deployed over the whole time the considered network is active. This phase, the operational KM, is the most time-consuming. On a regular basis, following steps have to be conducted within a control loop: basis target/ actual state deviations have to be analysed, potential measures, if needed, have to be consequently derived and rated. Thus, appropriate measures have to be selected and realized. The behaviour of the network has to be then observed over time, in order to be able to eventually evaluate the implemented measures.

### 4.6 Termination (of Service)

When, for whatever reason, the network terminates to operate or the network management decides not to make use of the offered services anymore, the Service Provider will terminate the service. After the official termination of the service, a series of debriefings with the involved key players will be conducted; hence, the gained „lessons learned“ will be evaluated. If necessary, the methodology (description and procedure models) will be updated, according to the gained inputs. The same applies to a possible update of the methods map and of the KM toolbox. Eventually, a final documentation will conclude the project.

## 5. INTERRELATION BETWEEN DESCRIPTION AND PROCEDURE MODEL

In order to be able to make use of the methodology, the Service Provider needs a further instrument, that shows which view of the description model (KM-tasks, Network, Design Areas, KM-Methods and Instruments) as well other potentially relevant views (e.g. Objective Model or Evaluation Model) has to be used in a specific phase of the procedure model (Initialisation, Analysis, Conceptual Design, Implementation, Operational Management, and Termination).

Figure 5 shows the basic idea of the interrelation between the two models. Clearly, the extent of such an interrelation has to be specified with the needed detail.

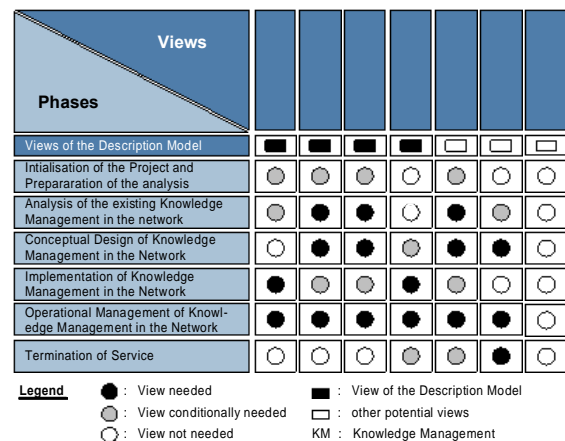

Figure 5: Interrelations between the models

## 6. CASE STUDY: KM IN AN INTER-ORGANISATIONAL NETWORK

In the following a case study of an inter-organisational network, in which the presented methodology is currently being applied, will be presented. The considered case involves the VIA-Network, a regional inter-organisational network of 20 small and medium enterprises (SME) in the automotive industry located in the German Federal State North Rhine-Westphalia (NRW). In this case study, the role of the service provider is deployed by the VIA-Consult GmbH, one of the network companies, that was founded by other network companies as a consultancy firm for the network.

During the *initialisation phase*, a series of workshops with five selected companies<sup>1</sup> of the VIA-network was conducted. Within this phase, the different expectations of all stakeholders were collected and a common understanding of KM was established. Since, until that moment, no Knowledge Management projects had been

<sup>1</sup> Fischer & Kaufmann GmbH & Co. KG, Kirchhoff Kutsch GmbH, Heinrichs GmbH & Co. KG, Heinrich Huhn GmbH & Co. KG, Krah RWI GmbH. VIA Consult GmbH & Co. KG acted as intermediary between the research institutes and the network companies and carried out the data collection to a large extent.

conducted, no specific problems could be identified in the field.

Hence, in the following phase, a detailed *analysis* of the existing network knowledge was carried out. The objectives of co-operation within the VIA-network are, among others, combined sourcing, know-how-exchange in working groups, joint projects and joint ventures. Since no specific area of cooperation or business processes could be specified for a support by KM beforehand, the main goal of the analysis of the network knowledge was the identification of potentials for knowledge transfer. Furthermore the collected data were also used for the development of a detailed map of the network knowledge in order to assist network partners in finding sources of knowledge for specific topics within the network.

The overall goal of the following phase, the *conceptual design*, was to select appropriate KM approaches for the support of inter-organisational business processes. From the data gained within the analysis, several potential areas for knowledge exchange could be identified. Work tasks that appeared to be suitable for an exchange of knowledge could be found mostly in non-productive areas. In the productive areas, mainly organisational topics were identified. Examples for the identified areas of potential knowledge sharing are: organisational concepts for the flow of goods within the firm, organisational concepts for reducing interfaces within job processing, analysis of customer satisfaction, and establishment of performance figures. As far as work tasks in the productive areas are concerned, the sharing of knowledge used in comparable technical processes should offer advantages. In the study at hand however, the network companies involved appeared to focus on the potentials in non-productive and organisational topics. Several possible explanations for this were identified: on the one hand in spite of technical work tasks, which appear to be similar on the level of abstraction analysed in the study, the companies manufacture specific products, so that they are not directly comparable. On the other hand the companies' core competencies are concentrated in the productive areas. This implies that the exchange of knowledge concerning these areas is more likely to be regarded as critical. A further explanation lies within the fact that the companies' core competencies are considered highly developed so that an exchange of knowledge and experience is sought in other areas.

During the following phase, the *implementation*, based upon the identified potentials for knowledge exchange and the results of the analysis and conceptual design, appropriate KM-measures as well as pilot areas for their implementation were chosen. The objective of such pilots was to initiate and support the transfer of knowledge and to generate best practices for the whole VIA-network. With the help of the method map developed within the project, the following

KM-measures were chosen: thematic working groups, Communities of Practice, as well as Yellow Pages and database-solutions. The areas in which such measures are going to be implemented are: remuneration, emergency planning, treatment of surface, performance figures/ controlling, analysis of customer satisfaction, and total productivity management.

At the current stage, the thematic working groups and the Communities of Practice are being initiated, while the technical solutions for the Yellow Pages and the databases are being selected.

## 7. CONCLUSIONS AND FURTHER NEED FOR ACTION

The methodology presented in this paper provides a framework for the analysis, conceptual design, implementation and operational management of KM within inter-organisational networks. The methodology consists of a description model, in which all the relevant elements (i.e. KM-Tasks, the network itself, KM Design Areas, KM Methods and Instruments) of KM within networked organisations are included, as well as a procedure model, in which the different phases of the KM life cycle in the network are introduced.

The application of the methodology in the VIA-network was also presented; in particular the phases of initialisation, analysis, conceptual design, and implementation were discussed. The next step will be the operational management over time of the selected KM-measures. In a final step the implemented KM-measures will be evaluated in the VIA-network and hence extended to the other 15 enterprises of the network.

As far as the theoretical framework is concerned, the current research issues are a deeper analysis of the interrelations between the elements of the design areas, since within the case study potentials could be highlighted; eventually, the development of an appropriate set of performance figures to evaluate the effects of KM-measures in the above-mentioned areas is also striven.

## ACKNOWLEDGEMENT

The Project „*Der Dienstleistungsmanager im Netzwerk der Zukunft*“ (“*Service Provider for Knowledge Networks*”) is funded by the German Federal Ministry of Education and Research (grant number: 01HW0206). The other partners are: Bauer Maschinen GmbH, the Chair of Product Development at Munich University of Technology, GPS Schuh & Co. GmbH, VIA Consult GmbH, WET Automotive Systems AG.

### ABSTRACT

The article proposes a more productive way and approach for an e-learning research methodology. The e-learning tools: the computer and the Internet are serious obstacles for sense making in the student's behaviour context. Their use defines in a way the user's behaviour. This article underlines the advantages of qualitative methods for this kind of research and vote for an ethnographic method. Our suggestion has many assets in order to understand and consider interactions. Communication processes tend to have a strong influence on learning behaviour and are almost neglected during quantitative methodology. Accurate and corrective feedback is essential for establishing and performing e-learning techniques. Our suggestions are highlighted by lessons learnt from Montpellier Business school experience.

**Keywords:** E learning, qualitative methodology, context, interaction, business school, France.

This article is an attempt to present the context of a long-term study conducted in Montpellier Business School. We are interested in the e-learning tool and how both teachers and students perceive it so that best results will be potentially attained. We are going to show you the different aspects of the subject by exposing it in terms of a system. A system whose complexity is obvious and thus the difficulties are numerous. The choice of our methodology was made by taking into account this complexity and we have no choice but being post-modern and transdisciplinary. Although results are not yet publishable, many lessons learnt from this experience can be presented. We are in the first phase of our research where context and methodology have an important role in making choices for the project in the future. In a global forum where both researchers and practitioners come together and share ideas as defined in the goal of this congress, our ambition is to share these ideas and exchange point of views and lessons learnt in the same field from colleagues. Theoretical significance is an important issue in academia, where construct validity, internal validity, generalizability and reliability of the research finding are hallmarks of good quality research. (e.g. Tahai and Meyer, 1999; Scandura and Williams, 2000)

### 1. THE CONTEXT

Montpellier Business School is doted with an e-learning tool since 2001. The first initiative was made in order to help students that during an exchange one-year-program with affiliated business schools all over the world could "attend" the same course with the ones in the Montpellier campus. As the years went by, e learning was introduced to all students regardless of their place of stay as a new learning tool. Both students and teachers were reluctant to this change. We'll see how we overcame this resistance to change progressively by measures taken for motivating both students and teachers to use this new tool.

"Our conceptual point of departure is that activities of individuals become meaningful only if they are studied in a systemic context, within the comprehensive social system. Research inspired by the qualitative paradigm strives at doing research in, rather than on organizations and has specially made use of the case study methodology." (Rouse and Daellenbach, 2000; Mintzberg, 1999; Eisenhardt, 1989).

Goffman as a product of the Chicago School emphasizes a qualitative analysis of the component parts of the interactive process. He explores the details of individual identity, group relations, the impact of environment, and the movement and interactive meaning of information. Interaction is viewed as a "performance" shaped by environment and audience, constructed to provide others with "impressions" that are consonant with the desired goals of the actor. It is not the interface that counts but the interaction. And most specifically we are interested in situated interactions/artefacts (in situ) and understand the users during these situations.

A learning situation is quite complex to comprehend. Jean Piaget is one of the most important theorists in the field of learning. According his studies, the central mechanism for the child to develop his intelligence depends on two complementary operations: assimilation and adaptation. The first consists in integrating new data in mental structures that already exist. The second is about changing the established structures and adapting to more complex structures. The young child explores his universe by tools he disposes such as his hands, his mouth and all five senses. We have observed the same mechanism on young students during class. As observed by René Spitz this type of mental and cognitive activity necessary to our personal development can be blocked by affective perturbations.

Another mechanism reinforces learning: the transfer between student and teacher.

It is not about the knowledge transfer but the affective “charges” of the student projected to his teacher. It is a mechanism that reminds us the psychoanalytic transfer. In all relationships this transfer exists even if actors are conscious or not.

This mechanism can be compared to what is commonly known as the Pygmalion effect. Robert Rosenthal studied this mechanism in the 60’s at the University of Harvard. He concluded that if the teacher believes in students’ chances for succeeding he could positively influence their performances. If on the other hand he has doubts, students are very likely going to confirm his belief. How is this Pygmalion effect going to be transposed in an e-learning situation?

We chose not to study cognitive activities such as memorization and motivation and their impact on learning. It is obvious that they play a key role. We should underline the paradox between the necessity to adapt and at the same time the resistance to change for seeking security. Man is between two opposed urges: life and death, Eros and Thanatos.

The e learning has a shattering effect on our way of learning and teaching as well. We are continuously seeking to adapt to a new environment. But what type of change is at stake? By putting aside financial stakes that will not be studied in this paper, we will be mostly interested in a comprehensive approach to established practices. What is the future of teachers? What are we expecting from them? Should they be the course “designers”, the tutors or both? What will this change bring about to their every day habits?

The massive use of information and communication technologies, as the Internet and the pedagogy used to accompany this tool ought to be innovative. The teacher is looking for means to achieve the best results and establish a particular methodology. He is constantly searching tools for his pedagogical activity. The innovative technology, the teacher’s distance and the differences compared to a traditional class impose new findings to manage this new learning situation.

Teachers must become information architects. Elaine and Roger Everden have focused their work in this area defining their branch of information architecture more generally:

“Information architecture is the foundation for managing information in general as a corporate resource. It describes the theory, principles, guidelines, standards, conventions and dimensions that are necessary to design an effective management framework for information. Its purpose is to design information structures that help people to use information in effective, productive and innovative ways.” (Everden and Everden, 2003)

A community of teachers is born where cooperation and solidarity are omnipresent not only between teachers but also between them and students.

Each student creates his own “strategy plan” for achieving the goal of the course. He is his own manager of time (rhythm) and pedagogy. They have the total freedom to proceed as they wish. Students are encouraged to evaluate themselves by quizzes (self-evaluation). The simplified teacher-transmitter, student-receiver sketch was replaced by the system teacher-student where the first is not the only knowledge holder but also a mediator.

## 2.CHANGE AS CO-EVOLUTION

“Resistance to change is considered as an obstacle to change implementation. People resist change because they feel uncertainty about their future, are concerned with potential loss of territory or are afraid to fail in front of new expectations and tasks.” (Wanberg and Bans, 2000)

Some key elements to successful change management are:

- “Assessing organizational culture with an emphasis on informal and formal communication and structure
- Supporting participation and involvement
- Understanding people’s fears and concerns and
- Setting up a training strategy aiming at offering education and support.

These tactics all take into account the importance of the human factor as a critical success or failure factor for understanding and managing change programmes.” (Vakola, 2002)

Technology is a key enabler for implementing change. Students already familiar with the Internet, game boy and other videogames shouldn’t have many problems to adapt. A study conducted by Sherry Turkle shows that the reaction in front of the computer varies and is very personal. French psychiatrists have used computers in a therapeutical context and can enumerate many advantages.

The computer is the mediator, the artefact that facilitates interpersonal exchange.

“Change is a never ending process of continuous transformation, as it ought to be in a world where Darwin’s motto about the responsiveness to change seems more “updated” than ever: It is either the strongest species that will survive, nor the most intelligent, but the ones most responsive to change”. (Prastacos, 2002)

The direction of Montpellier Business School taking into account the importance of the project is establishing a new organizational structure in order to motivate all the

personnel to take part in it. Teachers need to attain a certain level of confidence on this tool as Watzlawick has underlined in order to obtain change. The hierarchy of the institution is doing everything for helping them to obtain this confidence. Advantages for teachers included less class hours, training and technical support, more research activities and free Internet access.

### 3.METHODOLOGY CHOICES

“Despite the so-called interpretive or hermeneutic turn in the social sciences that has also influenced and, some would argue, undermined this discipline (Reinhardt, 2002), ethnography has clearly established itself as an important alternative to other qualitative approaches as a method for the applied social sciences.”

The definition of ethnography by Hamersley & Atkinson (1995) is one of the most quoted in the field: “... we shall interpret the term “ethnography” in a liberal way, not worrying much about what does or does not count as examples of it. We see the term as referring primarily to a particular method or sets of methods. In its most characteristic form it involves the ethnographer participating, overtly or covertly, in people's lives for an extended period of time, watching what happens; listening to what is said, asking questions—in fact, collecting whatever data is available to throw light on the issues that are the focus of the research”.

According to Garfinkel (1991), “there are good reasons for ethno methodological studies to specify the production and accountability of immortal, ordinary society—that miracle of familiar organisational things—as the local production and natural, reflexive accountability of the phenomena of order. Among those reasons is making discoverable one of those phenomena of order, but only one, namely what analysis incarnate in and as ordinary society, as practical actions locally and interactionally produced and witnessed embodied details, could adequately be”.

Observational methods by which an individual or individuals gather data on processes and behaviours are being chosen. They provide us with the opportunity to collect data on a wide range of behaviours, to capture a great variety of interactions and to openly explore the evaluation topic. We can develop a holistic perspective, an understanding of the context within which the projects operates. This may be especially important where it is not the event that is of interest but rather how the event fit into or is impacted by a sequence of events. Observational approaches also allow the evaluator to learn about things the participants or staff may be unaware of or that they are unwilling or unable to discuss in an interview or focus group.

The most fundamental distinction between various observational strategies concerns the extent to which the observer will be a participant in the setting being studied.

“The ideal is to negotiate and adopt that degree of participation that will yield the most meaningful data about the program given the characteristics of the participants, the nature of staff participant interactions, and the socio-political extent of the program”. (Patton, 1990)

As Hamersley suggests: “to rely on what people say about what they believe and do, without also observing what they do, is to neglect the complex relationship between attitudes and behaviour.”

It is not uncommon to think of organisations as systems (Parsons, 1951; Luhmann, 1971). More precisely: “a system is a structure of interacting, intercommunicating components that, as a group, act or operate individually and jointly to achieve a common goal through the concerted activity of the individual parts”(Thomas 1979). The study of ethnography is automatically the study of some form of organisation or system.

The relationship between people, events and activities is not context free. It can only be understood fully by an appreciation of the context and way in which people interpret their world. Starting by questioning how we make sense of our world in terms of our values, attitudes, actions and interpretations is an essential first step. Theories about what should be done and ways of acting are themselves the product of previously “taken for granted” action. Questioning assumptions and unravelling taken for granted views and perspectives helps to set new co-ordinates and thereby re- defines problems and issues (Aguinis, 1993; Schein 1992; 1996).

Orlando Fals Borda had written about action research: “action research as investigating reality in order to transform it”. “Action Science seeks to change work based and interpersonal behaviour and as such is particularly relevant for business organisations (Argyris, 1999; Argyris & Schon, 1991; Putman, 1999). It is an inquiry approach suited to an organisational culture, which appreciates double-loop learning and is committed to interpreting knowledge in a way that reveals organisational patterns, processes and defensive routines. In Action Science, intervention is psychological since it explores innermost feelings and emotional reactions, some of which are protected by personal defence mechanisms. As these defence mechanisms break down individuals may feel vulnerable and exposed. Risks to self and others involved are reduced if the group themselves are sensitive to others feelings and ensure participants finish sessions on a positive note.”

Dialogue between researchers and teachers and students was conducted during the three years in form of interviews. The research report is said to be a joint construction as a result of these dialogues. Each student is a different case study and all we can conclude is some trends. “Case to case generalization is based on

analogical reasoning. Such reasoning is only plausible when there are solid arguments that, when a particular researched case has characteristics which are relevant for the research conclusions, another case that has not been also researched also has these characteristics.”(Miller, Fredericks, 2003) How qualitative data become evidence for a claim? By blending observational methods for studying dynamic phenomena that change over time.

In order to comprehend an e-learning situation, we will conduct interviews, we'll make a case study that will be in situ and also take part in observations. We are in the first stage where about 20 interviews were made with teachers involved and reluctant ones as well as students. The sample of students was considering a large variety of behaviours: the enthusiastic, the indifferent, foreign students as well as potential students not familiarised with the tool yet

#### 4.CONCLUSION

Rapidity, adaptability, flexibility and autonomy are some of the key qualifications in the beginning of the third millennium. A good manager ought to be “intelligent” and proactive. In this context, students in business schools must learn to manage “change” and being able to adapt in different situations

It is quite delicate to make any kind of conclusions in this stage. It is more about asking a series of questions. If this questioning is pertinent our ambition is fulfilled.

Frontiers are abolished and distance is a key term we should not continue ignoring. E-learning education not only offers us the possibility to learn more and differently but also familiarizes us with the notion of distance that is no more an obstacle but a “banal” element of every day life.

### ABSTRACT

Adaptive User Interfaces have a long history rooted in the emergence of such eminent technologies as Artificial Intelligence, Soft Computing, Graphical User Interface, JAVA, Internet, and Mobile Services. More specifically, the advent and advancement of the Web and Mobile Learning Services has brought forward adaptivity as an immensely important issue for both efficacy and acceptability of such services. The success of such a learning process depends on the intelligent context-oriented presentation of the domain knowledge and its adaptivity in terms of complexity and granularity consistent to the learner's cognitive level/progress. Researchers have always deemed adaptive user interfaces as a promising solution in this regard. However, the richness in the human behavior, technological opportunities, and contextual nature of information offers daunting challenges. These require creativity, cross-domain synergy, cross-cultural and cross-demographic understanding, and an adequate representation of mission and conception of the task. This paper provides a review of state-of-the-art in adaptive user interface research in Intelligent Multimedia Educational Systems and related areas with an emphasis on core issues and future directions.

**Keywords:** Adaptivity, Adaptive User Interface, E-Learning, Preference Modeling, User Modeling, Multimedia, HCI

### 1. INTRODUCTION

The emergence of such revolutionary technologies as Graphical User Interface (GUI), Artificial Intelligence (AI), Soft Computing, Multimedia, Hypermedia, Internet, etc. has created an intense interest in computerized and ubiquitous educational systems like Intelligent Multimedia Educational Systems (IMES) with adaptivity at its core [12], [21], [28]. Indeed, individualized teaching is the most favored practice of instruction and different teaching strategies work best in different contexts. Consequently, the ability to adapt to an individual learner's needs as well as context could significantly stimulate both the learning process and the user engagement [13], [21], [26]. As such, an IMES can contribute to the success of learning if it adequately represents the domain tasks, concepts, and learning goals and intelligently adapt its presentation in terms of complexity and granularity according to the cognitive level/progress of the learner [21], [27].

The development of such pervasive enablers as the Web and Mobile Technologies has further highlighted the research in Adaptive User Interfaces (AUI) offering tremendous educational opportunities by removing temporal and spatial constraints as well as providing personalization and interactivity [10], [12]. However, it is the Web and Mobile Learning Services where the problem of 'being lost in hyperspace' becomes especially critical [13]. As such, the 'information overload' is no more a trite buzzword but a frequently encountered reality for many. Consequently, an adequate educational framework for IMES should focus on cognitive development and knowledge acquisition, through creative, efficient, efficacious, and intelligent tutoring strategies for presentation of the domain knowledge. An AUI in IMES is geared towards seeking

superior outcomes in the spatial and temporal separation as well as presentation of domain knowledge based on user's explicit and implicit preferences, constraints, cognitive progress, decision styles, learning objectives, and access modes.

The AUI has been an object of attention since long and has a significant role in IMES from cognitive, pedagogical, psychological, and social aspects. Adaptivity in IMES could come in terms of adaptation of multimedia content, presentation, navigational options, teaching strategies, etc. to user's needs [45]. In addition, the dynamics of today's society underscore the need for adaptive interfaces accessible by different user groups, including disabled and elderly [1]. However, the potentially diverse scope and heterogeneity of the target population pose greater challenges [27].

In view of diversity, subjectivity, and tedium involved in pertinent concepts and issues, we provide only a brief overview of such concepts. Furthermore, a few capabilities and caveats in the design and deployment of such systems are highlighted. Various promising and synergistic technological options for design and implementation of an AUI are presented for reference purposes, as well.

### 2. INTELLIGENT INTERFACE PARADIGMS

Research in intelligent user interfaces has been built on such notions as natural language understanding, explanation systems, intelligent tutoring systems, intelligent help systems, computer-aided instruction, multi-modal systems, model-based development, intelligent presentation systems, and agent-based interaction. As a result, several paradigms have been established. The most prevalent paradigms include

user-based interactions, model-based interaction and agent-based interaction [5], [16]. An IUI may facilitate the learner's selection through either *adaptive ordering* of options (based on frequency of use data), *adaptive prompting* (based on contextual information resulting from a model), or *guidance* (with the help of an agent). The boundaries of different paradigms and technologies are quite fuzzy. Nevertheless, here we provide a brief overview of the most popular paradigms.

### 2.1 User-based Interaction

One frequently cited indication of intelligence in UIs is the ability to adapt the output to the level of understanding and interests of individual users, typically served by adaptivity, adaptability, or dynamicity of the aspects of interaction [34]. An *adaptive* UI changes dynamically in response to its experience with learners [24]. Such an effect is typically achieved by using dedicated software tools responsible for acquiring and maintaining user models and reasoning towards suitable interface adaptations. In contrast, an *adaptable* UI provides tools that allow the user to tailor certain aspects of the interaction in using a system [13], [34]. Such systems allow the user to modify certain aspects of the interactive behavior. Whereas, in a *dynamic* UI the user's behavior is monitored just like with *adaptive* UI. However, instead of changing (adapting) a predefined presentation, dynamic hypermedia systems generate a presentation from "atomic" information items. The research in user-based interaction design is built upon advances in intelligent tutoring systems, learner modeling, explanation systems, and knowledge representation.

### 2.2 Model-based Interaction

Model-based Interaction development involves the use and articulation of reusable models and knowledge repositories encapsulating the wide variety of details pertaining to the UI development. It promises to decrease both the time and expertise required to create interfaces, through reusable models, automation, decision, and design support mechanisms. It enables design support such as critiquing, design refinements, and incremental updates. However, the current generation of model-based interface development tools has not appropriated the full range of the aforementioned potentialities [5].

### 2.3 Agent-based Interaction

This paradigm involves the use of software agents to delegate tasks concerning various facets of interaction [5], [15]. Although there is no agreed upon definition of intelligent agents, most intelligent agents are characterized by autonomy, adaptivity, pro-activity, and sociability [15], [31]. They usually contain a representation/model of belief in the state of the environment and have facilities to discover from

patterns of behaviour from user(s) and agent(s). There are three major types of agents involved in agent-based interaction: *interface agents* tie closely to an individual's goals, *task/tutor agents* involve processes associated with arbitrary problem-solving tasks, and *information/domain agents* connect to source(s) of information. An interface agent learns from user's actions working as an intelligent assistant. Whereas, tutor agent provides scaffolding (or envelope) to the learner and progressively removing it as the learner internalizes the knowledge. As such, these agents also require models of the learner, tutor, as well as domain in order to perform their tasks.

## 3. ADAPTATION TECHNIQUES

As already mentioned, adaptation in a UI can be served by adaptivity, adaptability, or dynamicity in the aspects of interaction. In IMES perspective, adaptation to both user and context are needed. Adaptation to user/learner requires a learner model containing attributes of the learner to which adaptations are sought. At the same time, adaptation to context requires such knowledge models as teacher model, domain model, and interaction model. The adaptation effect may be realized through adaptivity in content selection, presentation, recommendation, etc. [11]. Adaptation may also furnish navigational support [13]. Indeed, different adaptation techniques work most efficiently in different context and require meticulous selection of the most relevant technique as well as the need for adaptation in the adaptation technique(s), or meta-adaptation, during the cognitive progress of the learner [6], [13].

In IMES context, the adaptive navigation support is one of the simplest, earliest, and most extensively studied aspects of automatic adaptation. The underlying notion is to help users find their paths in hyperspace by adapting link presentation to the characteristics/model of the user. The popular means for incorporating adaptive navigation support are direct guidance, sorting, hiding, annotation, and generation of link structure suitable to the learner characteristics [13]. These techniques are used to achieve both global and local guidance/orientation support. Studies have demonstrated the effectiveness of various adaptive navigation support techniques in terms of browsing and learning efficiency [13]. Adaptive content selection is another aspect of adaptivity resulting from the varying interests and preferences of various users regarding available information. It allows information pieces relevant to learner's cognitive level and/or goals to be presented to the user. However, the selected content must be presented in a form appropriate to the user. Consequently, a natural extension to this would be the adaptive content presentation that exhibits different visual layout and/or media. Adaptive recommendations also form an important dimension in achieving effectiveness of an AUI by providing users suggestions about the future line of action.

An ideal scenario would be where the adaptive system has all or most of the adaptation techniques at its disposal. However, it requires a sound understanding of applicability and limitations of each adaptation technique as well as their combinations. Currently, there is a relative dearth of such complex and extensive studies because of obvious reasons.

#### 4. CORE ISSUES IN AUI

Significant research has been done in developing AUIs for accommodating the heterogeneity and evolution of user characteristics. It draws from such diverse fields as psychology, cognitive science, ergonomics, human-computer interaction, AI, etc. However, here we focus on some core issues in AUI within the IMES context.

The goal of adaptivity in IMES is to promote efficient learning rather than simply accommodation of a learner's preferences highlighting the need for a sound understanding of both user and context. The general requirements for a system adaptive to the user include an underlying theory associating user behavior to interface needs, an access to behavioral cues, a variety of interface designs alternatives, and knowledge models accumulating behavioral cues and needs [34], [21], [39]. Nevertheless, the need to make adaptivity actually work in commercially deployable systems while meeting the usability and acceptability requirements poses notable constraints on the theory [34].

A universal problem in any hypermedia navigation is cognitive overload and disorientation [13]. However, the keyhole effect resulting from the contextual, spatial, and temporal separation of information in IMES provides an opportunity to reduce the learner's cognitive overload and distraction [27]. For instance, the amount of information and its context may be constrained in early stages of training with progression based on user's current cognitive and learning capabilities etc [27].

Some possible negative effects of AUI are related to usability, privacy, and trust issues that should be adequately addressed [12], [29]. Indeed, the very idea of adaptivity violates several well-defined and accepted usability principles largely developed for rigid direct manipulation interfaces [41], [42]. Moreover, frequent adaptations reduce consistency in the UI, a much sought for goal in HCI, hampering the learning rate [6], [42].

For instance, a sudden and automatic change in the interface may confuse, disrupt, and frustrate the user. Moreover, the notorious Production Paradox suggests that learners may not adopt/learn strategies that improve long-term efficiency and efficacy. Instead, a learner may adopt a strategy that helps in accomplishing desired task on an ad hoc basis and adapting to such 'quick and dirty' strategies could even prove counter-productive.

Absolute, or near absolute, user control is another important usability consideration that is difficult to achieve in AUIs. It has been recommended that user

must get a 'sense of control' over automatic adaptations by making the system 'scrutable' [17]. However, studies in adaptive E-stores have indicated that, when adaptivity is based on implicit information, users want control of both the content and the context [6].

In contrast, AUIs serve many usability guidelines better than rigid interfaces such as reduced information and cognitive load, enhanced task support and visibility of relevant objects or actions, etc. Some researchers have even suggested that an AUI can be effective primarily when actions available to the user remain same.

Like any intelligent system, an AUI may make mistakes in determining the implicit intentions of the learner. The time needed to learn any user-controlled recovery mechanism hampers the system acceptance. Even the simplest of such recovery approaches may result in an increased cognitive load, confusion, and distraction of the user from the intended task. In addition, such user-controlled recovery mechanisms reduce the pedagogical efficacy of the system.

The foremost task in IEMS is to define such design goals as generalizability, scalability, portability, central data storage and ubiquitous access as well as higher responsiveness, learning rate, user engagement, user satisfaction, and reusability, etc. [15], [17], [10]. Nevertheless, the complexity, diversity, volatility, subjectivity, and multiplicity of considerations in designing an AUI mean that our expectations from such systems should be realistically limited.

The next important task in an AUI is the creation of knowledge model, as discussed later. Nevertheless, the richness of the human behavior, technological opportunities, contextual information, as well as multi-sensory nature of the IMES mean there is no panacea in such sensitive human-computer interaction area. Conceivably, the majority of adaptive systems in IMES context are research-level systems [12], [13]. Currently, Web courses present same static learning material to students with diverse cognitive and contextual goals, preferences, and capabilities [13]. Nevertheless, user-modeling experiments have confirmed the importance of a sound theoretical foundation operating in synergy of such practical issues as performance, reliability, and usability.

In IMES context, modeling the pedagogy and linking it to various user characteristics or learning styles is an important determinant of superior learning. Consequently, it is desirable to use the pedagogical strategy most suitable to the learner. As such, the pedagogy would also play an important role in determining the granularity and style of presentation.

#### 5. KNOWLEDGE MODELS IN AUI

An AUI can adapt to either the user or the context of

user's work. However, an effective AUI requires an ability to adapt to both user and context. This requires extending the basis of adaptation by complementing the classic user models with models of context such as purpose, subject domain, pedagogy, interaction mode (platform, location, time, bandwidth) etc. [13]. It means learning theories, concepts, pedagogies, and their impact on the instruction design and practice are important [27]. Consequently, various knowledge models are required in achieving adaptivity in IMES.

The initial LM could be generated by default values, a set of stereotype-based LMs, or querying learners. However, such stereotypical models lack coarse granularity. Furthermore, querying the users to build initial model increases cognitive and ergonomic load on users. Consequently, an effective LM needs to be constructed unobtrusively based on user behavior using both long-term and short-term information.

## 5.2 Domain Model

Primary models include user/learner model, domain expertise model, pedagogical/tutor expertise model, and interface model. A Learner Model (LM) captures the knowledge about the user for the system to respond to the needs of the user efficiently. A Domain Model (DM) represents the features of the particular domain that is of interest to the user. A Tutor Model (TM) holds the knowledge, capabilities, assumptions and limitations of the tutoring system itself. An Interface or Interaction Model (IM) possesses the dynamic representation of the dialogue between the user and the system. The defining boundaries of these models can be quite fuzzy and some other modules/models may also appear. Nevertheless, the separation of contents, instructional philosophies, and adaptation options or concept structures facilitates conceptualization as well as system maintenance.

The Domain Model (DM) is the abstract representations of the target subject area. It deals with the link relationships between the concepts and the decomposition of concepts in a structured hierarchy of sub-concepts and atomic information such as texts, images, sounds, and videos [33]. Such conceptual representations should enable the system to analyze, understand, explain, communicate, or predict some aspects of the domain. Tasks, objects, and data form basic building blocks in various DM paradigms. The Task based approaches seek to represent the domain in terms of tasks. The Object-oriented paradigm represents the domain in terms of the objects, the relationships between objects, and exchange of information between objects. Data-Oriented approaches tend to abstract the structure of the domain as a network of entities and the functions of the domain by a network of dataflows and processes.

## 5.1 Learner Model

The main objective of an AUI in IMES is to tailor the learner's information space by presenting learning material according to learner's cognitive level/progress, socio-cultural attributes, goals, plans, tasks, preferences, and beliefs [15]. This objective is highly dependent on the maintenance of adequate, efficient, and reliable LMs by explicitly representing and updating the user's characteristics, preferences, and behavior. This information is used by other components of the system for providing adaptivity. It has been frequently argued that an LM can result in improved interaction by removing the dissonance between learner's cognitive abilities and demands of interactions in IMES [8].

An LM tends to address three general purposes: inferring the user knowledge or general ability (Knowledge Assessment), recognizing the user plans or goals (Plan Recognition), and predicting the user inferences and future behavior (Action Prediction). It should be capable of representing a learner's multiple interests and misconceptions as well as flexible enough to adapt to changes in a user's cognitive level due to interaction with information. Consequently, an LM must deal with the uncertainty in making inferences about a user under incomplete and uncertain information, raising important issues discussed later. Nevertheless, studies have shown that adaptive student modeling can be remarkably robust and contribute to improved learning in IEMS environment [16], [34].

A DM mimics the expert system paradigm with an ability to generate multiple knowledge-based superior solutions instead of one ideal outcome, thereby endowing flexibility and robustness [3]. Such an approach would involve elaboration, articulation, enumeration, and ranking of competing design alternatives through propagation of design knowledge into the development cycle and embedding design recommendations into the interface implementation [5]

## 5.3 Tutoring Model

The Tutoring Model (TM) provides a model for the pedagogical philosophy allowing adaptation to different learning styles [37]. It should be able to dynamically incorporate individual differences among students. As such, it requires substantial efforts in knowledge acquisition and representation. TMs are primarily constructed around defined problem solving tasks and cognitive models, so they can interpret each student action (*model tracing*) and draw inferences about the student's knowledge state from each student action (*knowledge tracing*) such that the pedagogical decisions reflect the needs to each student [37].

## 5.4 Interface Model

The interface is the communication between the student and the aspects of the system. As such, an Interface Model (IM) is required for intelligently controlling the

dialogue, the screen layouts, and other interactions with the learner. Each interface element is linked to an internal representation of an instructional goal and the current state [16]. The two main aspects considered in IM are multimedia content and user exploration. The use of multimedia objects in IMES promises instructional efficacy. However, the complexity of the learning activity involving such a variety of tasks as information retrieval, navigation, and memorization means that just a naïve collection of multimedia objects does not promise improved, or even proper, learning [37]. Various tasks in AUI have different requirements and consequently need different multimedia objects for efficient and efficacious interaction. Consequently, learners need to be provided with diverse forms of interactivity that match the pedagogical objectives of the IMES.

## 6. UNCERTAINTY MANAGEMENT

In any human modeling, making inferences about the beliefs, abilities, motives, and future actions of people require a good deal of uncertainty management that may manifest as incomplete, inconsistent, imprecise, or uncertain information [4], [8]. Incompleteness suggests the unavailability of some of the information.

Inconsistency refers to the difference or conflict in the knowledge elicited from implicit or explicit information. Imprecision refers to values that are vaguely defined or measured inaccurately. Uncertain information points to the subjectivity in estimate about the value/rule.

The information available for inferencing in AUIs is inherently imprecise, vague, ambiguous, and incomplete with greater gap between the available evidence and drawn conclusions using fairly meager and haphazardly collected data [46]. The knowledge-intensive nature of various models in AUI implies that a little uncertainty in information may translate mischievously into the system response [47]. Consequently, any AUI decision mechanism requires robust ways of coping with such uncertainties. Unfortunately, the majority of theories and tools devised to handle subjectivities and uncertainties in information are quantitative in nature relying on crisp data. Such tools, in general, cannot handle the subjectivity and uncertainty emanating from all aforementioned sources [3], [35]. Thus, formulating effective ways of analysis and revision of knowledge models in AUI under uncertainty is an important research direction. Early solutions to this problem were based on heuristics or ad hoc techniques. Other approaches opted to constrain learners follow a predetermined line of reasoning, making it explicit. Nonetheless, such approaches could result in inflexible and overly constrained interface.

However, certain numerical uncertainty management tools have gained prominence. These methods for tackling uncertain knowledge are generally referred to as Soft Computing (SC). The role model for SC is the human mind and differs from conventional or hard

computing in its tolerance of imprecision, uncertainty and partial truth. As such these hold immense promise for AUI.

### 6.1 Deterministic Approaches

Deterministic approaches work under the simplifying assumption that all the required information required can be quantified a priori and made available in need [3]. Such approaches usually make use of arbitrary default, user-defined, or expected values that are possibly refined by the user during the course of interaction with IMES. Conceivably, these myopic approaches are not effective in such complex and mercurial environments as IMES. In addition, there are user-based approaches that rely on ad hoc methods such as getting weights, preferences, and properties through user inputs. The usefulness of such approaches is severely limited by cognitive, informational, and functional capabilities of the user. It also distracts the user from her main objective, i.e. learning the subject at hand. Furthermore, personalization based on user inputs cannot accommodate changes in learner's interests or cognitive progress [23].

### 6.2 Algorithmic Approaches

An extension of deterministic approach is the assumption that some prudently devised algorithms could encompass all plans and corresponding actions. Indeed, it has been shown that plan recognition could be treated as deduction under a particular set of assumptions about the possible causes of actions [25]. Various algorithmic approaches work by determining a learner's plan from a library of possible plan schemas [9]. Such content-based algorithms may perform well at determining the general context. However, these cannot easily evaluate qualitative attributes like user's decision style, perceived usefulness, timeliness of presentation, etc. Consequently, even a good user-modeling algorithm alone does not form a truly useful system [10]. Furthermore, such algorithms require all plans to be identified to explain the learner's behavior and result in combinatorial intractability of the search task. Some probabilistic, heuristic, or soft computing approaches may reduce the search space and make plan recognition more tractable. Nevertheless, the problem in adaptive IMES is more complicated in the sense that not only we have to predict the learner's intentions but also predict learner's cognitive progress based on which system should provide higher learning opportunities.

### 6.3 Probabilistic Approaches

The majority of uncertainty management methodologies quantify uncertainties in form of some probabilistic measures that are propagated during reasoning [35]. Examples include the Bayesian Belief Networks, Certainty Factors, Dempster-Shafer, etc. Such approaches are based on the premise that assigning a

certain value to a plan hypothesis reflects the likelihood of its being pursued by the user [23]. Thus, it lends itself to some probability-like measure for representing information about user's individual preferences [46]. The key issue in using probabilistic approaches is accurate representation of the probabilistic dependencies in the task domain. However, student modeling using probabilistic approaches is problematic due to dynamism in student's knowledge resulting from interaction with information.

Among such traditional uncertainty modeling tools, Bayesian Networks (BN) are a popular formalism approach in user modeling and establishing sensible policies for handling uncertainty in knowledge assessment and plan recognition. BN is based on Bayes' theorem where the evidence is encoded in a directed acyclical graph with nodes corresponding to single/multi-valued variables and links corresponding to probabilistic influence relationships.

However, representing various cognitive and pedagogical aspects using BN requires assigning probabilities to such events. As such, extensive empirical experimentations are needed to establish such probabilities. Alternatively, such conditional probabilities could be estimated by domain experts or based on a more general theory about the relationships among variables of these types. However, the estimation of such probabilities by human experts is often inconsistent and biased. Past studies involving such probabilistic approaches highlight the need for highly extensive usability studies of the system involving determination of probabilities for BNs by users and experts.

Another problem with BN is that it is valid only under the simplifying assumption that the presence of evidence also affects the negation of conclusion, which is not valid in most instances. In addition, BN is not well suited for providing explanation facilities.

Furthermore, the computational complexity of BN is sometimes prohibitive and representing a realistic problem solution could be quite large. In fact, it has been shown that the exact application of the Bayesian inference technique has an NP-hard nature [24]. Under dynamic conditions, the size and topology of the networks may hamper updating BN in real time. Moreover, if even a small change in the knowledge representation is required, it can affect a large number of sub-networks. Approximation techniques for applying Bayesian can be useful; however, such techniques are effective only under specified conditions.

In Certainty Factors (CF) approach, the knowledge is expressed in the form of rules and a confidence factor associated with each rule. It does not require statistical basis for supplying beliefs in events and allows simultaneous rule representation and quantification of uncertainty making it simpler and efficient compared to

BN. However, CF approach is not built on a solid theoretical foundation and results in many weaknesses such as the implicit assumption of independence among hypotheses [35].

The Dempster-Shafer (DS) theory of evidence addresses some of the weaknesses of the probabilistic approach including the representation of ignorance, the unnecessary requirement that the sum of beliefs in an event and its negation be 1 etc. [40]. DS formalism has been applied to the quantitative modeling of preferences in situations with partially or even completely missing statistical data and to compute the impact of new observations on the resulting assessment. However, it does not specify how the probabilities are to be computed or how the results are to be interpreted. Furthermore, in certain instances, obviously incorrect conclusions can be reached [2]. Moreover, the exponential nature of evidence and hypothesis spaces means application of DS is in the NP. The only way to dodge this problem is to use some heuristics to compute approximate solutions [24].

In short, such assessment of the user's action history can be helpful in establishing a numerical estimation of user's future behavior, similar to a priori probabilities over the set of all plans [15]. However, the implicit assumption of continuity in a user's attitude is clearly debatable as user behavior might change completely. Consequently, the underlying uncertainties and dynamics of the problem dictate the need for a methodology pertinent to incomplete, imprecise, inconsistent, and uncertain preferences and rules [4]. Most existing probabilistic techniques fail to deliver in uncertain environments falling in more than one of the aforementioned categories. This shortcoming is more evident and imperative when the available information is incomplete.

#### 6.4 Machine Learning

The traditional user modeling systems have disadvantages that can be overcome with ML techniques for adaptive learning [20]. For instance, an AUI in IMES requires an ability to continuously extend the system's knowledge about the applicability and efficacy of different adaptation techniques by observing the success of such techniques in different users/contexts. The ML techniques are capable of expressing a rich variety of non-linear decision surfaces [47]. Such techniques, in general, process training/input data and attempt to make decision or classification based on this input. Furthermore, one frequently used underlying assumption in ML is the improved predictive performance by using more training data [47].

ML-based user-adaptive systems work differently from traditional Knowledge Representation (KR) based approaches. Instead of a knowledge base, observations of user behavior and history of interactions are treated

as training examples used by Learning components. The knowledge acquisition is automatic and incremental. As such, learning results are revised steadily without any special revision mechanisms [32]. Some examples of ML techniques used as alternatives for enabling adaptivity are Artificial Neural Networks, Case-Based Reasoning, Memory-based Learning, Decision Tree Induction, and Learning Automata. Multi-strategy ML approaches have also been used to engender hybrid LMs. For instance, short-term and long-term interests of user can be incorporated in a hybrid model using techniques most suitable for the specific task [10].

Although the knowledge acquisition in ML is automatic and incremental, considering the dynamic nature of user's interests, cognitive skills, and goals, the ML approaches seem inappropriate in IMES. Furthermore, the KR is implicit and formats of learning results (probabilities, decision trees, etc.) are specific to the learning algorithm. Consequently, due to lack of generalized representation formalism, ML techniques are not easily amenable to reusing of learned results for other purposes such as explanation facilities [32]. Consequently, the eventual goal of constructing a learning system that requires no intervention from the designer other than a list of potentially useful features is still elusive in realistic applications. Nevertheless, the use of ML algorithms for user modeling purposes has attracted much attention.

### 6.5 Fuzzy Logic

A natural way to characterize the relationship between attributes in the LM and concepts in the DM is the use of fuzzy linguistic labels [32], [33]. People often reason in terms of vague and context dependent concepts in dealing with situations where they encounter uncertainty [43]. FL techniques are used for representing and reasoning with vague concepts to mimic human style of reasoning. This reasoning may be that of the user, whose inferences or evaluations are being anticipated, or it may be that of an expert whose knowledge constitutes the basis for the system's reasoning. A user modeling system based on FL renders reasoning easy for designers and users to understand and to modify [24], [26], [33].

Furthermore, explicit information gathered from students about cognitive understanding and interests are inherently vague and subjective because they themselves might not have precise knowledge or they might not be motivated or competent to express their knowledge precisely [26]. Moreover, such information is usually incomplete. As such, the values of the attributes can be expressed in terms of linguistic labels that are handled as fuzzy numbers. Such circumstances render FL a logical choice as the membership functions of FL are in general well-suited to the representation of such input, even if the subsequent processing does not use FL techniques.

FL claims a certain degree of human-likeness because of the way in which it captures human reasoning with vague concepts [2], [3], [43]. Consequently, it seems to be a good choice for both initialization and refinement of LM as well as DM by using linguistic labels for domain concepts selected by users and/or classifying user as one belonging to various stereotypical categories. Furthermore, it sanctions tuning of the parameters of a user modeling system based on feedback from system performance, a common approach used in the field of rule-based expert systems [3], [26]. Fuzzy adaptation rules may also facilitate automated detection of conflicts and inconsistencies in the set of rules and provide robust performance in such conflicting scenarios [33].

On the flip side, it has been argued that FL was not developed for the purpose of cognitive simulation. As such, it cannot be taken for granted that an FL treatment of a given problem corresponds to the way people would deal with it [24]. Furthermore, the task of determining the appropriate representations may still require considerable empirical testing and knowledge engineering [26]. Nevertheless, the same is true with any other uncertainty management technique. Indeed, FL has been shown to be effective and robust technique in a variety of fields involving reasoning with incomplete, inconsistent, imprecise, and uncertain information [2], [4], [35]. Moreover, FL is superior to other uncertainty management techniques in terms of the computational complexity. Consequently, we believe, FL has a significant role to play in cost-effective and robust knowledge modeling under uncertain conditions as well as reasoning with such knowledge in AUI/IMES.

## 7. FUTURE DIRECTION IN AUI

It is not easy to predict future of AUI in IMES due to fast changing computing technology and computer users. However, we believe AUI has a very promising as well as challenging future in IMES. Here we delineate few prolific research directions in this regard.

### 7.1 Logical Characterization

The Functional Representation of AUI in IMES is more prevalent and hinges on various knowledge models to capture knowledge for the system. However, it renders the analysis and comparison of IMES on technical level difficult as, by and large, most existing systems are designed for special purposes [18]. Consequently, there is a need for formulating a common language [22]. Recently, a logic-based definition of IMES has been proposed allowing an abstract generalized formalization [18], [22]. Standardization of educational formalism would also facilitate the specification of many instructional models [18]. The goal is to develop a standard meta-language to be used all over the world facilitating the reuse of adaptation techniques in different contexts by reasoning over facts described in

standardized metadata formats [18], [19], [22], [30], [38]. Furthermore, reasoning can be performed in wider context over distributed data. Consequently, such representation seems to fit well for facilitating explanation facilities.

## 7.2 Meta-Adaptivity

As already mentioned, different adaptation techniques work most efficiently in different contexts underscoring the need for adaptation in the adaptation techniques, or meta-adaptation, during the cognitive progress of the learner. However, most empirical studies in adaptation techniques are done in simplistic and well-defined 'with or without' scenario by varying only a specific adaptation aspect and there is need for more extensive testing.

## 7.3 Explanation Facilities

An Explanation Facility furnishes the ability to thoroughly explore the implications of knowledge models and bases of system's adaptations. Studies have shown that a significant amount of user's sense of control is attached to the ability to readily make sense of interaction with the system. Consequently, Explanation Facilities indicating to learners, if invoked, the reasoning behind actions seems to be a nice extension to existing AUI frameworks. Furthermore, it may provide users of an AUI a sense of control by making the system 'scrutable' [17]. Such functionality may also be complemented with a visible method for controlling the system's adaptations or the user profiles. In its simplest form, explanation facilities could show rules and their usage sequence in inferences regarding certain actions [17], [35]. However, decisions regarding the effective mode for presentation of explanations would be yet another interesting research direction. Some small-scale exploratory studies have highlighted value of, as well as the difficulty in, supporting explanation/control capability because of lack of visibility or novel nature of the notion [17]. It points towards the need for making the explanation/control capabilities both visible and comprehensible to the user. Once again, simple and linguistic format of FL brings power to provide explanation facilities in a simple, compact, efficacious, and comprehensible manner [4].

## 7.4 Novel Scenario Modeling

When users are inactive, existing models can detect these situations but do not know the cause. Some mechanism for inferring the cause of inaction, such as lack of motivation or understanding, and adapting the interface accordingly would be worth exploring. Moreover, an interesting and more complex situation would arise when a learner switches from one access device to another during the course of learning. As such, an apparent inaction of the user could also be a result of distraction to other interesting services as well as

multi-tasking. Modeling a multi-tasking user poses even more challenging problem. Nonetheless, such a user is quite common in today's Web and Mobile service users. Furthermore, a usual classroom-teaching scenario is group/collaborative work that facilitates rich interchange of information and ideas from one another as well as from teacher [15]. It requires sensitivity to cognitive, intellectual, social, and cultural diversity. Modeling for such scenarios in adaptive IMES would certainly become a major focus in this research area.

Similarly, exploring the role of emotions in user modeling and decision-making could be a purposeful exercise [46]. There is growing evidence that emotional states may affect performance by altering perception, cognition, selection, motor actuation, etc. and may influence attention, planning, learning, memory, and decision-making. Some preliminary research work in some simplistic situations can be found in literature [15]. However, extensive work is required for incorporating emotions in IMES in realistic terms. In this regard, various theoretical frameworks may provide useful tools, such as the OCC cognitive theory of emotion and Game/Drama Theory [46],[36]. Furthermore, an interesting direction could be knowledge representation that facilitates such soft knowledge as mental and conceptual models. Once again, we believe that FL could prove a powerful modeling tool in these scenarios.

## 7.5 Extensive and Comparative Evaluation

The real-world deployment of user modeling and user-adapted systems with a demonstrable effectiveness is a formidable task [16], [10]. Conceivably, a review of past AUI articles reveals insufficient empirical evaluations [14]. Nevertheless, empirical studies of actual users help reinforce, contradict, and refine designs to better accommodate and satisfy users in accomplishing their tasks. However, the upward trend is quite visible and bodes well for the future of AUI and several instances of successful real world deployment of AUI systems can be cited. Nevertheless, there are problems due to the relative inability to identify evaluation needs and insufficient mappings of such needs to available resources.

Various possible metrics for evaluating an interface are: subjective evaluation of interaction quality by the user, user-friendliness, effectiveness, degree of task simplification, generalizability, scalability, accessibility, acceptability, etc. [5], [34]. However, one of the objectives in AUIs is the higher interaction quality requiring absorption of such aspects as *usability*, *usefulness*, *suitability*, *tailorability*, etc. that might not be measurable with currently available evaluation means and measures. Despite the difficulty in quantifying these aspects, user's rating could be useful for evaluating an AUI. Nonetheless, comprehensive evaluation instruments and techniques for guiding the

design of adaptations are largely missing. The primary reason for this is the contextual nature of adaptations that often does not facilitate objective assessments [5]. Incorporation of learner's misconceptions, beside knowledge and cognitive progress, is an important consideration for an effective AUI. Consequently, it has been argued that LM should also be validated using external tests and comparisons with actual user behavior [45]. Conceivably, all this is quite difficult to achieve.

As already mentioned, a more general description on adaptation functionality would allow easy and effective reuse of adaptation techniques in various domains or contexts. This can be achieved by making metadata about different resources explicit using standardized descriptions [18]. Consequently, empirical studies of AUIs with several dimensions of adaptivity would certainly assist in developing tools for meta-adaptation.

### 7.6 Generalizability, Scalability, Portability

In terms of generalization and scalability of the system, more experiments must be performed in order to determine how the system would scale up to deal with more parameters of the AUI. Knowledge representation facilitating soft knowledge, other than facts/procedures, such as mental and conceptual models is a largely unexplored direction. Furthermore, knowledge representation facilitating scaling up to larger/broader domains is an important issue. As already mentioned, this goal is significantly dependent on formalism in AUI/IMES frameworks. In addition, one of the most relevant requirements for acceptability and pervasiveness of AUI/IMES is the platform independence or portability. Such issues need to address the much-desired reusability a reality. Furthermore, in an organizational context, adaptive educational software is not only a teaching/learning resource and a carrier of instructional strategies but also a source of much touted organizational and strategic changes. Consequently, the research in AUI can be extended to incorporate organizational changes in the research framework.

### 7.7 Reduction in Development Time

The future research in AUI/IMES seems to be geared towards forms that are more complex and involve various multimedia embodiments. It would require articulation of abstract design patterns, elaboration and enumeration of different design alternatives, ranking of competing alternatives (based on experts' opinions and other subjective design criteria), and propagation of design knowledge into the development cycle [5]. Consequently, the need for reducing the developmental cycle time through some intelligent decision support mechanism cannot be ignored [2].

Recently, an expert system paradigm based framework has been proposed for intelligent decision support in layout design with an application to the adaptive Web

page layout design [2], [3]. We believe that such knowledge-based decision support frameworks would be valuable in fast and easy generation, evaluation, and refinement of superior alternatives. Such efforts would reduce the cognitive overload and personal bias in building a system that is rich in alternatives for various users by making use of a combination of AUI/IMES techniques/technologies, philosophies/pedagogies, etc. Furthermore, some authoring application for analyzing the set of rules by expressing just properties, without having to be concerned with the methods and techniques of inferencing, is an interesting but challenging direction. Availability of an efficient, efficant and easy-to-use off-the-shelf tool towards this would certainly make designing and utilizing AUIs more attractive. Representing knowledge, skills and contexts at a meta-level in a standardized and easily interpretable graphic language might also facilitate reuse and adaptation of models from different sources.

## 10. SUMMARY

The purpose of this paper is to briefly introduce the issues, prospects, and difficulties associated with research in adaptive user interfaces within the IMES context. The success of the learning process in such an educational environment depends on the intelligent context-oriented presentation of the domain knowledge by the system and its adaptivity in terms of complexity and granularity consistent to the learner's cognitive skills and progress. The richness of the human behavior and technological opportunities mean there is no final solution in such sensitive human-computer interaction area. Nevertheless, we have tried to highlight the role of various paradigms, techniques, and technologies in creating efficant AUIs that may help in providing more flexible and enhanced IMES. Furthermore, a perfunctory review of future trends and research directions has been presented. We hope that this review of complexity as well as limitations of AUI and pertinent technologies would prove helpful in creating expectations that are more realistic. However, this is just a broad overview of AUI literature and by no means complete. An integrative and comparative review of various adaptation techniques, pertinent technologies, and knowledge models with specific consideration of Web and Mobile Learning would be a worthwhile effort

# Computer-Mediated Communication and Innovation: Do Communication Media Properties Influence Innovative Thinking Processes?

Leif Jarle Gressgård, Gunnar E. Christensen

NHH, Department of Strategy and Management, N-5005 Bergen, Norway.

leif.gressgard@nhh.no, gunnar.christensen@nhh.no

## ABSTRACT

This paper concerns potential impacts that characteristics of communication media in computer-mediated problem solving in groups have on group-members' innovative thinking. Different processes involved in effective idea generation and problem solving are presented, and we discuss how three characteristics of communication media relevant for group collaboration aiming at producing innovative ideas might influence the group process. A research model is presented, and hypotheses regarding the effects of affordances on innovative thinking are put forth. We finally describe a possible methodological approach that might be applied in order to test the proposed hypotheses.

**Key words:** CMC, Computer-mediated communication, Innovative thinking, Problem solving, Idea generation.

## 1. INTRODUCTION

Superior performance in product development and innovation is believed to be one of the main sources of competitive advantage in the modern market place, and information technology used to facilitate innovative and creative processes is used in a variety of organizational settings. In this business environment, where innovation processes are facilitated by computer-mediated communication, it is important to obtain knowledge of *whether (and in case how) qualities or properties of electronic communication media influence individuals' innovative thinking in group-based problem solving*. This research question is addressed in this paper.

Many studies in the computer-mediated communication (CMC) literature focus on differences between various "communication modes" (e.g. face-to-face and dispersed CMC), without digging deeper into the underlying qualities of the modes. However, in order to generate new knowledge on desirable use of ICT in groups, it is important to investigate how the distinctive characters of different CMC settings impact on relevant dependent variables. We will therefore put emphasis on variables that all mediated and non-mediated communication processes can be described and evaluated by in this paper. There are many theories that have been developed in this research stream, and accordingly there are many theoretical concepts describing underlying features of communication modes. Theories like Media Richness Theory [12], Media Synchronicity Theory [14] and Burgoon et al.'s [6,7] interactivity model all make efforts in describing the constituent parts of mediated communication. Based on these contributions, we discuss media properties that may be of particular importance for innovation processes in group-based problem solving. In studies occupied with the relationship between use of ICT in group interaction and innovation, the dependent (innovation) variables investigated are most

often the products or artifacts resulting from the group processes. Variables often found in this research domain are for example the number and quality of the ideas generated [e.g. 10]. Accordingly, little emphasis has been put on how communication media characteristics influence the *processes* which lead to better or more desirable scores on the before mentioned outcome variables. This research applies such a process perspective, and focus on innovative thinking processes for each individual in a group-based problem solving situation. The paper is organized as follows: We first present and discuss the theoretical constructs that are relevant for our study, then we present the research model and our hypotheses. In the final part we present a potential methodological approach for testing the hypothesized relationships.

## 2. THEORY

### 2.1 Innovative Thinking in Idea Generation

Innovation can be understood as a process of creating or modifying an idea and developing it to produce products, services, processes, structures, or policies that are new to the organization [24]. The phases in the innovation process are conceived to encompass the generation, development, and implementation of new ideas and behaviors [5]. This conceptualization of innovation is highly related to *organizational creativity*, which can be defined as "the creation of a valuable, useful new product, service, idea, procedure, or process by individuals working together in a complex social system" [23 p. 293]. Both innovation and organizational creativity are initiated with idea generation, and successful outcome of this phase is related to certain thinking processes. The concept of *thinking* is often construed as "an umbrella term for a range of *processes* associated with *"high-level" cognition*, such as reasoning, categorization, and judgment and decision making" [17 p. 266, our italics]. In a problem solving situation, the first process that

needs to be initiated is a search for alternatives. That means that the decision makers or problem solvers have to collect information that is relevant to the problem, and which may contribute to, or are necessary for, a successful change. After the search for alternatives, the decision makers need to select one specific solution that they find most appropriate for the task they face. There exists little controversy regarding the importance of these two “opposite” phases to be present in idea generation activities; in other words, successful completion of idea generation entails a combination of *divergent* and *convergent* thinking.

### 2.1.1 The Roles of Divergent and Convergent Thinking in Idea Generation

In a problem solving context, exercising divergent thinking involves starting with a specific problem and generating various options and perspectives on the problem. Convergent thinking follows the divergent process, and acts to narrow down the options available to obtain a number of “satisfying” solutions to the problem (figure 1).

Figure 1: Divergent and convergent thinking

In this context, divergent thinking refers to going off in new directions rather than thinking solely on one solution, and deriving a variety of ideas from given information. Following divergent thinking, the ideas and information will be organized using convergent thinking; i.e., putting the various ideas back together in some organized, structured way. Some authors advocate the deliberate distinction between divergent and convergent thinking processes. Belonging to this school of thought, Basadur et al. [4] identified a sequenced two-step thinking process called “ideation-evaluation”. They defined “ideation” as the production of ideas without evaluation, and “evaluation” as the application of judgment to the ideas produced. One of the reasons for making a clear distinction between these processes is to avoid that people hold back ideas they think are stupid or silly, and by this using divergent and convergent thinking interchangeably. To create significant improvements or entirely new products, services or processes, those ideas that seem absolutely preposterous or unachievable at first are needed. Empirical research has supported both the general separation of idea production from idea

selection and the more specific ideation-evaluation process [1,3,4].

Basadur and Finkbeiner [3] view ideation as having both *cognitive* and *attitudinal* elements. Effective ideation may thus “require specific attitudes favoring this kind of thinking, perhaps to help participants truly “let loose” and use more fully their unencumbered imaginations”(p. 38). Such attitudes may for example impact on decisions of whether ideas that are produced should be put forth, and are therefore important aspects of the idea generation process. This is consistent with several “general” theories concerning the linkage between attitudes and behavior, like Kraut’s [18] training model suggesting a causal chain whereby attitude change leads to performance change, and Fishbein and Azjen’s [15] theory of reasoned action proposing that behavior can be predicted by individual attitudes and social norms.

### 2.1.2 Attitudes Toward Idea Generation

According to Basadur et al. [4] and Basadur and Finkbeiner [3], persons have attitudes toward both ideation and evaluation, and they have identified several *attitudinal constructs* related to idea generation. Two of these constructs are “preference for ideation” and “tendency for premature critical evaluation of ideas”. The denotation of the first construct concerns mind-sets such as “being less likely to jump to conclusions as to what is the real problem”, and “more open-minded to new ideas and approaches [2 p. 22], while the mind-sets associated with the latter construct are more or less opposite<sup>1</sup>. Basadur and Finkbeiner developed internally valid and reliable measures of these constructs, which we will adopt in our study.

## 2.2 Communication Media: Capabilities

Many theories have been developed to categorize media qualities and explain media effects on communication outcomes [e.g. 16]. One of the most widely used media categorization theories is *Media Richness Theory* [12], which suggests that communication media can be ranked on a richness-leanness continuum, and asserts that task performance will be improved when tasks’ information needs are matched to a medium’s richness or it’s capabilities to facilitate shared meaning. Empirical tests have not been very supportive, however, particularly for new communication media [e.g. 8, 13]. Recognizing the weaknesses of Media Richness Theory, Dennis and Valacich [13] introduced *Media Synchronicity Theory*, which suggest that media have five capabilities that are important in understanding the effects of media use on the ability to communicate and process information; 1) immediacy of feedback, 2) symbol variety, 3)

<sup>1</sup> As “tendency for premature critical evaluation of ideas” is more or less antagonistic to “preference for ideation”, we use the term “preference for evaluation” for this particular attitude.

parallelism, 4) rehearsability, and 5) reprocessability. Both media richness theory and media synchronicity theory categorize media attributes in terms of what kind of properties or capabilities the different media possess. Following this kind of reasoning, Burgoon et al. [6,7] suggest two ways of characterizing the *interactivity* concept often used in discussions of CMC. First, it can be considered in terms of the structural properties of the medium, or second, by qualitative experiences as perceived by the user. Regarding the first categorization type, Burgoon et al. integrate the various analysis of media affordances into an extensive set of properties, consisting of: 1) *participation* (extent of engagement in the interaction), 2) *mediation* (whether the interaction is mediated or not), 3) *contingency* (extent to which contributions are dependent on prior postings), 4) *media and information richness* (whether the format utilizes one or more modalities, and the extent to which it supports symbol variety), 5) *geographical propinquity* (physically co-located or distributed participants), 6) *synchronicity* (same-time or asynchronous interaction), 7) *identification* (fully identified, partially identified or anonymous participants), 8) *parallelism* (whether the format permits concurrent communication and multiple addressees, or only permits serial messages), and 9) *anthropomorphism* (extent to which the system interface simulates or incorporates humanlike characteristics). Communication media can thus be described and evaluated in terms of their abilities to enable specific aspects or properties of the communication process. In other words, all communication processes can be characterized by certain *affordances*, and communication media differ in their capabilities to support and enable these affordances. We will place emphasis on three affordances that may influence attitudes toward idea generation: “synchronicity”, “parallelism”, and “identification”.

### 2.2.1 Synchronicity

Synchronicity refers to whether the interaction is same-time or not. A high level of synchronicity enables the interacting parties to give immediate feedback, which refers to the extent to which a medium enables users to give rapid responses to the communications they receive [12]. Opportunity for rapid bidirectional communication has been shown to affect communication outcomes by increasing interaction between the parties, allowing rapid assessment and modification of the message [25]. We thus define synchronicity as “the extent to which the participants engaged in a problem solving situation can give immediate feedback to the postings of other group members, and receive immediate feedback on their own postings from other group members”. We are concerned with the level of synchronicity *as perceived by the participants* in a group problem solving situation (as people may have different perceptions of the same

technology). The highest level of synchronicity is most likely to occur when interaction takes place in real time, and the level will decrease along with increasing time lag between messages from one participant and responses to these messages from another participant. It is important to emphasize that a high level of synchronicity does not assure immediate feedback; it is rather related to the *opportunities* that the participants have for giving rapid responses to the messages of others. Low synchronicity thus implies that the participants involved in interaction do not have the opportunity to give and receive immediate feedback.

### 2.2.2 Parallelism

Many electronic media can be structured to enable multiple interacting parties in one session, and parallelism refers to the number of simultaneous conversations that can *effectively* take place. High parallelism can increase the amount of information that can be simultaneously transmitted and received, but it can also decrease the effectiveness of information processing as it may lead to information overload. We define parallelism as “the participants’ opportunities to be engaged in simultaneous dialogues in a group problem solving situation”. High parallelism thus gives the participants opportunities to be engaged in multiple dialogues at the same time, and therefore they do not have to take turns in utterance of contributions. Low parallelism, on the other hand, means that all participants have to be engaged in a single dialogue, implying that only one member of the group can utter his/her ideas and comments at the same time. We are also for this affordance concerned with the levels as perceived by the participants in a group problem solving situation.

### 2.2.3 Identification

Individuals involved with idea generation may be influenced by the presence of others. Persons are concerned about how others perceive their ideas [10, 19,20], and depending on this evaluation apprehension, embedding idea generation in a group setting could either enhance or reduce an individual’s contribution of ideas. On the positive side, the group might provide encouragement, stimulation or reward for creative contributions, and on the negative side, contributors might anticipate embarrassment, hostile evaluation, conformity pressures or other punishments for proposing unusual ideas [9]. Several authors have identified the anonymity option as a particular virtue of Group Decision Support Systems in that anonymity encourages full participation of group members that otherwise would have been socially inhibited from expressing unpopular, novel or heretical opinions [21]. We define identification as “the extent to which the contributor of ideas, comments, etc. in a group problem solving situation is known by the other participants”. Similar to the other affordances, we are also in this

case interested in the level of identification as perceived by the participants.

Based on the theoretical review, we propose a research model that consists of “synchronicity”, “parallelism”, and “identification” as the independent variables, and “preference for ideation” and “preference for evaluation” as the dependent variables (figure 2).

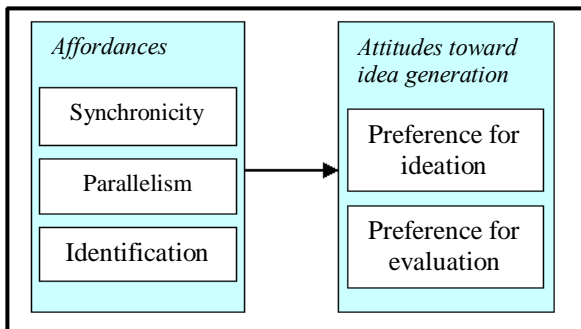

Figure 2: Research model

### 3. HYPOTHESES

#### 3.1 Effects of affordances on attitudes toward idea generation

Information and communication technologies differ in their abilities to support affordances of the communication process, and synchronicity, parallelism, and identification may contribute differently to innovative thinking. We therefore expect that affordances will have different effects on attitudes toward idea generation.

##### 3.1.1 Synchronicity

Feedback is a powerful tool for innovation processes, and it is important to emphasize the role of immediacy of feedback (timing) as a particular collaboration characteristic in idea generation. That is, timing of feedback is important in order to avoid a situation where evaluation stifles innovation before it has a chance to develop. While there are many different methodologies about how to most effectively engage in idea generating activities, one element that they have in common is that the free flow of initial ideas must occur without the interruptions of criticisms or evaluations. Low synchronicity enables both rehearsability and reprocessability, which may be regarded as “evaluative activities”. High synchronicity on the other hand, does not render possible a critical examination of neither the ideas that the sender is to put forth (rehearsability), nor the ideas or messages that an individual has received from other participants (reprocessability) before composing a response. Thus, interaction in same-time, although enabling interruption and immediate critical feedback, may have positive impacts on ideation. On this basis, the following hypothesis is put forth:

*H1: High degree of synchronicity correlates positively with “preference for ideation”, and low degree of synchronicity correlates positively with “preference for evaluation”.*

##### 3.1.2 Parallelism

According to Van de Ven et al. [22], an increase in the number of initiatives undertaken by a large number of interacting people enhances the probability of stimulating innovation. With reference to the distinction between ideation and evaluation, one aspect that support the assertion put forward by Van de Ven et al., is that high degree of parallelism makes it difficult to reprocess ideas that have been put forth, while at the same time being attentive to the ongoing discussion. Hence, there is no room for a comprehensive critical evaluation of all ideas that are posed. Another important aspect of parallelism regarding idea generation, which may be a consequence of the absence of opportunities for critical evaluation as discussed above, is that it can create an environment of interaction and discussion that facilitates hitchhiking. However, there will not be an exponential increase in hitchhiking effects with increasing parallelism. The reason for this is that individuals cognitive capacities are limited, thus there may be a problem of information overload if the number of participants exceeds a certain limit. Conversely, low (or absence of) parallelism will probably result in more (and critical) rehearsability of the ideas that the participants are to suggest. In these cases, the participants are aware of that they have the other participants’ full attention when contributing their ideas, and are thus likely to be more self-critical when communicating. The following hypothesis may be stated:

*H2: High degree of parallelism correlates positively with “preference for ideation” and low degree of parallelism correlates positively with “preference for evaluation”.*

##### 3.1.3 Identification

Participants in joint idea generating tasks are influenced by each other. This is particularly relevant when it comes to the participants’ decisions of whether or not to contribute and express their ideas. Most individuals are concerned about how others perceive and think of them, and can therefore be reluctant to express unorthodox or non-conforming ideas. Working in a group where the identities of the participants are known might inhibit a contributor who anticipates embarrassment, hostile evaluation, conformity pressures, or other punishments for proposing unusual ideas. In contrast, anonymity may lead to a reduction of these mechanisms. That is, it is reasonable to believe that the fear of getting negative comments will be lower if the interacting parties do not know the identity of each other. In other words, the barriers related to

idea expression that people experience, will be lower if the proposals can be done anonymously. Thus:

*H3: Unknown identities (anonymity) correlate positively with “preference for ideation” and known identities correlate positively with “preference for evaluation”.*

#### 4. METHOD

The focus of the study is on whether/how communication media influence individuals' innovative thinking processes within group settings. Thus there are three “key components” that the methodology must be based on in order to answer the research question: 1) The setting must involve group collaboration, 2) the participants must be involved in a joint problem solving situation, where the focus is placed on the participants' thinking processes, and 3) they must interact by use of electronic media (collaborative software / tools).

##### 4.1 Research Design

The design of the study must ensure that the measurement of the variables is adequate, and that the variance of affordances is sufficient for hypotheses testing. Further, when hypotheses suggesting a correlation between variables are posited, the research design must control for alternative explanations. In such situations, internal validity must be given priority [11], and an experimental design is therefore preferable. Subjects participating in the experiments will be randomly distributed into groups that will be given tasks which necessitate CMC between the members in order to be accomplished. Within the experimental groups, the affordances will be manipulated, and attitudes toward idea generation will be measured on an individual level. Each group will consist of 3-5 participants, and 2 groups will be needed for determining the effects of each affordance. As the objective of this study is to investigate the effects of specific affordances on attitudes toward idea generation, and not on revealing differences in effects of non-mediated versus electronically mediated interaction on these attitudes, we find it unnecessary to include FtF interaction as an experimental condition in the study. The design we will apply is illustrated in figure 3. When focusing on synchronicity, we compare the aggregate synchronicity-score in groups 2 and 3

	Group 1	Group 2	Group 3
<b>Synchronicity</b>	Low	High	
<b>Parallelism</b>	High	Low	High
<b>Identification</b>	Identified		Anonymous

Figure 3: Experimental design  
with the synchronicity-score in group 1. The same process is done for the other affordances as well

(groups 1 and 3 versus group 2 for parallelism, and groups 1 and 2 versus group 3 for identification).

##### 4.2 Tool kit and manipulation of affordances

The experimental conditions represent our manipulations of the independent variables. We will use specific Internet-based software for group collaboration (Groove 2.5), which has a set of basic functions that form the basis for the interaction between group members. For all experimental groups, the technology will be based on the same “framework”, with the exception of the specific configuration that is needed in order to provide for variation of affordances. In the next sections we describe how the variables will be manipulated.

Based on the definition of synchronicity proposed in section 2.2.1, we operationalize this variable as *the time that elapses from the messages of one participant are posted to these messages are received by another participant*. For groups 2 and 3, we will ensure (perceived) high synchronicity by letting the participants work online. By using the shared space in an online condition, all participants in a group will have the same user interface, meaning that the contributions of one participant will pop up immediately on the other participants' computer screens. In contrast, the participants in group 1 will work offline. During the one problem solving task, the participants will log into the shared group space every three minutes (one problem solving task lasts for 30 minutes). These online periods will be as short as possible, only enabling the work space to be updated.

The operational definition of parallelism we will use is as follows: *The degree to which it is possible for the participants to post their ideas and comments at the same time without interrupting others*. In the shared work spaces of groups 1 and 3, the level of parallelism should be high. Implementing this characteristic means that all participants in the groups will be able to post their contributions simultaneously without interrupting others. Conversely, the contributions of the participants in group 2 must be posted one at a time in order to avoid interruption of others. It is worth notice, however, that the collaborative software does allow for simultaneous postings in the same window, but this type of interaction will not be efficient (this will be the same as when people speak all at once in an FtF setting).

Based on the definition of identification proposed in section 2.2.3, this variable is operationalized as *whether or not the identities of the participants in a group problem solving situation are displayed along with (and thus linked to) the contributions of the participants*. In order to ensure *perceived identification*, the names of the contributors will be displayed together with their postings, meaning that the contributions can

be identified. The identities of the participants (both online and offline) in the shared space are also shown in a "list of participants". Contrary, in group 3, the identity of the participants will not be displayed together with their contributions and feedback, and the participants will not know the identities of the other group members.

## ABSTRACT

Customer knowledge is highly valued in today's business environment where supply is more than demand and firms are trying their best to differentiate themselves from their competitors. Building customer knowledge base through knowledge management provides firms with strategic weapon for customer value creation, average level of customer knowledge enhancement, cost and time reduction, service quality improvement and quicker customer knowledge creation. The main objective of this study is to propose a conceptual framework for exploring the relatedness of the three dimensions: resource provision, knowledge management process and customer knowledge performance. The proposed conceptual framework emphasizes the link between knowledge management with corporate mission and vision and that they set out the direction of corporate knowledge management. This study takes a kitchenware manufacturer and seller in Taiwan as an example to perform a field study to collect the concerned data for exploring the expressed relatedness among the three dimensions of the proposed framework as reported by the respondents in the case company. From the responses of the surveyed case company, it is also demonstrated how customer knowledge can be enhanced through resource provision and knowledge management and that people who surely understand their corporate mission and vision can outperform in knowledge management process and in customer knowledge performance compared with people who do not in this particular setting.

**Keywords:** customer knowledge, knowledge management, competitive advantages, vision, mission.

## 1. INTRODUCTION

The focus of global economics has shifted from labor-intensive or capital-intensive industries to technology-intensive and knowledge-intensive industries. Davenport and Prusak (1998) point out that knowledge has become the major asset of modern businesses and the key to retain their competitiveness. Nonaka (1991) also stresses that in the future in which the only thing that can be certain is high uncertainty, knowledge is a certain and sustainable source of competitive advantages. Platt, the CEO of HP, also indicates that if HP can know exactly what knowledge it has owned, its profit can be increased to three times of its current level (Davenport and Prusak, 1998). Therefore, corporate knowledge management has become a very important issue for modern businesses to retain and strengthen competitiveness in the era of knowledge economics.

Among all the knowledge that needs to be managed, customer knowledge is highly valued in today's business environment where supply is more than demand and firms are trying their best to differentiate themselves from their competitors. Building customer knowledge base through knowledge management provides firms with strategic weapon for customer value creation, average level of customer knowledge enhancement, cost and time reduction, service quality improvement and quicker customer knowledge creation.

Under severe global competition, ways of retaining and strengthening competitiveness in the era of knowledge economics by means of building customer knowledge base through corporate knowledge management need further investigation. A conceptual framework for managing customer knowledge and a case study that intend to investigate how this can be done is thus provided. This paper will proceed as follows: section 2 will discuss the background of the research; section 3 will present the research design and method; section 4 will provide the research findings, followed by section 5 to further discuss them; section 6 will summarize the paper.

## 2. BACKGROUND TO THE RESEARCH

Corporate vision refers to the desired future state of a business (Parikh and Neubauer, 1993; Schoemaker, 1992). Corporate mission refers to its purpose, why it exists, core competencies and who benefits from its operation (Brien and Meadows, 2000). Clear mission and vision enable people in a business to have clear objectives, sense of direction, priority, holistic consideration, co-ordinated actions and the basis of performance measures. Corporate mission and vision also choose for a business its current problems and those in its future, for it recognizes them when its current state significantly deviates from its mission and vision.

Corporate mission and vision should guide and regulate corporate knowledge management at a corporate level. Arthur Andersen Business Consulting and APQC (1996) stress that corporate vision, value and strategy set out a direction for a business regarding its knowledge management. Therefore, without the linkage of corporate knowledge management with corporate mission and vision, corporate knowledge tends to be managed for its own sake.

### **2.1. The important resource provision for corporate knowledge management**

From the survey of literature, this paper proposes two major resource inputs for successful corporate knowledge management: "incentives" and "organization and technology". These two resource inputs are detailed below.

1. Incentives: Knowledge is the source of power. A business cannot expect its employees to contribute their knowledge and share it with others without asking for rewards. A business should try to provide better treatment for those who contribute and share their knowledge than for those who do not. Stenmark (2001) also points out that knowledge sharing needs incentives and needs to make clear what rewards can be obtained.
2. Organization and technology: With delegated organization, delegated people will be responsible for the integration and co-ordination of inter-departmental knowledge management activities. Some well-known knowledge management case studies such as Arthur Andersen Business Consulting (Arthur Andersen Business Consulting and APQC, 1996) and Buckman Laboratories (Pan and Scarbrough, 1998) also set up delegated knowledge management departments. Regarding technology, related researches in the literature have clearly indicated that information technology alone cannot encourage the sharing of knowledge (Davenport, 1994, 1997; Cross and Baird, 2000). However, information technology and systems still play a very important instrumental role in the era of information and knowledge economics (Arthur Andersen Business Consulting and APQC, 1996; Davenport and Prusak, 1998).

### **2.2. Knowledge management process**

Beckman (1997) points out that there are eight steps of a knowledge management process: Knowledge Define, Knowledge Capture, Knowledge Select, Knowledge Store, Knowledge Share, Knowledge Apply, Knowledge Create and Knowledge Sell. The "Define" function of knowledge management process is to identify the core competence of a business and the related knowledge categories, demands and requirements needed by the identified core competence. The "Capture" function is to capture from the internal and external source of knowledge the needed knowledge and to document it. The "Select" function is to select among the captured

knowledge that which is appropriate. The "Store" function is to properly codify and store the selected knowledge. The "Share" function is to disseminate and transfer knowledge. The "Apply" function is to use, integrate and reuse knowledge to carry out tasks and solve problems. The "Create" function is to create new knowledge and to uncover the existing knowledge. The "Sell" function is to use knowledge to provide new products and services in order to consolidate customers and market and to create competitive advantages. Beckman's (1997) knowledge management process adopted by this paper with modified presentation is shown in Figure 1 below.

### **2.3. The source of knowledge**

After the survey of literature, this paper puts forward four sources of knowledge: artifacts, practices, regulation and system and networking. Artifacts are man-made creations such as products, architectures, blueprints, legal sentences and documents. Practices refer to how to accomplish a task. Brown (1991) indicates that knowledge does not necessarily exist merely in blueprints and technologies that are directly related to research and development of new products; local innovation that directly improves how people work onsite is also the creation of knowledge. Therefore, he continues, the opportunities for knowledge creation exist at all levels of a business and in its external customers. Nonaka (1991) also indicates that it is an important issue for corporate knowledge management to make tacit knowledge, such as how experts work, explicit and systematic through socialization, articulation, combination and internalization. Regulation and system, such as work procedures and formal and informal regulations, are the implementation of certain practices throughout a business and the codification of them if necessary and possible. Networking is regarded as a referring and problem-solving system composed of human networks. For instance, to know more about a problem related to production, one can ask people in the production department directly. One can also ask one's colleagues and they may refer him or her to the person they believe to know the problem best. Davenport and Prusak (1998) stress strongly that the key to successful problem-solving in a business is whether or not there is effective networking. Mintzberg (1973) also points out that managers spend more than 40% of their time on networking and communication; they acquire most of their important information through word of mouth, hearsay and gossip because they believe these will become the facts of tomorrow.

## **3. THE RESEARCH DESIGN AND METHOD**

### **3.1. The research design**

Understanding the importance of building customer knowledge base through knowledge management, this paper aims to propose a conceptual framework for

exploring the relatedness among the three dimensions of resource provision, knowledge management process and customer knowledge performance as shown in Figure 2 below. To take a strategic view of knowledge management, the identification of the mission and vision and of core competences is crucial for a business because it can then know what kind of knowledge can improve its core competences, achieve its mission and, in the long run, actualize its vision. Case study research and a structured questionnaire survey are adopted as the research method. A kitchenware manufacturer and seller in Taiwan is the focus of the research whose management, through the analysis of its mission and

vision, have considered the improvement of its customer knowledge will enhance its core competences. The structured questionnaire survey is adopted to collect the concerned data for analyzing the expressed relatedness among the three dimensions of the proposed conceptual framework as reported by the respondents in the case company. The collected data will also be utilized to further analyze how customer knowledge can be enhanced through resource provision, knowledge management process and customer knowledge performance in this particular setting.

Figure 1: Corporate knowledge management process  
Source: Adapted from Beckman (1997)

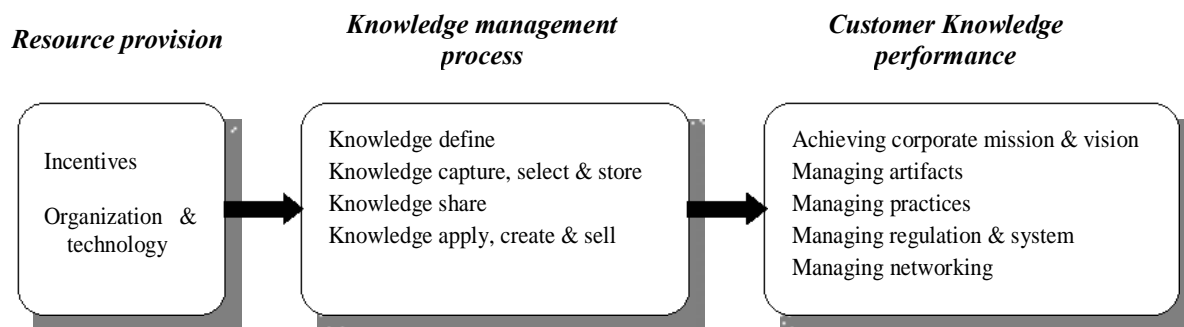

Figure 2: The proposed conceptual framework

For exploration of the dimension of resource provision, this paper proposes two major important resource inputs for successful corporate knowledge management including “Incentives” and “Organization and technology”, which have been mentioned above. For the exploration of the dimension of knowledge management process, this paper also adopts Beckman’s (1997) knowledge management process. The authors consulted senior managers of the case company and re-organized these eight steps into four steps, which would fit better their future planning for managing customer knowledge in their setting and could help them find out what step they should improve. These four steps were “Knowledge define”, “Knowledge capture, select and store”, “Knowledge share” and “Knowledge apply, create and sell”. For the exploration of the dimension of customer knowledge performance, this paper adopts the success of managing the four sources of knowledge - artifacts, practices, regulation and system and networking - as put forward by this paper above. Taking a strategic point of view of knowledge management process, this paper also adopts the success of achieving corporate mission and vision for the exploration of the dimension of customer knowledge performance. As mentioned above, clear corporate mission and vision enable people in a business to have clear objectives, sense of direction, priority, holistic consideration, coordinated actions and the basis of performance measures. They also set out the direction

of corporate knowledge management. Thus, it seems reasonable to assume that, under the clear guidance of corporate mission and vision, people who surely understand their corporate mission and vision can outperform in knowledge management process and in customer knowledge performance compared with people who do not. Based on the above, the objectives of the paper are to propose a framework which explores the relationship among the three dimensions of resources provision, knowledge management process and customer knowledge performance and show how the proposed framework can facilitate the enhancement of customer knowledge through resource provision and knowledge management process in this particular setting. The following hypotheses are also evolved:

H1: Resource provision is positively associated with greater success of knowledge management process.

H2: Knowledge management process is positively associated with greater customer knowledge performance.

H3: Respondents who surely understand their corporate mission and vision achieve greater success of knowledge management process than respondents who do not.

H4: Respondents who surely understand their corporate mission and vision achieve greater success of customer knowledge performance than respondents who do not.

### 3.2. Sample

As mentioned above, a kitchenware manufacturer and seller in Taiwan was selected for the survey setting. Founded in 1960s, the case company had stainless steel cookers as its major products and sold them in Taiwan, Japan, Northern America, Hong Kong, Australia and Malaysia. Highly emphasizing the importance of quality, the case company had been certified Japan's SG, U.S.A.'s UL and ISO 9001 and it had had the most advanced facilities for manufacturing stainless steel cookers in Asia. It had also devoted itself to continuous research and development to assure its customers of original taste, health and products' firmness. In the future, it had the vision of being the leading brand in the Chinese society. Despite its achievement, the case company had some serious problems such as how to differentiate itself from its competitors, increase market share and boost profits when the authors were invited for consultancy. Kitchenware market had been faced with severe competition worldwide. Building customer knowledge base through knowledge management provides for businesses an avenue for differentiating themselves from their competitors, increase market share and boost profits. A better understanding of customers made possible through knowledge management will enable customized products and services and sense of closeness and, subsequently, better customer relationships. Through the analysis of its mission and vision, the management of the case company considered the improvement of their customer knowledge being crucial for enhancing their core competences and long term competitiveness.

In terms of customer knowledge, the case company had invited its customers to a membership of its customer club. It provided for its members product warranty, services and direct mails. However, due to the lack of customer knowledge, the products' direct mails were delivered to all members without any segmentation. In the meantime, it also had little ideas about who its most profitable customers were. To know and serve its customer better and to enhance its customer knowledge through finding out for the case company in our study what resource provision and what step of knowledge management process it should improve were quite important under the circumstance. In our study, the unit of analysis was an employee in the case company. Questionnaires were sent to the employees in the various departments of the case company in its branches in Taiwan region. Respondents were asked to react using a five-point scale ranging from "Strongly disagree" to "Strongly agree". We got 54 responses from 54 questionnaires. The response rate was 100%.

### 3.3. Analysis

SPSS software package was adopted for data analysis in the paper. The data analysis methods were as follows.

#### 3.3.1 Descriptive statistics

For individual variable or factor, descriptive statistics was adopted to describe the mean and standard deviation of data.

#### 3.3.2 Reliability analysis

The value of Cronbach's alpha was adopted to examine the reliability of all constructs. For high reliability, the value of Cronbach's alpha should be greater than 0.7; reliability is low if its value is less than 0.3.

#### 3.3.3 Analysis of regression

Analysis of regression was adopted by this paper to explore the relationship between the dimensions of resource provision and know management process and the relationship between those of knowledge management process and customer knowledge performance.

#### 3.3.4 Analysis of variance

ANOVA was adopted by the study to examine the differences between respondents who surely understood their corporate mission and vision and respondents who did not regarding their success of knowledge management process and of customer knowledge performance.

## 4. RESULTS

### 4.1 Sample characteristics

Table 1 below summarizes the demographic characteristics of the respondents. Our sample was in the Taiwan region of the case company.

### 4.2 Instrument reliability

As mentioned above, the analysis of scale reliability was performed by computing and examining Cronbach's alpha coefficient. As shown below in Table 2, the values of Cronbach's alpha for most constructs were higher than 0.7 and were considered as reliable. Four components' reliabilities were between 0.5 and 0.6. They, however, still exceeded Nunally's (1967) suggested minimum reliability of 0.5 - 0.6 for instruments used in early stages of exploratory research. Due to the exploratory nature of the study, they were included in the subsequent data analysis activities.

### 4.3 Descriptive statistics of the three dimensions

#### 4.3.1 The resource provision dimension

The authors had done interviews with some managers and employees in the case company after the questionnaire survey to verify the findings of the study. They agreed upon the findings presented to them. The mean scores and standard deviations of the constructs are shown below in Table 3. In the dimension of "Resource provision", the mean scores of the constructs were more than 3 and between 3.75 and 3.80. The respondents

reported moderate positive attitude towards the resource provision for knowledge management process in the case company.

#### *4.3.2 The knowledge management process dimension*

In the dimension of "Knowledge management process", the mean scores of the constructs were more than 3 and between 3.36 and 3.67. The respondents reported moderate positive attitude towards the success of knowledge management process in the case company. Among the four steps of knowledge management process, the respondents demonstrated the greatest reported success in the step of "Knowledge define" and the least reported success in the step of "Knowledge apply, create and sell" in the case company.

#### *4.3.3 The customer knowledge performance dimension*

In the dimension of "Customer knowledge performance", the mean scores of the constructs were more than 3 and between 3.29 and 3.86. The respondents reported moderate positive attitude towards the success of customer knowledge performance in the case company. Among the constructs of customer knowledge performance, the respondents demonstrated the greatest reported success in "Achieving corporate mission and vision" and the least reported success in "Managing networking" in the case company.

### **4.4 Analysis of regression**

#### *4.4.1 The association of the dimension of "Resource provision" with that of "Knowledge management process"*

As shown below in Table 4, all the estimated regression coefficients were greater than zero and the component of "Organization and technology" was positively and statistically significantly associated with the success of four steps of knowledge management process. In the case company, however, our study did not provide empirical support for the association of "Incentives" with any of knowledge management process, which was quite contradictory against the claims on the importance of incentives for knowledge management in the literature. Nonetheless, in this particular setting, the case company had just decided to manage its customer knowledge systematically. All the steps of knowledge management process in the case company were voluntarily adopted by people rather than done for incentives provided by the case company. Under this circumstance, the provision of delegated organization and information technology seemed more helpful for the success of knowledge management process. In the long run after knowledge management process is carried out systematically at corporate level in the case company, the component of "Incentives" might show stronger association with the success of knowledge management process as suggested by the literature. Interviews with managers and employees of the case company after the questionnaire survey confirmed this argument.

As also shown below in Table 4, "Resource provision" explained 40.7% of the variance of the step of "Knowledge define"; 59.9% of the variance of the step of "Knowledge capture, select and store"; 36.4% of the variance of the step of "Knowledge share"; and 36.5 % of the variance of the step of "Knowledge apply, create and sell". Overall, the amount of variance explained by the proposed framework appeared reasonable.

#### *4.4.2 The association of the dimension of knowledge management process with that of customer knowledge performance*

As shown below in Table 5, most of the estimated regression coefficients were greater than zero and the step of "Knowledge apply, create and sell" was positively and statistically significantly associated with the success of five customer knowledge performance components. That is, in the case company, "Knowledge apply, create and sell" made great contribution on the success of achieving corporate mission and vision and managing artifacts, practice, regulation and system and networking. On the other hand, however, the step of "Knowledge define" was only helpful for achieving the corporate mission and vision and the step of "Knowledge share" made considerable contribution only on managing artifacts. For the step of "Knowledge acquire, select and store", three of the five estimated regression coefficients were negative with two of the three at 5% significance level indicating that the step was even harmful for customer knowledge performance in the case company. The strong negative association implies that people who reported to use less knowledge acquired, selected and stored by the case company, achieved more success on managing artifacts and networking. This might be because the acquired, selected and stored knowledge regarding artifacts and networking was outdated, mistaken, incomplete or inappropriately documented. Interviews with managers and employees of the case company after the questionnaire survey confirmed this argument.

The step of "Knowledge define" was helpful for achieving the corporate mission and vision. The strong positive association implies that people who reported to accepted more knowledge defined by the case company, did better on achieving corporate mission and vision. This might be because the case company depicted a clear picture of its mission and vision and core competences and defined what sort of knowledge might help the enhancement of core competences and achievement of mission and vision. However, our study did not provide empirical support for the association of "Knowledge define" with the managing of artifacts, practices, regulation and system and networking. As mentioned above, in this particular setting, the case company had just decided to manage its customer knowledge systematically. The systematic definition for specific knowledge sources had not been implemented at the corporate level. Thus, at this stage, "Knowledge define" did not associate with the success of managing of

knowledge sources in the case company. The step of "Knowledge share" made considerable contribution on managing artifacts. The strong positive association implies that people who reported to use more knowledge shared within the case company, managed artifacts better. This might be because artifacts could be attained more easily through the step of "Knowledge share" within the case company compared with practices, regulation and system and networking due to their tacit nature. Our study did not provide empirical support for the association of "Knowledge share" with achieving corporate mission and vision despite that people who reported to accepted more knowledge defined by the case company, did better on achieving corporate mission and vision as mentioned above. This has an interesting implication that convincing people to accept the mission, vision and core competences defined by the case company, rather than circulating unconvincing mission, vision and core competences through the step of "Knowledge share" could be more helpful for achieving corporate mission and vision. Interviews with managers and employees of the case company after the questionnaire survey confirmed the arguments mentioned above.

As also shown below in Table 5, "Knowledge management process" explained 56.2% of the variance of the success of "Achieving corporate mission and vision"; 54.5% of the variance of the success of "Managing artifacts"; 61.5% of the variance of the success of "Managing practices"; 64.1% of the variance of the success of "Managing regulation and system" and 56.8% of the variance of the success of "Managing networking". Overall, the amount of variance explained by the proposed framework appeared high.

#### 4.5 Analysis of variance

##### 4.5.1 The difference in the dimension of "Knowledge management process"

As shown below in Table 6, for four of the four knowledge management process, respondents who surely understood their corporate mission and vision reported statistically significant higher scores than respondents who did not. Therefore, in the case company, respondents who surely understood their corporate mission and vision achieved greater success of "Knowledge define", "Knowledge capture, select and store", "Knowledge share" and "Knowledge apply, create and sell" compared with respondents who did not.

##### 4.5.2 The difference in the dimension of "Customer knowledge performance"

As shown below in Table 7, for four of the five knowledge management performance measures, respondents who surely understood their corporate mission and vision reported statistically significant higher scores than respondents who did not. Therefore, in the case company, respondents who surely understood

their corporate mission and vision did better for "Achieving corporate mission and vision", "Managing artifacts", "Managing practice" and "Managing regulation and system" compared with respondents who did not.

## 5. CONCLUDING REMARKS

Under severe global competition, building customer knowledge base through knowledge management provides firms with strategic weapon to differentiate themselves from their competitors and to retain and strengthen competitiveness in the era of knowledge economics. Thus, this paper proposes a conceptual framework for exploring the relatedness of the three dimensions of resource provision, knowledge management process and customer knowledge performance and exploring how customer knowledge can be enhanced through resource provision and knowledge management. A case study has been provided for demonstrating and explaining how it operates. The proposed framework emphasizes the link of knowledge management to corporate mission and vision and that they set out the direction of corporate knowledge management. This study has taken a kitchenware manufacturer and seller in Taiwan as an example to perform a field study to collect the concerned data for exploring the expressed relatedness among the three dimensions of the proposed framework as reported by the respondents in the case company. As hypothesized, we found in the case company that resource provision was positively associated with greater success of knowledge management process and that knowledge management process was positively associated with greater customer knowledge performance. Also as hypothesized, we found in the case company that people who surely understood their corporate mission and vision achieved greater success of knowledge management process and of customer knowledge performance than people who did not. This study has taken as well the case company as an example to show how to enhance its customer knowledge through finding out what resource provision and what step of knowledge management process it should improve. This study has also demonstrated the link between corporate mission and vision and knowledge management as people who surely understand their corporate mission and vision can outperform in knowledge management process and in customer knowledge performance compared with people who do not.

### ABSTRACT

The trend of e-learning technologies is expanding fast. Web-based learning environments are becoming very common in the higher education institutions. Nowadays e-learning management systems are very popular. Many universities throughout the world deliver educational programs via the Internet. Developments of e-learning systems are generating great impact in the field of education services to improve the teaching and learning process, and overcome geographical distance. In recent years, various kinds of Internet technologies have become available for developers to implement such e-learning system that provide an e-learning gateway on the Internet. The rapid advancements in information and communication technologies, especially the networking and multimedia, have led to the development of many advanced e-learning systems these days. A user-friendly interface and a sophisticated data model are the essential design consideration to make the e-learning system easy-to-use for the instructors and learners. The need for such architecture is critical for designing the system and standards development. The system is developed under Computer Supported Cooperative Work framework and web portal technology. The system integrates all the critical and valuable communication tools that effectively improve the collaboration in an e-learning environment.

Keywords: e-learning, distance education, online education, virtual class

### 1. INTRODUCTION

Since the Internet emerged as a global information network, learning materials and information are available to any Internet user from any place at any time. For quite some times, people in education have been tremendously interested in using the facilities provided by the technologies of information and communication (TIC) [1]. In the recent years, the rapid advancements in technology and telecommunications, especially the Internet, have led to an explosive growth of web-based courses. The World Wide Web (WWW) is emerging as the most popular medium for delivering instruction and an increasing number of instructors are integrating various features of the Web in novel ways to provide exciting learning opportunities for their students. In addition, the use of Internet for education purposes has revolutionized distance learning. People have been tremendously interested in delivering online teaching and distance learning over the Internet. WebCT and Blackboard are the two of the most comprehensive systems widely used in most higher education institutions [2][3]. Course management system is a general term for server capabilities enabling online teaching functions, including presentation of contents, discussion groups, class management and related services. WebCT and Blackboard are the two e-learning systems which provide the most comprehensive tools and capabilities to support a sophisticated Internet-based learning environment. This paper introduces a new web-based toolkit Cyber Campus for instructors to deliver database-driven web systems in e-learning management.

This paper will provide an overview of the system structure in the Cyber Campus. Next it will focus on issues relating to the development of the communication and assessment modules in the system. These issues include some of the enabling technologies used in the development. After that, the performance of the system will be examined and compared with other e-learning system. Finally, this paper will be concluded with a summary of the system.

### 2. CYBER CAMPUS E-LEARNING SYSTEM

Cyber Campus is an all-in-one web-based e-learning system that integrates components including student management, course management, assessments, classroom allocation and communication into one complete package solution. The system is designed by using the framework based on Web Content Component Model (WCCM), which is a suitable model of web application that supports maintenance of content oriented web application [4]. In addition, the components will be developed using portal technology. An e-learning web portal serves as an integrated gateway in the online education centre website and provides users (instructors, learners and administrators) with a single point of access to the e-learning services [5]. Cyber Campus is implemented in PHP, MySQL and Java technology [6][7][8]. Figure 1 shows that the system provides users with a single access point to the e-learning portals.

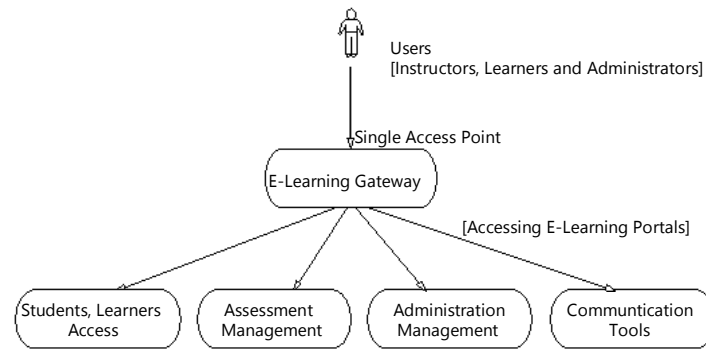

Figure 1. E-Learning Portal Gateway

Figure 2 shows the interaction between users under an user-friendly administrating, teaching and learning e-learning environment. Cyber Campus integrates web environment. It has provided administrators with a technology with database system and provides a centralized control in the entire system.

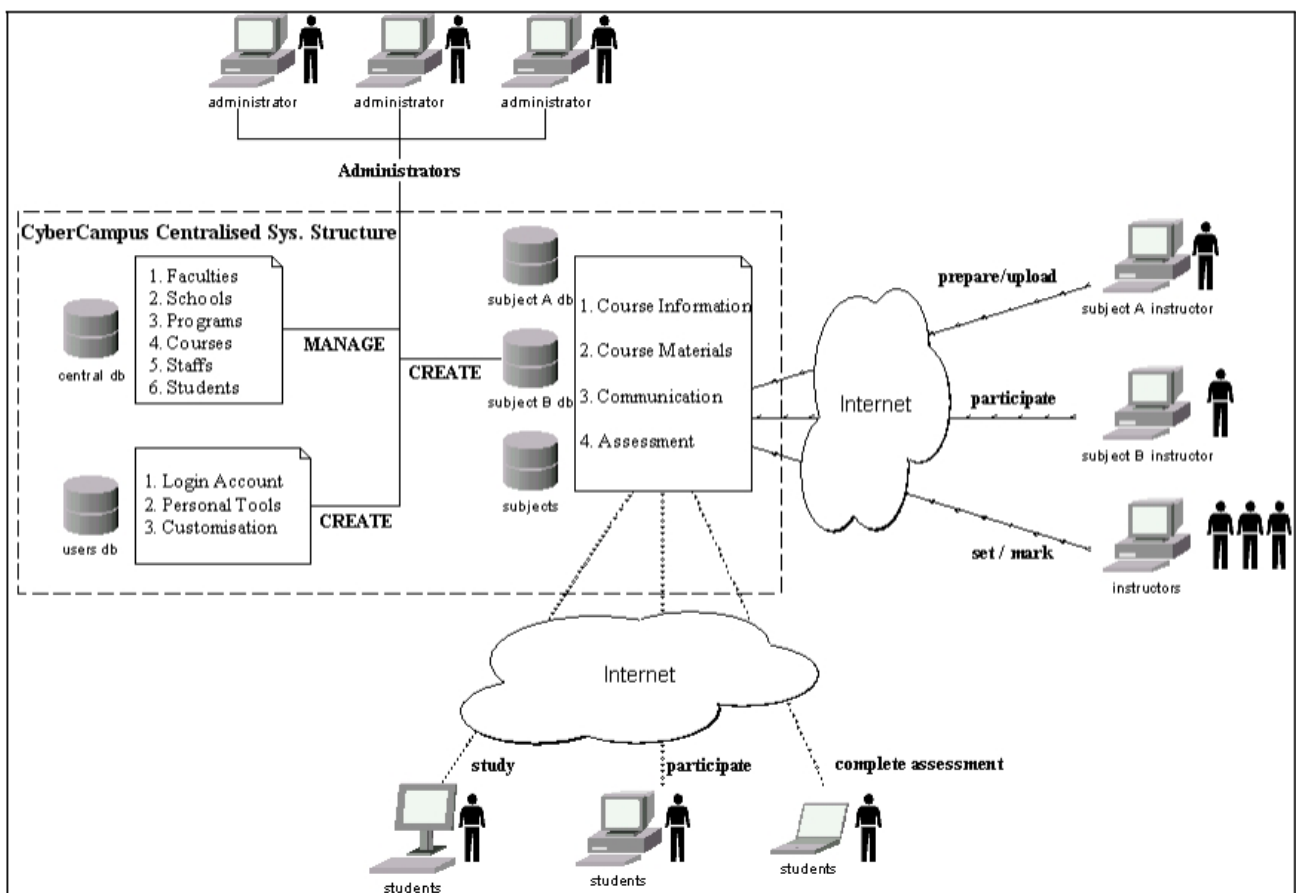

Figure 2. Cyber Campus e-Learning Environment

In addition, it includes many useful online education tools for the instructors and learners. The administration management module contains a set of functions, which help the administrators to manage the information resources in an easier and more efficient way.

### 3. SYNCHRONOUS CHANNELS COMMUNICATION

Cyber Campus is designed with a very comprehensive set of communication component on top of the core course management framework. This communication module is designed and implemented according to the concept of CSCW (Computer Supported Cooperative Work) [9]. Individually, the communication tools that Cyber Campus is designed of have many competitors that are currently in use by the corporate community. The synchronous collaboration component features the following sub modules:

### 3.1 E-Chat

The E-Chat module is written entirely with core Java and Java applet. The applet had to be compatible with Java 1.1.5 so as to work with Microsoft's default Java VM plug-in for Internet Explorer. The objective of this design is to ensure that the applet can be run from the most common web browser (i.e. Internet Explorer or Netscape Communicator). The online chat system is designed to be easily extendible and configurable no matter what sort of system it is deployed on, with minimal dependencies. The server includes a multithreaded object class, which spawns threads when users connect through the Java applet embedded in the dynamic html page. A maximum client limit is

imposed so as to hinder Denial of Service attacks. This design enables the server to handle multiple clients without heavy demand on the system.

The client's Java applet is designed to run from any web browsers. It is designed in a highly object-oriented behaviour, with the separation between the different design patterns of the back-end functions and the front-end graphical user interface. In addition, the client and the server communicate via TCP socket, which provides reliability and error correction in the network environment. Every e-chat session is saved in the database system. The user may, at a later stage, view the session information and the chat contents in each session. Instructors and learners can review any previous online chat discussion any time. Figure 3 shows the E-Chat module and its sub components.

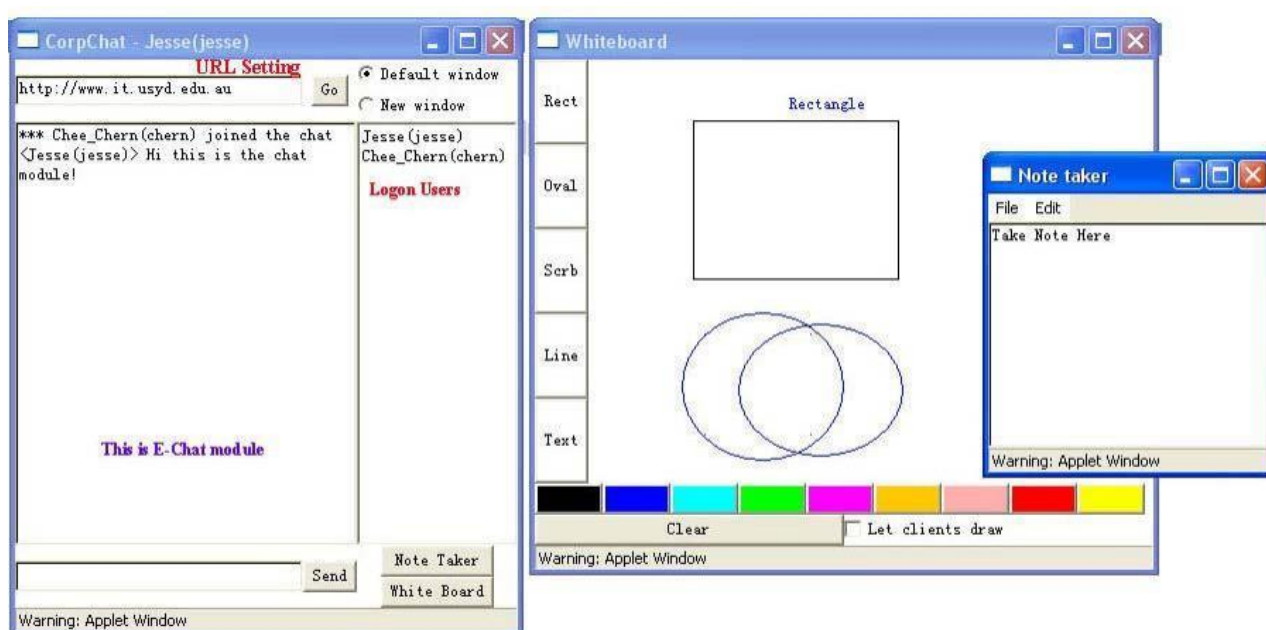

Figure 3. E-Chat Module And Its Components

### 3.2 Peer-to-peer File Transfer

In the e-chat module, the system also provides a 'File Transfer' function. This function allows active user in chat session to send file to other user in the same session. This function helps to improve the collaboration between the system users. In most existing system, users can only exchange files through email. Thus, any user without email is not able to communicate with other users. Cyber Campus has provided another alternative way for users to communicate in a much efficient way.

### 3.3 Electronic Whiteboard

In order to further improve the collaboration for students and tutors in their e-learning environment, the chat and synchronized group web browsing, users can idea of having an electronic whiteboard is implemented

in the Cyber Campus. The whiteboard allows students to perform drawing on the Internet. Users can share ideas and communicate in a graphical ways. Users can enter text; draw lines, rectangles, scribbling and ovals of any colour. The whiteboard is designed to have the option of saving the drawing and opening previous saved drawing or other standard image files. Again, this improves the communication and collaborative group work between the users. This component is similar to the E-Chat module, it is implemented purely in Java, and thus users can operate from any standard web browser on any platform.

### 3.4 Synchronized Group Web Browsing

Synchronized group web browsing is the next feature in the communication tools. With the combination of chat and synchronized group web browsing, users can be notified automatically when anyone joins or leaves

the session. The system is just like a virtual classroom session, student 'Chee' joined instructor in the chat and the user in the same session can interact with each session. The instructor can set an URL address in the other. In addition, instructor can direct active users' chat applet. When an URL is set, the instructor and browsers to the designated page by setting an URL every student in same session will have browsers address. Unlike other solutions, by utilizing Java displaying the contents from the preset specific URL. technology, this module can be directly integrated in the Instructor can use this tool to deliver teaching on the Cyber Campus without any additional effort. Figure 4 Internet. This achieves the basic requirements of a virtual classroom. Instructor 'Jesse' creates a new

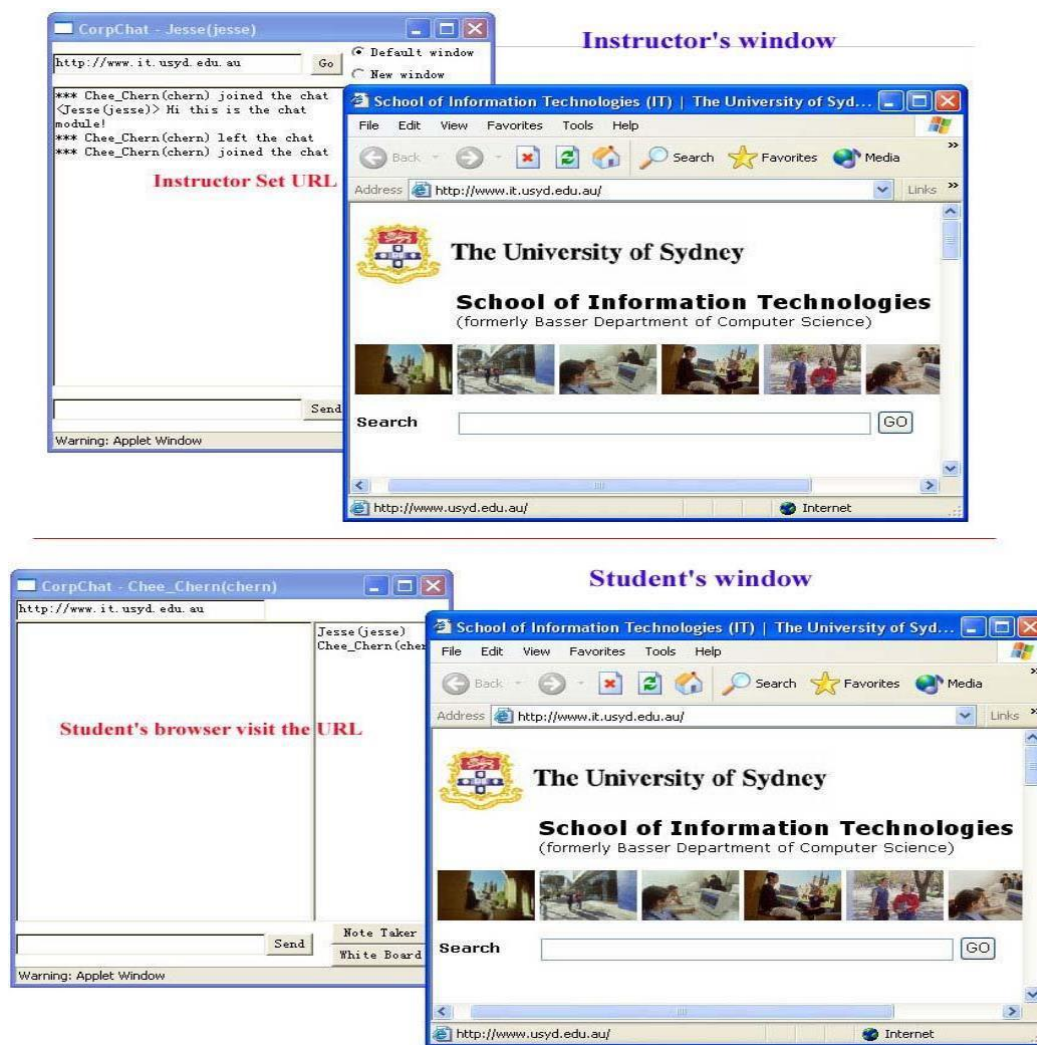

Figure 4. Synchronized Group Web Browsing Between Users

#### 4. ASSESSMENT MANAGEMENT

##### 4.1 Online Assessment

Assessment management is a very important module in any e-learning system. Cyber Campus has provided a wide range of options in setting up different kinds of assessments. The framework allows instructor to either create online assessment questions or upload project's related documents. In addition, the system allows instructor to create submission gateway and perform auto-marking on the online assessment. The following sections will further explain the design and functionalities in the assessment module.

In Cyber Campus, assessments are identified into two categories in term of the assessment nature: creating questions online or uploading the files. Instructor can easily setup assessment questions through a user-friendly interface. The system provides tools to construct questions including the following question format: multiple choice, true or false, short answer or essay-type questions. In addition, in the process of creating or editing assessment details, instructors can configure additional settings such as assessment's online

status, date, time and duration, time limit on each including course documents dissemination, tutor/learner question, solution and explanation. Once the interaction, assessments and course management system has successfully delivered teaching and learning assessment and questions are properly setup, students can login to the system and participate in the test. The system has proven its abilities and stability in its beta version.

#### 4.2 Online Submission

For non-online assessment or non-hardcopy submission, instructors can setup gateways to receive softcopy or electronic submissions of assignment from the students through the Internet. For each submission gateway, instructors can set some restrictions such as submission's due date, allowed number of submitted files, acceptable file extensions, late penalty and its online status. Furthermore, instructor can define each own marking scheme and use it as marking sheet in marking the submissions.

#### 4.3 Assessment Marking

This section can be further divided into four modules:

1. Auto-marking in online assessment.
2. Marking sheet on students' submissions.
3. Enter mark for traditional assessment.
4. Normal distribution on mark scaling.

For the online assessment with multiple choice or true/false questions, the system can perform auto-marking on the students' answers. However, for short answer and essay-type question, instructor is still required to review the answer and enter the mark manually.

From the submission management, instructor can view and retrieve students' submissions and mark the submissions with pre-define marking scheme. Late penalty will automatically be calculated upon the submission received from the student. Instructor can download submission's files and view history record of each student's submission.

As for traditional assessment, Camber Campus has provided an additional interface for instructors to manually enter the result into the system. Finally, instructor can perform mark scaling with function calculating the normal distribution. With graphical presentation of the results, instructor can easily identify the marks distribution of students' results.

### 5. SYSTEM PERFORMANCE

Cyber Campus e-learning system is successfully deployed in the School of Information Technologies, University of Sydney. One subject is selected to participate in the beta version of the system. The system is installed on a Window platform machine running on an Apache server. The system is used to serve as an e-learning system that provides instructor and learners with the full system functionalities

### 6. CONCLUSION

This paper introduced an e-learning system that integrates students management, course contents management and users collaboration into an all-in-one web-based application. The framework is carefully designed according to the model of WCCM, and the entire system will be implemented using portal technology [4][5]. In addition, the communication component is designed according to concept of CSCW [9]. The web-based multimedia e-learning system provides a centralised control in the database. CyberCampus is platform independent. It can be installed on any server and users can access the system through Internet/Intranet using standard web browser regardless of the client's operating system. The efficiency of collaboration and consultation is improved by providing an online chat session and simultaneous group web browsing environment that user could aware the presence of other participants. In addition, the system supports peer-to-peer connection for efficient files transmission between logon users. However, the system is still currently under constant improvement in the development phase. The latest version of whiteboard is still unable to save the drawings and open imaging file. Overall, Cyber Campus satisfies the requirements of a virtual classroom. The system will be the ideal system for any size of education organisation and it has proven its stability and abilities in its beta version.

### ABSTRACT

Despite the heavy promotion by the local government, the plentiful provision of IT educational tools, and the sufficient IT skills of prospective users, the adoption of IT in classroom education by primary and secondary school teachers in Hong Kong is still minor. By focusing on the use of IT educational Websites, which are freely available for teachers, this paper attempts to investigate the factors that influence the adoption of e-teaching in classrooms among primary and secondary school teachers in Hong Kong. With reference to the paradigms of information technology, cognitive thinking and organizational learning, a research model, together with a preliminary outline of the operationalization of the measures and data collection method for model testing, are presented in this paper. It is believed that the findings of the study proposed here could contribute to a more in-depth understanding on the adoption of IT tools by teachers, which is crucial for software developers to excel in this potentially enormous industry.

**Keywords:** e-teaching, primary and secondary education, IT adoption, educational Website

### 1. INTRODUCTION

The use of Information Technology (IT) in primary and secondary education has recently been receiving much attention in Asia, primarily due to the boom in using the Internet in the region as well as the potential in exploiting this medium to enhance interactive communication and collaborative learning (Kumar, 1996; Wong, 2000). In Hong Kong, there are various educational parties or software developers providing IT educational tools (e.g., animated movies and interactive games) for primary and secondary school teachers free of charge, with dedication to host them through the Internet for easy and extensive access (Table 1). Conceivably, the propagation of those materials could enable teachers to leverage multiple ways of classroom communication, information sharing, and learning effectiveness (Puntambekar et al., 1997; Wong, 2000). However the usage of IT (specifically adopted as a mean for effective

teaching) has not received as much interests and enthusiasm from teachers as expected.

In regard to the evolving growth of e-based education, we consider that a systemic inquiry of the disparity between the devoted propagation and actual adoption is crucial. Specifically, as teachers are the initiators of classroom e-education, this paper investigates the factors that influence the adoption of e-teaching among primary and secondary school teachers in Hong Kong. Section 2 describes the recent trends in IT development and usage in the educational sector of Hong Kong, which give rise to the motivation of a study proposed in this paper. Section 3 presents the highlights of e-teaching as well as e-learning in previous studies. Section 4 depicts a research model together with a preliminary outline of the operationalization of the measures and data collection method for model testing. Section 5 proposes the agenda for the study. Finally, a conclusion is given in Section 6.

## 2. EDUCATION AND IT IN HONG KONG

As mentioned above, it is mused that e-teaching is active in Hong Kong. The majority of the education tools are offered for use free of charge, and the government's 5-year strategy on IT in education launched in 1998 has substantially devoted financial resources, manpower and infrastructures in promoting the use of IT in primary and secondary education. Despite the availability of favorable condition of e-teaching, it is found that there are unmet promises and thwarted performance in regard to the low usage and slow diffusion. As of year 2000, about half of the primary and secondary school teachers still spent less than 5% of their teaching time in using IT (Education and Manpower Bureau, 2001). Besides, those adopted IT in their teaching tended to use primitive yet ineffective tools, which could hardly facilitate two-way communication or enhance learning effectiveness.

At present, little has been known about the reasons of the relatively low adoption rate of IT tools in classroom settings. As teachers are the initiators and reference stance of IT adoption in classroom learning, our study focus on the examination of the genuine factors that facilitate or inhibit e-teaching adoption in primary and secondary schools in Hong Kong. We ultimately identified studies related to IT adoption, learning, knowledge management and cognitive thinking are insightful and useful as the research paradigms for the proposed model.

## 3. E-TEACHING AND E-LEARNING

Educational reports seem supporting that time is a crucial factor to affect teachers' e-teaching behavior. For those teachers adopted electronic means in teaching mused that they have to spend a lot of time in taking up the technology, prior to the integrative use of with teaching content. Other teachers dropped out from e-teaching asserted that their time for e-teaching were distracted with the increasing load in other school work. Other non-adopters claimed that they may not draw much benefits from e-teaching. Other inhibiting factors include: lack of management support and oversight, lack of motivation to transit from traditional classroom teaching to e-teaching, incapable to cope with technology, lack of measurement on teaching effectiveness from adopting e-teaching.

Despite these hindrance, the benefits of adopting IT tools in learning has been ascertained. There have been studies that address the significance for e-learning in enhancing the organizational performance (e.g., Benbunan-Fich 2002, Frankola 2001, Honey 2001), types of learning (Jansen et al. 2002, Lytras et al. 2003, Taylor 2002) or success factors (e.g., Hiltz and Turoff 2002, Kerrin and Winfield 2001). Yet, only a few of them recognize learning as a process that transited from conventional face-to-face mode (teacher as dominant

player) to e-teaching (teacher in complement with technology) and e-learning (students as dominant player) (Crocetti 2002). Given the infant stage of technology deployment in the educational sector of Hong Kong, this study aims to examine the behaviors of teachers who are primary user groups, as such we can capitalize the values of technology in classrooms (e-teaching) and propagate to students for well-rounded learning process (e-learning).

## 4. PROPOSED MODEL

The innovative way for learning with IT as the medium of teaching encompasses a complex blend of socio-technological factors that influence the usage the technologies involved. A review of prior literature and empirical studies in regard to the paradigms of information technology, cognitive thinking and organizational learning was conducted. Several key notions were emerged that enable us to devise a proposed model for further study. It was found that the Technology Acceptance Model (TAM) (Davis 1989) is seminal as a starting point to investigate plausible elements that affect (either as enablers or inhibitors) the teachers to adopt IT in their teaching practice. In view of the intricate nature of individuals and their intersubjective interpretations towards the complex environment (Kettanurak et al. 2001), it is suggested that cognitive aspect is recognized as the precondition to govern one's behaviors and actions. In particular, the cognitive styles or personal traits have been attended and researched to explain the desirable outcomes undertaken by human (Akbar 2003, Choi and Lee 2003), which implies the relevance in the current studies. Exploring the learning cycle and knowledge management, it is deemed that the effective use of technology by teachers can be collated with the degree of diffusion of innovation (Rogers, 1995). More subtly, the diffusion can be extended with the depth and breadth of diffusion (Malhotra and Galletta 1999).

The proposed model is presented (Figure 1). The perceived usefulness and perceived ease of use are independent variables that affect the actual use (including infusion and diffusion encompassed within dotted line). The technology usage is mediated by the attitude presented by the users. Between the independent variables and mediating factors, it is proposed that the human traits as innovativeness, and the environmental context as social influence are moderators that influence the associations.

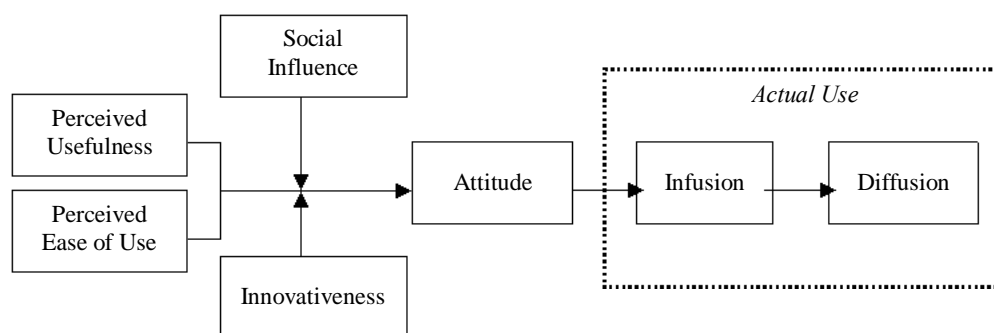

Figure 1. Proposed Model of E-Teaching in Hong Kong Education

Table 2. Operationalization of Measures – an Example

Constructs	Sample Measures in E-Teaching Context *	Reference
<b>Perceived Usefulness</b> Defined as the user's (i.e. teacher in this study) subjective belief that using a specific application system will increase his job performance.	Using X in my teaching would enable me to accomplish tasks more quickly.	Davis (1989) Chau and Hu (2001)
<b>Perceived Ease of Use</b> Defined as the extent of user expects that using a target system to be free of effort.	Learning to operate X would be easy for me.	Davis 1989 (Chau and Hu 2001)
<b>Social Influence</b> Defined as the extent of user's affection change or commitment to technology due to external force, for example peer group pressure or government mandates.	Colleagues in my school think we should avoid to use X. Government believes teachers should be enthusiastic to use X.	Malhotra and Galletta (1999) Lewis et al. (2003)
<b>Innovativeness</b> Defined as the degree user's inclination/personal traits towards doing things better (adaptive) or doing things differently (innovative).	Readily agrees with the team at work (Adaptor). Prefers changes to occur gradually (Innovator).	Kirton (1976) Garfield et al. (2001)
<b>Attitude</b> Defined as the user's desirability of his use of system.	Using X in my teaching is a good idea.	Taylor and Todd (1995)
<b>Infusion</b> Defined as the user's state in making use of a target system in a full and complete manner.	I have a thorough knowledge using X in my teaching. I can integrate the target system X in different teaching subjects.	Kishore and McLean (1998) Carter et al. (1999)
<b>Diffusion</b> Defined as the user's state in persuading other in the use of a target system.	I recommend X to my colleagues for effective teaching. I am committed to let my colleagues to explore the potency of X in teaching.	Kishore and McLean (1998) Carter et al. (1999) Lewis and Orton (2000)

\* X – denotes as a selected educational website

As illustrated in Figure 1, there are seven constructs entailed. The description of each construct is detailed in Table 2, with their examples of measurement item and reference source.

## 5. RESEARCH AGENDA

Understanding the technology adoption in Hong Kong education is significant to the policy makers and educators as it directs the ways to advance knowledge and competences of students, and competitiveness of people in the long run. Also, an understanding of the

factors that affect the adoption and diffusion of IT educational tools among teachers enables software developers to develop and promote their educational products in an effective and efficient manner. Therefore, the exploratory study needs further synthesis and empirical validation. A seven-stage of research task is planned.

1. Adopt validated instrument/ measurement items (Table 2)  
 ≥ Undertake minor wording changes to tailor them to the target context of education

2. Conducted Focus Group study to solicit qualitative data and opinion  
 $\geq$  Expose other unattended attributes of each construct
3. Synthesize and frame up results from stage (2)  
 $\geq$  Augment to the measure items in stage (1) and prepare initial questionnaire for pretest
4. Pretest with a sample of 50 teachers on their E-teaching behaviors  
 $\geq$  Include both adopters and non-adopters in the subject sample
5. Assess data for statistical generalization and refine the items  
 $\geq$  Base upon the validation on reliability and validity  
 $\geq$  Prepare the questionnaire for main survey
6. Collect data from the schools with IT adoption and without IT adoption in teaching  
 $\geq$  Seek help from government offices to institutionalize the survey
7. Compare results and generalize the features in each group  
 $\geq$  Draw implications on enhancement program on IT usage, for example culture, training and development and system design

## 6. CONCLUSION

The study proposed in this paper aims to explicate the underlying reasons for the (in)effective e-education phenomena in Hong Kong, specifically e-teaching. It is expected that the systemic approach of examination can shed lights on the entities for primary and secondary education, such as the government, management and teachers, in order to evaluate their planned initiatives, existing practices and possible remedies.

## E-Learning Performance and Students' Results Case of a French Business School

Emmanuel Houzé<sup>1</sup>, Régis Meissonier<sup>2</sup>

<sup>1</sup> CREGO - IAE – Montpellier II University – France; houze@iae.univ-montp2.fr

<sup>2</sup> CEROM – Montpellier Business School – France; rmeissonier@supco-montpellier.fr

### ABSTRACT

*E-learning* experiments in higher education are becoming more recurrent. However, these experiments are seldom tangibly applied to an entire academic year group. Integrating *e-learning* into a pedagogical program implies performance analysis in terms of both students and teachers, but also from the institute's point of view. Due to the lack of Information Systems based research into *e-learning* performance modeling, the article propose an analysis mixing this research area with some findings in Education Sciences.

The first part of this article presents an analysis of the main scientific publications on which we have built our research model. The second part presents the initial findings of our on-going research project at Montpellier Business School (France). A comparison between traditional teaching and face-to-face teaching was carried out using the student marks in five different courses of study. The results show that the teachers' predisposition to adopting these new teaching techniques is not directly related to an improvement in the students' results. In other words, the paper is consistent with the need to avoid any techno-centered approach to on-line education.

In the same way, the article concludes that a measure of the e-learning performance must not be limited to the students' results alone. Indeed, the case studied puts forward that the legitimacy of an *e-learning* project can lie more in the satisfaction of being able to meet new strategic challenges through its development, than in simply improving an existing teaching tool.

**Key-words:** *E-learning*, Performance, Learning, Higher studies, Business School

### 1. INTRODUCTION

Given the current economic context, in which the two driving forces are the globalization of trade and the development of information technologies, the sector of higher education is undergoing a genuine transformation. The e-learning phenomenon represents one of the most highly developed computer-assisted approaches in this educational evolution.

The gloomy economic climate, since 2002, in which this "new cognitive economy" is taking shape, proves (yet again) that the exhilaration expounded by an innovative concept does not automatically go hand in hand with the anticipated, or even expected, effectiveness. Consequently, introducing *e-learning* into the education sector reveals some obscurantism about its own performance.

Few scientific works have been published on the subject compared to other areas of application of information systems. This indicates the lack of theoretical corpus sufficiently consensual to come to terms with this issue. The contingency of the cases studied or even the newness of the concept could certainly be cited as causes. But, such observations do not legitimate research projects flouting theories which, despite being inherent, can nevertheless be associated with it.

In Management Sciences, it can be considered that research into information systems involves the contribution of organizational and technological

mechanisms that bring media to knowledge and information exchange. Traditionally, an information system is assessed from different view points, depending on: its efficiency, its effectiveness and how players use it and are satisfied with it. But, specific *e-learning*-related criteria have not been clearly identified. This is why the assessment criteria can, to a large degree, be taken from those used in education sciences, a field in which a lot of research has gone into how to assess learners (using technology or not). Therefore, we have chosen to combine these two fields, information systems and education sciences, in order to propose an *e-learning* experimentation performance analysis grid. The first part of this article presents an analysis of the main scientific publications on which we have built our research model. The second part presents the initial findings of our on-going research project at the Montpellier Business School (France). A comparison between traditional teaching and face-to-face teaching was carried out using the student marks in five different courses of study. The results show that the teachers' predisposition to adopting these new teaching techniques is not directly related to an improvement in the students' results.

For the moment, the initial data collected only allows us to conduct a comparative analysis of the marks obtained by students having attended these on-line lessons and the marks gained by those who previously attended traditional classes for the same courses. These results should be interpreted in the broader context of learning processes and overall performance measuring. The tests

presented hereafter, on the influence levels of various characteristics and factors, will be the subject of future publications.

## 2. LITERATURE ANALYSIS

Even if *e-learning*-based scientific publications in the educational field are less verbose than in other new technology fields of application, their combination makes it possible to envisage what the basis of an

analytical model - to gauge the performance of remote teaching approaches - could be like. Enhanced by the study of scientific works on information systems and education sciences, the following model offers an arrangement of the main influence factors as well as their relationships. It does not, of course, claim to be exhaustive but simply tries to lay the foundation for theoretical modeling, which can subsequently be improved by further research.

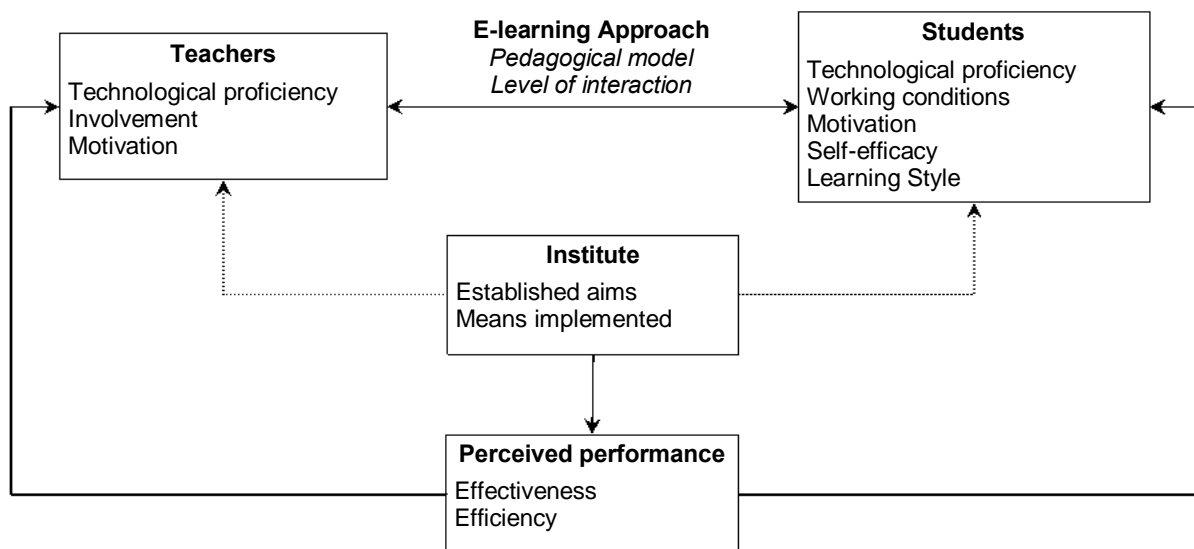

Figure 1: E-learning and performance flowchart

### 2.1. The *e-learning* approach

The first stage is of course to define the subject of our analysis and thus to determine the characteristics we retain from an *e-learning* approach. Indeed, rapid development of distance teaching, driven by spreading Internet technologies, has put a strain on neologisms

inducing multiple variations on the same theme. *E-learning*, *virtual class*, or even *digital campus* seem, at first sight, to be concepts whose main differences remain limited to the scope of the technological system installed and to the related pedagogical mode. The table below summarizes some of the definitions.

Table 1: E-learning definitions and similar concepts

	Description	Reference works
<i>E-learning</i>	Teaching method via a technological tool such as Internet, etc., allowing teachers to make all or part of their lessons available to a public of learners, and without any spatiotemporal restrictions. To a greater or lesser extent, <i>e-learning</i> systems often include means with which to: maintain an interaction with and follow-up on learners, personalize programs, assess or self-assess learner progress, etc.	Piccoli & al. (2001) Webster & Hackley(1997) Minnion & al. (2002) Tu & Corry (2002) Northrup (2002) Hirumi (2002)
<i>Virtual class</i>	Specific type of <i>e-learning</i> allowing the simulation of a teaching space representing the classroom via new technologies (interactive audio and/or audiovisual conversations, white board, assessment systems, group work, etc.) in addition to the benefits offered by the new technologies (asynchronous communications, file sharing, automated performance indicators, etc.).	Leidner & Jarvenpaa (1993) Hiltz (1995) Copolla & al. (2002) Bieber & al.(2002)
<i>Digital campus</i>	Generalization of the <i>e-learning</i> approach in a training institute's range of programs. In this case, the technological tools must also be able to deal with the associated administrative procedures (enrolment, school fees, course payment, etc.).	Work from the UO-MLR open university (Université Ouverte – Languedoc Roussillon). Case of Catalogne Open University

Because the technological tool implemented is supposed to become the main interface in the learning process, it clearly plays a central role in an *e-learning* analytical model. As an extension of the media richness theory,

some research projects reveal that the features this system makes available will render it more or less compatible with certain pedagogical models. (Webster & Hackley, 2001; Leidner & Jarvenpaa, 1995). In 2002,

research carried out by Minnion & *al.*, drew up various models related to psychological and philosophical trends:

- *Rationalism*: it is considered that knowledge can be transferred to the learner who, for this to happen, has to use his/her power of reasoning.
- *Objectivism*: knowledge comes from experience. The learning process is seen as an accumulation of knowledge.
- *Constructivism*: knowledge is the fruit born from interaction and exchange between learners. The teacher plays the role of organizer / group leader.
- *Imagination*: knowledge grows according to the learner's ability to create and scrutinize.

Depending on the subject taught, the teacher's preferences or the *student learning style*, one model is likely to be more suitable than another one. However, as yet, we do not have a scientific corpus enabling us to predetermine the efficiency of each one in different context. But the real danger reside probably more in not adopting any pedagogical model at all. In any event, this is what many case studies have highlighted in unsuccessful experiments noted (Piccoli & *al.*, 2002). Thus, strictly speaking, the content conveyed or the variety of matching technological features is not what guarantees the tool's effectiveness, but rather their appropriation in the context of one or several pedagogical models.

The features offered by new technologies (such as forums, chat rooms, team working tools, etc.) aim to afford learners a more active role in acquiring or developing their knowledge. Indeed, interaction is considered as one of the key factors in catching and holding the attention of a "virtual public" liberated from the classroom workplace (Webster & Hackley, 1997). However, the degree of interaction between students and teachers depends on how the two parties react.

In a conventional class lesson, the interactions affecting the students' attitude and performance take place spontaneously, in real time. Teachers interpret student behavior, answer questions, clarify concepts, give preference to discussion, structure the lesson according to the time frame, etc. This ability to initiate and facilitate such interactions, to encourage or steer *feed-back*, is what, among other things, characterizes the teaching profession. In an *e-learning* approach, communications are mainly asynchronous and, through technology, are media-based. Opportunities to interact in real time are generally confined to planned sessions which can be incorporated into the pedagogical approach at certain precise moments. It is therefore particularly useful to classify the possible types of interactions when using the *e-learning* solution (Hirumi, 2002)<sup>1</sup>.

The typology put forward by Moore (1989), widely used since then in education sciences, classifies interactions into three types, in relation to the sender and receiver: *learner-learner*, *learner-teacher* and *learner-content*. Let us look at each of these in more detail.

The *learner-content* interactions are defined as a process that consists of "*intellectually interacting with the content so as to bring about a change in understanding of the topic on the part of learners and to enhance their cognitive structures*" (Moore, 1989). Even when the students are alone, they have to commit themselves to this type of "internal" dialogue so as to encode and retain information (Berge, 2002). Content can only become knowledge for the student if this active cognition process occurs. In most cases, in a learning situation, content quickly becomes inert if there is a lack of immediate practical application ensuring this cognitive acquisition. It seems that making knowledge and skills available, just before an opportunity to use them, makes learning more effective (Gagné, Yekovich & Yekovich, 1993). This means it is vital to regularly alternate theoretical presentations with practical sessions in the courses offered (case studies, multiple-choice tests, etc.). This just-in-time requirement raises a certain number of questions concerning the simplification of the chosen cognitive approach and its long term effect on the student's skills.

The *learner-learner* interactions take place individually or in a group, with or without an instructor (Moore, 1989). As Northrup (2001) reminds us, *e-learning* is characterized by being able to learn anywhere and at any time via information technologies, but which may isolate the student. To overcome this feeling, group work or any other form of team work is often recommended. Forming social bonds and fulfilling part of the work as a team is not the only role of these learning activities. They also make it easier to reach the goal in terms of knowledge acquisition. The analysis of learning communities (Tu & Corry, 2002) shows us that besides individuals, the community learns even in a remote context. Vygotsky's research (1978) demonstrates just how important the social context is, and in particular interactions between learners, in the learning process. The environment should therefore stimulate exchanges between learners enabling beginners to take their shortcomings on board and to change their views through communication.

The aim of the *Learner-Teacher* interactions is to motivate and stimulate learners by allowing them to clarify concepts introduced in the content (Moore, 1989). One of the teacher's roles is therefore to interact with students, so as to help them overcome any difficulties that could not be resolved through contact with the subject matter or with other students. In addition, the teacher has to check the program is running smoothly. To do this, he/she ensures the program is being followed correctly by examining the path taken by each learner (time spent on the lesson, etc...) and lends guidance if a problem is identified. Tools such as individual forums or exercise correction can back up these interactions.

<sup>1</sup> Here we refer the reader to an education science literary review by Bannan-Ritland in 2002 regarding the concept of interaction in the e-learning field. We have only adopted the most accepted concepts.

Regular *feedback* often adds to student satisfaction with regard to this learning approach (Northrup, 2002). In this way, the teacher also strives to manage each student's progression.

A teacher, who consequently has to manage both teaching and learning, has to create an environment in which learners can be involved in projects, problem solving and other activities. The teacher is not a spectator but rather a co-discoverer who guides the learning process and encourages different types of interaction as well as reflection. Interactions are at the heart of learning, the success of which depends on the alignment between the aims, activities and feedback opportunities (Berge, 2002). In practice, the approaches aiming at improving these three types of interaction are those which are most likely to contribute to the success of e-learning<sup>2</sup>. These are the three explicit axes of success for our model, with the primary objectives being all those outlined by the school, the activities and the feedback which mainly takes place between the students and the teachers.

## 2.2. The Teachers

Introducing e-learning can require the teacher to make major changes and even transform his/her way of teaching (Jean, 2001; Copolla & al. 2002; Godinet & Caron, 2003). Exercises are no longer tied to the singular space and time frame in which they were confined. Content often provided orally has to be pre-formalized (in writing, audio, video, etc.). A separation of roles between lesson designer, tutors and various experts, means the course design shifts from *handcrafting to mass-production* and from *individual to group*. "Stage plays" combining verbal and non-verbal communications are replaced by more impersonal contact (if we refer to the richness of media theory in any case).

The pedagogical style also requires a transformation. The teacher moves from the position of holder of knowledge or facilitator in student development to a role of regulator. In fact this migration, from "*Sage on the Stage*" to the "*Guide on the Side*" introduced by Copolla & al., 1997 does not eliminate the various roles that a teacher is expected to play. Following a series of around twenty interviews, the authors conclude, for example, that virtual teachers continue to exercise their cognitive, emotional and even domineering roles. To do so, they have to develop new behavior and to be able to use information technologies to communicate some of those signals (via forums, Email, etc.).

Therefore, if teachers wish to capitalize on the potential offered by *e-learning*, they need to be able to manage information technologies. Even if assistants can relieve them of technical tasks, they should be able to interact

directly with learners and follow-up on their work via the platform, to make practical information available on-line, etc.

Similarly for information technologies in an organization (Sproull & al., 1987), all these reasons mean that introducing *e-learning* in an establishment can induce a form of anxiety and influence the level of motivation. For all that, some empirical research reveals that the teacher's level of involvement in *e-learning* is a decisive factor in its success (Piccoli & al., 2001; Webster & Hackley, 1997). These conclusions confirm the theory of social influence related to the use of technologies (Fulk & al., 1990) according to which behavioral models developed by some are based on behavior observed by others. The case of *e-learning* appears to make this issue even more striking as teachers and students hold asymmetrical positions and the former are supposed to act as role models for the latter.

In addition to being sufficiently familiar with information technologies, *e-learning* also necessitates a positive attitude towards them. Training teachers how to use them may simply not be enough to develop this type of culture.

## 2.3. The Learners

Teacher characteristics, for all that, would not be enough to predict the motivation and the active behavior that the students will develop. Going beyond the vigor attached to *e-learning*, we should not neglect the feeling of frustration or isolation that distance learning can exert on individuals (Hara & Kling 2000). The more virtual an organization becomes, the more users tend to need face-to-face encounters (Handy, 1995). In addition to being motivated for the lesson, students also have to be motivated to learn via the *e-learning* mechanism in relation to their own command of information technologies and how to use them.

This form of teaching therefore also involves a cultural change for the learners. They are required to develop a more active behavior, to access knowledge in a more open information space, whereas up until then they had been used to receiving it in the confines of a classroom. Therefore, learners have to acquire a high degree of autonomy, which is more supposed than facilitated by the e-learning mechanism. The e-learning approach is supposed to provide learners with greater freedom, but at the same time they have to be able to envisage their own self-efficacy. Even if follow-up monitoring by teachers appears as a prerequisite to learning (Piccoli, 2001, p. 8) it seldom include the control of the way students organize their work and manage their "virtual timetable".

Scientific and professional literature has, at length, dealt with pedagogical models that should be adopted in an e-learning activity. However it has often be done to the detriment of learning styles. This is probably due to the fact that this student characteristic cannot be known

<sup>2</sup> Report for the Canadian government in 2002: "Methods and strategies for promoting on-line interaction for students undergoing distance learning."

beforehand and that there can potentially be as many different learning styles as there are learners. On the other hand, some Education Science research (Honey &

Munford, 1992) identifies 4 main styles which seem pertinent to us to take into consideration when setting up an e-learning system and its performance model.

Table 2: characterization of learning styles

	Characteristics	Preferences in terms of <i>e-learning</i>
<i>Thinkers</i>	They base their learning on data collection, observation, and listening to others. They analyze before drawing any conclusions. In group work, they mainly play a support and advisory role. Thinkers like to have sufficient time to observe and prepare.	Communication and group work tools Documentary sources and links to other references Self assessment tools
<i>Activists</i>	They appreciate new experiences, tending to apply concepts directly to them and subsequently inferring consequences and points of interest from them.	Group work communication tools Project based on content offering room for creativity rather than instructions to be followed. Short-term work Exercises, simulations, project fulfillment
<i>Theorists</i>	They use a rational approach in their cognitive process. Their approach is procedural and analytical leaving little room for an emotional intelligence.	Preference for individual work rather than problem solving. Clear pedagogical objectives and learning methodology.
<i>Pragmatists</i>	They need to see in advance what empirical use and implication a piece of knowledge or technique will have in their professional activity. As down-to-earth people they need to tie theory and practice together.	Aims and lesson plans clearly identified. Practical guides Feedback from experience gained in the field, from expert opinion.

Besides the pedagogical models advocating active participation by students, from now on we can consider that the e-learning lesson can also be given in any number of ways thus covering the full spectrum of mentioned learning styles. However, this is not sufficient to deduce that it would be a good idea to allow a student to enroll solely for pedagogical models supporting his/her own learning style or personal preferences. For example, it could be necessary to initiate and train a *theorist* student in working group methods. Consequently, it is better to think in terms of management of the different learning styles than, simply, in terms of their applicability.

#### 2.4. The Institute

In scientific literature, the institute in which the e-learning activity is set up has a low profile or is totally eclipsed with respect to the proposed models.

However, the little research done emphasizes the organizational upheavals induced by e-learning as well as the subsequent and compulsory input from the institute (Jean, 2001). As previously highlighted, recorded field studies have mainly been proven experimentally between teachers and learners using a specific technological tool (*all things being equal otherwise*). In an era in which adopting information technologies represents a strategic challenge for schools, in our opinion, it is time to analyze the 'school-related' variables likely to play a role in the success of an on-line teaching activity.

Theories concerning the use of new technologies evoke the fact that their spread is a factor in their own acceptance. Spread is the process by which the technology is extended to other parts of the organization

(Goodman & Sproull, 1990). Opportunity is created for others to use this technology and to be aware that others use it. This spread is required in order to create a prescriptive general opinion of the new technology. Upheavals in the teaching activity brought about by *e-learning*, mean that its implementation depends on how determined a school is and resources available.

Adhering to a certain technology depends on individuals' determination, but also on how the management team "promotes" the idea (Salanick, 1977). And yet, there is a "values paradox" here (Sproull & Hofmeister, 1986): the more the technology is emphasized, the more severely it will be judged, if the pre-stated aims are not achieved. Adopting a new technology also depends on the symbolism associated with it (Prasad, 1993). This symbolism can be at the root of resistance or over zealous use. It also influences the system set up, thus becoming one of the primary reasons for adoption. For instance, as a symbol, modernity is a driving force in the spread of information technologies. This symbolism is the result of the combined effect of management and socio-cultural variables related to the field of application (higher education in our case). The way in which an *e-learning* project is introduced to the players involved will therefore also be an influential variable in terms of the perceived level of success related to the measured efficiency.

On-line learning brings about major changes in the teaching profession requiring just as much investment from the school. We should in particular mention:

- The incentive system for teachers: provisions regulating terms and conditions of employment for teachers is still out of phase with the rapid development of distance learning. For instance in the French university system, an hour's teaching is likened to a

service that has to be carried out, in due course, in a classroom and in front of students. This raises the problem of payment for e-learning type lessons and incentive measures taken to encourage teachers to put in an effort.

- Training for teachers and help in designing on-line lessons, multimedia resources, quizzes, student follow-up, etc.
- Forming an editorial committee entrusted with assessing teachers' work: meeting pre-determined quality criteria, abiding by copyright laws, etc.
- Media team responsible for transforming the resources developed by the teacher (web, flash, audio, video formats, etc.).
- Technical team responsible for putting the e-learning platform on-line and up-dating it.
- Etc.

Of course, all these factors determining the success of an e-learning tool, as well as those already presented in this article, are by no means an exhaustive list. The organizational complexity of educational establishments makes it difficult to predetermine the success or failure of any given project. This being said, we have the advantage of being able to analysis the success of a student in a learning situation using a relatively clear performance indicator, that of exam results.

## 2.5. Success of an E-Learning System

The main scientific research into experimenting with such systems (Bieber & *al.*, 2002; Minnion & *al.*, 2002; Coppola & *al.*, 2002; Piccoli & *al.*, 2001; Webster & Hackley, 1997; Hiltz, 1995; Alavi, 1995 & 1994) have analyzed the effects induced on learners and teachers in the following ways:

- learner-teacher interactions
- group exchange between learners themselves
- cognitive processes and pedagogical models
- cultural changes
- experience gained by the teacher and learner
- etc.

This experimental methodology-based research, often conducted on a test group of learners, has thus allowed the strengths and weaknesses of these tools to be brought to light - with regard to teaching and learning processes. It reveals that a multiplicity of influence factors confers a particularly subjective character to the idea learners and teachers may have of it. This can be explained through the differences in appraisal that each one makes of the: (1) pertinence of the set aims (purpose or acceptability concept), (2) relationship between the aims and the results achieved (effectiveness or usefulness concept) and (3) relationship between these results and the means (or effort) employed (efficiency or usability concept)<sup>3</sup>.

<sup>3</sup> The *purpose*, *effectiveness* and *efficiency* definitions, frequently used in Economic Sciences, are reiterated here (see the Caby & *al.*, 1999 article to this effect).

If the arguments in favor of trying *e-learning* are, initially, with a view to improving the training process, others are interested in the underlying economic and strategic potential for an institute in taking up such a project. In this connection, another perspective is to consider *e-learning* as a way to rationalize the organization's operating costs (Minnion & *al.*, 2002). If we deem that the knowledge to be transferred to learners and the interactions associated with their understanding can be formalized via a computer-communication process, then the hypothesis of reducing the operating costs of a teaching activity is a legitimate one. All of the following should, at first sight, contribute to reducing the cost of teaching per student and generate savings likely to secure a return on the technological investment: an automated didactic system, self-assessment functions, teachers called on essentially for pedagogical follow-up, less classroom space needed due to face-to-face lessons, etc. Some research even associates this reasoning with an emphasis on development or even as a competitive edge acquisition (Webster & Hackley, 2001; Dufner & *al.*, 1999).

The e-learning market nevertheless entered troubled times two years ago. Caution needs to be taken therefore, in terms of the amount of ambition it is suitable to attach to research into the degree of success of such distance teaching tools. The fact that some "e-training" centers have recently gone bankrupt warns us that viability of an economics model based on information technologies should surely first transit by the appropriation and use of the latter.

So without trying to test the hypothetical impact of e-learning on the reduction in operating costs or the creation of a competitive edge, we believe it is nevertheless also necessary to take the idea of performance from an institute's standpoint into account. Is it still coherent, in fact, to consider that an organization's investments in information technologies (regardless of the organization) are pertinent only if they form part of a growth strategy (Powell & Dent-Micaleff, 1997)? On the one hand, the return on investments is not always assessable on objective grounds:

- certain costs cannot be measured accurately (for example: the hourly production cost of creating or transforming a lesson)
- the context, between when the decision is made to invest and when the system actually bears fruit, can radically change
- labor regulations as yet do not cater for distance learning (case of the French university system)
- etc.

On the other hand, the decision to invest may also be motivated by less analytical ambitions in financial terms. For several years now, training centers have been

---

We have also drawn a parallel with the Education Sciences research on the *acceptability*, *usefulness* and *usability* idea (see the Tricot & *al.*, 2003 article to this effect).

subjected to a certain pressure concerning experimenting with or adopting distance learning systems (Webster & Hackley, 1997; Alavi & *al.*, 1995). Implementing them can therefore aim at promoting a modern image or even avoiding being marginalized in relation to developments in the field. Measuring effectiveness and efficiency as perceived by the institute's management team may also bear fruit in terms of overall success.

However, if we take the stance that the primary purpose of e-learning is to offer learners a working platform allowing them to improve their results (Maki & *al.*, 2000; Schutte, 1997; Hiltz, 1995; Webster & Hackley, 1997), it is appropriate to analyze the efficiency of the said potential in a real situation and context that goes beyond a mere simulation or experiment. The empirical part of the research in progress, for the moment, will concentrate on analyzing the results of an entire year group of students (400 learners) having taken five on-line courses as part of their syllabus and throughout the academic year.

### 3. RESEARCH FIELD

For the moment, the data collected only allows us to make a comparative analysis of the results of the students having taken these on-line courses with the results of those who had previously taken the same courses by traditional methods. Tests of influence levels of the depicted characteristics and factors (student satisfaction level, teacher involvement, pedagogical model, etc.) will be the subject of subsequent publications.

#### 3.1. The Institute

Montpellier Business School's *e-learning* project was given impetus in early 2001 with the decision to make it compulsory for students following the Business School program to do a year's study abroad. Consequently, at the start of the 2002 academic year, 400 students were dispatched to 130 different foreign partner universities. In addition to the lessons they attended in their host universities, these students had to follow some Montpellier Business School courses via the e-learning platform developed for this purpose. The challenge for the students was to obtain two diplomas in the same year. In any case, these courses had to be followed and validated for a student to be able to move on to the next year of studies. This is why group work was encouraged to complete assignments which required coaching by tutors as part of internal assessment.

For all that, e-learning was developed here in a bid to open the training program to the rest of the world. In this way, the primary aim was not as much to develop the pedagogical tool as to take full advantage of the distance learning opportunity. The following means were employed to achieve this goal:

- recruiting a researcher-teacher as person in charge of the e-learning project,
- enrolling the services of a computer engineering consultancy firm,
- training the teachers involved,
- implementing an editorial committee (made up of teachers representing the education and research departments) responsible for validating each teacher's work..

As an incentive and to give value to the teachers' work, a reduction in their teaching load was implemented:

Table 3: incentives for creating *e-learning* lessons in the case studied

<i>The year the e-learning lessons were created</i>	<i>Presenting and up-dating lessons in subsequent years</i>
<p>Reduction in the teaching load equivalent to the number of face-to-face teaching hours as per the course syllabus (disregarding the different year groups involved).</p> <p><i>Example: reduction of 30 hours for a 30-hour e-learning course to be taught the following year.</i></p> <p>Reduction of 100 hours in non-face-to-face teaching time. This reduction concerns tasks of the following type: taking part in student selection panels, managing cross-referenced projects, etc.</p>	<p>The e-learning teaching time that students have to fulfill is counted in the same way as the time spent attending face-to-face teaching periods.</p> <p><i>Example: if in a 30-hour course, a student year group has to spend 10 hours e-learning, these 10 hours will be counted in the annual teaching load that a university teacher has to provide.</i></p> <p>This time is, in particular, to be spent keeping the course up-to-date.</p> <p>A reduction in non-face-to-face teaching time (attributed as stipulated above) that the teacher should assign to giving the e-learning lesson (particularly for: answering the questions on the forum, posting practical information about the work expected, etc.). This reduction, on an annual basis, is equal to:</p> <ul style="list-style-type: none"> <li>• 100 hours.</li> <li>• If fewer than 400 students, the reduction is calculated according to the following weighting: 0.25 hour x number of students enrolled for the on-line course.</li> </ul> <p>In order to offer favorable teaching conditions (to organize certain modules, to up-date certain data, etc.), the teacher benefits from a teleworking scheme:</p> <ul style="list-style-type: none"> <li>• One day a week (a set day each year) he/she is exempt from having to be at Montpellier Business School.</li> <li>• A high-speed Internet connection is made available at the teacher's home (DSL, cable or Numéris line).</li> <li>• A mobile phone with a subscription for one hour's communication per month designed to cover his/her professional calls.</li> </ul>

This system of lightening the workload and related obligations has been formalized in the employment contract of all the teachers involved.

### 3.2. The E-Learning System

Emphasis has been put on an approach and a system affording the greatest possible flexibility to an innovative project whose specific needs had not been predetermined. Instead of buying an existing ready-made platform, the decision was taken to build a “homemade” one using open-source technologies. Developed by the group’s Webmaster, this platform, which is now in its fourth version, offers the same features as a professional product available on the market (content chunking, discussion forum, schedule for work to be handed in, glossary, quiz, etc.). This choice is justified by the fact that total control over the source code allows changes to be made at any time and specific needs met.

The e-learning platform includes, in particular, a system allowing the teacher to create lesson content on-line him/herself with the same ergonomics and the same functionalities as a conventional word-processor (copy, paste, text layout, inserting pictures or animated objects, etc.). As a result the teacher does not need any special IT skills.

### 3.3. The Learners

The 400 students on a year’s study abroad were hosted in a variety of universities in which they had computer rooms at their disposal allowing them to make full use of the e-learning platform functionalities. Incidentally, the only material needed was a computer (PC or Mac) connected to the Web with an Internet browser (and perhaps a printer if the student wanted to keep a hard copy of the lessons rather than viewing them in their electronic format). The questions or complaints made by the students (often by Email) were more oriented towards the conditions and difficulties of reconciling two courses at the same time, as opposed to problems with using Web technologies.

Table 4: main features of the *e-learning* tool implemented in the case studied

<i>Teacher environment</i>	<i>Student environment</i>
Zone for direct content design (put on-line according to an advanced WYSWYG <sup>4</sup> -type) allowing the teacher to create lesson content on-line him/herself.	Access to lesson content in the form of Web chunks and downloadable versions
System for creating a Quiz on-line with feed-back allowing the student to be directed in particular to parts of the lesson that need to be reworked.	Access to practical information (timetable, standard procedure instructions, etc.),
System giving the right to a student year group to access all or part of the lesson to be selected.	Access to “subject + correction” type exercises or self-assessment
Access, in his/her capacity as moderator, to his/her lesson forum: answering students’ questions on-line and managing messages	Access to a forum allowing the students to ask the teacher questions and share information and experiences among themselves. Practical tools: search engine, glossary, links, etc.

In terms of IT skills, these students could all be considered as having a satisfactory level for using the e-learning tool set up:

- in their first year of study on the Montpellier campus, they all had about 30 hours of compulsory computer science lessons,
- by the way, the platform requires no other skill than knowing how to use a Web browser.

### 3.4. The Teachers

The 5 teachers involved in the school’s project covered the following subject areas: Finance, Process Management, Auditing, Information Systems, and E-business. Each teacher was responsible for drafting the content of the lessons to be converted to *e-learning* material. To do so, they had to adhere to the following pedagogical model:

- Cut course content up into sessions equivalent to 2-hour-long face-to-face lessons
- Divide each of the sessions into “chapters” or units of learning of no more than 3 screen pages. The basis writing reference to be adhered to, in terms of volume, is 20 A4 pages per session.
- Set the students a case study type assignment (in groups of 5) covering all the sessions developed and as part of their internal assessment.
- Compile the glossary, reference bibliography as well as the links to other recommended websites.

The work submitted by each teacher was assessed by an “editorial board” before being authorized to go on-line in September 2002.

<sup>4</sup> “What You See Is What You Get”

The teachers were held by institutional accountability to ensure student follow-up. Given the number of students to monitor (400) scattered worldwide in different time zones, asynchronous communication proved to be the most appropriate vehicle for their interaction. It was also important for the school that the chosen system be as user-friendly as possible and not require any specific software to be installed on the 120 host university computers. This is why, the use of electronic forums relayed to Email (for any confidential communication) was given preference.

### 3.5. Analysis of the Results

The diagrams below compare the final examination results<sup>5</sup> of two year groups:

- (1) the 2002-2003 promotion, having followed all 5 courses on line
- (2) the previous year's promotion having attended class and followed these courses in the traditional way on campus at Montpellier Business School.

These 5 examinations were held on the same day, at Montpellier Business School Co., upon the students' return from abroad. They were in the form of multiple-choice tests containing the same number of questions / answers for each course and drawn from a database having been used by the teachers for several years. The level of difficulty was therefore similar to that of the previous year. Marking was not done by the teachers, but by the group's management team, with a scanner and software enabling the papers to be processed automatically.

As for the diagrams, they reveal a drop in the level in 4 out of 5 courses. Future research will concentrate precisely on collecting and analyzing data (both qualitative and quantitative) allowing these results to be explained. However, there is already an interesting fact that is worth our attention...

In terms of skills, none of the teachers had any special prior expertise in *e-learning*. And in fact the auditing teacher (the only subject to show an improvement in results compared to the previous year) showed a appreciably inferior command of information technologies than her 4 colleagues. The latter, for example, were used to: creating PowerPoint presentations, having their students search through reference sites on the Web or even giving exercises using specific software (Excel, MsProjects, Software Engineering Environment, etc.). The teacher in question declared not having used information technologies in her lessons up until then, and feeling more at home in the oral teaching mode (traditional lesson) than one that requires everything to be formalized in writing (*e-learning* lesson). In other words, the only subject

recording a higher level of student success is linked to the teacher with the least proficiency in new information and communication technologies.

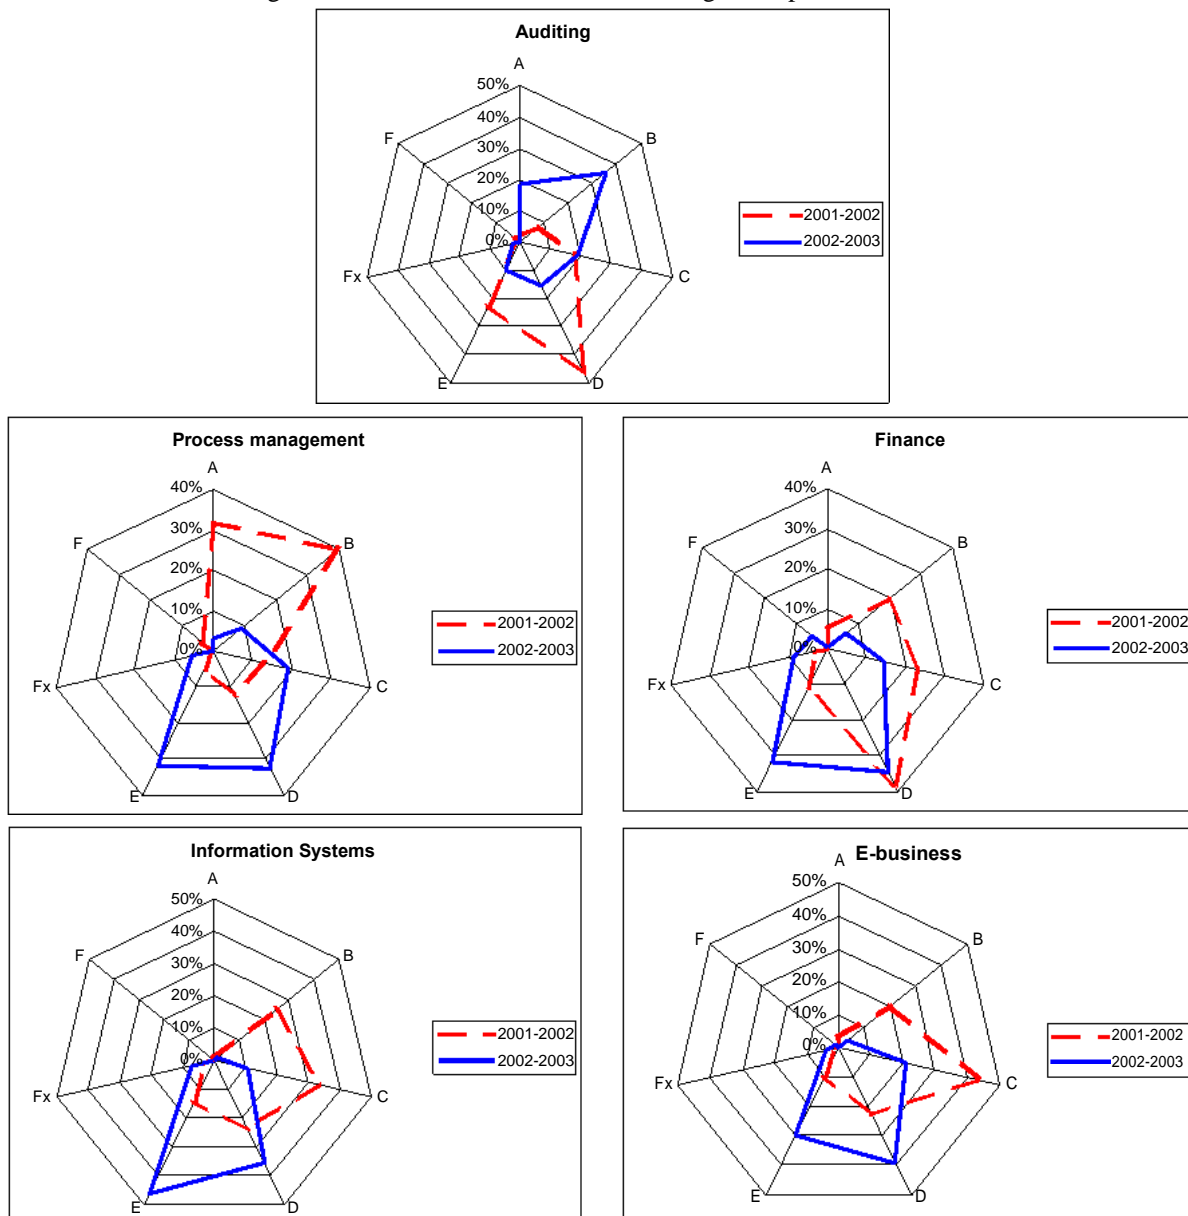

Consequently, this case, while unique, is it not enough to show that even if being conversant with information technologies is necessary for the "virtual teacher", it is not a determining factor in the success of an e-learning course? Is this not a perfect illustration of the need to dismiss professional reasoning as scientific in a techno-centered approach to on-line education?

On the one hand, given the diagrams, we could assert that the primary aim of such a tool has not been achieved. For all that, is this observation not worth putting into perspective so as not to adopt a simplistic approach to the legitimacy of this type of project? Indeed, this is the very first *in vivo* experiment for an institute, its teachers and students. These results can be interpreted as the formalization of the appropriation issues and cultural changes inferred by *e-learning* such as those we depicted in the literary analysis. For this reason, we believe that a methodology applied to the subject would be beneficial on a temporally longer system of reference, allowing the influence of this type of variable to be diluted.

For all that, over and above this decline in performance, the management team of Montpellier Business School considers the *e-learning* project as a success in as much as its implementation enabled the group to achieve the pre-determined globalization objective and to enroll an entire year group of students in a year's study abroad culminating in a double diploma. For this reason, the success of the tool must not be limited to examination results alone, but should include other indirect indicators. In this field example we see that the success of *e-learning* is closely linked to the success of the upstream project requiring its implementation.

<sup>5</sup> The results here are detailed according to the marking schedule applied in the target universities: A = Excellent; B = Very Good; C = Good; D = Fair; E = Unsatisfactory; Fx = Fail (with the right to re-sit); F = Fail (Student excluded)

Figure 2: Traditional class *versus* e-learning – comparison of exam results

#### 4. CONCLUSION

Cross-referencing two fields, information systems and education sciences, provides the opportunity to offer an explanatory model of the effectiveness of an e-learning tool. This model incorporates the teachers' and students' characteristics, but also the institutes' aims and means as well as the fundamental relationships between these three categories of player. The research carried out at the Montpellier business school initially only allows the results students obtained in traditional training to be compared with those gained in on-line training, which represents only the beginning of research intended to delve more deeply into the proposed model. However, these initial results support our reasoning: a view overly centered around technological determinism should logically be dismissed, in the same way as limiting the measure of success to the students results alone. The

aims of the school studied in this article show that the legitimacy of an *e-learning* project can lie more in the satisfaction of being able to meet new strategic challenges through its development than in simply improving an existing teaching tool.

## ABSTRACT

In this paper we report the benefits of using eXtended Markup Language (XML) to support financial knowledge management, which include indexing, organizing, association generation, cross-referencing, and retrieval of financial information to support the generation of knowledge. The current searching engines cannot provide sufficient performance, such as, recall, precision, extensibility, etc, to support users of financial information. XML is able to partially solve such problem by providing tags to create structures. XML provides a vendor-neutral approach to structure and organize contents. XML authors are allowed to create arbitrary tags to describe the format or structure of data, rather than restricted to a specific number of tags given in the specification of HTML. A prototype of XML-based ELeCtronic Financial Filing System (ELFFS-XML) has been developed to illustrate how to apply XML to model and add value to traditional HTML-based financial information by cross-linking related information from different data sources, which is an important step in moving from traditional information management to knowledge management. We compared the functionality of XML-based ELFFS with the original HTML-based ELFFS and SEDAR, an electronic filing system used in Canada, and recommended some directions for future development of similar electronic filing systems.

**Keywords:** Financial Knowledge Management, Electronic Financial Filing Systems, XML

## 1. INTRODUCTION

Corporate filings, news articles, trading data, information about the listed companies, etc, are some most frequently requested data by investors. Majority of financial data or information are disseminated through Internet hoping that they will be widely available. However, searching, retrieving, and utilizing financial data have become a major challenge to both users and researchers. Such challenge includes issues, such as, efficiency, precision, recall, relevance, and value creation. According to the 10th WWW User Survey, only around 25 percent of people used the WWW to access financial information on daily basis. The same survey also pointed out that more than 45 percent of the respondents felt that they were not able to find the information they needed. To solve these problems, content creation, representation, and management can be few areas to attack. It is possible to automate or semi-automate the process of content creation, collection, indexing, organizing, storage, and dissemination.

In this paper, we dissect the problems mentioned above into the life cycle of financial information and proposed a framework to use eXtended Markup Language (XML) to rectify these shortcomings. It is also hoped that it will help users to better manage financial *data* by systematically convert, synthesize, and create financial *knowledge* from *data and information*. It is a very important element in knowledge management [9]. To support this research, a prototype of XML-based ELeCtronic Financial Filing System (ELFFS-XML) has been developed to illustrate

how to apply XML to model traditional HTML-based financial information and providing value added services. We compared the functionality of XML-based ELFFS with the original HTML-based ELFFS and SEDAR and recommend some directions for future development of similar electronic filing systems.

For the rest of the paper, Section 2 provides a short discussion about related research works of financial filing systems as well as the issues and problems of organizing financial information on the Internet. Section 3 discusses the Financial Knowledge Management Framework. The implementation and major technologies of ELFFS-XML are discussed in Section 4. Experiment and user evaluation are discussed in Section 5. This paper is concluded with a discussion about future research.

## 2. FINANCIAL INFORMATION MANAGEMENT AND ITS ISSUES

Transparency and efficiency are two extremely important issues to the users of financial information [8]. Transparency can be defined as the visibility of a financial market and efficiency refers to the time and efforts that needed by users to search and retrieve the needed information. In order to make high quality decisions and narrow the gaps between private investors and corporate investors, both issues need to be solved.

Financial information/data were formerly disseminated through traditional media, such as five nationwide Securities and Exchange Commission (SEC) reading

rooms in the US. To obtain the needed information, investors had to travel to these locations, search, and then make photocopies, which was extremely inefficient. Private companies, such as Mead Data Central, also provided financial information via dedicated connections with extremely high charge that not every investor could afford.

Since the advent of the Internet and hypertext, most financial information were digitised and disseminated through Internet. In the following, we will discuss the existing Electronic Filing Systems and current financial information management issues.

### 2.1 Existing Electronic Filing Systems

As Internet appeared, a systematic solution – the electronic financial filing system was emerged to aid parties, such as, filers, regulators, and investors to collect, process, store, and organize financial information. Filers usually are the companies that need to file financial documents to the regulatory bodies, such as Securities Exchange Commission (SEC). They are required by law to submit information for disclosure to the public. The regulators are responsible for collecting the submissions, processing them, guaranteeing the information received are correct, valid, and sufficient, and making them available to the public.

Different countries have different electronic financial filing systems. SEDAR [3] is a Canadian project that focuses on building financial information repository to support investors. It collects financial reports or documents from Canadian listed companies, which can be in different formats, and creates a web accessible archive for users. EDGAR [2] (Electronic Data Gathering, Analysis and Retrieval) is the US efforts in supporting collecting, indexing, organizing, and disseminating financial filings through Internet. It provides facilities for filing parties to format their reports in SGML. EElectronic Financial Filing System (ELFFS), was an initiative at the University of Hong Kong endorsed by the Securities and Futures Commission (SFC) of Hong Kong Government to support digitising, collecting, archiving, and disseminating financial information using traditional HTML [8].

### 2.2 Current Management of Financial Information on the Internet

We have carefully analyzed and studied the strengths and weaknesses of each filing system, and found there are still lot of rooms for all the filing systems to improve. An ideal electronic filing system should allow collecting documents from submitters via Internet to increase the speed of transmission as well as lower the transmission costs. It should support processing and validating the submissions, store and create archives, organize, index, and extract the useful clues, trends,

and relationships buried in the data. This is a crucial step, which can be defined as knowledge generation.

From the day when the World Wide Web was born, a HyperText Markup Language (HTML) was needed to "mark up" contents in order to create the format that can be presented on the web. HTML, deals with two different views of the same piece of information: *what* the content is and *how* the content is presented. This is what *metadata* [4] is about. HTML documents are actually a mixture of both content and presentation instructions, which makes it very difficult to process by both human beings and machines. As some of the syntaxes used in HTML are not too strict, data extraction from a HTML document may not be even possible.

Over the past few years, Internet has become a major information source for investors and it provides information that covers almost all the major financial markets in the world. People started to create value from the huge amount of raw information, but processing it to create *knowledge* is difficult. Raw data exist in many forms, and when it comes to unstructured documents like HTML and all those generated by presentation-based software, content extraction becomes even more difficult. Quick adoption of Internet also accelerated the explosion of digital contents and information overload has become a major challenge. Data redundancy is another problem, e.g. one copy in the raw information and another copy in the presentable page. Keeping two sets of data not only cost more storage, but also cost more manage efforts.

### 2.3. A Survey about the User Issues

We conducted a survey to study the situation on the usage of financial information. 42 people are interviewed for the major problems they encountered when accessing financial information over Internet. 30 of them were investors, 10 were financial software developers and the remaining were information system administrators. Based on a scale of 1 to 10 (from least serious to the most serious), we found that the financial information on the Internet faced the following issues, the number in the bracket indicates the average score of severity:

The

1. **Too time consuming to gather** (8.13)
2. **Volatile to catch** (7.64)
3. **Distributed and fragmented in nature** (7.69)
4. **Bulky to store** (7.68)
5. **Too fast to collect** (7.54)
6. **Easily perishable** (7.49)
7. **Not unique** (7.34)
8. **Varying in content representation/format** (7.29)
9. **Difficult to be processed by human** (7.16)

### 3. FINANCIAL KNOWLEDGE MANAGEMENT

According to Thomas Davenport [7], knowledge management is a systematic attempt to create, gather, distribute and use knowledge. Matt Richtel [15] defines knowledge as information that is accessible and can be directly used to solve a problem while it is just raw and impenetrable. In simpler words, knowledge management is the methodology to add value to raw data and convert them into useful knowledge.

#### 3.1 Financial Knowledge Management Framework

From the point of view of an information producer,

we break up the Financial Knowledge Management into seven stages: *information creation, information collection, information storage, knowledge generation, knowledge dissemination, knowledge presentation and feedback*. It was derived from the knowledge management processes that discussed in previous section and was adapted specifically to suit the needs for Financial Disclosure and the development of the prototype (Figure 1). We have briefly categorized the information consumers into three groups, namely, individuals, financial regulators and value adders. Due to the scope of the paper, we will only discuss the needs of individual investors.

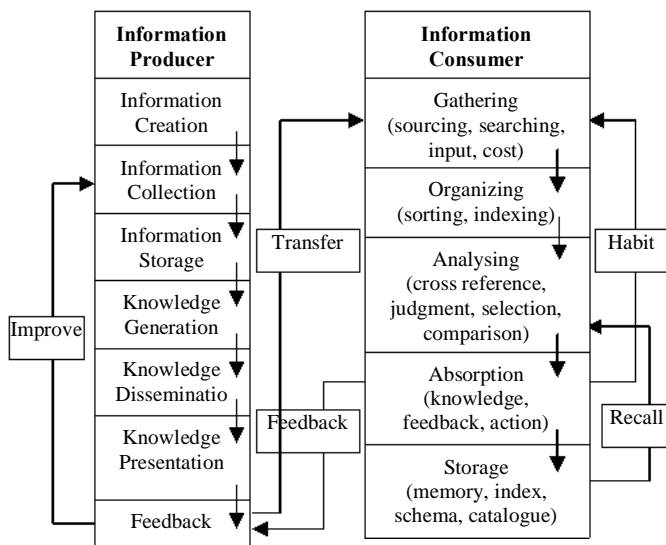

Figure 1: Financial Knowledge Management Framework

#### 3.2. Design of the Knowledge-based ELFFS-XML

Based on the Financial Knowledge Framework, we designed the general architecture of ELFFS-XML (Figure 2). In the following, we will discuss in detailed tasks in the each layer of the architecture.

##### 3.2.1. Information Creation

In ELFFS-XML, we aimed to provide facilities for content creators to create structured contents using XML. The first step was the conversion of the Java-

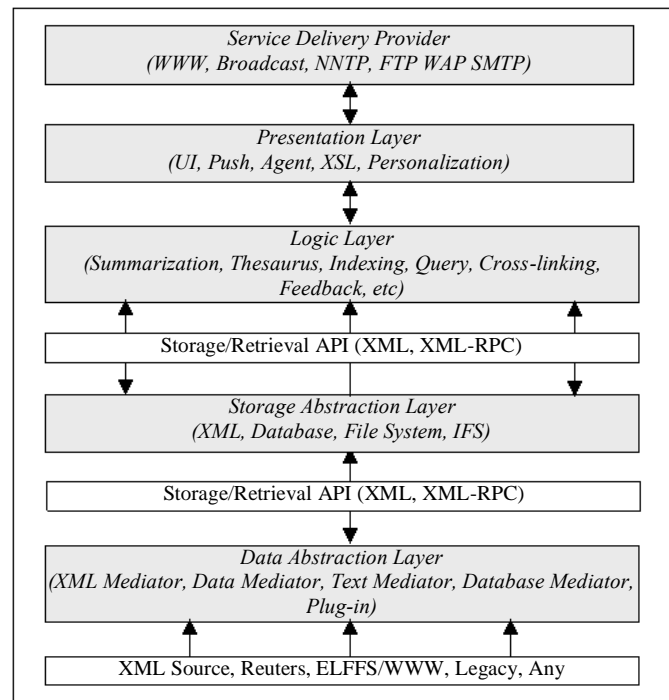

Figure 2: Architecture of ELFFS-XML

based cross platform Formatting Wizard for financial report filers. Users can input the data using a browser without knowing the details of XML.

##### 3.2.2. Information Collection/Storage

There are many financial information sources available. We have developed a set of retrieval agents that can connect to a variety of data sources including ELFFS financial report archive, Reuters, WWW, financial knowledge bases and other legacy sources. Each of them is working independently and the data they collect is converted into XML formatted files through a standard Application Programming Interfaces (API).

The XML files are placed in a traditional file system and an archive is formed gradually. They are recombined in real time using the "SYSTEM" entity feature of XML. Although it may increase access time, it actually increases the flexibility of handling these data. Until a general XML mass relational storage mechanism has been developed, we are staying with the primitive file system approach.

##### 3.2.3. Knowledge Generation

We have a multiplexing engine that chooses from different kinds of data sources and invoke the predefined logic for each source, such as data summarization and cross-linking. An XSL style sheet is applied to an XML document that contains the annual report repository. Because XSL can be used to perform many operations on XML tags, it is equivalent to a logic layer. We used a Java-Servlet Cocoon to perform this XSL transformation on the server side.

### 3.2.4. Knowledge Dissemination/ Presentation

The Extensible Style Language is used again here. Using various tools, the XSL processor can output different well-presented formats such as the Portable Document Format (PDF), HTML, WAP pages or even XML.

## 4. IMPLEMENTATION AND MAJOR TECHNOLOGIES OF ELFFS-XML

In this section, we will discuss the implementation and major technologies of ELFFS-XML.

### 4.1 Document Format

The financial document is XML formatted. It starts with the <filing> tags. There are 2 major "sections" inside, <data> and <body>. Inside <data>, there are a number of vital data about the document, such as document identifier, document title, date, and a couple of keywords. Inside <body>, there are <sidebar> and <maintext> tags and inside <maintext>, there are <paragraph> tags, where content of the report is mainly placed. Some key performance data about the report have been tagged, such as profit last year (<perf-profit-lastyr>), profit this year (<perf-profit-thisyr>). After this XML page is fed into an XML processor, a XML document tree is generated. Document contents and data can be easily extracted.

### 4.2 Generation of Tags and Schemas

In reality, almost all the filers do not markup their file using XML. Even if they do, they are using different DTDs. This imposes a new XML standard called eXtensible Business Reporting Language (XBRL), which attempt to provide a framework defined by a standards group for XML business report. In this paper, we attempted a different approach. We tried to use a combination of three methods to generate the tags, namely, statistical and information retrieval approach, accounting and auditing practice approach and investor feedback approach.

#### 4.2.1 Statistical Information Retrieval

A total of 5000 news article related to South East Asia available from Reuters, 200 governmental financial articles and 20 annual reports from different listed companies were pooled together to create the archive to support the identification of tags. We used several techniques to support tag generation. Two approaches are involved: the first one is calculating term frequency and document frequency of terms and phrases in all the documents; the second is using the concept space approach [11] as well as a couple of online financial and business dictionary to create our ELFFS thesaurus. Then we have performed object filtering and automatic indexing for each of our collected articles mentioned

above. A list of concepts was generated after we performed co-occurrence analysis. Term frequency and document frequency calculation were used to find out the combined weights of terms and phrases in the concept space. All the subjects in the automatically generated thesaurus were then used to help identify rotationally duplicated terms.

#### 4.2.2 Accounting and Auditing Practise

To improve the reality and practicability of the meta data, we examined the code of practices of several accounting firms and auditing firms. An additional list of tags was generated after this process.

#### 4.2.3 Investors' Feedback

Investors are usually the final recipient and consumer of the financial information. We have interviewed 20 investors about what information they want to see from different types of financial information.

## 5. EVALUATION OF ELFFS-XML

ELFFS-XML is evaluated by different criteria: system efficiency, tag generation performance and user satisfaction. Before the evaluation, we first take a look at how ELFFS-XML compares to other electronic financial filing systems.

### 5.1 Comparison with Other Financial Information Disclosure Systems

ELFFS-XML is compared with different such systems using the Financial Document Disclosure Model. The ELFFS and the SEDAR system were used as references (Table 1). It is not difficult to see that ELFFS-XML, in many ways, has trivial advantages.

### 5.2 Systems Efficiency

We have conducted a simple experiment revealing the size of an XML document can cost significantly more resources than a binary encoded document (store, network transfer, read, process.) We definitely need some ways to reduce the impact of this problem, but these are outside the scope of this paper.

### 5.3 XML Tag Generation Performance Evaluation

We conducted the experiment with the thesaurus agent (computer), a group of three experts in the field of accounting, finance and investment, and a group of five individual investors with different backgrounds. The thesaurus agent is running on a SUN-Enterprise 6500 server with 8 ULTRAsparc-II 400MHz CPUs and 3 GB of memory. Each of the experts and investors were given an accounting and a financial investment dictionary, twenty annual reports of Hong Kong, a list of twenty finance related web sites with a machine to

access those sites, a terminal that can access and view real time financial data from Reuters and 5000 pieces of archived Reuters news articles related to South East Asia market. After reading and examining these materials, the three groups of participants were asked to produce a list of tags they think useful. They are given a total of ten hours to come up with the list with

no limit on items. Both human and computer participants are only allowed to view web pages that are directed linked from the list of specified web sites to increase the fairness of the experiment. After the list was produced, the naming of the tags was adjusted so that they are consistent with each other in terms of semantic meanings.

	<b>SEDAR</b>	<b>ELFFS</b>	<b>ELFFS-XML</b>
<b>Information Creation</b>	extremely varied output format	formatting wizard , Java based , cross platform	formatting wizard, Java based, cross platform, keywords tagged, other XML aware editors supported
<b>Information Collection</b>	modem terminal upload	WWW secured via SSL	WWW secured via SSL
<b>Information Storage</b>	file systems based (usually 1 file), database	file systems based (usually multiple files), database	file systems based ( usually multiple files), XML archive, optional legacy database support
<b>Knowledge Generation</b>	document indexes	document indexes, full text indexes	document indexes, full text indexes, cross referencing with online news articles, keyword search, multiple documents comparison and querying
<b>Knowledge Dissemination</b>	WWW	WWW, SMTP (email)	WWW, WAP, SMTP (email)
<b>Knowledge Presentation</b>	Word documents, proprietary formats, need special proprietary viewer	HTML	XML/XSLT, server side transformation to HTML, browser independent presentation, document map, PDF for printing

Table 1: Comparison of Different Financial Information Disclosure Systems

Figure 6: Different Sets of ELFFS-XML Tags

To quantify the performance of the different approaches, we view the selected tags from each of the three groups as separate sets as in Figure 6. Visually, the more dark area a set has with respect to its own size, the better is its performance. Mathematically, we use precision and recall as our evaluation metric. We slightly modified this concept and revised equations are:

$$P = \frac{\text{number of good tags produced}}{\text{total number of tags produced}}$$

$$R = \frac{\text{number of good tags produced}}{\text{total number of good tags}}$$

Visually, good tags are those tags inside the dark grey and black area. We used the F-measure to combine both ratings. The F-measure is defined as:

$$F = \frac{(\beta^2 + 1)PR}{\beta^2 P + R}$$

$\beta = 1$  was chosen because we believe that precision and recall are equally important.

	# Correct	# Produced	Total Correct	P	R	F(1)
<b>Investors</b>	128	385	257	0.33	0.33	0.17
<b>Experts</b>	157	350	257	0.44	0.61	0.26
<b>Agent</b>	185	480	257	0.38	0.72	0.25

Table 2: Experiment Results for Different Tag Generation Approaches

## 6. CONCLUSION AND FUTURE RESEARCH

In this paper, we proposed a new approach to support indexing, organizing, and retrieval of financial information on the Internet using the eXtensible Markup Language (XML). The new approach includes models such as the document disclosure model, which was proposed to understand the underlying problems of information producers and consumers.

The strength of this new approach is that important data can be extracted relatively easily to facilitate easier creation of knowledge than the traditional HTML approach. ELFFS-XML can help to archive higher information transparency through the provision of filing standards and facilities to organize these information. End-users can gain benefits because they can obtain knowledge more easily. At the same time, it also provides multiple efficient delivery channels for end-users to receive the needed information at the lowest cost of time and money. It significantly bridges the gap between large corporate investors and small individuals, who are less resourceful.

We also found out that with the help of financial experts, computer agent, which automatically generate

metadata or tags from a multiple documents collected from different sources, can provide very good performance in terms of precision and recall. Despite how ideal it sounds, there are still works need to be done. Currently, the DTD defined for ELFFS-XML is in an experimental stage, which lacks sophistication and details. Many financial performance tags are still missing. We are looking forward to expand it into a full-fledged XML vocabulary and let government agencies evaluate its usefulness.

Scalability is another issue. Searching through a large text-base XML repository on a file-system-based storage can be very I/O intensive, which may become the bottleneck to large systems. Moreover, there are still no standard ways to query XML archive. All we have now is a XML parser and a set of procedures about how to use the parser. We are currently implement dbXML and XML-QL, which are SQL-like languages for XML, to improve performance and provide more features.

### ABSTRACT

Electronization or knowledgeization is under way in society, world-over. This process works the transformation of the industrial society into knowledge society, and requires a new level of border-crossing cooperation –and catalyzing of the same. This exploratory study seeks to make sense of catalyzing aimed at generating new knowledge on e-business by turning research initiatives stemming from Business, University, and Government (B.U.G.) from idea to knowledge. This action research based single case study focuses on eBRC, a university joint venture created as part of eTampere to fulfill the goals of eEurope. Theoretically, the study is anchored to network and service management literature.

**Keywords:** E-business, networks, service management, electronization, knowledge creation, knowledge society

### 1. INTRODUCTION

It can be argued that a major transformation process, of kin to industrialization, is under way in society, world-over. In the language of this study, the process referred to as ‘electronization’ or ‘knowledgeization’ works to transform the industrial society into knowledge society. It can be further argued that, to generate relevant knowledge on electronization or e-business, more and deeper interaction is needed across the sectors of Business, University, and Government (B.U.G.). [9] Based on far-reaching transformation strategies that involve the entire society, ranging from local strategies, such as eTampere, to international strategies, such as eEurope, it can be concluded that new type of catalysts are needed to tackle the challenges related to knowledge generation on e-business ([www.etampere.fi](http://www.etampere.fi), [www.europa.eu.int](http://www.europa.eu.int)).

The mission of this exploratory study is to make sense of catalyzing aimed at generating new knowledge on e-business by turning research initiatives stemming from B.U.G. from idea to knowledge. Following an action research based single-case-study strategy, the study focuses on eBRC, a university joint venture established as part of the eTampere knowledge society program to fulfill the goals of eEurope ([www.ebrc.fi](http://www.ebrc.fi)). The author team includes the founding co-directors, currently director and vice-chairman of eBRC and is led by the head of eBRC’s own electronic services and presence.

eBRC is a Tampere, Finland, based virtual research center, a 50-50 joint venture between two universities, Tampere University of Technology (TUT) and University of Tampere (UTA), established for a limited life (2001-2005) as part of eTampere. The mission of eBRC is to make sense of business in the knowledge society by enabling research, increasing B.U.G. networking, building a research project portfolio, and creating new, internationally acknowledged champions in its core research fields.

Theoretically, the study is anchored to the Nordic school approach by combining network research and service management thinking [6, 22]. Deriving from this tradition the remainder of the paper is structured into two main chapters: External Analysis (networks) and Internal Analysis (service management), before summarizing the findings in Conclusions.

### 2. EXTERNAL ANALYSIS

The transformation from industrial society to knowledge society is marked by two megatrends or phenomena that shape the organization and the operation of different kinds of organizations: (i) rapid technological development and (ii) networking. Herein, networking refers to all kinds of inter-organizational linkages between organizations, not only those that are caused or enabled by introduction of new technologies. The external analysis of the case organization is conducted by analyzing the environmental powers by using the two phenomena as lenses through which the environment is observed. It has to be noticed, however, that the phenomena are so closely related that it is sometimes extremely difficult to differentiate between the two. Consequently, the emphasis in the following analysis is on networking.

#### 2.1. Rapid technological development

Since the successful launch of the first commercial Internet browser, in 1995, we have witnessed a strong and rapid development of Internet related technologies. After the boom and bust, in 2000, Internet and other ICT based solutions have again steadily introduced new e-business innovations, which have had remarkable economic effects across several industrial sectors. Many traditional industrial companies have, since 2000, developed unique e-Business solutions and innovations incrementally with clear, strategy related goals with little or no remainders of the hype era [23]. The service sector is an example of an environment in which new technological innovations related to ICT-

solutions can be used in very different ways. Some services can be fully automated and transferred to e-business platforms, while other services simply cannot be automated, due to, for example, their overly 'high-touch' or complicated nature. [30]

The public sector organizations also face challenges in order to use the ICT enabled new forms and ways of operation effectively. Initiatives and practices referred to as 'eGovernment' have become an essential part of the development of public services. Public online services are perhaps the most popular ICT solution in public organizations. Such can take different forms (Internet, extranet, intranet) and cover various kinds of interactions (e.g., information exchange, negotiations, support, transactions) with different stakeholders (e.g., customers, suppliers, partners, internal customers). The concept of public online services is customer oriented in itself; the aim is to fulfill the customers' need in a cost effective way. [14, 24, 25]

eBRC's basic mission is related to enhancement of deployment –not development –of new technology. As a catalyst of electronization, eBRC aims at finding new types of business and operational models that employ the newest technology. Although development of new technology is not at core of eBRC's operation, it nevertheless creates challenges because, the faster the development, the faster new needs arise for concepts that enable deployment of the technology in question. In addition, eBRC is utilizing the newest technology in its own operation; mainly through public online service. eBRC's online service includes Internet, intranet and extranet solutions. The online service is targeted to the public, all those interested in e-business: Researchers involved in projects, research financiers, business practitioners, as well as eBRC's own team members. The different types of interactions covered include information exchange, communication and support. The special characteristic of eBRC's online service is the matching point function, which enables eBRC's key stakeholders (researchers, businesses, and research financiers) to find the right partners.

## 2.2. Networking

### 2.2.1. eBRC and its networks

It has been argued that networks of inter-organizational relationships are partly replacing traditional markets and hierarchical organizations [1, 7, 22]. Business firms and other entities enter into various kinds of dyadic arrangements such as joint ventures and strategic alliances, but also arrangements that concern numerous actors, such as supplier networks and research consortia, in order to gain strategic advantages and, simply, to operate more effectively. [29] It has also been argued that, in our rapidly changing society, networks offer a flexible way to cope with uncertainty and dynamic environmental pressures. These are

caused by globalization, technological development, regulatory uncertainties, ambiguous market signals, increasing innovation costs, unbalanced market structures, and increasing amount of information –to name the top challenges. [3, 22, 29]

In the network context, eBRC can be seen as an intermediary between different kinds of players representing researchers, businesses, and financiers. As in the case of the public sector service organizations, discussed above, eBRC also serves different customers in different levels. The services are targeted to the three groups, referred to above. In addition, eBRC serves the interests of its founder universities, as well as the underlying eTampere program, and the city of Tampere as key financier, and of course the society at large by providing the new knowledge. In traditional sense, it is also difficult to describe the suppliers of eBRC; the three main groups also represent the suppliers, as through their inputs eBRC is able to generate the value added to different customer groups. Consequently, it can be argued that the traditional view of vertical and horizontal networks (Möller-Halinen 1999) is not as such applicable to eBRC's operational format. In figure 1, the network of eBRC is described.

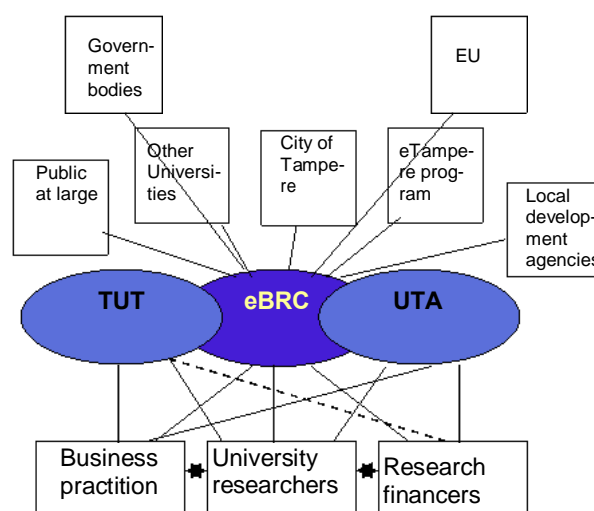

Figure 1. The eBRC network depicted

Figure 1 illustrates the network and key stakeholder groups of eBRC. As mentioned earlier, the role of the three key groups (see bottom of figure 1) can be described as both customers and suppliers, and thus the most suited nominator for them could be "partner". eBRC's relationships with its partners (partnerships) are long-term in nature, and the aim is to form mutual, cooperation based win-win relationships [1, 8]. For eBRC, the most challenging partnerships are those with businesses. During the last 20 years, Business-University relationships have gradually increased and intensified, as well as grown in relative importance. Two elements can be underscored in this development. First, universities possess such business and technical competence which, combined into a helicopter

perspective, can advance competitive advantage of business firms. Second, universities increasingly need to rely on external financing to finance their operations. Deeper Business-University cooperation has also been called for with the requirement for increased practical relevance of academic research. [28] eBRC is established by two universities with quite differing traditions with regard to Business-University cooperation. At the TUT, close relations with businesses are perceived as a natural element of scientific knowledge creation. At the UTA, such relations are clearly viewed with more skepticism, due to classic emphasis of the objectivity argument. The TUT tradition as 'the university of the industry' stems from its general roots in technology and engineering, while the UTA's more 'classic' university tradition from roots in humanities and social sciences.

eBRC's relationship with the city of Tampere is marked by the city's role as eBRC's main financier: eBRC's basic funding is based on a conditional five-year contract, in which results are evaluated twice a year. While this relationship is operatively not as deep as the relationships with the key stakeholder groups, eBRC, by definition, provides value to the city by performing its functions as a sub-program of eTampere. Of the other network partners (see top of figure 1), Other Universities form an interesting group as 'partner-competitors'. Besides cooperating, eBRC is also competing with them on research funding and business partners in research projects. These relationships can be described as 'co-optive'[2]. In such relationships the parties can cooperate in some functions and compete in others. Important is to be able to separate these two from each other in order to avoid conflicts.

### 2.2.2. eBRC as Intermediator

Discussion of business network intermediators has been scarce in the literature on business networks. Business networks are typically depicted as structures with no boundaries. In a network with no boundaries every actor can be regarded as intermediary as it is connected to several entities [10].

The intermediary role can also be approached as 'triad'[10, 31]. Havila [10] distinguishes between two types of triadic business relationships. First, the serial triad, is a relationship where the intermediary mediates most of the contacts between the other two actors. Serial triad reminds of a series of two dyads: (i) between intermediary and seller, and (ii) between intermediary and customer. Second, the unified triad, is a relationship where each actor has more or less equal contacts with each other, and thus this type of triad is like a group of three actors. It can be argued that, outside the context of triads, the actors can act as intermediators whose basic function is to mediate the relationships between other actors [12]. Chambers of Commerce are examples of organizations that operate

as intermediators between companies both on local and international level. eBRC can be also regarded as a specific type of intermediary in a network. The intermediating act is often performed in a certain project by, for example, finding a suitable business partner to a specific research project or helping researchers find the right financiers for their project.

In the literature related to intermediators in triads, it is argued that actors may have different roles or functions, and at different times any of the triad members may play one of the different roles. Mediator, *tertius gaudens*, and oppressor functions of the third party in the triad can be distinguished [26, 31]. The mediator is involved in both sides of the relationship (often buyer and seller), and aims at enhancing the relationship between the two by keeping them together. Thus the mediator is interested in finding solutions and creating situations, which benefit both parties. Mittilä[21] uses the term 'bistomer' for a similar type of intermediary in business relationships as mediator. The *tertius gaudens* and oppressor have the opposite attitudes as they are in the triad in order to satisfy their own interests. The *tertius gaudens* is ready to take advantage of every emerging possibility, but not taking an active role like the oppressor. [26, 31]

Järvelin and Koskela [12] have discovered two additional intermediary roles in the network context, labeled as 'initiator' and 'invisible hand'. The initiator is more or less door opener with a large contact base and a role of bringing different parties together. The invisible hand is an actor that only provides facilities for the other actors in order to help the others to build the contacts and relationships. The mediator, *tertius gaudens*, and oppressor roles can only exist in the ongoing relationships while initiator and invisible hand roles are central in the beginning of the relationships. eBRC can be in many cases regarded as an initiator which brings different actors together. In research projects more tightly connected to eBRC, it can also have a mediator role. In addition, by having created and launched an annual international research conference, eBRF ([www.ebrc.fi/conference2004](http://www.ebrc.fi/conference2004)), eBRC also acts as an invisible hand by offering a forum for networking.

## 3. INTERNAL ANALYSIS

Professional service organisations (or expert services or knowledge intensive services) can be seen as true embodiments of the emerging knowledge society; the products or outputs of these organizations represent knowledge or competence as such, and can be thus regarded as being fundamental elements of the society and its development [15, 21]. eBRC's offering is new and fresh in many different aspects; the research center operates in a way that utilizes the opportunities enabled by the rapid technological and social development. eBRC thrives to be a modern, virtual, and above all

dynamic meeting place for researchers, business practitioners, and financiers – a new type of actor in the field of academic research.

In order to clarify the service and to go deeper into the concept, basic principles of service management are utilized. Professional services are being characterized as the most intangible of services. The intangibility of these services concerns not only their physical nature but also their mental characteristics. As professional services are markedly intangible, they are also often quite hard to comprehend, both for the employers, customers and other stakeholders. (11, 12, 18, 19).

The intangible nature of professional service is also present at eBRC; the concept and services offered are abstract both physically and mentally; and it has taken time to 'educate' the different stakeholder groups. The other clear professional service characteristic that is present in eBRC's operation is the almost simultaneous production and consumption (and partly also marketing) of services, which causes problems for balancing with supply and demand. This can be partly solved via 'digital presence'.

A Special characteristic of professional services is also the importance of customer participation, especially as resources as they provide valuable information, serve as references, etc. [19]. As mentioned earlier, a customer segment of eBRC also serves as its key suppliers: A prime example of customer participation in production of professional services.

### 3.1. Service components

Products and services are described as bundles of different benefits. Kotler's [17] three-level structure of products focuses on the core benefit which is the target of the customers' needs. This benefit is served through the actual product which includes the brand name, packaging and other features. Finally the product concept is supplemented by augmented services and benefits such as warranties. Similar models have been developed for professional services. The basic level is the core service, which defines the key problem-solving element of the service. This is the service that the customer primarily desires. Support services include conditional, additional, and surplus support services. The support services make the service accessible or give the customer more choices and options to benefit from the entire set of services. [27]

#### 3.1.1. Core service

eBRC's core service or core benefit is project facilitation services which comprises matching of three stakeholder groups: researchers, business practitioners, and financiers. The objective is to create research and development projects by combining the stakeholders' interests. eBRC seeks to act as a catalyst in the

interface of researchers, businesses and financiers serving as a matchmaker in the process. Various research projects are conducted under the eBRC umbrella. The projects differ from expert opinions, drafted within weeks, to research programs lasting for years and comprising several subprojects. The focus is on research that is both academically valuable and purposeful for businesses.

The researchers from the founding universities serve as the key resource for eBRC and research initiatives often derive from within this group, from within each individual's own research field. An initiative for a research project can also stem from the practical needs of businesses or from the research financiers, often the EU or national government related research programs.

eBRC's role is to find and match the right partners and offer assistance in the funding process. Execution of the research projects is always led by an individual professor of a TUT or UTA institute or school and often joined by representatives of other such – outside or inside, Business or University, domestic or foreign – entities. In addition, eBRC works actively to develop different forms and tools for effective co-operation. It can also participate as a coordinator in the management of the projects.

#### 3.1.2. Actualised service

Marketing of professional services lies usually in the hands of the professionals themselves; the service is demonstrated through earlier work. Brand-awareness is, however, increasingly important and eBRC has also developed features and services that support its brand building. eBRC's service production includes several support services. There are no particular conditional support services; the core service can be utilized as is. As an additional support service eBRC offers the option to publish research results its publication series: Research Reports (RR). The publications are available both in print and electronic format.

To augment the offering, eBRC has surplus support services. It offers its stakeholders opportunities to network with each other both virtually and physically. At eBRC's web service the visitors can, for example, discuss topical issues and acquire the latest research information. The annual conference eBRF gathers the different stakeholders together and gives an opportunity to present ongoing research for instant feedback. eBRF is multidisciplinary window on current issues related to electronization and e-business research and a border-crossing meeting ground. Participating researchers have the option to publish their final research papers in *Frontiers of e-Business Research (FeBR)*, the conference proceedings.

### 3.2. Electronization of eBRC

E-business in an organization can take different forms

depending upon, for example, the nature of the product, processes, or organization. The development of e-business or electronization in a specific organization evolves often through different stages. The development starts from simple Internet applications and ends up with total organizational '(e)transformation'. [5, 16]

In figure 2, the 'eState' of an organization is depicted through three dimensions: Product, process and agent [4, 30].

Figure 2. Dimensions of e-business

Within figure 2, eBRC would become positioned somewhere in the middle. The product of eBRC is a service, but only part of it is in digital format; the process is only partly digitalized; and the agent is still more or less physical. Consequently, in the expert or professional services, the face-to-face interactions and the personal relationships play a central role, and this also still strongly the case with eBRC as well. The professional service needs to have a face/faces in order to create the credibility needed for starting cooperation.

### 3.3. Service process

Another efficient way of describing the service concept is to use process descriptions. As mentioned above, services are formed through different chains of functions. Due to the project nature of eBRC's operations, each service process is individualized. However, there are also features that are similar in each process. Every project starts from an analysis of the research field, examining the different parties and their interests. The research ideas are evaluated from several points of views and the feasibility is discussed. After a project begins, eBRC's role is to facilitate the process and follow its progression. The results can be reported in eBRC's publications and possibilities for teaching implementations and further research are examined. The eBRC process is described in figure 3.

Figure 3: The eBRC process: From Idea to Knowledge

## 4. CONCLUSIONS

There are historic, cultural, and financing-related barriers to working closely together across the borders between universities, even individual schools and institutes within a given university, let alone those between B.U.G. Nevertheless, faced with emergent phenomena such as evidence-based-policy thinking and the increased complexity related to utilizing ICT enabled models and to understanding what is relevant to business competence, societies need to (seek to) be successful in breaking borders, not just between nations, but also sectors of economy.

While it can be argued that at least generation of new knowledge on e-business, in the emerging knowledge society, requires deeper and ever more intensive cooperation between representatives of B.U.G, this is by all means easier said than done. In this single case study, an effort has been made to introduce and analyze catalyzing of new e-business knowledge by turning research initiatives, stemming from B.U.G., from idea to knowledge. Theoretically, the exploration has utilized the Nordic school approach: A combination of network research and service management thinking.

The case organization is faced with the challenges of a typical professional service organization with regard to, in particular, (i) the dual role of key stakeholders as both suppliers and customers and (ii) electronization of its own operation. In terms of electronization, organizations and operations in the B.U.G. interface need to cope with the challenges related to ever further virtualization of their Product, Process, and –last but not least –Agent.

## ABSTRACT

In accordance with Darwin's theory about "Survival of the fittest", whoever has better adapted himself to circumstances, will remain and continue the life, and vice versa, whoever can not do that, will die. If we consider organization as a biological organism, organization is essentially a special group that tries to survive and accord in a special environment, because organization, basically, is the thing that human has made it for the survival of himself. The biggest difference between human and other existing species that has conducted him to remain, progress, and development during many years, is the ability of thinking that others have very little quotient of that or don't have at all. History has shown that many existing species that have been apparently bigger and stronger than human, like dinosaurs, have died because of their incongruity and discordance with circumstances, but human, this apparently weak species, is continuing the life with using the essential factor of thinking and making decision. Organization contains people, and the most important factor that can help it to remain, consolidate, and surpass the competitors, in this knowledge-based economy, is thinking and using the powerful mind of organization, because nowadays, after many years from Industrial Revolution, with three production factors of land, capital and labor, in the century of information and creating organized R&D, knowledge and management have become the most important factors of production, and those organizations which better use these two factors, are more successful and permanent. Thus creating and then continues improvement of knowledge management in organization, as a process that create the "mind of organization", is inevitable, and during this course, not only knowledge of the organization's members will be gather and according to the role of the synergy, total knowledge of a group is more than all their individual knowledge, but also available data and information from environment, specially from customers, would constantly enter as the fuel of organization's mind and lead to develop "the mind of organization" which the result of that is performance found on the internal and external circumstances of organization, and finally "survival of the organization as the fittest". This paper is going to consider and survey creating this principle of the survival of organization (the mind of organization) and improve that, technologically and socially.

**Keywords:** Survival of the fittest, Knowledge management, Organizational memory, Organizational mind.

## 1. INTRODUCTION

In accordance with Darwin's theory about "survival of the fittest", whoever has better adapted himself to circumstances, will remain and continue the life, and vice versa, whoever can not do that, will die. Because due to resource limitation, there has been a continues competition between different existing species for survival. As Henderson has explained in his paper (The origin of strategy), competition began with life itself. The first one-cell organization required certain resources to maintain life. When these resources were adequate, the number grew from one generation to the next. As life evolved, these organisms became a resource for more

Complex forms of life, and so on up the food chain (Henderson, 1989). Human being may be at the top of the ecological chain, but we are still members of the ecological community, and therefore, no aspect of human life is untouched by Darwin's theory of evolution-survival of the fittest (Lessem, 1998).

Darwin's theory has shown, in the best way, how some existing species have been remained and how, some of them like dinosaurs, in spite of being bigger and stronger, have died. When any pair of species competed

for some essential resource, sooner or later one displaced the other (Henderson, 1989). In the other word, the fittest survive and prosper until they displaced their competitors or outgrow their resources (Henderson, 1989). Today more than a million distinct existing species has been cataloged, each with some unique advantage in competing for the resources it requires. At any given time, thousands of species are becoming extinct and thousands more are emerging (Henderson, 1989). The species that remain in this competition, have adapted themselves to environment by different unique ways, and human, as a kind of species, since a few millions years ago has also dealt with this competition. Living in an unstable and ever-changing environment has been his challenge and has constantly struggled for remaining and survival. History shows that the challenging way of survival has not been always the same, and has been changed in different times. Considering, Alvin Toffler's segmentation, as a base of this analyses, we can find that, human was exactly living like animals in "the age of Hunting", he has been ever in chasing and escaping. He did not have any fixed place and was continuously looking for other places for better hunting. But reviewing the archeological findings shows that, human; even at those starting days, has used from his mind, although simply. After that, with

emerging “the age of agriculture” and finding the importance of land, human has been gradually depended to the land, because he found to improve and develop his life and accord with circumstances that have surrounded him, again using the key factor of MIND. Furthermore, in this age, human, depending on the land and changing from wandering to dwelling, has gradually found the importance of co-operation and so has created the first step of emerging organization as a group of a people. In the next age, creating vapor machine and then Industrial revolution, has reduced the importance of land, as the most important factor of production, and has focused on capital, and whoever had more capital could better compete and remain in the field of competition. Big factories were created in this age and started mass production and distribution of uniform products in markets. After that emerging scientific management, has increased the importance of thinking, decision making and planning and it gradually lead to another evolution in human’s life, with using the power of MIND and thinking.

Inventing computer, developed the use of data, and prepared a field in order to gathering, analyzing, storing and applying it, and then creating internet, led to a limitless and high speed communication, with low cost, and all of these events caused to a basic change over, that reduced the role of traditional production factors and increased the importance of data as the base of businesses. In new age that is called “the age of network and digital economy” or “the age of information”, nobody and no organization is not able to be successful individually. Borderless and high speed communication, link organization and their customers together, and therefore survival of each, strongly depends to another.

In this new age that philosophers called postmodernism, data, information, and knowledge are playing the biggest role in the field of competition, because according to the postmodernism, market is customer's mind, and therefore it is not possible to obtain this post modern's complicated and ever-changing market, without proper knowledge. The postmodern consumer takes on multiple, sometimes even contradictory projects, to which s/he is marginally and momentarily committed, not taking anyone too seriously. This loose of commitment is observed in all walks of life. The consumer of postmodern culture appreciates and enjoys the paradox and the playfulness, the difference and the stair that such juxtapositions provide and enable. Contemporary actions of consumers tend to indicate that they maybe more "fickle" than explainable and, therefore, predictable. Consumers frequently change their self-concepts, characters, values and etc (Firat, Dholakia, Venkatesh, 1994).

So appropriate using of data, as the base of information and knowledge, is the most critical factor of the survival of organization, and nowadays, as a matter of fact,

gathering and optimum using of data is the biggest fear and apprehension of organizations.

As mentioned, the concept of organization has been strongly changed during different ages (since the age of agriculture up to now), and today, structure of the organization is quite different.

## 2. ORGANIZATION AS A WAY TO SURVIVAL

The great social transformations in history have been essentially organizationally based. The Roman Empire, the spread of Christianity, the growth and development of Capitalism and Socialism, and the current changes taking place in both Capitalism and Socialism have been and are accomplished through organizations (Hall, 1991).

Depending on the land, and finding the importance of living together and co-operation, created the first step of emerging the organization during the age of agriculture, and this course has developed and progressed up to now. Organizations are made of people and their relationships with one another (Daft, 1998).

This paper emphasizes that emergence of the organization, is essentially an attempt to the survival of human, which is not able to compete with competitors, individually. So, organization for human is a devise to accord him better with environment. The organizations are, fundamentally, social groups attempting to adapt and survive in their particular circumstances. Thus, formal organizations, like all other social groups, are governed by one overriding goal: survival (Scott, 1987). Thus organization strives to survive and to maintaining its equilibrium. And as Morgan says, organizations are open systems that need careful management to satisfy and balance internal needs and to adapt to environmental circumstances (Morgan, 1997).

The instinct of the survival of organization is due to some people who are beneficiary in organization, because organization is the source of power, wealth, prosperity, or dignity for them, so the desire of this group of the people, for keeping organization is usual, and in fact, they can help themselves to remain and progress, by keeping and developing organization. But this organization that is made in order to better accordance and finally survival, has some continues challenges in dealing with environment and competition. Hennan and Freeman in their article “The population economy of organization” have mentioned that, there are a number of obvious limitations on the ability of organizations to adapt. That is, there are a number of processes that generate structural inertia. The stronger the pressure, the lower the organizations’ adaptive flexibility and more likely that the logic of environmental selection is appropriated. In each distinguishable environmental configuration one finds, in equilibrium, only that organizational form optimally

adapted to the demands of the environment. In the other word, selection eliminates the weakest competitors (Shafritz, Steven ott, 1992).

So organization, like the other species in contact with environment and circumstances, accord and survive, or will be force to defeat and passing life. The environment selects out optimal combinations of organization (Shafritz, Steven ott, 1992). When any pair of species competed for some essential resource, sooner or latter one displaced the other (Henderson, 1989). As long as the resources with sustain organization are finite and populations have unlimited capacity to expand, competition must ensure (Shafritz, Steven ott, 1992). If every business could grow indefinitely, the total market would grow to an infinite size on a finite earth. It has never happened. Competitors perpetually crowd each other out (Henderson, 1989). Therefore, the organization that human has created for the survival, requires finding an appropriate solution for survival, in the complicated field of competition with other organization. This competition has strongly had a jumpy growth in the new age and has dramatically increased the speed of birth and death of organization. So that nowadays few organizations experience third decade of their life.

### 3. NEW COMPETITION AGE

The history of human's life, achieving to the land, gold and oil, has been the source of power and wealth. But suddenly, it was changed and knowledge was replaced. As a mater of fact, knowledge is the foundation stone of wealth (based on Lester Thurow,, 2000).

Today, the competitiveness of the firm relies less on traditional factors (capital, land and labor) than was true in the past (Sher and Lee, 2004). Moreover, knowledge will become not just a source of competitive advantage, but also the only source of it (Drucker, 1993).

In the twenty-first century landscape, firms must compete in a complex and challenging context that is being transformed by many factors, from globalization, technological development, and increasing rapid diffusion of new technology, to the development and use of knowledge (Hitt, Keats and Marie, 1998). And as Marquardte says, We live in the global age ( Marquardte, 1999). This new landscape requiring firms to do things differently in order to survive and prosper. Specifically, they must look to new sources of competitive advantage and engage in new form of competition (Jackson, Hitt, Denisi, 2003).

Therefore, organization was essentially faced to a complicated competition, because the priority of ever-changing data, information and knowledge. Peter Drucker says that: Increasingly, successful organizations are building competitive advantage through less controlling and more learning- that is,

through continually creating and sharing new knowledge (Drucker, etal. 1997).

And we emphasize that; knowledge management is the best way to adapting circumstances and achieving competitive advantage.

Most organizations today are focused on the value of knowledge (Plessis and Boon, 2004). Knowledge management equips organization to the same thing that was the factor of human's survival, during a few million years ago, and this determinant and effective factor is "Mind".

### 4. KNOWLEDGE MANAGEMENT

As we have mentioned above, today, knowledge has been becoming the main source of the organization, moreover knowledge will become not just a source of competitive advantage, but also the only source of it (Drucker, 1993).

Current management interests are also focused on knowledge management as a major determinant of business excellence and competitive advantage (Sher and Lee, 2004).

Primarily knowledge is about the way human being has constantly evolved and learnt from his experience. It is the embodiment of this soul experience; it is about his ability to analyzing it and passing on to the next generation. Even in the corporate context the sentiments may not change (Raman, 2003).

Organization, as a group of people, is consist of different individual minds and we constantly believe that an organization that wants to remain and survive in this knowledge-based environment, must equip himself to an integrated MIND. Knowledge management, as a powerful competitive weapon (Chang, 2004), is exactly the same thing that can lead to emerging a sustained competitive advantage in the complicated field of competition, with elaborate configuring of organization's MIND. In the other word, knowledge management is the key distinguishing factor of successful firms (Lee and Cho, 2003), and has also been described for its possible role in creating sustained competitive advantage for organization (Grant, 1996; Johansson and Olsen, 2003; and Lad and Wilson, 1994). Likewise, firms with high knowledge management capability in a key area should be able to respond very quickly to strategic moves by competitors (Gold etal, 2001), in order to gain competitive advantage over competitors (Grossman and Packer, 1998).

Knowledge management systems must enable knowledge to flow efficiently in order to enhance productivity, quality, innovation and business excellence (Sher and Lee, 2004). Also knowledge management reduces the operating costs of a firm and

creates added value to customers by significantly increasing product quality (Ofek and Sarvary, 2001). When the knowledge assets of the firm are exploited, the firm sees enhanced dynamic capabilities and increased business value. And dynamic capabilities refer to an organization's way of responding in a rapidly changing environment (Helfat, 1997).

Many researchers have defined knowledge management from various perspectives. For example, Raman explains that knowledge management is the way to keep knowledge growing through sharing (Raman, 2003).

In the other definition, knowledge management has been defined as an effort to not only explicit factual information, but also the tacit information, a knowledge that exist in an organization, usually in the minds of employees in order to advance the organization's mission (Broadbent, 1998; Davenport and Prusak, 1998). In the other word, knowledge management involves blending a company's internal and external information and turning it in to actionable knowledge via a technology platform (Dimattia, 1997).

This paper defines knowledge management as the process of creating appropriate solutions in accordance with circumstances, through social systems of organization that supported by technical systems. In fact, organization creates the process of learning, with using knowledge management. Learning has been defined as the process of acquiring new information (Braun, 1998). So organization, with using this process, is continuously exchanging data to information and knowledge, and finally achieving to a collective knowledge. From this perspective, learning is never complete, as new data, new events, or new contexts create opportunities for additional improvement, insight and innovation (Lessem, 1998). Continuing this process of learning, lead to a collective memory. By definition, memory refers to the persistence of learning in a state that can be revealed at a later time (Braun, 1998). A form of collective memory is organizational memory (Paul, Haseman and Ramamurthy, 2004).

Many researchers have defined organizational memory from various perspectives. For example, Stein and Zwass, defined organization memory as means by which knowledge from the past is brought to bear on present activities, thus resulting in higher or lower levels of organizational competitiveness (Stein and Zwass, 1995). And Chang, Cho and Lee have described it as a computer supported human interactive mechanism to store and facilitate knowledge for enhancing organizational effectiveness (Chang, Choi and Lee, 2004). So, organizational memory also can help organization to respond appropriately to environment with keeping and directing knowledge, but knowledge management is not only limited to acquiring, storing and exchanging the information, but also require to interpretate and organize information from various

perspectives. So, what ever that organization needs for survival, is more than memory, and this missing link of organization is MIND. Processing data can be performed by machine, but only the human mind can process knowledge or even information (Shera, 1983). Mind is the ability to be aware of things and to think and feel, or in the other word, mind is the source of one's thoughts and feelings. And Organizational mind in this paper has been described as the ability of team thinking and analyzing internal and external environment of organization, that enable the organization to feel properly and respond effectively to ever-changing and unstable circumstances better than competitors. If we think so about the organization, every aspect of organizational functioning depends on information processing of one form or another. In our view, organizational mind relies upon the interaction between individuals and technologies, so that it is not imitable because of the unique complex of individual and their interactions in each organization. In fact, in any competitive landscape it has been argued that intangible resources are more likely to produce a competitive advantage because they often are truly rare and can be more difficult for competitors to imitate (Jackson, Hitt, Denisi, 2003).

At this regard, systems (organizations) must have the capacity to sense, monitor, and scan significant aspects of their environment. They must be able to relate this information to the operating norms that guide system behavior. They must be able to detect significant deviations from these norms and, must be able to initiate corrective action when discrepancies are detected. If these four conditions are satisfied, a continuous process of information exchange is created between system and its environment, allowing the system to monitor changes and initiate appropriate response (Morgan, 1997).

## 5. CONCLUSION

This paper has been tried, with considering Darwin's theory regarding to survival of the fittest and dieing those existing species that are not able to adapt themselves to circumstance, has tried to show that human as a kind of existing species that has been placed at the highest point of biological organism chain, is not an exception, and has variously attempted to be accord with circumstances, all over his life, during different ages. But the thing that has helped him during these long periods, was been distinguishing factor of MIND.

With referring to Tofler's segmentation about the route of civilization, we have mentioned, how human can adapt himself with circumstances in each period, and with a comprehensive discussion of new age that has been called the age of information and digital, we have attempted to state unique specifications of the new age.

In the other section of this paper we have described the course of emerging and transformation of organization as a device that human has created in order to the survival. Knowledge management in this knowledge-driven age is the only one thing that can lead to a unique competitive advantage with conducting some interaction between individuals, technologies and methods. Therefore organizational mind is the missing link of organization, and the key distinguishing factor of survival, in new competition age. And finally, as Winston Churchill has truthfully said several years ago "the empires of the future are empire of the mind".

# Study on the Cultivation of Core Competence Based on Tacit Knowledge

Juanru Wang, Songzheng Zhao, Jin Yang

School of Management, Northwestern Polytechnical University, Xi'an 710072, China  
wjuanru@163.com, jinyang1973@163.com, zhaosongzheng@263.net

## ABSTRACT

This paper discusses the meaning and characteristics of core competence, analyzes the relationships between tacit knowledge and core competence, and gets the conclusion that tacit knowledge is the basis for the development of core competence. At last methods that can transfer tacit knowledge into core competence are discussed.

**Keywords :** Core Competence, Tacit Knowledge, Cultivation

## 1. INTRODUCTION

In the new business environment, characterized by an increased turbulence and complexity, an organization's capacity to create and sustain competitive advantages lies in what it knows, not what it owns. Therefore, knowledge, especially tacit knowledge, is increasingly considered an important source of sustainable competitive advantage. Thus, it is necessary for tacit knowledge to be converted into competence. So it is important and meaningful to study the cultivation on how to transfer tacit knowledge into core competence.

## 2. THE CONCEPT OF CORE COMPETENCE

C.K. Prahalad and Garry Hamel mentioned core competence in the paper of enterprise's core competence published in the Harvard Management comment. They think enterprise's core competence is accumulated knowledge in the organization, especially the knowledge that coordinates different product skills and combines with many technological schools<sup>[1][2]</sup>. It is a set of special skills and technologies that can provide additional value to customers. Dorothy Leonard-Barton defined enterprise's core competence as knowledge system identifying and offering advantages. It consists of four elements, knowledge base and skill, technical system, management system, and value system. Thus, core competence is a knowledge system embedded by enterprise's tacit knowledge, and must be accumulated by enterprise<sup>[3]</sup>. It is valuable and unique for an enterprise, which is difficult to be imitated and acquired by competitors.

From the concept of core competence, its characteristics can be summarized: 1) It is unique, which mainly manifests in tacit knowledge that is exclusive for enterprise and unique for whole industry<sup>[4]</sup>. 2) It is customer-oriented value, that is, it can make enterprise provide more value to customers. 3) It is dynamic. Knowledge structure, storage, and capability of enterprise will change with time and external environment, so core competence must be continuously updated. 4) It is synthetic. Core competence combines with many kinds of knowledge and technologies, and it

touches every aspects of enterprise. 5) It is inimitable. Once it forms, core competence will become the unique competitive advantages of enterprise, and other enterprises can not acquire this capability in short-term. 6) It has path-dependence. The formation of core competence depends on synthesizing existing knowledge storage, knowledge structure, and enterprise's absorptive capability, which all have stronger path-dependence.

## 3. RELATIONSHIPS BETWEEN TACIT KNOWLEDGE AND CORE COMPETENCE

Knowledge can be classified as tacit knowledge and explicit knowledge from the point of view epistemological. Explicit knowledge is defined as encoded knowledge, which can be expressed by words and figures, so it is easy to communicate and imitate by competitors. Tacit knowledge, however, is neither easily imitated nor clearly understood outside the enterprise, i.e. skills and practical knowledge. It can be classified into four types: scientific, conscious, communal, and automatic<sup>[5]</sup>. Scientific knowledge is social, abstract, and highly mobile. In this case, appropriability is an important issue. Alternatively, appropriability is less of a concern with automatic (individual-focused and taken for granted) or conscious (individual-focused and explicit) knowledge. To use automatic or conscious knowledge effectively, it must be integrated with the enterprise's complementary assets. Moral hazard is of concern if an individual or teams holds the tacit knowledge. Communal knowledge, on the other hand, is often interrelated with the culture. Four types of tacit knowledge are all enterprise specific and often can not be written or encoded. They also have an immutable, hard-to-decipher quality that can not be easily transmitted to others, and often represent a shared experience among organization members. They not only can be transferable within the enterprises relatively and widely, but also can be very difficult for other enterprises to copy or develop. So tacit knowledge is the basic resources for cultivating enterprise's core competencies.

The difficulty of expressing, codifying, and transmitting

tacit knowledge makes it easier for an enterprise to protect than that of explicit knowledge. So acquiring another enterprise's tacit knowledge requires hiring its people. But a single expert is unlikely to possess all of the knowledge needed to reestablish the desired organization in the new enterprise, since the knowledge underlying core competence is held by a number of people whose individual knowledge is incomplete. Moreover, tacit knowledge may only be effective when embedded in a particular enterprise culture, structure, a set of processes and routines. The difficulty of copying tacit knowledge enables tacit knowledge to be the basis of an inimitable competitive advantage, and usually, tacit knowledge can be converted into core competence only through transferring<sup>[6]</sup>, as show in Figure 1. For

example, the study of American government indicates the cost of each auto made in Japan is less 2200 \$ than that in America, because Japanese auto manufacturing uses advanced inventory control, personnel management, and quality management. So many large-scaled enterprises in American, such as, Ford, GE, and Chrysler, put many resources to mine and study the product knowledge of Japanese auto. Although great deals of data were collected, many consultants were invited, and relative books were written, American enterprises did not acquire competitive advantages like Japanese enterprise. Obviously, the successful advantage of Japanese enterprise based tacit knowledge is difficult to be imitated by others.

**Figure 1 Relationship between tacit knowledge and core competence**

#### **4. APPROACHES OF CULTIVATING CORE COMPETENCE**

Because tacit knowledge is much difficult for competitors to imitate than that of explicit knowledge, the ability to capture and transfer tacit knowledge is the key for cultivating competitive advantage. Following is some methods to spread tacit knowledge within an enterprise so that it can be transferred core competence.

##### **4.1 Learning by Apprenticeship**

Learning is often the route by which many enterprises can accelerate development of a knowledge base. Explicit knowledge can be readily transmitted and learned by others through documents. Tacit knowledge, on the other hand, is often captured in metaphors that outsiders can not easily decode, so it often can only be learned by apprenticeship or learning-by-doing.

Learning by apprenticeship is a good method to translate tacit knowledge, it helps the enterprise understand and define complex problems and, therefore, solve them in unique way<sup>[7]</sup>. Several things can be done to promote learning by apprenticeship in companies. First, managers can be taught how to coach. Second, their performance measures can include their efforts to train subordinates. Third, structured group discussions can be used to serve many of the educational functions of training with far lower costs in terms of human resources than that of one-to-one mentoring. For

example, in enterprise, R&D department hold regular conferences in which difficult problems are shared and discussed. Each participant has the opportunity to assess how the problems can be dealt with, and to hear the professional members of the department how to deal with the problems.

##### **4.2 Making effective communication**

Tacit knowledge can be transferred through personnel communication. The effective communication mechanisms in enterprise are net and teamwork. In enterprise, people can work through net informally with others having similar interests, or form communities of practice, to discuss their experiences, gather the ideas of others, and receive feedback on their own ideas. Communities of practice are groups of people sharing an interest in an issue who meet periodically to discuss problems, brainstorm, and share knowledge<sup>[8]</sup>. Meetings may be in person, or virtual. Optimally, information is stored in a database for future use. Companies can significantly facilitate the transmission and spread of tacit knowledge by supporting such net: providing the communications resources needed, giving people time to use net, and formally recognizing the community and its best contributors. When supported by the enterprise, communities of practice hold considerable potential for developing and spreading the expertise of an enterprise.

A common problem in teamwork is that they tend to deal with explicit knowledge, rather than tacit

knowledge. Therefore, companies need to arrange case discussions and other opportunities for individuals to exercise judgment and compare their decisions with those of experts. Working in teams can also present a platform for sharing tacit knowledge. When working in teams, people have an opportunity to observe how others conceptualize situations, approach problems, generate and evaluate solutions. The more people work together, and the more time they spend on socializing and talking about their experiences and sharing anecdotes, the more tacit knowledge they will share.

#### 4.3 Fostering Dynamic Routines

Another approach of cultivation core competences is instilling dynamic routines within the organization. Organization's dynamic routines fostering differentiated technological capabilities represented a critical enterprise-specific resource. Broadly speaking, dynamic routines refer to the organization's particular approaches that provide the basis for understanding and transferring tacit knowledge<sup>[5]</sup>. Routines are important for influencing the context of corporate strategy. Enterprise-specific routines established within the organization are based on the collective consciousness among its members. The complexity and dynamics of the organization's routines play a critical role in transferring tacit knowledge in the enterprise.

Moreover, numerous organizational routines enable the enterprise to envision and to develop combinations of different tacit knowledge that allow for more competitive. Combinations of routines allow for enterprise-specific combinations of tacit knowledge that are applicable to numerous products and processes. As a result, the risk of entering new markets is reduced. Accumulation of dynamic routines generates scaled economic benefits in learning. Dynamic organizational routines reflect the richness of the enterprise's learning patterns, as well as its potential for developing idiosyncratic know-how. And enterprise's ability to absorb new knowledge and to create new knowledge is related to the diversity of its learning base. Particularly in uncertain environments, the promotion of several organization routines enables the enterprise to absorb different types of knowledge, especially tacit knowledge to develop new skills faster. Therefore, application of dynamic routines increases causal ambiguity for competitors and increases the attractiveness of entering new markets.

#### 5. CONCLUSIONS

Tacit knowledge is the basis for cultivation competitive advantages. It can be spread within an enterprise, but it is very difficult for other enterprises to imitate. The predominant way that enterprises can facilitate the spread of tacit knowledge within themselves is by giving employees the chance to work with expertise. In addition, making effective communication and fostering dynamic routines also provide employees with the opportunity to develop their own tacit knowledge and communicate with other. The more tacit knowledge are communicated and transferred in enterprise, the easier core competence develops.

# The Relationship between Knowledge Sharing Behavior and the Effectiveness of Information Systems Strategic Planning (ISSP): An Empirical Study in Taiwan

**Jungchi Pai**

Department of Business Administration, Takming College, Taipei, Taiwan, China

E-mail: rogerpai@mail.takming.edu.tw

## ABSTRACT

“Improving information systems strategic planning” remains among one of top ten issues facing IS/IT executives and corporate general managers. As e-business strategies have received growing attention from enterprises, information systems strategic planning (ISSP) is now considered critical in developing a successful e-strategy. However, numerous researchers have examined the relationship between various factors and the effectiveness of information systems strategic planning, the effects of knowledge sharing behavior on the effectiveness of information systems strategic planning still have little been examined. The main purpose of this study is to examine the relationships between knowledge sharing and the effectiveness of information systems strategic planning. Furthermore, we explore the factors influencing knowledge sharing behavior among stakeholders in the ISSP process. Data were collected by a questionnaire survey sent to the IS directors of 805 large companies in Taiwan. Survey results indicate that knowledge sharing behavior influence of the effectiveness of information systems strategic planning. The implications of this finding for practice and future research are also examined herein.

**Keywords:** Information systems strategic planning (ISSP), e-business strategy, knowledge sharing

## 1. INTRODUCTION

ISSP has been identified as essential in integrating IT into an organization to increase a firm's strategic competitive advantage (Huysman *et al.*, 1994; Lederer and Sethi, 1996; Mentzas, 1997; Levy *et al.*, 1999). With the recent growth in interest in e-business and e-commerce, information systems strategic planning (ISSP) is widely viewed as an effective means of implementing a successful e-strategy (Lee and Pai, 2003). As the information technology environments and information systems applications are growing complex, the ISSP process that cannot be only handled by information systems professionals. A strategic IS/IT planning team which comprised of business managers, IS managers, user managers and unit managers can help the organization to achieve consensus through effective communication and interaction and achieve their information systems decision-making goals. Since these stakeholder groups have specific different explicit knowledge and implicit knowledge, how to effectively manage the knowledge and enhance knowledge sharing among stakeholders to be one of the most important issues in the ISSP process. Four types of knowledge must be integrated in the ISSP process, including business knowledge, organization-specific knowledge, IT/IS knowledge and management competencies. Furthermore, much research has been conducted in the area of ISSP in recent years. However, the relationship between knowledge sharing behavior among stakeholders and information systems strategic planning has been seldom examined empirically.

The main purpose of this study is to examine the

relationship between knowledge sharing behavior and the effectiveness of information systems strategic planning. Moreover, this study also examine the factors affecting the knowledge sharing among stakeholders in the IS strategic planning process. The hypothesized relationships were empirically tested using a field survey of Taiwan's large firms.

## 2. THEORETICAL BACKGROUND

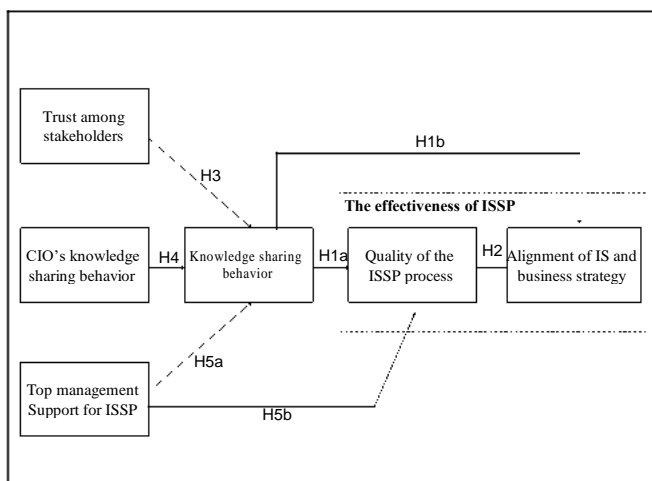

Information systems strategic planning has been described as a managerial and interactive learning process for integrating information systems considerations into the corporate planning process, aligning the application of information systems to business goals, developing detailed information systems plans and determining information requirements to achieve business objectives (Earl, 1989; Galliers, 1991; Teo and King, 1997; Cunningham, 2001). A growing amount of empirical work that has been conducted examining the relationship between ISSP and organizational context. However, there has been little empirical research that investigates the effects of knowledge sharing behavior among stakeholders on the effectiveness of information systems strategic planning. A lot of various types of knowledge must be integrated in the ISSP process such as IT/IS knowledge and business knowledge. Such knowledge may be “tacit” or “explicit” (Nonaka, 1994). Tacit knowledge resides in the minds of different stakeholders and has not been documented in a structured form, but such knowledge is important to the planning process. For example, the CIO possesses IT knowledge and experience, the CFO possesses organization-specific knowledge concerning finance and accounting, and CEO possesses business executive

knowledge and experience. These senior executives accumulate their IS/IT strategic planning knowledge over time through interactive learning processes. Different varieties of tacit knowledge exist in the minds of different interest groups, all with their own expertise, positions, perceptions, and powers. Consequently, these differences may result in difficulties in cooperation, and may affect the effectiveness of ISSP. To achieve the consistently planning objectives, “knowledge sharing” is necessary to the ISSP process.

### 3. RESEARCH MODEL AND HYPOTHESES

Based on the literature reviews, the research model (Figure 1) was first built, using knowledge management, behavioral, and IS planning theory as reference disciplines. The research model has three major parts, including knowledge sharing behavior, the factors affecting the knowledge sharing behavior and the effectiveness of information systems strategic planning.

**Figure 1 Research model**

Each stakeholder group in the IS/IT strategic planning process is perceived to have specific backgrounds and expertise (Earl, 1993). Consequently, knowledge sharing among different groups not only generates creative ideas but also reduces conflict (Hackney and Little, 1999). Furthermore, a general consensus and acceptable results for all group members can be reached, ensuring that all members of an organization participate effectively in IS/IT strategic planning. Moreover, effective knowledge sharing has been presented in the literature as one means for improving innovations and performance. Connelly and Kelloway (2003) argued that knowledge sharing is emerging as an important concept and is often cited as an antecedent of innovation. Huysman *et al.* (1994) indicated that ISSP is an innovative process. Knowledge sharing behavior among interested groups could help an organization to enhance its managerial capability, change organizational structures and reach a consensus of IS use and management (Kearns and Lederer, 2000). It is generally argued that these knowledge sharing influence creative IS/IT planning in organizations (Hackney and Little,

1999; Salmela *et al.*, 2000). Significantly, a successful IS/IT strategic planning process should consider knowledge sharing behavior among different stakeholder groups. Thus, we hypothesized:

**H1a:** Knowledge sharing behavior significantly and positively affects the quality of the ISSP process.

**H1b:** Knowledge sharing behavior significantly and positively affects the alignment of IS and business strategy.

As technology continues to evolve, grow and become increasingly complex, the information systems strategic planning process becomes complex and difficult to handle. Alignment of the information systems strategy and business strategy is generally considered the key to successful information systems strategic planning (Henderson and Venkatraman, 1993; Earl, 1993; Segars and Grover, 1999). Notably, a comprehensive information systems strategic planning process produces a higher quality information system plan that ensures better plan implementation, and in turn improves the alignment of the information systems and business strategies (Lederer and Salmela, 1996; Pun and Lee, 2000). Thus, we hypothesized:

**H2:** The quality of the process significantly and positively affects the alignment of IS and business strategy.

“Trust” has been as a key factor for social exchange process (Blau, 1964; Munch, 1993). There is no any contract or astriction exist in knowledge sharing among stakeholders in the planning process, therefore; trust among stakeholders is key to successful knowledge sharing. The trust will be established if the benefits can be get with each other in exchange process, then it will facilitate the knowledge sharing among stakeholders. It is likely that different stakeholders will have different reasons for wanting an ISP study to take place (Galliers, 1991; Ruohonen, 1991). CIOs being mainly concerned with the implementation of strategy, while user managers are not satisfied with the ISSP process perhaps because they seek more influence and general managers emphasize SISP method issues because they find strategy-making far from easy (Earl, 1990; Ruohonen, 1991). The goals and consensus will not be achieved if the trust among stakeholder groups is not existed. Thus, we hypothesized:

**H3:** Trust among stakeholders significantly and positively affects knowledge sharing behavior among stakeholders.

The CIO has been described as the corporate officer who truly understands the interconnection of the information flow to the business (Benjamin *et al.*, 1985; Stephens *et al.*, 1992). In some firms, IT expertise and knowledge exist in the minds of a few senior IS managers and are not communicated to others in the

firms. Top managers or user managers do not know enough about the strategic use of IT and are not familiar with IS/IT strategy issues and should learn more about IS/IT issues. Better CIO's knowledge sharing not only facilitates the integration of different views from stakeholder groups, but also facilitate these stakeholders more cooperative. From the above, we can understand that CIO's knowledge sharing can promote organizational members to understand what IS and IT can do for the company and be willing to take advantage of IS/IT opportunities when they arise, and then further promote the intention of sharing knowledge for other stakeholders. Thus, we hypothesized:

**H4:** *CIO's knowledge sharing behavior significantly and positively affects knowledge sharing behavior among stakeholders in the planning process.*

Top management support is considered a prerequisite for every successful IS discipline. Beatty *et al.* (2001) indicated that as in all innovative endeavors in the organization, top management support is extremely important. Earl (1993) also indicated that top management support is necessary for a successful ISSP since top management is responsible for a wide range of organizational processes and activities. Top management must not only realize that IT is not a panacea for all organizational problems, but also should be viewed IT as a resource to be deployed judiciously to support or influence business strategies in terms of streamlining business operations, reengineering business processes, forging electronic links with suppliers and customers, etc (Teo and Ang, 1999). Since top management support of the importance of IT/IS is a prerequisite for securing the commitment and involvement of top management. Thus, we hypothesized:

**H5a:** *Top management support for ISSP significantly and positively affects knowledge sharing behavior among stakeholders.*

**H5b:** *Top management support for ISSP significantly and positively affects the quality of the ISSP process.*

## 4. RESEARCH METHOD

### 4.1. Sample and Data collection

The sample adopted was the Corporate 1000 (the 1000 largest manufacturing and service companies in Taiwan), published by Commonwealth Magazine in 2003. To ensure the questionnaire was received by IS directors and to encourage a better response rate, two research assistants spent about three weeks telephoning these 1000 companies. Only those companies with formal IS departments qualified as participants. Such firms were then asked to provide the name of the IS director to whom a questionnaire should be mailed. Using this procedure, a list of 805 firms from various industries was compiled. Questionnaires were mailed to the 805 IS

directors. A cover letter explaining the objective of the study and a stamped return envelope were enclosed. Follow-up letters were sent about three weeks after the initial mailings. The decision to use the IS executives as informants herein is supported by previous research conducted by Segars and Grover (1998) and Gottschalk (1999).

### 4.2. Measure development

The research variables were defined as briefly as possible with multiple indicator items. From the literature on social exchange, knowledge management and IS management theory, we adopted the variables that have been used and validated by other researchers. All variables were measured with multiple items on a five point Likert-type scale, ranging from (5) strongly agree to (1) strongly disagree.

### 4.3. Pre-testing

The questionnaire was refined through two rounds of rigorous pre-testing. The pre-testing process focused on instrument clarity, question wording and validity. During the first round of pre-testing, five MIS doctoral students and three MIS professors were interviewed. During the second round of pre-testing, a revised questionnaire was pre-tested by three senior IS executives from manufacturing, banking and retail industries.

## 5. RESULTS

### 5.1. Sample characteristics

Of the 805 questionnaires distributed, 151 completed usable questionnaires were returned, for a response rate of 19%. The respondents are all information systems executives, and had worked in the information systems field for an average of 15.3 years. The respondents came from diverse industries, with manufacturing representing 17.1%, banking/finance/insurance 25.8%, computers/communication 23.8%, and the remainder coming from various other backgrounds such as real estate, construction, health and transportation. This result implies that ISSP is carried out in a wide variety firms.

### 5.2. Reliability and validity of research variables

Internal consistency (Cronbach's alpha) was calculated in order to assess the reliability of all constructs. The results in our study indicate that all the constructs are greater than 0.7. The constructs are therefore considered to exhibit adequate reliability (Nunnally, 1978). The content validity of questionnaire was established through a series of personal interviews with multiple IS executives. Construct validity was determined using factor analysis of the items comprising each construct. Principal component factor analysis with VARIMAX (orthogonal) rotation was used to determine if all

items measuring a construct cluster together and selection of factors with eigenvalues greater than one. Items with loadings of less than 0.5 on any factor were dropped from subsequent analyses. The results of the factor analyses for independent variables confirm that each construct is distinct from other constructs.

### 5.3. Hypothesis testing

The hypothesized relationships depicted in research model were testing using multiple regression analysis. No apparent colinearity problem among independent variable exists, as the variance inflation factors (VIF) for all independent variables are smaller than 3 (Neter *et al.*, 1997).

As predicted by H1a, knowledge sharing behavior significantly and positively affects the quality of the ISSP process ( $\beta=0.22$ ,  $p<0.01$ ). Moreover, knowledge sharing behavior significantly affects the alignment of IS and business strategy ( $\beta=0.29$ ,  $p<0.001$ ), supporting H1b. Furthermore, the quality of the ISSP process has a significant positive effect on the alignment of IS and business strategy. Thus, H2 is supported. As proposed H3, trust among stakeholders shows a positive relationship with knowledge sharing behavior ( $\beta=0.31$ ,  $p<0.001$ ). Consequently, H3 is supported. Moreover, H4 is supported since the CIO's knowledge sharing behavior has a significant positive effect on knowledge sharing behavior ( $\beta=0.17$ ,  $p<0.05$ ). Finally, top management support for ISSP has a strong significant effect on knowledge sharing behavior and the quality of the ISSP process, so H5a ( $\beta=0.43$ ,  $p<0.001$ ) and H5b ( $\beta=0.37$ ,  $p<0.01$ ) are supported.

## 6. DISCUSSION

Results of this study demonstrate that knowledge sharing behavior significantly affects the quality of the ISSP process (H1a) as well as alignment of IS and business strategy (H1b), implying that as ISSP become more important to organizations, effective knowledge sharing among stakeholders is required. ISSP requires views from a range of stakeholders and the knowledge sharing of these stakeholders to achieve common goals. Furthermore, different managerial groups should participate in planning, increasing mutual understanding and sharing the use of the information (Lederer and Mendelow, 1988; Reponen, 1993). ISSP is an iterative, ongoing and complex process that cannot be handled by just one person in an organization (Auer and Reponen, 1997). An effective knowledge sharing mechanisms can help planning participants share their implicit and tacit knowledge, and to achieve their decision-making goals. According to a recent study based on resource-based theory conducted by Kearns and Lederer (2003), the results showed that knowledge sharing processes of strategic IT alignment influence two sets of outcomes (including business plan reflecting the IT plan as well as

IT plan reflecting the business plan) and then yield competitive advantage for organizations. The findings of this study suggest that both practitioners and researchers should direct significant effort understanding shared knowledge, the factor which had the strongest influence on the quality of the ISSP process and alignment of business and IS strategies.

Trust among stakeholders was originally hypothesized to be related to knowledge sharing behavior. The results provide substantial evidence of this hypothesis, implying that mutual trust among stakeholders is essential to successful teamwork. Trust is a major component of the cooperative competency that is established in organizational theory (Sivadas and Dwyer, 2000). It has defined as the confidence a department (or stakeholder) has in the ability and motivation of the other department (or other stakeholders) to produce positive outcome for the organizations. The key objective of ISSP is to establish a strategic IS plan that is satisfactory to different groups. However, ISSP is so complex that it cannot be accomplished if the organization lacks mutual-trust among stakeholders. During planning, stakeholder groups are mutually interdependent and each has specific tasks and responsibilities. Accordingly, organizations require mutual-trust to achieve planning goals and ensure that the IS plan is implemented as expected.

CIO's knowledge sharing behavior was found to be positively and significantly associated with the knowledge sharing behavior among stakeholders (H4). Similar findings have proposed by previous researchers such as Stephens *et al.* (1992) suggest that the CIO operates as an executive rather than a functional manager. They further indicated that CIO is an active participant in strategy planning and acts as a bridge between the information group, the functional areas, and external entities. According to Teo and Ang (2001), senior information systems executives fail to win top management support because they talk in technical jargon that top management do not understand. IS executives should bear in mind that top management are more interested in knowing how IT can help leverage the company's competitive position. As a result, we can understand that CIO may focus on strategic issues rather than technical issues while sharing his IT knowledge with CEO.

Top management support for ISSP was found to positively and significantly affect the knowledge sharing among stakeholders and the quality of the ISSP process. The result was consistent with early findings of similar studies that indicated that top management is found to be important facilitator for effective IS strategic planning (Premkumar and King, 1992).

The results indicate that the casual relationship exist between the quality of the ISSP process and alignment of IS and business strategies. That is, the alignment

between IS strategy and business strategy improves with the quality of the ISSP process. The results are consistent with reports in the literatures (King, 1988; Premkumar and King, 1994; Lederer and Salmela, 1996). Since the quality of the ISSP process is a prerequisite of planning alignment, the factors affecting the quality of the ISSP process must be understood when undertaking ISSP. This study hypothesized the knowledge sharing behavior positively and significantly affects the quality of the ISSP process, the empirical evidence support this hypothesis.

## 7. CONCLUSIONS

To achieve the consistently planning objectives, knowledge sharing is necessary to IS/IT strategic planning. One important question is that of how knowledge sharing can be achieved in the IS/IT strategic planning process. According to Nambisan *et al.* (1999), numerous organizational mechanisms exist that can enhance knowledge sharing and transfer, including IT steering committee and strategic IS/IT team. Based on Mentzas (1997), this study suggested that four different types of strategic IS/IT teams should be specified when implementing an IS strategy, namely, functional, technical, guidance and coordination teams. Additionally, information technology can play a central role in knowledge sharing process (Hislop, 2002). In the ISSP process, some IT applications may help planning participants to share and transfer their knowledge. Such applications may include groupware, intranet and web-based applications (Bai and Lee, 2003). Furthermore, the cross-participation (CEO participate in IT planning and CIO participate in business planning) is necessary to elucidate the tacit knowledge that often remains undiscovered and is not shared in the organizational knowledge base (Johannessen *et al.*, 2001) and to make this personal knowledge explicit at the organizational level (Kearns and Lederer, 2003).

This study has the following limitations: First, the subjects of this study are IS executives in Taiwan. Consequently, cultural differences may exist between Taiwan's situation and other countries. Second, this study use CIO as an informant. The CEO was not used as an informant in this study **because** of the CEO possibly not being familiar with some of the detailed characteristics of information systems strategic planning examined in our research variables. The effectiveness of ISSP in this study includes technology-led measure items, thus making it difficult for CEOs to respond knowledgeably. Previously, most respondents in ISSP empirical research were CIOs (Premkumar and King, 1994; Segars and Grover, 1999; Gottschalk, 1999). In contrast, IS executives are more likely to be aware of and knowledgeable about the research variables, especially the measurement of ISSP success. Third, the sampling population included large businesses in Taiwan. However, the IS maturity of large organizations is greater than that of SMEs, meaning that the results herein may have

limited generalizability for SMEs.

Future research should focus on four areas, as motivated by limitations of the present study. First, future researchers might attempt to understand the conclusions about the knowledge sharing factors of this research through structured interviews in case studies of IS directors from ongoing or recently completed ISSP projects. Researchers might ask subjects why these factors are associated with the effectiveness of ISSP. Second, future researchers could consider more general factors that affecting knowledge sharing behavior such as task coordination, rewards and political behavior. Third, the subjects of this study are IS executives in Taiwan. Cultural differences may exist between Taiwan and other countries. Future research should be similarly carried out in other countries.

## ACKNOWLEDGMENTS

The authors would like to thank the National Science Council of Taiwan, China for financially supporting this research under Contract No. NSC92-2416-H-147-002.

## ABSTRACT

This paper applies evolutionary view to investigate the enterprise tech-innovation process and study the uncertainty of the routine, net environment and the innovational technique. In the end the measurement of risk is described as the uncertainty characteristic then induced the coherent characteristic between the risk and the uncertainty, which can be applied in the theory on the innovation management.

**Keywords :** information flow; uncertainty; net-environment

## 1. INTRODUCTION

It is not an isolated event that enterprise's technology is achieved newly under the network environment. It exists as the result of the course. During the process of its organization realizing, uncertainty is the most essential characteristic of technological innovation. This text believe that its ultimate behavior can be reflected by the deviation of the achieved degree of the strategic destination at the given time point.

Among the scholars, there are lots of viewpoints that connect each other and set against to the uncertainty roots in the tech-innovation. Theory of Impacting perspective [Markus, L. & Robey, 1988; Thompson, 1967]<sup>[1] [2]</sup> believed that the quantity of technological information and the technological means constitute the uncertain source; And believed that, the exquisiteness not only influences the professional technological innovation course, but could promote the organization ability of the technological innovation during the course of enterprises tech-innovation with the formers' promotion. Theory of selective perspective and theory of conflict [Orlikowski and Yates, 1994]<sup>[3]</sup> believed that technology is the product of human's interaction, design and allocation. All the communication techniques which applied by the organization results from the complex social interaction, among which the main conflict s come from the individual and organizational framework<sup>[4]</sup>.

In any case, this paper thinks the technological innovation as a coordination and uncertain course. We regard the incomplete knowledge and bounded rationality as the characteristic in the technological innovation course. Especially, because the object that tackles is incomplete restructure of the existing information, knowledge, technology, etc., during which the new knowledge must be created. Many domestic and foreign scholars have strong interests in the risk measurement of the enterprise's innovation course. Among the numerous viewpoints, a agreement is

achieved that risk founds on the goal-structure, which an aprioristic measurement index system is demanded while the index system couldn't be constructed by the economists and management experts at present<sup>[6] [7] [8]</sup>.

## 2. THE ROOTS OF THE UNCERTAINTY IN THE ENTERPRISE TECH-INNOVATION PROCESS UNDER THE NET ENVIRONMENT

The concept of the uncertainty in the enterprise tech-innovation process refers to the total deviation of the current conditions with included in each of the decision points of the enterprise tech-innovation process and the choices with difference effected on enterprise by the very points. The result it directly caused is the total difference of the tech-innovation activity and the final decision's difference (relative).

Any course of the enterprise tech-innovation under the net-environment has involved three most essential objects: enterprise's structure, net-environment and innovation technology as for an object. The tech-innovation process is not only the development of the technology but also the changes of the social productivities' structure.

### 2.1 The structure of enterprise

The structure of enterprise is an economy system with a unique becoming history. While the enterprise engaged in tech-innovation activity, it must have the resources of two respects at least: 1, the information resources precipitated in past history; and 2, the convention that forms by searching in its history. The information resources of enterprises have the characteristics of two respects: 1, the size of its information amount; 2, the quality that information has (accuracy). According to information theory, the amount of information could be described according to its entropy, and according to Qiu Yuanhua's viewpoint: the quality that information has could be described by its complex entropy. In a word, the amount of information resource and its accuracies at

the time  $t$  could be described by a complex entropy  $H(x_t)$  <sup>[9]</sup>.

$$\text{Definition: } H(x_t) = \sum_{k=1}^n |P(x_t) \ln P(x_t)| \\ = \sum_{k=1}^n |P(x_t) [\ln P(x_t) + i \arg \ln P(x_t)]|, \quad (2-1)$$

In which:  $x \in C$ . So  $H(x_t)$  indicates the above mentioned two respects of the information. It postulates the vector of information input in the course of the enterprise tech-innovation is  $X_t^{n_1} = (x_{t1}, x_{t2}, \dots, x_{tn_1})$

The output of a given information vector transacted by the enterprise's convention is:

$X_o^{n_2} = (x_{o1}, x_{o2}, \dots, x_{on_2})$ . The transformation for a given input information vector in the course of the

enterprise tech-innovation is  $W_t = \bigcup_{k=1}^{n_3} w_{tk}$ , which means that at the time  $t$ , the transformation which is suitable to any input information is selected in the ensemble:  $W_t = \bigcup_{k=1}^{n_3} w_{tk}$ . The probability for a given

$w_{tk}$  to transform the information is  $P_{tk}$ . Under the above-mentioned condition, the equation:  $X_o^{n_2} = X_t^{n_1} W_{tk}$  exists, in which  $k \in (1, 2, \dots, n_3)$ , i.e., when the input information vector

is  $x_{it}^{n_1}$ , enterprise chooses  $w_{tk}$  in  $W_t = \bigcup_{k=1}^{n_3} w_{tk}$  to

transform, the information's output is  $x_{ot}^{n_2}$ ; At the same time, from the viewpoint of enterprise's evolution, this kinds of enterprise could choose the uncertainty

of  $w_{tk}$  in  $W_t = \bigcup_{k=1}^{n_3} w_{tk}$  to make the enterprise tech-innovation process could be indicated by an iterated function system with probability, that is

$IFSP_E : (R^{n_2}, w_{t1}, w_{t2}, \dots, w_{tm_3}; P_{t1}, P_{t2}, \dots, P_{tm_3})$  while.

$$\sum_{k=1}^{n_3} P_{tk} = 1. \quad (2-2).$$

The above-mentioned  $IFSP$  is not only a fractal, but also because of its satisfactory characteristic of self-resemblance, it could explain the complexity in the evolution of the enterprise's becoming history very well <sup>[10]</sup>. Now discuss the becoming evolution of the convention in the course of enterprise tech-innovation. The transform set is one cluster of enterprise's routine that has acted on outside and inside existing information

resources  $W_t = \bigcup_{k=1}^{n_3} w_{tk}$ . It decides the information's characteristic and the evaluative course of itself at the

next time point. This paper believes that the evolution of enterprise's routine is not depended on the result that enterprises calculate in advance, but limited by the result that chosen by society network. Therefore, once enterprises choose  $w_{tk}$  to transform, when  $w_{tk}$  is used on next step, it must has already absorbed the result this time. Embodying in mathematics, it

$$w_{(t+1)k} = w_{tk} + \Delta w_{tk} \quad (2-3)$$

In which  $t_0$  is the cycle of choosing  $w_{tk}$ ;  $\Delta w_{tk}$  is the emendation matrix, which reflects the revision of routine because of choosing  $w_{tk}$  this time, namely the routine which the change causes is revised.

## 2.2 The network environment

The network environment represented by Internet dwindles the time lag greatly. Considering the network environment as a whole behavior characteristic for the system, the paper believes that the network environment could be regarded as an independent behavior subject because of the network imbedding formed in the course of the building of the innovation's object. Its behavior characteristic is similar with the enterprise's structure: namely it has certain information and convention. At the same time information is dealt with by the routine, the routine is evolving in this course. Besides of the fractal structure which is similar with the enterprise's structure, the pre-requisite factor of network environment is to choose function. This requires looking for a parameter of scaling the characteristic to confirm the choosing function.

Firstly,  $IFSP$  structure is used to indicate the self-evolution course of the network,

$IFSP_N : (R^{m_2}, w_{t1}, w_{t2}, \dots, w_{tm_3}; P_{t1}, P_{t2}, \dots, P_{tm_3})$  while,

$$\sum_{k=1}^{m_3} P_{tk} = 1 \quad (2-4).$$

On the other hand, in order to indicate the heredity and variation of the convention of the network, similarly

with enterprise's structure  $w_{(t+1)k} = w_{Ntk} + \Delta w_{Ntk}$ ,

$T_0$  is the circulation cycle of  $w_{Ntk}$  chosen for the

network;  $\Delta w_{Ntk}$  is the emendation matrix, which reflected the revision of convention because of choosing this time, namely the convention which the change causes is revised. Finally, to resolve the choosing function and scale the competition relation between convention and information, this paper sets about from the outside, confirms that  $IFSP_N$  is chosen to be

confirmed by the radius  $Z$  of the table in the technological convention that  $t$  may include constantly,  $Z_{(t)} = |\ln C_{tm} - \ln C_{t1}|$  (2-5),

Then  $Z_{(t)}$  has determined field of the choices of the information resources and convention resource in the network. where  $C_m$  is the cost of the technological information and convention  $S_m$ ,  $C_{t1}$  is the cost of technological information convention  $S_{t1}$ . Because the evolution of the network makes technological diffusion faster, enterprise's competition is aggravated in the network, then this paper supposes that  $Z'_{(t)} \leq 0$ . That means that with the evolution and development of the network, the difference on the cost of the information suitable for choosing and the routine will be smaller and smaller in the network. On the other hand, because of the variety of the network, the division among specialized departments of the technological innovation course will be more and more meticulous.

### 2.3 Tech-innovation as the object of development

Considering the object of enterprise's development and technological source, it is possible to have two kinds: 1).this tech-innovation is not existing in the environment of the network, namely the network environment does not have the same information as this, the existence of tech-innovation in the network environment gone on and existed by this enterprise, namely the original innovation in a normal sense; 2).this tech-innovation exists in the environment of the network, and does not exist in this specific enterprise, namely the imitation innovation in a normal sense.

Setting up the permutation of all kinds of technology when moment  $t$  of the environment of the whole network as follows:  $T_{Nt} = \{S_{t1}, S_{t2}, KS_m\}$  (2-6).

This permutation Satisfies the above-mentioned assumption: namely by virtue of competition of the society, the possible technology choosing included in  $T_{Nt}$  is confirmed by the radius of the table

$$Z_{(t)} = |\ln C_{t1} - \ln C_m|, \text{ and } T_{Nt} = \{S_{ti} \in T_{Nt}\}.$$

And two kinds of situations which are perhaps in of this tech-innovation of enterprise while discussing are expressed in order to make two types:

- 1),  $S_{t+T_E} \in T_{Nt}$ , namely this tech-innovation is imitation innovation. And
- 2),  $S_{t+T_E} \notin T_{Nt}$ ;  $S_{t+T_E} \in T_{N(t+T_N)}$ , namely this tech-innovation innovates originally.

### 3. ENTERPRISE TECH-INNOVATION RISK MODEL

The uncertainty in the course of enterprise tech-innovation of course could be divided into two levels according to aspect: 1.the deviation of the goal object and the routine it selected to use in the structure

of enterprise tech-innovation; 2. the risk that the uncertain factor in the course.

#### 3.1 The risk resulting from the routine

According to the above mentioned: The route where enterprise evolves can be determined by  $IFSP_E$ , its routine is  $[R^{n_2}: W_1, W_2, \dots, W_{n_2}]$ , it is a  $IFS_E$  with a compression factor  $0 \leq s < 1$ , and in which the transformation is  $w: h(x) \rightarrow h(x)$  (3-1).

$$\text{Define: } w(B) = \bigcup_{n=0}^{\infty} w_{k_t}(B) \quad \forall B \in h(x), \quad (3-2)$$

Where  $w_{k_t}$  is the compressive transform with a factor  $s$  in the space  $(h(x), h(x))$  which satisfied the following:

$$h(w(B), w(C)) \leq sh(B, C), \quad \forall B, C \in h(x). \quad (3-3)$$

In which its only fixed point  $A$  satisfies

$$A = w(A) = \bigcup_{n=0}^{\infty} w_{k_t}(A), \quad \text{and} \quad A = \lim_{n \rightarrow \infty} w^n(B)$$

$\forall B \in h(x)$ . It is a fractal. Now considering evolution of enterprise, definition of the corresponding displacement transformation  $S_t: A \rightarrow A$  of

$$w(B) = \bigcup_{n=0}^{\infty} w_{k_t}(B) \quad S(a) = w_{k_t}^{-1}(a), \quad \alpha \in w(B) \quad (3-4)$$

4). Dynamical system  $(A; S)$  is the displacement dynamical system going with  $IFSP_E$ . It can be written as following:  $S(a_n) = w_{k_t}^{-1}(a_n), \alpha \in w_n(B)$  (3-5).

Because of the sensitiveness  $S(a)$ , the difference of

$$\text{the tracks of } w(B) = \bigcup_{n=0}^N w_{k_t}(B) \text{ will extend with the}$$

effect of dynamical system, i.e.  $h_t(w(B), w(C))$  will change. In which  $h$  is the Hausdorff distance.

Therefore, it could be measured of the possibility of the difference between the direction which indicates the enterprise innovation and the direction of network evolution in the track space  $h_t(w_{(B)}, w_{(C)})_t$  thus leads

out conclusion 1): any uncertainty of enterprise tech-innovation is closely linked with the time  $t$  in the evolution track.

#### 3.2 Risk caused by the uncertainty factor's

Constructed being aforesaid:

$$IFSP_E: (R^{n_2}, w_{t1}, w_{t2}, \dots, w_{m_3}; P_{t1}, P_{t2}, \dots, P_{m_3})$$

according to the random density of model, ISFP can forms finite Markov chain. Its probability shows the probability factor in the random network chart, the

picture which outputs the result can be expressed with the matrix of making up.

We need to calculate the uncertainty in the course of the tech-innovation

$H_{I\Delta}$  shows the information flows impart entropy and the measurement of accuracy after the transformation, in which  $W_{kt}$  is the complex variable matrix.

In sum, the uncertainty of enterprise tech-innovation course can be shown by above-mentioned variables:  $Q = (h_i, H_{I\Delta})$ . The first part  $h_i$  has expressed the uncertainty's measurement of the object chosen in the tech-innovation; The second part  $H_{I\Delta}$  is the uncertainty of the tech-innovation course while organizing.

#### 4. THE MODEL DISCUSSING AND THE MEASUREMENT OF THE RISK

In the mathematics model of section 3, the economic meaning which represented by  $w_{tk}$  is provided by  $w_{tk}$

in the model  $W_t = \bigcup_{k=1}^{n_3} w_{tk}$ . Now we assume that  $w_{tk}$

presents the concept of economic cost, and indicates the difference measurement of the cost of individual enterprise innovation and that of network innovation in the realistic economic life;  $w_{tk}$  provides the matrix of information shift and processing, then  $h_i$  shows the difference of information output's availability in the social network.

The uncertainty at the second level could be confirmed by using two indexes of the complex variable. 1). Information transfer; 2). Accuracy of conducting of information. Thus forms a complex variable  $P_{kt}$  is the probability that transformation matrix appears, if this information flow is expressed by one chart, its mathematics expression formula must be an adjoining matrix of an unconnected chart, which expressed once enterprise chooses some to deal with the way, it has no other things to substitute choosing in the future, namely the history determines their evolution possibilities, the border matrix of unconnected chart must could be simplified to a Jordan matrix, and restrained the appearance probability of Jordan matrix own probability so can simplify its calculation.

It must be pointed out that risk is aiming at a given goal collection. Therefore, the risk measurement could be come out throughout comparing the uncertainty's index and the given goal collection index.

Definition: The risk index of the innovation activity way  $j$  is:  $R_j = 1 - \frac{\sum_{i=1}^{h-1} Q_{ij}}{Q_0(h-1)}$ , (4-1)

In which:  $Q_0$  is the given object restriction collection;  $h$  is the  $Q_0$ 's mark of the position according to  $Q_0$ . The choice could be decided by the following expressions: As for the given project  $j$ , the position form risk is  $R_x^{(1)} = r_x^{(1)} r_x^{(2)}$ , (4-2)

Risk of break even is:  $R_x^{(2)} = P(w \subset t) = \int_{-\infty}^t f(w) d(w) = F(t)$  (4-3)

Risk of aggressive is:  $R_x^{(3)} = P(w \subset T) = \int_{-\infty}^{+\infty} f(w) d(w) = F(T)$  (4-4)

In which  $r_x^{(1)} = - \int_{-\infty}^{+\infty} \ln f(w) dF(w)$ , (4-5)

$r_x^{(2)} = \begin{cases} 0 & T < \bar{x} - k\sigma_x \\ \frac{T + k\sigma_x - \bar{x}}{T - \bar{x} + 2k\sigma_x} & T \geq \bar{x} - k\sigma_x \end{cases}$ , (4-6)

$f(w)$  is the density distribute function for the restraining goal from collecting the element,  $\bar{x}$  is the mean value. Its density distributing function is lead out with corresponding density evolution method by above-mentioned IFSP.

#### 5. CONCLUSION

Throughout the research to the roots of the uncertainty and measurement of the risk in the enterprise tech-innovation process under the net environment, the paper's conclusions are as followed:

- 1). The uncertainty factor in the enterprise tech-innovation is decided by enterprise routine: the network and the innovation object;
- 2). Because enterprise is a organic structure, the using of fractal system to describe its evolution and the characteristic of self-similarity is felicitous; the measurement of the tech-innovation risk is come out from the uncertainty of the enterprise tech-innovation and the given object restriction collection;
- 3). Because the universal mathematics tools fail to appear, different mathematics tools are needed in the course of analyzing and researching enterprise tech-innovation process. A large amount of research on constructing and evolving the method and using with the density in IFSP needed, it is a focal point of next research to find out its measurable triggers value.

### ABSTRACT

In an uncertain environment, esp. facing a market transformed from sellers' market to buyers' market, each enterprise focus not just on competitors as traditionally, but on external system sources such as customer and government and inner system sources such as employee and material etc. As the globalization-economy, the market emphases and the influence of a government to an enterprise changed, and the importance of knowledge management in an enterprise's inner system emerged. Under this situation, the author thinks that we should not view an enterprise as a simple machine or just an open system any more, while a complex and conformity concept should be applied to research its operation model.

The traditional business operation model (BOM) is a closed "produce - sell" model. It focuses planning and decision, which means there should be a plan first then do it. In fact, the traditional BOM is a kind of initiative-passive model, the corresponding main management theory is management process and its function. While the modern BOM is an open "perceive - response" model. It emphases knowledge and intelligence, which means perceived something first and then feedback. Essentially, it is a passive-initiative model and the main relevant management theory is competition intelligence and knowledge management. Based on these analysis, the author think that relative to traditional businesses try to keep stabilization during a proceeding phase, i.e. quantitative change, the modern businesses should transform the perceived changes to profitable responses, i.e. qualitative change. We can use a loop course of "induction - explanation - decision - running - again induction" to explain it. In addition, facing the complexity, the management should pay more attention to "situation and harmony", but not just to "order and control".

**Keywords:** Uncertain Environment, Business Operation Model (BOM), Knowledge Management

### 1. FIRMS IN UNCERTAIN ENVIRONMENT

Almost all enterprises have realized that coming with commercial activities are the increasing transformation and unpredictability in the information age. In uncertain social environment, the objective a firm gamed with and the focus its gamed on both have been changed. To the external environment, the market transformed from sellers' to buyers' and the main problems that marketing faced are how to do a segmentation and how to operate the business according to customers' different demands. In the point of competitive strategy, there are so many discussions in traditional strategic theories, such as a series of competition theories from Porter. However, in the dynamic information age with more and more uncertainty, competitor will become copartner and strategies of cooperation and competition are often applied alternatively and the relevant strategy theories also become focal point of concern. Government regulation is very important to an enterprise's business operation no matter in the socialism market environment like China or in the pure capitalism economic environment like the U.S.. Especially in the process of economy's globality, the government control over enterprises is much stronger but not fainter than before. To the internal environment, intangible assets are more important than tangible assets.<sup>[1,2]</sup> Therefore, it means

that service becomes more significant than product itself from the point of output and the most important resources to an enterprise are intangible assets such as technique, trademark etc. from the aspect of input because these intangible assets' value have already exceeded that of tangible assets such as land, machine, stock-in-trade and financial assets etc. Compared with traditional economy, knowledge become the vital production factor in new economy. The status of knowledge in new economy is just like capital in industrial economy and land in agricultural economy.<sup>[3,4,5]</sup>

Even early in 1962, Simon pointed out that: "The change of pattern is inevitably to occur only if economics involves in the uncertainty research increasingly and pays more attention to the complexity of economy decision. Accordingly, business operation model (BOM) coincided with the economic circulation rules must be changed along with the increasing uncertainty of environment.

To the internal environment, an enterprise is an open dynamic non-linear system. First of all, an enterprise is an organism system communicating material, energy and information with the external environment and it has the motivity of self-perfecting and self-evolving. Second, an

enterprise is a non-linear system. This mainly attributes to the positive and negative feedback of an enterprise:<sup>[6]</sup> The positive feedbacks interrelated to an enterprise include economies of scale, knowledge accumulation, credit and cooperation, culture and tradition, while the negative feedbacks include the empiricism and conservatism of administrators which will increase to hurt they gumption, the aging techniques because of difficulties to retreat which will lead to reduce its competitiveness, the internal nepotism coming into being which will weaken the validity of inner management, the increasing internal organizations and management levels which will affect the enterprise's efficiency, and the increasing demands for resources which will restrain the power of enlarging reproduction. To be different from a

traditional isolated system (simple machine) or an open system only emphasizing external communication function, modern enterprise should be treated as an open dynamic non-linear system. At the same time, an enterprise should give enough attention to both sides-inside and outside- and harmonizes all kinds of resources and elements.

## 2. THE PATTERN CHANG OF ENTERPRISE'S BUSINESS OPERATION MODEL IN UNCERTAIN ENVIRONMENT

There is some qualitative change about an enterprise's business operation model in uncertain environment. It is showed just as following table:

	Environment Condition	Organizational Structure	Operation Model	Emphases	Operation Characteristics	Management Theory in Mainstream
Traditional Enterprise	Predictable and Stable	Pyramid Multi-layer Control Rigidly	"Produce-Sell" Closed Model	Plan and Decision	Planning first then Running, Initiative-Passive	Management Process and it's Function
Modern Enterprise	Dynamic Unpredictable Unstable	Flat Multi-department 、 Flexible Unite	"Perceive-Response" Open Model	Knowledge and Information	Perceive first then Response, Passive-Initiative	Competition Information and KM

In the traditional enterprises, all kinds of operation processes are integrated only in one high-level flow mode, which pre-determined the interaction role of the processes do to each other. So just one or two decisions might be viewed as reasonable only if they are involved in specific plans or in the permissive range of schedule. Having standard operation processes, detailed order and a rigid controlled mechanism, the traditional enterprise tries to keep stable in an action phase, and want to enhance efficiency hence increase profit through repeating the same thing and learning curve effect. This business operation model is called "produce-sell" closed model. It will not response until outside environment changes are so severe that they cannot be ignored. Since this model pays attention to planning and deciding, manifests planning first and operating followed, its essence is initiative-passive. The mainstream management theory adapted to it is management process and its function.

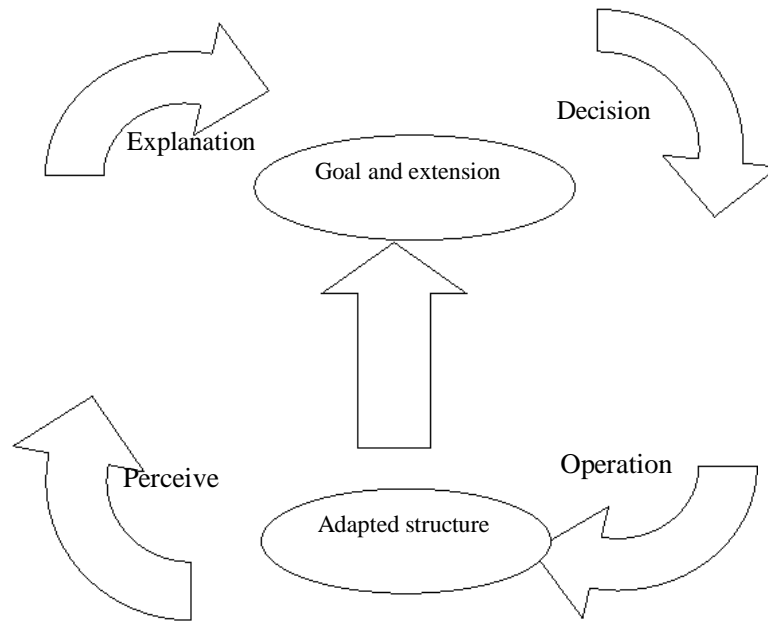

Facing complexities, modern enterprise must break the rigidity of its system and then divide the system into a few small parts, which are easier to manage. Like that, an enterprise can realize uniform action all over various functions, try to circulate in the adapted loop as quick as possible, and transform the perceived changes into a new profitable response. This business operation model (BOM) is called "perceive-response" open model, which doesn't ignore the environment's changes but focus on searching for developing signals actively, pays attention to knowledge and information, and gains great performance depending on the ability of adapting to

happenchance quickly. In essence, it is dynamic and unstable. So it will perceive initially and then response in action. It's a mode of passive initiative. The corresponding mainstream management theory is competitive information and knowledge management.

## 3. THE COUNTERMEASURE OF ENTERPRISE BUSINESS OPERATION MODEL IN UNCERTAIN ENVIRONMENT

In "sense-respond" model searching for scale adaptation, the following requirements of knowledge managements are especially important:<sup>[7]</sup> Organization should appoint the employee who can identify effective model to the relevant posts as some elements of organization is very easy to be influenced by high-level uncertainty in environment; Providing these employees some special support information according to their posts so that their ability to identify disturb and respond rightly can be increased; It is required to described out how an organization will and how it can create value in a systemic way.

In order to realizing operation benefit, modern enterprises should continually transform the perceived changes into profitable response basing on knowledge management theory in adapted loop courses of "induction — explanation — decision — running — again induction", that is to say, qualitative change. This course should not be like traditional businesses, which tries to keep stable in a action phase and in which only quantitative change happens. In addition, facing to the

Realizing Benefit via Knowledge Management

complexity, enterprise management should pay more attention to “environment and harmony” besides “order and control”.

# What All Stakeholders Should Do: Creating E-Learning Communities<sup>1</sup>

Zheng Zhao, Runtian Jing

School of Management, UESTC, Chengdu 610054, China  
fanhuijiaspec@163.com

## ABSTRACT

This paper examines how companies that offer e-learning products collaborate with their clients, external experts and end users. Given increased demands for more sophisticated learning products, it is becoming increasingly crucial for e-learning firms to source and exploit content, education, knowledge and expertise that are beyond the traditional boundaries of the firm. These changes raise a set of problems related to how firms can effectively interact and collaborate with other stakeholders in order to create, distribute and improve e-learning products. Based on some previous researches and the existing literature on “communities of practice”, it is proposed that “learning communities” should be established by leading firms to meet demands for new e-learning products.

**Keywords:** learning, e learning, learning community

This paper emphasizes on enterprises that produce digital educational and training materials, hereafter known as “e-learning” firms. E-learning is a fast growing multimedia sub-sector that has emerged to meet increased demand for digital and distance based learning and training materials in educational and workplace environments.

The focus of this paper is to research the ways in which e-learning firms collaborate and communicate with their clients, external experts and end users. These firms produce e-learning packages both for the market and for specific company clients. Given the increased demands for more sophisticated learning products, it is becoming increasingly crucial for firms to source and exploit content, education, knowledge and expertise that are beyond the traditional boundaries of the firm. This occurs in three ways. First, there is the sourcing of content from the client. Second, and increasingly, there is the need to draw advice from external learning experts. These may be experts in teaching and learning or in the subject being taught. It is now necessary for firms to open up their organization to exterior knowledge and know how, to create new collaborations. Third, given the necessity of providing effective learning that is sensitive to learner/end user needs, it is now more common to involve the end user within the development process - ensuring that e-learning products are able to engage with and enhance the learning of the end user. It involves more consultation, partnership and interaction with the end user than ever before (Russell, Calvey and Banks, 2003).

While the term “learning community” can be defined in many ways (Imel, 2001), it is used here to describe the interactions between the collection of “communities of practice” integral to the firm, and the range of external experts, clients and end users involved in the creation of

an e-learning product. Given the need for flexibility and creativity in this sub-sector (Swanson and Wise, 1997), the more firms can integrate external expertise, client creativity and learners’ knowledge and viewpoints, the more effective these “learning communities” and their e-learning products will be. However as we will see, while some successes have been realized, the strategies and pathways adopted in forming these new communities are often partial and uncertain. It’s possible to conclude that e-learning firms need to more fully engage in expanding their “learning communities” to ensure the continued production of innovative e-learning products.

## 1. A SOCIAL DEFINITION OF LEARNING

In a social learning system, competence is historically and socially defined. How to be a physicist or how to understand the position of the earth in the universe is something that scientific communities have established over time. Knowing, therefore, is a matter of displaying competences defined in social communities. The picture is more complex and dynamic than that, however. Our experience of life and social standards of competence of our communities are not necessarily, or even usually, congruent. We each experience knowing in our own ways. It is in this interplay that learning takes place.

Consider two extreme cases. Sometimes, we are newcomers. We join a new community. We feel like an idiot among the experts. We want to learn and apprentice ourselves. We want to become one of them. We feel an urgent need to align our experience with the competence defined. Their competence pulls our experience.

Sometimes, it is the other way round. We have been in a community for a long time. We know the rules. We are

<sup>1</sup> Supported by NSFC (70372032, 79900022)

thoroughly competent, in our own eyes and in the eyes of our peers. But something happens. We are sent to overseas. We go to a conference. We visit another department. We meet a “stranger” with a completely different perspective. Or we just take a long walk or engage in a deep conversation with a friend. Whatever the case may be, we have an experience that opens our eyes to a new way of looking at the world. This experience does not fully fit in the current practice of our home communities. We now see limitations we were not aware of before. We come back to our peers, try to communicate our experience, attempt to explain what we have to change how our community defines competence. We are using our experience to pull our community’s competence along.

Whether we are newcomers or experts, knowing always involves these two components: the competence that our communities have established over time, and our ongoing experience of the world as a member. Competence and experience can be in various relations to each other: from very congruent to very divergent. As two examples show, either can shape the other, although usually the process is not completely one-way. But, whenever the two are in close tension and either starts pulling the other, learning takes place. Learning so defined is interplay between social competence and personal experience. It is a dynamic, two-way relationship between people and the social learning systems in which they participate. It combines personal transformation with the evolution of social structures.

## 2. THE ADVANTAGES OF E-LEARNING

A considerable amount of research has been conducted on e-learning. In contrast with traditional classroom learning, e-learning brings distinct benefits to learners (Beam and Cameron, 1998; Hiltz and Wellman, 1997; McCloskey, Antonucci and Schug, 1998):

**Time and location flexibility.** E-learning eliminates the barriers of time and distance by offering just-in-time, on-the-job learning. It has potential to reach a global audience.

**Cost and time savings.** In e-learning, learners do not have to travel to a specific location. It is reported that the companies using online learning can expect an average of 50% in time savings and 40% to 60% in cost savings compared with conventional way (Khirallah, 2000).

**Self-paced learning.** E-learning fosters self-directed and self-paced learning by enabling learner-centric activities.

**Collaborative learning environment.** E-learning links each learner with physically dispersed experts and other learners, together to form an online collaborative learning community (Alavi and Leidner, 2001). By

electronic means, an e-Learning environment encourages learners to ask questions that they may not be able to ask in a conventional classroom, and to share different ideas with others more easily through online discussion forums.

**Unlimited use of learning material.** E-learning allows unlimited access and retrieval of electronic learning material. People can review information stored in centralized knowledge repositories over and over again. The learning material can be efficiently maintained and updated.

E-learning has become an inescapable element of business in the new economy. In 1999, companies in the United States spent \$62.5 billion on educating their employees, with more than \$3 billion spent on technology-delivered training (Khirallah, 2000). Effective and efficient learning methods are greatly required by companies to ensure employees and channel partners to be timely equipped with the latest information and advanced skills. Consequently, e-learning is being adopted by many companies to expand their learning market to previously out-of-reach employees (Wulf, 1996).

Today, thanks to the widespread access to the Internet, e-learning emerges as one of the fastest-moving trends in higher education. Thousands of online courses, including degree and certificate programs, are now being offered by educational institutions worldwide.

## 3. COMMUNITIES OF PRACTICE

Communities of practice are the basic building blocks of a social learning system because they are the social “container” of the competence that makes up such a system. By participating in these communities, we define with each other what constitutes competence in a given context. Communities of practice define competence by combining three elements (Wenger, 1998). First, members are bound together by their collectively developed understanding of what their community is about and they hold each other accountable to the sense of joint enterprise. To be competent is to understand the enterprise well enough to be able to contribute to it. Second, members build their community through mutual engagement. They interact with one another, establishing norms and relationships of mutuality that reflect these interactions. To be competent is to be able to engage with the community and be trusted as a partner in these interactions. Third, communities of practice have produced a shared memory of communal resources—language, routines, sensibilities, artifacts, tools, stories, styles, etc. To be competent is to have access to this resource and to be able to use it appropriately. Communities of practice grow out of a convergent interplay of competence and experience that involves mutual engagement. They offer an opportunity to negotiate competence through an

experience of direct participation. As a consequence, they remain important social units of learning even in the context of much larger systems that are constellations of interrelated communities of practice.

The firm is often seen as a key organization that can house the expertise, skills and knowledge necessary for efficient and effective e-learning production. Fransman's (1994) conception of the firm as a "processor of knowledge" (Amin, 2000) is perhaps an apposite description. E-learning firms process knowledge for their own uses but they also trade in knowledge. They draw upon the knowledge of in-house experts and, increasingly, outside subject matter experts and build this knowledge into products. They comprise sections, each with responsibility for, or claiming to own, part of the design and production process.

With these issues in mind, in recent years it has become common to refer to firms as a composite or collection of different "communities of practice". The idea of a community of practice was developed by Lave and Wenger (1990) as a theory for practice-based learning in which one could undertake "legitimate participation", to serve a kind of apprenticeship with a group of insiders in an organization; organizations being comprised of a range of different disciplinary groups or collectives, each charged with specific areas of responsibility. The theory was referred to by Brown and Duguid (1991) to support their contention that the separation of knowledge from practice is unsound. They argued that the ways in which people actually work differ from official descriptions and that "learning in working" is a better way to improve performance, and most characteristic of how firms share and develop knowledge. Wenger and Snyder (2000) later described a community of practice as a "group of people informally bound together by shared expertise and passion for a joint enterprise", with members inevitably sharing knowledge in order to solve problems in their organization. Yet, while these communities might be informal and resistant to supervision, they cannot exist without management support and structure they are bounded, to varying degrees, within the bureaucratic organization of the firm.

Given the ways in which "communities of practice" are often associated with firms working in the creative industries (Raffo et al, 2000), it is reasonable to test out how far firms were acting as "communities of practice" in the production of e-learning products. At first, some key questions need to be addressed: Can "communities of practice" operate across different organizations? Can they operate without geographical proximity? In e-learning, how does involvement with external agencies impact on the firms' "communities of practice"?

Given the increasing importance of outside experts, it became a big concern with how far agencies and forces external to the organization - whether in conflict,

cooperation or collaboration with the firm - are able to penetrate or impact upon Wenger's "locally negotiated regime of competence" and "shared histories of learning" that make up the community of practice (Amin, 2000). The e-learning firm negotiates with clients who commission products, with the external freelance experts who are selling their knowledge, the end users and with the firm's own staff who design and produce the e-learning products. The types of exchanges and relative bargaining positions of the parties to these negotiations vary according to the stage in the production. Knowledge is constantly passing through these stakeholders and the firms ought to be able to benefit from these internal and external challenges in terms of enhancing their own performance.

Further, referring to Amin's (2000) discussion of the definitions of communities of practice offered by Wenger (1998), while the key dimensions of "mutual engagement", "joint enterprise" and "shared repertoire", can be individually applied to many of the firms delivering e-learning, as well as the clients and end users—it should be discovered whether such mutuality was as pronounced within the collaborative and convergent networks and communities as necessary for the production of e-learning products. From the existing literature, communities of practice as defined is not multi or inter-organizational. The groups studied by writers on communities of practice are usually involved in discrete organizations or task based activities, for instance Wenger's group dealing with insurance claims, where decisions are negotiated within a given organizational framework but on the basis of tacit knowledge or unwritten convention. The emphasis is on close study of single organizations, rather than on the diffuse and diverse networks that make up the whole production process. In an area where management skills and knowledge for effective production can be acquired through extended and exterior communities of clients, experts and learners, where mechanisms for the creation, exchange and possession of knowledge are much harder to define and where relying on others (non-firm members) is a necessary imperative, the received notion of a community of practice begins to unravel thus it is needed to develop a more appropriate understanding of how communities of practice operate within the context of production in the e-learning.

As production of e-learning products necessarily involves members of communities working in different organizations, the firm ceases to have primacy in terms of bounding the parameters of creativity and communication, or defining e-learning products. Just as Tyre and Von Hippel (1997) refer to communal or collaborative processes and "the importance of such collaborative processes [being] that no one person embodies the requisite knowledge to comprehend complex organizational problems or the requisite variety to clarify equivocal issues", the definition of learning is no longer bound by the needs or objectives of the

individual firm. The primacy of the firm may be compromised for the greater good of the production process and the advancement of the learning community of which the firm is a member. All of these cannot be contained within the conventional understanding of the firm as a bounded set of “communities of practice” - a more open-ended conceptualization is needed in order to capture the range of communities required to produce quality e-learning materials. Extending communities of practice, into “learning communities” is one route that firms can follow to enhance the quality of e-learning products, as well as to help create a more open and reflexive attitude to learning within the firm itself.

#### 4. DEVELOPING E-LEARNING PRODUCTS

Before examining the components of the learning community, it is useful to reflect on the particular kinds of e-learning products that companies were producing. Most commonly, firms were producing interactive CD-ROM's or Web-based products — sometimes converging the two—and while the content of products differed, three broad product types can be identified. Each involves a different level of community involvement from the four key parties involved: the firm, external experts, the client and the end user.

Organization-specific “rule based”. In certain cases, learning material is ready made and is converted into technology-based. Some of this is rule based, for example the conversion of client companies' internal regulations or induction procedures. The appreciation of how learners learn should not be underestimated, but the client companies' needs and those of their learners are relatively easy to define. Much of the work concerns creating rule sets and programming. There is some literature on instructional design (Christian-Carter, 2001). In these products the learning and learning design are largely the province of the firm and the client external experts and learners are less likely to be involved in this learning community.

Organization-specific “non-rule-based”. In the production of e-learning materials, there is a growing emphasis upon client and end user needs. Open ended and non-rule based learning is becoming more popular. Firms are therefore beginning to involve the client or end user in the creative process and this requires the involvement of new disciplines such as the learning designer in order to create or facilitate specific products and/or forms of delivery. The concentration of firms on the clients' or end users' learning requirements leads us to argue for a complex assessment of the types of creativity necessary for effective production, one that incorporates understanding of the interpretation of client needs, the design of the learning approach and the graphic design and technical elements. In these products the firm, the client and the end user are often closely involved in the design, development and evaluation -

potentially a creative learning community.

Non-organization-specific. Some e-learning products may be generic, but often broadly targeting a particular occupational, educational or industry sector. In other cases, the product is produced speculatively for general sale. Whichever the case, the company producing the products has to acquire knowledge and decide on the outcomes and objectives of the e-learning. In general sale products, the firm and its designers will usually not have any sustained engagement or full knowledge of the individual client or end users themselves. Thus, the notion that end users are engaged in the wider “learning community” is limited. In this kind of generic production, the notion of a learning community may be firm-led, drawing upon established commercial models of design expertise, learning delivery or market research.

However, it is in the case of “total-open” learning products, supported by a range of tools and e-coaches, that another type of “learning community” may come more into play. Individual or small groups of learners, from all walks of life at different times, might be invited to register or share knowledge of the product. The link between members is professional or emotional rather than organizational.

#### 5. LEARNING COMMUNITIES

As argued, in e-learning production, the extension of a “community of practice” into a “learning community” involves integration and exchange between the firm and its internal communities with the external world - most notably exterior experts, the client and communities of end users. While client and end user might be one and the same, it is more common for companies, schools or universities to act as the client and their staff or students to be identified as the end users. By describing how each of these constituencies have a role in the production of e-learning products this paper explores how effective e-learning can be better obtained through a more open and open ended approach, one embedded within informal “learning communities”.

##### 5.1 The firm in the learning community

While the firm, as a set of communities of practice, is engaged in formal, structured, but also informal and tacit modes of learning (Amin, 2000). The successful e-learning company is one that is pushing the learning dimension much more to the fore - both in terms of product and production process. In terms of product, the way in which this is most evident is in the increased creation of specific roles for an in-house expert in the design and delivery of learning. Often referred to as the “learning designer”, this figure acts as the designer, director and evaluator of learning needs and outcomes in the production process.

The role of a “learning designer” will vary from company to company but most crucial is an outward looking, experimental approach to learning. For the learning designer, the parameters of learning are worked out in and through the production process in a manner contingent on a range of issues including client needs, resource constraints and educational principles. It is against the background of this process of negotiation with external agencies that innovative firms have increased the development of learning dialogues and attempted to redefine and reposition the role of a “learning designer”.

Many of firms were engaging with a varied client base, producing e-learning across industrial or educational sectors. Such expansion has increased the primacy of the role of the learning designer. Good learning designers should be “experts in not knowing” and can ideally work with any type of content. Clearly a figure that can manage and manipulate any kind of content to effect and implement an effective e-learning process must be attractive in a growing e-learning marketplace.

As well as employing learning designers, in terms of production, firms are becoming more outward looking and experimental in their search to create a learning community. This involves integrating external experts into the production of e-learning products. Many firms have established their own forums and network of individual practitioners and organizations interested in e-learning.

## 5.2 External experts in the learning community

Given that many small firms are unable to employ a full time learning designer, and with the need for ultimate flexibility in a fast changing and uncertain market place, the role of external experts, such as freelance learning designers, evaluators and educators becomes more crucial.

The role of external experts has grown in recent years as multimedia firms with strong technical and design competence but little in the way of educational expertise are looking to integrate the “learning” dimension into the product and production process. These experts are often members of informal networks, often, though not necessarily geographically “clustered” around the commissioning firm, but bound together by a history of collaboration, shared experience and know how. Given the high levels of self-employment and freelance work in this sector, the role of the “external” expert is more salient and vital than in other, more traditional industry sectors - making them key members of any learning communities.

## 5.3 The clients in the learning community

The client must now play a central role in the formation and maintenance of a learning community. Attitudes

to clients varied among the firms, with some of them talking about managing their clients’ expectations and the “whole process being managing the client to accept the creative”. However, others took a different view, seeing the client’s creative contribution as a central part of developing e-learning products. Although there was general agreement that clients’ needs were often difficult to define, a problem often complicated by the clients’ lack of appreciation of the scope of e-learning - the point about collaboration is that clients become involved with the developers at an early stage in the production process and can provide creative input into the design and development of e-learning materials - while, at the same time enhancing their own understanding of e-learning within the context of their own organization. For the firms the negotiations with clients and the meeting of their needs assumed a central role.

While the extent to which clients are engaged will vary, it was clearly evident that more successful and progressive firms understood the client as central in the definition and delivery of e-learning - not merely a customer to be satisfied. This ensures that the issue of learning - for both parties - remains open and subject to creative development.

## 5.4 The learners in the learning community

While firms, external experts and clients can often generate productive learning communities; the involvement of end users/ learners is an area that needs more work. The needs of both individual and groups of learners are often subordinated to concerns over development and design, time-scale, budget, distribution, price and so on. But there are a number of other, more hidden reasons why end user learning needs and experiences are often secondary concerns. It may be that in the provision of tried and tested “rule based” software, learners’ needs are assumed to be simple and straightforward and unworthy of detailed consideration. Further, it is often the case that clients assume that their staff or student learning needs are homogenous. Also, firms themselves may feel uncertain in challenging client’s identification of what the learner’s needs are - particularly in the case where the client is an educational institution. Even when partnerships involve the end user, there is no guarantee that the learners’ input will be as valued as that of the firm or the experts. However, for a growing number of firms, the integration of the end user is now deemed crucial. These firms come to realize the primary focus of attention needs to be on the needs of the learners.

Not only are firms looking to expand their collaboration, an increasing tendency now aims to generate a dynamic among learners and encourage them to share learning experiences and stories, and generally to engage more widely with the providers and producers of e-learning. Creating a set of mechanisms whereby all parties can

provide feedback and engage in the production process is the ultimate goal. How this can be achieved, however, remains a crucial question.

### **5.5 Mechanisms for managing the learning community**

How are these four disparate constituents of learning communities able to bind and act to effect the development of e-learning and e-learning products? It is indicated that certain emotional and conceptual leaps must be made to open out all stakeholders to reach an openness which requires the development of relationships with reciprocity and trust (Cross and Baird, 2000). For example, the firm needs the expert's knowledge and the expert needs to trust the firm with it. Trust and friendly collaboration are pivotal in cementing this kind of community (Ingrams and Roberts, 2000).

Geographical proximity remains important in the learning community. External experts and learners in face to face exchanges remains the best way for identifying and agreeing objectives, processes and outcomes and for helping to facilitate trust. In production, it was noted that face-to-face meetings avoided endless e-mails, course content was largely written within face-to-face meetings, and problems caused by the lack of understanding of each other's functions and of the development process itself could be overcome with face-to-face exchanges.

Where it was not possible to meet directly the clients or external experts a secondary option was to use Internet Technology to enable relationships to be maintained across distance - this was a strategy many firms employed. However, often, firms found it difficult to meet or engage with the learners or end users, face to face or at distance. But if learners are to become more central to the learning community then mechanisms for integration must be found.

Some firms now make it a priority to update knowledge, to provide toolkits for learners, interactive resource centres with archived documents, links to material and more opportunities for learners "to do things themselves". Additionally, "e-coaches" now assume a central role in cementing the dispersed body of learners into the learning community. Learners may be more engaged in feedback activities, ongoing consultation and development discussions allowing learners to create content and put it on line themselves and to generally enhance the contribution of learners in the e-learning production process.

### **5.6 Barriers to the formation of learning communities**

After revealing some of the possibilities and strategies of new learning communities, it would be misleading to

suggest that this is a general or even a widespread process - many firms remain locked into the traditional separation of the firm from the external world, prioritise firm expertise over external knowledge and give short shrift to opening up the debate within the firm or questioning the qualities of their products. Some firms claiming that its size and attitude allowed it the luxury of debate on learning theory, was later criticized by its own staff for its concentration on deadlines and profits which discouraged staff from being innovative. It seems clear that while some learners are encouraged to use tools experimentally to construct their learning, create their own content and upload whatever they like into their shared space, the capacity of many companies to experiment, make mistakes and survive is limited.

The economic pressures placed upon a company may make it difficult to enjoy the luxury of debate on learning - this is accepted. All activities take place within budgetary, human resource and time limitations. Even if the firm wishes to develop a network of external experts, clients and learners, a decision has to be made whether to formalize and structure this network - and incur maintenance costs through communication, meetings, events and so on, or to leave it open ended and informal, but potentially losing impetus. Finally, even when learning communities are in evidence, the power relationships within that network may be asymmetrical - not everyone is able to shape the direction or definition of learning exactly as they would wish.

## **6. CONCLUSIONS**

The creation of e-learning products involves new convergences of technology, media, skills and, increasingly, individuals and organizations themselves. The management of firms and production processes must now focus on the human aspects of these convergences - the learning community. In this article, this has led to the increased utilization of client knowledge and the involvement of the external experts, clients and end users, providing an added, challenging dimension.

As more firms enter this sub-sector and as "learning design" has the potential to become a profession in its own right, the need to acquire knowledge from outside sources will increase. This question of knowledge acquisition over distance therefore applies to firms as well as learners. There seemed to be an irony in that firms find face to face meetings essential in the development of distance and e-learning products - a necessity perhaps only partially offset by new relational communities that are emerging across geographical space. The end result is a loosely bounded learning community comprising of members from a variety of organizations and groups interacting face to face and at a distance.

As more and more firms look to enter the e-learning market, not all will come ready equipped with learning designers or a discrete learning philosophy - this may undermine the quality and effectiveness of e-learning products. But by engaging in exchange with clients, experts and learners - firms can go some way to resolve the current dilemmas of this emergent industry; namely how to provide materials that are sufficiently researched, tested and appropriate for a diverse, and fast expanding, range of end users.

## What E-Learning Providers and End Users Should Do Respectively before Initiating Such a Learning Project <sup>1</sup>

Zheng Zhao, Runtian Jing

School of Management, UESTC, Chengdu, 610054, China  
fanhuijiaspec@163.com

### ABSTRACT

As an E-learning provider, before offering such a product it needs to carry out a thorough analysis in order to understand the customers and trends, and evaluate external environmental forces which include market demand, political and legal forces, social and ethical influences, technology and competition. Through conducting a thorough analysis, a clear strategy can be developed that identifies which customers the e-learning provider is to target and where their product or services will be best positioned. To some extent providers are forced continually to forecast, monitor and assess this environment and to adapt e-learning products or services accordingly before offering learning products. To implement e-learning project successfully, the end users need to understand what e-learning is good at and not so good at. When this basic analysis is complete, one can go into the organization looking for specific learning needs that could be met with e-learning. The advantage of starting by doing is that users will find out where they need help, and where they can manage perfectly well on their own. For any company, the returns must be considered carefully before undertaking such a program. In this article, it also explores the benefits of e-learning investments with a particular focus upon measuring the value of delivering an enterprise e-learning initiative. In addition to the many measurable returns, the paper offers a number of formulas for calculating the ROI and justifying the cost. The article concludes with guidelines detailing the implementation of e-learning initiative.

**Keywords:** E-learning, Internet technology, distance learning

### 1. THE BENEFITS OF E-LEARNING

Rather than waiting for a scheduled course to occur, employers and employee now can turn to e-learning programs - available every day, any hour. The "just-in-time" nature of e-learning means specialized learning is available at the moment it's needed without worrying about classroom or instructor availability. The result is that learning is accomplished more rapidly while ensuring content consistency and standardization. In addition, e-learning can streamline the education process by freeing educators' time to focus on learning contents, supplemental information development, and learners' educational needs. E-learning's more efficient use of time can increase productivity and decrease learning costs (Smith, 2001). The benefits of e-learning are as follows.

**Efficient learning time.** There is minimal work time lost with just-in-time learning. The user can learn anywhere and at anytime at their convenience: self-paced, self-managed, learning-on-demand, distance learning and open learning. The individual can immediately apply what he or she learns to the job when this takes place in the working environment.

**Cost-effective learning.** E-learning products can be delivered to any networked computer, to a large number of individuals. Programs can be delivered and re-used

with fewer costs than with traditional learning methods. There are no expenses required for the individual's travel, subsistence, or accommodation as with off-site instructor-led courses.

**Efficient management.** The self-managed learner is a useful resource to the organization, given the right learning and guidance (Pedler et al., 1997). The empowered individuals can organize their own learning methods within the e-learning environment thus freeing up their managers to do other tasks.

**Customization.** E-learning courses can be customized to meet the organization's specific needs. This flexible learning environment can also be department, product or individual specific.

**Knowledge exchange and sharing.** Individuals can share their new knowledge and skills with others in the team and department. This increases the comprehension of other employees by integrating and sharing information with other departments, suppliers and customers.

**Job performance is increased.** Understanding is developed from achieving greater knowledge retention by wanting to learn (Tarr, 1998). Hence, fewer unproductive mistakes are made in the organization. Self-motivated, self-disciplined, self-reliant and self-assessed employees are more autonomous and can

<sup>1</sup> Supported by NSFC (70372032, 79900022)

contribute better to the whole organization performance (Pedler et al., 1997).

There is a lower turnover of staff. Employees are more confident, competent and valued, due to the learning climate and are more likely to stay in the organization (Reay, 1994). Organizations that offer ongoing education have a higher rate of employee retention and benefit from a better-skilled workforce. Organizations are becoming aware of the importance of continual learning.

Acceptance of organization change. Self-directed individuals accept organization change more readily as they adapt by learning new techniques and processes (Reay, 1994). The author French (1999), identifies the self-directed learning benefits to a company by: "... employees who see themselves in a learning environment add value to the companies, increase productivity, are more accepting of change, and can adapt to movement within the company".

Accessibility to current information and new material. Knowledge and skills within an organization can be continually updated through e-learning. The organization can adapt more quickly to the environment in which it operates, due to better-informed employees. According to Steed (1999), skill transfer and retention with e-learning is at least 30 per cent more effective than instructor-led learning.

Utilization of existing resources. A Web browser provides the interface to the Internet and this can access the e-learning environment on any operating platform, such as Windows, UNIX or Mac. A learning program can be delivered to any networked computer without using a different program for different platform.

Consistency and control of learning material and revisions. After the original implementation of an e-learning program that links to Web-based information, further program changes, additions, enhancements and developments can be made on the server where the program resides and everyone in organization can access the latest updated version.

## 2. E-LEARNING PROVIDERS

E-learning providers are likely to be more successful in attracting customers, if they are much closer to the external environment. Forecasting, understanding and assessing the environment are the greatest challenges and opportunities for e-learning providers. The environment consists of the following uncontrollable factors: market demand, political and legal forces, social and ethical influences, technology and competition.

These factors need to be measured and analyzed using market research and forecasting techniques. The information collected becomes essential to the decision

making of the strategy for an e-learning provider. The factors are discussed next.

### 2.1 Market demand

The demand for products and services relies on the economic and behavioral aspects of the consumer. A behavioral aspect such as lifestyle trends creates new demands and indicates opportunities for new product development. This influences the direction of an e-learning provider's strategy. An example of lifestyle trends includes individuals working longer hours with greater demands imposed on them, giving less time to keep up-to-date with information and to learn it (Pearn, Roderick and Mulrooney, 1995). Also, the geographic locations of an organization increase global business travel for the individuals, which create problems for them about keeping informed, trained and educated. The Internet provides the means for e-learning, not only to satisfy the economic and social change, but also the accessibility to the individual for learning, by promoting a self-directed and flexible learning approach. Demographic changes affect market demand and therefore the strategy. There is an increase in the number of people that are self-employed and working from home, especially in the service sector (Bickerton et al., 1996). The fastest growing group in higher education is part-time students older than 25 (DfEE, 1999). This group tends to seek education to advance their careers, increase their salaries and self-development. For universities and business-to-consumer (B2C) learning providers, these individuals are ideal customers for having e-learning delivered to their home or offices.

### 2.2 Political and legal forces

The political and legal processes in society affect the way in which an e-learning provider operates. Changes in legal regulations and requirements give rise to many new opportunities and threats, and influence the way in which products and services are offered. Legal requirements that regulate the marketing and advertising products and services over the Internet include: Pricing Regulations, National Standards, Consumer Rights etc.

There are accredited standards being created for e-learning creation. Both e-learning providers and standards committees are recognizing the need to encourage development of Web-based content similar to that of computer software programming. The Sharable Content Object Reference Model (SCORM) standards under development by the United States Department of Defense's Advance Distributed Learning Network (ADL) addresses the need for modular, reusable e-learning content in universities and companies to teach procedures and skills. Other accredited standards include developments from the Institute of Electrical and Electronics Engineers' Learning Technology

Standards Committee (IEEE LTSC); Instructional Management System (IMS) Global Learning Consortium and ARIADNE, a European Union project, that focuses on the creation of standards for e-learning content, management and technology. The IEEE LTSC has also initiated the move of this work to the full International Standards Organization (ISO) standards by establishing ISO Joint Technical Committee 1 (JTC1) Sub Committee 36 (SC36) on Learning Technology.

### 2.3 Social and ethical Influences

Active involvement by consumer and pressure groups has forced the need for social responsibility and protection of the company's reputation to be important. In order to maintain a good image and reputation among customers, e-learning providers must avoid: misleading ambiguous advertising, inadequate product and service information and hidden financial charges.

The following points can present threats to the organization wanting to provide e-learning:

The e-learning approach can be too innovative for non-technical customers. E-learning needs appropriate understanding and commitment from the customer's management and all those involved in the organization (Gupta et al., 2000).

Organizations can be reluctant to learn over the Internet entirely. Distance-learning courses, such as for further or higher education, where learning is via books, videos and e-mail correspondences has been more accepted by organizations.

Individuals need to understand before accepting any new methods of learning. Decreasing instructor-led learning can make learners anxious. Therefore all affected customers need to be involved at the beginning of the e-learning implementation with the e-learning provider. Also e-learning maybe needs to be introduced into an organization gradually and combined with instructor-led way. This blended learning is more likely to be tolerated by individuals and the organization.

Organizations have a vast amount of knowledge, information and lessons learnt in a wide variety of procedures and in individuals' heads. This diffused knowledge needs to be managed and integrated with the e-learning systems properly (Gupta et al., 2000).

Ethical concerns, including learner privacy, are important to the customer. Internet tools can track Web site visitors, and many customers can provide extensive personal information. This may leave customers open to information abuse if the e-learning providers make unauthorized use of the information in offering their products or exchange electronic lists with other businesses.

### 2.4 Technology

Internet technology has a direct impact on e-learning providers and end users. With e-learning, the Internet provides the technology element that makes up the product and its delivery as well as providing the distribution channels and a means to promote the e-learning product or services.

Web-based tools and technologies provide the means for designing, developing and delivering e-learning content. The technology includes Web browsers that provide the interface to the Internet, and hypertext markup language (HTML), the standard language that Web pages are written in, that is supported by Web browsers. Web authoring systems assist Web designers to develop the e-learning environments. These consist of either HTML editors or Web page layout programs like Microsoft FrontPage or Macromedia Dreamweaver, and Web development programs like Authorware and ToolBook. Internet tools used can be synchronous or asynchronous communication tools: synchronous tools, including whiteboards, video and audio conferencing, allow individuals to interact in real-time over the Web. Asynchronous tools, including e-mail and forums, allow individuals to learn at any time (French, 1999). Groupware is the technology that allows a group of people to collectively work on shared information and documents over the Web using the synchronous and asynchronous tools (Ravet and Layte, 1997).

Customers can use search engines to find any information regarding the e-learning providers and their e-learning products and services. The e-learning providers need to embed keywords and page titles into their Web pages using the Web authoring systems, in order for the search engines to retrieve a description of an e-learning provider's Web site (Hanson, 2000). However, there are problems affecting search engines. A search will sometimes return thousands of results. Facing this, most users will abandon the search if their desired information is not found in the first or second screen. E-learning providers must therefore make sure their important Web pages are listed within all major search engines and use their Web page content to place important Web pages high on the return list in keywords searches.

Currently there are limitations related to the network capacity of the Internet, the bandwidth, which governs the rate at which information can be transmitted. The reason why video and audio transmission can be relatively slow over the Internet is that the bandwidth cannot cope with the large file sizes (Steed, 1999). Solutions to this are presently being developed by the telecommunication industries. One solution is asymmetric digital subscriber line (ADSL), which uses the existing copper telephone wires. In the meantime a technology called streaming is alleviating the problem for transmitting video, audio and animation sequences,

where an application or file is broken down into small chunks and delivers the beginning of the application while concurrently sending the other compressed chunks.

Security is an important aspect of e-learning and a major area of concern for consumers. If organization learning involves sensitive corporate information, or if payment is necessary over the Internet, then a greater amount of security should be used. The following are the main areas related to Internet security (Hall, 2000; Steed, 1999):

**Access control.** There are techniques to control which users have access to the information. Corporate Intranets are often protected through the use of firewalls that are gateways between the Intranet and the Internet. The process of authenticating users by issuing them with username and passwords is another type of access control.

**Information confidentiality.** Encryption is the technology used to ensure information passing through the Internet remains private. It does this by basically scrambling the information from the sender and unscrambling the information for the receiver only. Web browsers and Web servers are being developed with encryption technology built in.

The following points can present technology threats:

Present bandwidth limitations for e-learning means performance for sound, video and complex graphics can be slow, causing long waiting times for these files to download from the Internet, affecting the flow of the learning process.

The initial development time and costs can be significant for authoring customized Web pages for the learning environment and integrating the delivery environment.

Internet connection can be lost or broken due to problems with either the Internet service provider (ISP) or the organization's IT department.

An information infrastructure, i.e. networked PCs, and resources are required within the customer's organization. Therefore, the design, development, implementation, security and management of the e-learning content may need to be maintained by an e-learning provider.

## 2.5 Competition

Competition is probably the most dynamic of all the environmental forces (Bickerton et al., 1996). A strategy must take into consideration the competitive situation of the environment in which the e-learning provider operates. Successful e-learning providers must satisfy the needs of the customers better than its competitors.

Understanding competitors' strengths and weaknesses, market share and positioning are essential. Careful monitoring and evaluation of the competition, enables the e-learning provider to make better decisions (Kotler et al., 1996).

Not only does the Internet provide access to e-learning for many customers, but also to the competition. It is easy for a competitor to see what other e-learning providers are trying to achieve as well as view their Web site and e-learning products offered. Currently a strong growth and relatively low barriers to entry are attracting newcomers, including competitors from other related business areas such as the consulting industry.

## 3. E-LEARNING END USERS

Over the last twenty years, the success rate for implementations of technology-based learning has not been high. Huge numbers of companies have spent countless millions on failed initiatives in pursuit of what we now call e-learning.

How can user be sure that it's investment in e-learning will be worthwhile or enduring? Part of the answer lies in the technology. This part is easy to deal with because of global technology developments: The universal adoption of Windows and the html-based web browser, the emerging standards in e-learning, broadband access, networked PCs and better security measures.

How to deal with the rest part of the answer is the main concern of this section.

First, before implementing e-learning, user needs to understand what e-learning is good at and not so good at.

There are skills that can't be learned through an e-learning course. For example, imagine expecting someone to e-learn how to ride a bicycle. User could spend vast sums creating a simulator. Effective? Hardly.

However, user can deliver knowledge and understand more effectively by computer than by any other way, and all skills are enhanced by knowledge and understanding. Achieving this through e-learning frees user to put more energy into practical exercises, role-playing, etc.

So if an organization wants to provide e-learning for its people, and someone tries to offer an online education system, or an exploratory learning system, or a "total solution" that claims to do away with the need for live learning altogether, the managers of the organization must know what to do. Meanwhile managers should not feel they have reduced power from their self-directed, continually learning workforce, as they themselves are also employees of the organization and must also keep their skills update. The manager's emerging role in

e-learning is to act more as facilitator and support the employees through coaching, guiding, mentoring and encouraging continuous learning.

When basic analysis is finished, what should end user do?

1. Go out into organization looking for specific learning needs that could be met with e-learning. If companies do not have the resources to carry out a thorough Needs Analysis, talking to line managers will soon reveal some specific needs. For example, the sales force may need more thorough product knowledge, clerical staff may need to understand how to use computer more effectively.
2. Choose one (or more) urgent need for which e-learning would be suitable. But do not imagine for one second that this is a total e-learning solution. End user needs to train its staff in products, processes and procedures. Without employing specialists, user can start with a very specific topic, or more than one if having the resources, and lay out the information employees need to know and understand.
3. Make it happen. Get one team to do it or employ consultants to do it. The line manager (sales, production, clerical) who identified the pressing learning needs may well be a "leader" and help make it happen. Often a keen manager will find staff members who can contribute knowledge of the subject matter, familiarity with the target learners and their culture, and enthusiasm for the introduction of e-learning. Be realistic in ambitions. Don't aim for perfection or the ultimate in sophistication on first project. Stay practical. Countless organizations are spending more on compiling reports on e-learning, which do not take a single step towards a solution.
4. Evaluate the results. By all means collect learners' reactions to the e-learning. They will be valuable, but do not mislead into thinking that the response to a question about the effectiveness of a course is an actual measure of its effectiveness. E-learning lends itself to paired modules - a learning course and an assessment test. The test is not meant to fail people. It is there to allow them to demonstrate their competence. If everyone achieves a very high score on test, it is perfect. If not, managers should review (a) the questions, in case they are badly worded or needlessly tricky, and (b) the learning content, as there may be topics that are not adequately explained. Remember, however, that the benefits of e-learning are difficult to quantify in terms of changes of behavior and productivity and return on investment.
5. Learn from the experience. Consider what was successful about this pilot. Learn from any failures and shortcomings certainly, but most of all, build on success. User will learn more from this one experience than from five years of reading reports, setting up meetings, and

preparing strategy documents.

6. Calling on the experts for help. Of course, as user carry out e-learning implementation more widely through organization, it may wish to draw on the expertise of specialists in various disciplines. End users cannot escape the e-learning experts entirely, but when anyone tells that one strategy or another is a must-have, user should ask them to explain, without using jargon, exactly what the benefit will be. And if user doesn't really understand the explanation, don't invest in e-learning.

#### 4. CALCULATING THE VALUE OF E-LEARNING

Many companies view learning budget strictly as a cost center, which is susceptible to cuts when the business needs to reduce expenses. For any company, the returns must be considered carefully before undertaking a learning project. In this section, we explore the benefits of e-learning investments with a particular focus upon measuring the value of implementing an e-learning initiative. In addition to the many measurable returns, the section offers a number of formulas for calculating the return on investment (ROI) and justifying the cost.

E-learning is the future wave, but if the wave is ever to come, corporations must prove that it delivers a tangible return on investment. If early adopters integrate methodologies to demonstrate ROI, the wave will change corporate forever.

It is difficult to assign a monetary value to e-learning's benefits. Calculating airline ticket savings because a whole division took an online course is straightforward; but calculating improvements in a manager's interaction with direct reports after an online communications course is more demanding. These improvements are at least as valuable as the travel savings realized by e-learning, but more difficult to measure and justify to senior level decision makers.

Many evaluation experts have developed models to determine the value of specific learning experiences. Any company can follow these formulae to calculate ROI from a learning initiative.

Several ROI models have been developed, but two stand out as practical to implement and be effective in delivery. These two methods, a model by Kirkpatrick (1994) and an enhancement by his colleague, Phillips (1996), form a logical framework to view ROI both from a human performance and business performance perspective. Critical to both is the concept of "chain of effect", which links benefit levels, derived from learning, together. Each level of measurement impacts the previous and next levels. Without accounting for these links, it is difficult to conclude that learning is responsible for any performance improvements.

In his original model, *Evaluating Training Programs: The Four Levels*, Kirkpatrick (1994) considers the value of learning on four levels: participant reaction, skills acquired, skills implemented and organizational benefits accrued. In his book, *Accountability in Human Resource Management*, Phillips (1996) suggests adding another level to Kirkpatrick's model to calculate the return on investment generated by learning. Thus a corporation cannot ultimately measure ROI in isolation; it must base it on measurements gathered at the four preceding levels.

Evaluation is aided by using a question and answer methodology:

Level I – “What are participants’ reactions to the learning and what do they plan to do with the material?” Learners measure this answer with surveys or questionnaires that measure whether the learning was meaningful or enjoyable. These surveys should also include sections on how the employee plans to implement the lessons learned.

Level II – “What skills, knowledge, or attitudes have been changed or acquired and to what extent?” Achievement tests measure how well the employee learned the information or skill presented.

Level III – “Did participants apply what they learned to their jobs?” Observer ratings and observations measure the degree to which the employee applies what he or she has learned. Observers (usually managers and supervisors) must be thoroughly informed in the evaluation system. Managers need to establish a system for leveling out the inconsistencies between observers’ judgment.

Level IV – “Did this on-the-job application produce measurable results?” These results may include increases in productivity and efficiency, decreases in absenteeism and occupational accidents, decreases in customer complaints, etc. Isolating the effects of learning from other variables that produce an effect in these areas, either through statistics or by using a control group, is vital to getting a clear picture of ROI.

Level V – “Did the monetary value of the produced results exceed the cost?” This is the measurement of ROI, which can be calculated in several ways.

The fifth level gets down to quantify the actual return on a company's monetary investment in learning and requires a mathematical formula to determine an answer. Evaluation experts have developed three common formulae for measuring learning ROI, each reflecting a different concept of what a company's return on learning investment can be:

(1)  $TACFP - TACNP = PNS$ . Subtracting the total administrative costs of the new e-learning program

(TACNP) from those of the former traditional learning program (TACFP) gives the projected net savings (PNS) for learning administration. Although cost savings are certainly important, ROI encompasses much more than just that.

(2)  $TCL / \text{number of students} = CPS$ . Dividing the total cost of learning (TCL) by the number of students gives the cost per student (CPS) of the learning. This is useful, but again is not a true measure of return on investment. Both formulae, although frequently cited as measures of return on investment, do not measure what monetary value or profit is derived from learning investment.

(3)  $TB (\text{in\$}) / TLC = ROI\%$ . Dividing the total benefits (TB) of learning in dollars by the total learning program cost (TLC) gives the percentage of ROI in a program. To calculate this formula and get a percentage of ROI, we must determine the tangible benefits of learning and assign a monetary value to benefits such as:

Increase in productivity (units produced, items sold, forms processed, tasks completed, etc.); Improvement in quality (less scrap, less waste, less rework of product, fewer defects, etc.); Reduction in staff turnover; Reduction in lost-time injuries; Reduction in workers' compensation insurance claims; Increase in customer satisfaction as reflected in an increase in repeat sales.

These benefits are often called measurable benefits because the results can be converted easily into a monetary value. Other benefits such as improved communication, enhanced corporate image, improved conflict resolution, increased sensitivity to human diversity, improved employee morale and increased employee loyalty are intangible benefits and more difficult to convert into a monetary value.

With so many benefits to its credit, a company's learning investment should not end up only on the expense side of the balance sheet, ready for budget slicing. By measuring the results of learning carefully and tying learning to strategic metrics used to measure business success, the return on investment from learning can be demonstrated to the company decision makers.

## 5. GUIDELINES OF IMPLEMENTING E-LEARNING

Many companies have recognized the value of e-learning and view these efforts as an investment in the company's future. Everyone knows a well-educated workforce is vital to a company's success.

### 5.1 Decision-making

To successfully implement e-learning, first determine how it fits into the organization's needs. Identify needs, articulate how technological tools can help meet those needs, then search for content that's appropriate for the learning's intended purpose. Consider creating a team of

stakeholders to facilitate decision-making that seeks to design a consistent e-learning strategy. To best understand learning needs throughout organization, the team should include representatives from all divisions of the organization.

Create a strategic implementation plan. At first, the organization may have to focus on one of needs rather than tackling every suggested learning issue. Prioritize learning initiatives, create phases and articulate evaluation guidelines to ensure successful implementation from an educational and business perspective.

Once the value of and appropriate use for e-learning are well defined, focus on technological and content-related decisions. First, determine if there's already an e-learning program in place. If e-learning isn't currently in place, articulate necessary performance requirements to guide the search for an appropriate solution.

From a technological perspective, a key component to launch a successful e-learning strategy includes an understanding of learning-management systems and the environment in which e-learning will be carried out. Many e-learning providers offer learning-management systems for different end users. Some are simply technological platforms or structures within which an organization can house its own content, others come with content components.

Before determining the actual technological components, consider content availability. Question each e-learning provider about the kind of content its platform offers and if the content is included in the implementation cost or if it's extra. Also inquire if other content can be added to the platform. These steps will ensure that the platform meets both technological and content requirements.

## 5.2 Implementation

To generate interest, market the program by demonstrating how employees will benefit from its availability. Provide information explaining the efficiencies and increased productivity that will ultimately be realized from the learning. These efforts will help generate a target around the initiative that'll see it through to a successful implementation.

To augment learning benefits, a blended-learning approach, which combines e-learning with traditional classroom instruction, can be used. The e-learning program can serve as the theoretical foundation upon which participants can build specific skills, either within a classroom or lab setting (Rosenberg, 2001). Such a model capitalizes on the benefits offered by e-learning and optimizes education with face-to-face activities that can accommodate various learning styles, provide social interaction, and focus on communicating.

To create a blended-learning approach, simply determine what tasks can be performed electronically, which ones need a face-to-face or hands-on approach, and how to mix the two. Educational outcomes may remain the same as those articulated for the current construct or modified for the new model. Blended-learning environments may enhance educators' effectiveness, enabling them to use time previously spent delivering basic educational content to focus on specific learning needs of each student.

## 5.3 Evaluating procedure

Now consider numerous issues about ROI evaluation. Although generally difficult to measure, several direct costs are easy to quantify, such as the number of students, the number of instructors needed. Also calculate the cost of copying handouts, resources such as textbooks, fees charged by the providers, and any travel or room rental expenses.

To begin the evaluation process, quantify the direct and indirect costs for each student. Then quantify costs associated with the educator presenting the learning. The educator's total savings in time and salary is the combined totals of the time and money saved in preparation and teaching. If the educator doesn't spend time preparing for and teaching the basic part of the courses, then he or she can dedicate that time to other educational activities while the learner still acquires the fundamental knowledge via the e-learning solution. Hence, the educator's productivity is increased, effectively doubling his or her educational output. In addition, be sure to include indirect costs necessary to implement e-learning.

The benefits of e-learning include employees' satisfaction level and such business efficiencies as cost and/or time reduction gained by its implementation (Raths, 2001). After calculating total costs and benefits, we can use those formulae mentioned in the previous section to evaluate the e-learning program.

Maybe it is necessary to evaluate whether or not participants are achieving competencies at the same or higher levels than with instructor-led classroom learning.

## 6. CONCLUSION

The e-learning provider has little control over the external environment in which it operates, and so it is necessary to continually assess this environment and to adapt its e-learning product or services accordingly. Market demand, political and legal forces, social and ethical influences, technology and competition are five main forces affecting e-learning provider's strategy. From conducting a thorough analysis, providers can identify which customers to target and where their product or services will be best positioned.

Before initiating an e-learning project, end user needs to understand what e-learning is good at and not so good at. Doing this will help user find out where it needs help, and where it can manage perfectly well on its own. The paper also explores the greater benefits of an e-learning initiative and offers a number of formulas for calculating the ROI and justifying the cost. At last, the guidelines of implementing e-learning project were discussed.

# A High Performance XML Querying Architecture

Fangju Wang, Hui Shen

Department of Computing and Information Science, University of Guelph  
Guelph, Ontario, Canada, N1G 2W1

## ABSTRACT

Data exchange on the Internet plays an essential role in electronic business (e-business). A recent trend in e-business is to create distributed databases to facilitate data exchange. In most cases, the distributed databases are developed by integrating existing systems, which may be in different database models, and on different hardware and/or software platforms. Heterogeneity may cause many difficulties. A solution to the difficulties is XML (the Extensible Markup Language). XML is becoming the dominant language for exchanging data on the Internet. To develop XML systems for practical applications, developers have to address the performance issues. In this paper, we describe a new XML querying architecture that can be used to build high performance systems. Experiments indicate that the architecture performs better than Oracle XML DB, which is one of the most commonly used commercial DBMSs for XML.

**Keywords:** XML, database, index, query processing

## 1. INTRODUCTION

In recent years, the needs for Internet data exchange between organizations have grown rapidly, especially in electronic business (e-business). For example, in e-business of B2B (business to business), companies may offer customers and partners to access their databases for information about their products and services. Brokers or consultants may need to process data from databases of many companies for best satisfying client requirements. There has been a trend in e-business to integrate existing stand-alone databases into distributed databases for facilitating data exchange.

XML (Extensible Markup Language) is becoming a major markup language for data exchange on the Internet. The language is especially useful in developing heterogeneous distributed databases, in which databases in different models, and/or on different kinds of platforms are combined into integrated systems. With XML, data from heterogeneous sources can be encoded as XML documents, transmitted on the Internet, and processed together. It has been widely accepted that XML is an indispensable tool in e-business, and that e-business cannot develop well without it.

Performance is a key issue in building a successful XML-based database. The querying techniques for the traditional relational databases were developed to manipulate record sets. High performance of the techniques is achieved by efficient read/write, search, and partitioning of records. However, XML documents are structured as hierarchical trees of nodes, which are essentially different from the table and record structures of the relational data. The querying techniques developed for relational data cannot be directly adopted for XML data. The special features of XML data require new techniques for querying XML data. Currently, research on querying techniques for XML data, including indexing and querying processing,

is still at the preliminary stage. At the time of this writing, there have been no broadly accepted querying techniques XML databases.

In this paper, we describe a new querying architecture, which consists of three indexes, a block parser, and two query processing algorithms. Experiments indicate that the architecture may perform better than Oracle XML DB, one of the most commonly used commercial DBMSs for XML data.

## 2. RELATED WORK

The related work includes XML data indexing and query processing for XML databases. Most papers about XML indexes focus on building path indexes on XML documents. In [3], an adaptive path index, APEX, is proposed to keep all paths to improve query performance. Ashraf and co-workers proposed two techniques: path tree and Markov tables [1]. They build a path tree to ensure that it fits in memory by deleting low-frequency nodes. Path information is contained in the Markov table.

In the work by Li [6], the index structure is composed of three major components: element index, attribute index and structure index, all of those indexes are based on a numbering scheme. For most index structures for XML data proposed so far, update is a problem because XML element's coordinates are expressed by absolute values. In [5], Kha proposed an indexing structure based on the relative region coordinate that can effectively deal with the update problem.

The existing indexing techniques have major disadvantages. The most severe ones are that the sizes of indexes are very big and the time for building indexes for large XML documents may be very long. For example, in Lore, the total size of the indexes on an XML document of 465 megabytes is 2.2 times larger than the original file size and the time for

## 4. QUERY PROCESSING ALGORITHMS

In this section, we describe the algorithms based on the indexes for achieving high querying performance.

### 4.1 Block identification algorithm

The block identification algorithm is used to find the disk blocks containing a given element. The algorithm compares the element's StartEID and EndEID pair with each block's tag information in the block index. In this algorithm, variable *StartBlock* is used to represent the block containing the tag with StartEID and variable *EndBlock* is used to represent the block containing the tag with EndEID. Either *StartBlock* or *EndBlock* is the sequential block number assigned to a block in the block index. The input of this algorithm is the StartEID and EndEID pair of the element to be found, the output is the *StartBlock* and *EndBlock* pair of the block(s) to read. The content of the element crosses over the blocks between *StartBlock* and *EndBlock*.

### 4.2 Block parser

After the block or blocks containing a given element are read from the disk, we need a special parser to parse the content in the blocks to get the element. This parser is the *block parser*. Along with the block index, the block parser allows an element to be retrieved quickly.

There are two popular XML parsers: SAX and DOM. Both have to scan the entire document from the beginning to end. Scanning XML documents is usually costly. The block parser only parses the contents of the blocks of interests instead of scanning the whole document. It thus helps minimize the I/O costs in retrieving elements.

In the block parser, an *EID counter* is defined to trace the element ID assigned to every element's tag and a *step stack* is defined to trace the element's name in the block. The block parser initializes the EID counter and the step stack by the tag's information recorded in block index.

The blocks to be parsed are a sequence of blocks between *StartBlock* and *EndBlock*. The parsing is started from the first character in the first of those blocks. When the block parser reads a start tag, it pushes the element's name in that tag as a step onto the top of the step stack. When the block parser reads an end tag, it pops up the step from the top of the step stack. There is an exception: when the first tag is a start tag, block parser ignores it and does nothing.

A path, here called *stack path*, can be built by connecting the steps from the bottom to the top in the step stack. Every time after pushing an element's name to the step stack, the block parser builds a stack path and looks up for PID in path index for the stack path. Here, the PID is called *stack PID*. If the stack PID is

among the PIDs of the source nodes in the query trees, the block parser stores the content between the current start tag and its matching end tag into a buffer in main memory or to temporary files on disk.

### 4.3 Single-root query algorithm

We categorize XML queries into the *single-root queries* and *multi-root queries* and apply different algorithms to process them. In the following discussion, the queries are represented in the Xquery language. A query has a For clause, a WHERE clause, and a RETURN clause.

In a single-root query, there is only one variable defined in the FOR clause that can serve as the root of all the paths referenced in the query. *Source elements*, which are elements referenced in the WHERE clause, must be processed in the scope of root elements. Source elements in different root element scopes cannot be processed together. The result of the operation can be generated within the scope of every root element.

First of all, the PID assigned to the root node is used to obtain the first StartEID and EndEID pair from the element index. The first root element's scope can be built by the StartEID and EndEID pair. Then, the PID assigned to every source element is used to read the corresponding element index. By an algorithm for determining the "ancestor-descendent" relationships, every source element's StartEID and EndEID pair is compared with the root element's scope and then all source elements' StartEID and EndEID pairs in the current root query element's scope are decided.

Through the "Block Identification Algorithm", the exact blocks containing a desired source element in the WHERE clause can be identified. The content of these blocks can be read and parsed by the block parser to fetch the content of that element to a buffer. When all the source elements in the WHERE clause are fetched, the query condition is evaluated. When a set of source elements satisfies the query condition, the blocks containing the associated elements in the RETURN clause are identified. The content of the blocks are parsed and values of those elements are output as the result immediately. Figure 2 is the diagram illustrating this algorithm.

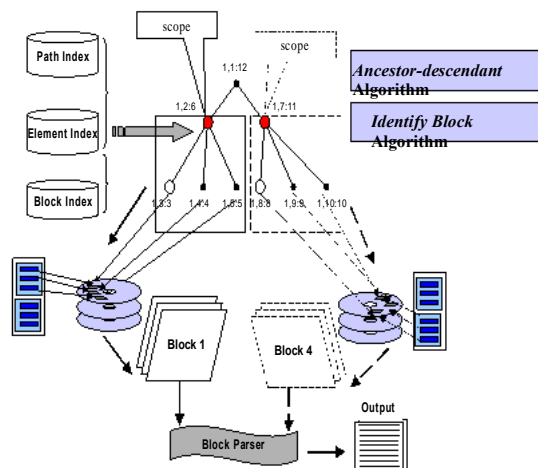

Figure 2. Single-root query algorithm

#### 4.4 Multi-root query algorithm

In a multi-root query, there are more than one variable defined in the FOR clause that can serve as roots of the paths referenced in the WHERE and RETURN clauses. The multi-root query algorithm is more complicated than the single-root query algorithm. Roughly a multi-root query is similar to a join query in the relational data model. A join operation is related to two root element classes. In the following, “A” refers to the first of the two root element classes and “B” refers to the second root element classes. A source element class in the WHERE clause is called *WHERE element class*. The element in a WHERE element class is called a *WHERE element*. A WHERE element class is always associated with root element class “A” or “B”. The join operation is performed by comparing a WHERE element within the scope of an element of “A” with all the WHERE elements within the scopes of all the elements in “B”.

We can use an element class’s PID to get its element index. From A’s element index, we can get the scope of each element by its StartEID and EndEID pair. We can get a WHERE element with a StartEID and EndEID pair within this scope through the algorithm for determining the ancestor-descendent relationship. Then the blocks containing the WHERE element can be identified by the Block Identification Algorithm. The WHERE element can be fetched by using the block parser. And then the fetched WHERE element and this scope are stored together into a value set.

The procedure is conducted on all the pairs of WHERE elements. At a point of time we can get two sets of WHERE elements. The first contains the WHERE elements within the scope of an element in “A”. The second contains the WHERE elements within the scope

of an element in “B”. We execute the query operation on these two sets of WHERE elements. The join operation would be executed by comparing every WHERE element in the first set with all WHERE elements in the second set.

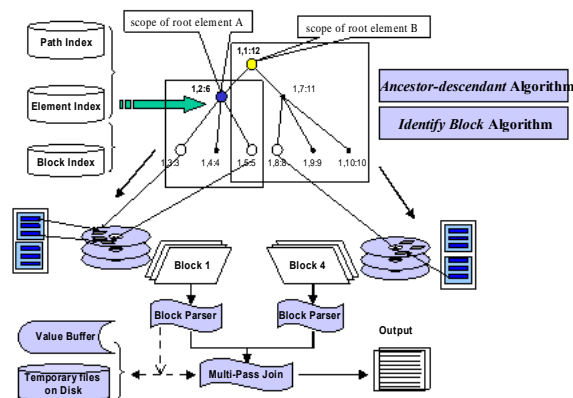

Figure 3. Multi-root query algorithm

When the join condition is satisfied by a pair of WHERE elements, the pair of the corresponding root element’s scopes is recorded as an *intermediate root scope pair*. The two scopes in an intermediate root scope pair represent the root element in “A” and in “B” respectively, and hereafter called *intermediate scope A* and *intermediate scope B* respectively. After the execution of the join operation, we can get a set of intermediate root scope pairs.

Every source element class in the RETURN clause (here, called *RETURN element class*) is associated with a query node in the query tree with its associated root query element class “A” or “B”. The element in a RETURN element class is called *RETURN element*. Only the RETURN element in either an intermediate scope A or B is *valid* for the output. Figure 3 shows the multi-root query algorithm.

## 5. EXPERIMENTS AND RESULTS

In this section, we describe the experiments and present experimental results.

### 5.1 Test environment

The computer used for the experiments is a desktop station with a 2.0 GHz Intel Celeron IV processor, 512 MB RAM and a 120 GB Seagate hard disk. The querying architecture is implemented in the C language on Linux 7.3. For comparison, the same queries are executed in Oracle XML DB, which is installed on Windows 2000. Both the Windows and Linux operating systems are on the same machine.

The test data are from Oracle. They are XML documents of sizes of about 3, 8, 10, 30, 60, 100, 300,

and 600 megabytes, on a schema of “purchasing orders”. For each document, we examine the total size of indexes and the time for creating indexes in both our system and Oracle XML DB. A set of queries are applied to the data. The queries are used to perform operations of selection, equal join,  $\theta$ -join on the data. The time required by both systems are recorded and compared.

## 5.2 Experimental results

### 5.2.1 Building indexes

Figure 4 Space used by the two systems.

A path index is a memory structure that is generated by parsing the schema. Generally the size of a schema is very small, so we ignore the time for parsing a schema to create the path index. The time spent on building the other two indexes is significantly affected by the time for parsing the document and the time for writing element index and block index to disk.

Figures 4 and 5 gives the comparison of the space usage in Oracle and our system, and the time required by the two system to organize data and create indexes. Our system needs 20% to 40% of the time by Oracle XML DB and more space when data sizes are big.

Figure 5. Time required by the two systems.

### 5.2.2 A query of selection

The following query is designed to select an element and retrieve its parent as well as all the children of the parent element. This is a single-root query.

For \$c in document("PurchaseOrder.XML")/PurchaseOrder/  
Where \$c/Reference="ADAMS-20011127121040988PST"

Figure 5. Comparison of the time for executing the selection query.

Figure 5 illustrates the response time for evaluating the selection query with XML documents of different sizes in both Oracle XML DB and our system. The results indicates our system is faster than Oracle XML DB when executing such a query.

### 5.2.3 A query of document join

The following is a query for joining two XML documents. The WHERE clause includes an equality condition. Element pairs satisfying the condition are selected and the number of the elements in one of the classes are returned as query results.

For \$c in document("PurchaseOrder1.XML") /Purchase  
Order/,  
\$d in document("PurchaseOrder2.XML")/Purchase  
Order/ShippingInstructions  
Where \$c/Requestor=\$d/Name  
Return DISTINCT({\$c/Requestor})

Figure 6 shows the experimental results in testing this query. The time required by our system is basically proportional to the document size. For most of the documents, our system performs better than Oracle XML DB. Since we have no knowledge about how exactly Oracle handles the data, we are unable to explain the behavior of Oracle.

Figure 6. Comparison of the required for executing the join query.

## 6. CONCLUSION

In this research, we develop a novel architecture for querying XML data. The core of this architecture includes the block index and block parser, which overcome disadvantages of the existing general purpose indexing systems: large sizes and long creation time. Based on the indexing system, a set of algorithms can achieve high performance in evaluating queries. Experiments indicate that the system implementing the architecture requires less time to create the indexes than the time by Oracle XML DB to load the same files. Our system is 2 to 12 times faster than Oracle XML DB. For most of the test data, our system is faster than Oracle XML DB in executing the same queries. Our system requires only 0.5 % to 50% of the time required by Oracle XML DB to evaluate the same test queries.

### ABSTRACT

Support Vector Machines(SVMs) have succeeded in many classification fields. Some researchers have tried to apply SVMs to Intrusion Detection recently and got desirable results. By analyzing C-SVM theoretically and experimentally, we found that C-SVM had some properties which showed C-SVM was not most suitable for Network Intrusion Detection. First, C-SVM has different classification error rates on different classes if the sizes of training classes are uneven. Second, C-SVM is over-dependent on every training sample, even if the samples are duplicated. Third, C-SVM does not make a difference between training samples. According to these characteristics of C-SVM and the fact that the size of network normal data is always much larger than that of intrusion data and the fact that the importance of attack data is different from each other, an extended C-SVM, termed weighted C-SVM is proposed in this paper. Weighted C-SVM introduces two parameters, class weights and sample weights. Class weights are used to adjust false negative rate and false positive rate of each intrusion class. And sample weights are used to emphasize importance of some intrusion samples. Experiments showed that Weighted C-SVM was more effective than C-SVM in network intrusion detection systems.

### 1. INTRODUCTION

With the rapidly increasing connectivity and accessibility to the Internet, network security has been paid more and more attention to. Intrusion detection systems are considered an effective measure against network attacks. Intrusion is generally defined as violating confidentiality, integrity and availability of computer or computer network system[1]. The kernel of intrusion detection is to extract the behavior model of networks. Currently, many methods have been applied to create intrusion detection model, including Neural Networks, Data Mining, and so on[2]. All these methods learn on training data sets first to create detection model, and then use the detection model created by learning process to monitor future behaviors of network. Intrusion detection is a classification problem in nature. It classifies the network behavior to normal class and attack class, or normal class and attack classes. The previous is a binary classification problem and the other is a multi-class classification problem.

Support vector machines are canonized by many researchers and have been applied to many classification fields successfully. The advantages of SVMs over conventional classification methods are its high generalization ability especially if the number of training data is small, its adaptability to various classification problems by changing kernel functions, and its global optimal solution. Recently, some researchers began to apply SVM technology to intrusion

detection. Mukkamala, et al.[3] described approaches to intrusion detection using support vector machines and demonstrated that efficient and accurate classifiers can be built to detect intrusions using SVMs. They also compared the performance of neural networks based and SVM based systems for intrusion detection, and concluded that at the same level of accuracy, the training time for SVMs was significantly shorter, and running time of SVMs was also notably shorter. They also used SVMs in feature ranking and selection for intrusion detection systems[4] and identifying key variables for intrusion detection [5]. In these papers, they did only binary classification experiments, and got very desirable results. John S. Baras and Maben Rabi[6] used SVMs to detect intrusion on a host computer system. In order to handle variable-length strings, the approach combined the ability of an HMM generative model. Ming Luo, et al.[7] and Fugate, et al. [8] used unsupervised clustering and support vector machines to anomaly detection. Other works on applications of support vector machines on intrusion detection can be found in[9],[10],[11],[12].

Figure 1. Principle of support vector machines

## 2. SUPPORT VECTOR MACHINES

Support Vector Machines, proposed by Cortes and Vapnik[13][14], is a relative new machine learning methodology based on statistical learning theory. This support vector machine is considered as the standard support vector machine and C-SVM[15][16]. Its basic idea is to find the hyperplane which can separate data belonging to two classes with maximum margin. This hyperplane is called optimal hyperplane. Figure 1 shows the principle of SVMs.

In Figure 1, the points marked with rectangles are Support Vectors (SVs), which determine the hyperplane and the margin. In the case of nonlinear separation, SVMs use a map  $f: X \rightarrow H$  to transform each data point  $x$  to  $f(x)$  in higher dimensional feature  $H$  so that the data points can be separate linearly more probably.  $X$  is called input space, and  $H$  is called feature space. If  $f(x)$  can not separate linearly in  $H$ , then SVMs find a hyperplane in  $H$  that minimize the error cost. This kind of hyperplane is called optimal hyperplane.

### 2.1 C-Support Vector Machine

Given  $Z = \{(x_i, y_i) | x_i \in \mathbb{R}^n, y_i \in \{+1, -1\}, i = 1, 2, \dots, m\}$  set of samples, where  $x_i$  is a data vector,  $y_i$  is the label of the class that  $x_i$  belongs to. In order to seek the hyperplane that best separates the two classes from each other with the widest margin, we need to solve the following optimization problem[14]:

$$\min_{w, b} \Psi(w, b) = \frac{1}{2} \|w\|^2 + C \sum_{i=1}^m \xi_i, \quad (1)$$

$$\text{s.t. } y_i(\langle w, x_i \rangle + b) \geq 1 - \xi_i \quad (2)$$

$$\text{and } \xi_i \geq 0, i = 1, \dots, m. \quad (3)$$

Where  $w$  is a normal vector of the hyperplane  $\langle w, x \rangle + b = 0$ ,  $b$  is the bias of the hyperplane,  $C$  is a penalty factor that determines the tradeoff between the maximization of the margin and the minimization of error cost,  $\langle w, x \rangle$  denotes dot product of  $w$  and  $x$ , each  $\xi_i$  is a slack variable that denotes the distance from  $x_i$  to margin plane  $\langle w, x \rangle + b = y_i$ . In order to separate data more precisely, we use a map  $f: X \rightarrow H$ ,

where  $H$  is a higher dimensional space. Taking into account the compute complexity, we select a kernel function  $k(x, x') = \langle \phi(x), \phi(x') \rangle$ . Introducing Lagrange multipliers  $a_i$  and  $b_i$ , we have:

$$L(w, x, b, a, b) = \frac{1}{2} \|w\|^2 + C \sum_{i=1}^m a_i x_i - \sum_{i=1}^m [a_i (y_i (\langle w, f(x_i) \rangle + b) - 1 + \xi_i) + b_i \xi_i]. \quad (4)$$

This function has to be minimized with respect to the primal variables  $w, x, b$ , and maximized with respect to the dual variables  $a_i, b_i$ . To eliminate the former, we compute the corresponding partial derivatives and set them to 0, obtaining:

$$\frac{\partial L}{\partial w} = w - \sum_{i=1}^m a_i y_i f(x_i) = 0, \quad (5)$$

$$\frac{\partial L}{\partial b} = - \sum_{i=1}^m a_i y_i = 0, \quad (6)$$

$$\frac{\partial L}{\partial x_i} = C - a_i - b_i = 0. \quad (7)$$

Substituting (5), (6) and (7) into  $L$ , using  $b_i \geq 0$ , and incorporating kernels for dot products, we obtain the dual Lagrangian:

$$\max_{a, b} W(a) = \sum_{i=1}^m a_i - \frac{1}{2} \sum_{i, j=1}^m a_i a_j y_i y_j k(x_i, x_j), \quad (8)$$

$$\text{s.t. } 0 \leq a_i \leq C, i = 1, \dots, m, \quad (9)$$

$$\text{and } \sum_{i=1}^m a_i y_i = 0. \quad (10)$$

where  $a_i, i=1, \dots, m$ , are Lagrange multipliers. If  $a_i > 0$ , then  $x_i$  lies on or in margin, and  $x_i$  is called a standard support vector. If  $0 < a_i < C$ , then  $x_i$  lies on margin, and  $x_i$  is called a in-bound support vector. If  $a_i = C$ , then  $x_i$  lies in margin or misclassified, and  $x_i$  is called a bounded support vector[15]. By solving the above dual Lagrangian, we obtain:

$$w = \sum_{i=1}^m a_i y_i f(x_i). \quad (11)$$

To Compute  $b$ , we take into account that due to KKT conditions, for in-bound support vectors for which  $\xi_i = 0$ , constrain (2) becomes

$$\sum_{i=1}^m y_i a_i k(x_i, x_j) + b = y_j. \quad (12)$$

Thus,  $b$  can for instance be obtained by averaging

$$b = y_j - \sum_{i=1}^m y_i a_i k(x_i, x_j). \quad (13)$$

over all data with  $a_i > 0$  [15]. The resulting decision function can be shown as

$$f(x) = \text{sgn}\left(\sum_{i=1}^m y_i a_i k(x_i, x) + b\right). \quad (14)$$

From (14), we know that using SVMs to classify new data need not to compute  $w$  after training SVMs. In most cases, we don't know the map  $f$ . After training SVMs, we store kernel function  $k_{x_i}$  which is nonzero and corresponding  $y_i, x_i$ , or store kernel function  $k_{a_i, y_i}$  and corresponding  $x_i$ . When a new data point needs to be classified, we can use these stored values and decision function (14) to classify.

## 2.2 Analysis of C-SVM

In C-SVM, the KKT condition is:

$$a_i(y_i(< w f(x) > +)b - 1) x = 0 \quad (15)$$

$$b_i x_i = (C - a_i) x_i = 0. \quad (16)$$

Therefore, there are three cases as follows:

- 1) If  $a_i = 0$ , according to (16), then  $x_i = 0$ .  $x_i$  is correctly classified.
- 2) If  $0 < a_i < C$ , according to (15) and (16), then  $y_i(< w f(x) > +)b - 1 = 0$  and  $x_i = 0$ .  $x_i$  is a in-bound support vector.
- 3) If  $a_i = C$ , according to (15) and (16), then  $y_i(< w f(x) > +)b - 1 = 0$  and  $x_i \neq 0$ .  $x_i$  is a bounded support vector. If  $0 < x_i \leq 1$ ,  $x_i$  is correctly classified. If  $x_i > 1$ ,  $x_i$  is misclassified.

Suppose  $N_{BSV+}, N_{BSV-}$  are the number of bounded support vectors in positive class and negative class respectively, and  $N_{SV+}, N_{SV-}$  are the number of support vectors in positive class and negative class respectively, and  $m, m$  are the number of data points in positive class and negative class respectively. According to (10), we have:

$$\sum_{i=1}^m a_i = \sum_{i=1: y_i=+1}^m a_i + \sum_{i=1: y_i=-1}^m a_i. \quad (17)$$

$$\sum_{y_i=+1} a_i = \sum_{y_i=-1} a_i. \quad (18)$$

$$N_{BSV+} \sum_{y_i=+1} a_i = \sum_{y_i=+1} a_i. \quad (19)$$

$$N_{SV+} \sum_{y_i=+1} a_i = \sum_{y_i=+1} a_i. \quad (20)$$

Incorporating (19) and (20), we have:

$$N_{BSV+} \sum_{y_i=+1} a_i = N_{SV+} C. \quad (21)$$

Similarly, we can obtain:

$$N_{BSV-} \sum_{y_i=-1} a_i = N_{SV-} C. \quad (22)$$

Dividing (21), (22) by  $C \times m$  and  $C \times m$  respectively,

and supposing  $\sum_{y_i=+1} a_i = \sum_{y_i=-1} a_i = A$ , we obtain:

$$\frac{N_{BSV+}}{m} \neq \frac{A}{C \times m} \quad \frac{N_{SV+}}{m}. \quad (23)$$

$$\frac{N_{BSV-}}{m} \neq \frac{A}{C \times m} \quad \frac{N_{SV-}}{m}. \quad (24)$$

From (23) and (24), we know that:

- 1) If  $m_+ = m_-$ , the fraction of bounded support vectors and fraction of support vectors in positive class is equal to that in negative class.
- 2) If  $m_+ > m_-$ , the fraction of bounded support vectors and fraction of support vectors in positive class is less than that in negative class.
- 3) If  $m_+ < m_-$ , the fraction of bounded support vectors and fraction of support vectors in positive class is greater than that in negative class.
- 4) Omitting any data point, even if it is a duplicated data point, will influence the result of classification.

Besides the four above characteristics, we can know intuitively C-SVM has other characteristics as follows:

- 5) If the training set has duplicated samples, there would be more duplicated support vectors. In this case, classification will be slower.
- 6) C-SVM does not take different importance of training samples into account. This would result in misclassification of important samples.

According to the characteristics analyzed above, we can conclude that C-SVM is not most suitable to intrusion detection. In intrusion detection, the training sets generally contain more normal samples than attack samples and contain many duplicated samples. New SVMs overcoming the shortcomings of C-SVM are needed.

## 3. WEIGHTED C-SUPPORT VECTOR MACHINE

In this section, we propose a novel C-SVM, termed weighted C-SVM, WC-SVM for short. The primal question in WC-SVM is

$$\min (w, \xi, \rho) = \frac{1}{2} \|w\|^2 + \mu \sum_{i=1}^m \xi_i, \quad (28)$$

$$\text{s.t. } y_i(< w, x > +)b \geq -\xi_i, \quad (29)$$

$$\text{and } \xi_i \geq 0, i = 1, \dots, m. \quad (30)$$

Where  $\mu_{y_i} \geq 1$  is the weight factor of class  $y_i$ ,  $\xi_i > 0$  is

the important factor of data point  $i$ . The bigger  $i$  is, the more important  $i$  is. The primal question in WC-SVM is same as that of C-SVM if each  $\mu_{y_i}$  is specified

to 1. Comparing (1) and (28), we can understand the meaning of  $\sum \xi_i$  in (28).  $\sum \xi_i$  in (28) is practical cost of errors, and that  $\sum \xi_i$  in (1) is geometric cost of errors.

With method same as that in C-SVM, we can obtain dual Lagrangian:

$$\max W(a) = \sum_{i=1}^m a_i - \frac{1}{2} \sum_{i,j=1}^m a_i a_j y_i y_j k(x_i, x_j) \quad (31)$$

$$\text{s.t. } 0 \leq a_i \leq C \mu_{y_i}, i = 1, \dots, m \quad (32)$$

$$\text{and } \sum_{i=1}^m a_i y_i = 0. \quad (33)$$

The decision function is

$$f(x) = \text{sgn} \left( \sum_{i=1}^m y_i a_i k(x, x_i) + b \right). \quad (34)$$

With analysis method same as in C-SVM, we have:

$$\frac{N_{BSV+}}{m_+} \# \frac{A}{C \sum_{y_i} \xi_i m_+} \frac{N_{SV+}}{m_+}. \quad (35)$$

$$\frac{N_{BSV-}}{m_-} \# \frac{A}{C \sum_{y_i} \xi_i m_-} \frac{N_{SV-}}{m_-}. \quad (36)$$

We can control the upper bound on the fraction of margin errors and fraction of SVs of each class by tuning the parameter  $\xi_i$  and  $\xi_i$  in (35) and (36). We think this is useful and important in network intrusion detections. First, attack data is always much less than normal data in sample set. If C-SVM is used, error rate on attack data will be bigger than that on normal data. This is not expected if the attack data contains some data whose corresponding behavior is very harmful to network systems. Second, detection is needed to be real time to avoid attack. We know from (14) and (34) that the number of SVs influences the detection speed. Although C-SVM provides a mean to tune the tradeoff between fraction of margin errors and fraction of SVs, the mean tunes the tradeoff of attack data and normal data simultaneously. In practice, we prefer tuning the tradeoff of each class independently to tuning the tradeoff of each class simultaneously. WC-SVM has advantages over C-SVM in these aspects apparently.

Moreover, attack behaviors do different harms to network systems. Some behaviors harm the systems seriously, and others do slightly. Some new behaviors are very harmful, and we expect IDS can detect them as long as the training sample set contains the data corresponding to them. If the data corresponding to the new harmful behaviors is very sparse in training set, C-SVM would misclassify them. This will result in false negatives in IDS. We introduce an important factor for every train sample in WC-SVM in order to handle this case. If some data in training set is important, we can assign a big value to their corresponding  $\xi_i$ s, otherwise, we can assign a small value to their corresponding  $\xi_i$ s.

#### 4. EXPERIMENTS

In this section, we use some experiment results to compare C-SVM and WC-SVM. Experiments on C-SVM were done with libsvm[17], and experiments on WC-SVM were done with a new program based on libsvm. Training samples and testing samples were selected randomly from KDD'99 data[18]. The kernel function used is RBF. Results of experiments are shown in Table 1, Table 2 and Table 3.

In Table 1, MR, NC, AC, NS denote Margin Errors, Normal Class, Attack Class and the Number of SVs

respectively. In Table 2, FNR, FPR denote False Negative Rates and False Positive Rates respectively. In Table 3, NCAS, NMNST, IFNS denote the Number of Changed Attack Samples, the Number of Misclassified New Samples in Training, Important Factor of New Samples respectively.

Table 1. Results of training experiments

Experiment No.	1	2	3
Number of Attack Data	1000	100	500
Number of Normal Data	1000	2000	3000
C-SVM	C	1000	1000
	Time(Seconds)	3.30	1.48
	ME of NC	0	14
	ME of AC	103	18
	NS in NC	196	115
WC-SVM	NS in AC	118	47
	C	1000	1000
	$\mu_{+1}$	1	1
	$\mu_{-1}$	10	20
	$s_i$	1	1
	Time(Seconds)	65.51	3.645
	ME of NC	120	50
	ME of AC	0	0
	NS in NC	215	168
	NS in AC	43	21

Table 2. Results of test experiments

Experiment No. of Model	1	2	3
Number of Test Samples	2000	2000	2000
C-SVM	Time(Seconds)	2.53	1.16
	FNR(%)	100	75.60
	FPR(%)	0.19	8.34
WC-SVM	Time(Seconds)	1.64	1.39
	FNR(%)	93.40	25.32
	FPR(%)	13.04	56.60

Table 3. Results of test experiments on samples with important factors

Experiment No.	1	2	3
NCAS	10	15	20
Number of Test Samples	2000	2000	2000
C-SVM	NMNST	2	2
WC-SVM	IFNS	10	20
	NMNST	1	0

From results of experiments, we know that WC-SVM provide us means to adjust the correct rate and error rate of classification of each class and to emphasize the importance of each training sample.

#### 5. CONCLUSIONS

We have presented a new SVM termed WC-SVM. From the point of application, WC-SVM has advantages over C-SVM. We can not only specify a weight factor for each training set but also specify an importance factor for each data point. If a data point is misclassified, the penalty error in WC-SVM equals the product of the penalty error in C-SVM and the importance factor of this point and the weight factor of the class which this point belongs to. This results in lower misclassification rates of training classes which have bigger weight factors and results in less probability of misclassification of training samples which have bigger important factors. In our opinion, this idea is useful to

intrusion detection. This is because we always need different classification performance, and we need to run intrusion detection systems before we collect much attack data.

# Customers Confidence in E-Business: An Evaluation of Australian Practices A Case Study

**Daniel Chandran**

Faculty of Information Technology, University of Technology, Sydney, Australia  
noble@it.uts.edu.au

## ABSTRACT

Many Internet users perceive that there is a large risk to their privacy and security when they buy products and services or submit personal information online. Although the perception of risk may be greater than the actual risk, it is still a cause for concern. An e-business must address customers' perceived risk just as much as any actual risks. In other words, the issue of trust is fundamental as security and privacy issues are of major concern for many users. Customers are looking for security policies and procedures businesses are implementing and their responsibilities in keeping customer information secure.

This paper deals with trust e-businesses can create through their websites. A comprehensive set of criteria had been used to evaluate Web sources with a high level of meticulousness. Criteria include accuracy, authority, currency, scope, and relevance. A methodology has been developed and two main industries actively operating in e-business within Australia, namely, the Banking and Retail industries have been chosen. Under each industry, two businesses were identified and sources evaluated. It is presumed that using such criteria would help to gain customers confidence. Findings are reported.

**Keywords:** e-commerce, Privacy and Security, Trust, Evaluation Criteria.

## 1. INTRODUCTION

The Internet provides instant and universal access to a range of business sites. Any business that offers services through the Internet needs to be concerned about network security as it is being constantly attacked. A computer network system is exposed to potential threats from anywhere on the public network. Businesses need to protect against such threats and implement stringent security measures. Many Internet users perceive that there is a large risk to their privacy and security when they buy products and services or submit personal information online. Although the perception of risk may be greater than the actual risk, it is still an issue for concern. An e-business must address customers' perceived risk just as much as any actual risks. From the point of customers, they are concerned about the hackers who can gain access to steal their information.

Trust can be defined as faith or confidence in a person or organisation. The level of security depends on the nature of business and the risks involved. For example, a web site providing information on the products of a company may not require the same level of security as an online banking Website. An e-business must identify the security issues that would provide the business more confidence and better relationship among its customers.

In the last few years, e-commerce went through difficult path of decline. One of the reasons is that the customers were not sure about the design and security holes. E-business in Australia is widespread and delivering benefits to the national economy. This paper is written from the customers' point of view and tries to list the

ways through which the customers can evaluate the sources in terms of security and privacy before they can conduct any business online. Some frequently asked questions are:

- § How is the data protected once it is delivered to the e-business?
- § How are credit card transactions authenticated and authorized?
- § Can I trust this Website?
- § How can I best evaluate e-business information provided on the Internet?

When the customers are satisfied with the security measures provided by the business, they make frequent return visits to the web site or make repeat purchases from the web site. If they are not confident about the policies, the situation could change. Several customers research about a product on the website and purchase it offline. Customers may not understand the security policies described in the websites. In such a situation, how can they come to a conclusion whether a particular site is secure? It is important that users undertake a systematic approach to select sources, which they consider as secure. To exchange information through the use of technology, we must be certain that it is as safe as exchanging information face-to-face. In this study, numerous web searches were carried out to gather and select sources pertaining to businesses that offer online business in Australia and the information they provide to their customers.

A range of measures is required to inculcate confidence in customers to conduct business over the Internet.

Customers may have to evaluate sources with a high level of meticulousness, by using a comprehensive set of criteria. Criteria include Accuracy, Authority, Currency, Scope, and relevance. A methodology has been developed for this research and two main industries actively operating in e-business within Australia, namely, the Banking, and Retail industries identified. Under each category, two businesses were chosen and the sources evaluated. It is presumed that using such a set of criteria would help customers to gain confidence to choose and use a web site. Findings are reported.

## 2. AUSTRALIAN INTERNET USAGES

The intensity of Internet use by Australians is among the highest in the world. Australia ranks sixth in the world in terms of the total number of Internet users, despite its relatively small population (4). At the end of September 2003, total Internet subscribers in Australia numbered over 5.2 million, an increase of 135,000 (3%) from the end of March 2003. This modest increase follows the larger increases recorded in the previous two collections, 11% at the end of March 2003 and 8% at the end of September 2002. Majority of these were in the household market with over 3.9 million subscribers. Every second household has home Internet access. (5.9). Australian businesses earned A\$43 billion (USD24 billion) in online revenue from December 2000 to mid 2002 (5).

Australian firms using e-business are saving between one to five percent of ongoing costs, while 10 percent of the businesses save 15 percent or more. (*Allen Consulting Group, Built for Businesses, Australia's Internet Economy, June 2001*). Online purchases of Web services such as recruiting and banking are becoming increasingly popular. (*NUA Internet Surveys, 26 July 2002*). Australian B2B e-commerce transactions were worth \$6.2 billion in 2001 and likely to rise to \$87 billion by 2006 (*International Data Corporation March 2002 Report "Australia B2B eCommerce forecast, 2001-2006*). At the end of March 2002, the number of registered online banking users almost doubled to reach 5.23 million, up from 2.77 million in 2001. The total number of online transactions for the quarter ending March 2002 was 64.3 million, up 7 percent on quarter 1 of 2001 (*NUA Internet Surveys, 10 July 2002*). Usage of Internet banking has grown up to 36 percent in June 2003 from 15 percent in December 2000. Purchasing goods and services increased by 4 percent in June 2003 compared to 2000.(10).

Australian businesses and IT leaders representing medium and large organisations rate security as either "very important" or "important". IDC Survey reports, Governments, business and individuals are moving forward with a heightened sense of security and the inherent interdependent responsibilities. The study also revealed that investment in IT security is increasingly

being driven by strategic initiatives and less in response to security breaches to the organisation. Key drivers behind IT security investment are (i) Increased Internet and Intranet usage and (ii) Mobile computing

## 3. SECURITY STANDARDS AND POLICIES

The importance of security standardization and certification for e-commerce industry remains an important issue for businesses intending to conduct e-commerce over the Internet. Implementation of security systems must address threats on an ongoing basis. Standard security practices like ISO 17799 and AS/NZS/BS-7799 are used to prevent, detect and contain security breaches and obtain compliance certification. These standards cover critical aspects of good organisational security, which contains a comprehensive set of security controls to improve the level of security within any organisation. The standard is based on assuring integrity, availability, and confidentiality of information assets.

Security is not just the technology alone, but also having solid security policies and following ideal security practices. Without clear standard security policies and practices, e-commerce organisations will not be able to gain the trust of customers or business partners. Therefore the security needs will have to be provided as a set of centralized managed services ensuring corporate interface and information protection. As the e-commerce industry expands, the demands on security level also increases. Business requirements for security changes and the control to threats have to be addressed. It is better to utilise an approach based upon best practices, which has some form of track record, to prevent, detect and contain security breaches. Some security standards in practice serve as a single reference point for identifying a range of controls needed for most situations where information systems are used in industry and commerce.

The author experienced some limitations in gathering information relating to security breaches occurred due to security safeguards and inadequate security management. Hence, it is not possible to document specific scenarios and the measures taken to overcome such breaches. Data is collected through interviews, business websites, publications/white papers related to the issues concerning security and privacy. Though organisations are not willing to reveal previous security breaches, one could see the number of changes introduced in the security issues in the last few years.

## 4. EVALUATION METHODOLOGY

The triangular relationship between customer, e-business and data security is very simple and clear. In order to safely conduct business and exchange information through the use of technology, we still must be certain that it is as safe as exchanging information

face-to-face. As data loss and breach of privacy are serious concerns in e-trade, it is necessary for the customers to apply a few criteria to evaluate sources to reduce the risk of losing valuable information. In this paper, the author identified specific areas in e-business and evaluated the contents of these web sites. The study also helped in getting a broader understanding of data security adopted by businesses in Australia.

#### 4.1 Methodology

- § Defining the task
- § Selecting known businesses within the industries chosen
- § Selecting a set of criteria for evaluation
- § Evaluating the sources using the criteria
- § Writing a conclusive statement using the information gathered

#### 4.2 Defining the Task

To locate information, two types of industries actively operating in e-business, have been identified. They are

1. *Banking industry* - for its necessity of state-of-the-art security in all online transactions/transmissions

2. *Retail industry* – as it tends to operate on a smaller scale, and generally assumed to have less security.

#### 4.3 Selecting businesses within the industries chosen

Two major banks in Australia, namely, *Westpac Banking Corporation* and *Commonwealth Bank of Australia* were chosen for the Banking Industry. For Retail Industry, *Woolworths Home Shop*, a major super market and *Roses Only*, a leading online florist, were chosen.

#### 4.4 Selecting criteria to evaluate potential sources

The Three Basic criteria chosen to evaluate information security in e-commerce industry are:

- Confidentiality
- Integrity
- Availability

Confidentiality is ensuring that information is accessible only to those who are authorized to have access. Integrity is ensuring accurate, reliable and complete information protected from unauthorized alteration; and Availability is assuring information and associated assets accessible only to authorized users.

The above three criteria further elaborated into:

Criteria	Explanation
<b>Relevance</b>	How is this relevant to data security in eBusiness
<b>Authority</b>	Where is this information coming from?
<b>Currency</b>	When was this information published/updated? What has changed since this was published?
<b>Scope</b>	Does the information cover all aspects of Security issues? To what detail are aspects of this covered?
<b>Accuracy</b>	How accurate is the information provided? Can it be verified?

### 5. SOURCE EVALUATION

#### 5.1 Banking Industry

Criteria	Westpac	Commonwealth Bank of Australia
<b>Relevance</b>	The policy states, "We are committed to protecting and maintaining the privacy, accuracy and security of your personal and financial information". Uses up-to-date and secure technology methods to protect information online using multiple firewalls, secure passwords and sign in processes. Personal information is passed through secure server using encryption technology. The site provides a guarantee "when you use Internet Banking, you can be confident that we employ the highest level of security to protect your accounts and personal information". To confirm that the data is encrypted, a symbol of a lock appears at the bottom.	The Bank takes care of the protection of customers' information and transaction instructions seriously. As part of maintaining the highest level of customer service, the Commonwealth Bank has implemented system security controls, encryption of sensitive data and regular security reviews as well as a five minute time-out on <b>Net Bank</b> to avoid anyone else accessing your banking details on your computer. Net Bank assures the customers of safety, security, privacy and protection. "We guarantee it!" This means that the customers will not be liable for any unauthorised transaction as a result of using <b>NetBank</b> . It uses 128-bit encryption of all customer data. Customers use Individual Client Numbers and Passwords. The Commonwealth Bank engaged Admiral Computing (Australia) to independently assess the security measures the Commonwealth Bank developed.
<b>Authority</b>	It is found in its official Website: <a href="http://www.westpac.com.au">www.westpac.com.au</a>	<b>Issued by:</b> Commonwealth Bank of Australia ABN 48 123 123 124, <a href="http://www.commbank.com.au">www.commbank.com.au</a>
<b>Currency</b>	Current. The Website is committed to bring	Current. Electronic Banking Product Disclosure

	customers up to date on the latest security features of online banking.	Statement Date: 5 February 2004
<b>Scope</b>	Describes security features extensively. The security section gives detail information on how to “protect yourself while banking online.”. It also provides latest news on fraud issues, online security and safeguarding customer computer.	<i>Security and Privacy Statement</i> explains how customers’ personal information will be treated as they access and interact with the Web Site. Information covers aspects of security, information collection and handling, how a breach could happen and how to prevent it.
<b>Accuracy</b>	“Ask Westpac” provides answers to questions about its products or services.	The Support Centre answers FAQs. Customers are further supported by NetBank Help Desk on <b>13 2828</b> .

## 5.2 Retail Industry

Criteria	Woolworths	Roses only
<b>Relevance</b>	First level of security is customers login into Woolworths HomeShop with a username and password. Assures that the username and password are examined in a secure session and cannot be accessed by anyone else. This is the second level of security. While browsing around the shopping aisles, no secure data is being passed around and while checking out of the supermarket, another secure session allowing the purchase process to happen safely and privately. It uses the Secure Sockets Layer (SSL). This ensures that the information sent between customer browser and the Webserver cannot be read by others. Secure sessions allow determining the correct products and prices and when the customers purchase products.	<i>Rosesonly.com.au</i> is a secured site using a VeriSign Digital Certificate. This ensures that all information will be encrypted. If any other user intercepts the communication, they will only be able to view an encrypted form. This makes it almost impossible to be intercepted by an unauthorised party. It explains that when the customers order on <i>rosesonly.com</i> , Firstly, a security notice will appear. Also, a secure icon will appear on the browser. For Microsoft Internet Explorer, a lock icon  and Netscape it is a key icon.   The Secure site can also be identified by the address. 'https://'. The industry standard for encryption technology, SSL is used which is compatible with Internet Explorer, Netscape and most other browsers.
<b>Authority</b>	Woolworths Limited <a href="http://www.homeshop.com.au/info/SecurityTechFAQ.asp">http://www.homeshop.com.au/info/SecurityTechFAQ.asp</a>	<a href="http://www.rosesonly.com.au/Security.asp#sec8">http://www.rosesonly.com.au/Security.asp#sec8</a>
<b>Currency</b>	Last Updated: Monday, 20 September 2004	Current 2004 Roses Only
<b>Scope</b>	Covers most aspects of Security issues. Explains in detail the use of cookies and Java script.	Security and Privacy section highlights information about Collection and Use of information, cookies, privacy in emails, security and browsers.
<b>Accuracy</b>	For Questions or problems regarding Woolworths HomeShop, call customer representatives on 1300 666 377	<a href="http://www.rosesonly.com.au">www.rosesonly.com.au</a> is a Verisign Secure site. Its validity period is from 06 Nov 03 –05 Nov 04 (checked on 22 Sep 2004)

## 6. CONCLUSION

The degree of satisfaction through online should be equal to the service they get in an offline environment. This paper addresses a need for a framework to better understand customers’ online trust. The model reflects consumers’ expectations. Businesses can develop e-business strategies to attract more customers through trust in their web sites. As a new form of conducting business over the Internet, e business involves uncertainty and risk than traditional way of doing business. It is obvious that all the businesses mentioned in this paper continue to maintain their eBusiness practices with superior quality, accuracy and currency. It can be concluded that each of the

four businesses place major emphasis on their privacy and security policies. Each use the strongest form of SSL encryption (128-bit), which provides a very high level of protection against unauthorised access and prevent unauthorised persons from reading information customers send to the business, while it is in transit over the Internet. Ensuring security gives confidence and assurance to the customer for a safe transaction. In answering the question *how can we best evaluate e-business information for security purposes?* The above four examples from two major industries would provide some insight in finding information that could be trusted from eBusiness web sites. All these websites identify data security measures implemented and address issues of privacy. All the sites

offer considerable amount of customer advice and information on their methods of protection. Some of the sites mention possible instances of where data security could be breached and how to identify them (i.e. Fraud, hoax emails). The banking industries have shown they have highlighted strongly on the issues of security and protecting of customers privacy. This is mainly due to the fact they are dealing with valuable assets and are needed to reassure customers, especially potential clients who will be investing through their banking system.

## Internet Security and Digital Certificates: How Much Do You Know About Them?

Nena Lim

UQ Business School, The University of Queensland, Brisbane, QLD 4072, Australia  
n.lim@business.uq.edu.au

### ABSTRACT

The objective of this paper is to investigate to what extent the general public knows about Internet security and digital certificates as well as how likely they would use digital certificates if the certificates are free and ready for them to use. The Hong Kong SAR government introduced a new multi-application smart identity card to its residents in August 2003. As the government wants to encourage its residents to adopt electronic commerce, residents can choose to embed a free digital certificate in their smart identity cards. A survey was conducted in Hong Kong SAR in January 2004 and one hundred and forty questionnaires were returned. Results show that the respondents' self-reported knowledge of several key concepts related to Internet security were inconsistent. Moreover, respondents did not seem to have much understanding of the usefulness of the digital certificates nor did they appear to be too keen to use the digital certificates for electronic transactions.

**Keywords:** digital certificate, electronic certificate, PKI, Hong Kong SAR smart identity card

### 1. INTRODUCTION

Internet security has been repeatedly shown to be a major worry of consumers and an obstacle for the success of electronic commerce [1-3]. One of the solutions researchers and businesses have found for this problem is the adoption of digital certificates (also known as electronic certificates) for Internet communications and transactions. A digital certificate establishes an individual or an organization's identity in the cyber world. Issued by a certification authority (CA), each digital certificate includes information such as the name of the certificate holder/organization, a unique serial number, the expiration date of the certificate, a copy of the certificate holder/organization's public key, and a digital signature of the certification authority. The mechanism of digital certificates relies on the public key infrastructure (PKI) to achieve on-line authentication. Under the PKI, individuals with no prior relationship can achieve confidentiality and authentication when they swap information over the Internet or conduct electronic commerce transactions [1].

Although PKI has already existed for several decades, many consumers still hesitate to get involved in electronic commerce transactions. Why? One possible explanation is that although public key encryption algorithms have progressed quickly since 1970s [4], consumers do not feel any safer because they do not know how PKI works nor do they understand the protection digital certificates can offer. The objective of this paper is to investigate to what extent the general public knows about Internet security and digital certificates as well as how likely they would use digital certificates if the certificates are free and ready for them to use.

### 2. HONG KONG SAR SMART IDENTITY CARD

The Hong Kong Special Administration Region (SAR) has a population of 6.8 million in mid-2003 [5]. Sixty-eight percent of households in Hong Kong SAR have personal computers and nearly all these households (89%) have Internet access [6]. The Hong Kong SAR government introduced a new multi-application smart identity card to its residents in August 2003. In addition to immigration purposes such as facilitating automated immigration clearance at border control points, a Hong Kong SAR smart identity card also includes several non-immigration applications.

Residents can now use the digital certificates embedded in their identity cards to update or check personal data kept by the government. With the embedded digital certificates, residents can also encrypt email messages, conduct on-line share trading and on-line betting etc. [7]. Residents can use the digital certificate free for one year because the Hong Kong SAR government wants to encourage people to adopt electronic commerce [8]. Despite the good intentions of the government, do the Hong Kong SAR residents understand what digital certificates are? Are they ready to trust and hence utilize the digital certificates for electronic commerce transactions? To what extent will the goal of Hong Kong SAR government of creating a critical mass for electronic commerce be achieved?

By the beginning of August 2004, over 420,000 smart identity card holders have opted for the free digital certificate [9]. This figure equals to only six percent of the entire population. Assuming more people opt for the digital certificate after the promotion of some renowned celebrities, the key issue one should remember is: a high Internet connectivity rate or even ownership rate of digital certificate does not necessarily lead to individuals' acceptance of electronic commerce.

Citizens in Finland do not consider it worthwhile to pay 10 Euros for a digital certificate [10]. Similarly, a low acceptance rate of digital certificate was reported in Germany. Less than one percent of students in a German university applied for a smart card which has a digital certificate embedded in it. The cards and card readers were heavily subsidized by the university. Yet even computer science students did not show too much interest in the cards. Those who got the cards only used them infrequently [10].

### 3. METHODOLOGY

To investigate their understanding of Internet security and digital certificates as well as their readiness in using the free digital certificates, a survey of Hong Kong residents was conducted in January 2004. One hundred and fifty questionnaires were distributed to associate degree students who have enrolled in an advanced accounting course at the City University of Hong Kong. One hundred and forty questionnaires were returned. Among the respondents, 72 percent were female and 27 percent were male. They aged from 20 to 23. The average age was 20.8. Most respondents had five to eight years experience of using computer and five to six years experience of using the Internet. Ninety-nine percent had computers at home.

### 4. RESULTS

In a seven-point Likert scale, the average self-reported knowledge of Internet security in general was 3.7 and only one respondent indicated he/she had no knowledge of Internet security. Yet interestingly respondents' self-reported knowledge of PKI was much lower with an average score of only 2.3. Fifty-four respondents indicated that they knew nothing about PKI. Similar results exist for respondents' self-reported knowledge of certification authorities and digital certificates. The respondents' average knowledge of certification authorities and digital certificates were 2.35 and 3.3 respectively. The relatively higher self-rating of digital certificate is unsurprising because ten percent of the respondents already owned valid digital certificates. These people must have obtained the certificates on their own because according to the government schedule it was not their turns to apply for the new identity cards yet. The results raise an interesting question on the inconsistency of respondents' self-reported knowledge. Did people really know about Internet security or did they over-estimate their understanding?

There is no significant difference between the "have" and "have not" groups of digital certificates in all aspects except their knowledge of digital certificates. Out of the 125 respondents who did not have a valid digital certificate, two-thirds did not know what applications digital certificates could provide. After being told the applications they could use, these respondents were not keen to use those applications. For

example, while 119 respondents use electronic mails regularly, only 20 percent indicated that they might use the digital certificates to encrypt their emails. Furthermore, two-thirds of these respondents were not aware that they would need to have a smart-card reader to use the free digital certificate embedded in their smart identity card for on-line applications. Once they were aware of the equipment requirement, 95 percent indicated they were either unsure or unlikely to purchase a smart card reader. Such results are unsurprising as smart card readers have been shown to be a major obstacle of smart card adoption [10]. Although 40 percent of respondents indicated they would opt to include the free digital certificates into their identity cards, 93 percent of them would not pay the annual fee themselves once the certificates expire after one year. Results also indicate that those who were willing to buy smart card readers are more likely to pay annual fees ( $r = 0.425$ ).

### 5. CONCLUSIONS

In summary, results of this study show that the self-reported knowledge of respondents of several key concepts related to Internet security were inconsistent. It is doubtful how much they really know. Moreover, respondents did not seem to have much understanding of the usefulness of the digital certificates embedded in their new smart identity cards and they did not appear to be too keen to use the digital certificates for electronic transactions. To achieve its objective of promoting electronic commerce transactions, we recommend the Hong Kong SAR government to consider further educating its residents on Internet security because results of this study suggest that the general public in Hong Kong is unlikely to make good use of the digital certificates. While some forms of public education such as exhibitions were conducted in the past, results suggested that more should be done. For example, promotions of useful applications such as on-line submission of tax returns can be used to attract usage of digital certificates. Moreover, more advertising and education are required to familiarize residents with the benefits of digital certificates. One way to educate the general public is to start from students, from primary schools to tertiary institutions, so that the next generation will be more ready to face the electronic age.

# Secure Mobile Agents in Electronic Commerce by Using Undetachable Signatures from Pairings

Yang Shi, Xiaoping Wang, Liming Cao, Jianxin Ren

Department of Computer Science and Technology, Tongji University, Shanghai 200092, China  
cnshiyang@yahoo.com.cn

## ABSTRACT

It is expected that mobile agents technology will bring significant benefits to electronic commerce. But security issues, especially threats from malicious hosts, become a great obstacle of widespread deployment of applications in electronic commerce based on mobile agents technology. Undetachable digital signature is a category of digital signatures to secure mobile agents against malicious hosts. An undetachable signature scheme by using encrypted functions from bilinear pairings was proposed in this paper. The security of this scheme is based on the computational intractability of discrete logarithm problem and computational Diffie-Hellman problem on gap Diffie-Hellman group. Furthermore, the scheme satisfies all the requirements of a strong non-designated proxy signature i.e. verifiability, strong unforgeability, strong identifiability, strong undeniability and preventions of misuse. An undetachable threshold signature scheme that enable the customer to provide mobile agents with 'shares' of the undetachable signature function is also provided. It is able to provide more reliability than classical undetachable signatures.

**Keywords:** electronic commerce, mobile agents, undetachable digital signatures, bilinear pairings

## 1. INTRODUCTION

Mobile agents technology are attracting a great deal of interest from both industry and academia since middle of 1990's. Compared with traditional computing models, e.g. client/server, mobile agents technology has following advantages[1][2][3]:

- ò Autonomous mobile agents strive to achieve a given goal without permanent observation by its owner. As a matter of consequence, the user is free to take care of other tasks, saving time in the process.
- ò If a host is being shut down, all mobile agents executing on that machine are warned and given time to dispatch and continue their operation on another host in the network.
- ò Users may dispatch mobile agents over a temporary network connection to a target network. After dispatching, the temporary network link may be brought down until a later point in time.

Mobile agents technique brings significant benefits to electronic commerce because of these advantages. But on the other hand, there are also some problems. The most important one is security.

Threats to the security of mobile agents generally fall into four comprehensive classes[4]:

- ò Agent against agent platform
- ò Agent platform against agent
- ò Agent against other agents
- ò Other entities against agent system

Hohl[5] identified the following attacks: spying out code; spying out data; spying out control flow; manipulation of code; manipulation of data;

manipulation of control flow; incorrect execution of code; masquerading of the host; denial of execution; spying out interaction with other agents; manipulation of interaction with other agents; returning wrong results of system calls issued by the agent.

Thus, security issues, especially threats from potentially malicious hosts become a great obstacle of widespread deployment of applications in electronic commerce based on mobile agents technique.

## 2. PREVIOUS WORKS ABOUT UNDETACHABLE DIGITAL SIGNATURES

### 2.1 The preliminary idea

Before 1998, many researchers believed that, on malicious hosts, mobile agents were impossible to prevent tampering unless trusted and tamper-resistant hardware is available. Following points[6] are considered by them:

- ò Cleartext data can be read and changed.
- ò Cleartext programs can be manipulated.
- ò Cleartext messages can be faked.

But Sander and Tschudin[7] pointed out that this belief is incorrect because mobile agents do not have to be executed in cleartext form. They proposed the idea of undetachable digital signatures that allows a mobile agent to effectively produce a digital signature inside a remote and possibly malicious host without the host being able to deduce the agent's secret or to reuse the signature routine for arbitrary documents. Here is a brief introduction of the idea.

Let  $Sig$  be a rational function used by  $C$  (a customer) to produce the digital signature  $Sig(m)$  of an arbitrary message  $m$ . Furthermore suppose the message  $m$  is the result of a rational function  $f$  applied to some input data  $x$ . Finally the verification function  $Ver$  that  $C$  publishes in order to let others check the validity of the digital signature  $z$  is regarded to be a valid signature of  $m$  if and only if:

$$z = Sig(m) \quad (1)$$

For letting the customer's mobile agent create "undetachable" signatures, he computes:

$$f_{Signed} = Sig \circ f \quad (2)$$

Then he sends  $f_{Signed}$  and  $f$  to  $S$  (a shop) with his mobile agent.  $S$  evaluates:

$$m = f(x) \quad (3)$$

$$z = f_{Signed}(x) \quad (4)$$

Though the signature function,  $Sig$ , is not known by others, every one can verify the validity of a message  $m$  by testing:

$$Ver(z) = m \quad (5)$$

## 2.2 The first implementation

Although Sander and Tschudin tried to give an outline of undetachable digital signatures by using birational functions based on Shamir's work[8]. Unfortunately no secure undetachable digital signatures scheme has been proposed until 2000. In 2000 Kotzanikolaou, Burmester and Chrissikopoulos presented an RSA implementation[9] of undetachable digital signatures. But this scheme does not provide server's non-repudiation because it does not contain server's signature[10].

## 2.3 Strong proxy signatures and other implementations

In 2001 Lee, Kim and Kim provided an RSA based construction of undetachable digital signatures called "Strong Non-designated Proxy Signature" [10]. Their scheme enhanced [9] and often be acronymized as "LKK-SPS" scheme. A scheme of undetachable threshold signature[13] was proposed by Borselius, Mitchell and Wilson in the same year. In 2002, a strong proxy signature scheme with proxy signer privacy protection[11] was given and a pragmatic alternative to undetachable signatures[12] was also proposed.

## 3. BILINEAR PAIRINGS AND SIGNATURE SCHEMES BASED ON THEM

### 3.1 Mathematical preliminaries of Bilinear Pairings

Let  $G_1$  be a cyclic group generated by  $P$ , whose

order is a prime  $q$ , and  $G_2$  be a cyclic multiplicative group of the same order  $q$ : The discrete logarithm problems in both  $G_1$  and  $G_2$  are hard. Let  $e: G_1 \times G_1 \rightarrow G_2$  be a pairing satisfies the following conditions:

ò Bilinear: (6) and (7) or (8)

$$e(P_1 + P_2, Q) = e(P_1, Q)e(P_2, Q) \quad (6)$$

$$e(P, Q_1 + Q_2) = e(P, Q_1)e(P, Q_2) \quad (7)$$

$$e(aP, bQ) = e(P, Q)^{ab} \quad (8)$$

ò Non-degenerate: There exists  $P \in G_1$  and

$$Q \in G_1 \text{ subject to (9).}$$

$$e(P, Q) \neq 1 \quad (9)$$

ò Computability: There is an efficient algorithm to compute  $e(P, Q)$  for all  $\{P, Q\} \subseteq G_1$

We note that the Weil and Tate pairings associated with supersingular elliptic curves or abelian varieties can be modified to create such bilinear maps. Suppose that  $G$  is an additive group. Four mathematical problems is defined as follow [14][15].

ò Discrete Logarithm Problem (DLP):

Given two group elements  $P$  and  $Q$ , and an integer  $n$ , such that (10) is satisfied whenever such an integer exists.

$$Q = nP \quad (10)$$

ò Decision Diffie-Hellman Problem (DDHP):

For  $\{a, b, c\} \subseteq Z_q^*$ , given  $P, aP, bP, cP$  decide whether:

$$c \equiv ab \pmod{q} \quad (11)$$

ò Computational Diffie-Hellman Problem (CDHP):

$$\text{For } \{a, b\} \subseteq Z_q^* \quad P, aP, bP$$

compute  $abP$

ò Gap Diffie-Hellman Problem (GDHP):

A class of problems where DDHP is easy while CDHP is hard.

We assume through this paper that CDHP and DLP are intractable, which means there is no polynomial time algorithm to solve CDHP or DLP with non-negligible probability. When the DDHP is easy but the CDHP is hard on the group  $G_1$ ,  $G_1$  is called a Gap Diffie-Hellman (GDH) group. Such groups can be found on supersingular elliptic curves or hyperelliptic curves over finite fields, and the bilinear pairings can be derived from the Weil or Tate pairing  $e: G_1 \times G_1 \rightarrow G_2$ . Our schemes of this paper can be built on any GDH group. More mathematical background can be found in [14][16][17][18]. Now, some system parameters should be defined for Sec. 4 as following: Let  $P$  be a generator of  $G_1$ , the bilinear

paring is  $e : G_1 \times G_1 \rightarrow G_2$ . Moreover, to hash functions are given here:  $H_1 : \{0,1\}^* \rightarrow Z_q$  and  $H_2 : \{0,1\}^* \rightarrow G_1$ . The implementation of these hash functions can be referred to works such as [25]. But the choice of conventional hash functions should be very carefully because many hash functions were cracked recently [26].

### 3.2 A Survey of Signature Schemes Based on Bilinear Pairings

In recent years, variety schemes of digital signatures have been proposed. For threshold signatures, Boldyreva[15] proposed a robust proactive threshold signature scheme, a multi-signature scheme and a blind signature scheme which work in any Gap Diffie Hellman group in 2002. Then Vo, Zhang and Kim[19] presented a new threshold blind digital signature based on pairings without the third party. For Multisignatures, Lin, Wu and Zhang[20] proposed a new structured multi-signature scheme from the Gap Diffie-Hellman Group that considers the signing order among co-signers. Boneh, Boyen and Shacham[21] constructed a short group signature scheme based on the Strong Diffie-Hellman assumption. Nguyen[22] proposed a group signature scheme with constant-size parameters that does not require any trapdoor secret, thereby, allows sharing of public parameters among organizations. As to Blind signature, Chow et al.[23] gave an unlinkable partially blind signature scheme and an ID-based unlinkable partially blind signature scheme. Furthermore, Zhang et al.[24] addressed that it was easy to design proxy signature and proxy blind signature from the conventional ID-based signature schemes using bilinear pairings and gave some concrete schemes based on existed ID-based signature schemes.

## 4. UNDETACHABLE SIGNATURES BASED ON BILINEAR PAIRINGS

### 4.1 Settings

Assume that all participants have the common system parameters:  $(G_1, G_2, e, q, P, H_1, H_2)$ .

Settings about the customer :

- ò Let  $C$  be an identifier for the Customer.
- ò Let  $s_C$  be the signature key of  $C$ .
- ò Let  $PU_C$  be the verification key of  $C$  where:

$$PU_C = s_C P \quad (12)$$

- ò Let  $req\_C$  be the constraints of the Customer.
- ò Let  $T_C$  be the timestamp of  $req\_C$

Settings about shops :

- ò Let  $S$  be an identifier for a shop.

- ò Let  $s_S$  be the signature key of  $S$ .
  - ò Let  $PU_S$  be the verification key of  $S$  where:
- $$PU_S = s_S P \quad (13)$$
- ò Let  $bid\_S$  be the bid information of  $S$ .
  - ò Let  $T_S$  be the timestamp of  $bid\_S$ .
  - ò Let  $\varphi : G_1 \rightarrow \{0,1\}^*$  be a function mapping a point of  $G_1$  into a binary string.

### 4.2 Security scheme

The Customer does following operations :

- ò Computes:
- $$H_C = H_2(C \parallel req\_C \parallel T_C) \quad (14)$$

- ò Computes:
- $$K_C = s_C \cdot H_C \quad (15)$$

- ò Gives  $(C \parallel req\_C \parallel T_C)$  to the Agent.

- ò Gives to the Agent as part of its executable code the undetachable signature function pair:

$$f(\cdot) = (\cdot)H_C \quad (16)$$

and

$$f_{Signed}(\cdot) = (\cdot)K_C \quad (17)$$

Suppose :

$$Sig(x) = s(\cdot) \quad (18)$$

It turns out the following proposition:

**Proposition 1.** The functions above construct an undetachable digital signature scheme.

**Proof.**

$$\begin{aligned} & (Sig \circ f)(\cdot) \\ &= Sig(f(\cdot)) \\ &= Sig((\cdot)H_C) \\ &= s_C((\cdot)H_C) \\ &= (\cdot)s_C H_C \\ &= (\cdot)K_C \\ &= f_{Signed}(\cdot) \end{aligned} \quad (19)$$

After the Agent migrated to the host of  $S$ , the validity of the mobile agent should be verified first by checking:

$$e(K_C, P) \stackrel{?}{=} e(H_C, PU_C) \quad (20)$$

If it is a valid signature of  $C$ , then  $S$  does following operations :

- ò Computes:
- $$H_S = H_2(C \parallel req\_C \parallel T_C \parallel S \parallel bid\_S \parallel T_S) \quad (21)$$

- ò Computes:
- $$Y = s_S H_S \quad (22)$$

ò Computes:

$$x = H_1(\varphi(Y)) \quad (23)$$

ò Computes:

$$z = f_{Signed}(x) \quad (24)$$

ò Gives  $(x, z, Y, H_S, S, bid\_S, T_S)$  to the mobile agent.

After the mobile agent goes back to  $C$ . The correctness of (21) and (23) should be verified first. Then the verification should be performed by formula (25):

$$e(Y)P(=e(H_S, PU_S)) \quad (25)$$

### 4.3 Security Analysis

The following proposition can be obtained because  $G_1$  is a GDH group.

**Proposition 2.** A transaction is valid if and only if (20), (21), (23) and (25) are true.

**Proof.** If the mobile Agent is not detached before it migrated to the host of  $S$ , then:

$$\begin{aligned} & e(K_C, P) \\ &= e(s_C H_C, P) \\ &= e(H_C, P)^{s_C} \\ &= e(H_C, s_C P) \\ &= e(H_C, PU_C) \end{aligned} \quad (26)$$

If an opponent Oscar want to modify  $C$ 's bid information when  $C$ 's agent mobiles to his host, he has to construct a new undetachable digital signature pair  $(H_C, K_C)$  of the Customer which will include modified constraints  $req\_C$  of the Customer. But this needs to solve the computational difficult problems mentions in section 3.1.

Furthermore, if a transaction is valid:

$$\begin{aligned} & e(Y)P \\ &= e(s_S H_S, P) \\ &= e(H_S, P)^{s_S} \\ &= e(H_S, s_S P) \\ &= e(H_S, PU_S) \end{aligned} \quad (27)$$

Similar to equation (20), the security of (23) and (25) also relies upon the difficulty of the problems computational infeasible to solve at present.

## 5. UNDETACHABLE THRESHOLD SIGNATURES

### 5.1 Basic Idea

The notion of undetachable threshold signatures was introduced in [27]. An undetachable threshold signature scheme will enable the customer,  $C$ , to provide  $n$  mobile agents with 'shares' of the signature key (where the shares will be a function of  $req\_C$  and  $T_C$ ). For more details about undetachable threshold signature such as their usage and application can be found in [27].

### 5.2 Security Scheme

Based on undetachable signature scheme proposed in section 4, a variety of secret sharing scheme can be used to construct undetachable threshold signatures by converting  $s_C$  into signature shares. An example using Lagrange Polynomial Interpolation is given here:

Suppose  $f$  is a polynomial over  $Z_q$  with degree  $t-1$  subject to (28).

$$s_C = f(0) \quad (28)$$

Operations in equations (29) to (32) and (38) are performed over  $Z_q$ .

Let:

$$s_i = f(i), \quad i=1,2,\dots,n \quad (29)$$

Then any one has  $t$  shares can obtain  $s_C$  by calculating (30)

$$s_C = \sum_{j=1}^t \left( s_{i_j} \frac{\prod_{h=1, h \neq j}^t i_h}{\prod_{h=1, h \neq j}^t (i_h - i_j)} \right) \quad (30)$$

To simplify the description we suppose the  $t$  shares are  $s_1, \dots, s_t$ , thus:

$$s_C = \sum_{j=1}^t (s_j) l_j \quad (31)$$

Where:

$$l_j = \frac{\prod_{h=1, h \neq j}^t h}{\prod_{h=1, h \neq j}^t (h - j)} \quad (32)$$

Then  $C$  does following extra operations

ò Computes:

$$PC_i = s_i P, \quad i=1,2,\dots,n \quad (33)$$

and (34) instead of (14).

$$\begin{aligned} H_C &= H_2(C \parallel req\_C \parallel T_C \parallel \\ &PC_1 \parallel \dots \parallel PC_n) \end{aligned} \quad (34)$$

ò Computes:

$$K_i = s_i H_C, \quad i=1,2,\dots,n \quad (35)$$

ò Gives  $PC_1 \parallel L \parallel PC_n$  to these  $n$  agents.

Finally,  $C$  gives (36) to the  $i$ -th agent as part of its executable code instead of (17):

$$f_{Signed,i}(\cdot) = (\cdot)K_i \quad (36)$$

After the  $i$ -th Agent migrated to the host of  $S$ , the validity of the mobile agent should be verified first the by checking:

$$e(K_i, P) \stackrel{?}{=} e(H_i, PC) \quad (37)$$

It is clear that a shop has  $t$  or more than  $t$  shares can reconstruct  $f_{Signed}$  by (38). But anyone cannot reconstruct  $f_{Signed}$  from less than  $t$  shares.

$$f_{Signed}(\cdot) = \sum_{i=1}^t [l_i f_{Signed,i}(\cdot)] \quad (38)$$

After a shop has reconstruct  $f_{Signed}$  successfully, other operations are similar to undetachable signatures proposed in section 4. So redundant words are omitted.

## 6. CONCLUSION

In this paper, we have presented a novel implementation of undetachable digital signatures and a correspondent security scheme. Compared to [9][10], our scheme uses a different cryptosystem to construct undetachable signatures. This implementation of undetachable digital signatures is based on non-interactive CEF (Computing with Encrypted Functions) from bilinear pairings to protect the original signature function  $Sig$  by encrypting it with a function  $f$  to obtain the encrypted function  $f_{Signed}$  defined as the composition of  $Sig$  and  $f$ . Furthermore, the scheme satisfies all the five requirements of a strong non-designated proxy signature proposed by Lee et al. in [10] as follow: First, verifiability: A proxy signer can create a valid proxy signature for the original signer. But the original signer and any third party cannot create a valid proxy signature with the name of proxy signer, Second, strong unforgeability: Anyone can determine the identity of the corresponding proxy signer form a proxy signature. Third, strong identifiability: Once a proxy signer creates a valid proxy signature on behalf of an original signer, the proxy signer cannot repudiate his signature creation against anyone. Fourth, strong undeniability: It should be confident that proxy key pair cannot be used for other purpose. In the case of misuse, the responsibility of proxy signer should be determined explicitly. Finally, preventions of misuse: From a proxy signature a verifier can be convinced of the original signer's agreement on the signed message.

As to the undetachable threshold signature scheme proposed in the paper, it has following features: First, each agent can use their share to sign a message  $M$ , e.g. a piece of bid information, of their choice to obtain

a 'signature share'. Second, The 'correctness' of a signature share can be verified independently of any other signature shares. Third, any shop, when equipped with  $t$  different signature shares restricted with the same request of  $C$  for the same message  $M$ , can construct a signature on  $M$  which will be verifiable by any party with a trusted copy of public key of  $C$ , and which will also enable the corresponding  $req\_C$  and  $T_C$  to be verified. Finally, knowledge of less than  $t$  different signature shares for the same message  $M$  cannot be used to construct a valid signature one the message  $M$ , knowledge of any number of different signature shares for messages other than the message  $M$  will not enable the construction of a valid signature on  $M$  and knowledge of any number of different signature shares for request other than  $req\_C$  or with a different time stamp will not enable the construction of a valid signature with associated  $req\_C$  and  $T_C$ . So our scheme satisfied all the requirements of undetachable threshold signatures defined in [27] and provide more reliability than classical undetachable signatures.

### ABSTRACT

It has been widely recognized that RFID related technologies will greatly improve the visibility, the efficiency and the collaboration of industry supply chain. In this new “product driven” supply chain scenario, manufacturer, supplier, and third party share and coordinate the use of diverse resources in distributed “virtual organizations”. It challenges the security issues, which demand new technical approaches. In collaboration with researchers in Auto-ID Labs China, we have developed a service-oriented framework based on CA and Web Services, which supports inexpensive mediation of product information among rapidly evolving, heterogeneous information sources. Our architecture defines a user-driven security model that allows users to create entities and policy domains within virtual organizations. We emphasize that standard Web Services tools and software provide both stateless and stateful forms of secured communication.

**Keywords:** security service, RFID, supply chain, PKI

### 1. INTRODUCTION

Radio frequency identification (RFID) is a powerful new technology that is helping companies to improve visibility into their inventory data and increase accuracy across supply chain networks. When RFID tags are attached to products, boxes, and pallets, the items can be followed automatically as they move, providing a real-time and accurate view of inventory[1]. The technology is so effective that organizations such as Wal-Mart, Metro, and the U.S. Department of Defense now require their suppliers to deliver goods with RFID tags.

The Auto-ID Center in MIT, was launched in late 1999, has developed RFID tags which are cheap enough to be disposable and readers which are agile enough to be deployed globally[2]. According to Auto-ID Center's researching, the various components of the Auto-ID infrastructure includes (Figure 1):

- ò Hardware – such as RFID tags and readers but also including optical readers and other types of sensors.
- ò Savant – a software platform for interfacing to various types of readers and filtering the data generated when the tags are within range of the readers.
- ò The Electronic Product Code (EPC) – a unique identification number for each object – the minimum information which must be stored on its ID tag.
- ò The Object name service (ONS) – an extension of the domain name service (DNS), which provides a method of converting an EPC into the network address of the corresponding networked database, which in turn holds the product data for that object.
- ò The EPC Information Server (formerly PML Server) – an open standard XML Schema for representing information about products and

communicating this information globally in a unified manner, between parties who otherwise have disparate databases, data storage formats and who use diverse application programs to act upon the product data.

- ò Control systems – to provide feedback into the supply chain or manufacturing process, using the data generated by EPC readings.

### EPC Network Architecture-across Enterprises

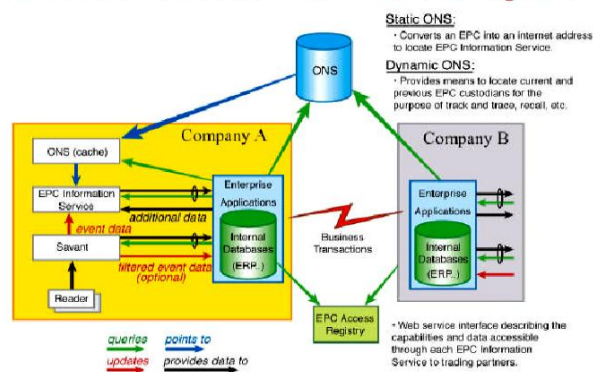

Figure 1 EPC Network Architecture  
Source: Autoidcenter.org

Since each unique object will have a unique identifier, in the form of the EPC, each object will become an individual, with its own individual history about how it passed through supply chain. In this “product driven” supply chain scenario, manufacturer, supplier, and third party (like carrier, distribute center) share and coordinate the use of diverse resources in distributed “virtual organizations”.

Let us consider a simple business scenario. The suppliers and customers (manufacturers) collaborate by sharing information and exchanging plans via the Supplier Managed Inventory (SMI) process. The SMI process is a supplier-driver replenishment and planning process, which is based on min/max stock balance levels, on current demand, in-transits and planned shipments.

With RFID enabled, the application now should support the handling of massive amounts of Auto-ID data through connectivity with readers, tags, and other devices; and integration of high-volume RFID data with back-end business processes. The dynamic and multi-parties nature of these environments introduces challenging security issues that demand new technical approaches. Most of data are sensitive, and every server exposed on internet will be attacked, and so on.

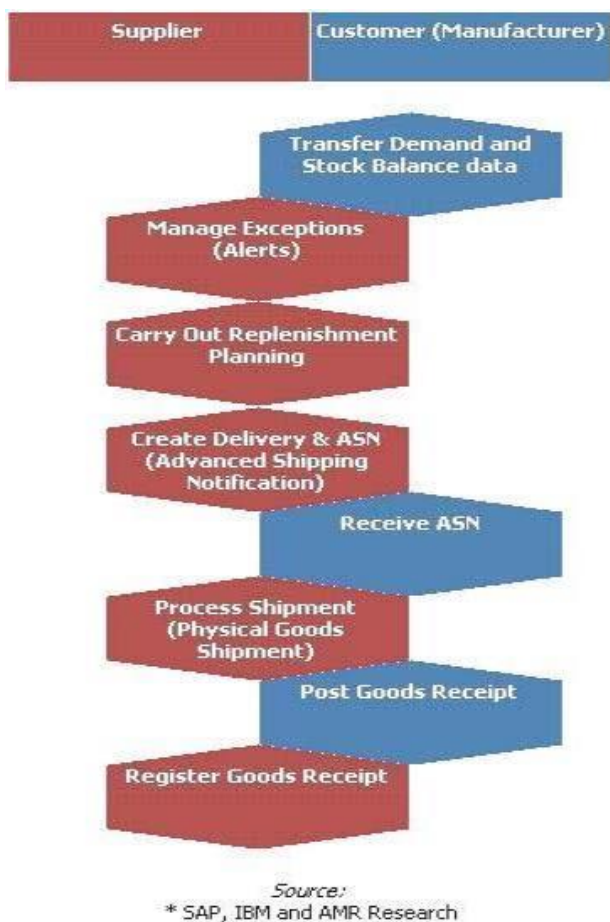

Figure 2 SMI scenario

The remainder of this article is organized as follows. In Section 2, we investigated related work on security web service and certificate validation. Then we propose a design of security system model, emphasizes on security web service and privilege management infrastructure. Finally, we explain function for system and then we conclude this paper with a brief discussion of future work.

## 2. RELATED WORK

### 2.1 CA-based Trust Model

One commonly used identity token is provided by an X.509 public key certificate. An X.509 “public key certificate” is defined in ITUT standard [3] as “the public key of a user, together with some other information, rendered unforgeable by encipherment with the private key of the certification authority which issued it.” [Section 3.3.44]

In practice an X.509 certificate as defined by the PKIX X.509 Certificate Profile RFC[] contains a public key, a subject name in the form of a multi-component Distinguished Name [DN] and a validity period and is signed by a trusted third party called a Certification Authority (CA). The X.509 certificates are used with the TLS(SSL) security protocol to make a secure authenticated connection between two parties. X.509 certificates are exchanged between entities, usually in a phase where no security has yet been negotiated (no data integrity or confidentiality). The certificates are first tested for validity by checking the expiration dates, possible revocation, acceptable key usage and if they are signed by trusted CA. If the certificates pass all these checks their public keys are then used to build a challenge handshake to prove that each entity that sent a certificate has the corresponding private key.

There are other public/private key based schemes such as PGP keys[4], SSH keys [5] and the SPKI [6] keys and protocols. The PKIX/X.509 scheme has a smallish set of trusted third parties (CAs) to sign identity certificates that contain a subscriber’s public key. This improves the scaling properties of public key distribution since only the CA’s public key needs to be distributed in an out-of-band secure manner. Another feature of the X.509-TLS infrastructure is that it supports multiple independent CAs. In a supply chain, each company may choose which CAs it will accept for binding DNs and public keys. At this point, most of the current solutions allow for short-term proxy certificates, stored with unencrypted private keys, to which a user has delegated his identity. These certificates are correctly formatted X.509 certificates, except that they are marked as proxy certificates and are signed by an end entity rather than a CA[7].

### 2.2 XML Web Service Security

The XML security standards define XML vocabularies and processing rules. These standards use legacy cryptographic and security technologies, as well as emerging XML technologies, to provide a flexible, extensible and practical solution toward meeting security requirements. The XML security standards include XML digital signature [8] for integrity and signing solutions, XML encryption [9] for confidentiality, XML key management (XKMS) [10] for public key registration,

location and validation, security assertion markup languages (SAML) [11] for conveying authentication, authorization and attribute assertions, XML access control markup language (XACML) [12] for defining access control rules, and platform for privacy preferences (P3P) [13] for defining privacy policies and preferences. Major use cases include securing web services (WS-Security) [14].

### 2.3 RBAC Policies in Privilege Management

Role Based Access Controls (RBAC) has generated significant interest in the last decade. The main entities in RBAC are the users, the roles and the permissions. A role can represent a job function, a qualification or expertise. A permission represents the right to access a target in a particular mode. Roles are assigned to users in a many to many relationship, and permissions are granted to roles, again in a many to many relationship. There is thus a level of indirection between a user and his access rights. The benefits of RBAC are widely discussed on lots of papers [15].

Edition 4 of X.509 [3], published in 2001, is the first edition to fully standardize the certificates of a Privilege Management Infrastructure (PMI). X.509 supports RBAC by defining role specification attribute certificates that hold the permissions granted to each role, and role assignment attribute certificates that assign various roles to the users. Each role and name component in X.509 and LDAP [16] is an attribute type, attribute value pair. Thus roles and name components are easily interchangeable. The user is identified by either his/her LDAP Distinguished Name or his public key certificate (issuer and serial number). Role assignment ACs may point to their corresponding role specification AC via the role specification certificate identifier extension.

A policy is defined which states the rules for assigning roles to users, and permissions to roles. The policy can then be used to control the accesses to all the targets within the policy domain [17]. In practice, now we have APIs that read in the XML Policy, parse it, and use it to control access to targets within the policy domain. The API caller, typically an application gateway, passes the authenticated name of the user, and this is used to retrieve the user's attribute certificates (ACs) from the configured directory (In most cases, LDAP server is used). The API caller passes the user's requested action on his chosen target, and again this is checked against the policy. The API returns either granted or denied to the caller.

### 3. SECURITY MODEL FOR RFID-ENABLED SCM

We now turn to outline the proposed structure of a prototype SSS (SCM Security Server).

Web services technologies allow software components to be defined in terms of access methods, bindings of these methods to specific communication mechanisms, and

mechanisms for discovering relevant services. Now, the Simple Object Access Protocol (SOAP) and the Web Services Description Language (WSDL) are widely used in many applications.

SSS defines standard Web service interfaces and behaviors that add to Web services the concepts of stateful service and secure invocation, as well as other capabilities needed to address RFID-specific requirements. These interfaces and behaviors define what is called a "SSS Service" and allow users to manage the web service's life-cycle, as allowed by policy, and to create sophisticated distributed services.

Our SSS security model casts security functions as SSS services. This strategy allows well-defined protocols and interfaces to be defined for these services and permits an application to outsource security functionality by using a security service with a particular implementation to fit its current need.

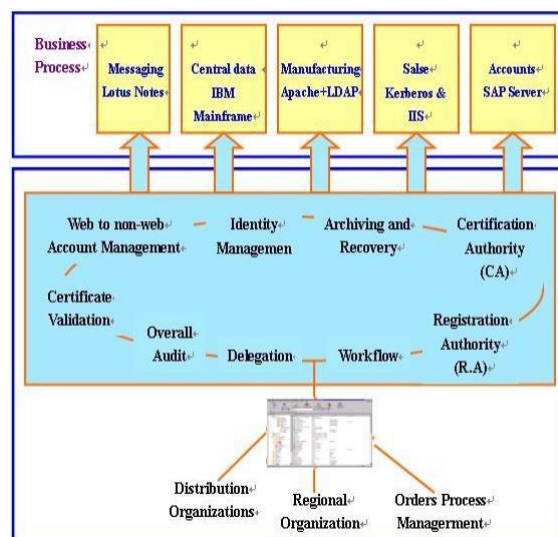

Figure 3 SSS for RFID enabled SCM

The security services include the following.

- ò Certificate Validation service (CAS): A service that handles the details of processing and validating the binding among the subject identity, the subject public key, and subject attributes.
- ò Authorization service: A service that evaluates policy rules regarding the decision to allow the attempted actions based on information about the requestor, and details of the request.
- ò Identity Management service: A service that takes a user's identity in one domain and returns the identity in another (e.g. between X.509 and Kerberos).
- ò Archiving and Recovery: A service that handles archiving and recovery of encryption keys.
- ò Administration Service: provide administration workflow with approval and escalation controls.
- ò Overall Audit: A service that securely logs relevant information about events.

For example, SSS perform path validation on a certificate chain according to the local policy and with local PKI facilities, such as certificate revocation (CRLs) or through an OCSP(Online Certificate Status Protocol). The SSS client generates an ‘SSS validate’ request. This is essentially asking the SSS server to go and find out the status of the server’s certificate. Then the SSS server performs a series of validation tasks. After certificate status is determined, SSS server replies to client application with status of the server’s certificate and application acts accordingly. We use CA database connection protocol for the purpose of that the server obtains real-time certificate status information from CAs. The client use OCSP protocol.

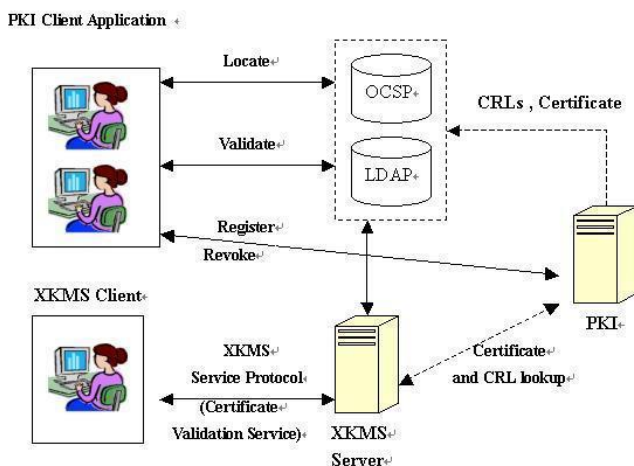

Figure 4 Identify Service

## 4. PMI IMPLEMENTATION

There are three main components to the PMI implementation – the authorization policy, the privilege allocator (PA) and the PMI application programming interface (API).

### 4.1 Authorization Policy

The authorization policy specifies who has what type of access to which targets and under what conditions. The xml.org published a document type definition (DTD) for the X.500 PMI RBAC policy. It provided a meta-language that holds the rules for creating the XML policies. The DTD comprise the following components.

- o SubjectPolicy
- o RoleHierarchyPolicy
- o SOAPolicy
- o RoleAssignmentPolicy
- o TargetPolicy
- o ActionPolicy
- o TargetAccessPolicy

The SOA creates the authorization policy for the domain using his or her preferred XML editing tool and stores this in a local file to be used later by the PA.

### 4.2 Privilege Allocator

The SOA uses the PA to allocate roles to users in the form of role-assignment ACs. In the simple case of RFID supply chain, there are two roles – ASN issuer and ASN receiver. Issues can download any ASN that are produced.

Once the role-assignment ACs have been created by the PA, they are stored in a LDAP directory.

Another function of the PA is to create an authorization policy that is signed digitally as a policy AC. The policy AC is a standard X.509 AC. The PA prompts the SOA for the name of the policy field and then it copies the contents into the attribute value. After the SOA has signed the policy AC, the PA stores it in the SOA’s entry in the LDAP directory.

### 4.3 API

A standard authorization API has already been defined by the Open Group in 2000. It is called the AZN API and is specified in the C language. It is based on the ISO 10181-3 access control framework and specifies the interface between the access control enforcement function (AEF) and the access control decision function (ADF).

We rewrite the AZN API with Object-Oriented method, and select Java language for development. After these works, the application gateway use API to “construct” and PMI Java Object, and complete the work by invoke the methods of this object. The main methods include: GetCreds, Decision, and Shutdown.

When a user initiates a call to the target, the AEF authenticates the users, then passes LDAP DN to the ADF through a call to GetCreds. The ADF uses this DN to retrieve all role ACs of the user from the list of LDAP URIs (“pull mode”). The role ACs are validated against the policy e.g. to check that the DN is within a valid subject domain, and to check that the ACs are within the validity time of the policy etc. Once the user has been successfully authenticated he will attempt to perform actions on the target. At each attempt, the AEF passes the subject object, the target name, and the attempted action along with its parameters, to the ADF via a call to Decision. The Decision method will return “Granted” or “Denied” after executing the checking.

Shutdown method is designed to be used in dynamically deploy new policy in domain. The AEF can follow the call to Shutdown with a new Constructor call, and this will cause the ADF to read in the latest policy and be ready to make access control decisions again.

## 5. EXPERIMENT

The first demo system for SSS has been implemented based on the design described in previous section. Some

open source projects are used in the demo system, like Tomcat, Apache SOAP, openCA, and so on. The security API depends core Java security technology, includes Java Authentication and Authorization Service (JAAS), Java Cryptography Extensions (JCE) and Java Secure Socket Extensions (JSSE).

Security service is complicated system. From the running result, there are many works to do in the future. We should consider the performance on the real Internet environment. We need add more robust integration with exist system. And next step, the private keys are generated in the Tags or cards, they can be used as soon as the user is in possession of his tag or card.

## 6. CONCLUSION

RFID technology is changing the way organizations manage their supply chain networks. With RFID, inventory data becomes more transparent and more accurate, enabling organizations to speed up delivery, respond more quickly to customer demand. But integrating RFID into existing systems has been problematic, especially, it let suppliers, manufacturers, and customers become a virtual organization across the unsafe internet. We propose a security approach on open web service to validate certificate based on current web security environment, and a privilege management infrastructure used in collaborative business scenario Our approach will be a model for the future security system that offers security of open web service security.

## **ABSTRACT**

A survey of college students from both IS and CS programs was undertaken to understand student recognition and awareness of information security issues in course learning. Comparisons will be made for students before and after taking the security class as well as between the two different majors. The results of the study will demonstrate possible differences in perceptions between students of two majors, and identify security issues which have not been identified so that students and institutions are able to improve academic achievements by better tailored security curriculum and training. The findings will also provide feedback to future employers of the students.

**Keywords:** information security, assurance, awareness, perception, recognition

## **1. INTRODUCTION**

Information security and assurance is becoming a mission-critical component of today's business enterprises, governments, and academic institutes. Notably, after the 9-11 tragedy, more people, such as government leaders, business managers, IT practitioners, and academic researchers, have realized the crucial importance of information security, which, without proper management and supervision, could trigger unforeseeable catastrophe. As a result, a variety of computer and information security training and courses have surfaced at torrent levels in both academia and industry in a bid to improve and revamp employees' and students' awareness, recognition, and assessment of information security. In industry, companies giving serious consideration to information security now yearn to hiring information security/assurance specialists who are able to help them underpin security control, management, supervision, and centralization.

Accordingly, major colleges or universities are endeavoring to open security-related courses, in either Management Information Systems (MIS) programs in Colleges of Business Administration or Computer Science (CS) programs in Colleges of Computer Science/Engineering or both, to spawn these desired information security specialists. And MIS and/or CS major students are enthusiastically interested in taking these courses in an effort to cater to the increasing market demand. The trend is expected to continue to grow in the years ahead as information security and assurance unveils its very importance in today's computing community.

According to literature, a number of researchers have already designed a variety of security frameworks and indicated and measured the importance of establishing security management and control [9, 10, 15, 16]. However, quite a few researches have shed light on assessment of students' information security awareness and recognition from both MIS and CS perspectives in course learning, despite the fact that both academic divisions offer security-related courses at major colleges or universities in the United States. In addition, employers are eager to discover the fitness between the sophisticated work requirements and college graduates' capabilities of handling security issues in the real world. This research, therefore, focuses on observing and identifying undergraduate and graduate MIS and CS major students' awareness, perception, and recognition with regard to information security in course learning.

This research project, funded by a major southern university's Center for Computer Security Research (CCSR) in the United States, intends to answer three questions:

1. What are the security issues recognized by student majors in CS vs. MIS?
2. Are there any differences in their security management skills after taking the security class?
3. Are there any differences in their security technology skills after taking the security class?

## **2. LITERATURE REVIEW**

### **2.1 Technical Skills and Managerial Skills for IS Security**

As more organizations become so dependent on

computer-based and telecommunications-intensive information systems, security has become a vital element for organizations of all types. The unlimited access by a large, knowledgeable community of end users from desktop, dial-in, and network facilities creates a new and extremely vulnerable environment [10]. Each year, billions of dollars worth of information resources are stolen, vandalized, and otherwise misused due to a growing number of industrial spies, computer "hackers," and even unwitting employees [7]. Additionally, Arce and Levy [2] found that the weakest link has shifted from the technology area to the physical area, the human resource area, the policy area, and even individual operating desktop operating systems.

Information and system security has different meanings in the modern business environment. For some, the concept implies reliability (protection against accidental problems) and defensibility (protection against deliberate misuse). For others, IS security is placed into a people context and takes in to account culture, policies, organizational structures, and operating environments. Security technologies tend to address purely technical issues, such as the use of passwords for authentication, or cryptography to guard integrity, and largely ignore the human involvement [4].

Security experts have adopted security measures into four distinct, sequential activities: deterrence, prevention, detection, and recovery [5, 11, 12]. These four classes of sequential actions have a strong theoretical basis in deterrence theory. That is information security actions can deter potential computer abusers from committing acts that implicitly or explicitly violate organizational policy and lower systems risk [16].

In the corporate world, information security is generally seen as being of interest to the IT department, and so many professionals do not give adequate importance to the security concerns of an organization [3]. Straub [16] pointed out that managerial perception of the system security can influence organization security planning and strategies. To ensure the wholeness and soundness of information systems and organization, a security manager will have to take on the role of maintaining integrity of the organizational infrastructure, not just the technical information systems. Therefore, information system security is not a technical problem but a social and organizational problem because the technical systems have to be operated and used by people.

The theory of computer security offers a formal method for security engineering. It has three components: policy, mechanism, and assurance. The theory implies that to achieve a coherent security architecture, security must be considered from the outset, not as an afterthought. Competence in design for security policy enforcement, testing for security, and assessment of security must be part of the education of system

implementers [8]. This agrees with Straub's model for effective system security management.

## 2.2 Importance of Security Awareness

Security awareness programs are a form of deterrent countermeasure which deserves special mention because educating users as well as their superiors about security yields major benefits [16]. In a survey about MIS management perceptions of the organization security threat, Loch et. al. [10] found out that there is a lack of awareness of the security risks and employee education regarding prevention measures. Managerial awareness is the key to successful security management [16]. To heightened security awareness on the part of managers, professionals, technicians, contractors, etc., all relevant groups should be provided with sufficient training and supporting reference materials to allow them to properly protect and otherwise manage information assets. There are needs to look to organizational theory, management science, and the developing field of information systems instead, for aid and succor in combating threats to security.

## 2.3 Need for Security Curriculum

Information security jobs in networking and databases will be hot in the next three to five years according to a IT workforce survey in 2004 by Information Technology Association of America [1]. Yet the number of skilled practitioners of computer security who are able to address the complexities of modern technology and are familiar with successful approaches to system security is very small [8]. The recent US Presidential Commission on Critical Infrastructure Protection recommends developing education on methods of "reducing vulnerabilities and responding to attacks on critical infrastructures." The commission recognizes the need to make the "required skills set much broader and deeper in educational level for computer scientists, network engineers, electronic engineers, and business process engineers." By moving to an educational system that cultivates an appropriate knowledge of security, we can increase the likelihood that our next generation of IT workers will have the background needed to design and develop systems that are engineered to be reliable and secure.

When talking about security in engineer education, Irvine [8] gave two important criteria for selecting outcomes for information security education: The education must result in graduates prepared for the security challenges they will encounter in their professional roles; the specific education outcomes for security in a given educational program must be consistent with those of the larger engineering context. Vaughn also considered that the computer science community has an obligation to train its graduates in known protection requirements, causes, vulnerabilities, current research, needed research, and to some extent,

computing ethics so that the graduates could be prepared to defend themselves and their employees from common threats that are known today and to help them understand the problem sufficiently such that they can contribute to discovery of the future solutions that are yet to be found [18].

It has been suggested that security insights must be integrated within the existing information systems programs, rather than be treated separately. There are two possible approaches: computer security could be the focus of the curriculum, which would investigate the foundations and technical approaches to security in considerable depth; a computer science or computer engineering curriculum could choose to use computer security as an important property to be addressed in all coursework [8]. Therefore, it is rare to find computer security course offerings at most academic institutions today. A comprehensive pedagogical approach would suggest that current CS course content be modified to include course specific discussion related to security in networks, database, operating systems, architectures, and software engineering followed by a capstone course learned at the end of the program that is specific to information security issues [18]. Topics appropriate to security-oriented curriculum include security policy models; formal methods applied to system specification, development, and analysis; hardware and software protection mechanisms; security system design, implementation, and testing; database security; modern cryptography; cryptographic protocols; identification and authentication; and coherent network security architecture. Ideally, computer science and computer engineering texts, course materials, and laboratory exercises would have computer security completely integrated into appropriate topics and add a highly relevant dimension to the program- a feature prized by prospective employers [8]. Unfortunately, such materials do not yet exist. The coverage on techniques in security-related textbooks is moderate while other issues like security management have little in depth coverage. Therefore, the classroom coverage of security issue depends on the willingness of instructors to provide supplementary materials [13] because textbooks for courses in computer security provide only a good foundation for the student to learn the techniques that are used with computer systems and networks. In the interim, however, security-related supplements can be used.

Computer science and Information systems are two most common academic subdivisions in the computing field. While computer science examines topics related to computer concepts at technical levels of analysis by formulating processes/methods/algorithms largely using mathematically-based conceptual analysis, information

science topics related largely to organizational concepts, especially usage/operation and technology transfer, although they also explore systems/software topics, all primarily at a behavioral level of analysis.

Glass et al. [6] conducted a study of representative and well-recognized journals from each field over the five-year period 1995-1999, and determined that system security and data security have been given minimal attention in the information systems arena. Reichgelt et al. [14] compared baccalaureate programs in IS, IT and CS. Their study shows that although data security ranked eighth of frequencies for topics offered by the surveyed universities, it is mostly integrated in the curriculum of computer science rather than a separate course. There are very few IS curriculum that cover the security topic.

The Center of Academic Excellence in Information Assurance Education Program was created to help academic institutions prepare security engineers for work in the government IT security area. Universities have responded to this call by setting up separate security course and offering security-oriented course in majors like information system. Students tend to naturally gravitate to this subject area as one of interest and one that offers good skills and knowledge that employers may find attractive [17]. It would be interesting to find out how the security courses are taught in different disciplines by comparing students recognition and awareness of information and system security before and after taking the class. The instructors and institutions can improve the program to fit student background and tailor the course content for future employer needs.

### 3. RESEARCH METHOD

An empirical investigation will be conducted in *Business Information Systems Security Management* class in the College of Business's MIS program (Course number BIS 6133 for both senior undergraduate and graduate MIS majors) this fall semester starting August 2004. Then data will be collected in the *Information and Computer Security* class in the College of Computer Science and Engineering's CS program (Course number 6243 for both senior undergraduate and graduate CS majors) the following spring semester in 2005 at a major southern university in the United States.

The security technologies and security management skills collected from prior security studies are listed in table 1. These skills are either currently in use or have been proposed by security researchers/practitioners for its importance in computer/system security.

Table 1. List of Issues in Security Technology and Security Management

Security technology	Security management
1. Anti-virus/Malware	1. Disaster recovery
2. Access-control	2. Data backup
3. Firewall	3. Security management policies
4. Password/Log-in	4. Employee education
5. Encryption	5. Patch management
6. Smart card	6. Identity management
7. Authentication	7. Vulnerability management
8. Intrusion detection	8. Procedure of log management
9. Virtual private network (VPN)	9. Procedure of incident report
10. Wireless security	10. Procedure of system maintenance
11. Contents filters	11. Procedure for approval of changes
12. Digital certificate	12. Documentation of changes
13. Network sniffers	13. Budget control
14. Biometric	

Survey questionnaires will be administered prior to and after these two security courses in order to measure any significant change on students' recognition and awareness of information security from both MIS and CS perspectives. Student demographic information such as gender, age, years of computer usage, ownership of computer and experience of other security courses will also be collected for analysis.

#### 4. POSSIBLE FINDINGS

Since we only have data from one out of the four data collections designed for the study, there is no data analysis to report at this point.

A significant limitation of this study is the sample used. Both classes that will be investigated are from the same university and are comparatively small in size because of the availability of separately offered security courses. Also, both are single section courses and are taught on different terms at different times. Future studies should also include students in other universities and courses which has security as an integrated part of the course.

The final result of the study will identify how students' skills and/or perceptions of information security management and technology change after finishing the class. The research findings will be used to help students and instructors achieve further academic excellence in both colleges by fine tuning security curriculums and training and by providing business employers with more instrumental feedbacks with respect to efficient hiring of MIS and CS graduates in the job market.

#### ACKNOWLEDGEMENT

A number of people have generously given valuable time and effort towards this article. The authors appreciate Dr. Ray Vaughn, Professor of Computer Science and Engineering, for the support of The Mississippi State University Center for Computer Security Research (CCSR), and Dr. Merrill Warkentin

and Dr. J. P. Shim, Professors of Management Information Systems at Mississippi State University, for their research directions and suggestions.

## A Mediator to Integrate Databases and Legacy Systems: The Mediated Data Integration (MeDInt) Mediator

Chaiyaporn Chirathamjaree

School of Computer and Information Science, Edith Cowan University, Perth, 6050, Australia  
c.chirathamjaree@ecu.edu.au

### ABSTRACT

To interoperate data sources which differ structurally and semantically, particular problems occur, for example, problems of changing schema in data sources will affect the integrated schema. In this paper, conflicts between heterogeneous systems are investigated and existing approaches to integration are reviewed. We propose a new mediated approach employing the Mediated Data Integration Mediator (MeDInt), and wrapping techniques as the main components for the integration of databases and legacy systems. The MeDInt mediator acts as an intermediate medium transforming queries to sub-queries, integrating result data and resolving conflicts. Wrappers then transform sub-queries to specific local queries so that each local system is able to understand the queries. This framework is currently being developed to make the integration process more widely accessible by using standard tools. A prototype is implemented to demonstrate the model.

**Keywords:** Conflict Resolution, Heterogeneous Databases, Integration, Legacy Systems, Mediation, Wrappers

### 1. INTRODUCTION

The information required for decision making by executives in organizations is normally scattered across disparate data sources including databases and legacy systems. To gain a competitive advantage, it is extremely important for executives to be able to obtain one unique view of information in an accurate and timely manner. To do this, it is necessary to interoperate multiple data sources, which differ structurally and semantically. In the process of interoperating any two or more database systems, there are critical problems that need to be solved, for instance, some databases are designed from different models, objects which have the same meaning in different databases might have different names, and objects which have the same meaning in different systems might be measured by different units. Furthermore, there are identity conflicts, representation conflicts, scope conflicts, etc [1; 2; 4; 8; 9]. Although several researchers have studied the conflicts and integration of heterogeneous database systems [1; 9; 11; 13; 14; 17], there is still no common methodology for resolving conflicts and integrating such databases. Particularly, few studies have focused on the integration of databases and legacy systems. In legacy systems, the semantics are hidden and hard to determine. In fact, some legacy systems store data to flat files, which are completely different in schematic design from database management systems (DBMSs).

Another significant issue is that almost all research on database integration presents pre-integration approaches using global schema techniques, which require complete integration. All local views are mapped by one global view. This method is convenient for users but it does not operate in the real-time manner because the global view must be created before query processing. As a result when only one object of a local system is

modified, it affects the global schema requiring huge changes [4]. Furthermore, schema and semantic conflicts must be solved in the process of the global schema creation. The more data sources involved, the more difficult such conflicts are to be solved. This research focuses on the database and legacy integrating solution that avoids using the global schema pre-integration approach.

The Mediated Data Integration (MeDInt) Mediator is introduced in an attempt to overcome the above difficulties. It has been developed by focusing on providing a solution to interoperate heterogeneous data sources by transforming both the queries and the data transparently. Furthermore, this approach does not only solve schema and semantic heterogeneities, but also conflicts from different query languages and data models, namely data model heterogeneity.

### 2. RELATED WORKS

#### 2.1 Conflicts and Resolution

Information from different sources can not be presented to users if it has not passed the process of conflict resolution. In terms of database integration, conflicts are differences of relevant data between component local database systems. The taxonomy of conflicts in this paper is divided into Schema conflicts and Semantic conflicts.

Schema conflicts are discrepancies in the structures or models of heterogeneous database management systems. Naming conflicts [8], Structural conflicts [4; 8; 9], and Identity conflicts fall into this conflict category. Naming conflicts are the synonyms or homonyms of objects in local systems. Structural conflicts are the different uses of data models to represent the same object. Identity

conflicts occurs when the different attributes, as a key, are used to access the same meaning information.

Semantic conflicts are discrepancies in the meaning of related data among heterogeneous systems such as Naming conflicts, Representation conflicts [3; 4], Scaling conflicts [2], Granularity conflicts, Precision conflicts [1], Missing data, Scope conflicts, and Computational conflicts [2]. Naming conflicts are able to occur in data itself as well as in the structure of data. Representation conflicts or Format heterogeneities are the different uses of formats or data types to represent the same meaning objects. The different units of measurement generate Scaling conflicts.

From a survey of the literature, several methods to resolve conflicts have been found. In the case of Naming conflicts, a catalog [7], tables [4], or meta-data repository [1] can be used for maintaining these correspondences. An Object Exchange model [12] is able to transform semantics into simple structures that are powerful enough to represent complex information by using meaningful tags or labels. Kim [7] suggests three ways to resolve different representations of equivalent data: static lookup tables, arithmetic expressions, and mappings. In addition, a formulae has been suggested by Holowczak & Li [4] for converting values in one system to correspond with units in another system. They also introduce Superclasses to encapsulate each component database to create their relationships. Differences in attribute naming are solved by aliases [1; 4]. By using benefits of functions, Hongjun [5] proposes a data mining approach to discover data value conversion rules. Furthermore, independent views can be constructed to solve Structural conflicts. A view neither depends on any specific names nor on changes when schemas are modified [9].

## 2.2 Integration Approaches

Numerous integration approaches have been introduced throughout the last twenty years to bring about the interoperability among heterogeneous systems. Missier, Rusinkiewicz, & Jin [10] categorise heterogeneity resolution methodologies into four main broad approaches: Translation, Integrated, Decentralised, and Broker based.

Translation approach needs highly specialised translation for each pair of local database systems. Therefore, the number of translators grows up exponentially especially when local systems increase. The development of these ad hoc programs is expensive in terms of both time and money.

In Tight-coupling approach or fully integrated approach, individual schema from multiple data sources is merged by one or more schemas. If only one schema is prepared, it is called a global schema approach.

Otherwise, it is called a federated database approach. The global schema approach allows access of multiple data sources by providing the conceptual global schema as a logically centralised database [6]. Multiple local schemas are consolidated to create the global schema. Users are able to use one database language to query the global schema without understanding any local schemas. Generally, problems of heterogeneity must be resolved in the process of creating the global schema. A major difficulty is the process of creating global schema which thoroughly understands the differences between the independently-designed heterogeneous local schemas, and homogenises such differences [7]. This approach is more difficult when the number of databases increases. Another approach, the federated database, also allows users to query more than one federated schema without knowledge of local data sources. This approach still requires complete pre-integration. The federated schema must be developed before issuing any queries, so any changes in local schemas would affect the federated schema.

Loose-coupling approach [2] or decentralized approach has been introduced in an attempt to resolve the problems arising from tight-coupling approaches by discarding either pre- or partial-integrated global schema. This approach allows users to query local database systems directly without any global schemas by placing the integration responsibility on users. Multi-database manipulation languages, which are capable of managing semantic conflicts through their specification, are provided as query language tools that are able to communicate with the local databases. Users can see all the local schemas and create their own logical export schema from selected schemas relevant to the information they need [3]. However, it requires users to have semantic understanding and to be able to resolve conflicts in creating their schema, which will be numerous with large numbers of data sources. In Broker-based approach, the crucial part is the conflict detector module using shared ontologies, but the process of doing those ontologies is not completely automated.

The limitations of the above integration approaches have led integration technologies towards a new variety of solutions. Various theories have been applied to solve integration problems such as the object-oriented model, knowledge base [11; 14; 16], ontology [13], and modeling [4].

## 3. THE MeDInt MEDIATOR

The research has introduced a heterogeneous database integration model incorporating a mediator and wrappers as intermediate layers between the application and data sources. The mediator, MeDInt (Figure 1), serves as an information integrator, between the application and wrappers. Generally, mediators are responsible for retrieving information from data sources, for transforming received data into a common

representation, and for integrating the homogenised data [15]. In this model, the MeDInt Mediator acts as an

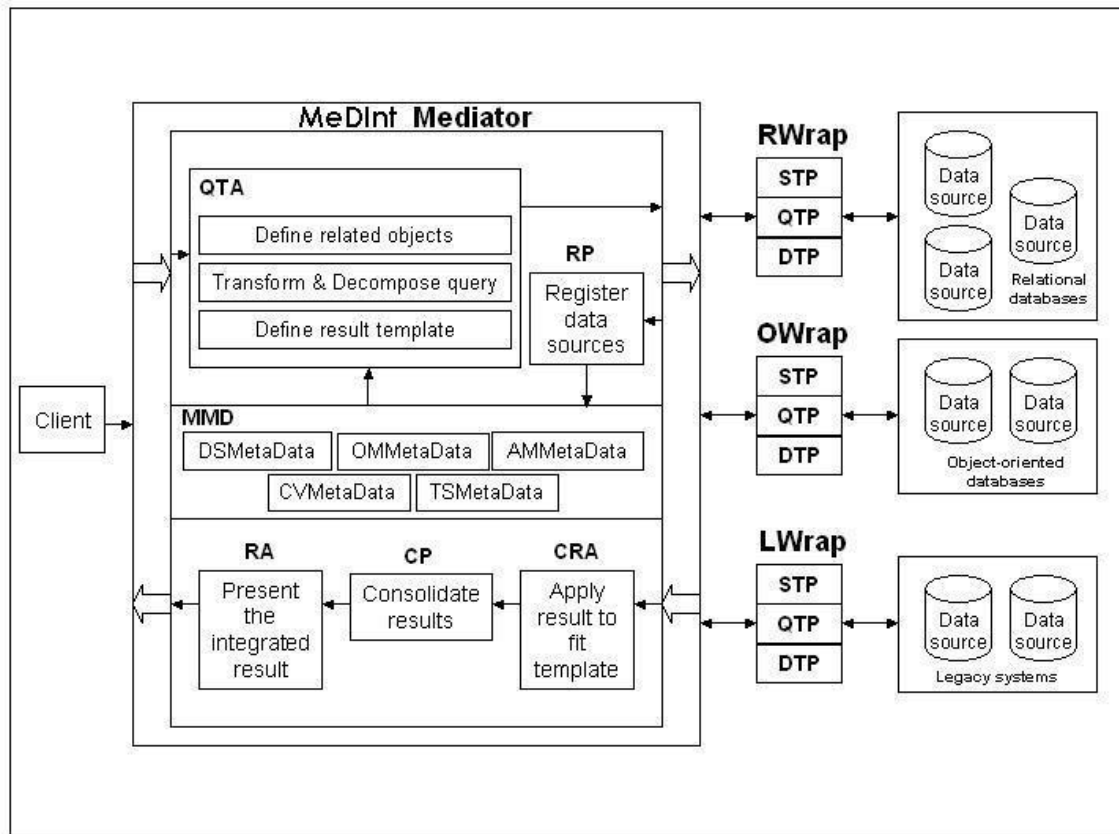

Figure 1. The MeDInt mediator

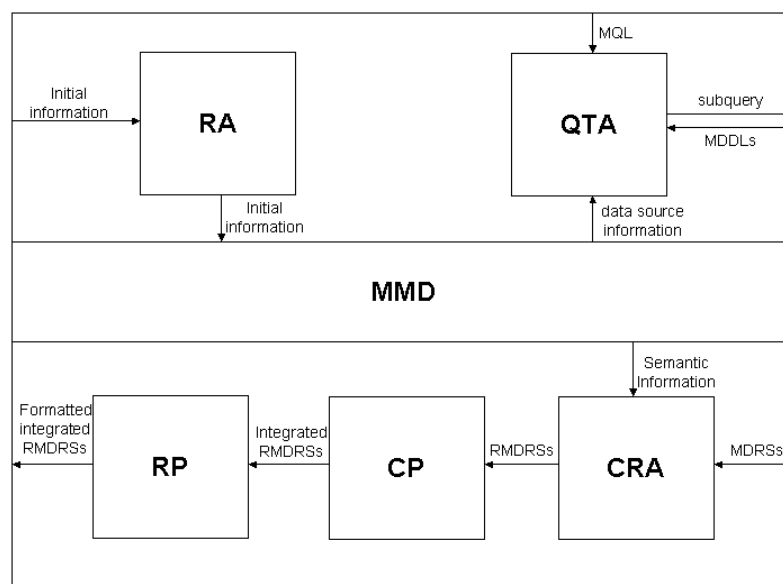

Figure 2. The six components of the MeDInt mediator

interchangeable agent and facilitator for wrappers and clients. It consists of six components working together transparently to facilitate clients and data sources to achieve the following tasks:

- transforming and decomposing the submitted query into subqueries and then distribute them to associated wrappers;
- providing both schematic and semantic knowledge which is critical for query transformation and conflict resolutions;

- resolving conflicts; and
- consolidating query results.

All the functions above are served by six components (Figure 2), which are the Registering Processor (RP), the Query Transformation Agent (QTA), the Mediated MetaData (MMD), the Conflict Resolution Agent (CRA), the Consolidation Processor (CP) and the Rendering Agent (RA).

Wrappers are in the intermediate layer between the MedInt Mediator and data sources. A wrapper is invoked when a data source in a difference data model is added to the integration system. Wrappers mainly act as translators providing the MedInt Mediator with information in the common data model used in the integration system by dealing with the data model heterogeneities of different data sources. The principle objective of wrappers is dealing with data model heterogeneities including the different data definition languages and data manipulation languages by mapping variety data models to the Mediated Data Model. Each MedInt wrapper is composed of a Schema Translation Processor, a Query Translation Processor and a Data Translation Processor. One novel feature of the architecture is to push unshared characteristics the wrappers to reduce the amount of middleware modification when a data source is added, removed or modified. In addition, the use of the Mediated Data Model eliminates problems relating to the data model heterogeneity by providing from the common data model acknowledgeable by components in the MedInt Mediator.

#### 4. Medint PROCESSES

When a new data source is added to the integration system, it is registered to the Mediated MetaData (MMD). Data source information, for example, assigned name, location, type, description, and constraints relating to its structure and semantics are collected into the Data Source Metadata (DSMetaData), a category of MMD. A query from a user to retrieve the information from heterogeneous data sources is sent to the MedInt Mediator instead of directly to the data sources. The required objects are determined and a request is submitted to the wrapper to get the related object schema definitions. The submitted query from the user is transformed to a specific query language appropriate to the database management system of the data source. A template for the results is created from the results obtained from multiple data sources. This method does not try to resolve conflicts directly which would be more difficult and complicated.

After getting a response data back from data sources, a component of a wrapper translates the query results into the Mediated Data Representation Structure (MDRS). The conflict resolution is done by applying all MDRSs to fit into the structure of the predefined template. The

resultant MDRSs that are structurally equivalent are then integrated and consolidated. Finally the integrated result is sent to the user.

This approach overcomes the weakness inherent in other approaches that require the physical or logical integration of component schemas. Only the query result from each source, according to the result template, will be integrated instead. The template will be created from the submitted query. The resultant data from each data source will be applied to fit to the template which is the means by which the heterogeneities are resolved.

#### 5. RESULTS AND DISCUSSION

A number of example problems of heterogeneities from a number of information systems that require integration have been tested. The objectives are to demonstrate the integration process using the MedInt mediator and to evaluate its correctness.

Test problem 1 is a Hotel Reservation Information System which provides information for travel agencies. The information systems of contacted hotels need to be interoperated. Heterogeneities have been found when integrating them. The 2<sup>nd</sup> test problem is a university information system which is composed of a relational system and an object-oriented system.

The proposed MedInt Architecture and MDM have been tested for functionalities and the outcomes look promising. Results (Table 1) indicate that the objectives in resolving conflicts both structurally and semantically have been achieved. From the table mentioned above, the following three categories of heterogeneities have been determined: Model, Schema, and Semantic. All of them have been solved as shown by the MedInt with the support of the MDM (the Mediated Data Model has been developed in this study specifically for describing and representing heterogeneous data both schematically and semantically) which is suitable for homogenising different data models, schemas and semantics of component data sources. Another feature of our proposed model is that it can be implemented in any languages. We have chosen XML as the implementation language in the prototype because it offers a number of advantages. XML is platform independent, provides self-described tags which are easy to understand. It is also suitable for describing schema and semantic of objects in a real world since XML is based on an object-oriented model.

Table 1 Summary of the heterogeneities resolved by the MeDInt mediator

Heterogeneities	Conflicts	Test Problem1	Test Problem2	
			Query 1	Query 2
Model		✓	✓	✓
Schema	Naming	✓	✓	✓
	Structural	✓	✓	
	Specialisation		✓	✓
	Relationship		✓	
Semantic	Naming		✓	
	Scaling	✓		✓
	Abstraction			✓
	Representation	✓		

## 6. CONCLUSION AND FUTURE WORKS

The research proposes the MeDInt Mediator as the framework based on the mediated approach for the integration of heterogeneous data sources to solve conflicts occurring when interoperability is required. The paper presents a new approach for achieving the interoperability of multiple data sources logically integrated at the time the query is issued. The system is able to describe or represent heterogeneous data both schematically and semantically. No pre-integration is required before users can issue their queries. This avoids the problem of local schema evolution which usually happens in dynamic systems. Further investigations are planned to cover the query performance issues. Another possible future work is to incorporate the write access through the updating of master data sources and the replication of data sources.

# A Multi-Attribute Group Decision Approach Based on Rough Set Theory and Application in Supply Chain Partner Selection

Wenqi Jiang, Zhongsheng Hua

Business School, USTC, Hefei, Anhui 230026, China  
wqjiang@ustc.edu, wq\_jiang@sina.com.cn

## ABSTRACT

In multi-attribute group decision, decision makers (DMs) are willing or able to provide only incomplete information because of time pressure, lack of knowledge or data, and their limited expertise related with problem domain, so the alternative sets judged by different decision makers are inconsistent in allusion to a certain decision problem, how to form consistent alternative sets becomes a very important problem. There have been a few studies considering incomplete information in group settings, but few papers consider the adjustment of inconsistent alternative sets. We suggest a method, utilizing individual decision results to form consistent alternative sets based on Rough Set theory. The method can be depicted as follows: (1) decision matrix of every decision maker is transformed to decision table through an new discretization algorithm of condition attributes; (2) we analyze the harmony of decision table of every DM in order to filter some extra alternatives with the result that new alternative sets are formed; (3) if the new alternative sets of different DMs are inconsistent all the same, learning quality of DMs for any inconsistent alternative is a standard of accepting the alternative.

**Keywords:** group decision; inconsistent; Rough Set; reasoning learning

## 1. INTRODUCTION

A supply chain is a set of facilities, supplies, customers, products and methods of controlling inventory, purchasing, and distribution. As the global economy has become a reality, only through alliances can firms create more value, it becomes very important for studying the relation of alliances, the management of which is a complicated process in which appropriate partner selection is an important phase. Commonly, decision makers from stock, quality, production, technology and R&D department select partners from many partners with whom they expect to cooperate, some difficult problems exist in partner selection: (1) decision makers from different branches have different preference for the measurement indexes and inaccurate information because of time pressure, lack of knowledge and data, so the partner (alternative) sets offered by different decision-makers will be inconsistent, incomplete and incorrect; (2) different partners and their styles will cause generous number of probable partner combinations, so some alternatives must be thrown off to improve the efficiency of supply chain partner combinations., how to form consistent alternative sets becomes very important. At present, two major approaches are applied in adjusting alternatives: (a) filtering some alternatives using attribute value<sup>[1-3]</sup>; (b) configuration learning is used such as artificial neural networks which can not add new rules to the incomplete rule sets<sup>[4-7]</sup>. However, the two approaches can't solve the problem of inconsistent alternative sets. Rough set theory<sup>[8]</sup>, which uses the concept of equivalence classes as its basic principle, was proposed by Zdzislaw Pawlak in 1982 and has been used in reasoning and knowledge acquisition for expert systems.

The idea of this paper can be depicted as follows: (1) the

relative benefit value of all alternatives in a decision matrix are computed through TOPSIS method, an algorithm is presented that condition attributes are discretized with the difference between weight of condition attributes and significance of condition attributes for every patulous decision matrix; secondly, we filter some extra alternatives in decision table by analysis of the harmony of decision table, and the new alternative sets judged by every decision makers are formed, if inconsistent alternative exists in the new alternative sets of different decision makers, learning quality of decision makers for any inconsistent alternative is a standard of accepting the alternative.

## 2. THE CAUSE OF THE INCONSISTENT ALTERNATIVE SETS

The process of supply chain partner selection includes filtering wildly, filtering carefully, fining and affirming, tracking and appraising. At the stage of filtering wildly, decision-makers from different branches who have different preference for the measurement indexes often make selections from many alternatives offered, and it is difficult for them to gain complete information, so the alternative sets given by different decision-makers are possibly inconsistent<sup>[10-11]</sup>.

With the hypothesis that the alternative definition is same and decision-makers are  $\{DM_i, i = 1, 2, \dots, m\}$  whose alternatives are  $A_i = \{A_j, j = 1, 2, \dots, m\}$ , for any  $A_i$  and  $A_j$ , we can describe their relation as follows ( $\alpha$  is presented in advance):

$$(1) A_i \setminus A_j = \phi$$

$$(2) \max\left(\frac{\text{card}(A_i | A_j)}{\text{card}(A_i)}, \frac{\text{card}(A_i | A_j)}{\text{card}(A_j)}\right) < \alpha, \text{ more}$$

than  $A_i | A_j \neq \emptyset$ .

$$(3) \min\left(\frac{\text{card}(A_i | A_j)}{\text{card}(A_i)}, \frac{\text{card}(A_i | A_j)}{\text{card}(A_j)}\right) > \alpha, \text{ more}$$

than  $A_i \neq A_j$ .

$$(4) A_i = A_j.$$

Our aim is to form consistent alternative sets in favor of group appraisement. This paper applies rough set theory [8-9] which is introduced by Pawlak (1982) to analyze the inconsistent problem in supply chain partner selection and tries to give a method of forming consistent alternative sets, the adjusting process can be depicted as figure 1:

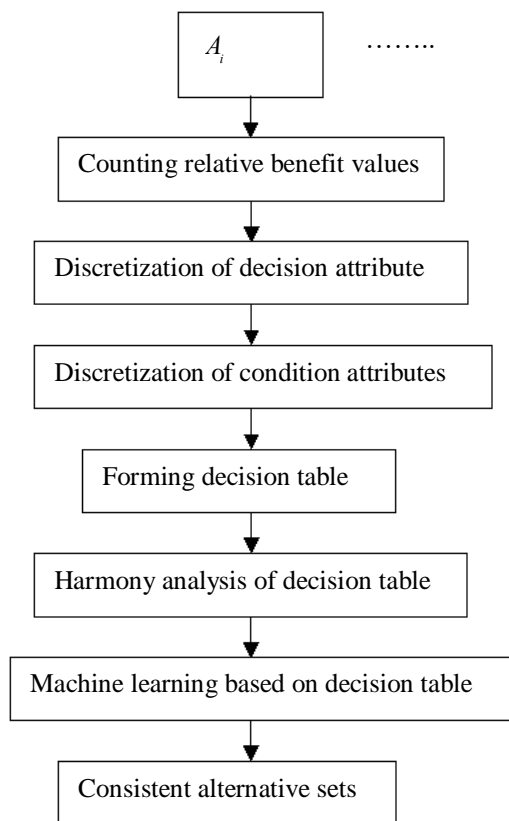

Figure1 : Adjusting procedure figure of inconsistent alternatives

### 3. ATTRIBUTES DISCRETIZATION

The process of converting data sets with continuous attributes into input data sets with discrete attributes, called discretization, was studied in many papers [12-16], the major methods include the equal-interval-width method, the equal-frequency method, NalveScaler method, SemiNaiveScaler method, etc, but these methods don't contact multi-attribute decision with Rough Set Theory. In the process of multi-attribute decision matrix transformed to decision table, two

difficult problems are put forward that are the unknown value of decision attribute and how to discretize the attributes.

In decision table, the significance of condition attributes reflects weight of condition attributes, by whose difference we can discretize the condition attributes. The procedure can be depicted as follows:

(1) Because the value of decision attribute ( $U(a_{ip})$ ) can be computed by many methods, the paper applies TOPSIS method to compute  $U(a_{ip})$  which reflects the near degree between the value of alternative  $a_{ip}$  and perfect alternative, the decision matrix and patulous matrix of  $DM_i (i = 1, 2, \dots, m)$  can be depicted as table 1 and table 2. We can classify  $U(a_{ip})$  into three sorts:

$U(a_{ip}) > 0.5$   $U(a_{ip}) < 0.5$   $U(a_{ip}) = 0.5$  the coding are 0, 1, 2 respectively.

(2) The weight of condition attributes of every decision matrix are computed by entropy method, so we can gain

$$w_q(i) = \frac{\ln l_i + \sum_{p=1}^{l_i} b'_{pq}(i) \ln b'_{pq}(i)}{\sum_{q=1}^n \ln l_i + \sum_{z=1}^{l_i} b'_{zq}(i) \ln b'_{zq}(i)}, \text{ the vector of}$$

condition attributes judged by  $DM_i$  is  $w(i) = (w_1(i), w_2(i), \dots, w_n(i))$ .

Table1 : The decision matrix judged by  $DM_i$

	$C_1$	.....	$C_n$
$a_{i1}$	$b_{11}(i)$	.....	$b_{1n}(i)$
$a_{i2}$	$b_{12}(i)$	.....	$b_{2n}(i)$
.....	.....	.....	...
$a_{il_i}$	$b_{l_i1}(i)$	.....	$b_{l_in}(i)$

Table2 : The patulous decision matrix judged by  $DM_i$

	$C_1$	.....	$C_n$	$U_i(a_p)$
$a_{i1}$	$b_{11}(i)$	.....	$b_{1n}(i)$	$U(a_{i1})$
$a_{i2}$	$b_{12}(i)$	.....	$b_{2n}(i)$	$U(a_{i2})$
.....	.....	.....	...	.....
$a_{il_i}$	$b_{l_i1}(i)$	.....	$b_{l_in}(i)$	$U(a_{il_i})$

Where:  $\{C_1, C_2, \dots, C_n\}$  is a finite set of condition attributes,  $b_{pq}(i)$  shows the value of alternative  $a_{ip}$  under the condition attribute  $C_q (q \in (1, 2, \dots, n))$ . Because the units of different condition attributes may be inconsistent,  $b_{pq}(i)$  need be changed into

$$b'_{pq}(i) (b'_{pq}(i)) = \frac{b_{pq}(i)}{\sqrt{\sum_{p=1}^l b_{pq}^2(i)}}.$$

(3) For condition attribute  $C_q$ ,  $b'_{pq}(i)$  can be arrayed sort ascending, we give the former class number  $m_q = 2$  and apply classification clustering method to classifying the condition attributes into  $m_q$ .

(4) We compute the significance of condition attributes of decision table of every decision maker which is  $r_c(D) - r_{c-c_q}(D)$ , the standardization of the value of  $r_c(D) - r_{c-c_q}(D)$  is the effect indexes of condition

attributes which is  $v_q(i) = \frac{r_c(D) - r_{c-c_q}(D)}{\sum_{q=1}^n (r_c(D) - r_{c-c_q}(D))}$ , if the

significance of all condition attributes is 0, the effect indexes of every condition attribute should be same, which is  $\frac{1}{n}$ , the vector of the effect indexes can be depicted as  $v(i) = (v_1(i), v_2(i), \dots, v_n(i))$ .

(5) The difference between the significance of condition attributes and the weight of condition attributes

$$d_{vw}(i) (d_{vw}(i)) = \frac{\sqrt{\sum_{q=1}^n (v_q(i) - w_q(i))^2}}{n} \text{ is computed.}$$

Because the interval spot of condition attributes is finite, the least value exists. In order to reduce to the computing times, we can think of  $d_{vw}(i) \leq \beta$  ( $\beta$  is presented in advance) as the last discretization result. If the former discretization can not satisfy the request which is  $d_{vw}(i) \leq \beta$ , we can find the maximal sensitive degree

$$\max(|\frac{\Delta d_{vw}(i)}{\Delta x_q}|) \text{ and change the class of } C_q. \text{ At last, we}$$

also code the condition attributes such as 0, 1, 2, etc, and compute the classifying interval of all condition attributes at the same time.

#### 4. CONFLICTING ALTERNATIVES ANALYSIS IN DECISION TABLE

Decision table which includes many alternatives is a knowledge expression system, a alternative is a decision rule, extra alternatives exist in decision table because of the deficient condition attributes and untrue stylebooks.

In table 2, if  $\{b_q^+(i)\}$  and  $\{b_q^-(i)\}$  denote the perfect

point and imperfect point,  $U(a_{ip})$  can be depicted as follows:

$$U(a_{ip}) = \frac{\sqrt{\sum_{q=1}^n (b'_{pq}(i) - b_q^-(i))^2}}{\sqrt{\sum_{q=1}^n (b'_{pq}(i) - b_q^+(i))^2} + \sqrt{\sum_{q=1}^n (b'_{pq}(i) - b_q^-(i))^2}}$$

The value of some condition attributes may belong to the same interval in which if the value of  $b'_{pq}(i)$  tend to

upper end, the value of  $\sqrt{\sum_{q=1}^n (b'_{pq}(i) - b_q^-(i))^2}$  will enlarge and the value of  $\sqrt{\sum_{q=1}^n (b'_{pq}(i) - b_q^+(i))^2}$  will decrease, at last  $U(a_{ip})$  will be at different sort.

With the hypothesis of the equation that  $A = \bigcup_{i=1}^m A_i$  and  $A_i = A \cup A_{i1}$ , if some  $A_i (A_i \cap (\bigcup_{i \neq 1}^m A_i) = \emptyset)$  exists, a

method<sup>[17]</sup> is offered to adjust  $A_j$ . We can analyze the place of conflicting alternatives, if they belong to  $A$ , none alternatives will be deleted; if they belong to  $A$  and  $A_{i1}$ , we will delete the alternative in  $A_{i1}$ ; if they belong to  $A_{i1}$ , we will analyze the conflicting alternatives by the significance of condition attributes and delete the alternative whose major attribute value is smaller.

So all decision makers will form new alternative sets  $A'_G = \{A'_1, A'_2, \dots, A'_m\}$ , where  $A'_i = \{a'_{i1}, a'_{i2}, \dots\}$ ,  $A'_i = A \cup A_{i2}$ .

#### 5. REASONING LEARNING

If the alternative sets  $A'_i$  judged by  $DM_i (i=1, 2, \dots, m)$  are inconsistent, the decision makers need reasoning learning which include how to add new learning rules to former decision table and how to compute the learning quality for the new alternative. We can depict the adjusting process as follows:

(1) With the hypothesis of that the inconsistent alternative sets are  $\bigcup_{i=1}^m A_{i2}$  which is  $A' = \{a'_1, a'_2, \dots, a'_r\}$ , and the learning alternative sets chose by  $DM_i$  is  $\bigcup_{i=1}^m A_{i2} - A_{i2}$ .

(2) The weight sets of the decision makers are  $\{\lambda_1, \lambda_2, \dots, \lambda_m\}$  we need find the learning decision makers. For example, for inconsistent alternative  $a_r$ , the decision makers sets is  $\{DM_1, \dots, DM_x\}$ , the weight of the  $DM_t$  ( $t = 1, 2, \dots, x$ ) will change as  $\{\lambda'_1, \lambda'_2, \dots, \lambda'_x\}$

where  $\lambda'_t = \frac{\lambda_t}{\sum_{t=1}^x \lambda_t}$ , the learning attributing value of the

learning decision makers for  $a_r$  is

$$\{\sum_{t=1}^x \lambda'_t b'_{t1}, \dots, \sum_{t=1}^x \lambda'_t b'_{tm}\}$$

(3)  $DM_y$  ( $y = x+1, \dots, m$ ) collates the learning attributing value as the classifying interval of  $DM_y$  and gives the corresponding coding, then the new decision rules come into being.

(4) Computing the learning quality. Considering the relation between learning alternative and intrinsic alternatives, if they conflict, the learning quality can be depicted as follows:

$$k = \frac{\text{card}(\text{pos}_c(D)) - \text{card}(x)_{\text{ind}(C)}}{\text{card}(U) + 1}$$

where  $x]_{\text{ind}(C)}$  denotes the equivalence classification including the new example  $x$ .

If the example is new, the learning quality is:

$$k = \frac{\text{card}(\text{pos}_c(D)) + 1}{\text{card}(U) + 1}$$

So for alternative  $a_r$ , the learning quality

is  $f(a_r) = \sum_{y=x+1}^m \lambda'_y f_y(a_r)$ , if  $f(a_r) > \gamma$  ( $\gamma$  is presented in

advance), the alternatives will be accepted, or the alternative will be deleted.

## 6. CONCLUSION

This paper analyzes the cause of developing inconsistent alternative sets in multi-attribute group decision, and gives a method of forming consistent alternative sets based on Rough set Theory. The method includes three phrases: attribute discretization, conflicting alternatives deleting in decision table and reasoning learning, and it is applied in supply chain partner selection. In the process of reasoning learning, the paper gives a new rule based on the judgment of the other decision makers, so learning decision makers may get the impact of the other decision makers, how to keep the independence in learning process for the learning decision makers is very difficult, the author

will continue studying the problem.

## ABSTRACT

Clustering over categorical attributes is an important yet tough task. In this paper, we present a new algorithm K-means II to extend the famous K-means algorithm which is efficient only on numerical clustering, by using new cluster center definitions and new similarity measures. Thus, our algorithm can be used in categorical clustering while preserving the efficiency. Experiments on both real-life datasets and synthetic datasets show that the K-means II algorithm can produce high quality results and deserve good scalability at the same time.

**Keywords:** clustering, categorical attributes, similarity, data mining

## 1. INTRODUCTION

Clustering is a widely used technique in which data points are partitioned into groups, in such a way that points in the same group, or cluster, are similar, and are dissimilar otherwise <sup>[1]</sup>. Much of the previous work focuses on numerical data which can be exploited to naturally defined distance functions between points. There are many algorithms proved to work quite well under numerical conditions, such as K-means <sup>[2]</sup>, and so on.

However, much of the data in practice are categorical, where attribute values can not be naturally ordered as numerical values. Clustering for categorical attributes is thus an important task: it is applicable in different domains, e.g. an e-business recommender system. Let's consider a market basket database in a recommender system containing one transaction per customer, each transaction containing the set of items purchased by the specific customer. The transactions can be viewed as tuples with their attributes not numerical but categorical. As is shown in [3], we can set the attribute value as True if and only if an item is purchased; otherwise, it is False. We can cluster over the dataset and get the characterizations of each group, which can be used in targeted marketing and advertising. The characterizations are also effective in predicting buying patterns of new customers based on their profiles. Another example of categorical attributes may be "color" which can get values from the domain {black, yellow, white}. Something should be noted, that not all values of categorical attributes are of interest in practice during clustering. For example, we do not pay much attention to attribute value "False" while clustering on the market basket database.

Categorical clustering is yet a tough work, because the former familiar clustering algorithms for numerical attributes cannot be used directly. Fortunately, several algorithms have been proposed in this domain.

ROCK <sup>[3]</sup> is an adaptation of an agglomerative hierarchical clustering algorithm. They define "links" as the sum of number of common neighbors between two tuples, and then optimize the "links" based criterion function. We can get good results by using this algorithm. However, with the increase of the dataset size, scalability will degrade.

K-modes <sup>[4, 5]</sup> is an algorithm extending the K-means algorithm to work for categorical attributes. They define a new dissimilarity measure for categorical objects, "modes", instead of means, and then use a frequency-based method to update modes in the clustering process. It is scalable as the number of clusters and the dataset size increases. However, the algorithm is unstable because of non-uniqueness of the modes.

STIRR <sup>[6]</sup> is an iterative algorithm based on non-linear dynamical systems. Some research shows that the known dynamical systems cannot guarantee convergence <sup>[7]</sup>.

There are a few other clustering algorithms trying to solve the categorical clustering problem from different perspectives, such as CACTUS <sup>[8]</sup>, Squeezer <sup>[9]</sup>, COOLCAT <sup>[10]</sup>, and so on. In this paper, we present K-means II, a new clustering algorithm for categorical attributes. Similar to K-modes, K-means II also extends K-means to categorical space. It modifies the definitions of cluster centers and similarity measures. Like K-means, it can achieve both high quality results and scalability.

The rest of this paper is organized as follows. In Section 2, several definitions related to categorical clustering are given. Section 3 shows our new algorithm in details. Some basic analysis is given in this section as well. In Section 4, experimental results on both real-life datasets and synthetic datasets are demonstrated. Finally, the conclusion is in Section 5.

## 2. DEFINITIONS

In this section, several definitions related to categorical clustering are given. Our definitions are quite like those in [5].

Definition 1: Let  $A_1, A_2, \dots, A_n$  be  $n$  attributes describing a space  $\Omega$ , and  $D_1, D_2, \dots, D_n$  the domains of the attributes respectively.  $D$  is defined as categorical if it is finite and unordered, e.g., for any  $a, b \in D_i$ , either  $a=b$ , or  $a \neq b$ .  $A_i$  is then called a categorical attribute.  $\Omega$  is a categorical space if all  $A_1, A_2, \dots, A_n$  are categorical.

Definition 2:  $A_i$  is called Boolean attribute if  $A_i$  is categorical and has two different values. For simplicity, we often represent  $D_i$  as  $\{0, 1\}$ .  $\Omega$  is called a Boolean space if all  $A_1, A_2, \dots, A_n$  are Boolean. The market basket dataset above is a case in point.

Definition 3: Let the dataset  $D$  be a set of tuples where each tuple  $t: t \in D_1 \times D_2 \times \dots \times D_n$ . If  $\Omega$  is a categorical space, each data object  $X$  in the dataset  $D$  can also be represented as a conjunction of attribute-value pairs:  $(A_1=x_1) \cap (A_2=x_2) \cap \dots \cap (A_n=x_n)$ , where  $x_i \in D_i$ , for  $i=1, 2, \dots, n$ . For the sake of simplicity, we present  $X$  as a tuple:  $(x_1, x_2, \dots, x_n) \in D_1 \times D_2 \times \dots \times D_n$ .

## 3. K-MEANS II ALGORITHM

In this section, we introduce a new clustering algorithm over categorical space -- K-means II, which is named after the famous K-means clustering algorithm. Since our K-means II is similar with K-means, two main problems are met in our algorithm as well, which are the calculations of the cluster centers and the similarity measures between tuples and cluster centers. Therefore, we will solve the two problems before putting out our new algorithm.

### 3.1 Cluster Centers

We now define the center of a cluster as follows. Let  $C = \{X_1, X_2, \dots, X_m\}$  be a cluster of data objects, with  $X_i = (x_{i,1}, x_{i,2}, \dots, x_{i,n})$ , for  $i=1, 2, \dots, m$ . Let  $f(a)$  be the number of the tuples with their  $j$ -th attributes' value as "a" in the cluster. Define  $P_j(a)$  as the percentage of a, thus  $P_j(a) = f_j(a)/m$ . Furthermore, let  $P_j$  be the conjunction of  $P_j(a)$ , for all  $a \in D_j$ . Finally, we can define the cluster center  $Q$  as follows:

$$Q = (P_1, P_2, \dots, P_n) \quad (1)$$

### 3.2 Similarity Measurement

Before we define the similarity between the tuple  $X$  and the cluster center  $Q$ , we first define the similarity between the  $j$ -th attribute of  $X$  and the  $j$ -th attribute of  $Q$  as:

$$\delta_{i,j} = P_j(x_{i,j}) \quad (2)$$

The following definition shows the similarity  $\delta_i$  between  $X_i$  and  $Q$ :

$$\delta_i = \sum_{j=1}^n \delta_{i,j} / n \quad (3)$$

$\delta_i$  works quite well when all values in  $D_j$  ( $j=1, 2, \dots, n$ ) are of great importance in clustering the dataset. However, in practice, we sometimes do not pay much attention to some attribute values. As is shown in Section I, the attribute value "False" is not of interest to us in the market basket. Therefore, we should modify the above definitions.

Let  $V_j$  be the set of important values of  $A_j$  therefore,  $V_j \subseteq D_j$ . Then we define the similarity  $\delta'_{i,j}$  between the  $j$ -th attribute of  $X$  and the  $j$ -th attribute of  $Q$  and its weight  $\theta_{i,j}$ .

$$\delta'_{i,j} = \begin{cases} P_j(x_{i,j}), & x_{i,j} \in V_j \\ 0, & x_{i,j} \notin V_j \end{cases} \quad (4)$$

$$\theta_{i,j} = \begin{cases} 1, & x_{i,j} \in V_j \\ \sum_{a \in V_j} P_j(a), & x_{i,j} \notin V_j \end{cases} \quad (5)$$

Thus, we can get the similarity  $\delta'_i$  between  $X_i$  and  $Q$ :

$$\delta'_i = \sum_{j=1}^n \delta'_{i,j} / \sum_{j=1}^n \theta_{i,j} \quad (6)$$

When  $V_j = D_j$  (for  $j=1, 2, \dots, n$ ), or in other words, when all values in  $D_j$  ( $j=1, 2, \dots, n$ ) are of great importance in clustering the dataset, the two similarity  $\delta'_i$  and  $\delta_i$  equals. Thus, we can use  $\delta'_i$  to replace  $\delta_i$ . Finally, we get the function  $\text{Sim}(X, Q)$  to compute the similarity between tuple  $X$  and the cluster center  $Q$  as follows:

$$\text{Sim}(X, Q) = \delta'_i \quad (7)$$

The above formula  $\text{Sim}(X, Q)$  seems to be quite complex and odd. However, it does derive from the famous simple match coefficient and Jaccard's coefficient\* developed to show the similarity for binary data. The function  $\text{Sim}(X, Q)$  extends the above two

\* The two are coefficients developed for binary data. Let  $a$ =conjoint presence (1, 1),  $b$ =mismatch (1, 0),  $c$ =mismatch (0, 1), and  $d$ =conjoint absence (0, 0). Then Simple Matching Coefficient =  $(a+d)/(a+b+c+d)$ . Absence and presence as well as matches and mismatches have equal weights in this coefficient. Jaccard's Coefficient =  $a/(a+b+c)$ . Conjoint absence (0, 0) is ignored in the coefficient.

functions, and can be used not only for binary data.

### 3.3 Our Algorithm

Our K-means II algorithm is similar to the famous K-means<sup>[2]</sup> algorithm. It can also be described in four steps.

Step 1: Select  $k$  cluster centers randomly. (We may choose the first  $k$  tuples as the beginning cluster centers)

Step 2: For each tuple  $X_i$ , calculate the similarities between  $X_i$  and  $Q_l$  which is  $\text{Sim}(X_i, Q_l)$ , for  $l=1, 2, \dots, k$ . Assign  $X_i$  to the cluster  $Q_l$  (from the formal cluster  $Q_l$ ) so that the similarity between  $X_i$  and  $Q_l$  is the largest.

Step 3: Calculate the new  $k$  cluster centers, one for each cluster. Update both  $Q_l$  and  $Q$ .

Step 4: Go to Step 2 until no tuple has changed clusters after a full cycle test of the whole dataset. Otherwise, end.

### 3.4 Selection of $k$

The selection of  $k$  plays an important role in the final cluster result. To facilitate the selection, we define a notion  $\Delta$  to show the average similarity of the whole dataset.

$$\Delta = \frac{\sum_{X_i \in D} \text{Sim}(X_i, Q)}{\text{num}} \quad (8)$$

$Q$  is the center of the cluster which  $X_i$  is in, and  $\text{num}$  is the total number of tuples in the dataset. It is not surprising that  $\Delta$  increases as  $k$  increases. If  $\Delta$  is too small, it indicates that  $k$  is not chosen properly, and we should increase  $k$ . So it seems that we will get accurate results if we set  $k$  at a high level. However, if  $k$  is too large, we will not get very good cluster results, either. We can use  $\Delta$  as an index to select an acceptable  $k$  by experiments.

### 3.5 Time Complexity

The time complexity of K-means II algorithm depends on the size of dataset ( $\text{num}$ ), the number of attributes ( $n$ ), the number of iterations ( $i$ ), and the number of clusters ( $k$ ). Thus we can get that our algorithm has the worst-case time complexity  $O(\text{num} \cdot n \cdot i \cdot k)$ . It shows that the time complexity is linear with the size of dataset, the number of attributes and the number of clusters. Therefore, we can make the conclusion that our algorithm deserves good scalability.

## 4. EXPERIMENTAL RESULTS

In this section, the results about the performance of K-means II are demonstrated. We examine the quality of the clustering results on real-life datasets, and the

efficiency on synthetic datasets. Our algorithm is implemented in Java. All the experiments are conducted on a Pentium III-600 machine with 256M of RAM running Windows XP Professional.

### 4.1 Real-Life Datasets

We experiment our algorithm on two real-life datasets. One is the Congressional Voting dataset, and the other is the Mushroom dataset, both of which can be obtained from the UCI Machine Learning Repository<sup>[11]</sup>. The two datasets are also used in the algorithm ROCK which can produce good clustering results<sup>[3]</sup>. Thus, we can compare our K-means II with ROCK.

**Congressional Voting Dataset:** It is the United States Congressional Voting Records in 1984. Each record corresponds to one Congress man's votes on 16 issues. Nearly all attributes are Boolean (Yes and No) values, and a few contain missing values. A classification label of Republican or Democrat is provided with each data record. The dataset contains tuples for 168 Republicans and 267 Democrats.

**Mushroom Dataset:** Each tuple in the dataset contains information that describes the physical characteristics of a single mushroom, with a poisonous or edible label. All attributes are categorical. It has 8124 different mushroom records, of which 4208 are edible. A few contain missing values, as is in Congressional Voting Dataset.

Table 1: results for congressional voting dataset

ROCK			K-means II (k=4)		
No.	Rep.	Dem.	No.	Rep.	Dem.
1	144	22	1	23	3
2	5	201	2	140	30
K-means II (k=2)			3	1	34
No.	Rep.	Dem.	4	4	200
1	7	220			
2	161	47			

As Table 1 illustrates, both ROCK and K-means II can identify clusters with the majority of Republicans or Democrats. Due to the elimination of tuples, the sum of the sizes of clusters is not equal to 435 in ROCK. However, K-means II does not eliminate any tuples. As is suggested in sub-section 3.4, we can increase the average similarity  $\Delta$  by increasing  $k$ . Tables 1 also shows the results of K-means II when  $k=4$ . The result is quite accurate and encouraging. Therefore, we can conclude that K-means II can produce good clustering results as ROCK does.

Table 2 describes the clustering results for Mushroom dataset by using ROCK and K-means II. Nearly all clusters found by both algorithms are pure edible or

poisonous ones. Exceptions occur in cluster 5 and 10 (K-means II), and in cluster 15 (ROCK). It shows that both algorithms perform well.

Table 2: results for mushroom dataset

ROCK					
No.	Edible	Poisonous	No.	Edible	Poisonous
1	96	0	12	48	0
2	0	256	13	0	288
3	704	0	14	192	0
4	96	0	15	32	72
5	768	0	16	0	1728
6	0	192	17	288	0
7	1728	0	18	0	8
8	0	32	19	192	0
9	0	1296	20	16	0
10	0	8	21	0	36
11	48	0			
K-means II (k=27, Δ=0.81)					
No.	Edible	Poisonous	No.	Edible	Poisonous
1	192	0	15	224	0
2	96	0	16	0	864
3	288	0	17	0	40
4	372	0	18	192	0
5	16	72	19	0	864
6	276	0	20	324	0
7	0	675	21	32	0
8	192	0	22	324	0
9	0	288	23	432	0
10	96	8	24	128	0
11	768	0	25	0	256
12	0	621	26	160	0
13	0	192	27	0	36
14	96	0			

Experiments on both datasets show that our algorithm can produce accurate clustering results as ROCK does. We can conclude that our algorithm can produce high quality clusters.

#### 4.2 Synthetic Datasets

In order to test the scalability of our algorithm, we experiment with synthetic datasets which are generated by using a data generator. We set the number of attribute values for each attribute to 5. All possible values are produced with (approximately) equal probability. We test three scalabilities of the algorithm using these datasets. The first one is the scalability of our algorithm against the dataset size, the second is the scalability against the number of clusters, and the third is the scalability against the number of attributes. In Figure 1,

the dataset size is increased from 10000 to 100000, and the numbers of attributes and clusters are fixed to 10 and 30 respectively. Figure 2 shows the results when increasing number of clusters from 10 to 50, and the cluster size and the number of attributes are set to 10000 and 10. In Figure 3, we increase the number of attributes from 10 to 40, and we set cluster size at 10000 and the number of clusters at 30 fixedly.

These results are very encouraging because they show clearly a linear increase in time as the cluster size, the number of clusters, and the number of attributes increase. They accord with the analysis in sub-section 3.5. Therefore, we can make the conclusion that our algorithm has good scalability with respect to the above three dimensions.

Figure 1: scalability to dataset size (attributes: 10, clusters: 30)

Figure 2: scalability to clusters (dataset size: 10000, attributes: 10)

Figure 3: scalability to attributes (dataset size: 10000, clusters: 30)

#### 5. CONCLUSION

Clustering of categorical attributes is an important yet difficult task. In this paper, we propose an efficient algorithm called K-means II. Both analysis and experiments show that our algorithm can produce high quality results and at the same time deserve good scalability.

The K-means II algorithm has made extensions to the K-means algorithm by using new cluster center definitions and new similarity measures. Thus, the K-means II can be used in categorical clustering while preserving its efficiency. The new definition of cluster

center can also be used as characteristic descriptions which are useful in interpreting clustering results. Another advantage is that the algorithm can handle attribute values which are not of interest. Thus, the algorithm can handle missing values very easily, because missing values can be viewed as new attribute values which are not of interest while measuring the similarity.

For the future work plan, we will revise K-means II to make it more efficient on very large dataset size, for examples, datasets with billions of tuples. The extension to K-means II to make it work on mixed numerical and categorical attributes is another direction for us.

### ABSTRACT

The double-quick growth of EB has caused commodities overload, where our customers are not longer able to efficiently choose the products adapt to them. In order to overcome the situation that both companies and customers are facing, we present a personalized recommendation, although several recommendation systems which may have some disadvantages have been developed. In this paper, we focus on the association rule mining by EFFICIENT algorithm which can simple discovery rapidly the all association rules without any information loss. The EFFICIENT algorithm which comes of the conventional Apriori algorithm integrates the notions of fast algorithm and predigested algorithm to find the interesting association rules in a given transaction data sets. We believe that the procedure should be accepted, and experiment with real-life databases show that the proposed algorithm is efficient one.

**Keywords:** Association Rules, Data Mining, Procedure, Algorithm, Personalized Recommendation

### 1. INTRODUCTION

Electronic Business has been growing rapidly, keeping pace with the Web <sup>[1]</sup>. According to the investigations of Angus Reid Group in March 2000, there have been more than three hundred million users using the Internet in the world, and there will be three billion ones by 2005 <sup>[2]</sup>. Its rapid growth has made both companies and customers face a new situation in which companies find it harder to survive due to more and more competition, the opportunity for customers to choose among more and more commodities has increased the burden of information processing before they select which ones meet their needs. In order to solve the problem, researches and practitioners have stressed the need for marketing strategies, for example one-to-one marketing, CRM and mass customization engineering. So under this condition a personalized commodities recommendation which helps our customers find the ones they prefer are very important and useful.

The great amount of data not only gives the statistics, but also offers the resources of experiences and knowledge. Data mining, as one of the promising technologies since 1990s, is to some extent a non-traditional data-driven method to discover novel, useful, hidden knowledge from massive data sets <sup>[3]</sup>. The discovery of interesting association among business decision making processes, such as catalog design, cross marketing, and loss-leader analysis <sup>[4]</sup>. Data mining is one of the most popular techniques that can find potential business knowledge from enterprise databases in support of making better decision, it can discovery potentially significant patterns and rules underlying the database. It can be categorized into several interesting areas, such as association rules, clustering, decision tree analysis and so on. Association rule mining finds interesting association or correlation relationships among a large set of data items. *Market basket analysis* is the typical example of association rule

mining<sup>[4]</sup>.

However, on one hand rules explosion is a problem of concern, as conventional mining algorithms often produce too many rules for decision makers to digest <sup>[5]</sup>, on the other hand, some rules can miss important information; Addition, the rules of many algorithms are limited to single item. To overcome the shortcomings, we improve on the Apriori Algorithm with EFFICIENT Algorithm. Such a rule set can mine interesting knowledge rapidly without any information loss. At the same time, it can save a large of time and become simpler.

The paper concentrates on the EFFICIENT Algorithm and the recommend procedure of personalize commodities. We begin by show the procedure in section 2. We make clear the basic concept of association rule mining and the EFFICIENT Algorithm in section 3. And section 4 present an example. Finally, we summarize the conclusion and the future research work in section 5.

### 2. PROCEDURE

Data mining is an interactive and iterative process <sup>[2]</sup>. "How are association rules mined from large database?" General speaking, association rule mining includes the following two-step process <sup>[4]</sup>.

**STEP I : Find all frequent itemsets:** By definition, each of these itemsets will occur at least as frequently as a pre-determined minimum support count.

**STEP II : Generate strong association rules from the frequent itemsets:** By definition, these rules must satisfy minimum support and minimum confidence.

In this paper, we only focus on the recommendation problem which help customer to find which products they would like to purchase for every one at a specific time; at the same time, the companies can discovery the

rule and recommend related product to their goods. From prepare to discover the relations of the commodities which have been recorded in computers.

Fig. 1: Flow of data mining

Fig. 2 outlines the procedure of data mining steps. It includes six steps which are cycle [2] [3]

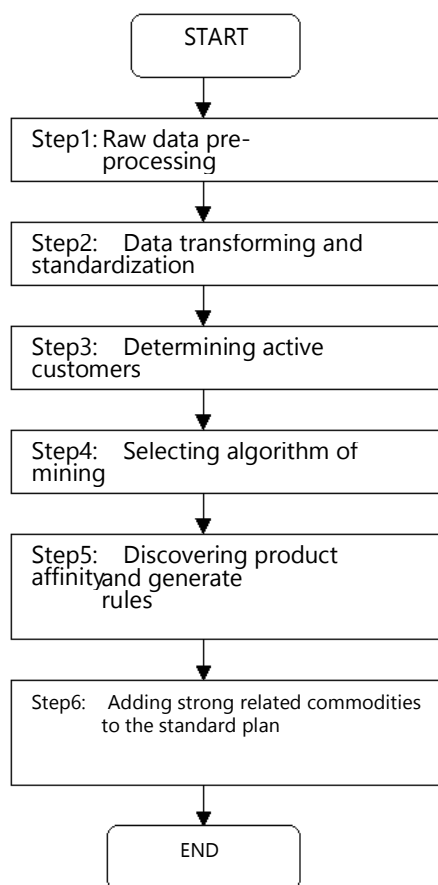

Fig. 2: Procedures of data mining

### 2.1 Raw data pre-processing

A database consists of current and historical detailed item, summarized data items and metadata. We select database and create a fact table; Next, selecting attributes and dimensions; Finally, we deal with the data, such as filtering data.

### 2.2 Data Transforming and Standardization

In this step, we transform data and standardize them to

### 2.3 Determine Active Customers

Making a commendation only for customers who are likely to buy recommended commodities could avoid the *false positives* of a poor recommendation. In this step, we can use decision tree induction to perform the task of selecting active customers.

### 2.4 Select Algorithm of Mining

In step4, we should select an appropriate algorithm, although a lot of algorithm can solve mining problem. Some ones have limits which can not sit for many conditions, and some others are complex and invalid. Therefore, we need an efficient algorithm which can fast and simple solve the mining work. EFFICIENT Algorithm which be provided with the character will be referred in section 3.

### 2.5 Discovering Product Affinity & Generate Rules

In this step, we first search for meaningful relationships or affinities among product classes through mining association rule from large transaction.

Finding association rules at level-k by the following steps and the process of mining will be detailed showed in section4. 1) Get the consequents of rules from  $I_k$  with one item in the consequent; 2) Set up minimum support and minimum confidence. At different lever set the *min-supp* and *min-conf* different value. Such is distinctness from the traditional threshold; 3) Call *acceleration* (large k- itemset, set of m-item consequents); 4) Call the *predigestion* Algorithm; 5) Obtain the affinity between the stander commodities and target commodities.

### 2.6 Add Related Commodities

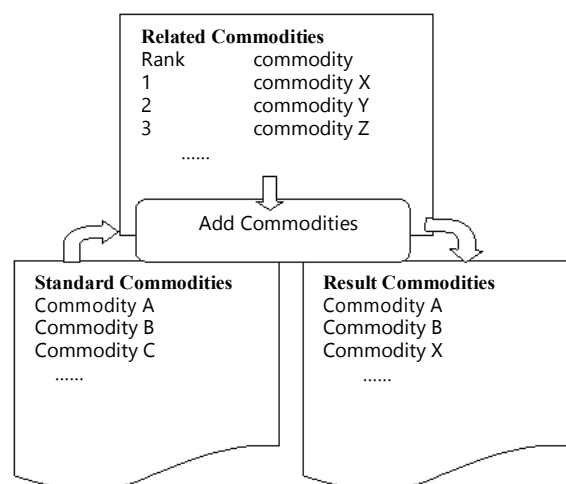

Fig 3: Add commodities to standard plan

We find related commodities are strong related to target commodities, add the related commodities to the standard plan and get the specific sales promotion proposal plan which is prepare to perform the recommendation. This last step can show in fig 3.

The following is the last procedure, but it is the one which realizes the recommend. It is the important phase which verifies the mining work is useful and efficiency or not.

In fact, the process of mining is a cycle one. When finish a recommendation, the new sale date will be next mined, the consequence still will be done .....At the same time, the rule will be corrected. We can name this process dynamic process.

### 3. ALGORITHM

*"How can we help or guide the mining procedure to discovery interesting association? What language constructs are useful in defining a data mining query language for association rule mining?"* [4] In this section, we will find these answers.

#### 3.1 Preliminary Description

Let  $J = \{i_1, i_2, \dots, i_n\}$  be a set of items. Let  $D$  be a set of database transaction where each transaction  $T$  is a set of items such that  $T \subseteq J$ . Each transaction is associated with an identifier, called TID. Let  $A$  be a set of items. A transaction  $T$  is said to contain  $A$  if and only if  $A \subseteq T$ . An association rule is an implication of the form  $A \Rightarrow B$ , where  $A \subset J$ ,  $B \subset J$ , and  $A \cap B = \emptyset$ . The rule  $A \Rightarrow B$  holds in the transaction in  $D$  that contain  $A \cup B$ . This is taken to be the probability,  $P(A \cup B)$  [4].

Rule support and confidence are two measure of rule interestingness. They respectively reflect the usefulness and certainty of discovery rules. The following is the description of them:

$$\text{Support}(A \Rightarrow B) = P(A \cup B) = P(A \cup B) \quad (1)$$

$$\text{Confidence}(A \Rightarrow B) = P(B|A) = P(A \cup B)/P(A) \quad (2)$$

If both the support and confidence are equal, we can use equation (3). If the reverse confidence  $(A \Rightarrow B) = 1.0$ , when  $B$  appear,  $A$  must also appear [3].

$$\begin{aligned} \text{Reverse confidence}(A \Rightarrow B) &= P(A|B) \\ &= P(A \cup B)/P(B) \end{aligned} \quad (3)$$

#### 3.2 Apriori Algorithm

Agrawal, Imielinski, and Swami introduced the notion of association rules in 1993. The basic Apriori algorithm regarded as a conventional method, was developed by Agrawal and Srikant (1994) and Uthrusamy (1994). Many research efforts have then been made in two directions: one is to extend the notion of

association rules, giving rise to various extensions such as generalized association rules, fuzzy association rules, etc; the other is to improve the algorithm in various ways such as fast algorithms, sampling algorithm, and so on.

Apriori is an influential algorithm for mining frequent itemsets for Boolean association rules. It employs an iterative approach known as a level-wise search, where  $k$ -itemsets are used to explore  $(k+1)$ -itemsets. First, find the set of frequent 1-itemsets. This set is denoted  $L_1$  which is used to find  $L_2$ , the set of frequent 2-itemsets used to find  $L_3$ , .... That all nonempty subsets of a frequent itemset must also be frequent is the Apriori property [4].

The Apriori Algorithm finds the frequent itemsets by using candidate generation. In order to find  $L_k$  from  $L_{k-1}$ , a two-step process which consist join and prune should be done. If  $(l_1[1] = l_2[1]) \wedge (l_1[2] = l_2[2]) \wedge \dots \wedge (l_1[k-2] = l_2[k-2]) \wedge (l_1[k-1] < l_2[k-1])$ ,  $l_1$  and  $l_2$  of  $L_{k-1}$  can join, where the condition  $l_1[k-1] < l_2[k-1]$  simple ensure that no duplicates are generated.  $C_k$  the set of candidates, is a superset of  $L_k$  that is, its members may or may not be frequent, but all of the frequent  $k$ -itemsets are included in  $C_k$ . If any  $(k-1)$ -subset of a candidate  $k$ -itemset is not in  $L_{k-1}$  then the candidate cannot be frequent either and so can be removed from  $C_k$  [4][5].

#### 3.3 EFFICIENT Algorithm

EFFICIENT Algorithm is a fast and simple algorithm, which can save a great deal of time without missing useful information. Now let we see many properties of the algorithm [5][9]. First, EFFICIENT Algorithm is simple, in some cases, it is enough, does not need other complex one to solve simple question, such as we can use association rule to class. Second, it count very fast, can decrease the work of CPU, then save significant time. Next, the algorithm pierces into limits of the single item which is required by some algorithms. Finally, generating the focused and interested rules does not need to obtain all rules without miss information.

The flowing is the EFFICIENT algorithm, which includes "acceleration" and "predigestion" actions [3][5][6].

```
// EFFICIENT Algorithm
1) for all large k-itemsets  $l_k, k \geq 2$  do begin
2)    $C_k = \{\text{frequent 1-itemsets}\}$ ;
3)   if (the value of consequent item = 1)
4)     call acceleration ( $l_k, C_k$ );
5)   else call predigestion ( $l_k, l_k$ );
6) end
//acceleration algorithm
7) Procedure acceleration
   ( $l_k, C_k$  is set of m-item consequents, x)
8)  $x = x + 1$ ;
9) if ( $k > m + 1$ ) then begin
10)   $C_{m+1} = \text{acceleration}(C_k)$ ;
11)  for all  $c_{m+1} \in C_{m+1}$  do begin
12)    conf = supp( $l_k$ ) / supp( $l_k - c_{m+1}$ );
```

```

13)   if (conf  $\geq$  minconf) then
14)       output the rule  $(l \rightarrow c_{m+1}) \Rightarrow c_{m+1}$ 
        with confidenc=conf and support=supp(l);
15)   else delete  $c_{m+1}$  from  $C_{m+1}$ 
16)   end
17)   call acceleration  $(l \rightarrow c_{m+1})$ 
18) end
//predigestion algorithm
19) Procedure predigestion  $(l \rightarrow c_m)$ 
20)    $C = [(m-1)\text{-itemsets } c_m - l \mid m-1 \leq c_m]$ ;
21)   for all  $c_{m-1} \in C$  do begin
22)       conf =supp(l)/supp( $c_{m-1}$ )
23)       if (conf  $\geq$  minconf)
24)           then begin output the rule  $c_{m-1} \Rightarrow (l \rightarrow c_m)$ 
                        with confidence=conf(l) and support=supp(l);
25)           if  $(m-1 > 1)$  then call predigestion  $(l \rightarrow c_{m-1})$ 
26)       end
27)   end

```

Fig 4:The EFFICIENT Algorithm

To generate rules, for every large itemset  $l$ , we find all non-empty subset of  $l$ . For every such subset  $c$ , we output the rule:  $c \Rightarrow (l-c)$ , if the support is at least minsupp. The algorithm does not miss any rule because the support of any supplementary item,  $c'$  of  $c$  must be as great as the support of  $c$ . So the confidence of the rule  $c' \Rightarrow (l-c')$  cannot be more than the confidence of  $c \Rightarrow (l-c)$ . By rewriting, if rule  $(l-c) \Rightarrow c$  hold, all rules of the form  $(l-c') \Rightarrow c'$  must also hold ( $c'$  is non-empty subset of  $c$ ). If  $AC \Rightarrow BD$  holds, then  $ABC \Rightarrow D$  or  $ACD \Rightarrow B$  must also hold. When call acceleration  $(ABCDE, ABCE)$ , we can find that  $ACE \Rightarrow BD$  is hold, but  $ABC \Rightarrow DE$  is not [4][8]

**Proof:**  $ACE \Rightarrow BD$

$\therefore Dconf(X \Rightarrow YZ) = Dconf(X \Rightarrow Y) * Dconf(XY \Rightarrow Z)$   
 $Dconf(X \Rightarrow Y) \geq Dconf(X \Rightarrow YZ)$  and  
 $Dconf(XY \Rightarrow Z) \geq Dconf(X \Rightarrow YZ)$ , and  
 $supp(XY \Rightarrow Z) = Dsupp(XY \Rightarrow Z) \leq Dsupp(X \Rightarrow Y)$   
 $\therefore XY \Rightarrow Z$  from  $X \Rightarrow YZ$

Let  $X=ACE$ ,  $Y=B$ ,  $Z=D$ , then get  $ABCE \Rightarrow D$  from  $ACE \Rightarrow BD$ , that is  $ACE \Rightarrow BD$  can be expressed by  $ABCE \Rightarrow D$ .

#### 4. EXAMPLE

##### 4.1 Generate Candidate & Frequent Itemsets

This study uses the example to describe the program execution of EFFICIENT Algorithm. The example includes seven transaction records, as show in table 1.

Table 1:The table of database D

TID	List of item	TID	List of item
T1	ABCDE	T5	ABCE
T2	BCE	T6	ACE
T3	ACD	T7	ABCE
T4	BE		

The following is the process of transaction:

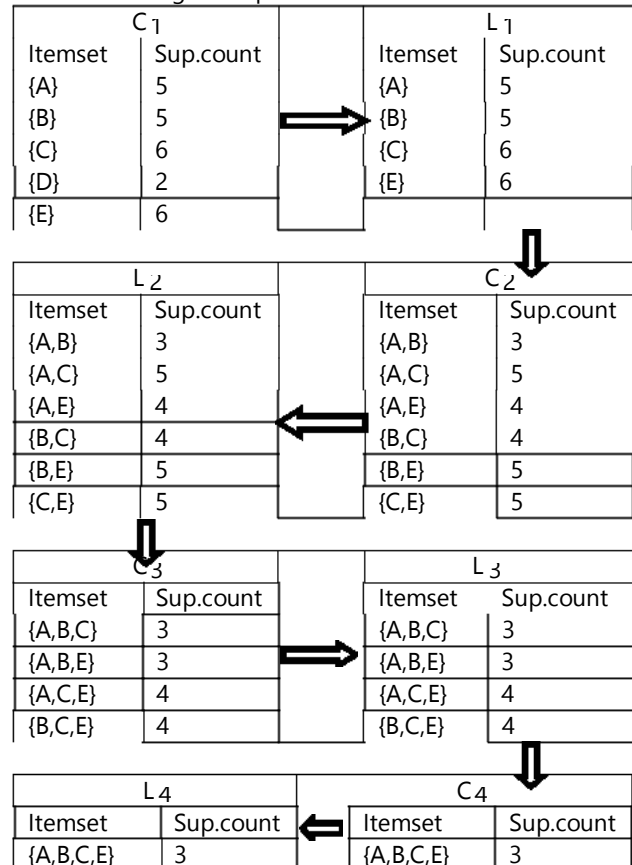

Fig.5: Generate of candidate and frequent itemsets

The minimum length threshold of large itemsets which at different phase is different value, we let the number of items of the first phase be 3 while the min-sup is defined based on the generation of itemsets in various lengths. In the following phases, we can find that the min-supp is changing, that does not appear in additional algorithm. The result is used to prepare the next step which mines the rules.

Table2: All association rules

No.	Rules	Supp	Conf	No.	Rules	Supp	Conf
	limit1	4/7	80%		limit3	3/7	75%
1	$A \Rightarrow C$	5/7	100%	14	$ABC \Rightarrow E$	3/7	100%
2	$A \Rightarrow E$	4/7	80%	15	$ABE \Rightarrow C$	3/7	100%
3	$B \Rightarrow C$	4/7	80%	16	$ACE \Rightarrow B$	3/7	75%
4	$B \Rightarrow E$	5/7	100%	17	$BCE \Rightarrow A$	3/7	75%
5	$C \Rightarrow E$	5/7	83%		limit4	3/7	75%
	limit2	3/7	80%	18	$B \Rightarrow CE$	4/7	80%
6	$AC \Rightarrow E$	4/7	80%	19	$A \Rightarrow CE$	4/7	80%
7	$AE \Rightarrow C$	4/7	100%		limit5	2/7	70%
8	$CE \Rightarrow A$	4/7	80%	20	$AB \Rightarrow CE$	3/7	100%
9	$BC \Rightarrow E$	4/7	100%	21	$AE \Rightarrow BC$	3/7	75%
10	$BE \Rightarrow C$	4/7	80%				
11	$CE \Rightarrow B$	4/7	80%	22	$BC \Rightarrow AE$	3/7	75%
12	$AB \Rightarrow C$	3/7	100%		Limit6	2/7	60%
13	$AB \Rightarrow E$	3/7	100%	23	$A \Rightarrow BCE$	3/7	60%

Table3: Derived rules

No.	Rules	Derived from
#18	$B \Rightarrow CE$	$\{3:B \Rightarrow C, 9:BC \Rightarrow E\}$
#19	$A \Rightarrow CE$	$\{1:A \Rightarrow C, 6:AC \Rightarrow E\}$
#20	$AB \Rightarrow CE$	$\{12:AB \Rightarrow C, 14:ABC \Rightarrow E\}$
#21	$AE \Rightarrow BC$	$\{7:AE \Rightarrow C, 16:ACE \Rightarrow B\}$
#22	$BC \Rightarrow AE$	$\{9:BC \Rightarrow E, 17:BCE \Rightarrow A\}$
#23	$A \Rightarrow BCE$	$\{19:A \Rightarrow CE, 16:ACE \Rightarrow B\}$
Replaced by		$\{1:A \Rightarrow C, 6:AC \Rightarrow E, 16:ACE \Rightarrow B\}$

#### 4.2 Mine Rule by Using EFFICIENT Algorithm <sup>[3],[9]</sup>

The following is presented to help illustrate the idea of EFFICIENT Algorithm. If we let the minconf and minsupport have different value, we can get the following table which has some new or different rules.

From the process of mining, we can find that it is more efficient and easier than before. The different between mining for EFFICIENT Algorithm and mining for all association rules is that, to extract the former from any k-frequent itemset  $(i_1, i_2, \dots, i_k)$ . The frequent itemset consisting of k-items, one only needs to examine certain frequent itemsets, namely its (k-1)-frequent sub-itemsets instead of all j-frequent sub-itemsets  $(j=1, 2, \dots, k-1)$ . In fact, only  $k(k-1)$  sub-itemsets can be checked, but  $(2^k-2)$  sub-itemsets should be done in all association rules.

#### 5. CONCLUSIONS AND FUTURE WORK

In this paper, we introduce a kind of algorithm, EFFICIENT Algorithm which retains all information in the original rule set and save mass time, but has a very smaller size and discovery all significant association rules between items in a large database of transactions. We can draw a conclusion that all qualified association rules can be derived from the EFFICIENT algorithm. The next work is being conducted on further algorithmic optimizations. Besides, more efficient association rules mining may also be the future work. In addition, we will attempt to use the technology of array to solve the mining work, which is a spick-and-span exploration. We believe that data mining is an important new application area for database, combining commercial interest with diverting research questions.

## ABSTRACT

This paper proposes a DEA-based approach to credit scoring. Compared with conventional models such as multiple discriminant analysis, logistic regression analysis, and neural networks for business failure prediction, which require extra a priori information, this new approach solely requires ex-post information to calculate credit scores. For the empirical evidence, this methodology was applied to current financial data of external audited 1061 manufacturing firms comprising the credit portfolio of one of the largest credit guarantee organizations in Korea. Using financial ratios, the methodology could synthesize a firm's overall performance into a single financial credibility score. The empirical results were also validated by supporting analyses (regression analysis and discriminant analysis) and by testing the model's discriminatory power using actual bankruptcy cases of 103 firms. In addition, we propose a practical credit rating method using the predicted DEA scores.

**Keywords:** Credit scoring, Credit rating, Data envelopment analysis, Financial performance

## 1. INTRODUCTION

Credit scoring problems are basically in the scope of classification agenda (Anderson, 1984; Chen and Huang, 2003; Dillion and Goldstein, 1984; Hand, 1981; Johnson and Wichern 1998; Lee et al., 2002; Morrison, 1990; West, 2000) that is a commonly encountered decision making task in businesses, and it is a typical classification problem to categorize an object into one of predefined groups or classed based on a number of observed attributes related to that object (Zhang, 2000).

So far, a variety of methods such as linear probability and multivariate conditional probability models, the recursive partitioning algorithm, artificial intelligence approaches, multi-criteria decision-making (MCDM), mathematical programming approaches have been proposed to support the credit decision (Bryant, 1997; Buta, 1994; Coakley and Brown, 2000; Davis et al., 1992; Dimitras et al., 1996, 1999; Emel et al., 2003; Falbo, 1991; Frydman et al., 1985; Martin, 1997; Reichert et al., 1983; Roy, 1991; Tam and Kiang, 1992; Troutt et al., 1996; Zopounidis and Doumpos, 1998).

Offering financial institutions a means for evaluating the risk of their credit portfolio in a timely manner, such models can provide an important body of information to help them formulate their respective risk management strategies. In fact, banking authorities such as Bank of International Settlements (BIS), the World Bank, the IMF, and the Federal Reserve all encourage commercial banks to develop internal models to better quantify financial risks.<sup>1</sup>

The purpose of this paper is to suggest a new approach to credit scoring, which is based on DEA. As opposed to well-known methods such as multiple discriminant analysis, logistic regression analysis, and neural networks, which require ex ante information of "good/bad" classification, this approach only needs ex post information of the observed set of input and output data of the objects of interest (client firms) to calculate their respective credit scores. With these scores, we also provide a practical credit rating methods to classify client firms into several balanced classes.

## 2. LITERATURE REVIEW

In the credit industry, neural networks (NN) has recently been claimed to be an accurate tool for credit analysis among others (Desai et al., 1996; Malhotra and Malhotra, 2002; West, 2000). Desai et al. (1996) have explored the abilities of NN and the traditional statistical techniques such as linear discriminant analysis (LDA) and logistic regression analysis (LRA) in constructing credit scoring models. They claimed that NN shows a promise if the performance measure is the percentage of bad loans accurately classified. However, if the performance measure is the percentage of good and bad loans accurately classified, LRA is as good as NN. The percentage of bad loans correctly classified is an important performance measure for credit scoring models since the cost of granting a loan to a defaulter is much larger than that of rejecting a good applicant (Desai et al., 1996).

West (2000) has also investigated the accuracy of quantitative models commonly used by the credit industry. The results indicated that NN could improve the credit scoring accuracy. He also suggested that LRA is a good alternative to NN while LDA, k-nearest neighbor (k-NN), and CART (classification and

<sup>1</sup> The Basel Committee on Banking Supervision (1999), English and Nelson (1998), the Federal Reserve System Task Force on Internal Credit Risk Models (1998), Lopez and Saidenberg (2000), and Treacy and Carey (2000) represent some recent documents addressing these issues.

regression tree) did not produce encouraging results. Commonly considered as a black-box technique without logic or rule-based explanations for the input-output approximation, the main shortcoming of applying NN to credit scoring lies in the difficulty of explaining the underlying principle for the decision to rejected applications (West, 2000).

Although NN and other traditional methods for credit scoring require ex ante information for business failure prediction, it is more useful in practice to build a credit scoring model based on ex post financial information. The idea is to develop a meaningful "peer group analysis" with specific financial characteristics that distinguish between two or more groups, and in the late 1990s, data envelopment analysis (DEA) was introduced to this peer group analysis for business failure prediction (Troutt et al., 1996; Simak, 1999; Cielen and Vanhoof, 1999).

As opposed to broadly known MDA, LRA, NN approach, DEA requires solely ex-post information, i.e. the observed set of input and output data, to calculate the credit scores. Yeh (1996) was one of the pioneers to combine DEA with financial ratio analysis. She utilized DEA to evaluate bank performance. Her study empirically demonstrated that DEA, in conjunction with financial ratio analysis, can effectively aggregate and reclassify perplexing ratios into meaningful financial dimensions, which enable analysts to gain an insight into the operating strategies of banks. Emel et al. (2003) proposed a credit scoring methodology based on DEA. Although their approach, which is applied to the limited number of Turkey's commercial banks, is not relatively delicate compared with conventional statistical analyses, it provides the base of this study.

DEA converts a multiplicity of input and output measures into a unit-free single performance index formed as a ratio of aggregated output to aggregated input. Conceptually, DEA compares the DMUs' observed outputs and inputs in order to identify the relative "best practices" for a chosen observation set. Based on these best observations, an efficient frontier is established, and the degrees of efficiency of other units with respect to the efficient frontier are measured. Therefore, in the context of credit scoring, the performance index via DEA measures the relative credit riskiness of the firms within credit portfolio (Emel et al., 2003). DEA, which computes a firm's efficiency by transforming inputs into outputs relative to its peers, may provide a fine mechanism for deriving appropriate categories for this purpose.

### 3. RESEARCH METHODOLOGY

The research methodology consists of seven steps, as outlined in Fig. 1. The first three steps deal with selection of firms for the study and with identification of indicators that may be used to evaluate the firms'

financial performance. Step 4 uses DEA to obtain credibility scores of the firms. Step 5 validates the DEA-based credibility scores by comparing them against those obtained via regression and discriminant analyses, and by using actual bankruptcy cases. Finally, Step 6 proposes a credit rating method by investigating the distribution of good/bad firms' credibility scores.

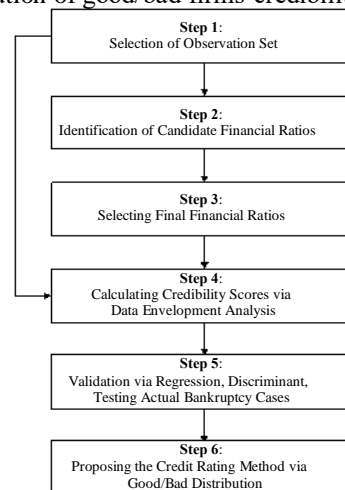

Fig. 1. Flowchart of the research methodology

*Step 1: Selection of observation set.* We select the firms applying for new credit allocation or whose credit limits are already allocated by the credit authority. At this stage, a certain degree of "homogeneity" in terms of industrial difference and scale-size is ensured among the firms. In this paper, we select only external audited manufacturing firms as a sample in order to satisfy this property.

*Step 2: Identification of candidate financial ratios.* The most common dimensions considered in financial performance evaluation are growth, liquidity, activity, profitability, productivity, and cost structure aspects. In order to cover these dimensions, a broad set of financial ratios needs to be computed. Some ratios in this set, however, may be similar to each other in terms of underlying financial meanings or in terms of mathematical properties. To identify diverse and financially meaningful ratios in this model, the literature review as well as loan officers' experience-based insight was employed.

*Step 3: Selecting final financial ratios.* The final selection of financial indicators is based on the expert opinion as well as the statistical factor analysis. The resulting set of indicators contains the most relevant financial classification dimensions while recognizing the mathematical relationships among the ratios.

*Step 4: Calculating credibility scores via data envelopment analysis.* In DEA, physical or monetary magnitudes are typically used as the input/output set. However, to eliminate scale-size effects in this study, financial ratios were used instead. The resulting DEA score is a relative ratio of two combined linear ratios. Also, we took advantage of multi-criteria ranking

feature of DEA, a feature based on selection of the relatively best practices within the observation set, and on the radial distance from the efficient frontier comprising these best practices (Charnes et al., 1978; Oral and Yolalan, 1990).

*Step 5: Validation via regression, discriminant, and testing actual bankruptcy cases.* The purpose of this step is to establish the extent to which DEA results coincide with those of regression analysis, discriminant analysis, and actual bankruptcy cases.

(a) *Regression analysis (RA)*: In some cases, due to data anomalies, DEA may not sufficiently discriminate firms' efficiencies. Thus, there is a need to test the explanatory power of the indicator set used in DEA. Linear regression analysis is suggested as a test criterion. For this purpose, the DEA scores are taken as the dependent variable, while the financial ratios used in DEA are set to be the independent variables.

(b) *Discriminant analysis (DA)*: DA is used to establish the extent to which DEA scores can be used to classify the sample firms into two groups: "good" firms and "bad" firms. DA is a statistical technique used to classify an observation into one of a priori established groupings dependent upon the observation's individual characteristics. DA attempts to derive the linear combination of characteristics which best discriminates between predefined groups. In this study, financial performance, as measured by DEA, is used as the qualitative (i.e. a priori grouping) variable. There are two performance groups: The good firms group and the bad firms group. The good firms group is defined as those observations with DEA scores over a specific value, whereas the bad firms group is defined as those observations with DEA scores below that value. As will be discussed later, the specific value was chosen by taking into account the distribution of DEA scores. The financial ratios are used as explanatory variables in DA. One can then generate a discriminant function, and calculate the hit ratio (the percentage of right classifications) that shows the degree to which DA validates the classification obtained via DEA.

(c) *Testing actual bankruptcy cases*: The consistency of the DEA results is also checked against testing actual bankruptcy firms. The objective is to see the usefulness of DEA scores as a risk management tool in practical viewpoint.

*Step 6: Proposing the credit rating method via good/bad distribution.* Commercial banks or other financial institutions are adopting various credit rating methods to manage the client firms' credit riskiness, most of which utilize the probability of default derived by the neural networks or logistic regression analysis. In practice, an ex post approach is more useful in order to diagnose the financial performance of client firms and to rate their credit status. In this study, we propose a practical credit

rating method by investigating the distribution of the firms' credibility scores.

#### 4. EMPIRICAL ANALYSIS

The DEA-based approach was applied to current financial data of external audited 1061 manufacturing firms comprising the credit portfolio of one of the largest credit guarantee organizations in Korea.

##### 4.1 The sample data

At the beginning of the study, there were approximately 1400 firms for which data were available. In order to provide a certain degree of homogeneity among firms in the observation set, however, the outliers, i.e. those firms having several ratios that deviate significantly (more than two standard deviations) from the corresponding mean, were removed and the data for the remaining 1061 firms were used.

##### 4.2 Selection of financial ratios

Commonly accepted financial dimensions such as growth, liquidity, activity, profitability, productivity, and cost structure aspects are considered as a guideline to identify candidate financial ratios. From the previous studies (Altman, 1968; Beaver, 1966; Dimitras et al., 1996; Eisenbeis, 1978; Emel et al. 2003; Falbo, 1991; Jensen, 1992; Lee et al. 1997; Lee et al., 1999; Martin, 1997; Peel et al., 1986), we first selected 57 financial ratios, of which 43 ratios were grouped under previously mentioned dimensions through factor analysis. The loan officers' experience-based knowledge was then used to select final financial ratios that represent a firm's multidimensional financial characteristics. Combining the credit department officers' expert knowledge, the literature survey, and the authors' best judgment, we selected the final set of 6 financial ratios, and classified them as input and output variables for DEA.

The inputs to be minimized are financial expenses to sales, current liabilities ratio and absolute value of 1-fixed assets ratio, as defined in Table 1.

**Table 1. Input variables for DEA**

Input variables	Formula
financial expenses to sales (FE)	financial expenses ÷ sales
current liabilities ratio (CL)	current liabilities ÷ owners' equity
1-fixed assets ratio  (ABS)	1-(fixed assets÷owners' equity)

First, the ratio of financial expenses to sales (FE) shows the ability of a firm to pay financial expenses, which indicates the credit worthiness of a firm. Second, current liabilities ratio (CL) is a proportion of current liabilities to owners' equity. This ratio is an indicator to measure stability of a capital structure. If this ratio becomes

higher, a capital structure and a financial liquidity are in unstable status. Third, the absolute value of “1 minus fixed assets ratio”(ABS) shows that fixed assets of a client firm should balance its capital base. If banks finance fixed assets with liabilities, especially current liabilities (since fixed assets will not bring revenues to the bank, at least in the short run), the client will have problems in paying back the credit. This will also lead to cash flow problems for the bank. Hence, the ratio of fixed assets to capital base should be close to one. As this ratio moves away from unity (1) in either direction, it indicates an imbalance.

The outputs to be maximized are capital adequacy ratio, current ratio and interest coverage ratio, as defined in Table 2.

**Table 2. Output variables for DEA**

Output variables	Formula
capital adequacy ratio (CA)	owners' equity ÷ total assets
current ratio (CR)	current assets ÷ current liabilities
interest coverage ratio (IC)	(EBIT + interest expenses) ÷ interest expenses

First, the capital adequacy ratio (CA) is a proportion of owners' equity to total assets. This ratio is an indicator of the capital adequacy of the firm. The more a firm finances itself with its own resources (the higher this ratio is), the less risky it is evaluated by credit authorities. Second, the current ratio (CR) is an indicator of the client's liquidity. The more liquid the firm is, the easier it can pay its current obligations. Therefore, the higher this ratio is, the better liquidity position the firm is in. Third, the interest coverage ratio (IC) is an indicator that shows the ability of a firm to pay its interest expenses with operating income. Therefore, the higher this ratio is, the more profitable the firm is.

### 4.3 Calculating financial credibility scores via DEA

Setting FE, CL, and ABS as input variables while CA, CR, and IC as output variables, we ran DEA algorithm and computed the financial performance (credibility) scores of the 1061 firms. The scores were calculated using input-oriented CCR model assuming constant returns to scale. In this application, DEA scores were given as percentage points. Hence, the range of scores in the original model, i.e. 0-1, will be reported as 0-100.

The resulting DEA credibility scores vary between 13.04 and 100. Firms with DEA score of 100 are considered best firms and are said to fall on “efficient frontier.” Fig. 2 shows the distribution of DEA scores for the 1061 sampled firms.

As seen in Fig. 2, there are 16 firms with DEA scores of 100. As the DEA score of a firm is lower than others, its financial performance is considered relatively worse than other firms in the observation set. It is thus considered to be closer to a probable bad risk in the context of loan extension process.

Fig. 2. Distribution of the DEA scores for the 1061 sampled firms

### 4.4 Validating DEA scores

(a) *Regression analysis*: In this context, DEA credibility score acts as the dependent variable while the six ratios are considered as the independent variables. To prevent overestimation, the regression was run excluding the “best observations” (firms with DEA score of 100).

**Table 3. Regression analysis results**

R <sup>2</sup> = 0.741; F = 491.803 (Sig. = .000)					
	Unstandardized Coefficients	Standard Error	t-value	p-value	VIF
Constant	72.94035	3.772205	19.33626	0.000	
FE	-109.653	21.6798	-5.05785	0.000	1.446
CL	-50.8614	3.123891	-16.2814	0.000	1.726
ABS	-56.3548	3.039185	-18.5427	0.000	1.411
CA	47.45822	4.30213	11.03133	0.000	1.790
CR	17.36333	1.085729	15.99233	0.000	1.273
IC	1.146138	0.184531	6.211091	0.000	1.324

As shown in Table 3, all the variables have expected directions and are statistically significant, which tells us that the DEA algorithm successfully accounted for all six ratios at a statistically significant level.

Equation (1) represents the estimated regression relationship. This can be seen as a linear approximation of the DEA results. If the observation set is statistically large enough, the regression equation may also be used to evaluate a new credit applicant without having to run all the steps to derive its DEA score. In other words, by using Equation (1), it is possible to compute the linear approximation of its DEA score without having to run the DEA algorithm each time a new observation is added.

Using the regression equation, we computed the “fitted DEA scores” and compared them with those obtained by DEA. As shown in Fig. 3, the actual DEA scores and the fitted scores do not differ significantly. The matched-pairs t test also assured that there is no significant difference between the actual scores and the fitted ones (t-value=0.000, p-value=1.000).

Fig. 3. Actual vs. fitted DEA scores

(b) *Discriminant analysis*: An attempt was made to approximate the DEA results through DA. The firms were classified into two groups with respect to their DEA scores. The “cut-off” point between good and bad firms was selected in an ex post subjective manner, giving due consideration to the distribution of the DEA scores.

**Table 4. Discriminant analysis result**

		Selected Group		
		Good	Bad	Total
Predicted Group	Good	440 (84.9%)	57 (11.0%)	497
	Bad	78 (15.1%)	461 (89.0%)	539
	Total	518	518	1036

In this study, median of DEA scores is selected as the cut-off point due to their skewed distribution. Thus, 518 firms were classified as good while the remaining ones were classified as bad. Next, DA was run with the above classification scheme as the category variable and the six ratios as the independent variables. The DA generated a discriminant function with five of the six ratios included (only IC being excluded). Table 4 showed that DA resulted in  $(440+461)/(518+518)$  or 87.0% hit ratio.

Equation (2) represents the unstandardized canonical discriminant function:

$$Z = -3.2 + 9.0FE + 4.4CL + 5.6ABS - 3.4CA - 1.5CR(2)$$

As shown in Fig. 4, the DA-generated ranking did not differ significantly from that obtained by DEA, which is also statistically ensured by Spearman test (rank order correlation coefficient=0.882, p-value=0.0001). This tells us that the financial credibility scores derived by DEA can indeed be linearly approximated by DA, and provide useful information for business failure prediction.

**Fig. 4. DEA vs. DA rankings of sampled firms.**

(c) *Testing actual bankruptcy cases*: We also checked consistency of the DEA results using actual bankruptcy cases of 103 firms. As shown in Table 5, the hit ratio of bankruptcy classification turned out to be 78.6%. This result shows the usefulness of DEA-based methodology in financial distress prediction while DEA only considers ex post information of the firms.

**Table 5. Classification result of actual bankruptcy firms**

		Predicted Group		
		Good	Bad	Total
Actual Group	Bad	22 (21.4%)	81 (78.6%)	103

#### 4.5 Credit rating method

From a practical risk management point of view, the fitted DEA scores (via regression analysis) of credit applicant firms should be classified into several classes such as A, B, C, and so on. Table 6 shows the frequency distribution of good/bad firms' actual DEA scores with equal class intervals.

**Table 6. Original frequency distribution of good/bad firms**

Class	Good	Bad	Sum	% of Bad	% of Sum
Below 20	76	25	101	24.8%	8.7%
20-40	360	46	406	11.3%	34.9%
40-60	402	27	429	6.3%	36.9%
60-80	173	5	178	2.8%	15.3%
80-100	48	0	48	0.0%	4.1%
Upper 100	2	0	2	0.0%	0.2%
Total	1061	103	1164	8.8%	

As one can see in Table 6, the relative frequency of bad firms (% of Bad) decreases as the DEA scores increase. This means that the DEA score can serve as a very useful indicator to quantify the credit worthiness of the applicant firms, and thus banks or other financial institutions may grade the client firms' credit according to the DEA score classes. For example, a firm with DEA score ranged from 20 to 40 may be graded “E.” However, the frequency of the firms in each DEA score class (% of Sum) in Table 6 has a drawback in real world applications.

**Table 7. Modified frequency distribution of good/bad firms**

Interval	Good	Bad	Sum	% of Bad	% of Sum
Below 25	138	37	175	21.1%	15.0%
25-35	186	28	214	13.1%	18.4%
35-45	219	16	235	6.8%	20.2%
45-55	222	15	237	6.3%	20.4%
55-70	177	7	184	3.8%	15.8%
Upper 70	119	0	119	0.0%	10.2%
Total	1061	103	1164	8.8%	

**Fig. 6. Histogram of modified frequency distribution**

Commercial banks or other financial institutions do not normally grade the client firms as shown in Table 6 due to their respective internal business policies. Table 6 shows the DEA score distribution (% of Sum) is skewed to the right, which indicates that there are too many firms in low grades. This way of credit rating would not be practiced in real world applications. In general, commercial banks or other financial institutions want to grade the client firms according to the normal curve.<sup>2</sup>

<sup>2</sup> According to the internal policies of financial institutions, their respective credit rating distributions may differ. In this study, however, we assume that the normal distribution is

Fortunately, this problem may be solved through adjusting the class interval of DEA scores. Table 7 and Fig. 6 show the DEA score distribution of the client firms with modified class intervals.

As seen in Table 7 and Fig. 6, the modified distribution of the client firms guarantees that the bankruptcy ratio (% of Bad) decreases as the DEA score increases, and the frequency of the firms in each class (% of Sum) approximately follows the normal distribution.

## 5. CONCLUSIONS

This paper presents a new method of credit scoring using DEA. As opposed to broadly known multiple discriminant analysis, logistic regression analysis, and neural networks, DEA requires only ex post information to calculate credit scores. The discriminatory power of this method was also tested by comparing its results against those obtained by regression analysis and discriminant analysis, and by using actual bankruptcy cases. The empirical results suggest that this new approach can serve as a promising alternative for augmenting and/or replacing current credit scoring methods used by commercial banks and credit industry.

In terms of managerial implications, this method also gives a clear insight into how "bad" firms can improve their respective financial credibility. From the empirical results, it is shown that "good" firms have higher liquidity, lower bank loans, higher capital adequacy, and more balance between their equities and fixed assets. We also suggested a practical credit rating method using the estimated DEA scores derived by the method.

In addition, this new method *ipso-facto* allows the commercial banks or other financial institutions to monitor the exposures of their respective credit portfolios on an ongoing basis and to take preventive actions against the clients' defaults in an early stage.

## ABSTRACT

To study the process of pricing in capital market and look for a new way for decision support in financial market, according to the mechanism of artificial neural network, Capital Market Structure Model is developed in this case due to the influence between bargainer and price of asset in market. During proof-test, result of chaos forecast under the capital market structure model shows that chaos forecast capability of the Capital Market Structure Model is good for decision support.

**Key words:** chaos; forecast; capital market structure model.

In financial market, the bargainer always concentrated in same place and the information spread quickly, meanwhile, bargainer and price are affected by each other. This means that the bargainer will influence the asset price in financial market when they trading. As we know, the decision of trading always after the changing of asset price in market. The new price also will influence the new decision of trading. So we can conclude that the bargainer and the price of asset in financial market are also influenced by each other continually. It is very important to study the principle of the influence before predict the tendency of asset price in financial market, because we need to know the process of price changing to support our decision.

According to related papers in recent years, most of the researches about the asset forecast make use of the Artificial Neural Network (ANN). In the cases of positive research about forecast by using of the Artificial Neural Network, theories of chaos and fuzzy are apply to improve the data processing. In addition, wavelet theory is applies in forecast.

According to the fundamental concepts of dynamical reconstruction theory and multi resolution analysis, YangYiwen, LiuGuizhong and ZhangZongping<sup>[1]</sup> take the reconstructed state vectors as multiple inputs to neural network to predict stock index trend of Shanghai Stock Exchange (SSE) in future multiple trading days.

We can get high accuracy in imitating nonlinear curve through ANN, but we don't know the relationship among input variables in ANN. So when ANN is applies to forecast in capital market, we can't explain the process of pricing, which means we get the result without reason.

The way of price forecast can't explain the process of pricing and will not be variable in economics, and also will not make people know much more about the market. This is the key problem people faced in price forecast when ANN is applies to it. People can't explain the meaning of weights and biases of ANN in real market.

Until now, except researches of forecast by using ANN or wavelet theory directly, no research of forecast due to the principle of the influence among bargainers and prices in financial market has been reported.

The purpose of this study is to fund a structure model of capital market due to principle of influence among bargainers and prices in capital market according to the idea by which ANN is founded. This structure model applies to forecast the future price in capital market. To insure the validity of forecast, chaos theory is applied to account the available length of non-periodic cycle of stock price.

## 1 ABOUT THE CAPITAL MARKET STRUCTURE MODEL

The main purpose of founding the CMSM is to analysis the process of pricing and forecast future price. Here the capital market means the security market in which information spread quickly, bargainer concentrated in same place. The model condition Hypothesis as follow:

- 1.1 Bargainer with the same averseness to risk will has the same game in bargaining.
- 1.2 The sensitivity of every bargainer to losing is higher than which to earning<sup>[2]</sup>.
- 1.3 The decision of bargaining is made due to the changing of price.
- 1.4 The rate of price fluctuating is less than 100% every time.
- 1.5 There is no influence outside economy.
- 1.6 there is a relationship which can be described as S curve between the influence of bargainer's asset portfolio changing to asset price and real surplus<sup>[2]</sup>. (figure 2)

The model is applies to analysis the process when bargainer and prices influencing each other.

Time t		Time t+1
asset(k=1~n)	bargainer (j=1~m)	asset (k=1~n)

Figure1 : Capital Market Structure Model

In this model, there are  $n$  assets and  $m$  kinds of bargainer. Bargainer is partitioned into  $m$  kinds due to the degree of averseness to risk. The degree of averseness to risk of bargainer  $j$  is  $\theta_j$ . In time  $t$ , the price of asset  $k$  is  $P_{k,t}$ ,  $k=1\sim n$ , and its price fluctuating rate is shown in equation (1):

$$\Delta P_{k,t} = (P_{k,t} - P_{k,t-1}) / P_{k,t-1} \quad (1)$$

The weight of influence from price fluctuating rate  $\Delta P_{k,t}$  to bargainer  $j$  is  $w_{kj}$ , the whole influence come from the price fluctuating rate of  $n$  asset of bargainer  $j$  is  $\sum_{k=1}^n w_{kj} \Delta p_{k,t}$ . deducting from  $\theta_j$ , the real influence to the decision of bargainer  $j$  is  $\sum_{k=1}^n w_{kj} \Delta p_{k,t} - \theta_j$ . If

$\sum_{k=1}^n w_{kj} \Delta p_{k,t} - \theta_j \neq 0$ , bargainer will changing his portfolio of assets. The influence of this changing to whole market will be  $f(\sum_{k=1}^n w_{kj} \Delta p_{k,t} - \theta_j)$

The function  $f(x)$  means the transformation from this influence to the changing of market. The weight of influence from bargainer  $j$  to asset  $k$  is  $v_{jk}$ , so the influence from the portfolio changing of bargainer  $j$  to the price fluctuating rate of asset  $k$  is  $v_{jk} f(\sum_{k=1}^n w_{kj} \Delta p_{k,t} - \theta_j)$ . All the influence from portfolio changing of  $m$  kind of bargainer to the price fluctuating rate of asset  $k$  is

$\sum_{j=1}^m v_{jk} f(\sum_{k=1}^n w_{kj} \Delta p_{k,t} - \theta_j)$ , which is shown in

equation(2) :

$$\Delta P_{k,t+1} = \sum_{j=1}^m v_{jk} f(\sum_{k=1}^n w_{kj} \Delta p_{k,t} - \theta_j) \quad (2)$$

The price of asset  $k$  in time  $t+1$  is shown in equation(3) :

$$P_{k,t+1} = P_{k,t} (1 + \Delta P_{k,t+1}) \quad (3)$$

In this model, the function  $f(x)$  is the key factor in describing the process of price fluctuating of asset  $k$  deduced from  $\Delta P_{k,t}$  to  $\Delta P_{k,t+1}$ .

According to the Prospect theory of Kahneman and Tversky<sup>[2]</sup>, the relationship between the subjective value and real surplus can be described by S curve. Because the behavior of bargainer is decided by his subjective value in bargaining, here we assume that there is a relationship which can be described as S curve between the influence of bargainer's asset portfolio changing to asset price and real surplus. It is showed as follow:

Figure 2 : Relationship between Influence from Bargainer to Price and Surplus

Because the sensitivity of every bargainer to losing is higher than which to earning, so here the slope of curve above axis  $X$  is less than which under axis  $X$  in figure 2.

Due to the Hypothesis, value of  $f(x)$  is inside the zone  $(-1, 1)$  :

$$f(x) = \begin{cases} a \cdot b \cdot \tan \operatorname{sig}(x), & x \neq \theta \\ 0, & x = \theta \\ b \cdot \tan \operatorname{sig}(x), & x \neq \theta \end{cases} \quad (4)$$

In Chinese stock market, if daily price is applies, the constant  $b$  should be 10%.

To proof-test capability of the model, here the method of chaos forecast jointed to forecast price of stock in Shanghai Stock Market through the model.

To forecast under chaos theory, the historic time series data of a stock must be rebuilt- in special phase space, so the model must predigested. In the new model, the historic time series data is rebuilt- in a phase space with  $n$  dimensions.

Figure 3 : Predigested CMSM

Here it is assumed that bargainer change their portfolios according data  $\Delta P_{k,t}$ ,  $k=1 \sim n-1$ , influence of this changing to the price will be  $\Delta P_{n,t}$

$$\Delta P_{n,t} = \sum_{j=1}^m v_{jn} \sum_{k=1}^{n-1} (w_{kj} \Delta p_{k,t} - \theta_j) \quad (5)$$

there is no changing with function  $f(x)$ .

Weights  $w_{kj}$ ,  $v_{jn}$  and averseness to risk  $\theta_j$  can be accounted by error propagation.

## 2. A RESEARCH OF STOCK PRICE FORECAST

Some researches show that Shanghai Stock Market is a chaos economy<sup>[3][4]</sup>, and those papers also show that it is available<sup>[5]</sup> in short-term forecast. Here the historic daily price fluctuating of stock 600622 from May17,1993 to

Oct.10,2003 are apply to this research, software MATLAB 6.01 is also applies in data computing.

Figure 4 : Process of Chaos Forecast through CMSM

First of all, the length of non-periodic cycle of stock price fluctuating should be accounted by V-Stat. developed by Hurst:

$$V_n = (R/S)_n / \sqrt{n} \quad (6)$$

$(R/S)_n$  can be accounted as follows :

$$x_m = (x_1 + \dots + x_n) / n, \quad x_r = 1 \sim n \quad (7)$$

$$\Delta x_i = (x_i - x_m), \quad i = 1 \sim n \quad (8)$$

$$y_r = \sum_{i=1}^r \Delta x_i; \quad r = 1 \sim n \quad (9)$$

$$R_n = \max(y_r) - \min(y_r); \quad r = 1 \sim n \quad (10)$$

$$S_n = \sqrt{\frac{1}{n} \sum_{r=1}^n (x_r - x_m)^2} \quad (11)$$

$$R_n / S_n = \frac{\max(y_r) - \min(y_r)}{\sqrt{\frac{1}{n} \sum_{r=1}^n (x_r - x_m)^2}} \quad (12)$$

If  $(R/S)_n$  is independence and stochastic, and changing with the square root of time, we will get a horizontal line in a figure which with the X axis of  $\log(n)$  and the Y axis of  $(R/S)_n$ . If the changing rate of  $(R/S)_n$  is faster than which of time square root, we will get a decline curve in the figure. Otherwise, we will get an upswept curve.

When the curve changing its trend, it means the end of non-periodic cycle, so the length of non-periodic cycle is gotten.

When analyzing the historic price fluctuating of stock 600622, we find that the non-periodic cycle is 30 days. It means that the available length in forecasting is 30 days.

Figure 5 : V-Stat. of 600622

According to Wolf.,<sup>[6]</sup> the product of the number of phase space dimension and arrearage equal to the length of non-periodic cycle. There are 5 working days every week, so the number of dimension is 5, Accordingly, the arrearage should be 6 days.

After the process of rebuilt in phase space, the one dimension historic time series is convert into 5 dimension time series. 4 of 5 dimension time series is taken as the input data, and the 5th dimension of time series is taken as the output data. When forecasting, we can use the data of 1<sup>st</sup> and 7<sup>th</sup> and 13<sup>th</sup> and 19<sup>th</sup> to predict the value of 25<sup>th</sup>. According to the principle of pricing, it can be explained that bargainer change their stock portfolios due to price fluctuating occurred at 1<sup>st</sup> and 7<sup>th</sup> and 13<sup>th</sup> and 19<sup>th</sup> those 4 Days, all influences of portfolio changing will decide the pricing at the day of 25<sup>th</sup>. Most of historic data are apply to train CMSM, less of them are apply to proof-test the accuracy of the CMSM. The constant of  $\alpha$  is 0.816, and the number of kinds of bargainer is 9. Percentage of daily price fluctuating forecasted and its error list as follows:

Table 1: Percent of daily price fluctuating forecasted and pricing error

NO.	Real value (%)	Accounted value(%)	Error(%) of pricing
1	0.13	0.84	0.71
2	-0.41	2.68	3.09
3	-0.88	2.02	2.90
4	1.74	-0.94	-2.68
5	-0.32	1.42	1.75
6	-1.06	0.33	1.38
7	-0.96	0.85	1.80
8	-3.04	3.24	6.28
9	-1.01	-3.10	-2.09

### 3. CONCLUSION

Through the work of test-proof about the CMSM in forecasting the daily price fluctuating, we can find that the CMSM is applies to price forecasting in chaos economy because of the accuracy which shows that 8 of the 9 cases in price forecasting with its error less than 3.5% and there is only one case of price forecasting with its error more than 5%. So CMSM is apply to consult in decision-making.

### ABSTRACT

In the past, most incremental mining and online mining algorithms considered finding the set of association rules or patterns consistent with the entire set of data inserted so far. Users can not easily obtain the results from their only interested portion of data. For providing ad-hoc, query-driven and online mining supports, we first propose a relation called *multidimensional pattern relation* to structurally and systematically store the context information and the mining information for later analysis. Each tuple in the relation comes from an inserted dataset in the database. This concept is similar to the construction of a data warehouse for OLAP. However, unlike the summarized information of fact attributes in a data warehouse, the mined patterns in the multidimensional pattern relation can not be directly aggregated to satisfy users' mining requests. We then develop an online mining approach called *Three-phased Online Association Rule Mining* (TOARM) based on the proposed multidimensional pattern relation to support online generation of association rules under multidimensional considerations. Experiments for both homogeneous and heterogeneous datasets are made, with results showing the effectiveness of the proposed approach.

**Keywords:** association rule, incremental mining, multidimensional mining, constraint-based mining, data warehouse

### 1. INTRODUCTION

Data mining technology has become increasingly important in the field of large databases and data warehouses. This technology helps discover non-trivial, implicit, previously unknown and potentially useful knowledge [3][9][16], thus being able to aid managers in making good decision. Among various types of databases and mined knowledge, mining association rules from transaction databases is the most interesting and popular. Previous works on mining association rules could be classified into batch mining approaches [2][4][5][7][20][22][24] and incremental mining approaches [10][11][13][18][23][25] according to the processing ways. Most of them have focused on finding association rules or patterns in a specified part of a database [15]. Some contexts (circumstance information) such as region, time and branch have usually been ignored in mining requests. Users can not easily obtain association rules or patterns from their only interested portion of data. However, decision-makers usually diversely consider problems at different aspects [14][15][16]. They may need to analyze market demands, customer preferences, localities, and short-term/long-term trends. They may also want to understand the change of discovered patterns or rules in different dimensions. This may decrease the usage of mining in online decision support for multidimensional data.

In this paper, we attempt to extend the concept of *effectively utilizing previously discovered patterns* in incremental data mining to support online generation of

association rules under multidimensional considerations. We first propose the *multidimensional pattern relation* to structurally and systematically store the additional context information and mining information for each inserted dataset. It is conceptually similar to the construction of a data warehouse for OLAP [8][19][26]. Both of them preprocess the underlying data in advance, integrate related information, and store the results in a centralized structural repository for later use and analysis. However, unlike the summarized information of fact attributes in a data warehouse, the mined patterns in the multidimensional pattern relation can not be directly aggregated to satisfy users' mining requests. We then develop a *Three-phased Online Association Rule Mining* (TOARM) approach to effectively and efficiently satisfy diverse mining requests. It mainly consists of three phases, *generation of candidate itemsets*, *reduction of candidate itemsets*, and *generation of association rules*. The phase for *generation of candidate itemsets* selects the tuples satisfying the context constraints in a mining request and generates the candidate itemsets from the matched tuples. After that, the phase for *reduction of candidate itemsets* calculates the upper-bound supports of the candidate itemsets and adopts two pruning strategies to reduce the number of candidate itemsets. Finally, the phase for *generation of association rules* finds the final large itemsets and then derives the association rules from them. Experimental results also show the effectiveness of the proposed TOARM approach.

## 2. RELATED WORK

An association rule indicates a relationship among items such that the occurrence of certain items in a transaction would imply the occurrence of some other items in the same transaction. The process of mining association rules can roughly be decomposed into two tasks [4]: *finding large itemsets* and *generating interesting association rules*. The first task discovers the itemsets that satisfy a user-specified *minimum support* from a given database. It is used to obtain the statistically significant patterns. The second task finds the association rules that satisfy a user-specified *minimum confidence* from the large itemsets. Since this process is rather costly and time-consuming, some famous mining algorithms, such as Apriori [4], DIC [7], DHP [22], Partition [24], Sampling [20] and GSP [5], were proposed to achieve this purpose. Among them, the Apriori algorithm, which is the best well-known, utilizes a level-wise candidate generation approach to reduce its search space, such that only the large itemsets found in the previous level are treated as seeds for generating the candidate itemsets in the current level. This level-by-level property can greatly reduce the number of itemsets to be considered in a mining process. Many following algorithms were then based on this property and attempted to further reduce candidate itemsets and I/O costs. Comprehensive overviews can be referred to in [9][16].

Most of the mining algorithms process data in a batch way and must re-process the entire database whenever either the data stored in a database or the thresholds (i.e. the minimum support or the minimum confidence) set by users are changed. They do not utilize previously mined patterns for later maintenance, and may require considerable computation time to obtain the updated set of association rules or patterns [10]. Recently, some researchers have developed incremental mining algorithms to maintain association rules without re-processing the entire database whenever the database is updated. Examples include the FUP-based algorithms proposed by Cheung et al. [10][11], the adaptive algorithm proposed by Sarda and Srinivas [23], the incremental mining algorithm based on the concept of *pre-large itemsets* proposed by Hong et al. [18], and the incremental updating technique based on the concept of *negative border* proposed by Thomas et al. [25] and Feldman et al. [13]. The common idea of the above researches lies in that the previously mined patterns are stored in advance for later usage. When new transactions are inserted or old records are deleted, a large part of the final results can be obtained by comparing the patterns mined from the newly inserted transactions or deleted records with the pre-stored mined knowledge. Only a small portion of patterns needs to be re-processed against the entire database. Much computation time can thus be saved in this way. Among the above approaches, the FUP-based algorithms [10][11] store the previously mined large

itemsets for later maintenance. Some other approaches utilize the *pre-large itemsets* [18] and the *negative border* [13][25] to enlarge the amount of pre-stored mined information for further improving the maintenance performance at the expense of storage spaces.

## 3. THE MULTIDIMENSIONAL PATTERN RELATION

A multidimensional pattern relation schema *MPR* is a special relation schema for storing mining information. An *MPR* consists of three types of attributes, *identification (ID)*, *context*, and *content*. There is only one identification attribute for an *MPR*. It is used to uniquely label the tuples. Context attributes describe the contexts (circumstance information) of an individual block of data which are gathered together from a specific business viewpoint. Examples of context attributes are region, time and branch. Content attributes describe available mining information which is discovered from each individual block of data by a batch mining algorithm. Examples of content attributes include the number of transactions, the number of mined patterns, and the set of previously mined large itemsets with their supports.

The set of all previously mined patterns with their supports for an individual block of data is called a *pattern set (ps)* in this paper. Assume the minimum support is  $s$  and there are  $l$  large itemsets discovered from an individual block of data. A pattern set can be represented as  $ps = \{(x_i, s_i) \mid s_i \geq s \text{ and } 1 \leq i \leq l\}$ , where  $x_i$  is a large itemset and  $s_i$  is its support. The pattern set is thus a principal content attribute for an inserted block of data.

A multidimensional pattern relation schema *MPR* with  $n_1$  context attributes and  $n_2$  content attributes can be represented as  $MPR(ID, CX_1, CX_2, \dots, CX_{n_1}, CN_1, CN_2, \dots, CN_{n_2})$ , where *ID* is an identification attribute,  $CX_i, 1 \leq i \leq n_1$ , is a context attribute, and  $CN_i, 1 \leq i \leq n_2$ , is a content attribute. Assume a multidimensional pattern relation *mpr*, which is an instance of the given *MPR*, includes tuples  $\{t_1, \dots, t_m\}$ . Each tuple  $t_i = (id_i, cx_{i1}, cx_{i2}, \dots, cx_{in_1}, cn_{i1}, cn_{i2}, \dots, cn_{in_2})$  in *mpr* indicates that for the block of data under the contexts of  $cx_{i1}, cx_{i2}, \dots$ , and  $cx_{in_1}$ , the mining information contains  $cn_{i1}, cn_{i2}, \dots$ , and  $cn_{in_2}$ .

**Example 1:** Table 1 shows a multidimensional pattern relation with the initial minimum support set at 5%. *ID* is an identification attribute, *Region*, *Branch* and *Time* are context attributes, and *No\_Trans*, *No\_Patterns* and *Pattern\_Sets* are content attributes. The *Pattern\_Sets*

attribute records the sets of mined large itemsets from the previous data blocks. For example, the tuple with  $ID = 1$  shows that seven large itemsets,  $\{(A, 10\%), (B, 11\%), (C, 9\%), (AB, 8\%), (AC, 7\%), (BC, 6\%), (ABC, 6\%)\}$ , are discovered from 10000 transactions and under the contexts of  $Region = CA$ ,  $Branch = San Francisco$  and  $Time = 2003/10$ . The other tuples have similar meaning.  $\text{\textcircled{C}}$

Table 1: A multidimensional pattern relation with minimum support = 5%

ID	Region	Branch	Time	No_ Trans.	No_ Patterns	Pattern_Sets (Itemset, Support)
1	CA	San Francisco	2003/10	10000	7	(A,10%),(B,11%), (C,9%),(AB,8%), (AC,7%),(BC,6%), (ABC,6%)
2	CA	San Francisco	2003/11	15000	3	(A,5%),(B,7%),(C, 5%)
3	CA	San Francisco	2003/12	12000	2	(A,5%),(C,9%)

#### 4. MULTIDIMENSIONAL ONLINE MINING FOR ASSOCIATION RULES

The goal of online mining is to find the association rules satisfying the constraints in a mining request on line. The types of mining requests allowed can grow up through the usage of the proposed multidimensional pattern relation. In this paper, an online mining approach called *Three-phased Online Association Rule Mining* (TOARM) is proposed to achieve the mining task from a multidimensional pattern relation. TOARM first selects the tuples from the relation satisfying the constraints in a mining request. It then integrates and outputs the mining information in these tuples to users. Before describing the TOARM approach, we first formally define the problem to be solved and some related terminology. Some lemmas are also derived (The detailed proofs are omitted here).

Assume  $mpr = \{t_1, t_2, \dots, t_n\}$  is a multidimensional pattern relation based on an initial minimum support  $s$ . Given a mining request  $q$  with a set of contexts  $cx_q$ , a new minimum support  $s_q$  ( $s_q \geq s$ ), and a new minimum confidence  $conf_q$ , the proposed algorithm will effectively and efficiently derive the association rules satisfying  $s_q$ ,  $conf_q$  and  $cx_q$ . A tuple with  $cx_q$  in a multidimensional pattern relation is called a *matched*

*tuple*. Let  $t_i$  denote the  $i$ -th tuple in a multidimensional pattern relation,  $t_i.trans$  denote the number of transactions kept in  $t_i$ ,  $t_i.ps$  denote the pattern set in  $t_i$ , and  $t_i.s_x$  denote the actual support of an itemset  $x$  in  $t_i$ .

**Lemma 1:** For each itemset  $x$  satisfying  $s_q$  and  $cx_q$  in a mining request  $q$ , there exists at least a matched tuple  $t$ , such that  $t.s_x$  satisfies  $s_q$ .  $\text{\textcircled{C}}$

**Lemma 2:** For each itemset  $x$  satisfying  $s_q$  and  $cx_q$  in a mining request  $q$ , it must be among the candidate itemsets obtained by collecting the ones whose supports are larger than or equal to  $s_q$  in at least one matched tuple.  $\text{\textcircled{C}}$

**Lemma 3:** If  $x$  is a candidate itemset, then  $\forall x' \subset x$ ,  $x'$  is also a candidate itemset.  $\text{\textcircled{C}}$

The *appearing count*  $Count_x^{appearing}$  of a candidate itemset  $x$  is defined as the count of  $x$  calculated from the matched tuples in which  $x$  appears. Thus:

$$Count_x^{appearing} = \sum_{t_i \in \text{matched tuples} \ \& \ x \in t_i.ps} t_i.trans * t_i.s_x. \quad (1)$$

The *upper-bound count*  $Count_x^{UB}$  of a candidate itemset  $x$  is defined as the upper bound count of  $x$  calculated from the matched tuples in which  $x$  does not appear. Thus:

$$Count_x^{UB} = \sum_{t_i \in \text{matched tuples} \ \& \ x \notin t_i.ps} (t_i.trans * s - 1). \quad (2)$$

Let  $Match\_Trans$  denote the number of transactions in the matched tuples. Thus:

$$Match\_Trans = \sum_{t_i \in \text{matched tuples}} t_i.trans. \quad (3)$$

The *upper-bound support*  $s_x^{UB}$  of a candidate itemset  $x$  is thus calculated as:

$$s_x^{UB} = \frac{Count_x^{appearing} + Count_x^{UB}}{Match\_Trans}. \quad (4)$$

**Lemma 4:** If  $x$  is a candidate itemset and  $s_x$  is its actual support, then  $s_x \leq s_x^{UB}$ .  $\text{\textcircled{C}}$

**Lemma 5:** If  $x$  is a candidate itemset, then  $\forall x' \subset x$ ,  $s_{x'}^{UB} \geq s_x^{UB}$ .  $\text{\textcircled{C}}$

**Lemma 6:** If a candidate itemset  $x$  is contained in all the matched tuples, then  $s_x^{UB} = s_x$ .  $\text{\textcircled{C}}$

### **The Three-phased Online Association Rule Mining (TOARM) approach:**

**INPUT:** A multidimensional pattern relation based on an initial minimum support  $s$  and a mining request  $q$  with a set of contexts  $cx_q$ , a minimum support  $s_q$  and a minimum confidence  $conf_q$ .

**OUTPUT:** A set of association rules satisfying the mining request  $q$ .

#### **Phase 1: Generation of candidate itemsets:**

(a) Select the tuples satisfying  $cx_q$  from the multidimensional pattern relation.

(b) Gather the candidate itemsets appearing in the matched tuples.

(c) Calculate  $Count_x^{appearing}$  and  $Count_x^{UB}$  for each candidate itemset  $x$ .

#### **Phase 2: Reduction of candidate itemsets:**

(a) Calculate the upper-bound support  $s_x^{UB}$  of each candidate itemset  $x$  by the formula:

$$s_x^{UB} = \frac{Count_x^{appearing} + Count_x^{UB}}{Match\_Trans}.$$

(b) Discard the candidate itemset  $x$  and its proper supersets from the candidate set if  $s_x^{UB} \leq s_q$ .

(c) Put  $x$  into the set of large itemsets if  $s_x^{UB} = \frac{Count_x^{appearing}}{Match\_Trans}$  and  $s_x^{UB} \geq s_q$ .

#### **Phase 3: Generation of association rules:**

(a) Check whether each remaining candidate itemset  $x$  is large by scanning the underlying blocks of data for the matched tuples in which  $x$  does not appear.

(b) Generate the association rules satisfying the minimum confidence  $conf_q$  from the set of large itemsets.

The TOARM approach only considers the itemsets appearing in the matched tuples and satisfying the minimum support as the candidate ones. It also uses two pruning strategies to reduce the number of candidate itemsets. It therefore only needs to re-process the remaining candidate itemsets against the underlying blocks of data for the matched tuples in which they do not appear. Due to the above consideration, the cost of re-processing underlying blocks of data by the TOARM approach is less than that by typical batch mining or incremental mining approaches.

**Example 2:** For the multidimensional pattern relation given in Table 1, assume a mining request  $q$  is to get the patterns under the contexts  $cx_q$  of *Region = CA* and *Time = 2003/11~2003/12* and satisfying the minimum support  $s_q = 5.5\%$ . According to Lemma 2, the set of candidate itemsets is  $\{\{A\}, \{B\}, \{C\}, \{AB\}\}$ , which is the union of the itemsets appearing in the pattern sets and with their supports larger than 5.5%. Among these candidate itemsets, in Phase 2, the TOARM approach can remove the candidate itemsets  $\{A\}$  and  $\{AB\}$  according to Lemmas 4 and 5, and put the candidate itemset  $\{C\}$  into the set of large itemsets for  $q$  according

to Lemma 6. Only the remaining candidate itemset  $\{B\}$  needs to be further processed in Phase 3.

## **6. EXPERIMENTS**

The experiments were implemented in Java on a workstation with dual XEON 2.8GHz processors and 2048MB main memory, running RedHat 9.0 operation system. The datasets were generated by a generator similar to that used in [4]. The generator first generated  $L$  maximal potentially large itemsets, each with an average size of  $I$  items. The items in a potentially large itemset were randomly chosen from the total  $N$  items according to its actual size. The generator then generated  $D$  transactions, each with an average size of  $T$  items. The items in a transaction were generated according to the  $L$  maximal potentially large itemsets in a probabilistic way.

The two groups of datasets generated in the above way and used in our experiments are listed in Table 2, where the datasets in the same group had the same  $D$ ,  $T$  and  $I$  values but different  $L$  or  $N$  values. Each dataset was treated as a block of data in the database. Among the two groups, Group 2 could be thought of as heterogeneous because of its varied  $N$  values. This group of datasets was used to show the effect of heterogeneous blocks of data on our approach.

Table 2: The two groups of datasets generated for the experiments

Group	Size	Datasets	D	T	I	L	N
1	10	$T10I8D10KL^I$ to $T10I8D10KL^{I0}$	10000	10	8	200 to 245	100
2	10	$T10I8D10KN^I$ to $T10I8D10KN^{I0}$	10000	10	8	200	100 to 145

The TOARM and the Apriori algorithms were then run for Groups 1 and 2 along with different minimum supports ranging from 0.022 to 0.04 in the mining requests. The execution times spent by the two algorithms for each group are respectively shown in Figures 1 and 2. From Figures 1, it is easily seen that the execution time by the TOARM algorithm on Groups 1 was always much less than that by the Apriori algorithm. This is because the datasets in this group was homogeneous, meaning they used the same set of items in each group. In this situation, the number of candidate itemsets considered by the TOARM algorithm was much closer to the number of the final large itemsets than that by the Apriori algorithm. The former thus had a more compact candidate set than the latter.

Figure 1: The execution time spent by the two algorithms for Group 1

On the contrary, the datasets in Group 2 were heterogeneous, meaning they used different sets of items. In this situation, the number of candidate itemsets considered by the TOARM algorithm was much larger than the number of the final large itemsets since most of the candidate itemsets appeared in only one or few tuples in the multidimensional pattern relation. But, since the TOARM algorithm adopted two pruning strategies in Phase 2 and only re-processed the remaining candidate itemsets in Phase 3 against the underlying datasets in which they do not appear, the execution time spent by the TOARM algorithm was usually still less than that spent by the Apriori algorithm. This is also consistent with the results shown in Figure 2.

Figure 2: The execution time spent by the two algorithms for Group 2

## 7. CONCLUSION

In this paper, we have extended the concept of effectively utilizing previously discovered patterns in incremental mining to online decision support under multidimensional considerations. By structurally and systematically storing the additional context information and mining information in the multidimensional pattern relation, our proposed TOARM approach can easily and efficiently derive the association rules satisfying diverse user-concerned constraints. From the experimental results, the proposed TOARM approach is more efficient than the well-known Apriori approach especially for homogeneous datasets.

## ABSTRACT

As information overload problem more serious on the Internet, it becomes an important issue for users to retrieve information effectively. An information recommendation system is helpful for providing user information meet he/she requirements appropriately. However the traditional recommendation concepts usual classify a user into one preference class. It seems unreasonable because a user may possess interests about many information classes generally. In this study we propose a new recommendation concept in information recommendation system, namely club member, differs from content-based and collaboration filter method. It can classify a user into some clubs which he/she interests with different preference degrees.

In order to classify users into multi-club with different preference degrees, fuzzy association rule based on data mining technology is applied in this study. Fuzzy association rules are generated by discovering and analyzing the members' feature in the same club. According to fuzzy association rules, a new user can be classified into some clubs that he/she may interest with preference degrees. It is helpful for an information recommendation system to provide user more suitable information in accordance with their preferences precisely.

**Keywords:** Preference classification, Recommendation system, Data Mining, Fuzzy association rule

## 1. INTRODUCTION

The Internet, with continuous progress in computer technology and the pervasion of network environments, has become a major channel for modern people to acquire information (Chen and Tai, 2003). As amounts of information increase on the Internet, Users also face the serious problem of information overload simultaneously (Ribak et al., 2003; Sugiyama et al., 2004; Fang and Sheng, 2004). Under this circumstance, Web tools have become more important for developing better solutions to assist people in acquiring information easily and effectively (Sugiyama et al., 2004).

Thus far, Recommendation Systems (RSs) are regarded as one of effective solutions for assisting people to acquire information on the Internet (Garcia et al., 2004). Furthermore, RSs differ from traditional search engine tools or portal websites; it applies active information recommendation methods to replace passive keyword search methods. It is helpful for user to acquire suitable information in less time and effort (Chen and Tai, 2003). Nowadays, content-based and collaborative filter are two popular means applied in the RSs. Although they really emerge excellent performance in information recommendation, there are some problems still cannot be resolve. In order to provide user more abundance and suitable information, a new recommendation concept is proposed in this study, namely club member, differs from content-based and collaboration filter method. It allows a user can acquire a variety of information from some clubs that he/she interests.

In order to classify users into multi-club with different preference degrees, fuzzy association rule based on data mining technology is applied in this study. Fuzzy association rules are generated by discovering and analyzing the members' feature in the same club. Those fuzzy association rules can classify a new coming user into those clubs that he/she maybe interests with preference degrees. It is helpful for an information RS to provide user more suitable information in accordance with their preferences precisely.

## 2. RECOMMENDATION SYSTEM

Generally speaking, RS is applied to recommend user suitable information, e.g. news, products or services, which meet he/she interests or requirements (Chen and Tai, 2003). For the sake of achieving this goal, it must rely on several effective methods to analyze or predict user's preference and purchase trend to improve the accuracy ratio of recommendation (Garcia et al., 2004; Zhang and Iyenger, 2002). Recently, most of recommendation means can be divided into collaborative filter and content-based. Their definitions, advantages and drawbacks are described as follows (Weng and Liu, 2004; Wang et al., 2004)

### 2.1. Content-based approach

It recommends user information according to the results of similarity measurement between item-feature and target-feature. In general, a term vector is applied to represent information content and relevant profile (e.g. category, user and information) (Shih and Karger, 2004;

Wang et al., 2004). A recommendation system will process similarity measurement and determine how to recommend information to user (as shown in Fig. 1).

There are several ways can be applied as follows:

1. According to the result of similarity measurement between each piece of information and each category, information can be classified to appropriate category. A user can acquire recommendation information from his/her preference categories.
2. According to the result of similarity measurement between each piece of information and each user profile, information will be recommended to those users whose feature is similar to information feature directly.
3. According to the result of similarity measurement between each piece of information and the other information, information will be recommended to those users who had read relevant information in the past.

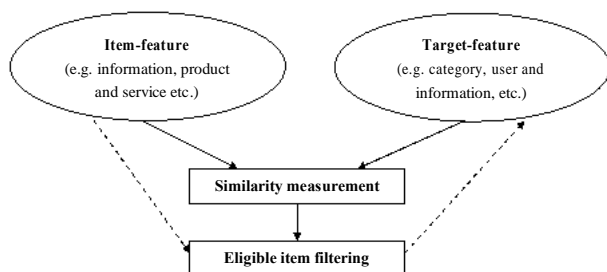

Fig. 1 Concept of content-based approach

Contented-based approach possesses advantages include:

1. A user will acquire information meet his preference feature or category appropriately.
2. Even though a piece of information cannot interest anyone in the past, it is still possible to be recommended to someone.
3. When user accepts recommendation information and makes feedback to the system, collaborative filter can support the RS (Weng and Liu, 2004).

It also possesses drawbacks include:

1. Multi-media information, such as image, sound and video data cannot be transformed into term vector. It makes the RS cannot define the content of those data type and process similarity measurement.
2. If the RS recommends user information according to user past browsing record or purchasing history, unique or different information will hardly be recommended to user (Weng and Liu, 2004).
3. Both the content of term vector and the number of term will determine the similarity degree between two features.
4. A user cannot acquire any information come from the other user with similar interests.

## 2.2. Collaborative filter analysis

In this concept, a preliminary supposition is “a set of users possess similar feature (e.g. preference, taste, purchasing trend and browsing pattern) will possess the

same interests. So a user will interest these information comes from the other members’ past browsing record or purchasing history in the same group.” Therefore, users are clustered to several groups according to their feature. The RS will recommend information to all members in the same group (as shown in Fig. 2). Collaborative filter analysis possesses advantages include:

1. The RS recommends information to all members in the same group; meanwhile, item-feature need not be analyzed in advance. This advantage makes multi-media information can be recommended without content definition or similarity measurement.
2. The recommended item could be different from users’ past preference or experiments. Therefore, it is possible to draw up potential needs and interests of users (Herlocker et al., 2000).
3. Even though a user has not any browsing record or purchasing history, he/she can still acquire information from the other members in the same group.

It also possesses drawbacks include:

1. The RS must perform user clustering to locate user-group with similar interest or pattern.
2. Information (item) not yet rated or purchased could not be recommended to other users (Weng and Liu, 2004).
3. As usual, clustering method makes the centroid unstable while a new user joins. Although it is a effective method to locate user’s group, it makes the members of user-group will unstable in any time.
4. When the RS perform user clustering, a user should belong to a specific group at least. Whereas a user cannot understand or realize the meaning of group which he/she stays.

Fig. 2 Concept of collaborative filter analysis

## 2.3. Club member concept

In a real world, people may possess several interests or hobbies with different preference degree at the same time. This concept differs from traditional content-base approach and collaborative filter analysis. It emphasizes that a user can be recommended to join some interesting clubs or groups under rational conditions. According to the multi-club concept, a user can acquire information not only from the other members in the same club, but also from the other interesting clubs (as shown in Fig. 3). The club member concept can predict a user’s interest intend and provide information meet he/she interests more flexible and effective in a RS. Several advantages of this method are described as follows:

1. Each club has clearly topic and meaning to represent itself, it is different from traditional ambiguity

in collaborative filtering analysis.

2. Once a user is classified to a specific club, he/she will stay in the club until he/she loss interest.
3. Each user can possess more interest choices with different preference degree. It can satisfy user's requirements for multi-interest.
4. A user can acquire information shared by the other members in the same club.
5. It is helpful for finding potential users from new coming users, and also eliciting new products consuming target from existed members.
6. Collaborative filtering and content-based are still support this concept, users can share information each other in the same club and acquire information that classified to this club by RS.

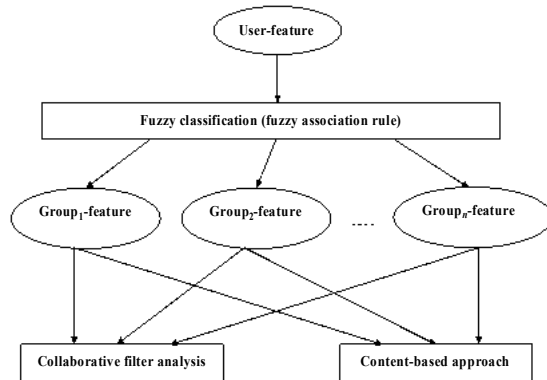

Fig. 3 Concept of club member

### 3. FUZZY ASSOCIATION RULE

In general, the interesting or preference of each user is difficult to describe clearly. In order to provide users multi-club service in the RS, fuzzy association rules are applied to classify users into appropriate clubs. For the sake of obtaining valuable fuzzy association rule for classification problem, data mining technology based on Apriori algorithm (Hu et al., 2004) is applied in this study.

#### 3.1. Fuzzy partition methods

Fuzz sets and linguistic variables concepts were proposed by Zadeh (1965, 1975ab, 1976); they are feasible to represent the diversity of degree of the feature with different linguistic value in many applications (Hu et al., 2004). Formally, a linguistic variable is characterized by a quintuple (Pedrycz and Gomide, 1998; Chen and Jong, 1997; Zimmermann, 1991) denoted by  $(x, T(x), U, G, M)$ , in which  $x$  is the name of the variable;  $T(x)$  denotes the set of names of linguistic values or terms, which are linguistic words or sentences in a natural language, of  $x$ ;  $U$  denotes a universe of discourse;  $G$  is syntactic rule for generating values of  $x$ ; and  $M$  is semantic rule for associating a linguistic value with a meaning. Using the simple fuzzy partition methods, each attributes can be partitioned by various linguistic values.

In this paper, each quantitative attribute is partitioned by simple fuzzy partition methods with triangle membership function. For example, the attribute "Age" is divided into 3 linguistic values (low, medium, high) and its membership function is predefined as follows (shown as Fig. 4). These membership functions can be represented by triangle fuzzy numbers. For example, the linguistic variable  $A_{med}^{Age}$  can be represented as  $A_{med}^{Age} = (l, m, u)$ , where  $m$  is the hedge value of linguistic variable  $A_{med}^{Age}$ .

Fig. 4 Linguistic values of "Age"

$$m_{low}^{Age}(x) = \begin{cases} 1, & x < l \\ \frac{m-x}{m-l}, & l \leq x \leq m \\ 0, & x > m \end{cases} \quad (1)$$

$$m_{med}^{Age}(x) = \begin{cases} \frac{x-l}{m-l}, & l < x \leq m \\ \frac{u-x}{u-m}, & m < x < u \\ 0, & \text{otherwise} \end{cases} \quad (2)$$

$$m_{high}^{Age}(x) = \begin{cases} 0, & x < m \\ \frac{u-x}{u-m}, & m \leq x \leq u \\ 1, & x > u \end{cases} \quad (3)$$

In addition, each qualitative attribute is partitioned by a finite number of linguistic values in accordance with its categories. For example, the attribute "Gender" is divided into 2 linguistic values and its membership function is predefined as follows.

$$m_{male}^{Gender}(x) = \begin{cases} 1, & \text{if } x = \text{male} \\ 0, & \text{otherwise} \end{cases} \quad (4)$$

$$m_{female}^{Gender}(x) = \begin{cases} 1, & \text{if } x = \text{female} \\ 0, & \text{otherwise} \end{cases} \quad (5)$$

Each attribute is partitioned into appropriate linguistic value and obtained its membership in accordance with membership function, respectively. These linguistic

values are regarded as initial candidate fuzzy grids to generate the other large fuzzy grids and fuzzy association rule for classification in following tasks.

### 3.2. Fuzzy association rule

In order to generate valuable fuzzy association rule for classification, the large fuzzy grid concept is applied in this paper. If a database possesses  $k$  attributes and  $n$  tuples of member profile, the fuzzy classification rules are generated as follows.

Step 1. Perform the fuzzy partition to generate initial candidate fuzzy grids.

Step 2. Scan the database, and fuzzy support (FS) value is calculated as follows (Ishibuchi et al., 2001a; Ishibuchi et al., 2001b; Hu et al., 2002).

$$FS(A_{s_i}^{x_i}) = \frac{1}{n} \sum_{j=1}^n m_{s_i}^{x_i}(d_j^{x_i}) \quad (6)$$

where,  $x_i$  is the  $i$ th attribute,  $s_i$  is the term of degree in  $x_i$ ,  $A_{s_i}^{x_i}$  is the linguistic value of  $s_i$  in the  $i$ th attribute,  $m_{s_i}^{x_i}$  is the membership function of  $s_i$  in the  $i$ th attribute,  $d_j^{x_i}$  is the original value of the  $i$ th attribute in the  $j$ th tuple.

Step 3. If the FS value of linguistic value is larger than or equal to the user-specified min FS, it will be regarded as an eligible fuzzy grid.

Step 4. Those eligible fuzzy grids are combined to calculate their FS value as follows.

$$FS(A_{s_1}^{x_1}, A_{s_2}^{x_2}, \dots, A_{s_k}^{x_k}) = \frac{1}{n} \sum_{j=1}^n [m_{s_1}^{x_1}(d_j^{x_1}) \cdot m_{s_2}^{x_2}(d_j^{x_2}) \cdot \dots \cdot m_{s_k}^{x_k}(d_j^{x_k})] \quad (7)$$

Step 5. Go to step 3 to check the FS value of each fuzzy association rule. It will stop when only one rule is larger than or equal to the user-specified min FS. Otherwise, the processes between steps 3 to 5 will repeat again.

Step 6. Filter out ineffective fuzzy association rules with fuzzy confidence. The general fuzzy classification rule denoted by  $R$  is stated as

$$R: A_{s_1}^{x_1} \times A_{s_2}^{x_2} \times \dots \times A_{s_k}^{x_k} \Rightarrow A_{s_a}^{x_a} \quad \text{with CF}(R) \quad (8)$$

where,  $x_a$  ( $1 \leq a \leq k$ ) is the class label and  $CF(R)$  is the certainty grade of  $R$ . It means that: if  $x_1$  is  $A_{s_1}^{x_1}$  and  $x_2$  is  $A_{s_2}^{x_2}$  and ... and  $x_k$  is  $A_{s_k}^{x_k}$ , then  $x_a$  is  $A_{s_a}^{x_a}$  with certainty grade  $CF(R)$ . The fuzzy confidence (Ishibuchi et al., 2001a; Ishibuchi et al., 2001b; Hu et al., 2002) of  $R$  is defined as follows:

$$FC(R) = FS(A_{s_1}^{x_1} \times A_{s_2}^{x_2} \times \dots \times A_{s_k}^{x_k} \times A_{s_a}^{x_a}) / FS(A_{s_1}^{x_1} \times A_{s_2}^{x_2} \times \dots \times A_{s_k}^{x_k}) \quad (9)$$

When the  $FC(R)$  of rule  $R$  is not larger than or equal to the user-specified min FC, the rule  $R$  will be regarded as ineffective fuzzy association rule and filtered out.

Step 7. Prune the redundant fuzzy association rules. If there exist two rules, denoted by  $R$  and  $S$ , possessing same consequence, and the antecedence of  $R$  is contained in  $S$ , then  $R$  is redundant and can be discarded.

## 4. EXAMPLE

There are 10 tuples of members profile in an exercise club as shown in Table 1. In this paper, the fuzzy classification rule is applied to classify a new coming user into multi-club with different preference degree. Hence, it is essential to locate effective association rule from the profile of existing member in each club. According to these classification rules, a new user can be classified into interesting clubs more effectively. The processes of generate fuzzy classification rule are described as follows.

Step 1. Perform fuzzy partition to transform original value of each attribute into linguistic value. We apply membership mapping table (shown as Table 2) to assign each education degree with a suitable membership in accordance with linguistic value, respectively. The other attributes are partitioned into linguistic values and obtained membership by membership functions. The linguistic value of each attribute is shown as Table 3. For example, the original value of attribute "Age" of member 10 is 43, and then membership degrees are 0.65, 0.35 and 0 for  $A_{high}^{Age}$ ,  $A_{med}^{Age}$  and  $A_{low}^{Age}$ , respectively.

Step 2. Scan the database, and the FS of each linguistic value is calculated (shown as Table 4). For example, the FS of  $A_{high}^{Age}$  is calculated as.

$$FS(A_{high}^{Age}) = \frac{1}{10} (1 + 1 + 0.2 + 0 + 0.1 + 0.3 + 1 + 0 + 0 + 0.65) = 0.43$$

Step 3. Find the eligible fuzzy grids that FS value is larger than or equal to the user-specified min FS (In this case, the min FS is 0.3).

Step 4. In this case, the fuzzy classification rules aim to judge a new coming user whether interests this club or not. Therefore, the eligible linguistic value of "Preference" will be regarded as classification label to mining the association rules between preference degrees with other attributes.

Step 5. After the third scan, only one rule is larger than or equal to the user-specified min FS and the eligible large fuzzy grids are shown in Table 5.

Step 6. Calculate FC value of those eligible large fuzzy grids, and then filter out those ineffective fuzzy association rules that FC value is smaller than the

user-specified min FC(In this case, the min FC is 0.5).

Step 7. When the redundant fuzzy association rules are pruned, the fuzzy classification rule is remained only one as “If Age is medium, Education is high, then Preference is medium.”

Table 1 Member's profile

Member	Age	Education	Income(K)	Preference
1	50	Doctor	56	0.96
2	56	Bachelor	67	0.89
3	34	Master	34	0.56
4	23	Bachelor	34	0.34
5	32	Master	23	0.52
6	36	Master	78	0.73
7	53	Bachelor	74	0.62
8	28	Master	32	0.55
9	25	Bachelor	55	0.47
10	43	Doctor	60	0.32

Table 2 Education membership mapping

Education	Top	High	Medium
Doctor	1	1	0
Master	0.8	1	0
Bachelor	0.5	0.8	0.3

Table 3 Linguistic value of each attribute

Attribute	High	Medium	Low
Age	(50,50,30)	(50,30,10)	(30,10,10)
Income	(90,90,50)	(90,50,20)	(50,20,20)
Preference	(0.8,0.8,0.4)	(0.8,0.4,0)	(0.4,0,0)

Table 4 FS value of each linguistic value

Attribute	High	Medium	Low
Age	0.43	0.51	0.07
Income	0.23	0.52	0.26
Preference	0.46	0.50	0.04
	Top	High	Medium
Education	0.72	0.92	0.12

Table 5 Fuzzy classification rules

Fuzzy association rule	FS(R)	FC(R)
$A_{top}^{Edu} \Rightarrow A_{high}^{pref}$	0.34	0.47
$A_{top}^{Edu} \Rightarrow A_{med}^{pref}$	0.35	0.49
$A_{high}^{Edu} \Rightarrow A_{high}^{pref}$	0.43	0.47
$A_{high}^{Edu} \Rightarrow A_{med}^{pref}$	0.46	0.50
$A_{med}^{Age} \Rightarrow A_{med}^{pref}$	0.33	0.64
$A_{med}^{Age} \times A_{high}^{Edu} \Rightarrow A_{med}^{pref}$	0.30	0.63

## 5. CONCLUSION

As information explosive grows, people must face the information overload more serious than before. RSs provide several solutions for people to acquire information meet their requirements. In order to achieve this goal, RSs need more effective and precisely method to improve the quality of information recommendation.

In this paper, we propose a club-member concept to allow a user can acquire more information from a variety of interesting clubs. In addition, fuzzy association rule based on data mining technology is applied to classify users into multi-club with different preference degrees in accordance with his/her personal features. Those fuzzy association rules can assist RSs to classify a new user into some suitable or interesting clubs for user. It is helpful for user to acquire more information from RSs more easily and effectively.

## ABSTRACT

In general, most human physiological organs systems, which are constructed by collecting more than one part to perform either single or multiple functions. In addition, the successive times between failures are not necessarily identically distributed. More generally, they can become smaller (an indication of deterioration). However, if any organic deterioration is detected, then the decision of when to take the intervention, given the costs of diagnosis and therapeutics, is of fundamental importance. At the time of the decision, the degree of future human organic deterioration, which is likely to be uncertain, is of primary interest for the decision maker (for example, determining the prevalence of disease, doing a population survey, or measuring the level of a toxin). This paper develops a possible structural design of decision support systems by considering the sensitivity analysis as well as the optimal prior and posterior decisions. The proposed design of Bayesian decision support systems facilitates the effective use of the computing capability of computers and provides a systematic way to integrate the expert's opinions and the sampling information which will furnish decision makers with valuable support for quality decision-making.

**Keywords:** Aging Chronic Diseases; non-homogeneous Poisson process (NHPP); Bayesian Decision Theory; Decision Support Systems.

## 1. INTRODUCTION

Demographic shifts in the population will lead to a further increase in the proportion of elderly and consequently of people with chronic diseases. For example, almost 75 percent of the elderly (age 65 and over) have at least one chronic. About 50 percent have at least two chronic diseases [5]. In addition, aging is a strong socially appealing issue with many implications for users as well as providers of healthcare. In general, most human physiological organs, which are constructed by collecting more than one part to perform either single or multiple functions. However, the successive times between failures are not necessarily identically distributed. More generally, they can become smaller (an indication of deterioration). If any organic deterioration is detected, then the decision of when to take the intervention, given the costs of treatments and failures, is of fundamental importance. At the time of the decision, the degree of future organic deterioration, which is likely to be uncertain, is of primary interest for the decision maker. Naturally, gathering additional data will not always be economical. It is of special interest to determine analytically or numerically the conditions under which it will be worthwhile to collect additional information. Therefore, we propose a Bayesian decision process to provide a significantly improved methodology for dealing with the decision problems of physiological organs systems which can determine the conditions for taking the different actions, and thereby help the decision-maker maximize expected profit (or minimize expected loss).

## 2. MODELS FOR DESCRIBING AGING

In order to model aging in chronic diseases, the

non-homogeneous Poisson process (NHPP) was introduced since it seems more plausible for human physiological system consisting of many organs. The system failure process is time-dependent and its intensity function of the failure process is assumed to be of the form  $\lambda(x) = \lambda_0 h(\beta; x)$ , where  $\lambda_0$  is the scale factor,  $\beta$  is the aging deteriorating rate,  $x$  is the elapsed time, and  $h(\cdot)$  can be any function that reflects the deteriorating process. Suppose that the system has a planned lifetime (i.e., time horizon)  $T$  and let the decision has to be made at time  $t$ . The crucial two-action decision is whether at time  $t$ , the failure rate of the system will be too high (in which case some risk reduction action needs to be taken), or whether it will still be within an acceptable range (in which case we can keep operating the system according to the status quo). Another option is to gather additional information before the final decision is made.

Bayesian decision analysis has been well developed for decades [3,18], especially in the fields of statistical decisions [2,7], reliability engineering [4,9], quality management [1,16], and decision science [6,15]. The basic elements of the Bayesian decision process are as follows:

- (a) Parameter space  $\Theta : \{(\lambda_0, \beta) | \lambda_0 > 0\}$ , where  $\lambda_0$  is the scale factor and  $\beta$  is the deterioration rate. Both parameters are uncertain and can be estimated through experts' opinions.
- (b) Action space  $A : \{a_1, a_2\}$ , where  $a_1$  is the status quo, and  $a_2$  is the risk reduction action. (We eventually expand this to consider a third possible action, the collection of additional information).
- (c) Loss function  $L$ : a real function defined on  $\Theta \times A$ . If we decide to keep the system operating, then the loss we face is  $L(\theta, a_1)$ ; if we decide to take the risk reduction

action, then the loss we face is  $L(\theta, a_2)$ .

(d) Sample space  $S$ : The additional information available to be collected. For example, the successive failure times till the  $n$ . failure can be denoted as the likelihood function of the form

$$f_{X_1, X_2, \dots, X_n}(x_1, x_2, \dots, x_n) = \left[ \prod_{i=1}^{n^*} \lambda(x_i) \right] \exp(-\Lambda(x_{n^*})) \quad (1)$$

where  $\Lambda(x) = \int_0^x \lambda(u) du$  is the mean number of failures by time  $x$  in the NHPP. The cost of collecting this additional information should also be reflected in the decision process.

The following terminology will be used throughout this paper:

$C_A$ : the cost of a failure if it occurs.

$C_R$ : the cost of the proposed risk reduction action.

$C_I$ : the cost of collecting additional information.

$\rho$ : the reduction in failure rate that would result from the proposed risk reduction action ( $0 < \rho < 1$ ).

$M$ : the expected number of failures during the time period  $[t, T]$  under the status quo.

The decision variable we are dealing with is then the expected number of failures during the time period  $[t, T]$ , i.e.,

$$M \equiv M(T, t, \lambda_0, \beta) = \int_t^T \lambda(s) ds \quad (2)$$

Note that the expected number of failures  $M$  is itself a random variable, since it is a function of the two uncertain parameters  $\lambda_0$  and  $\beta$ , and this is the case where Bayesian analysis can be effectively performed. Suppose that the risk reduction action will reduce the failure intensity by a fraction  $\rho$ , where  $0 < \rho < 1$ , then the expected number of failures in  $[t; T]$ , if the risk reduction action is taken is given by

$$\int_t^T \lambda(s)(1 - \rho) ds = (1 - \rho) M. \quad (3)$$

On the basis of the assumptions given above, we therefore have a two-action problem with a linear loss function, where the loss for taking action  $a_1$  (i.e., continuing with the status quo) is  $C_A M$  and the loss for taking action  $a_2$  (i.e., undertaking the risk reduction action) is  $C_A(1 - \rho)M + C_R$ . The expected loss for the status quo is simply  $C_A E\{M\}$ , and the expected loss for the risk reduction action is  $C_A(1 - \rho)E\{M\} + C_R$ . A natural conjugate prior for the power-law failure model proposed in [10] is given by

$$f(\lambda_0, \beta) = K' \lambda_0^{m-1} \beta^{m-1} [\exp(-\alpha) y_m^m]^{-1} \exp(-\lambda_0 c y_m^\beta) \quad (4)$$

and also a natural conjugate prior for the exponential failure model proposed is given by

$$f(\lambda_0, \beta) = K' \lambda_0^m \exp\left\{ \beta \alpha (m+1) y_m - \lambda_0 c \frac{\exp(\beta y_m) - 1}{\beta} \right\} \quad (5)$$

where  $K'$  and  $K''$  are the normalizing constants, and the parameters  $c$  and  $\alpha$  can be chosen to give the desired

values of expectations for  $\lambda_0$  and  $\beta$ , respectively, and the parameters  $m$  and  $y_m$  can be chosen to give the desired degrees of dispersions for  $\lambda_0$  and  $\beta$ , respectively [10,11,12,13]. Both the natural conjugate priors allow for dependence between  $\lambda_0$  and  $\beta$  and have relatively simple closed-form expressions for their moments. Furthermore, the joint prior distribution about  $\lambda_0$  and  $\beta$  in the Bayesian decision process can be straightforwardly derived.

### 3. THE DECISION SUPPORT SYSTEM

The Bayesian decision process mentioned in the previous section is capable of not only dealing with the uncertainties but also taking into account prior knowledge. However, this process cannot be easily performed; in particular, it requires the technology of numerical integration for carrying out complicated computations. To deal with the problem and to provide decision makers an efficient information system as well, we proposed a structural design of DSS to assist decision makers in making optimal decisions of minimum losses for deteriorating systems.

According to the interpretations about effective and efficient DSSs from [8,20], several required functions should be included in our study. First, the DSS needs to provide the optimal prior decision without using failure data for Bayesian updating. In such a case, the decision is based only on the uncertainties quantified by decision makers. Secondly, the DSS has to notify the decision maker whether collecting additional information is desirable or not. In some cases, the decision maker might not be confident or comfortable about the prior decision since the prior information is too vague. Therefore, collecting failure data could be another alternative before making the final decision. Furthermore, the DSS also needs to provide the optimal posterior decision. It should integrate the quantified prior information and the collected failure data. Finally, the DSS should have the ability to perform sensitivity analysis about each uncertain factor since decision makers might not be satisfied with the numerical values they applied in the system. The DSS has to allow decision makers change each uncertain entity (e.g. deteriorating rate), and therefore derives a range of such uncertain entities within which the optimal decision remains unchanged. Also, the ability of performing what-if analysis is crucial for the DSS [14,17,19]. It is of important interest for decision makers to see what the resulting decision will be once they change some parameters. According to the discussion above, the inputs to the DSS would be the uncertainties mentioned previously and the failure data (if available), and the outputs would be the optimal prior decision, the optimal posterior decision, and the results of the sensitivity analysis and what-if analysis. In order to perform the required complicated numerical integration for the decision process, the specifications of hardware and software should be closely considered. The hardware should have the ability to correctly and quickly respond to decision makers before they get impatient and

the software should be easily and reliably programmed and maintained.

The DSS includes three major processes, which are decision derivation, sensitivity analysis, and what-if analysis, respectively. These processes along with the information database are the essence of the DSS. Figs. 1 and 2 show the system follow chart and the system framework of the DSS, respectively [14]. The DSS has input, output, and process three major parts. The detailed information descriptions of each part are as follows:

Fig.1. System follow chart of the DSS.

Fig.2. The system framework of the DSS.

**Prior information part:** The prior information has eleven elements and are described as follows:

- (1) *System lifetime*: The expected performing time of the physiological organs systems. (the measuring unit would be year.)
- (2) *Initial service date*: The date that the physiological organs systems first start.
- (3) *Decision time*: The actual time for decision makers to make the decision of whether maintaining the status quo or undertaking a risk reduction action.
- (4) *Cost of failure*: The cost or loss once the failure actually occurs.
- (5) *Cost of risk reduction action*: The cost for undertaking the risk reduction action.
- (6) *Risk reduction factor*: The fraction of the original function of the system that the risk reduction action can retrieve.
- (7) *Cost of collecting information*: The cost of collecting the failure data.
- (8)  $E\{\text{Scale Factor}\}$ : The expected value of the scale factor.
- (9)  $SD\{\text{Scale Factor}\}$ : The standard deviation of the scale factor.
- (10)  $E\{\text{Deterioration Rate}\}$ : The expected value of the deterioration rate.
- (11)  $SD\{\text{Deterioration Rate}\}$ : The standard deviation of the deterioration rate.

**Sampling information part:** The sampling information is for inputting the observed failure data.

**Decision part:** The decision part provides the optimal decisions that are suggested by the DSS. There are five output elements that can be valuable to decision makers for making the final decision. We introduce them as follows:

- (1) *Expected value of sampling information (EVSI)*: The EVSI can be treated as an indicator for determining whether to collect the failure data. In particular, if the EVSI were greater than the cost of collecting information applied in the prior information area, then collecting the failure data would be desirable; otherwise, collecting the failure data is not desirable.
- (2) *Prior  $E\{\# \text{ of Failure}\}$* : The expected number of failures for the remaining system lifetime under the status quo which is estimated by using the prior information only. This value shows the performance of the system if no risk reduction action is considered.
- (3) *Prior decision*: The suggested decision is based only on the prior information. It could be either maintaining the status quo or undertaking the risk reduction action. If collecting the failure data is evaluated as not desirable, then the prior decision suggested by the DSS should be considered as the optimal decision.
- (4) *Posterior  $E\{\# \text{ of Failure}\}$* : The expected number of failures for the remaining system lifetime under status quo which is estimated by using both the prior information and the failure data. This value shows the performance of the system if no risk reduction action is

Prior Information

Derive the Prior Decision  
and Calculate the EVSI

considered when the prior knowledge of the system and the failure data are both applied to evaluate the system.

(5) *Posterior decision*: The suggested decision is based on both the prior information and the failure data. It could be either maintaining the status quo or undertaking the risk reduction action. Once the failure data is applied, the posterior decision suggested by the DSS should be considered as the optimal decision.

Once the decision area shows the decisions suggested by the DSS, the decision maker can perform further analysis to ensure the suggested optimal decisions are reliable. Sensitivity analysis can show the degree of importance for each prior parameter and study how they affect the optimal decisions. The DSS can provide one-way sensitivity analysis by using each element in the prior information as the changing factor. The results would be the ranges of the prior parameters that are of special interest in which the optimal decisions remain unchanged. The DSS also provides what-if analysis by changing the values of the prior parameters in the prior information and see if the optimal decisions are still unchanged or not.

#### 4. CONCLUSIONS

This proposed structural design of DSS for risk management of deterioration in physiological organs systems can provide decision support techniques not only for taking action in the light of all available relevant information, but also for maximizing expected profit (or minimizing expected loss). It can deal with uncertain prior knowledge about the physiological organs systems by considering the optimal prior decision, the sensitivity analysis, and possibly, the optimal posterior decision (if actual failure data were available), and provide decision makers the effective support for quality decision making.

# An Ant-based Clustering Algorithm in Data Mining

Yong Tang, Yongkai Ma

Management School, University of Electronic and Science of China, Chengdu 610054, China  
{TangYong, Mayongkai}@uestc.edu.cn

## ABSTRACT

A new algorithm ABC (Ant based Clustering) inspired from behavior of the real ants is proposed for clustering in data mining. ABC employs some ants clustering in the searching space. Different from some clustering algorithms, instead of picking or dropping data objects, artificial ants in ABC find and merge the similar data points in their vision range, also a following and randomly route choosing strategy is introduced. Computational simulation results show that ABC is efficient, and the clustering results can be achieved in short time and maintain stably.

**Keywords:** data mining, clustering, ant colony algorithm

## 1. INTRODUCTION

Clustering is an important area in data mining. The purpose of clustering is to cluster a great deal of objects into groups according to the rule that is “things of one kind come together”. The similarity of objects in a cluster should be as big as possible while the difference of objects in different clusters should be as big as possible too. Clustering has been applied in many domains, such as spatial data analysis, image processing, marketing and pattern recognition etc. Wildly used clustering algorithms are K-means, density based DBSCAN and network based STING etc [1,2]. Our ant based clustering algorithm, which is inspired by the collective behavior of real ants can avoid some shortages like (1) There is no need to determine the number of clusters artificially in advance in ABC. However, in general algorithms, users have to set the number as an input parameter. This requires rigorous domain knowledge for users, and on the other hand, the final clustering result is every sensitive to the initial number of clusters set in advance. But the truth is that, the number of clusters is not obvious especially when the data point is in a high-dimension space or the cluster rule is hard to tell. While in ABC, the clustering is going automatically, namely ABC might find the number of clusters by itself and when the clustering standard is chosen properly, the number of clusters and the results are credible and stable. (2) ABC can find clusters in any shape. Clustering algorithms based on the Euclidean distance output sphere-shape clusters, which is not a good way to describe the spatial distribution of data points in the space. In ABC, we introduce a clustering space or can be called as searching space. The position of a data point in the clustering space has no relations to its position in the high-dimensions data space. We randomly project data points in the data space into the clustering space, after doing that, we cluster them and the final distribution is our output, which indirectly indicates the distribution of data points in the original data space. (3) ABC can achieve the global optimization. Some algorithms are easily to stick into local optimizations. The ant based clustering algorithm

proposed in our research is a typical nature-inspired bionic algorithm. Artificial ants in the algorithm simulate the clustering behaviors of real ants to do random searches in clustering spaces, and taken the data points as the objects needed to be clustered. Every ant chooses a similar object in its vision range to move, meanwhile update the mount of the pheromone on the route to guide other ants. Repeatedly, the similar data points are clustered, when the count of iterations is reach an initial number or the error is less than an initial value we output the result. This algorithm does not require domain knowledge, and is able to generate the global clusters automatically. (4) ABC can process large mount of data in batches. General algorithms need to process all the data in one time, which is unrealistic when the data scale is large for the space and time limitations. Because ABC is a self-heuristic algorithm, it can process new inputs based on present clustering results, and adjust the clustering results dynamically.

## 2. A DESCRIPTION OF CLUSTERING PROBLEMS IN DATA MINING

First, we give a brief describe of the clustering problems. Data collected from different domains are usually in high-dimensions. And the distribution is what clustering concerns. Mathematically, we have  $n$  discrete data points  $X_1, \dots, X_n$ , which scattering in the  $d$  dimensions space  $\mathfrak{R}$  and for every point  $X_i = (X_{i,1}, \dots, X_{i,d})^T$ . Then we can define the distance between any two data points  $X_i$  and  $X_j$  as

$$d_{X_i, X_j} = \left( \sum_{k=1}^d p_k (X_{i,k} - X_{j,k})^2 \right)^{\frac{1}{2}}, \text{ where } p_k \text{ is the}$$

weight for the  $k$  dimension of data point  $X_i$  indicating the contribution of the  $k$  dimension under a certain of evaluating standard. To measure the result of the clustering also to see if the satisfaction of the clustering is met or not, error  $\varepsilon$  is introduced. For example, in the K-Means algorithm, after getting  $K$

clusters, we can calculate the geometrical centers of these  $K$  clusters as  $C_i, i=1, \dots, K$  and their

corresponding errors  $\varepsilon = \sum_{j=1}^K \sum_{i=1}^{N_j} d_{x_i, C_j}$ , where  $N_j$

is the number of data points fall into the same cluster whose center is  $C_j$ . When the error  $\varepsilon$  is smaller than a set value, we accept the clustering results otherwise we adjust the clusters. Existing clustering algorithms includes Hierarchical methods, Partitioning Methods, Grid-Based Methods and Density-Based Methods. And there are still some problems should be considered: (1) the outliers (2) applying users' domain knowledge in the clustering analysis (3) clustering large amount of data.

### 3. AN ANALYSIS OF CLUSTERING ALGORITHM

Ant in natural world is kind of typical social insect. By observing the collection behaviors of some objects such as food and corpses of ant colonies, biologists find that even without a centralized control mechanism, a colony of ants can do collections together in a very efficient way. This inspires us to deal our data points by simulating the collective behaviors of ant colony. Deneubourg [3] proposed a model to describe the clustering behaviors of ants, the basic idea is that ant can pick up and drop down objects with a probability rule as  $P_{pickup} = (k_1 / (k_1 + f))^2$  and  $P_{drop} = (f / (k_2 + f))^2$  for picking up and dropping down respectively. And  $f$  is the coefficient describes an ant's sensitive ability of its environment,  $k_1$  and  $k_2$  are limitations. Lumer and Faieta [4] improved this

model by using  $d_{O_i, O_j} = (\sum_{k=1}^d (O_{ik} - O_{jk})^2)^{\frac{1}{2}}$  to

denote the Euclidean distance between two objects  $O_i$  and  $O_j$ . And the environmental parameter of object

$O_i$  in a range of  $s$  is defined as  $f(O_i) = \frac{1}{s^2} \sum_{O_j \in Neighbour_{sxs}(i)} [1 - \frac{d(O_i, O_j)}{\alpha}]$  We see

that if object  $O_i$  is similar to its environment,  $f(O_i)$  will be relatively big, otherwise  $f(O_i)$  will be small. Thus the probability for picking up and dropping down is redefined as:  $P_{pickup}(O_i) = (\frac{k_1}{k_1 + f(O_i)})^2$  and

$P_{drop}(O_i) = \begin{cases} 2f(O_i) & \text{if } f(O_i) < k_2 \\ 1 & \text{if } f(O_i) \geq k_2 \end{cases}$ . again  $k_1$

and  $k_2$  are limitations. Kuntz [5,6,7] applied this method in VLSI and Wu [8] did related work in the

clustering of WEB document. In the model of Deneubourg [3], Lumer and Faieta [4], at first, data points are randomly projected onto a 2-dimension plane, notice that the positions of data points on the plane have nothing to do with their positions in the data space. Then artificial ants do random movements, they pick up a data objects with probability  $P_{pickup}$  and drop data objects with  $P_{drop}$ . After some runs, the algorithm output the clustering results. The potential problem this kind of algorithm may have is that it might get stick in a halfway and fail to get data points clustered thoroughly, in other words, similar data points which should be clustered in a group, form several sub-clusters in the space and cannot be clustered together in a cluster any more. The reason for this is that  $f(O_i)$  is used to denote the similarity of  $O_i$  to its local environment, when  $O_i$  is surrendered by some similar data points, the probability for  $O_i$  to be picked up will be small, consequently  $O_i$  might not be picked up any more, which means the  $O_i$  is fixed on the 2-dimension plane, its position will not be changed. Essentially, this result is locally optimized rather than global optimization we are seeking for. Monmarche [9] combined this kind of algorithm with K-means to achieve a fast clustering speed. Ant based clustering uses lots of ants searching in the space randomly with an enforcement of the pheromone on their routes to guide other ants. This positive feedback able the algorithm to guild further searches based on the already available searching experience and knowledge. The original model is first proposed by Dorigo [10] and performs very well in solving TSP and JSP, etc [11]. Yang [12] defines the mount of the pheromone between objects  $O_i$  and  $O_j$

as  $\tau_{O_i, O_j}(t) = \begin{cases} 1, & d(O_i, O_j) \leq r \\ 0, & d(O_i, O_j) > r \end{cases}$ , and  $O_i$  is

clustered into  $O_j$  with a probability

$P_{ij} = \tau_{ij}^{\alpha} \eta_{ij}^{\beta} / \sum_{s \in Neighbour(i)} \tau_{sj}^{\alpha} \eta_{sj}^{\beta}$ , where  $\tau_{ij}$  denotes

the mount of pheromone,  $\eta_{ij}$  is the knowledge of the environment, which can be defined as

$\eta_{ij} = 1/d(O_i, O_j)$ . Obviously, the smaller the

distance between  $O_i$  and  $O_j$ , the more the mount of the pheromone, namely the higher the probability  $O_i$  and  $O_j$  been clustered in a same cluster.

### 4. NEW ANT BASED CLUSTERING ALGORITHM, THE IDEA AND STEPS

In our research we propose a new ant based clustering

algorithm. With a closer look at the behavior of real ants we believe that the vision ability of ants is limited in a certain range, namely their eyesight is limited, we use  $r$  to present the range ants can see. And ants are different, so they should not be treated in a same way. In our algorithm, some ants are big and some are small, namely their range of eyesight is in a direct proportion to the number of data points the  $Cell_i$  has where the

ant occupies, then we get  $r = k \sqrt{\frac{l^2}{N}} / 2, k = 1, 2, \dots$ ,

$k$  for the number of data points been clustered on  $Cell_i$ ,  $l$  is the width of the plane,  $N$  is the number of ants. So, an ant will see farther if  $Cell_i$  has more data points. We let bigger ants search first in our algorithm, which is described as following:

(1) Randomly projects data points onto a 2D plane. One cell can only have one data point at most.

(2) Randomly place  $m$  ants, every ant carries the data points on a  $Cell_i$ .

(2.1) For ant  $Ant_i$ , we calculate its eyesight range

$r = k \sqrt{\frac{l^2}{N}} / 2, k = 1, 2, \dots$ , where  $k$  is the number

of data points been clustered on  $Cell_i$ .

(2.2) Calculate the average center of the data points on  $Cell_i$  where ant  $Ant_i$  is. The center is

$\overline{C}_i = \frac{1}{k} \sum_{j=1}^k O_j$ . If ant  $Ant_i$  finds there are data

points on cell  $Cell_j$ , and  $d(\overline{C}_i, \overline{C}_j) \leq d$ , where  $d$

is a gate-value, then  $Cell_j$  is added into a candidates

set *Candidate*. After the search, ant  $Ant_i$  finds out the most similar cell  $Cell^*$  then merges all the data

points carried by  $Ant_i$  with the data points on  $Cell^*$  and at the same time, we update the mount of

pheromone on the path between  $Cell_i$  and  $Cell^*$  to

1, namely  $\tau_{Cell_i, Cell^*} = 1$  which indicates that this path

has been walked by  $Ant$ . Ant  $Ant_i$  is always trying to follow the path, which has been taken by those ants

set off from  $Cell_i$ , in other words, it attempts to find

$Cell_k$ , where  $\tau_{Cell_i, Cell_k} = 1$ . If this attempt is failed,

we randomly move the data points of cell  $Cell_i$  to a

cell  $Cell_r$  on the plane, to avoid mistakes we must

make sure that there are no data points on  $Cell_r$ .

(3) When all ants finish their moves, we calculate the

total error  $\epsilon = \sum_{j=1}^K \sum_{i=1}^{N_j} d_{x_i, C_j}$ , once final condition is

met, namely  $\epsilon \leq \epsilon_0$ , we output the clustering results and stop, otherwise go back to 2 and continue. Of course, we can set a count number *Count*, when the iterations gets *Count* or there is no changes in the clustering results, we stop and output.

In (1), as other algorithms do, we randomly project data points onto the 2D plane, we must remember that the 2D plane is a search space, the positions of n-D data points in the data space have nothing to do with the positions in the 2D plane. In this algorithm, artificial ants can handle both single data points and data points sets as well. Thus the problem we mentioned before can be avoided, that is a single data point cannot be moved for the similarity to its environment. By introducing the pheromone, we make the system have a kind of memory so that former searching experience can be reused to guild following searches. Artificial ants have vision range and in the searching process adapting a route-following and random choosing strategy make them closer to real ants in the nature.

## 5. SIMULATIONS

We apply the discussed ant based clustering algorithm in simulations. In this research, we use IRIS [13] in UCI machine learning database as our test dataset. There are 150 data points in the dataset and every data point has four parameters. There are 3 clusters: Iris Setosa, Iris Versicolor and Iris Virginica, each cluster has 50 data points. Our simulation environment is: OS: Windows XP, CPU: P4 1.5GHz, Memory: 128MB, Language is C. Our settings are: 10 ants, width for the plane is 15, *Count* is 100, *Count* will descend by one. After multiple simulations, we find that the ABC is good: average running time is less than 10 seconds, the number of clusters found by ABC is 3, mistaken points is between 4 and 5. One of the best run, only one data point is mistakenly clustered that is the NO.124 data point should be clustered in Iris Virginica but is clustered in Iris Versicolor instead. Wu did similar work [8].

Fig.1- Fig.4 is the process in a run. Fig.5 is the process of a run. We see that when *Count* = 25, we get 3 clusters and the result maintain stably.

Fig.1 Count=0

Fig.3 Count=18

Fig.4 Count=25

Fig.5 A process of clustering

## 6. CONCLUSION

Clustering analysis is one of the major areas in data mining and it has been widely applied in many domains. Clustering problems are usually in high dimensions and large scale. Nature-inspired algorithms have been used in many domains. We proposed an ant-based algorithm applying artificial ants in the searching space. Vision range concept is introduced with following strategy and random choosing strategy. The simulations show that the algorithm is fast and able to find the number of clusters automatically. As further work, we can consider: (1) At first we use ABC to find the number of clusters automatically, then we use other algorithms to do further clustering. (2) In ABC, we introduce a less similar data points kicking strategy to assure the correctness and reliability.

Applying nature inspired algorithms like ant colony algorithm to complex problems such as multiple objectives optimization, general function optimization and clustering analysis is something of swarm intelligence. As we have mentioned before, the original ant colony algorithm can solve every complex combinatorial optimization problems especially those can be abstracted into network optimization problems such as TSP etc. Swarm intelligence has a very important feature that is despite of the lacking of a centralized controlling mechanism or information spreading ways in certain structural forms ant colony can do things very effectively. Economic and social systems on complex networks can learn a lot from the collective behaviors of ant colony. The route choosing strategy used in the multiple objectives optimization inspires us to consider the decentralized collective behaviors in a brand new way. In other words, the artificial ant colony is a typical multiple agents system and the ant based clustering algorithm will be a good choice in the network clustering.

## An Interactive Web Meeting System Using Multicast Technology

Ook Lee<sup>1</sup>

<sup>1</sup>College of Information and Communications, Hanyang University, Seoul, Korea(South)  
ooklee@hanyang.ac.kr

### ABSTRACT

Using a dedicated line for video conferencing is usually costly. A solution to solve this problem is to use a web-based video conferencing technology. However the existing webbased video conferencing technology needs too much bandwidth which makes two-way exchange of images too slow in the web environment. In this paper, a new web-based video conferencing system is introduced which has overcome this problem by using multicast method. The technique called tunneling which can preserve bandwidth enables this system to do multicast with minimum delay. Thus instead of using dedicated line-based video conferencing, web-based two-way multicasting technology is a better alternative.

**Keywords:** video conferencing, IP channeling, multicasting

### 1. INTRODUCTION

This article explains a web-based two-way multicasting technology. Web technology is used for many communication purposes. People post messages on the web board, and do chatting on a web environment. Due to the development of web cameras, nowadays many web surfers engage in multimedia chatting. In other words, people can conduct video conferencing through a web page. This method is definitely cheaper than non-web-based video conferencing which usually utilizes dedicated lines or satellites. This mode is called unicast which can not be used for multiple presentation of moving images in the same screen. In unicast mode one can only see one screen where a single moving image is projected. Of course it is possible to add multiple screens, however this requires separate lines, i.e., multiple number of unicast video conferencing systems. But it is also true that the unicast method provides high quality picture and no delays in projecting moving images whereas existing web-based multicasting method carries significant delays in showing moving images, which can result in irritation and inconvenience for participants. Furthermore two-way, or interactive conversation in the existing web-based multicasting systems is often slow and limited to just two parties; realtimesimultaneous multi-party conversation is usually not available. In this paper, the new web-based multicasting system that overcame the problem of "delay" in projecting moving images and allow real-time simultaneous multi-party video conferencing. This is possible through a technology called "tunneling" which reduces the delay time at the negligible rate. This web-based interactive multicasting system can replace expensive non-web-based unicast-style video conferencing technology as well as slow web-based existing video conferencing technology. With this system, one can not only do video conferencing but also broadcasting any video over the web page where the whole screen is divided into sections of showing participants' moving images. In other words, teaching a distance course with this system will cost much less than existing TV-based

method. Webbased learning has been around already for quite a while. But the problem of lack of interactivity and delays of showing moving images hindered further development in real-time multicasting-based distance education. This new technology will contribute a lot to distance education area by providing much cheaper and faster solution that can be interactive and multiparty-participation-possible. Web-based distance education is one of the most promising area in electronic commerce. And the success of web-based learning relies on the maturity of information technology infrastructure of the nation. There are studies showing the fact that the information technology infrastructure for electronic commerce is a key factor for the success of electronic commerce [1][2]. For example, high-speed Internet service available for most of the nation's population is a critical success factor for the rapid rise of electronic commerce in South Korea. Korea has been recognized worldwide as one of a few nations with highly developed information technology and Internet infrastructure. As for the highspeed Internet usage rate, Korea is reported as the number one country in the world. More than 10 million users subscribe to high-speed Internet services via such means as ADSL, VDSL, community LAN, and satellite. When taking the total number of Korean population into consideration, the high-speed Internet subscription rate in Korea is roughly 21% according to the Korean government ministry news [3]. This is a remarkably high usage rate when compared to those of other OECD countries since the average rate of highspeed Internet subscription in OECD countries is just 1.26% [4]. For many consumers in Korea, the Internet is just a part of their normal daily life. With the high-speed Internet available at very cheap price for almost all households, many electronic commerce firms flourish. Thus web-based multicasting video conferencing system is workable well in this highly-developed information technology infrastructure and web-based learning industry can be benefited much from this new technology.

## 2. WEB-BASED MULTICASTING VIDEO CONFERENCING SYSTEM

Web-based multicasting video conferencing system employs none Mbone router-supporting method. This method makes a different compared to the existing unicast-style video conferencing technology. In the existing technology, the system can not send multicasting data packet in M-bone supporting network environment. Regardless of support of Mbone by its routers, the web-based multicasting video conferencing system can send multicasting data packet by using tunneling technology. Figure 1 shows how tunneling technology works. In the existing method, data packets

are unicast from a server to a router and to a subrouter computer. In this way, two-way IP multicasting is not possible. However with IP tunneling technology the sub-router computer will recover data packets in webbased multicasting video conferencing system. This way also allows receiving data packets in reverse direction. Thus two-way IP multicasting is possible in the new system. What makes the new system superior is the fact that the time delay of showing moving images is less than 0.5 second, which means that the time delay is almost negligible. Figure 2 shows an actual example of video conferencing screen using the new system. In this example, 6 people are participating in two-way realtime video conferencing.

Figure 1

Figure 2

## 3. CONCLUSION

This system is a better system compared to the existing

system since it solves the bandwidth problem. In the existing unicast system multi-party meetings need too much network bandwidth. Namely the size of bandwidth

of the unicast system is bandwidth per person \* # of people \*\*2. For example, when 10 people are using the unicast system, the system requires  $128 \text{ kbps} * 10^{**2} = 12,800 \text{ kbps}$ , which is too much for the network to serve without significant time delay. On the contrary, in the web-based multicasting video conferencing system, the bandwidth is preserved using IP tunneling technology. Thus data packet transfer is effective through sharing. The bandwidth calculation for the new system is as following: bandwidth per person \* 4 \* (# of remote sites). For example, when 10 people are using the web-based multicasting video conferencing system, the system requires  $128 \text{ kbps} * 4 * 1(\text{one location}) = 512 \text{ kbps}$ . In one meeting room with two remote connection,  $128 \text{ kbps} * 4 * 2(\text{two locations}) = 1,024 \text{ kbps}$ . Thus no matter how many people are participating, the bandwidth of the new system is not affected by it. This is why the new system generates almost no time delay. The webbased multicast

video conferencing system can accomplish effective use of broadband Internet and provide high-quality video conferencing. This system will play an important role in promoting national IT infrastructure for distance learning industry which is rapidly growing in Korea.

# An Investment Decision Support System (IDSS) for Identifying Positive, Neutral and Negative Investment Opportunity Ranges with Risk Control in Stock Markets

Wanli Chen

Faculty of Information Technology, University of Technology, Sydney, 2007, Australia  
wchen@it.uts.edu.au

## ABSTRACT

While there are a number of finance methods (fundamental analysis, technical analysis, contrarians' theory, risks management, etc) used in stock markets to help make investment decisions, they have different strengths and weakness. It is observed that these different finance methods are not being integrated by existing technologies in a systematic way, thus their performance for identifying investment opportunities is limited. In this research, I propose a systematic method (i.e. an IDSS system) to take advantage of and to optimize existing and newly proposed methods in order to obtain better investment performance, through identification and classification of Positive, Neutral and Negative investment opportunity ranges and related risks. This IDSS system will be mainly based on *Turning Point Model* and *Optimized AutoSplit* method, which help find hidden investment opportunities and risk variables, particularly a stock's unique trend. The key methodology is to use Decision Tree theory with finance knowledge. The IDSS system will be built on the top of *F-trade platform* which has been already developed by UTS Data Mining team and has a RDP structure, with agent-based distributed expert systems. Initial system evaluation shows that the system successfully identified investment opportunity ranges, outperforming the benchmark index and other systems.

**Keywords:** DSS, E-commerce, stock markets, RDP, turning point model, AutoSplit

## 1 BACKGROUND

While stock market is studied to be predictable, it has a number of finance methods with different strengths and weakness to identify investment opportunities. It is necessary to integrate them in a systematic way to take advantage of their strengths, but literature shows that few IT systems have accomplished it. Therefore, I design an Investment Decision Support System (IDSS) to integrate their strength in order to identify investment opportunities and risk factors.

**Stock Investment Opportunity Identifiability:** Research on the microstructure of security markets has concluded that the intersection of supply and demand curves for stocks determines stock price and accordingly liquidity [1]. For many years, stock investment opportunity identifiability has been studied by both academics and practitioners. It was observed that two competing explanations have been offered for it. Proponents of EMH (e.g. [2]) maintain that such identifiability results from time-varying equilibrium expected returns generated by rational pricing in an efficient market that compensates for the level of risk undertaken. Critics of EMH (e.g. [3]) argue that the identifiability of investment opportunities reflects the psychological factors, social movements, noise trading, and fashions or "fads" of irrational investors in a speculative market.

**Necessity of Integrating Distinct Finance Methods:** While there are so many finance methods (such as fundamental analysis, technical analysis, contrarians' theory, etc) in capital markets to help identify investment opportunities, they have different

characteristics and accordingly, strengths, weakness ([4], [5], [6], etc). For example, fundamental analysis focuses on stock's real value and its long term benefit, while technical analysis focuses on stock's price and volume changes and tries to achieve short-term profit. It is observed that these different methods are not integrated in a systematic way thus their performance for sound decision making are limited [7]. However, there is an increasing need of integration of different methods in stock markets, and it is becoming more and more common for practitioners to use different methods simultaneously to get an optimized result [8].

**Current Information Technologies for Identifying Stock Investment Opportunities:** There are a number of expert systems, knowledge engineering and other technologies to accomplish identification of stock investment opportunities. Many employ technical analysis momentum heuristics, and some use neural networks to learn patterns. Example include: neural networks learning from past price history [9]; neural network using knowledge of real world events [10]; fuzzy expert system combining several sources of information [11] rough sets to extract trading rules from price history [12]; data mining employing signal processing techniques [13]; grey theory and fuzzification [14]; and rules [15] or agents [16] using technical heuristics combined with other sorts of knowledge in an expert system framework. However, these information technologies mainly focus on technical analysis and few considered integrating different finance methods in a systematic way to achieve an optimized performance than any single method does; more importantly, they often ignore or

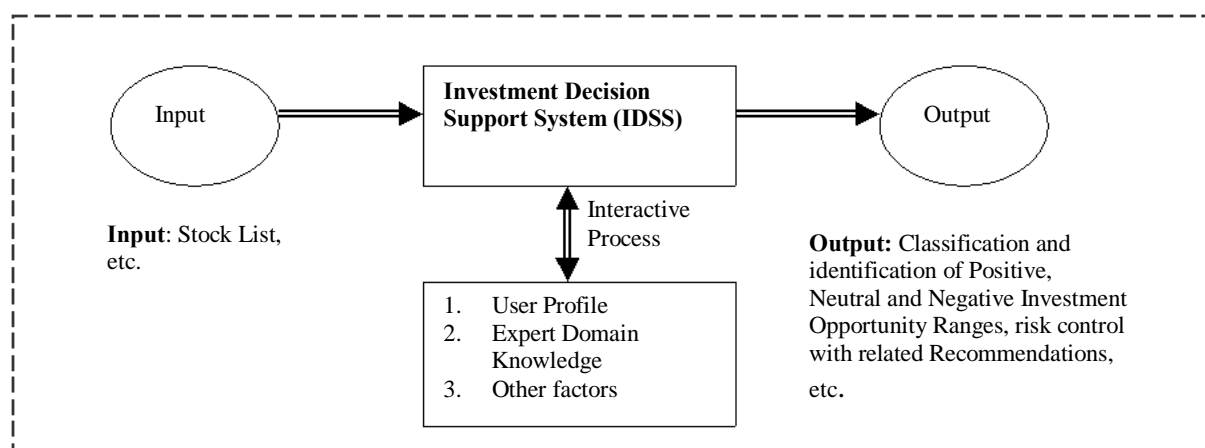

misunderstand importance of expert's domain knowledge and its distribution, therefore, their performance for sound investment decision is limited and they can not well meet the need of identifying investment opportunities for finance industry (i.e. brokerage firms).

Therefore, in this paper, I focus on designing an Investment Decision Support System (IDSS) for integrating both above-mentioned existing methods and proposed new methods in both finance and IT to help identify investment opportunities and risk factors, which can create a better performance than the benchmark index and other systems. In section 2, I will provide a

detailed description of Investment Decision System (IDSS) and related methodologies, including *Turning Point Model* and *Optimized AutoSplit Method*, and how to use them to identify investment opportunities and risk. In section 3, I will introduce IDSS implementation and its evaluation. Section 4 is conclusion.

## 2 INVESTMENT DECISION SUPPORT SYSTEM (IDSS) AND RELATED METHODOLOGIES

**2.1** As the kernel of IDSS, a simplified architecture was depicted in Figure 1.

**Figure 1:** a simplified architecture of IDSS system

### 2.2 Turning Point Model

As shown in Figure 1, in order to build architecture of IDSS system, it is important to clarify three concepts: *Positive, Neutral and Negative Investment Opportunity*

*Ranges*. This Section provided a brief Introduction of *Turning Point Model* and the three concepts. A basic structure of “*Turning Point Model*” was depicted in Figure 2.

**Figure 2:** a basic structure of *Turning Point Model*.

From Figure 2, following methods can be derived to help identify investment opportunities and risks:

1) **Supporting Point (or Neutral Point):** This is the fuzzy point of indicating stocks' real value, where the market is rational and its effect is neutral (neither positive nor negative). Note that *Supporting Point* could move within a range when fundamental factors affect stock's real value, represented by Neutral Range ( ).

2) **Positive Turning Point:** This is the fuzzy point where market undervalues stocks to such an extreme extent that most investors run away and the rest are waiting on sell side of order book, but it starts turning positive because of contrarians' entry and others' subsequent following. The signals include: large (percentage) investors or/and previous large profit-makers start buying, combining with other related signals, such as their

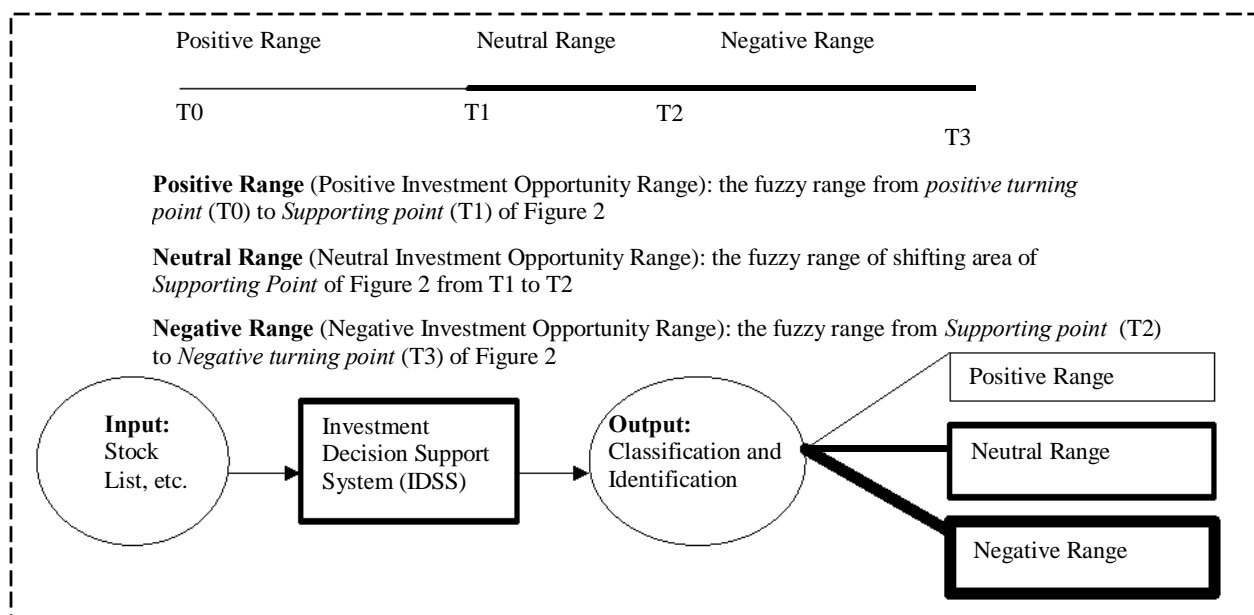

historic behavior and trading patterns in similar situations, fundamental info (such as lowest P/E), how close they are to important fundamental info source, the confidence extent in which they can be followed, and medias' apparent exacerbation of stock's bad side.

- 3) **Accelerating Speed (++)**: Moving from Positive Turning Point, some leading investors notice contrarians' entry signal and start buying, then more and more investors follows. This trend moves on until it passes supporting point. *Accelerating speed* indicates the change extent of market movement and growth, which becomes faster and faster.
- 4) **Negative Turning Point**: when above trend moves beyond supporting point, most new investors are becoming over-optimistic about it and rush in. The lever becomes so unbalanced that a *negative turning point* comes. This is the fuzzy point where the stock value is extremely overvalued and most investors already rush in out of mood.
- 5) **Decreasing Speed (--)**: it indicates that the extent of change of market movement and growth when it is close to *negative turning point*, becomes slower and slower. The speed even decreases to become negative since most possible investors are already in, and investment temperature starts turning cooler from its hottest moment. Therefore, market

*Decreasing Speed* and cooling signals need be observed for investment, i.e., large (percentage) investors and/or previous large profit-makers procedurally leave the market and small investors now dominate a high percentage but their growth speed is decreasing even to be negative, and demand decreasing speed and supply increasing speed become equal which make no "momentum" any more.

- 6) **Relevant Balance**: it indicates the extent of out-of-balance of a point to balance line, and the model assumes that lever will finally bounce back to balance line.
- 7) **Turning Angle**: when lever is out of balance, it moves up and down and extent is *turning angle*.
- 8) **Weight (■)**: it indicates the weight of changes of a particular point, including multiplier of changes of volume, price, depth, individual (large) investors' market affectability etc.
- 9) **Weight Distance Multiplier**: it is a point's distance to *Supporting Point* multiplied by *weight*.
- 10) **Risk Factors Coefficiency**: the risk extent of a particular point can be identified based on its distance to *positive turning point*, *negative turning point* and *supporting point*, multiplied by weight, turning angle, speed, and other factors.

Figure 3 simplified Figure 2 and depicted how to use *Turning Point Model* in IDSS system.

**Figure 3:** a simplified *Turning Point Model* and its usage in IDSS system

Benefits of using *Turning Point Model* and three concepts in IDSS system include:

- It avoids identifying an exact trading point which is difficult and unnecessary in real stock trading practice and it ignores frequent fluctuations in a short time; instead, IDSS system can use *Turning Point Model* to identify accurate different types of investment opportunity ranges for a mid-term time, which is much easier and suitable for stock trading practice and can create higher profit.
- The model integrates concepts and strengths of Fundamental Analysis, Technical Analysis, Contrarians' theory, etc. Based on it, IDSS can create better output than any single method does.
- The model also proposes new concepts and methods which can help better identify investment opportunities and related risks than most conventional methods do.

### 2.3 Optimized AutoSplit Methods

In order for IDSS to efficiently identify Positive, Neutral and Negative Investment ranges, I use *Optimized Autosplit Methods* to help identify these hidden investment features and risk variables. Pan et al [17] proposed AutoSplit Method and claimed that it is able to find features which are mutually independent and able to discover non-orthogonal features. However, it is mainly designed for image processing and not suitable for capital markets, thus it has much room for improvement. I proposed optimized AutoSplit methods to help better find investment opportunities and risk factors:

- 1) Setting Precondition of AutoSplit: AutoSplit method assumes that stock data distribution is not Gaussian (normal) and used a company as an attribute, without any proof. To improve it, I judge if stock data distribution is Gaussian as first step. If it is Gaussian, SVD is more suitable; if not, AutoSplit method is suitable. I use following methods to judge it:
  - Ø Using *Kolmogorov-Smirnov test to test Gaussian distribution*. I used GraphPad InStat software, when “ $P < 0.10$ ” (small P values), the population is unlikely to be Gaussian.
  - Ø Using *Shapiro-Wilk normality test or Dgostino-Pearson omnibus test*.
- 2) Integrating Multi-dimensional methods: in the experiment, AutoSplit only considers price thus data set is one dimensional. While in practice more types of data (i.e. company, price, volume, depth, spread or fundamental factors (P/E, Asset/liability), etc) need to be considered for prediction, the data set should be multi-dimensional. To improve it, I
  - Ø add multiple loops into algorithm to handle multi-dimensions, and
  - Ø Include (price, volume, any other data type) as a data cube.
- 2) Integrating with streaming methods: AutoSplit method does not consider change among time windows thus it is not quite useful for predicting trend. To improve it, I integrate following window models with it:
  - Ø *Landmark windows*: Aggregates are computed based on the values between a specific time point called the landmark and the present. Similarly, data stream can be divided into a “baseline window” and a “sliding window” and compare two data sets.
  - Ø *Sliding windows*: Aggregates are computed based on the last w values in the data stream. The size of a sliding window w is predefined.
  - Ø *Damped window*. The weights of data decrease exponentially into the past.
- 3) Reverse AutoSplit: While time is treated as major attributes and controls the order of data in AutoSplit method, reversely I treat time as a common attribute and use other attribute (such as price) to control the order and compare the results

to see new patterns (say, what time patterns shows at a particular price range).

- 4) Improving the experiments: Experiments can be improved in following ways:
  - Ø While it claims h1 and h2 represents the general trend and internet bubble of share price series, it can be proved by including DJIA index and Nastaq index (or IT industry particular index) as an attribute. If the claim is right, DJIA and Nastaq index should have highest
  - Ø To get richer or more interesting experiment results by doing following tasks:
    - a. Using intraday trading data as data source rather than weekly closing price;
    - b. Using real-time data as data set;
    - c. Conducting “auto-split” first within an industry, then across industries;
    - d. Findings of hidden variables should relate to domain knowledge;
- 5) Improving analysis of experiment results: Current AutoSplit focuses on major variables and ignore less significant ones, but less significant variables can have important impact on stock market and investment. I improve analysis of experimental results in following ways:
  - Ø To see if less significant hidden variables disclose more important information;
  - Ø To detect bursts of activities or abrupt changes in real time;
  - Ø To mine outlier or unusual patterns in stream data;
  - Ø To make the number of hidden variables more accurate: AutoSplit assumes that the number of hidden variables is the same as the number of attributes and it also use the *Whitening* step to control the number, thus it may ignore or mix important variables. Therefore, I assess the assumption first to make the number of hidden variables accurate.

Initial experimental results show that above methods are of research value and can play an important role in the success of IDSS, for instance:

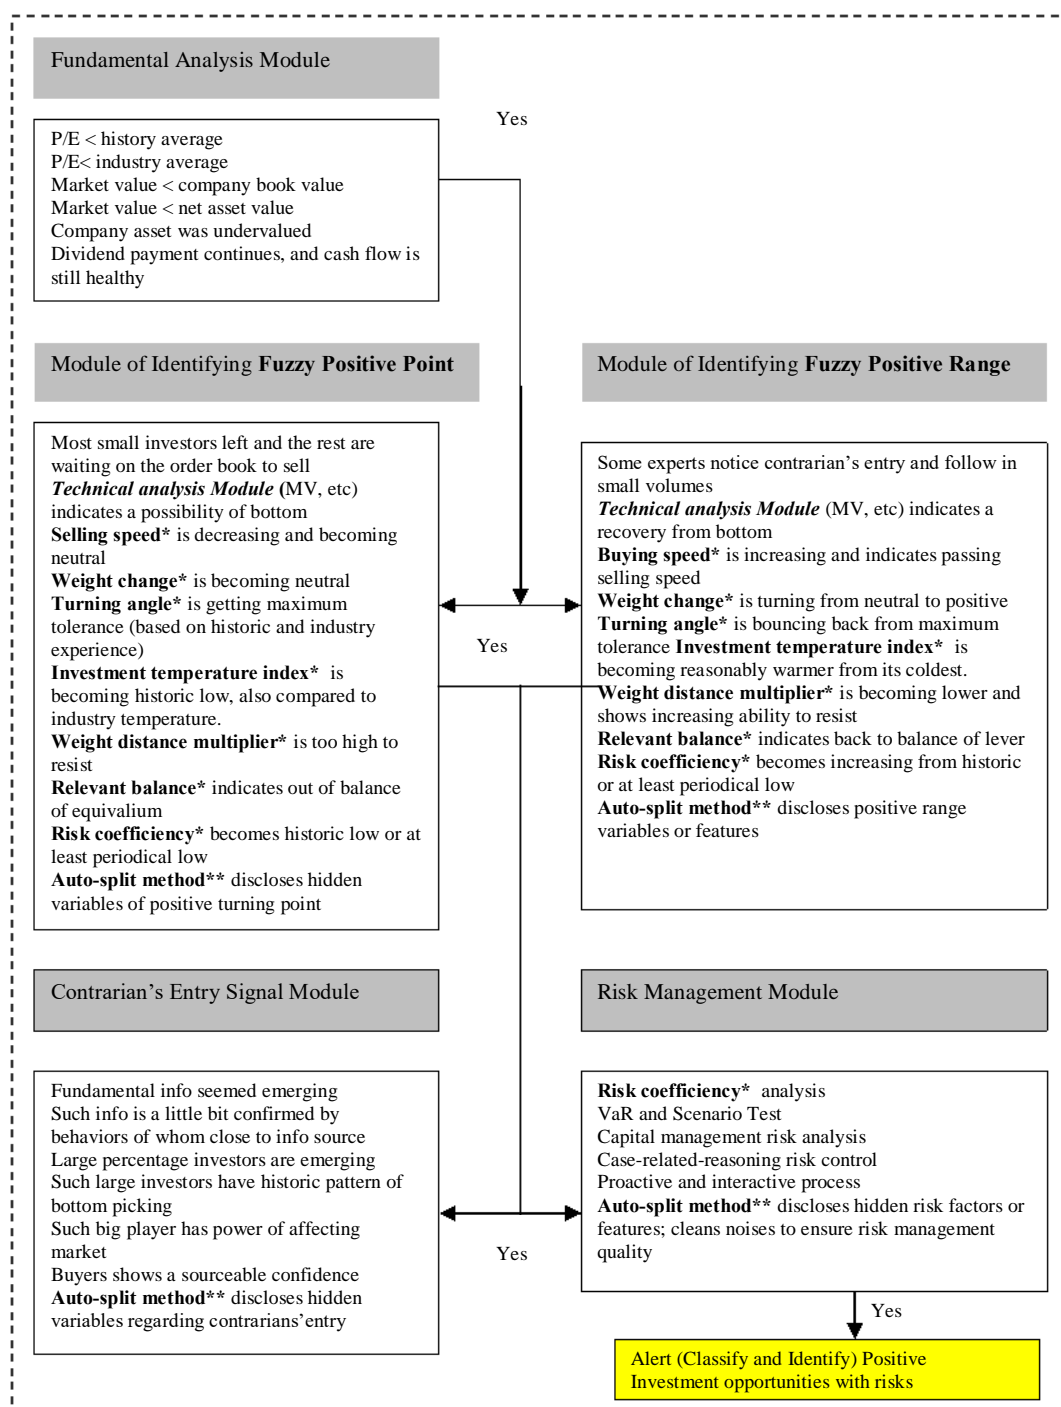

- They efficiently identify a stock’s unique trends which only belong to the stock itself.
- They more efficiently help find hidden important investment opportunity variables and risk factors for sound investment decisions than conventional methods do.

### 2.4 a Sample of Investment Decision Support System (IDSS)

Based on the architecture of IDSS system (Figure 1), concepts of *Positive, Neutral and Negative Investment Opportunity Ranges* (Figure 2 and Figure 3) and *Optimized AutoSplit Model*, a sample of *Investment Decision Support System* (of identifying Positive Point and Range) was roughly depicted in Figure 4. Note that

this sample shows Decision Tree methodology broadly, but in details and implementation, IDSS uses fuzzy

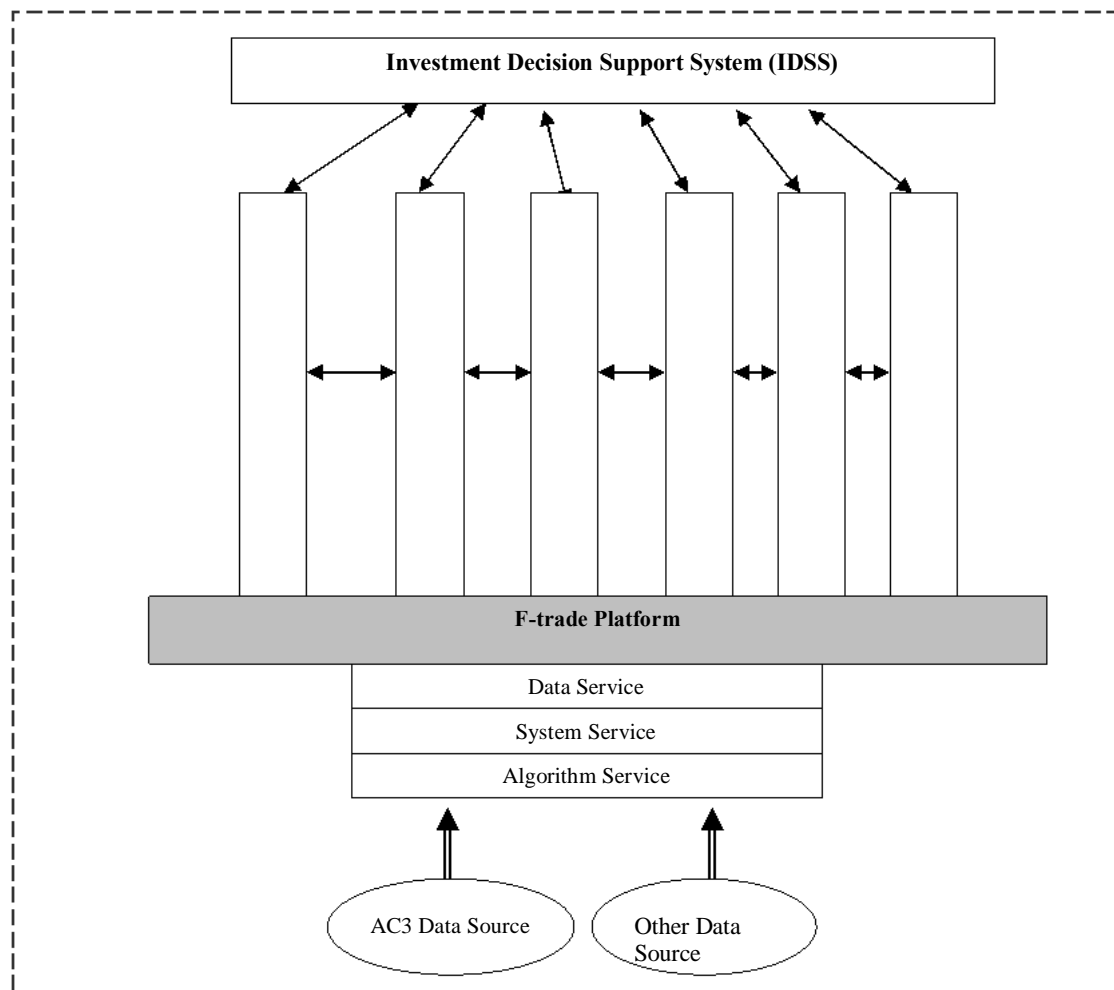

rules rather than Boolean rules.

**Figure 4:** a sample *Investment Decision Support System* for identifying fuzzy **Positive** *Investment Opportunity Ranges* with Risk Control. \* parts come from *Turning Point* model; \*\* parts come from *AutoSplit* method.

As shown in Figure 4, IDSS system is constituted by six modules, including Fundamental analysis module, Technical Analysis module, Identifying Fuzzy (Positive or Negative) Turning Point module, Identifying fuzzy (Positive or Negative) Investment Range module, Contrarian's Entry Signal module and Risk Control module. All these six modules are totally implemented

on existing Capital Market Cooperative Research Center (CMCRC) project *F-trade platform*, thus they will greatly benefit from strengths of *F-trade platform*. On the other hand, IDSS system extends the functions of *F-trade platform* and makes it more powerful. Their relationship was depicted in Figure 5.

**Figure 5:** Relationship of IDSS System Modules and CRC project *F-trade platform*

Functionalities of six modules under IDSS system are described in this section:

- *Fundamental analysis module*: This module analyses fundamental factors which determines and affect a stock's real value. As show in Figure 4 & 5, the module may consider financial ratios such as P/E, financial figures such as book value, net asset value, cash flow, dividends payment and so on. It is mainly used to assess if the stock is undervalued or overvalued and the extent.
- *Technical analysis module*: This module uses existing technical analysis methods and algorithms such as Moving Average to evaluate the condition and trend of stock movement.
- *Identifying Fuzzy Turning Point module*: In this module, concepts and methods of *Turning Point Model* will be used to help assess if the stock is at fuzzy Positive Turning Point (in figure 4) or Negative Turning Point. It uses methods of Selling speed, Weight change, Turning angle, Investment temperature index, Weight distance multiplier, etc. Additionally, I adopt *Optimized Auto-split method* to help identify hidden variables and features of fuzzy Turning Point.
- *Identifying Fuzzy Investment Range module*: This module adopts same methods used by above module, but they are used to assess if stock is in fuzzy range, rather than turning points.
- *Contrarians' Entry Signal module*: Contrarians have the power of affecting market thus their entry means a turnaround of market. Not only quantitative methods (i.e. transaction details on orderbook, hidden variables of *Auto-split method*), but experts' experience and judgments work.
- *Risk Control module*: As risk and return are closed related, risk control is closely related to above modules. Not only traditional risk control methods (including VaR, Stress test, capital management, etc), but new methods from *Turning Point model* and *Auto-split method* work.

While IDSS system (top module) depends on above six modules, it has much more important roles. For example, IDSS will decide which of above six modules and other knowledge source will be used, how to use, and how to integrate and optimize the results from individual module to get an ideal output (i.e., classification and identification of *Positive, Neutral and Negative Ranges*). In follow section, I use a RDP model to depict a detailed system structure of IDSS.

Figure 6 used a RDP (Requestor-Dispatcher-Provider) model to depict the structure of IDSS. Simply speaking, once *Requestor* sends users' request to *Dispatcher*, *Dispatcher* will choose appropriate *Provider*, and then

*Provider* will look into model base, knowledge base, data base and expert domains to find appropriate solution. On a reverse way, the solution will be passed to users. It includes:

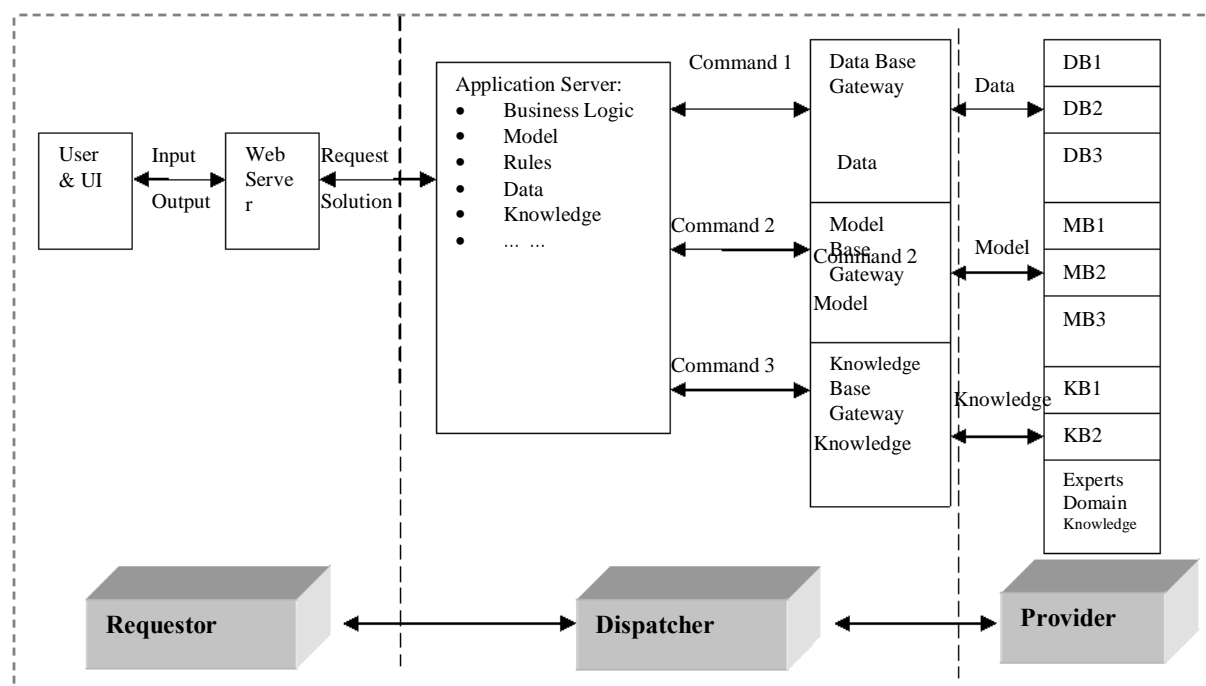

Figure 6: a System Structure of IDSS by Using RDP Model

(1) **Investment Requestor:** It contains user interface and web server and covers all aspects of the communications (i.e., input and output, problems and solutions) between a user (i.e., brokers, individual investors) and the IDSS; as a result, it derives much of the power, flexibility, and ease of use of IDSS. For example, it could send users' request of classifying a particular stock (i.e. BHP) at a particular time point (i.e. right now) to following Dispatcher Subsystem. It includes: 1) menu or form interface to issue requests to the DSS; 2) customized visual (or graphical) forms to collect, revise customer/stock/company data. Additionally, the messages (of solution) emitted by the IDSS may consist of graphical presentation of some decisions; textual responses; displays of results via customized visual forms. For example, a classification with parameters (like certainty, weight, coefficients, etc) is depicted with the help of a 3-D graph or chart.

(2) **Investment Dispatcher:** Once receiving particular user requests, *investment dispatcher* will process them immediately. It may contain application server and gateways of database, model base and knowledge base. Note that this processing very well requires the *Investment Dispatcher* to draw on *Investment Provider* contents. The processing also changes the knowledge held in the *Investment Provider*. In either event, the *Investment Dispatcher* will issue a response to the user. Basically, the *Investment Dispatcher* has following abilities:

- **Knowledge acquisition:** for example, an *Investment Dispatcher* acquires knowledge about what a user wants the IDSS to do (i.e. request) or what is happening in the surrounding world (i.e. fundamental information, technical factors, risk information and market reaction, expert's opinion, etc). The *Investment Dispatcher* may draw on *Investment Provider* contents when using its acquisition ability. For example, its interpretation of a request (i.e., classification of positive, neutral or negative ranges of BHP at current time) may be based on previously acquired linguistic knowledge (i.e., *Turning Point or Ranges Models*). On the other hand, Knowledge acquisition ability can cause a change in the *Investment Provider*. For example, new knowledge obtained (i.e., company info, stock info, market info, etc) may be added in, edit or replace existing ones.
- **Knowledge selection/derivation:** The *Investment Dispatcher* is able to selectively recall or derives knowledge in following *Investment Provider* that forms a solution. For example, to classify BHP at current time, the *Investment dispatcher* may recall or derive knowledge from Experts' domain knowledge (i.e., experience of trading BHP stock), Fundamental knowledge (i.e., BHP company info), technical knowledge (i.e., Stock price and volume history), market reactions (i.e.,

contrarians' entry, market constituent) and so on. Additionally, it gives the ability to create, combine, revise, and delete models, knowledge and datasets in an *Investment Provider*. For example, some false or invalid market info (i.e., proven rumors) is identified useless and could be deleted from *Investment Provider*.

(3) **Investment Provider:** In response to *investment dispatcher's* command, the *Investment Provider* provides requested knowledge from model base, knowledge base, data base and expert domains (with fuzzy logic), which together will form a solution. It includes following components:

- **Model Bases:** It contains models and building blocks used to develop applications to run IDSS system. It may contain standard models (e.g. financial models like *DCF* or Risk models like *VaR*) and customized models (i.e. *Turning Point and Ranges Models*). Such models identify relationships among some collection of variables and numbers (i.e., constants). They may relate variables and constants within a series of numeric expressions involved in equations or inequalities, within a graph of nodes and arcs (e.g., a decision tree used in Figure 5 and 6), or via an arrangement of numbers in a data set. In effect, these are alternative ways to characterize a problem which a dispatcher uses to manufacture a solution. For example, using a *VaR* model to assess risks; using *ROI*, *IRR*, *NPV*, or a *Discounted Cash-flow* model to assess company value. All these models can be organized into what is called a model case. Note that problems that can be analyzed by the same dispatcher form a model class.
- **Knowledge Bases:** Knowledge may include descriptive, procedural and reasoning knowledge. For example, *Investment Provider* may contain knowledge about how long to retain historical data about a particular stock, or which inactive stock or invalid information should be discarded from the knowledge base. Additionally, descriptive knowledge will reside in the form of a particular company's data. A quantity of important knowledge comes from six modules discussed above. It may include (fuzzy) "IF-THEN" rules, for instance:  
**Rule 1:**  
**IF:** current P/E / history average of P/E < 0.8  
**AND**  
 Current P/E / industry average < 0.7 **AND**  
 Market value / company book value < 0.8 **AND**  
 Market value / net asset value < 0.7 **AND**  
 Company asset (land, plant, goodwill, etc) was undervalued by 30% **AND**  
 Dividend payment is consistent in last 5 year **AND**  
 Dividend payment is increasing by 10% each year **AND**

Cash flow is positive and healthy in last 3 years and future 1 year

**THEN:** Fundamental side of the stock is "GOOD" CF=80 (CF: Certainty Factor)

- **Data Bases:** Data could flow from several sources, i.e. Australian Centre for Advanced Computing & Communications (ac3) and other sources (i.e., announcements from ASX) and the databases formed contain variety of data forms and types. Their gateway provides necessary functions of data access, extraction, capture, integration and management. Particularly, it may be employed to accurately track and selectively recall descriptive knowledge in a relational database about a particular stock/company/market situation that satisfies a particular request or need.
- **Expert Domain Knowledge with Fuzzy Logic:** *Investment Provider* is also composed of expert (or other intelligent) domain knowledge and it provides the necessary execution and integration of the expert subsystems. It realizes that domain knowledge (or Investment sense) of experts (such as brokers, fund managers or large investors) could play an important role in IDSS execution process and make a real difference to sound investment decisions. For instance, the expert subsystem draws on descriptive and reasoning knowledge to infer advice in response to a user's request for a recommendation. The advice is comparable to that of a human expert. The expert knowledge acquisition process involves obtaining, structuring, and formalizing the knowledge of experts. Additionally, experts' domain knowledge and users' profiles could interactively affect IDSS (see Figure 1). For example, based on a broker's knowledge and experience (or investment sense), he could observe a unique Contrarians' Entry Signal and assess its importance. Then he can interact with IDSS system to manipulate above-discussed six modules to create a better result. On the other hand, results of individual modules could strengthen experts' knowledge base and then improve their interaction. Additionally, results of individual modules can become the basis for experts to decide which module to use or how to integrate them using particular optimization methods.

Note that often a human expert (i.e. a broker) is confronted with the task of making some sense out of a fuzzy situation, since one or more of the factors involved in the reasoning process is unclear or out of focus, in the sense that it has simultaneously several plausible appearances. For instance, an investment expert who reasons about the macroeconomic outlook (or company/stock outlook) might simultaneously

think that the outlook is good (60% certain) or fair (40% certain), each with some degree of certainty. The outlooks might be fuzzy. Therefore, fuzzy logic technology is useful in such fuzzy situation. Fuzzy variable and its own certainty factors become an important part of expert knowledge base.

IDSS may involve cooperation of a few of sub-expert systems which distribute in different sites (i.e. brokerage firms), thus it is necessary to organize them to integrate their intelligence and to achieve a better solution. For instance, stock broker A at *Sydney* can provide particular company info (i.e. BHP), stock broker B at *Melbourne* can provide a macroeconomic knowledge (i.e. energy), stock broker C at *Brisbane* can expertise in BHP stock traders' behaviors, and stock broker D at *Caines* can observe contrarian's activities. In order for an investor E at *Perth* to make a sound investment decision for BHP stock, it is necessary to integrate intelligence at five different sites. Therefore, I propose an agent-based distributed expert system which supports the sharing, managing, searching and presentation of distributed experts' knowledge. Note that such agent-based distributed expert systems have four kinds of cooperation which are *horizontal* cooperation, *tree* cooperation, *recursive* cooperation, and *hybrid* cooperation [18]. An intelligent agent is an object with its own knowledge and information base. Each intelligent agent acts in parallel with other intelligent agents and cooperates with a selected set of other agents to achieve a common set of goals. Intelligent agents must be able to recognize events, determine the meaning of those events and then take actions on behalf of a user. Figure 7 depicts sample *horizontal* agent-based distributed expert

systems, which may integrates usage of Matchmaker and Broker structure in different situations. For instance, if expert systems at Sydney, Melbourne and Perth involve a large volume of communication and communication speed is slow (type1), it is better to use Matchmaker structure, as once match was made, expert systems at Perth can communicate with ones at Sydney and Melbourne directly thus no need of matchmaker's involvement again. On the contrary, in case of expert systems at Brisbane, Caines and Perth, communication is quite fast and volume is small (Type 2), Broker structure is more suitable, as involvement of broker will not slow communication but will increase accuracy. Figure 8 depicts two types of distribution. In type 1, agent 2 of ES Melbourne & agent 3 of ES Sydney advertise their intelligence x (BHP company info) and y (energy sector's macroeconomic info) to Matchmaker (process 1a & 1b). Agent 1 of ES Perth needs intelligence of both x and y to make an investment decision, thus it asks matchmaker and the matchmaker answers with agent 2 and agent 3 (process 2 & 3). Once agent 1 of Perth receives the answer, it contacts agent 2 of ES Sydney and agent 3 of ES Melbourne directly and get corresponding intelligence x and y (process 4 & 5). In type 2, agent 1 of ES Perth can not contact agent 4 of Brisbane ES and agent 5 of Caines directly, on the contrary, it need to send request of p (BHP traders' behavior) and q (contrarian's observation) first to broker (process 6), then broker will get answers from agent 4 and 5 (process 7), then broker sends answers to agent 1 (process 8). Note in large distributed expert systems, both Matchmaker and Broker may be adopted, according to distribution difference and characteristics of expert systems.

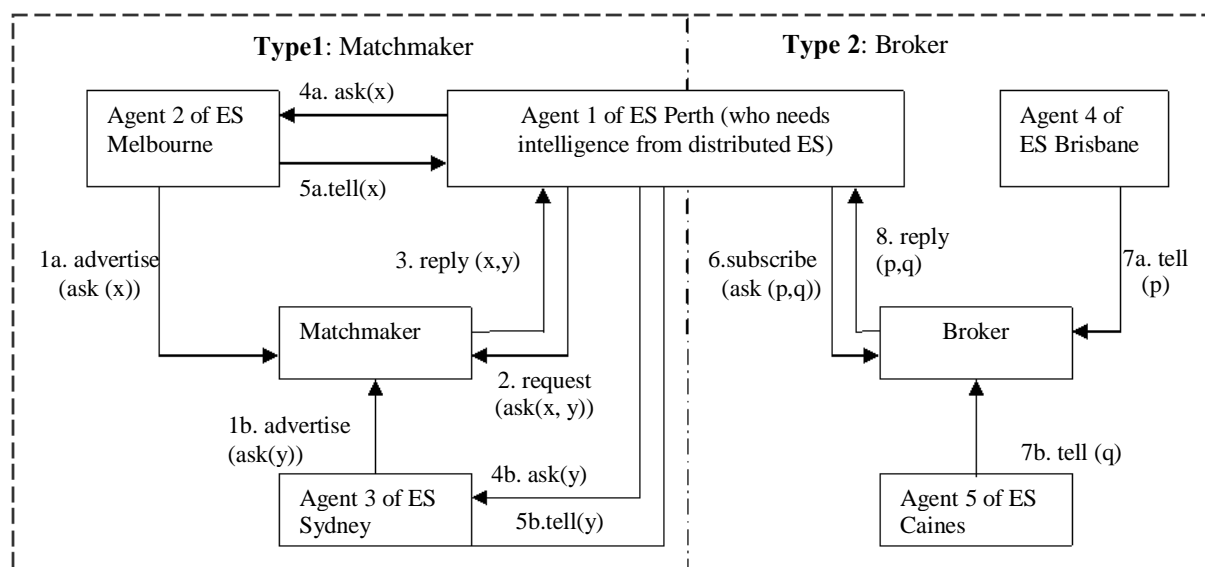

Figure 7: sample agent-based distributed expert systems

### 3. IDSS SYSTEM IMPLEMENTATION AND EVALUATION

Proposed IDSS is a KB-DSS in essence, thus building it involves the capabilities, functionality and structures of both DSS and ES with the emphasis on the support of DSS. I adopted a KB-DSS methodology proposed by Klein and Methlie [19]. Additionally, Evolutionary Prototyping proposed by Turbon and Aronson [20] was used as an aid. The initial prototype was implemented by mainly using Jess and Java. An industry partner, Tricom (www.tricom.com.au), contributed expert domain knowledge and involved in IDSS implementation.

Based on initial prototype, I got following initial evaluation results:

- 1) Real transaction results. For instance, IDSS system picks up 10 stocks at an experiment and return is over 20%, which is higher than benchmark (i.e. ASX index) and most fund performance.
- 2) Experts' feedback. Experts (such as brokers, fund managers or large investors) are users and interact with the system. An industry partner TRICOM (broker) gave positive feedbacks (like ease of use, usefulness or other features) in both experiment and real trading practice.
- 3) Compared to other stock trading support systems, IDSS shows better performance in experiments, including effectiveness, ease of use, powerfulness of system functions, efficiency, etc.

While further implementation is in progress and more evaluation will be done, I expect a more efficient IDSS to be finalized and more solid experimental results to be obtained by December 2004.

### 4. CONCLUSIONS

I propose an Investment Decision Support System (IDSS) in order to get better mid-term investment results than conventional methods, through identification and classification of Positive, Neutral and Negative investment opportunity ranges and related risks. This IDSS system takes advantage of and optimizes existing methods and newly proposed methods - *Turning Point Model* (in finance) and *Optimized AutoSplit method* (in IT), which can help better identify investment opportunities and risks features. Initial system evaluation shows that the IDSS system (with proposed methods) can successfully identify and classify investment opportunity ranges and other hidden variables, outperforming the benchmark index and other systems.

## ABSTRACT

A Bayesian network is a graphical model for representing probabilistic relationships among a set of variables. It is an important model for business analysis. Bayesian network learning methods have been applied to business analysis where data privacy is not considered. However, how to learn a Bayesian network over private data presents a much greater challenge. In this paper, we develop an approach to tackle the problem of Bayesian network induction on private data which may contain missing values. The basic idea of our proposed approach is that we combine randomization technique with Expectation Maximization (EM) algorithm. The purpose of using randomization is to disguise the raw data. EM algorithm is applied for missing values in the private data set. We also present a method to conduct Bayesian network construction, which is one of data mining computations, from the disguised data.

**Keywords:** Bayesian network, randomization, EM algorithm, privacy.

## 1. INTRODUCTION

A Bayesian network is a high-level representation of a probability distribution over a set of variables that are used for constructing a model of the problem domain. It has been widely used in sales decision making, marketing systems, risk analysis, cost benefit factor inference in E-services, and other business applications. As Bill Gates mentioned, in Los Angeles Times on October 28, 1996, that Microsoft's competitive advantage was its expertise in Bayesian network. The Bayesian framework offers many advantages over alternative modeling approaches. A Bayesian network can be used to compute the predictive distribution on effects of possible actions since it is a model of the problem domain probability distribution. For instance, it can be used for the optimal procedure of making decision in risk analysis. Bayesian network model has been also found to be very robust to tolerate small alterations. Thus, it can be used for sales marketing systems since these systems need to be able to follow market changes rapidly without making much modification on the model. In addition, expert domain knowledge can be coded as prior distribution in Bayesian modeling.

Over the last decade, the Bayesian network has been widely utilized and various techniques have been developed to learn Bayesian networks from data. Although the techniques that have been developed are effective, new techniques dealing with Bayesian network induction over private data are required. In other words, we need methods to learn a Bayesian network with data privacy preserved. In particular, we try to solve the following type of problem: To improve their services, business agents want to obtain certain information about their customers. For instance, the information of interest can be the probability that a customer buys butter given that she bought bread. In

order to collect the information from its customers, a business agent sends out a survey containing a set of questions. Customers are expected to answer those questions and send their answers back. However, because the survey contains questions regarding private information, not every user feels comfortable to disclose her answers to those questions. To protect customers' privacy, they need somehow mask their answers before sending them back to the agent. We observe that randomization can be used to hide customers' answers. This is because on one hand the raw data values of the original customer's information can be disguised via randomization, on the other hand, their probability distribution can be approximately estimated from the disguised data by agents for business analysis. In practice, even though randomization protection techniques are utilized, some customers still do not provide their data. Therefore, the collected data usually contain missing values. The challenge is how to conduct data mining from the disguised data with missing values?

To address this challenge, we propose to combine the proposed *Multi-Group Randomization* technique with the Expectation Maximization (EM) algorithm [2]. The basic idea of multi-group randomization technique is to partition attributes of a data set into several groups and randomize data in each group independently so that business agents can't tell with probabilities better than a pre-defined threshold whether the data from a customer contain truthful information or false information. Although information from each individual customer is scrambled, if the number of customers is significantly large, the aggregate information of these customers can be estimated with decent accuracy. Such property is useful for building a Bayesian network, since it is based on aggregate values of a data set, rather than individual data items. The EM algorithm is a general iterative algorithm for parameter estimation by

maximum likelihood when some of the random variables involved are not completely observed. It formalizes an intuitive idea for obtaining parameter estimates when some of the data are missing. The term EM was introduced in [2] where proof of general results about the behavior of the algorithm was given as well as a large number of applications was introduced.

The rest of the paper is organized as the follows: We describe the background of Bayesian network in Section 2. In Section 3, we briefly describe how multi-group randomized response technique works. Then in section 4, we describe the EM algorithm. We give an algorithm to build a Bayesian network on disguised data with missing values in Section 5. In Section 6, we discuss related work. We give our conclusion in Section 7.

## 2. BACKGROUND OF BAYESIAN NETWORKS

A Bayesian network [10] is a representation of probabilistic conditional independence. The network model is a directed acyclic graph (DAC) in which a node represents a random variable and a directed link or an arrow denotes the conditional probability of a child node given its parent node with the arrow pointing from the parent to the child. Suppose a network  $BN_1$  have  $n$  nodes. Associated with each node (e.g.,  $X_i$ ,  $i \in [1, \dots, n]$ ) is a conditional probability table (CPT) that shows the probabilistic dependency relationships between  $X_i$  and its parent nodes,  $Parent(X_i)$ , i.e.,  $P(X_i = x_i | Parent(X_i) = pa_i, D, BN_1)$ , where  $D$  is the dataset,  $BN_1$  is the network model, and  $x_i$  and  $pa_i$  are values of  $X_i$  and  $Parent(X_i)$ , respectively. An entry of the CPT is a network parameter.

A Bayesian network may be inductively learnt from a data set [6]. As discussed in [6], inductive Bayesian learning involves the selection of network models and the estimation of parameters (e.g., the CPTs). Given a complete data set  $D$ , learning of the best Bayesian network model is carried out by computing the posterior probability  $P(BN_1 | D)$  for different  $BN_1$ , and selecting the one with the largest value. From the Bayes rule,  $P(BN_1 | D)$  is determined by the likelihood  $P(D | BN_1)$ , the prior  $P(BN_1)$ , and the data probability  $D$ :

$$P(BN_1 | D) = \frac{P(D | BN_1) \cdot P(BN_1)}{P(D)}$$

Given the prior  $P(BN_1)$ , the model selection is determined by  $P(D | BN_1)$ . Assume the best model is denoted as  $BN$ . The network parameters are estimated with the data of  $D$  and the prior probability distribution of parameters. In this paper, we assume the Bayesian

network model is known, and will mainly consider the induction of parameters or the conditional probability tables. Suppose the uniform prior is used. (See [6] for different prior probabilities.) The CPT entry associated with the values of  $X_i = x_i$  and  $Parent(X_i) = pa_i$  is as follows:

$$P(X_i = x_i | Parent(X_i) = pa_i, D, BN_1) = \frac{\#(X_i = x_i, Parent(X_i) = pa_i) + 1}{\#(Parent(X_i) = pa_i) + |X_i|} \quad \text{EQ.(1)}$$

for a complete data set  $D$  (i.e.,  $D$  without missing value), where  $\#(\cdot)$  stands for the total number of the records that satisfies conditions in  $(\cdot)$ , and  $|X_i|$  denotes the number of values that  $X_i$  has. Divide both the numerator and the denominator of EQ.(1) by the total number of data records ( $|D|$ ) to obtain

$$\begin{aligned} & \frac{\#(X_i = x_i, Parent(X_i) = pa_i) / |D| + 1 / |D|}{\#(Parent(X_i) = pa_i) / |D| + |X_i| / |D|} \\ &= \frac{P(X_i = x_i, Parent(X_i) = pa_i) + 1 / |D|}{P(Parent(X_i) = pa_i) + |X_i| / |D|} \end{aligned}$$

In this paper, we will use  $P(X_i = x_i)$  to denote the probability measure obtained from the frequency count  $\#(X_i = x_i) / |D|$ .

## 3. MULTI-GROUP RANDOMIZED RESPONSE TECHNIQUES

*Randomized Response* techniques were firstly introduced in [11] as a technique to solve the following survey problem: to estimate the percentage of people in a population that has attribute A, queries are sent to a group of people. Since the attribute A is related to some confidential aspects of human life, respondents may decide not to reply at all or to reply with incorrect answers. To enhance the level of cooperation, instead of asking each respondent whether she has attribute A, the interviewer asks each respondent two related questions, the answers to which are opposite to each other [11]. For example, the questions could be like the following. If the statement is correct, the respondent answers "yes"; otherwise, she answers "no".

1. I have the sensitive attribute A.
2. I do not have the sensitive attribute A.

Respondents use a randomizing device to decide which question to answer, without letting the interviewer know which question is answered. The randomizing device is designed in such a way that the probability of choosing the first question is  $q$ , and the probability of choosing the second question is  $1-q$ . Although the interviewer learns the responses (e.g., "yes" or "no"), he does not know which question was answered by the respondents. Thus the respondents' privacy is preserved. Since the interviewer's interest is to get the answer to the first

question, and the answer to the second question is exactly the opposite to the answer for the first one, if the respondent chooses to answer the first question, we say that she is telling the truth; if the respondent chooses to answer the second question, we say that she is telling a lie. To estimate the percentage of people who has the attribute A, we have

$$P^*(A = \text{yes}) = P(A = \text{yes}) \cdot q + P(A = \text{no}) \cdot (1 - q)$$

$$P^*(A = \text{no}) = P(A = \text{no}) \cdot q + P(A = \text{yes}) \cdot (1 - q)$$

where  $P^*(A = \text{yes})$  is the proportion of the "yes" responses obtained from the survey data.  $P^*(A = \text{no})$  is the proportion of the "no" responses obtained from the survey data.  $P(A = \text{yes})$  is the estimated proportion of the "yes" responses to the sensitive questions.  $P(A = \text{no})$  is the estimated proportion of the "no" responses to the sensitive questions. Getting  $P(A = \text{yes})$  and  $P(A = \text{no})$  is the goal of the survey. By solving the above equations, we can get  $P(A = \text{yes})$  and  $P(A = \text{no})$  if  $q \neq 0.5$ .

In this section, we develop a multi-group randomized response technique to deal with the problem of Bayesian network construction where multiple attributes are normally involved.

### 3.1 Notations

In this paper, we assume data are binary. Suppose there are  $N$  attributes  $(A_1, A_2, \dots, A_N)$  in a data set. Let  $L$  represent any logical expression based on those attributes (e.g.,  $L = (A_1 = 1) \wedge (A_2 = 0)$ ); let  $\bar{L}$  denote the logical expression that reverses the 1's in  $L$  to 0's and 0's to 1's; we call  $\bar{L}$  the opposite of  $L$  in value assignments. For example, for the  $L$  in the previous example,  $\bar{L} = (A_1 = 0 \wedge A_2 = 1)$ . Let  $P^*(L)$  be the proportion of the records in the whole *disguised* data set that satisfy  $L = \text{true}$ . Let  $P(L)$  be the proportion of the records in the whole *undisguised* data set that satisfy  $L = \text{true}$  (the undisguised data set contains the true data, but it does not exist).  $P^*(L)$  can be observed directly from the disguised data, but  $P(L)$ , the actual proportion that we are interested in, cannot be observed from the disguised data because the undisguised data set is not available to anybody; we have to estimate  $P(L)$ . Our goal is to find a way to estimate  $P(L)$  from  $P^*(L)$ . In our multi-group scheme, we also divide each expression  $L$  into multiple sub-expressions. For example, in a  $m$ -group scheme, we write  $L = L_1 L_2 L_3 \dots L_m$ , where  $L_i$  contains only the attributes in the group  $i$ .

### 3.2 One-Group Scheme

In the one-group scheme, all the attributes are put in the same group, and all the attributes are either reversed

together or keeping the same values. In other words, when sending the private data to the central database, users either tell the truth about all their answers to the sensitive questions or tell the lie about all their answers.

The probability for the first event is  $q$ , and the probability for the second event is  $1 - q$ . The general model for the one-group scheme is described in the following:

$$P^*(L) = P(L) \cdot q + P(\bar{L}) \cdot (1 - q)$$

$$P^*(\bar{L}) = P(\bar{L}) \cdot q + P(L) \cdot (1 - q)$$

$L$  denotes any logic expression among the attributes, for instance,  $L$  could be  $(A_1 = 0, A_2 = 1, A_3 = 0, A_4 = 0)$  and represents the case when attribute 1 is 0, attribute 2 is 1, attribute 3 is 0, and attribute 4 is 0. The above model can be simplified. Let  $M_1$  denote the coefficients matrix of the above equations, and let  $p = q$  and  $q = (1 - q)$ , then

$$\begin{Bmatrix} P^*(0\text{Bar}) \\ P^*(1\text{Bar}) \end{Bmatrix} = M_1 \begin{Bmatrix} P(0\text{Bar}) \\ P(1\text{Bar}) \end{Bmatrix} \quad \text{Eq. (3)}$$

Where  $0\text{Bar} = L$ ,  $1\text{Bar} = \bar{L}$ , and

$$M_1 = \begin{bmatrix} p & q \\ q & p \end{bmatrix}$$

### 3.3 Two-Group Scheme

In the one-group scheme, if the interviewer somehow knows whether the respondents tell a truth or a lie for one attribute, she can immediately obtain all the true values for all other attributes of a respondent's response. To improve the privacy level, data providers divide all the attributes into two groups (All the data providers should group the attributes in the same way, e.g., if one user lets attribute  $A_1$  and  $A_2$  be in group 1, then other users also let attribute  $A_1$  and  $A_2$  be in group 1). They then apply the randomized response techniques for each group *independently*. For example, the users can tell the truth for one group while telling the lie for the other group. With this scheme, even if the interviewers know information about one group, they will not be able to derive the information for the other group because they are disguised independently.

To show how to estimate  $P(L_1 L_2)$ , we look at all the contributions to  $P^*(L_1 L_2)$ . There are four parts that contribute to  $P^*(L_1 L_2)$ :

1.  $P(L_1 L_2)$ : users tell the truth about all the answers for both groups; the probability for this event is  $q^2$ .

2.  $P(L_1 \bar{L}_2)$ : users tell the truth about all the answers for group 1 and tell the lie about all the answers for group 2; the probability for this event is  $q \cdot (1-q)$ .

3.  $P(\bar{L}_1 L_2)$ : users tell the lie about all the answers for group 1 and tell the truth about all the answers for group 2; the probability for this event is  $q \cdot (1-q)$ .

4.  $P(\bar{L}_1 \bar{L}_2)$ : users tell the lie about all the answers for both groups; the probability of this event is  $(1-q)^2$ .

We then have the following equation:

$$P^*(L_1 L_2) = P(L_1 L_2) \cdot q^2 + P(L_1 \bar{L}_2) \cdot q(1-q) + P(\bar{L}_1 L_2) \cdot q(1-q) + P(\bar{L}_1 \bar{L}_2) \cdot (1-q)^2$$

There are four unknown variables in the above equation ( $P(L_1 L_2), P(L_1 \bar{L}_2), P(\bar{L}_1 L_2), P(\bar{L}_1 \bar{L}_2)$ ). To solve the above equation, we need three more equations. We can derive them using the similar method. The final equations are described in the following:

$$\begin{Bmatrix} P^*(0Bar) \\ P^*(1Bar) \\ P^*(2Bar) \end{Bmatrix} = M_2 \cdot \begin{Bmatrix} P(0Bar) \\ P(1Bar) \\ P(2Bar) \end{Bmatrix}$$

where  $0Bar = L_1 L_2$ ,  $1Bar = L_1 \bar{L}_2 + \bar{L}_1 L_2$ ,  $2Bar = \bar{L}_1 \bar{L}_2$ ,  $M_2$  is the coefficients matrix, and let  $p = q$  and  $q = 1-q$ , then,

$$M_2 = \begin{bmatrix} p^2 & pq & q^2 \\ 2pq & p^2 + q^2 & 2pq \\ q^2 & pq & p^2 \end{bmatrix}$$

By solving the above equations, we can get  $P(L_1 L_2) = P(0Bar)$

### 3.5 Multi-Group Scheme

Similar techniques can be employed to extend the above schemes to three-group scheme, four-group scheme, and so on. In the following, we will give a general formula for the m-group scheme, where we apply randomized response techniques for each group *independently*.

$$\begin{Bmatrix} P^*(0Bar) \\ P^*(1Bar) \\ \vdots \\ P^*(mBar) \end{Bmatrix} = M_m \cdot \begin{Bmatrix} P(0Bar) \\ P(1Bar) \\ \vdots \\ P(mBar) \end{Bmatrix}$$

Where

$0Bar = L_1 L_2 L_3 \dots L_m$ ,  $1Bar = \bar{L}_1 L_2 L_3 \dots L_m$ ,  $L_1 L_2 \bar{L}_3 \dots L_m$ , ...,  $mBar = \bar{L}_1 \bar{L}_2 \bar{L}_3 \dots \bar{L}_m$  and  $M_m$  is the coefficients matrix. Let  $p = q$  and  $q = 1 - q$ , then

$$M_m = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \dots & a_{1(n+1)} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2(n+1)} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3(n+1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{(n+1)1} & a_{(n+1)2} & a_{(n+1)3} & \dots & a_{(n+1)(n+1)} \end{bmatrix}$$

The coefficient matrix is different for different group scheme. The values of  $a_{ij}$  can be derived as we did for two-group scheme. After we derive the coefficient matrix, we can solve the above equation and obtain  $P(E_1 E_2 \dots E_n) = P(0Bar)$  since  $P^*(0Bar), P^*(1Bar), \dots, P^*(nBar)$ , can be obtained from the randomized data.

### 4. EM ALGORITHM

The Expectation Maximization (EM) algorithm [2, 8] is a general algorithm for maximum likelihood estimation where the data are incomplete or the likelihood function involves hidden variables. The EM algorithm starts with randomly assigned values to all the parameters to be estimated. It then iteratively alternates between two steps, called the expectation step (i.e., the E-step) and the maximization step (i.e., the M-step), respectively. In the E-step, it computes the expected likelihood for the complete data (Q-function) where the expectation is taken with regards to the computed conditional distribution of the hidden variables given the current settings of parameters and our observed data. In the M-step, it re-estimates all the parameters by maximizing the Q-function. Once we have a new generation of parameter values, we can repeat the E-step and M-step. The above process continues until the likelihood converges.

Assume that the joint probability for hidden data Y and observed data Z is parameterized using  $m$ , as  $P(y, z | m)$ . The marginal probability for Z is then  $P(z | m) = \sum_y P(y, z | m)$ . Given observed data z, we

want to find the value of  $m$  that maximizes the log likelihood,  $L(m) = \log P(z | m)$ . The procedures of the EM algorithm are as follows:

1. Initialize  $m^{(0)}$  randomly or heuristically according to prior knowledge about what the optimal parameter value might be.

2. Iteratively improve the estimate of  $m$  by alternating between the following two steps:

(a) E-step: Compute a distribution  $\hat{P}^{(i)}$  over the range Y

such that  $\tilde{P}^{(t)} = P(y | z, m^{t-1})$ .

(b) M-step: Set  $m^{(t)}$  to the  $m$  that maximizes  $E_{\tilde{P}^{(t)}}(\log P(y, z | m))$ .

3. Stop when the algorithm converges to a local maximum.

## 5. CONSTRUCTION OF A BAYESIAN NETWORK

The problem of learning Bayesian networks comes in several varieties. The structure of the network can be either *known* or *unknown*, and the variables in the network can be either *fully observable* or *with missing values*. In this paper, we consider the case of *known structure* and *with missing values*. Since the structure is known, construction requires only the computation of the CPT for each node. We will describe how to compute the CPTs when data set is complete, and then present an algorithm to deal with Bayesian network construction when the data set D is disguised and incomplete. Let parent nodes of the  $i$ th node be  $Y_{1,L}, Y_p$ . To obtain CPT entries of node  $i$ , we need to compute the two terms:

$$P(X_i = x_i, Y_{1,L} = y_{1,L}, Y_p = y_p) \text{ and } P(Y_{1,L} = y_{1,L}, Y_p = y_p)$$

Since

$$\begin{aligned} &P(X_i = x_i | \text{Parent}(X_i) = pa_i, D, BN) \\ &= \frac{P(X_i = x_i, Y_{1,L} = y_{1,L}, Y_p = y_p) + 1/|D|}{P(Y_{1,L} = y_{1,L}, Y_p = y_p) + |X_i|/|D|} \end{aligned}$$

When data set D is undisguised and complete, these two terms can be easily computed. But, it is not the case if D is disguised and incomplete. We provide the following algorithm to deal with Bayesian network construction when the data set D is disguised and incomplete.

Step I: Estimate missing values

Use EM algorithm to estimate the missing values in the disguised data set and obtain a complete data set CD. Please note that the distribution of randomized data very likely differs from the data distribution before randomization. Therefore, we need test the data distribution after randomization and apply proper EM algorithm.

Step II: Compute CPTs

Apply the estimation model of the randomized technique described in Section 3 to estimate those terms needed for the CPT entries. Consider the Wet-grass example, where wet-grass ( $W$ ) can be caused by either rain ( $R$ ) or sprinkling ( $S$ ). The particular CTP of grass being wet, given rain and sprinkling is as follows.

$$\begin{aligned} &P(W = t | S = t, R = t, CD, BN) \\ &= \frac{P(W = t, S = t, R = t) + 1/|CD|}{P(S = t, R = t) + |W|/|CD|} \end{aligned}$$

( $|CD|$  denotes the total number of records in the complete data set.) Assume the data set is disguised using one-group scheme. We compute  $P^*(W = t, S = t, R = t)$  and  $P^*(W = f, S = f, R = f)$  on the data set CD. We then apply one-group estimation model to compute  $P(W = t, S = t, R = t)$ .

$$\begin{Bmatrix} P^*(W = t, S = t, R = t) \\ P^*(W = f, S = f, R = f) \end{Bmatrix} = M_1 \cdot \begin{Bmatrix} P(W = t, S = t, R = t) \\ P(W = f, S = f, R = f) \end{Bmatrix}$$

where  $M_1 = \begin{bmatrix} q & 1-q \\ 1-q & q \end{bmatrix}$ . Similarly,  $P(S = t, R = t)$  can be

computed. Hence, we can calculate  $P(W = t | S = t, R = t)$ . With a similar calculation, other CPTs can be obtained.

## 6. PREVIOUS WORK

There are two existing approaches to solve privacy preserving data mining problems. One is the perturbation approach, the other is the secure multi-party computation approach. Agrawal and Srikant proposed a scheme for privacy-preserving data mining using random perturbation [3]. In their scheme, a random number is added to the value of a sensitive attribute. For example, if  $x_i$  is the value of a sensitive attribute,  $x_i + r$ , rather than  $x_i$ , will appear in the database, where  $r$  is a random value drawn from some distribution. The paper shows that if the random number is generated with some known distribution (e.g., uniform or Gaussian distribution), it is possible to recover the distribution of the values of that sensitive attribute. With the independence assumption of the attributes, the paper then shows that a decision tree classifier can be built with the knowledge of distribution of each attribute. Du and Zhan [4] proposed to use randomized response techniques [11] to tackle privacy-preserving data mining problem. In their scheme, they do not assume the independence of the attributes. Rizvi and Haritsa presented a scheme called MASK to mine associations with secrecy constraints in [9], and Evfimievski et al. proposed an approach to conduct privacy preserving association rule mining based on randomization techniques [1]. Kargupta et al. further analyze the effectiveness of randomization approach in [5]. Several SMC-based privacy preserving data mining schemes have been proposed [7, 7, 13]. These studies mainly focused on two-party distributed computing, and each party usually contributes a set of records. In our proposed research, we focus on centralized computing, and each participant only has certain number of records to contribute. All records are

combined together into a central database before the computation begins.

## 7. CONCLUSION AND FUTURE WORK

As mentioned, Bayesian network learning is proven to be valuable to the business world. In this paper, we have combined multi-group randomized response techniques with EM algorithm for constructing Bayesian networks over disguised data set where some data values are missing. In our future work, we will continue refining our technique to handle various risk-analyses in business. We will also extend our solution to data sets consisting of non-binary data types.

## ABSTRACT

The wafer defects influence the yield of a wafer. The integrated circuits (IC) manufacturers usually use a Poisson distribution based c-chart to monitor the lot-to-lot wafer defects. As the wafer size increases, defects on wafer tend to cluster. When the c-chart is used, the clustered defects frequently cause erroneous results. The main objective of this study is to develop a hierarchical adaptive control process to monitor the clustered defects effectively and detect the wafer-to-wafer variation and lot-to-lot variation simultaneously using data mining technique.

**Keywords:** wafer defects, c-chart, defect clustering, adaptive control chart, data mining.

## 1. INTRODUCTION

The IC fabrication has been the most popular industry in recent decades. The key competitive ability of IC products is the wafer yield. The wafer yield is defined by the percentage of the chip without defects on a wafer. To enhance the wafer yield, most IC manufacturers employ a Poisson distribution based defect control chart (c-chart) to monitor the wafer defects. The c-chart is proved to be effective when wafer size is small (e.g., four or six inches wafers). As the wafer size has been enlarged to twelve-inch, the manufacturing process becomes very complicated. Consequently, the clustering phenomenon of the defects becomes increasingly apparent. This phenomenon will affect the accuracy of the c-chart. When the conventional c-chart is used to monitor the large-size wafers, the clustered defects frequently cause erroneous results. That is, the c-chart may cause too many false alarms. This is because c-chart requires that the occurrence of a defect in any location is independent of the occurrence of defects in other locations.

The IC manufacturing process is composed of hundreds of steps. At each step, many possible factors may affect the quality of a wafer. There are three types of wafer variations: within-wafer variation, wafer-to-wafer variation and lot-to-lot variation. The c-chart can only detect the lot-to-lot variation under the condition that the defects are scattered randomly on a wafer and there is no wafer-to-wafer variation. Besides, the cost of sampling wafers from a lot becomes expensive for large-size wafers. An adaptive control chart may be utilized to reduce the sampling cost. Therefore, the main objective of this study is to develop a complete adaptive detecting procedure of wafer defects, which concerns both multiple variations and clustering phenomenon. Using the proposed procedure, the wafer defects can be controlled efficiently with low sampling cost.

## 2. DOCUMENTATION DISCUSSION

### 2.1 Clustering analysis [4]

Cluster analysis is a popular data mining technique used for combining observations into groups or clusters such that each cluster is homogeneous with respect to certain characteristics and observations of one cluster should be different from the observations of other clusters. In hierarchical cluster analysis, clusters are formed hierarchically such that the number of clusters at each step is  $n-1$ ,  $n-2$ ,  $n-3$ , and so on. A number of different algorithms for hierarchical clustering were developed. These algorithms differed mainly with respect to how distances between two clusters are computed. The Euclidean distance for  $p$  variables is a common formula used for computing the distance between two observations. The distance is utilized as a measure of similarity in cluster analysis.

### 2.2 Three-step hierarchical control process

In the IC manufacturing process, there are three types of wafer variations: within-wafer variation, wafer-to-wafer variation and lot-to-lot variation may cause the yield loss. Wells and Smith [5] claimed that the three variations must be under control to assure the quality of a wafer and they proposed a step-by-step control process as follows:

(1) Determine the uniformity of a wafer.

Calculate the non-uniformity ( $NU$ ) of each wafer:

$$NU = 2\hat{V} \text{ and } \hat{V} = 100\hat{s}^2 / \bar{X} \quad (1)$$

Where  $\hat{s}^2$  and  $\bar{X}$  represents the estimated standard deviation and mean.

(2) Draw  $\bar{X}_{NU} - R_{NU}$  control chart using the values of  $NU$  to determine whether the non-uniformity of each wafer is under control.

(3) Determine the lot-to-lot variation.

(i) Calculate the average run value of every lot.

(ii) Draw  $\bar{X} - MR$  chart to determine whether the lot-to-lot variation is under control.

(4) Calculate the total variations of the process

$$\hat{s}_{TOTAL} = (\hat{s}_R^2 + \hat{s}_W^2 + \hat{s}_L^2)^{1/2} \quad (2)$$

The estimated within wafer variation can be calculated using the average non-uniformity of every lot. The formula is given as follows:

$$\hat{s}_L = (\bar{X}_{NU})(\bar{X})/200 \quad (3)$$

Moreover, the wafer-to-wafer variation can also be obtained using the average range of every lot. The formula is given as follows:

$$\hat{s}_W = \bar{R}/d_2 \quad (4)$$

Finally, the estimated lot-to-lot variation can be obtained using the average moving-range of every lot. The formula is given as follows:

$$\hat{s}_R = \overline{MR}/d_2 \quad (5)$$

The control process proposed by Wells and Smith has two drawbacks: it can only detect the large shift of the process, that is, it is not sensitive to the small shift; it can only be used in the quantitative quality characters.

### 2.3 Adaptive control chart

Adaptive control chart is a special kind of quality control tool in which the sample size and the sampling interval are changeable. It utilizes the previous sample data as a basis to fluctuate the sampling sizes and sampling intervals. When sample points are near out of control, a stricter sampling scheme (e.g., larger sample size and shorter sampling period) is adopted to detect the out-of control situation efficiently. When sample points are near the target value, a looser sampling scheme (e.g., smaller sample size and longer sampling period) is adopted to save the sampling cost.

In order to determine when to adopt the strict, normal or loose sampling scheme, the upper and lower warning limits must be constructed within the upper and lower control limits. If a sample point falls within the warning limits, a loose sampling scheme is utilized. If a sample point falls between the warning limits and the control limits, a strict sampling scheme should be utilized. The basic model of an adaptive control chart is depicted in Fig.1.

### 2.4 $\bar{X}$ adaptive control chart [3]

The assumptions and parameters of designing a  $\bar{X}$  adaptive control chart can be described as follows:

(1) Assumptions

(i) The observations follow a Normal

Figure.1 Adaptive control chart

distribution.

(ii) Suppose the sample size and the sampling interval of the traditional control chart are  $n_0$  and  $t_0$ , respectively. A sampling scheme of  $n_1$  (small sample size) and  $h_1$  (long sample interval), or  $n_2$  (large sample size) and  $h_2$  (short sampling interval) is determined for an adaptive control chart. When the process is in control, the sample size and sampling interval of an adaptive control chart should be the same as a traditional  $\bar{X}$  control chart. That is,

$$E[t(i)] = n_0 \quad (6)$$

$$E[t(i)] = t_0 \quad (7)$$

(2) Design of parameters

(i) Let  $I_1$  be the zone within the warning limits,  $I_2$  be the zone between the control limits and warning limits, and  $I_3$  be the zone within the control limits. The lower and upper boundaries of  $I_1$ ,  $I_2$  and  $I_3$  are defined as follows:

$$I_1 = [-w, w] \quad (8)$$

$$I_2 = (LCL, -w) \cup (w, UCL) \quad (9)$$

$$I_3 = (LCL, UCL) \quad (10)$$

(ii) From the assumption (ii), the following equation can be obtained:

$$n_0 \Pr(Z \in I_3) = n_1 \Pr(Z \in I_1) + n_2 \Pr(Z \in I_2) \quad (11)$$

Because  $Z$  follows a standard normal distribution, the following results can be obtained:

$$\Pr(Z \in I_3) = 2f(w) - 1$$

$$\Pr(Z \in I_2) = 2(f(UCL) - f(w)) \quad (12)$$

$$\Pr(Z \in I_1) = 2f(UCL) - 1$$

Using (11) and (12), the warning limits can be rewritten as follows:

$$w = f^{-1} \left[ \frac{2f(UCL)[n_0 - n_2] + n_1 - n_0}{2(n_1 - n_2)} \right] \quad (13)$$

For a given sampling interval, a formula derived from (11) and (12) is given as follows:

$$t_0 \Pr(Z \in I_3) = t_1 \Pr(Z \in I_1) + t_2 \Pr(Z \in I_2) \quad (14)$$

$w$  can then be rewritten as follows:

$$w = f^{-1} \left[ \frac{2f(UCL)[t_0 - t_1] + t_2 - t_0}{2(t_2 - t_1)} \right] \quad (15)$$

After obtaining  $w$ , fix any three of the four parameters  $n_1$ ,  $n_2$ ,  $t_1$  and  $t_2$ , the last parameter can be calculated using (13) and (15). For example, fixing the values of  $n_1$ ,  $n_2$ , and  $t_1$ ,  $t_2$ ,  $b$  and  $c$  can be obtained by setting (13)=(15):

$$t_2 = \frac{t_0(n_1 - n_2) - b - t_1 c}{n_1 - n_2 - c},$$

$$b = 2(t_0 - t_1)(n_1 - n_2)f(UCL),$$

$$c = 2(n_0 - n_2)f(UCL) + (n_1 - n_0).$$

### 3. CONSTRUCT A HIERARCHICAL CONTROL PROCESS FOR CLUSTERED DEFECTS

This study utilizes the clustering analysis to adjust the number of defects on a wafer when the cluster phenomenon is detected. By doing so, the defect clusters are distributed randomly on a wafer and the type I error of the c-chart can then be reduced. The uniformity of a wafer is calculated and the adaptive control chart is employed to detect the wafer-to-wafer and lot-to-lot variations. The proposed procedure for detecting the clustered defect is described in the following:

**Step 1:** Obtain the wafer map using KLA 2110 wafer inspection system.

Cluster analysis is utilized to combine the clustered defects. Treat all defects in a cluster as one defect and the location of this defect is the location of the cluster's center. Recalculate the number of defects on each wafer

Use a goodness of fit test to check whether the adjusted (reduced) number of defects satisfies the assumption of a Poisson distribution. If it does, go to Step 2; otherwise, repeat Step 1.

**Step 2:** Determine whether the wafer-to-wafer variation is in control.

Calculate the value of  $NU$  using the adjusted number of defects on a wafer. Transfer the values of  $NU$  to satisfy the normality assumption. The  $\bar{X}_{NU} - R_{NU}$  chart and  $X - MR$  chart are constructed to detect the wafer-to-wafer variation.

**Step3:** Determine whether the lot-to-lot variation is in control.

The proposed adaptive  $U$  control chart is developed based on the  $\bar{X}$  control chart. In monitoring IC manufacturing process, the wafers are usually sampled from every lot. The sampling interval is treated as a fixed constant (e.g., a lot). Therefore, only the sample size needs to be changed according to the previous sampling result. The process of using  $U$  control chart to monitor the lot-to-lot variation is described as follows:

1. Standardize the sample data. Because  $m$  and  $s$  are unknown, they are estimated using the historical data.. The transformation formula is :

$$Z_i = \frac{u_i - m}{\sqrt{s^2/n_i}} \cong \frac{u_i - \bar{u}}{\sqrt{\bar{u}/n_i}} \quad (16)$$

where  $\bar{u}$  is the mean number of defects on each wafer and the variance is the same as the mean since the number of adjusted defects on a wafer follows a Poisson distribution.

2. Contract different sampling schemes (strict and loose) for different sample size  $n_1$  and  $n_2$ .

3. Determine the control limits and the warning limits of the  $U$  control chart. The control limits are  $\pm 3$  since the sample data is standardized. The warning limits can be obtained using the following formula:

$$w = f^{-1} \left[ \frac{2f(UCL)[n_0 - n_2] + n_1 - n_0}{2(n_1 - n_2)} \right] \quad (17)$$

4. Plot the sample points on the  $U$  control chart. If a sample point falls outside of the control limits, the process is said to be out of control.. If a sample point falls between the control limits and the warning limits,  $n_2$  is adopted as the next sample size. If a sample point falls within the warning limits,  $n_1$  will be used as the next sample size.

5. Return to Step2 to perform the next sampling.

### 4. CASE STUDY

This section presents a case study to demonstrate the effectiveness of the proposed approach. The required data in this case study are obtained from an IC manufacturing company in Taiwan. When the wafer goes through the process of "Metal 2 Etch," the

coordinates of the wafer's defects are collected using a KLA 2110 wafer inspection system which is a standard inspection tool utilizing the laser scan technique. Follow the steps described in Section 3, the result of each step is given as follows.

**Step 1 :** There are forty lots of wafers and each lot has twenty-five wafers. Two wafers, the fifth and the twenty-fifth wafers, of every lot were selected. The coordinates of defects and the number of defects are obtained for each wafer.

Fig. 1. The revised  $\bar{X}$  control chart

Fig.2. The revised  $MR$  control chart

**Step2:** The  $\bar{X}_{NU} - R_{NU}$  chart and  $\bar{X} - MR$  chart are constructed to detect the wafer-to-wafer variation. The results are shown in Fig, 1 and 2. No wafer-to-wafer variations are observed in these two charts.

**Step3 :**

$$w = f^{-1} \left[ \frac{2f(3)[1.5-2]+1-1.5}{2(1-2)} \right]$$

$$= f^{-1}[0.74935]$$

$$= 0.675$$

Fig 3. The proposed  $\bar{U}$  adaptive control chart

Fig..4. The traditional c-chart

The  $\bar{U}$  adaptive control chart can detect 11 out-of-control lots; while the traditional c-chart only detect 5 out-of-control points. Consequently, the proposed control process can detect small shift and determine the source of variation coming from the wafer-to-wafer variation or the lot-to-lot variation.

## 5. CONCLUSION

As the wafer size increases, a wafer's defects are no longer randomly distributed. They tend to cluster. In this study, a procedure is proposed to monitor the wafer defects in IC manufacturing. The Clustering Analysis is employed to adjust the number of wafer defects, thereby allowing not only the adjusted number of defects to satisfy the assumption of Poisson distribution but the conventional c-chart to still be used as well. The adaptive control chart is utilized to reduce the sampling cost. The proposed approach can reduce the false alarms caused by the clustered defects. The effectiveness of the proposed approach is demonstrated through a case study.

## ABSTRACT

The unexpected road blockage problem (URBP for short) is considered for the case when some blockages occur on the road at certain times and such blockages would be revealed only upon reaching them. Papadimitriou and Yannakakis proved that devising a strategy that guarantees a given competitive ratio is PSPACE-complete if the number of edges that might be blocked is not fixed; Bar-noy and Schieber considered the deterministic and stochastic variations of the recoverable-URBP in the worst-case criterion. In this paper, we present an offline algorithm for the recoverable-URBP optimal solution and the complexity of the algorithm is  $O(n^2)$  ( $n$  is the number of nodes). Two online strategies, waiting strategy and the Greedy strategy, are proposed and the competitive ratios of the two strategies are given. Furthermore, we compare the two strategies based on competitive ratio analysis.

**Keywords:** decision making, unexpected road blockage, offline algorithm, competitive ratio

## 1. INTRODUCTION

The unexpected road blockage problem (URBP for short) can be stated as follows, a traveler knows a graph (a map)  $G(V, E)$ , and the traveler has to go from  $s$  (origin) to  $t$  (destination). However, the map is unreliable, some blockages may occur on the road at certain times (blocked by unexpected events).

The unexpected road blockage problem is first introduced by Papadimitriou and Yannakakis [1], they proved that if the number of roads that might be blocked is not fixed, and then devising an online algorithm with a bounded competitive ratio is PSPACE-complete. Bar-Noy and Schieber [2] studied several variations of the problem. In the recoverable-URBP, each site is associated with a recovery time to reopen any blocked road that is adjacent to it, they presented a polynomial-time traveling strategy that guarantees the shortest worst-case travel time, in the case where an upper bound on the number of blockages is known in advance, and the recovery times are not long relative to the travel times. For the stochastic recoverable-URBP, they present an  $O(m \log n)$  ( $n$  and  $m$  are the number of nodes and edges) time algorithm for designing a travel strategy from all sites to a fixed destination that guarantees the shortest expected travel time, under the assumption that the recovery time of the blocked edges are smaller than the edge's passing time. For the deterministic recoverable-URBP, they gave an  $O(k^2 m + kn \log n)$  ( $k$  is the number of that road blockages) time algorithm for designing a travel strategy from all sites to a fixed destination guarantees the shortest worst-case travel time, under the assumption that the recovery time of the blocked edges are smaller than the edge's passing time. But, the assumption made in [2] is impractical for most transportation process. In the Irrecoverable URBP, once

a road is blocked, it remains blocked forever. Y.Xu et al [3] proposed two strategies, greedy strategy and reposition strategy, and showed that  $2k+1$  and  $2^{k+1}-1$  are their tight competitive ratios [4] [5] respectively, and proved that no online strategy has competitive ratio less than  $2k+1$  for Irrecoverable online URBP and in most cases, greedy strategy is better than reposition even though the competitive ratio of the former strategy is greater than the later ones.

In this paper, we focus on the recoverable URBP. We present an offline algorithm for the optimal solution based on analysis of the blocked edges cost (time) which is effected by the different starting time and end time of blockages, and the memory makes the problem be unfit for a converse solution of dynamic programming. The algorithm is a modification to the Dijkstra algorithm [6] and the complexity of the algorithm is  $O(n^2)$ . Then, according to the different assumptions on the recovery time, we present two different strategies, waiting strategy and the Greedy strategy; we show the competitive ratios of the two strategies. Furthermore, the comparison between these two strategies is discussed based on competitive ratio analysis.

## 2. PROBLEM STATEMENTS AND FORMULATION

Suppose the traveler has to go from  $s$  to  $t$ . He knows a map that consists of set of roads between two sites. The traveler will choose a shortest road ( $SR$  for short) from  $s$  to  $t$ . At certain times, the  $SR$  will be blocked by some events, such as traffic accidents. Assume that the blockages are recoverable. If all of the blockages' position and its recovery time are known in advance, the problem is considered as an offline

problem. If the blocked edges occur one by one without any predictable information, the problem is considered as an online problem.

### 3. AN OFFLINE ALGORITHM

Let  $G(V, E)$  denote an edge weighted graph with  $|V|$  vertices.  $v_1$  denotes the origin and  $v_n$  the destination,  $E = \{e_{ij} / (v_i, v_j), v_i, v_j \in V, i \neq j\}$  denote the set of the edges between the two sites,  $T(v_1)$  denotes the starting time of  $v_1$ ,  $T(e_{ij})$  denotes the passing time of  $e_{ij}$  without the blockage,  $T'(e_{ij})$  denotes the recovery time segment of the blockage on  $e_{ij}$ ,  $T'(e_{ij}) = [t_i', t_i'']$ ,  $t_i'$  denotes starting time of the blockage,  $t_i''$  denotes the end time of the blockage.

For convenience of the discussion, we do not distinguish the cost and the time for the traveler. In addition, all discussions are based on the following essential assumptions:

- (1) The traveler only stays at the vertices of  $G$ .
- (2) The blockage occurs on the  $e_{ij}$  only once.
- (3)  $T_1(v_1) = 0$

#### 3.1 The analysis of waiting time $T_1'(e_{ij})$

Let  $t_i$  denote the reaching time of the  $v_i$  who is the starting vertex of  $e_{ij}$ ,  $T_1'(e_{ij})$  denotes the waiting time of  $e_{ij}$ . The waiting time  $T_1'(e_{ij})$  is different from the blockages' recovery time  $T(e_{ij})$ . we consider the several cases of  $T_1'(e_{ij})$  under the different starting time and end time of blockages as follows:

- (1) If the starting time of the blockage occurs in  $[0, t_i]$  ( $t_i' < t_i'' < t_i$ ) then  $T_1'(e_{ij}) = 0$
- (2) If the starting time of the blockage occurs in  $[t_i, t_i'']$  ( $t_i \leq t_i' \leq t_i''$ ), and  $t_i' \leq T(e_{ij}) + t_i$  then  $T_1'(e_{ij}) = t_i'' - t_i$
- (3) If the starting time of the blockage occurs in  $(t_i, t_i'']$  ( $t_i < t_i' \leq t_i''$ ), and  $t_i' > T(e_{ij}) + t_i$  then  $T_1'(e_{ij}) = 0$
- (4) If the starting time of the blockage occurs in  $(t_i', t_i'']$  ( $t_i' < t_i < t_i''$ ) then  $T_1'(e_{ij}) = t_i'' - t_i$

From the above analysis, we can obtain a lemma as follows:

**Lemma 1** If the blockages are recoverable, then the

passing time of the blocked edge  $e_{ij}$  is only relative with the  $t_i''$  and  $T(e_{ij})$ , but irrelative with  $t_i'$ .

#### 3.2 Algorithm analysis

Let  $T_1(v_n)$  denote the shortest time from  $v_1$  to  $v_n$ ,  $P(v_i)$  (the shortest time from  $v_1$  to  $v_i$ ) denote the permanence label of  $v_i$ ,  $L$  (the upper bound for the passing time of the shortest paths from  $v_1$  to  $v_i$ ) denote the temperament label of  $v_i$ .

Step 1:

Let  $S_0 = \{v_1\}$ ,  $i = 1, \bar{S} = V \setminus \{v_1\}$  ( $= L \setminus \{v_1\}$ )

( $\bar{S}$  denotes the adjacent vertices set of  $v_i$ )

and

$$\begin{cases} T_1(v_1) = 0 \\ L(v_i) = \infty \end{cases} \quad v_i \in \bar{S}$$

Step 2

If  $v_n \in S_i$ , then end the computation, otherwise, turn to the next step.

Step 3

If  $v_j \notin S_i$  and  $e_{kj} = (v_k, v_j) \in E$ , from the analysis in section 3.1, compute the  $T_1'(e_{kj})$  and  $T(e_{kj}) + T_1'(e_{kj})$

Step 4

If  $L(v_j) \geq P(v_k) + (T(e_{kj}) + T_1'(e_{kj}))$ , then modify the  $L(v_j)$  to  $P(v_k) + (T(e_{kj}) + T_1'(e_{kj}))$ , Otherwise, turn to the next step.

Step 5

Let  $L(v_{i_i}) = \min_{v_j \in S} \{L(v_j)\}$ ,

if  $L(v_{i_i}) \leq +\infty$ , then update the  $L$  of  $v_{i_i}$  to  $P$ ,

and let  $P(v_{j_i}) = L(v_{j_i})$  and

$S_{i+1} = S_i \cup \{v_{j_i}\}$  ( $k = j_i$ ), then, update  $i$  to  $i+1$  and turn to step 2, otherwise, end the computation. At this time, if  $v \in S_i$  then  $T_1(v) = P(v)$ , if  $v \notin S_i$  then  $T_1(v) = L(v)$ .

#### 3.3 The complexity of algorithm analysis

Let  $n$  and  $m$  be the number of vertices and edges

in  $G(V, E)$ . In the worst-case criterion, when the traveler reaches the vertex  $v_i$ , and find all of edge which starting vertex is  $v_i$  have the blockages, we know that the computation times of  $T_1'(e_{ij})$  is  $m$ , the computation times of step3 is  $2m$  and the computation times of step3 is  $O(n^2)$  at most. From the above analysis, we know that the complexity of the algorithm is  $O(n^2)$ .

**Theorem 1** The algorithm can compute the passing time of shortest path from  $v_1$  to  $v_n$  within  $O(n^2)$  time.

#### 4. THE ONLNGE STRATEGY

Since the blockages are recoverable, when the traveler reaches the blockage, he may choose such strategies: one is that he stays at the blockage and waits for reopening of the road, then go on along the  $SR$ . It is reasonable for the traveler to wait until the road is reopened if the recoverable time is not too long. Another strategy that he chooses an efficient path goes along a new path or waits until the road reopening.

Let  $G(V, E)$  denote an edge weighted graph with  $|V|$  vertices,  $s$  denote the origin and  $t$  denote the destination,  $\delta(e_1, e_2, \dots, e_k)$   $e_i = (x_i, y_i)$

$(i = 1, 2, \dots, k)$  denote the blocked edges sequences,

$x_i (i = 1, 2, \dots, k)$  denote the beginning vertex of

$e_i, y_i (i = 1, 2, \dots, k)$  denote the ending vertex of

$e_i, t'(e_i)$  denote the recovery time for the blockage

happened at  $e_i, t(e_i)$  denote the passing time of the

$e_i, S(s, t)$  denote the cost (time) from  $s$  to  $t$

without any blockage,  $x_i - t$  denote the road from  $x_i$  to  $t$  on  $SR$ .

For convenience of the discussion, we do not distinguish the cost and the time for the traveler. In addition, all discussions are based on the following essential assumptions:

- (1)  $G$  is connected even when the blocked edges are removed.
- (2) The blockage information is available to the traveler only when he reaches it, and the passed path cannot be blocked.
- (3) When the traveler meets a blockage, he may obtain the information about the recovery time.

For the classical online problem, the competitive ratio is a constant irrelative with the sequences of events. Let

$C_{opt}(\delta)$  denote the cost of the optimal offline problem,

$C_A(\delta)$  denote the cost of the strategy  $A$  for the online problem. Strategy  $A$  is called  $\alpha$ -competitive<sup>[7][8]</sup> if the following inequality holds  $C_A(\delta) \leq \alpha \cdot C_{opt}(\delta) + \beta$ ,

where  $\alpha$  and  $\beta$  are constants irrelative with  $R$ .

Papadimitriou and Yannakakis proved that if the number of roads that might be blocked is not fixed, and then the online algorithm with a constant competitive ratio does not exist. For the URBP, we give a new definition for the function competitive ratio. Let  $C_{opt}(\delta)$  denote the cost of the optimal solution for the offline case for the traveler to go from  $s$  to  $t$ ,  $C_A(\delta)$  denote the cost of the online strategy  $A$  for the traveler to go from  $s$  to  $t$ .

Strategy  $A$  is called  $f(k)$ -competitive, if the following inequality holds

$$C_A(\delta) \leq f(k) C_{opt}(\delta)$$

where  $f(k)$  is relative with  $k$ .

We will analyze the performance of the different strategies and show the competitive ratio in the following sections.

We use the following reasonable fact to bind the optimal solution.

FACT:  $C_{opt}(\delta)$  is no less than  $S(s, t)$ .

##### 4.1 The Waiting Strategy

WS (Waiting Strategy): when the traveler reaches  $e_i$  (along the  $SR$ ) and finds that  $e_i$  is blocked and cannot pass through within  $t(e_i)$ , he choose to stay at  $x_i$  and wait for reopening of the road, then go on along the  $x_i$ . Denote this strategy as  $W$ .

The total cost of the traveler from  $s$  to  $t$  with  $W$  is

$$C_W(\delta) = S(s, t) + \sum_{i=1}^k t'(e_i) \quad (4.1)$$

From (4.1) the following equality holds

$$C_W(\delta) = \left[ 1 + \frac{\sum_{i=1}^k t'(e_i)}{S(s, t)} \right] S(s, t) \quad (4.2)$$

In order to get clearer, we make the following assumptions and all the assumptions are in accordance with the reality.

**Assumption 1**  $t'(e_i) \leq \alpha \cdot t(e_i)$  for any  $e_i$ .  
 ( $\alpha_i, i = 1, 2, \dots, k$ ) denotes the ratio of  $t'(e_i)$  to  $t(e_i)$ ,  $\alpha = \max\{\alpha_1, \alpha_2, \dots, \alpha_k\}$

As

$$\sum_{i=1}^k t(e_i) \leq S(s, t)$$

we have

$$\sum_{i=1}^k t'(e_i) \leq \alpha S(s, t)$$

Substitute into (4.1), the following inequality holds:

$$C_W(\delta) \leq (1 + \alpha) S(s, t) \quad (4.3)$$

From the above analysis, we can obtain the following theorem:

**Theorem 2** If  $t'(e_i) \leq \alpha \cdot t(e_i)$  holds, then the competitive ratio of  $W$  is  $1 + \alpha$ .

According to the definition of the competitive strategy and competitive ratio, we could conclude that  $W$  is a competitive strategy with competitive ratio  $(1 + \alpha)$  for online recoverable URBP.

Similar, if  $\alpha = 1$ , from theorem 2, we have

**Corollary 1** If  $t'(e_i) \leq t(e_i)$  holds, then the competitive ratio of  $W$  is 2.

From the above discussion, it can be found that the competitive ratio of Waiting strategy only related to  $\alpha$  (the ratio between recovery time  $t'(e_i)$  and passing time  $t(e_i)$ ), and it has no relation with the blockages numbers and their positions. When  $\alpha = 1$ , the travel time would not exceed the two times of the  $S(s, t)$ .

For waiting strategy, let  $S(x_i, t)$  denote the passing time from  $x_i$  to  $t$  when the  $i$ -th blocked edge occurs on  $S(s, t)$ . Because the blocked edges always happen at the  $SR$ , so we could further relax our assumptions.

**Assumption 2**  $t'(e_i) \leq \alpha \cdot S(x_i, t)$  for any  $e_i$ .  
 ( $\alpha_i, i = 1, 2, \dots, k$ ) denotes the ratio of  $t'(e_i)$  to  $S(x_i, t)$ ,  $\alpha = \max\{\alpha_1, \alpha_2, \dots, \alpha_k\}$

For  $S(x_i, t) \leq S(s, t)$

then  $\sum_{i=1}^k t'(e_i) \leq k \cdot \alpha S(s, t)$

Substitute into (4.1), the following inequality holds:

$$C_W(\delta) \leq (1 + k \cdot \alpha) S(s, t)$$

**Theorem 3** If  $t'(e_i) \leq \alpha \cdot S(x_i, t)$  holds, then the

competitive ratio of  $W$  is  $1 + k \cdot \alpha$

Similarly, if  $\alpha = 1$ , from theorem 1, then, we have

**Corollary 2** If  $t'(e_i) \leq S(x_i, t)$  holds, then the

competitive ratio of  $W$  is  $k + 1$ .

From the proof of theorem 3, we would find that when the assumption is further relaxed, if

$t'(e_i) \leq \alpha \cdot S(x_i, t)$  (the theorem 3 and corollary 2

always hold.

## 4.2 The Greedy Strategy

GS(Greedy Strategy): when the traveler reaches  $e_i$  (along the  $SR$ ) and finds that  $e_i$  is blocked and can not pass through within  $t(e_i)$ , he choose an efficient path, staying at  $x_i$  and waiting for reopening of the road and go on along the  $x_i - t$  or choose a new shortest path from  $x_i$  to  $t$  without the blockages, whichever is better. Denote this strategy as  $G$ .

Let  $L'(x_i, t)$  denote the cost of the road that the traveler hasn't finished. If the traveler waits at the  $x_i$  and goes through when the  $e_i$  is recovered, then the passing time would be denoted as  $L'(x_i, t) + t'(e_i)$ . If the traveler always finds a new shortest path from  $x_i$  to  $t$  without the blockages and denotes it as  $L''(x_i, t)$ , then the greedy strategy should choose the path with

$$\min\{L(x_i, t) + t'(e_i), L''(x_i, t)\}.$$

Denote  $L(s, x_i)$  as the travel time before arriving  $e_i$ ,  $S(v_1, x_1)$  as the travel time from  $v_1$  to  $x_1$  on  $SR$ ,  $S(x_1, v_n)$  as the travel time from  $x_1$  to  $v_n$  on  $SR$ ,  $C_G(\delta)$  as the total travel time from  $s$  to  $t$  by taking the greedy strategy. For simplicity, we suppose that every time the traveler chooses a new optimal path without waiting when he encounters the blocked edges, we can obtain:

$$L''(x_i, t) \leq L'(x_i, t) + t'(e_i) \quad (i = 1, 2, \dots, k)$$

In the worst case, all the blocked edges happen at the chosen optimal path and we can obtain:

$$C_G(\delta) = L(s, x_i) + L''(x_i, t) \quad (i = 1, 2, \dots, k)$$

**Assumption 1**  $t'(e_i) \leq \alpha \cdot t(e_i)$  for any

$e_i, (\alpha_i, i = 1, 2, \dots, k)$  denotes the ratio of  $t'(e_i)$  to  $t(e_i)$ ,  $\alpha = \max\{\alpha_1, \alpha_2, \dots, \alpha_k\}$

If there is only one blocked edge, we have

$$C_G(e_1) = L(s, x_1) + L''(x_1, t)$$

Since

$$L''(x_1, t) \leq L'(x_1, t) + t'(e_1)$$

$$t'(e_1) \leq \alpha \cdot t(e_1)$$

and

$$t(e_1) \leq L'(x_1, t)$$

$$L(s, x_1) = S(s, x_1)$$

$$L'(x_1, t) = S(x_1, t)$$

We obtain

$$L''(x_1, t) \leq (1 + \alpha)S(x_1, t)$$

$$\begin{aligned} C_G(e_1) &= S(s, x_1) + (1 + \alpha)S(x_1, t) \\ &= S(s, t) + \alpha S(x_1, t) \end{aligned}$$

$$S(x_1, t) \leq S(s, t)$$

$$C_G(e_1) \leq (1 + \alpha)S(s, t)$$

When encountering the second blocked edge, we also have

$$\begin{aligned} C_G(e_1, e_2) &= L(s, x_2) + L''(x_2, t) \\ &\leq L(s, x_2) + L'(x_2, t) + t'(e_2) \end{aligned}$$

Since

$$L'(x_2, t) = L''(x_1, t) - L''(x_1, x_2)$$

$$L(s, x_2) = L(s, x_1) + L''(x_1, x_2)$$

we have

$$C_G(e_1, e_2) \leq L(s, x_1) + L''(x_1, t) + t'(e_2)$$

Since  $t'(e_2) \leq \alpha \cdot t(e_2)$

$$t(e_2) \leq L''(x_1, t)$$

we have

$$C_G(e_1, e_2) \leq L(s, x_1) + (1 + \alpha)L''(x_1, t)$$

Since

$$L''(x_1, t) \leq (1 + \alpha)L'(x_1, t)$$

$$L(s, x_1) = S(s, x_1)$$

$$L'(x_1, t) = S(x_1, t)$$

we have

$$C_G(e_1, e_2) \leq (1 + \alpha)S(s, t)$$

Similarly, it could be concluded that

$$C_G(e_1, e_2, \dots, e_k) \leq (1 + \alpha)S(s, t)$$

Therefore the following theorem holds :

**Theorem 4** If  $t'(e_i) \leq \alpha \cdot t(e_i)$  holds, then the competitive ratio of  $G$  is  $(1 + \alpha)^k$ .

Similar, if  $\alpha = 1$ , from Theorem 4, we have

**Corollary 3** If  $t'(e_i) \leq t(e_i)$  holds, then the competitive ratio of  $G$  is  $2^k$ .

From the proof of theorem 4, we would find that when the assumption is further relaxed, if

$$t'(e_i) \leq \alpha \cdot S'(x_i, t), t'(e_i) \leq \alpha \cdot S'(x_i, t)$$

and corollary 3 always hold.

### 4.3 Comparisons between two strategies

Table 1 Competitive ratio between Two Strategies

Recovery time assumption	Competitive ratio	
	Waiting strategy	Greedy strategy
$t'(e_i) \leq t(e_i)$	2	$2^k$
$t'(e_i) \leq \alpha \cdot t(e_i)$	$1 + \alpha$	$(1 + \alpha)^k$
$t'(e_i) \leq S(s, t)$	$k + 1$	$2^k$
$t'(e_i) \leq \alpha \cdot S(s, t)$	$1 + k \cdot \alpha$	$(1 + \alpha)^k$

From the above analysis, within the assumption  $t'(e_i) \leq \alpha \cdot t(e_i)$ , we know that the competitive ratio of  $W$  does not relate itself to the number of the blockages, if  $0 < \alpha < 1$ , then  $S(s, t) \leq C_W(s, t)$ . In this case, the total

waiting (cost) time is very little comparing with the moving cost on  $SR$  (just as a red light for the traffic control), this means the  $W$  strategy is more efficient and the total cost (time) taken by using strategy  $W$  approaches the cost (time) taken by an offline optimal.

If  $\alpha > 1$  then  $C_W(s, t) \leq (1 + \alpha)S(s, t)$ . In this case, the total (cost) time of waiting may be very long (such as a traffic accident happens), but it needs to consider in more details to evaluate the performance of the  $W$  strategy. From (4.3), we see that the competitive ratio is mainly dependent on the ration between the total waiting time and the  $S(s, t)$ , not only on  $\alpha$ , this means that in some cases, even if  $\alpha$  is very larger, but the performance of  $W$  may still be very efficient. For the worst case (all  $\alpha_i$  are the same and  $\alpha$  is a large),  $W$  is not as efficient as the traveler expected.

We know that the competitive ratio of greedy strategy increases exponentially in anyone assumption, so, even in the worst case, waiting strategy is better than greedy strategy when the blocked edges always happen on the newly chosen path. However, people always would like to choose the greedy strategy when encounter the jam. They think that the greedy strategy is efficient and the cost of moving is less than waiting. In fact, this choice reflects that people do not have the correct expectation on unexpected crisis. Since greedy is widely acquired, so in what situation is greedy strategy superior to

waiting strategy would be the future direction of the research.

## 5. CONCLUSION

As discussed in the paper, we present an offline algorithm for the Recoverable URBP based on that the blocked edges cost (time) is effected by the different starting time and end time of blockages, and the memory makes the problem be unfit for a converse solution of dynamic programming. The algorithm is a modification to the Dijkstra algorithm, and the complexity of the algorithm is  $O(n^2)$ . The optimization theory always treats the problem from perspectives of stand-by and assumes that the constraints do not vary, which is always non-realistic. The competitive algorithm may shed some light on the optimization of the problem taking the variations of critical factors. We study the online strategies when the blockages that occur one by one without any predictable information except whose recovery time are known. By making different assumptions on the recovery time of blocked edges, two strategies, waiting strategy and the greedy strategy are proposed and the competitive ratios of the two strategies are given. Furthermore, by comparing these two strategies, it could be found that waiting strategy is superior to greedy strategy in the same assumption. For the recoverable URBP, there have some further direction to work, such as how to deal with the problem when blocked happen at the vertices.

## Discovering Fuzzy Functional Dependencies as Semantic Knowledge in Large Databases

Xue Wang, Guoqing Chen

School of Economics and Management, Tsinghua University, Beijing 100084, China  
{wangx3.03, chengq}@em.tsinghua.edu.cn

### ABSTRACT

Fuzzy functional dependency (FFD) is a kind of semantic knowledge and can be discovered from a large volume of business data. Sectional FFD and Attribute FFD are discussed so as to reflect semantics of the business world and express useful information that is natural for people to comprehend. The experimental results on an insurance data set show that the proposed method can extract knowledge efficiently and effectively.

**Keywords:** data mining, knowledge discovery, fuzzy functional dependency, Sectional FFD, Attribute FFD.

### 1. INTRODUCTION

Widespread internet applications and e-business practices have resulted in a rapid growth of the database size that is beyond the scope of expert human capabilities to scan all the collected data and to discover the useful knowledge hidden in it. Therefore, data mining and knowledge discovery, for finding interesting patterns, dependencies, summaries, regularities, etc, has become an increasingly important subject in the research area of database and business intelligence.

of the data. For example, we may get a FFD at the attribute level (Attribute FFD), such as Age  $\sim$  Salary (Age fuzzy determines Salary), but some times, we may only get FFD for sub-classes of attribute values (Sectional FFD), such as Age(young)  $\sim$  Salary(low). Hence the construction and discovery of Sectional FFD is useful and novel and can serve as a type of interesting pattern and aid to enrich the knowledge base of a company.

### 2. SECTIONAL FFDs AND ATTRIBUTE FFDs

Functional dependency (FD) is important in both database design and maintenance. The classical definition of FD is: X functionally determines Y, (or Y is functionally dependent on X), denoted by  $X \rightarrow Y$ , if and only if

$\forall t_1, t_2 \in R$ , if  $t_1(X) = t_2(X)$  then  $t_1(Y) = t_2(Y)$ . But in real world applications, information is often incomplete or

#### 2.1 Notions

ambiguous. For example, customers may not be willing to provide their actual age but "about twenty", "middle aged", "25-30" or the like. With the inception of fuzzy logic [13] to model imprecise information, fuzzy extensions has been introduced into functional dependency and linguistic summarization of quantitative data values. different aspects since 1980's (Prade et al. [5] Raju et al.[6] Bhuinya et al.[1], Chen et al.[2][3], Cubero et al[4], Saxena et al.[7], S.Ben Yahia et al.[11], etc). A general setting of fuzzy functional dependencies proposed by Chen et al is as follows [2]:

Let  $U$  be the set of all attributes for a relation scheme  $R$  and  $X, Y \subseteq U$ . X functionally determines Y (or Y is functionally dependent on X) to the degree  $\phi$ , denoted by

$X \rightarrow_{\phi} Y$ , if and only if for any tuples  $t_1, t_2$ ,  

$$\min_{t_1, t_2 \in R} I(c(X(t_1), X(t_2)), c(Y(t_1), Y(t_2))) \geq \phi \quad (1)$$

where  $\phi \in [0,1]$   $I$  is a fuzzy implication operator (FIO) and  $c$  is an equality measure.

When dealing with fuzzy data, linguistic labels are defined in a unified way with membership grades. Examples of these labels are small, large and young. In some situations, such labels are used to represent abstract and linguistic summarization of quantitative data values. Thus, the data concerned can be represented in the form of a vector like  $V(\mu_1/L_1, \mu_2/L_2 \dots \mu_n/L_n)$ , where  $L_1 \dots L_n$  are labels and  $\mu_1 \dots \mu_n$  are membership grades. Next, we replace this vector with the maximal membership grade and its corresponding label  $\mu_i/L_i$  where  $\mu = \max(\mu_1 \dots \mu_n)$ . For instance, "about 50" can be translated into "0.9/old".

**Definition 1** Let  $U$  be the set of all attributes for a relation scheme  $R$ , and  $X, Y \subseteq U$ ,  $L_1 \dots L_n$  are labels of X and  $L'_1 \dots L'_n$  are labels of Y. For a tuple  $t$  in  $R$ , its X and Y values are  $\mu_i/L_i$  and  $\mu'_j/L'_j$ .  $\theta, \alpha \in [0,1]$ , where  $\alpha$  is a given threshold.  $t$  satisfies a tuple relation to the degree  $\theta$ , denoted by  $X(t, i) \sim_{\theta} Y(t, j)$  if and only if

$$\theta = I(\mu_i, \mu'_j) \geq \alpha \quad (2)$$

In a similar spirit, our previous work [12] presented a specific type of fuzzy functional dependency based on tuples and label closeness measures, which has a good arithmetic efficiency in the context of data mining. In addition, it can reflect both overall and partial knowledge. In FIOs are Lukasiewicz operator, Kleene-Dienes operator, Gödel operator, R operator, etc. Here, we choose R

implication operator [8] as an example to derive a specific form of tuple relation which has some good properties as stated in section 2.3.

$$I_{R_0}(a, b) = \begin{cases} 1 & \text{if } a \leq b \\ \max(1-a, b) & \text{otherwise} \end{cases} \quad (3)$$

**Definition 2** Label closeness measure which describes the relationship between two given labels denoted by  $\sigma(L_i, L_j)$ , satisfies the following properties:

- 1)  $\sigma(L_i, L_i) = 1$  (4)
- 2)  $\sigma(L_i, L_j) = \sigma(L_j, L_i)$  (5)

More specifically, for  $L^* = \{L_1, \dots, L_n\}$ , let  $\Theta(L^*) = \min(\sigma(L_i, L_j) \mid L_i, L_j \in L^*)$  and for  $L^{**} = \{L_1^*, L_1^*, \dots, L_n^*\}$ , which is a set of sets  $\Theta(L^{**}) = \min(\sigma(L_1^*), \sigma(L_1^*) \dots \sigma(L_n^*))$ .

**Definition 3** For any label  $L_i$  of  $X$ , all tuples satisfying the tuple relation  $X(t, L_i) \sim_{\theta} Y(t, L'_j)$  compose a set  $T_i$ . more formally,  $T_i = \{t \mid X(t, L_i) \sim_{\theta} Y(t, L'_j)\}$ . All those  $L'_j$  compose a set named LA Sectional FFD, denoted by  $X(L_i) \sim_{\theta} Y(L_i^*)$  is valid if and only if

$$\Theta(L_i^*) \geq \beta \quad (6)$$

where  $\beta$  is a given threshold between 0 and 1,  $\theta = \min(\Theta)$ .

**Definition 4** An Attribute FFD (AFFD)  $X \sim_{\theta} Y$  holds if and only if for any two label  $L_i$  and  $L_j$ , the Sectional FFDs  $X(L_i) \sim_{\theta} Y(L_i^*)$  hold and

$$I'(\sigma(L_i, L_j), \sigma(L_i^*, L_j^*)) \geq \omega \quad (7)$$

where  $I'$  is a FIO and  $\omega$  is a given threshold.  $\Theta' = \min(\Theta)$ .

Here we also use  $R$  to derive a specific form of FFD. We can easily see, if  $L^*$  is a single element set, the Sectional FFD  $X(L_i) \sim_{\theta} Y(L_i^*)$  mentioned above is surely valid.

## 2.2 An Example

The following table is part of a fuzzy relational database. The membership functions of attribute labels are given in figure 2. (with  $\omega=0.7$ ,  $\alpha=0.7$ )

T#	Age	Salary
t1	Young	1200
t2	35	0.8/low
t3	About 30	About 1500
t4	50-55	3800
t5	0.9/old	5000
t6	60	0.9/high

Table 1 Example data table

Figure 2 Membership functions

**The first step:** transform all values in table 1 into table 2 using maximal membership grade and its corresponding label.

T#	Age	Salary
t1	1/young	0.8/low
t2	0.75/young	0.8/low
t3	0.7/young	0.72/low
t4	0.75/old	0.8/high
T5	0.9/old	1/high
T6	1/old	0.9/high

Table 2 Transformed data

**The second step:** check if for every tuple, the tuple relation holds. We can easily derive that  $\text{Age}(t_1, \text{young}) \sim_{0.8} \text{Salary}(t_1, \text{low})$ ,  $\text{Age}(t_2, \text{young}) \sim_{0.75} \text{Salary}(t_2, \text{low})$ ,  $\text{Age}(t_3, \text{young}) \sim_{0.72} \text{Salary}(t_3, \text{low})$ ,  $\text{Age}(t_4, \text{old}) \sim_{0.75} \text{Salary}(t_4, \text{high})$ ,  $\text{Age}(t_5, \text{old}) \sim_{0.9} \text{Salary}(t_5, \text{high})$ ,  $\text{Age}(t_6, \text{old}) \sim_{0.9} \text{Salary}(t_6, \text{high})$ . If the threshold  $\alpha = 0.7$  then all tuple relations hold.

**The third step:** for attribute Age, label young has three tuples  $t_1, t_2$  and  $t_3$ , the corresponding label in attribute Salary  $L^* = \{\text{low}\}$ ,  $L^*$  is a single element set, so the sectional FFD  $\text{Age}(\text{young}) \sim_{0.72} \text{Salary}(\text{low})$  holds. In the same way, we can easily derive  $\text{Age}(\text{old}) \sim_{0.9} \text{Salary}(\text{high})$ , in addition,  $R(\sigma(\text{young}, \text{old}), \sigma(\text{low}, \text{high})) = 1 > \omega$ , then the Attribute FFD  $\text{Age} \sim_{0.72} \text{Salary}$  holds.

Notably, if the salary of the first tuple is 0.8/high instead of 0.8/low, we will get  $\text{Age}(\text{young}) \sim_{0.8} \text{Salary}(t_1, \text{high})$ . Therefore, for the left side label "young",  $L^* = \{\text{low}, \text{high}\}$ , we have to compute  $\sigma(\text{low}, \text{high})$ . If  $\sigma(\text{low}, \text{high})$  is below the given threshold, the Sectional FFD  $\text{Age}(\text{young}) \sim_{\theta} \text{Salary}(\text{low}, \text{high})$  is denied.

## 2.3 Properties

It can be proved that Attribute fuzzy functional dependencies with  $R$  implication operator have the following important properties.

- 1) **Reflexivity:** if  $Y \subseteq X \subseteq U$ , where  $X$  is a set of attributes, the  $X \sim_{\theta} Y$  holds. It is a trivial fuzzy functional dependency.
- 2) **Augmentation:** if  $X \sim_{\theta} Y$  holds, then for  $Z \subseteq U$ ,  $XZ \sim_{\theta} YZ$  holds.
- 3) **Union Rule:** if  $X \sim_{\theta} Y$ ,  $X \sim_{\theta} Z$ , then  $X \sim_{\theta} YZ$ .
- 4) **Decomposition Rule:** if  $X \sim_{\theta} Y$ ,  $Z \subseteq Y$ , where  $Y$  is a set of attributes, then  $X \sim_{\theta} Z$ .
- 5) **Partial Transitivity:** if  $X \sim_{\theta} Y$  and  $Y \sim_{\eta} Z$  with  $\tau, \eta \geq 1/2$ , then  $X \sim_{\gamma} Z$  holds with  $\gamma = \min(\tau, \eta)$ .

### 3. MINING ALGORITHM

In this section, we'll present a mining algorithm to discover Sectional FFDs and Attribute FFDs.

As shown in section 2.3, the AFFD  $X \sim YZ$  can be decomposed into  $X \sim Y$  and  $X \sim Z$ . Therefore we will deliberate to find non-trivial AFFDs, each with a single attribute in its right-hand side. We can derive the minimal FFD set using a map listed below. For example, the line between X and XY means we will check whether the AFFD  $X \sim Y$  holds, in the same way, the line between XY and XYZ means we will check whether the AFFD  $XY \sim Z$  holds. An algorithm of the mining procedure for  $X \sim Y$  is as follows.

Figure 3 Map for mining

INITIALIZING:

for each Label  $L_k$  of X

$L_k^* := \phi$ ;

sectional\_flag(k) := valid;

attribute\_flag := valid;

end for

MINING

for each t in R

get corresponding X,Y value/ $\mu_i, \mu_j/L'_j$ ;

compute  $\theta := I(\mu_i, \mu'_j)$ ;

if  $\theta < \alpha$

tuple relation is denied;

sectional\_flag(i) := denied;

else

add  $L'_j$  into the set  $L_k^*$ ;

end if

end for

for every label  $L_i$  of X

if sectional\_flag(i) = valid &  $|L_i^*| \geq \beta$

the sectional FFD  $X(L_i) \sim Y(L_i^*)$  holds;

else

attribute\_flag := denied;

end if

end for

if attribute\_flag = valid

for every two labels  $L_i, L_j$  of X

if  $I(\sigma(L_i, L_j), \sigma(L_i^*, L_j^*)) < \omega$

attribute\_flag := denied;

break;

end if

end for

end if

if attribute\_flag = valid

the Attribute FFD  $X \sim Y$  holds

end if

When mining such FFDs from databases, we need to check every tuple to see if it satisfies tuple relation and compute label closeness value. For  $X \sim Y$ , if X has  $M$  labels and Y has  $M'$  labels, the algorithm's complexity is at  $O(N + M^2 + M'^2)$ . In general,  $M, M' < N$ , so valuable patterns could be discovered quite efficiently.

### 4. EXPERIMENTAL RESULTS

We have carried out an experiment on a real business data set <http://www.smr.nl>. The algorithm was developed in C language, and run on PC with PIII866, RAM 256M, and Windows 2000 professional.

#### 4.1 Data Description

The data set is a real set of an insurance company, provided by "Dutch Data Mining company sentient machine research". It contains 5822 tuples (transactions) and 86 attributes such as "number of houses", "customer main type", "average size household", etc. Because of space limitation, we only present the results discovered between the first 10 attributes within all tuples. Table 3 gives a general description of these first 10 attributes.

No	Description	Domain
1	Customer Subtype	1 High Income, expensive child ... 15 Household with children ... 41 Mixed rurals
2	Number of houses	Number of 1-10
3	Avg size household	1-6 (1 is the smallest, 6 the largest)
4	Avg age	1 20-30 years ... 6 70-80 years
5	Customer main type	1 Successful hedonists ... 8 Family with grown ups ... 10 Farmers
6	Roman catholic	0 0% 1 1 - 10% ... 9 100%
7	Protestant	0 0% ... 9 100%
8	Other religion	0 0% ... 9 100%
9	No religion	0 0%... ... 9 100%
10	Married	0 0% ... 9 100%

Table 3 Data Description

#### 4.2 Data Preparation

Among the descriptions above, we can see that there are

fuzzy values, such as "Avg size household", graded knowledge is deemed interesting and novel, which may values, such as "Avg age" and crisp values, such as provide decision-makers with a better understanding of "Customer Subtype". We first transformed all fuzzy the customers. terms or graded figures into a unified type – linguistic labels with corresponding membership grades. For example, there are six ranks in the attribute of "Avg size household" – "1, the smallest and 6 the largest". We in this paper, we have discussed Attribute FFD and transfer them into 3 labels as "small, middle, large", and Sectional FFD as a kind of semantic knowledge which the original graded values can be translated as shown in Table 4.

Rank	Label/value
1	small/1
2	small/0.9
3	medium/0.9
4	medium/1
5	large/0.9
6	large/1

Table 4 Fuzzy values of "Avg size household"

At the same time, we defined label closeness measures. For example  $\sigma$  (small, medium) = 0.8,  $\sigma$  (medium, large) = 0.8,  $\sigma$  (small, large) = 0.

#### 4.3 Results

For illustrative purposes, we only list several sectional FFDs (Table 5) and Attribute FFDs (Table 6) with top  $\theta$  values.

No	Sectional FFDs
1	Sub type [ 15 ] $\sim \rightarrow$ number of houses [ many ]
2	Sub type [ 15 ] $\sim \rightarrow$ age [ old ]
3	Sub type [ 15 ] $\sim \rightarrow$ protestant [ medium ]
4	age [ young ] $\sim \rightarrow$ number of houses [ small ]
5	Number of houses[huge] $\rightarrow$ size of household [ small ]
6	Protestant [large] $\rightarrow$ roman catholic [very small, small]

Table 5. Sectional FFDs

No	Sectional FFDs
1	sub type $\rightarrow$ main type
2	number of houses $\rightarrow$ size of household
3	size of household $\rightarrow$ number of houses
4	size of household $\rightarrow$ age
5	age $\rightarrow$ number of houses
6	age $\rightarrow$ size of household
7	main type $\rightarrow$ number of houses
8	roman catholic $\rightarrow$ number of houses
9	married $\rightarrow$ number of houses

Table 6. Attribute FFDs

From the Attribute FFDs discovered, we can find some interesting patterns. For example, "number of houses" are determined by "size of household", "avg age", "main type", "roman catholic", "married", etc. Therefore "number of houses" is dependent on other attributes to a great extent. As to Sectional FFDs, they can reflect dependencies that hold partially. We can find that among Sectional FFDs, customers of "sub type 15" have many other behaviors in common. They are all old, have many houses, more than 50% of them are protestant. Such

## 5. CONCLUSION

In this paper, we have discussed Attribute FFD and Sectional FFD as a kind of semantic knowledge which can reflect overall or partial knowledge of the data in a manner that is natural for people to comprehend. The experimental results on an insurance data set showed that the proposed method can extract knowledge efficiently and effectively.

# E-Business Data Warehouse Design and Implementation

Xudong Chen

Computer Department, Jiaying University, MeiZhou 514015, China  
chenxd@jyu.edu.cn

## ABSTRACT

E-Business have a variety of on-line transaction processing (OLTP) systems and operational database. Data Warehouse is different from operational database. A data warehouse is a subject-oriented, integrated, time-variant, and non-volatile collection of data in support of management's decision-making process. The features of Data Warehouse cause the its design process and strategies to be different from the ones for OLTP Systems. This paper presents a brief description of approaches that address the data warehouse Design and Implementation for E-business.

**Keywords:** E-Business, Data Warehouse, Data Warehouse Design, OLAP , Dimensional models

## 1. INTRODUCTION

In the last decade, we witnessed numerous extraordinary business and technology innovations, such as business process reengineering, enterprise resource planning systems, and electronic business<sup>[6]</sup>. As transaction databases become more powerful, communication networks grow, and the flow of commerce expands, E-Business have accumulated a variety of on-line transaction processing (OLTP) systems and operational database.

OLTP systems (such as financial, order, work scheduling) which create operational data operational data focuses on transactional functions. This data is part of the corporate infrastructure. It is detailed, nonredundant, and updateable.

However, the rapidly changing market dynamics, competitive pressures, globalization of the commercial markets, reduced profit margins, and other similar factors forced business to review their structures, approaches and strategies<sup>[1]</sup>.

A data warehouse collects, organizes, and makes data available for the purpose of analysis in order to give management the ability to access and analyze information about its business. This type of data can be called informational data. The systems used to work with informational data are referred to as online analytical processing (OLAP).

OLAP is the technology that enables client applications to efficiently access the data organized by data market and data warehouse. Data warehouse, provide a database organized for OLAP rather than OLTP, can solve OLTP problems.

Data warehousing is one of the most important strategic initiatives in the information systems field. These repositories of data play critical roles in understanding customer behavior in customer to business e-commerce, connecting trading partners along the supply chain, implementing customer relationship management

strategies, and supporting comprehensive performance measurement systems<sup>[7]</sup>.

## 2. DATA WAREHOUSING ARCHITECTURE

Bill Inmon defined the term data warehouse: "A (data) warehouse is a subject-oriented, integrated, time-variant, and non-volatile collection of data in support of management's decision-making process."<sup>[4]</sup>. Subject-oriented: Data that gives information about a particular subject. Integrated: Data that is gathered into the data warehouse from a variety of sources and merged into a coherent whole. Time-variant: All data in the data warehouse is identified with a particular time period.

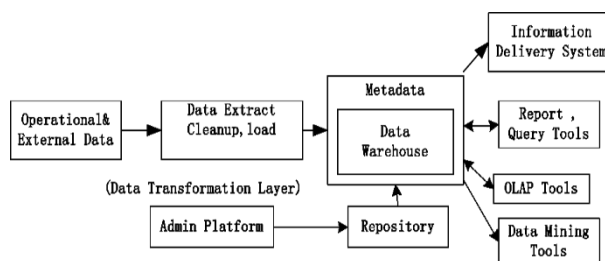

Fig. 1 Data Warehouse Architecture (Refers to Berson 1997)

Data warehouse architecture is based on a relational database management systems server that functions as the central repository for informational data (see Fig.1). Data transformation layer involves a wide range of transformations that have to be applied to source data, for example data quality control and data cleaning, data integration, and conversions that are necessary for adapting data to the DW structures. Metadata: It is data about data that describes the data warehouse, used for building, maintaining, managing, and using the data warehouse. Information delivery system: It distributes data warehouse to other data warehouse and end-user. Data Mining: It is the process of discovering meaningful new correlations, patterns, and trends by mining large amounts of data stored in data warehouse.

### 3. DATA WAREHOUSE DESIGN AND IMPLEMENT

#### 3.1 Data warehouse design

Data warehouse design is different from traditional OLTP. Kimball, Ralph (1996) proposed Nine-Step Method in the Design of Data Warehouse<sup>[3]</sup>: 1. Choosing the subject matter. 2. Deciding what a fact table represents. 3. Identifying and conforming the dimensions. 4. Choosing the facts. 5. Storing precalculations in the fact table. 6. Rounding out the dimension tables. 7. Choosing the duration of the database. 8. The need to track slowly changing dimensions. 9. Deciding the query priorities and the query modes.

Most successful data warehouses design are based on a dimensional model. Dimensional models<sup>[2,5]</sup> represent data with a "cube" structure, making more compatible logical data representation with OLAP data management. The key to build data warehousing is data design. The business users know what data they need and how they want to use it. Focus on the users, determine what data is needed, locate sources for the data, and organize the data in a dimensional model that represents the business needs.

The basic concepts of dimensional modelling include: A fact, dimensions and measures. A fact is a collection of related data items, consisting of measures and context data. It typically represents business items or business transactions. A dimension is a collection of data that describe one business dimension. Dimensions determine the contextual background for the facts; they are the parameters over which we want to perform OLAP. A measure is a numeric attribute of a fact, representing the performance or behaviour of the business relative to the dimensions.

The principal characteristic of a dimensional model is a set of detailed business facts surrounded by multiple dimensions that describe those facts. When realized in a database, the schema for a dimensional model contains a central fact table and multiple dimension tables. A dimensional model may produce a star schema or a snowflake schema.

Fig. 2 The star schema example

The star schema is the basic structure for a dimensional model. It has one large fact table and a set of smaller dimensions tables arranged in a radial pattern around the central table.

In this example (see Fig. 2): Sales table is fact table. Time table, customer table, Seller table, Product table and Manufacturing table are dimensional table.

The snowflake schema is the result of decomposing one or more of the dimensions. The many-to-one relationships among sets of attributes of a dimension can separate new dimension tables, forming a hierarchy.

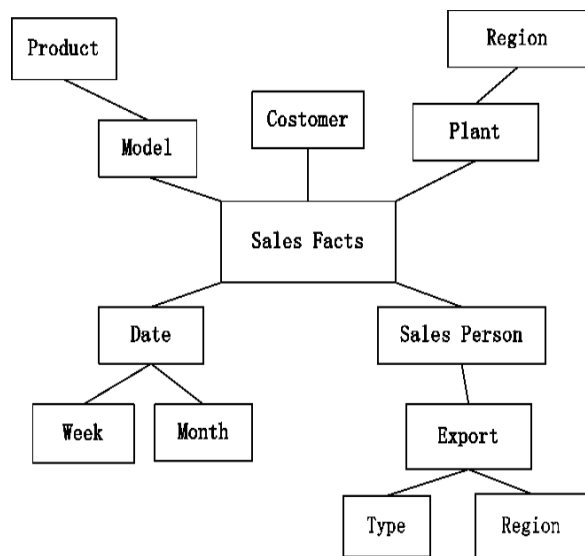

Fig. 3 The snowflake schema example

In this example(see Fig. 3), Sales table is fact table, but one or more dimension tables do not join directly to the fact table but must join through other dimension tables.

Both star and snowflake schemas are dimensional models; the difference is in their physical implementations. Snowflake schemas support ease of dimension maintenance because they are more normalized. Star schemas are easier for direct user access and often support simpler and more efficient queries.

#### 3.2 Data Warehouse Implementation

Data Warehouse implementation must include mechanisms to migrate data into the data warehouse database. This process of data migration is generally referred to as the extraction, transformation, and loading (ETL) process (see Fig. 4).

Fig. 4 The Data Warehouse Implementation Process

During the ETL process, data is extracted from an OLTP database, transformed to match the data warehouse schema, and loaded into the data warehouse database. Many data warehouses also incorporate data from non-OLTP systems, such as text files, legacy systems, and spreadsheets; such data also requires extraction, transformation, and loading.

### 3.2.1 Extract data from source systems

This phase is responsible for extracting data from the source system. During extraction, data may be removed from the source system or a copy made and the original data retained in the source system. It is common to move historical data that accumulates in an operational OLTP system to a data warehouse to maintain OLTP performance and efficiency.

### 3.2.2 Transform the data

This phase is responsible for data validation, data accuracy, data type conversion, and business rule application. Data Validation: Check that all rows in the fact table match rows in dimension tables to enforce data integrity. Data Accuracy: Ensure that fields contain appropriate values, such as only "off" or "on" in a status field. Data Type Conversion: Ensure that all values for a specified field are stored the same way in the data warehouse regardless of how they were stored in the source system. Business Rule Application: Ensure that the rules of the business are enforced on the data stored in the warehouse.

### 3.2.3 Load data to Data warehouse

This phase is responsible for loading transformed data into the data warehouse database. Data warehouses are usually updated periodically rather than continuously, and large numbers of records are often loaded to multiple tables in a single data load. The data warehouse is often taken offline during update operations.

### 3.2.4 User and application access the data

This phase rely on a suite of tools. The best way to choose this suite includes the definition of different types of access to the data and selecting the best tool for that kind of access. In general, access types include: Reporting, Ranking, Multivariable analysis, Time series analysis, Data visualization, graphing, charting, and pivoting, Statistical analysis, Artificial intelligence technique, OLAP tool, data mining tool, etc. Many tools and applications can be used to access warehouse data.

## 4. CONCLUSION

As transaction databases become more powerful, communication networks grow, and the flow of commerce expands, E-Business have accumulated a variety of on-line transaction processing (OLTP) systems and operational database. Data Warehouse is different from operational database. Data warehouses have been used to support business decision makers. A data warehouse is a subject-oriented, integrated, time-variant, and non-volatile collection of data in support of management's decision-making process.

The key to build data warehousing is data design. The business users know what data they need and how they want to use it. Focus on the users, determine what data is needed, locate sources for the data, and organize the data in a dimensional model that represents the business needs. Dimensional modeling is the foundation of data warehouse design. A dimensional model may produce a star schema or a snowflake schema. the schema for a dimensional model contains a central fact table and multiple dimension tables.

Data Warehouse implementation include: extracting, transforming, and loading the data into the data warehouse, creating the OLAP and data mining analytical applications, developing end-user tools.

### ABSTRACT

This paper use linear regression and non-linear artificial neural network (ANN) model to analyze how the four economic factors: national income (NI), population (POP), gross of domestic production (GDP), and consumer price index (CPI), affect Taiwan's electricity consumption, furthermore, develop an economic forecasting model. Both models agree with that POP and NI are of the most influence on electricity consumption, whereas GDP of the least. Then, we compare the out-of-sample forecasting capabilities of the two models. The comparing result indicates that the linear model is obviously of higher bias value than that of ANN model, and of weaker ability of forecasting capability on peaks or bottoms. This probably results from: 1) linear regression model is built on the logarithm function of electricity consumption, and ANN is built on the original data; 2) ANN model is capable of catching sophisticated non-linear integrating effects. Consequently, ANN model is the more appropriate between the two to be applied to building an economic forecasting model of Taiwan's electricity consumption.

**Keywords:** electricity consumption, artificial neural network, linear regression

### 1. INTRODUCTION

Modeling electrical demand and energy consumption is usually based on historical consumption and the relationship of this consumption to other relevant variables, such as: economic, demographic, climatic, energy price, etc. Multivariate modeling along with cointegration techniques or regression analysis were used in a number of studies on different countries [1-7] to investigate the influence of different determinants on energy consumption. Recently, some studies address to compare forecasting performance for energy consumption using different models on different countries [8-10]. Variables affecting demand and energy consumption may vary from one region to another. A model developed for one region may not be appropriate for another region. Electrical consumption models are required for a variety of utility activities. Therefore, model should be developed for different region for efficient planning and organization.

Taiwan's energy consumption rises sharply from 52.01 million kiloliters of oil in 1990 to 103.42 million kiloliters of oil in 2003 because of rapid economy growth and higher living standard. Among the energy forms consumed, petroleum took up 44.2% in 1990 to 39% in 2003; coal 12.8% to 10.7%; natural gas & liquid natural gas 3% to 2.3%, and electricity 40% to 48%. Electricity consumption takes up almost 50% of the total final energy consumption in 2003. The main object of this study is to analyze and discuss Taiwan's electricity consumption. We focus on the effect brought by four economic factors: NI, POP, GDP, and CPI, on electricity consumption (ELEC) for Taiwan. Moreover, to build a linear and a non-linear economy forecasting models which could be useful to relating government authorities for controlling electrical energy supply.

The rest of this paper is organized as follows: section 2 records the results of data analysis and review. Section 3 presents the empirical results and comparing results of linear and nonlinear models, whereas the last section briefs our findings and concludes.

### 2. DATA ANALYSIS

The data applied here are 156 monthly data recorded January 1990 through December 2002. The first 132 data recorded 1990 through 2000 are studied to build the forecasting model, while the last 24 data recorded 2001 through 2002 are applied to testify the model. ELEC and the four economic factors: NI, POP, GDP, and CPI, are collected from AREMOS database supervised by the Education Ministry Taiwan. The factor NI has rather high linear relativity with POP (0.99) and CPI (0.97), while POP reacts the same to CPI (0.96). The scatter plot of ELEC to four economic factors exhibit logarithmic trend. So, Log (ELEC) is considered dependent variable in this research. Fig. 1 shows the electricity consumed annually from 1990 to 2002. The consumption gradually increases to hit the peak in summertime, and decreases to the bottom in wintertime.

Fig. 1 Electricity consumption in Taiwan

### 3. EMPIRICAL RESULTS

The following five linear and one nonlinear models are used to find how POP, NI, GDP, and CPI affect Taiwan's electricity consumption, furthermore to build a forecasting model for the issue.

#### 3.1 Multiple linear regression models

This section analyzes and discusses the effect that the four economic factors have on electricity consumption with linear regression model, and develops an economic forecasting model. Because of the linear relationships between logarithm function of electricity consumption and economic factors, this paper use the Log (ELEC) as dependent variable. Taking multicollinearity into account, the experimental formulas are extracted after deleting NI and CPI variables selected by the models with statistics of Mallows C(p) [11], Adj-R<sup>2</sup>, and VIF.

$$\text{Model 1: } LELEC_t = a_1 + b_1 TEMP_t + c_1 GDP_t + e_{1t}$$

$$\text{Model 2: } LELEC_t = a_2 + b_2 TEMP_t + c_2 CPI_t + e_{2t}$$

$$\text{Model 3: } LELEC_t = a_3 + b_3 TEMP_t + c_3 POP_t + e_{3t}$$

$$\text{Model 4: } LELEC_t = a_4 + b_4 TEMP_t + c_4 NI_t + e_{4t}$$

$$\text{Model 5: } LELEC_t = a_5 + b_5 TEMP_t + c_5 NI_t + d_5 GDP_t + e_{5t}$$

where  $LELEC = \text{Log (ELEC)}$ .

Model 1- 4 present how the four economic factors affect electricity consumption under controlled the temperature,

respectively. Table 1 indicates that POP and NI affect Taiwan's electricity consumption the most reaching 95.18% and 95.17% respectively followed by CPI (92.48%), while GDP the least (59.25%). The normality test for residuals of each model is recorded in Table 1.

Though GDP and CPI are both significant indicators to a country's economy, they don't affect Taiwan's electricity consumption as much as the others. This could result from Taiwan government's enforcement on electricity saving and economizing policy.

Model 5, the best economic forecasting model for electricity consumption, is formulated after deleting NI and CPI variables selected by the statistics of Mallows C(p), Adj-R<sup>2</sup>, and VIF. The procedure is practiced to prevent multicollinearity. Compared with model 4, model 5 shows that GDP has significant effect on Taiwan's electricity consumption, but it only surpasses model 4 by 0.34 (=0.9551 - 0.9517). The last row in Table 1 present the estimated coefficient values of standardized regression model. It shows the most crucial factors affecting Taiwan's electricity consumption, according to priority, are NI (0.803), TEMP (0.381), and GDP (0.082). The result agrees with those of model 1 to 4. The Adj-R<sup>2</sup> of model 5 reaches 0.9551, and passes the normality test for residuals ( $p\text{-val}=0.1438$ ). Below is the formula of model 5:

$$LELEC = 14.639 + 0.024 TEMP + 1.47 \times 10^6 NI + 5.44 \times 10^8 GDP$$

Table 1 Coefficients using regression and standardized regression

		Intercept	TEMP	GDP	CPI	M	NI	Adj-R <sup>2</sup>	Normality ( $p\text{-val}$ )	Size
Model 1	Estimate	14.462* (120.71)	0.028* (7.77)	4.07E-7* (10.92)				<b>0.5925</b>	0.0060	132
	Standardized	0	0.434	0.610						
Model 2	Estimate	13.134* (176.36)	0.022* (14.42)		0.027* (34.88)			0.9248	0.3100	132
	Standardized	0	0.349		0.845					
Model 3	Estimate	8.019* (47.27)	0.023* (18.29)			3.59E-4* (44.38)		0.9518	0.0379	132
	Standardized	0	0.355			0.860				
Model 4	Estimate	14.726* (466.41)	0.024* (19.69)				1.57E-6* (44.33)	<b>0.9517</b>	0.0197	132
	Standardized	0	0.381				0.857			
Model 5	Estimate	<b>14.639*</b> (364.79)	<b>0.024*</b> (20.45)	<b>5.44E-8*</b> (3.30)			<b>1.47E-6*</b> (32.30)	<b>0.9551</b>	<b>0.1438</b>	132
	Standardized	0	<b>0.381</b>	<b>0.082</b>			<b>0.803</b>			

\* Indicates statistical significance at the 0.05 level.

$t$  statistics are in the parentheses.

The model residuals are amplified by exponential transformation because we are fitting the regression model to transformed data (Log (ELEC)) and then must convert prediction for logarithmic back to untransformed units. So, we build a non-linear ANN model on the original value of electricity consumption.

#### 3.2 ANN models

The artificial neural network (ANN) consists of an input layer, an output layer and one or more intervening layers also referred to as hidden layers. Each layer consists of multiple neurons that are connected to neurons in adjacent layers. The connection weights and node biases are the model parameters.

To use an ANN model for forecasting, forecasters must first build it. The model building process is called the network training or learning. Usually, in applications of ANNs, total available data are split into a training set and a test set. The training set is used to build the network model and then the forecasting ability of the network is evaluated from the test set. In this paper, the 132 monthly data recorded 1990 through 2000 are training samples, while the 24 monthly data recorded 2001 through 2002 are testing samples. POP, NI, GDP, CPI, and TEMP are the network input values, and electricity consumption is network output value. More than 60 experiments are performed to determine the best combination of the learning rate, momentum, number of hidden layers, number of hidden nodes, learning rule, and transfer

$$S_i = \frac{\partial \hat{Y}}{\partial X_i} = \sum_{t=1}^h \frac{\partial \hat{Y}}{\partial NET_t} \frac{\partial NET_t}{\partial Z_t} \frac{\partial Z_t}{\partial NET_t} \frac{\partial NET_t}{\partial X_i} = \sum_{t=1}^h [f'(NET_t) v_t f'(NET_t) w_{it}] \quad (1)$$

The absolute sensitivity value of each input variable represents its relative effect with electricity consumption. Crucial factors affecting electricity consumption are, by priority, NI, POP, TEMP, CPI and GDP, and their absolute sensitivities are 15.142, 7.696, 3.068, 2.344 and 0.989 (see Table 2). The result agrees with that of regression model on which the economy indicators, GDP and CPI, are not the key factors to Taiwan's electricity consumption, but POP and NI.

Table 2 The sensitivities of electricity consumption to five economic factors

	TEMP	GDP	CPI	POP	NI
Sensitivity	<b>3.068</b>	<b>0.989</b>	<b>-2.344</b>	<b>7.696</b>	<b>15.142</b>

Once the two models to predict monthly electricity consumption are developed, we empirically examine the relative effectiveness of the models in predicting electricity consumption using the data from January 2001 to December 2002.

### 3.3 Out-of-sample forecasting performance results

We use three statistics: RMSE, MAE, MAPE, and scatter diagram to see the out-of-sample ability of the linear and the non-linear models. Table 3 shows the three statistic values fall sharply from 1509559.37, 1342149.39, and 8.60% of linear model to 635378.69, 460738.5, and 3.29% of ANN model. It is because of: 1) the dependent variable of regression model is the logarithm value of electric consumption, while the artificial neural network model trains the original value of electricity consumption; 2) the ANN is capable of catching sophisticated non-linear integrating effect. Fig. 6 presents the forecasting values of two forecasting models and ELEC actual value. It clearly shows that the ANN forecast value is closer to the ELEC actual value, and regression model is weaker on foretelling peaks and bottoms. This result proves that the ANN is more appropriate to be applied to build an economic forecasting model for Taiwan's electricity consumption.

function to utilize.

Throughout the training, the NeuralWare utility, 'SAVEBEST' is used to monitor and save the lowest root mean square (RMS) error value from the testing set. The best RMS error result is obtained using a learning rate of 0.2, a momentum of 0.1, and 6 neurons in a single hidden layer that use the generalized delta learning rule and a sigmoid transfer function. The architecture of the best network contains 5 input layer neurons, 6 hidden neurons, and 1 output layer neuron (5:6:1 architecture). The estimations of connection weights  $w_{it}$  and  $v_t$  are obtained, then apply them to formula (1) to calculate the sensitivities  $\hat{S}_i$  (Hwang, Choi, Oh, & Marks [12]).

Table 3 Comparing forecasting measurement errors

	RMSE	MAE	MAPE
Regression	1509559.37	1342149.39	8.60%
ANN	<b>635378.69</b>	<b>460738.50</b>	<b>3.19%</b>

Fig. 2 Actual and forecasted values for Taiwan's electricity consumption

## 4. CONCLUSION

By adopting linear regression and non-linear ANN models, surprisingly, we find that economy indicators, GDP and CPI, have less effect on Taiwan's electricity consumption than POP and NI. By ANN model, we obtain the crucial factors are, by priority, NI, POP, TEMP, CPI and GDP. Three factors: NI, TEMP, GDP are contained in the best linear economic forecasting model, after excluding the multicollinearity among five factors. By comparing three statistics values: RMSE, MAE, MAPE, and scatter diagram for out-of-sample of two models, ANN's forecasting capability is higher than that of the regression model, and regression model is weaker on foretelling peaks and bottoms. To sum up, the artificial neural network model is more appropriate between the two to help us build the economy-forecasting model of Taiwan's electricity consumption. Furthermore, it is possible to use linear and nonlinear hybrid model and univariate time series to forecast electricity consumption in Taiwan.

## ABSTRACT

In this paper, we proposed and trained a fuzzy neural network system to estimate future logistics demand. The structure of neural network in the system is similar to that of BP network, except that here the nonlinear sigmoid functions in the networks are replaced by fuzzy reasoning process and wavelet functions respectively. Moreover, the trained network system is put into practical logistics demand forecasting. The experimental results show that it has good properties such as a fast convergence, high precision and strong function approximation ability and is good at predicting future logistics amount.

**Keywords:** logistics demand, forecasting, fuzzy logic, wavelet neural networks

## 1. INTRODUCTION

In reality, it is significant to estimate future logistics amount as to a logistics manager in a company. Accurate prediction of logistics amount will help the managers to make decision more right. The indefinite nature of the market means that there is a significant need for accurate forecasts of future business, both short- and long-term. Hence, managers, researchers and policy makers have recognized the necessity of accurate forecast of logistics demand. They have tried to apply various kinds of mathematical techniques to reflect the quantitative relationship between a specific demand and its impact factors. On the other hand, another approach to set up a relationship model for the dependent variable only based on its past data or performance. The relationship model is then used to estimate future data.

Previous relationship modeling methods have been largely based on time-series models and multivariate regression analyses. In summary, there are many forecast approaches in the world, each of which has remarkable superiority and unavoidable weakness.

Back-propagation (BP) neural network can establish function approximation for specific input and output relationship without a given model. Nevertheless, the traditional BP network has some weaknesses that are easy to relapse into local minimum point and its computation convergence speed is somewhat slower, which affect the enhancement of reliability and accuracy of prediction model. Thus, we put forward a novel prediction model for the logistics demand based on the combination of fuzzy logic and neural network. We combine fuzzy reasoning theory with neural network in order to improve the precision and convergence speed of the prediction model. So, a neural network-driven fuzzy reasoning system is proposed on the basis of improved Takagi-Sugeno reasoning model. The system consists of  $P+1$  neural networks, the

networks  $NN_1 \sim NN_P$  denote the functions in the conclusion parts of the  $P$  rules respectively, and this type of networks are called expert networks;  $NN_{P+1}$  is used to calculate the fitness of each rule corresponding to input vector, this type of networks is called gate network. Thus, the topology structure of the neural network-driven fuzzy reasoning system is determined.

We think that it is feasible to model the relationship among the time-series historic data of logistics demand using fuzzy neural networks system. Namely, making no assumption about other impact factors, time-series forecast models based on fuzzy neural networks can use historical data as the input and output variables to form a univariate or multivariate mathematical function to reflect the relationship among these statistical data.

## 2. FUZZY NEURAL NETWORKS SYSTEM

### 2.1 Introduction to Fuzzy Neural Networks

In recent years, artificial neural network, a commonly used nonlinear function approximation tool, has shown huge advantages in forecasting, pattern identification, optimization technique and signal processing for its good properties such as nonlinear, flexible and valid self-organization study et al. Back-propagation (BP) neural network, a typical case of neural networks, is used most widely and is more mature than other networks. Unlike the classic mathematic methods, BP networks can approximate the specific input and output relationship without a certain model. Therefore, we usually attempt to set up a BP ANN model for logistics demand prediction. Nevertheless, traditional BP network has some weaknesses that it is easy to relapse into local minimum point and computation convergence speed is somewhat slower, which affect the enhancement of reliability and precision of prediction model. So, we intend to combine fuzzy reasoning theory with neural networks in order to improve the precision and convergence speed of simulation model.

Thus, a neural network-driven fuzzy reasoning system is proposed on the basis of improved Takagi-Sugeno reasoning model. The system consists of  $P+1$  neural networks, the networks  $NN_1 \sim NN_P$  denote the functions in the conclusion parts of the  $P$  rules respectively, and  $NN_{P+1}$  is used to calculate the fitness of each rule corresponding to input vector.

As there are a good deal of practical application of fuzzy neural networks are reported up to now, its superiority for solving complicated non-linear problems has been proved by these researches and taken seriously by scholars gradually.

In this paper, we intend to approximate and fit the functional relationship between the among the statistic data of logistics demand using the neural network driven fuzzy reasoning system abovementioned, and corresponding learning algorithm of fuzzy neural networks system is proposed there. Thus, a prediction model of logistics demand based on fuzzy neural networks system is hereby founded and is put into practice.

## 2.2 Fuzzy Neural Networks System

As to a fuzzy system with  $n$ -input and single output, a regular style of fuzzy rules is:

If  $x_1$  is  $A_1$ ,  $x_2$  is  $A_2$ , ...,  $x_n$  is  $A_n$ , then  $y$  is  $B_j$ , where  $A_1, A_2, \dots, A_n$  and  $B_j$  is fuzzy subsets. In the conclusion part, the model substituting fuzzy set  $B_j$  with a function is commonly called Takagi-Sugeno (TS) model.

If  $x_1$  is  $A_1$ ,  $x_2$  is  $A_2$ , ...,  $x_n$  is  $A_n$ , then  $y = f_j(x)$ , where  $f_j(x)$  is a linear combination of input variables, namely

$$f_j(x) = c_j^1 x_1 + c_j^2 x_2 + \dots + c_j^n x_n + c_j^{n+1} \quad (1)$$

The model divide input space into linear spaces because the input variables are independent each other. When we use the two models abovementioned to divide input space into nonlinear spaces, it is necessary to have an elaborate division at first. But, it will result in the rapid increase of the number of fuzzy rules. To avoid the happening of such a situation, it is convenient to adopt the number of following model:

$$\text{If } X \in P_j, \text{ then } y = f_j(X) \quad (2)$$

Where  $X = (x_1, x_2, \dots, x_n)$ ,  $P_j$  is a partial space divided from input space. In the formula (2), the membership function cannot be determined as formula independently, so we only acquire the joint membership function in the condition part using neural networks, similarly, the function in the conclusion part can also be expressed by neural networks. Thus, a fuzzy system based on neural networks is proposed and its structure is shown in Fig 1.

The system consists of  $P+1$  neural networks, where  $NN_1 \sim NN_P$  denote the functions in the conclusions of the  $P$  rules,  $NN_{P+1}$  is used to calculate the fitness of each rule corresponding to input vector. The output of the

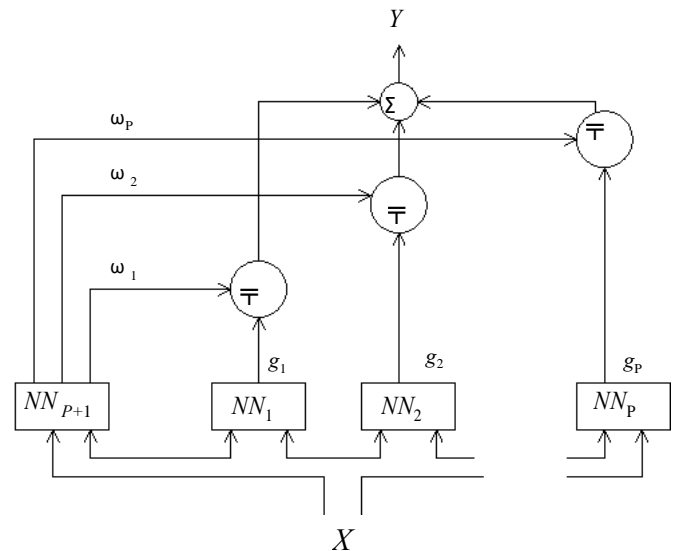

Fig.1 A fuzzy neural networks system

fuzzy system can be calculated by the following formula

$$Y = \sum_{j=1}^P \omega_j g_j \quad (3)$$

Where  $g_j$  is the output value of the network  $NN_j$  and  $\omega_j$  is its corresponding fitness. The system is called an  $NN$ -driven fuzzy reasoning system.

We stipulate three kind of function of the fuzzy system as follows:

1) Determine the number of fuzzy rules by the use of  $K$ -means clustering method.

2) Design and train the neural network  $NN_{P+1}$  to calculate the fitness of each rule corresponding to input vector.

3) Design and train the neural network  $NN_j$  to denote the nonlinear function in the conclusion part in the fuzzy system.

The steps of establishing and training the fuzzy system are as follows:

Step 1. Collect training sample for the fuzzy system.

Step 2. Use  $K$ -means method to cluster input vectors, and each cluster corresponds to a rule. Because the samples are clustered into  $P$  teams, there are  $P$  fuzzy rules for the fuzzy reasoning system.

Step 3. Train the network  $NN_{P+1}$ , which has  $n$  inputs and  $P$  outputs in its structure. The training samples can be constructed using the following method:

If the training sample  $X$  is clustered into the  $S$ -th team, we have:

$$\omega_j^i = \begin{cases} on & j = S \\ off & j \neq S \end{cases} \quad j = 1, 2, \dots, P \quad (4)$$

Namely,

$$W^i = (\omega_1^i, \omega_2^i, \dots, \omega_S^i, \omega_{S+1}^i, \dots, \omega_P^i)^T$$

Where *on/off* correspond to 1 or 0 respectively. But the

output of the activation function in the neural networks is not absolutely 1 or 0. Here we replace them with 0.9/0.1, which can accelerate the training process of networks. Thus, we can construct training sample  $(X_i, W^i)$  for the network  $NN_{P+1}$ . After a certain number of training, the final fitness vector  $W = (\omega_1, \omega_2, \dots, \omega_P)^T$  for each network  $NN_j$  ( $j=1, \dots, P$ ) is gained.

Step 4. Train the networks  $NN_1 \sim NN_P$ . Assume that  $NN_s$  ( $s=1, \dots, P$ ) corresponds to the  $S$ -th rule, thus, all of the samples in the  $S$ -th cluster is the training data for the network  $NN_s$ . Then, back-propagation algorithm is applied to train the networks  $NN_1 \sim NN_P$ .

### 2.3 Applying Wavelet Transformation and Wavelet Network in the Networks $NN_j$

In nature, wavelet transform is a kind of integral transform among various parameters:

$$\omega(a, b) = \int_{-\infty}^{+\infty} f(t) \cdot \frac{1}{\sqrt{a}} h\left(\frac{t-b}{a}\right) dt \quad (5)$$

where  $f(t)$  is a function with compact support set,  $h(a, b, t)$  is called wavelet such that

$$h(a, b, t) = \frac{1}{\sqrt{|a|}} h_{\text{basic}}\left(\frac{t-b}{a}\right)$$

Here  $h_{\text{basic}}(t)$  is called basic wavelet or mother wavelet,  $\frac{1}{\sqrt{|a|}}$  is the coefficient of normalization, and

$a, b$  are dilation and translation factor of  $h(a, b, t)$ . As to a signal or function  $f(t)$ , the identification of its local structure can be conducted by adjusting those two parameters to change the size and place of wavelet bases window to realize.

From the wavelet theory and latest research reports, we know that an arbitrary function  $f(x) \in L^2(R^n)$  can be approximated closely as

$$f(x) \approx \sum_{j=1}^n \omega_j \varphi\left(\frac{x-b_j}{a_j}\right) \quad (6)$$

Formula (6) is a general mathematic description for wavelet network, where  $n$  is the number of network nodes,  $\varphi(\bullet)$  is basic wavelet,  $b_j$  is translation factor,  $a_j$  is dilation factor and  $\omega_j$  is link weight of the network.

Wavelet networks is a type of novel feedforward network on the basis of wavelet analysis theory. It utilizes wavelet space as the characteristic space of style identification, and realizes the feature identification by the weighed sum of the inner product for basic wavelet and signal vector. Because it is a combination of time-frequency localization characteristic of wavelet transform and self-study function of artificial neural network, it owns such capabilities as valid function approximating and error bearing. The function relationship of formula (6) can be

realized by using linear superposition of nonlinear basic wavelet, namely, we can approximate formula (6) using the limited terms of wavelet series.

Assume that there is a three-layer wavelet network whose input vector is  $X=(x_1, x_2, \dots, x_n)$  and output vector is  $Y=(y_1, y_2, \dots, y_m)$  and the number of its neurons is  $n, q, m$ , respectively and the link weights of the network are  $\omega_{ij}$  and  $\omega_{jk}$ . Thus, the nonlinear function  $f(\bullet)$  in formula (6) can be fitted using basic wavelet  $h(a, b, t)$ . So, we have

$$f(\bullet) = \sum_{j=1}^q \omega_{jk} h\left(\frac{\sum_{i=1}^n (\omega_{ij} x_i) - b_j}{a_j}\right) \quad (7)$$

where  $a_j, b_j$  are the dilation factor and translation factor respectively, and  $q$  is the number of wavelons in the hidden layer.

Put the input and output vector of  $P$  samples into the network, and calculate the output values and the system error of the network. To assess the approximation results, we select the least squares objective function as a figure of merit, namely

$$E = \frac{1}{2} \sum_{l=1}^P \sum_{k=1}^m (d_{lk} - y_{lk})^2 \quad (8)$$

where  $y_{lk}$  is the actual value of  $l$ th sample on the  $k$ th output node in the network, and  $d_{lk}$  is the ideal value of the  $k$ th output node accordingly.

In the training process of wavelet network, we select Morlet mother wavelet as the basic wavelet approximating the nonlinear function such that

$$h(t) = \cos(1.75t) \exp\left(-\frac{t^2}{2}\right) \quad (9)$$

The steps of wavelet network training are as follows:

Step 1. Initializing the parameters of the wavelet network. Using random generator, the link weights of the network  $\omega_{ij}, \omega_{jk}$  and the dilation factor  $a_j$  and translation factor  $b_j$  of basic wavelets are evaluated with random number.

Step 2. Project study samples data into the network.

Step 3. Carry out the self-study of network and gain the output vector and error of network.

Step 4. Calculate the instantaneous gradient vector.

Step 5. Carry out error back-propagation and revise the parameters of the networks.

Step 6. While the absolute value of the error is less than the precision, stop the training process. Otherwise, turn to Step 3.

Step 7. Put the trained wavelet network into the practice.

The functions in the conclusion part of the fuzzy reasoning system are all expressed by wavelet neural

networks  $NN_j (j=1, \dots, P)$ .

### 3. FUZZY NEURAL NETWORKS SYSTEM FOR LOGISTICS DEMAND FORECATING

In the work here, this novel networks system is applied to model logistics forecasting. What we should do firstly is to decide the variables denoting the input-output relationship for it. Generally, whichever networks can be used in time-series prediction if it can accept actual input and brings out actual output. If the prediction objective is a future point in a single time-series, it is feasible to use the former  $n-1$  points before this point as the historic data to estimate its value. In a time series, every  $n$  neighboring point can be used

as training samples. Here, the proposed fuzzy neural networks system is used as a time-series prediction model for logistics demand. Namely, every  $n-1$  neighboring point can be used as training sample and put into the system to estimate the value of the  $n$ -th point.

So, the training sample data and testing data of fuzzy neural networks for logistics forecasting are collected and constructed. In the process of practical application, for the difference in the dimension and magnitude of sample data, all inputs are scaled to lied in  $[0, 1]$  range in advance using reasonable estimation of the maximum and minimum values for each input.

Table 1. Comparison between prediction and the actual value of rail freight amount in China

Year	1989	1990	1991	1992	1993	1994	1995	1996	1997
Actual	151489	150681	152893	157627	162663	163093	165855	168803	169734
Prediction	151390	150540	157512	157432	160565	162187	166238	169126	170163

We apply the trained networks system in the study of actual logistics forecasting and by comparison with historical statistics data to test its properties. The experimental results are contrast to that of actual data and shown in Table 1. The experimental results show that although there a certain error in the prediction values to some extents, the simulation model can forecast logistics demand properly and accurately.

### 4. CONCLUSIONS

In this paper, we proposed and trained an improved fuzzy neural networks system with the data of past logistics demand data. The structure of the networks in the system is similar to that of BP network, except that here the nonlinear sigmoid functions in the networks are replaced by fuzzy reasoning process and wavelet functions respectively. Moreover, the trained network is put into practical logistics demand forecasting. The experimental results show that the fuzzy neural network has good properties such as a fast convergence, high precision and strong function approximation ability. Furthermore, it also demonstrates that the fuzzy neural network system is good at predicting future logistics amount because of its non-strict requirements for input

variables and not needing plenty of sample data, which ensure that it is suitable for the actual forecasting and outperforms other classic prediction methods and is significant to in applied in the planning of logistics system in both a company and a city.

# Maximising Technology Efficiencies for SMEs Using Computer Intelligence

Adrian Collins

University of Wollongong, Australia  
adrian@uow.edu.au

## ABSTRACT

This paper is part of a series which present elements of our research into technology adoption and usability problems faced by small businesses (SME's) in Australia. We discuss our approach to research in the small business area, the importance of aggregating small businesses into vertical technology sectors and the usability improvements which can be expected from this collaborative approach. In this paper we focus on information retrieval requirements and the related usability problems which confront small businesses. We discuss adoption and usability issues, requirements and risks using a business case study, then introduce experiments which it is hoped will deliver efficiency improvements to information retrieval applications for small businesses.

**Keywords;** Small Business, collaborative approach, content ranking

## 1. INTRODUCTION

Our goal is to help SME's find innovative and novel ways to utilise technology. We believe SME's can significantly benefit from a selective adoption of technologies to improve efficiencies for staff by improving communication and information sharing facilities with other organisations. Technology adoption can be extremely cost effective for small business and provide a genuine return on short term investment. Our research aim is to test the viability of improving access to technology for SME's by using a collaborative approach to investment, acquisition and adoption of information and communication technology. It is hoped that this approach will allow individual SME's to spread the cost and risk of eBusiness adoption and use by entering into vertical market collectives. Typically, around 25% of Australian businesses are making some use of electronic business (eBusiness) to reduce the cost of doing business or improve profit potential. Recent research into the local region has found that eBusiness adoption by SMEs is as low as 6%. The major reasons for not adopting eBusiness technology by SMEs:

- Not relevant to the business profile
- Technology is too complicated
- The organisation does not have the resources to implement the technology

## 2. AGGREGATING SME'S INTO A VERTICAL SECTOR

In Australia, many small businesses are focused on supporting a single, larger business entity or market area. In this case, the SME will have implemented the necessary technology and infrastructure to complete the business process in the most profitable way but lacks the resources to further expand. Many organisations would like to grow their business but due to a lack of resources (finances, staff, expertise etc.) cannot take advantage of growth opportunities. This lack of resources also acts as

a barrier to adopting technology which allows them to expand and service new markets. We propose a collaborative approach in which small business stakeholders can pool resources and construct an eBusiness facility that all share. This approach fosters closer business relationships and allows individual SMEs to pool resources by aligning organisations with similar attributes into vertical markets (technology wise). Once organisations with similar attributes are aligned, benefits can be derived by developing and implementing common software solutions which both reduce the cost of doing business and maximise operational efficiencies within the organisation.

An example of organisations with similar attributes is the mercantile agent market, which has more than 1000 small, independent organisations operating in Australia. A mercantile agent acts on a client's behalf and represents persons and firms by collecting overdue debt and by identifying individuals and organisations implicated in credit fraud and theft. When these types of small organisations are analyzed, we observe that while they are physically separate small organisations involved in a specific business task, the area and scope of their business overlaps that of other small businesses involved in similar operational activities. In the main, mercantile agencies perform services such as:

- Collection: make demands for payment of overdue debts
- Investigation: obtain information and report on the personal character, occupation, activities or actions of persons or businesses
- Process serving: deliver court issued documents for a variety of reasons including debt recovery, family law proceedings, civil and criminal litigation.
- Repossession: act for principals when financial contracts (leases, bills of sale, hire purchase agreements etc.) have been broken. Seeking payment of arrears or the balance of a loan facility

or else to recover the goods on behalf of the principal.

While the operational activities are different among the organisations within the vertical market, there is a significant overlap in many areas. Agents share the same types of clients, acting for banks, financiers, lawyers, insurers, the general business community or individuals. In addition, they share many similar information processing requirements. Document Management Systems (DMS), precedents, document archival, mail merging, diary systems, backup and disaster recovery.

We hypothesize that small businesses can save considerable capital investment dollars by aggregating their processing requirements and benefit by collaboration [1]. These benefits are achieved via the use of portal technology which has been shown to result in a number of business and technical benefits:

- Increased productivity and efficiency
- Provides organisations with the ability to present a central point of access to data and organizational documentation
- Facilitates mobile and pervasive device access
- Increases marketing opportunities
- Provides access to component based solutions

### 3. CASE STUDY

A mercantile agency typically follows the business model shown in figure 1. Currently 10% of matters are handled outside the local court domain. The business sees this as a major growth area, but the trade off is being able to maximise business efficiencies and promote a larger client base against maintaining a small number of personnel. In order to maximise business efficiencies, the organisation invests in technology, deciding that technology adoption will grow the business exponentially, while investment in staff with only grow the business according to the number of additional staff members.

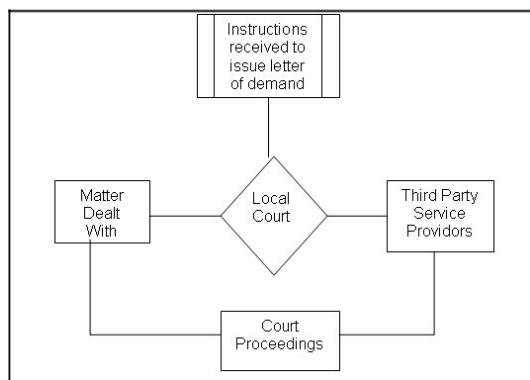

Figure 1.

When the matter is to be dealt with (handled locally), the staff communicate with the debtor and local court on the clients behalf, this process may also include

communication with solicitors on both sides. However, when the debtor resides in another locality, the matter may need to be heard in that court locality. In this case, service providers who may act on the mercantile agencies behalf must be located, fees negotiated, and paid before action can commence in that locality. This presents a major problem for the organisation, because there is no recognised registry of agents. The organisation must locate potential service providers using either regional telephone directories or the internet. We further discuss this problem in section 3.2 and propose a possible solution.

## 4. PROCESSING SCENARIOS

### 4.1 Document Management System

The case study organisation also maintains a DMS (Document Management System) with standard processing requirements, ie. Creation and maintenance of documents which typically relate to judgment matters in a default of payment claim:

- Letter of Demand
- Issue of Statement of Claim
- Service of Statement of Claim
- Default Judgment
- Writ of Execution or Warrant
- Examination Summons
- Matter action record

Many documents may be created for a single matter, and these documents need to be retained in hard copy (and online) for a number of years (7) by law. Given this requirement, an efficient method of retrieving specific documents was identified in the case study, as well as a method of locating documents which contain details of cases with a similar pattern to a case being prepared currently. Locating documents which relate to similar matters allows the small operator to use the original documents as precedents or templates for the current case. Often, phrasing, fee structures, outsourcing agencies and methods of solution can be duplicated with very little change to the current matter. To facilitate this process, an intelligent ranking and extraction process can be used to leverage a document search engine and identify matters which relate to the search criteria.

To this end, a number of search requirements were identified in the study:

**Name Search** - Allows each kind of document stored in the repository to be found by its name. Long file names, spaces and foreign characters are supported by the name search method. Folders can also be retrieved using this method. In the case that the exact name is unknown, a wildcard search would be available.

**Full Text Search** - This is the most extensive method for conducting a document search. A user is able to search for a single word or phrase, a complex expression, or an extensive range of search standards. Misspellings

can affect the accuracy of the search, which is a major limitation, and this issue needs to be addressed.

**Index Search** –As the repository becomes large, this method is most suitable. Users can perform alphanumeric character searches to find index information. These searches include wild card expressions and range searches, date and date range searches to locate appropriate matters.

The mercantile agency also maintains electronic notes on matters which are filed in the document repository, the business study identified a requirement to search these notes for pattern matching criteria in order to compare outcomes and legal precedents for dealing with current matters

#### 4.2 Location Of Costs and Fees using the Web

As a means of growing the business, the mercantile agency is looking at accepting the task of debt collection in other localities. In order to process and recover a debt, service fees applicable to the matter may relate to:

- Sheriff costs
- Process Server costs
- Solicitor costs
- Land Titles search fees
- Motor Vehicle records search fees
- ASIC (Australian Securities and Investments Commission) search fees
- Registrar General search fees

All these service providers have sliding fee schedules which require the mercantile agency to determine the fee structure which will apply when dealing with a matter in that particular jurisdiction. Court fees in each jurisdiction may also differ for a particular type of document to be lodged, and these other agencies such as court appointed Sheriffs or investigators who can locate and serve documents on behalf of the mercantile agent must be contacted and paid prior to acting on behalf of the mercantile agency. In addition, court lodgment fees are continually changing, so the source of the fee structure needs to be periodically reviewed to ensure that the current fees are being paid when court documents are lodged. For example, refer to these sites for examples of the disparity in content and style of the fee structure information available in various court localities

[http://www.nt.gov.au/ntsc/doc/almanac/2004\\_almanac.pdf](http://www.nt.gov.au/ntsc/doc/almanac/2004_almanac.pdf)  
<http://www.lawlink.nsw.gov.au/sc/sc.nsf/pages/filingfees>  
[http://www.lawlink.nsw.gov.au/dc.nsf/pages/dc\\_fees](http://www.lawlink.nsw.gov.au/dc.nsf/pages/dc_fees)  
[http://www.courts.tas.gov.au/magistrate/circulars/cir2000\\_8.htm](http://www.courts.tas.gov.au/magistrate/circulars/cir2000_8.htm)

Use of the Web to locate information relating to fee comparison, goods and services procurement, as well as access to electoral role information for skip tracing is also an expected area of growth for the mercantile

industry. So the use of intelligent agents to mine the Web for relevant information is of great benefit to all businesses, but particularly relevant to a small business. The major logistical problem for the user of the Web to provide information (at this stage) is the lack of formal content standards as well as the lack of location directories for accessing the data in a structured manner.

As a means of improving office efficiencies, we propose a series of experiments using an ontology driven information system which gathers and builds a knowledge base relating to a specific subject content domain. We intend to build on Brin's Dual Iterative Pattern Relation Extraction (DIPRE) [2] method to construct a semantic ontology of domain patterns which is then used to build the knowledge base. Our system first uses a set of training pages to generate a conceptual map (ontology) of the physical training pages. The application will then use the ontology to search a text repository such as a document management system or the Web. The objective is to rank the results into a meaningful knowledge base of information relating to the subject domain.

#### 5. RELATED WORK

Related work using extraction analysis methods to develop ontologies and information domains by 'trawling' the World Wide Web was begun in earnest at the same time as the Internet became a commercial entity. Research to identify phrase patterns which surround the target domain was begun by Riloff et. al. in 1996[3]. Riloff separated initial content retrieval into relevant and non-relevant domains using a frequency algorithm to determine relevance. Content deemed relevant was then used to generate patterns for subsequent retrieval runs which better filtered the content relating to the target domain. In 1998, Sergey Brin developed a more formal, iterative method for the discovery and containment of patterns (DIPRE - Dual Iterative Pattern Relation Extraction). Brin's approach has been extended by a number of research efforts including Yangarber et al. [4], Soderland and Etzioni (University of Washington) [5] and Agichtein and Gravano (Columbia University) [6] to generate domain ontologies and Q/A query facilities.

Etzioni's group generate ontology repositories using the 'Knowitall' tool they developed. Agichtein's research developed 'Snowball' which also uses an iterative approach using domain seeds to begin the extraction process. Our work is also similar to Crescenzi's Roadrunner [7] project in terms of the use of example pages to build a pattern ontology as a parser for the extracted corpus. Using this method, discovery starts with a few training pages which are known to be good indicators of the topic of interest. These patterns are used to retrieve some relevant content; the content is scanned for associated phrase patterns, and the process

is repeated, refining the target to develop the ontology or specific answer set. In our experiments, we attempt to deliver a tangible efficiency benefit to the user by applying these techniques to the business problem. We use the Web corpus to locate and acquire information on court related fees applicable to the recouping of outstanding debts in court jurisdictions within regional Australia. Our objectives in this paper are to use these techniques to develop semi automated intelligent processes which build patterns from each extraction iteration, then compare these patterns against semantic rules generated from the 'bootstrap' template.

## 6. INFORMATION RETRIEVAL

### 6.1 Prelude To Experiments

This section details the architectural design and setup for our experiments. We begin with the development of a browser based request/response interface which interacts with the user, provides input to the Web search engine, Web Service, or application specific search engine. This means the module constructs both a standard html request as well as a SOAP request. An application specific search engine will be expected to accept XML requests, the app server will deliver document URL's to the receiving interface.

When the user begins a session, initialization information is requested, such as an iteration count which limits our run, one or more learning pages which are used to create the ontology and a variable number of key words or phrases which we use to bootstrap our initial search criteria. For our purposes, we define an ontology as a conceptual image of the training pages which we store as a tree of nodes centered around the bootstrap keywords and phrases. We build our tree by first accepting and storing the users search arguments and any example pages used to generate the ontology of patterns including date and time and users id. The contents of the first extraction run are cleaned, to provide input to the pattern maker. The cleaner counts the number of hits of each keyword and passes this to the pattern maker which uses this information as a probability of usefulness. The pattern maker accepts the resultset strings from the receiving interface and clusters [8] them according to occurrence (refer to Figure 2). Patterns are created using the DIPRE algorithm for each pattern identified (keyword or phrase). Each run generates new patterns which are analyzed and compared to the ontology for relevance.

Our initial business goal is to locate and rank pages according to the closeness of the match with the training pages. The system orders the users desired information and builds a knowledge base on URL, location, fee type and fee value.

So on the first run, the discriminators (patterns) which surround the keywords and key phrases are saved and used in the second and subsequent runs. We calculate a probability for the relevance of each page returned and first try to select most obvious discriminators, then loosen constraints and select NEAR discriminators.

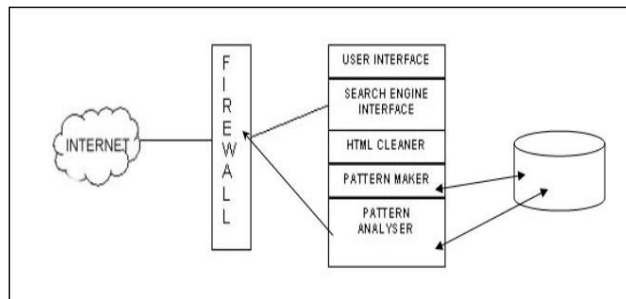

Figure 2.

## 7. FUTURE WORK

We report the details of our design and results of our experiments in later papers in the series. Our longer term objective is to investigate the introduction of intelligence into Web based applications as a way of improving human/computer interaction efficiencies. We focus our research in the area of small to medium business enterprises (SME's) as this market (SME's) account for more than 90% of Australian businesses [1].

Our work provides us the opportunity to:

- Research and develop applications which utilize the 'semantic' web [9] and related content presentation standards being developed.
- Research the development of agent based software using a genuine commercial environment from which to draw requirements.
- Develop leading edge software solutions which deliver tangible cost saving benefits for small businesses.

## ABSTRACT

An organization's environment is increasingly complex. Business demand on environmental scanning has significantly increased in recent years due to an attempt to assist management in planning an organization's strategies and responses. The conventional technique for environmental scanning is event detection from text documents such as news stories. Event detection methods recognize events while they neglect to discover the changes of events. This work develops an event change detection (ECD) approach that combines association rule mining and change mining techniques. Detecting changes of events aids managers in making fast responses to the change of external environments. Association rule mining is employed to discover the subject behaviors of events from news stories. Changes of events are identified by comparing the subject behaviors of events from different time periods. The discovered event changes can provide effective decision support for decision makers to capture environmental information in a timely manner and make adequate decisions.

**Keywords:** Environmental Scanning, Change Mining, Association Rule Mining, Event Tracking, Event Detection

## 1. INTRODUCTION

With the rapid growth of Internet, the business environment today has become more complex and changeable. Environmental scanning has received considerable attention in business in recent years due to its benefits of assisting management in planning the organization's future course of action [4].

News is the best information source for businesses to get environment information (event) because of its comprehensive content. Event detection is the major research field in news, and it plays an important role for supporting environmental scanning [14]. Event detection identifies streams of news stories that discuss new events [1][2][16][17]. Organization managers can be aware of new events in their environment via event detection technologies. Event detection methods are concerned only with recognizing new events and neglect to discover the changes between these news stories. But in fact, changes of environment occur not only through new events but also in existing events.

The purpose of environmental scanning is not only to identify changes of the content of news stories that describe the same or different events, but also to aid business managers to be sensitive to the external environment resulting in a fast response to the environment. Detecting event changes is a critical work for businesses.

An event change is the change of event trends in two time periods. For example, the trend of telecommunications industries in 2001 was to provide educational services to customers, while the trend of telecommunications industries in 2002 was to provide recreational services. The change of service types is named event change.

These trends are discovered from news stories of events- "Services provided in telecommunications industries (telecom services)" in 2001 and 2002 respectively.

To capture the changes of events, we must first determine the subject behaviors of an event. A subject behavior of an event is an incident that is described in most news stories, and it can be characterized by the relationships of 4W properties (When, Who, Where and What). The relationships between 4Ws may change with time, but these changes will be important information for decision making for business managers. For instance, if telecommunication companies were reported to provide recreational services (What property) in most news stories of the event "telecom services", "telecom services" can be viewed as a subject behavior of the event. If subject behaviors of different time periods are different, event change occurs.

In this research, association rule mining is employed to identify the subject behaviors of events from news stories.

Information needs usually vary with time, situation and people. Business managers may require different levels of information in developing different strategies. A decision maker may not only need to know the business operations of individual companies but also the operations of industries. To meet all possible information needs in environmental scanning, it is necessary to construct a concept hierarchy according to the content of news stories.

Motivated by the needs for capturing event changes, the goal of this research is to develop an event change identification (ECI) technique. The proposed technique combines the change mining approach and concept hierarchy to provide useful environment changes to enhance environmental scanning.

The remainder of this paper is organized as follows. Section 2 reviews literatures relevant to this research, including environmental scanning, event tracking and detection, association rule mining and change mining technologies. Section 3 introduces our event changes identification technique. In Section 4, we describe methods to detect event changes. Finally, the contributions of this study are summarized in Section 5.

## 2. LITERATURE REVIEW

This section reviews literatures relevant to this research, including environmental scanning, event tracking and detection, association rule mining, and changes mining technologies.

### 2.1. Environmental Scanning

To adapt to the environment and subsequently develop effective responses to secure or improve the business' position in the future, environmental scanning is important [4][7].

Environmental scanning acquires and uses information about a business's external environment, which is used by business managers to make decisions and plans [4]. Consequently, it is essential to scan the external business environment to improve a business's future.

### 2.2. Event Tracking and Detection

Event tracking and detection techniques are proposed to support people detecting new events and tracking subsequent news stories that discuss previous events. Event tracking starts from a set of pre-classified news stories, and searches out all subsequent stories that discuss the same event [1][17]. The goal of event tracking is to locate follow-up news stories of a manager's event of interest.

Event detection is the major research field in news, and it plays an important role for supporting environmental scanning [14]. The goal of event detection is to identify streams of news stories that discuss new events [1][2][16][17]. Organization managers can become aware of new events in their environment via event detection technologies. But changes of environment occur not only during new events but also during existing events. Business administrators need to be notified before an event takes place, not just when it happens.

### 2.3. Association Rule Mining

Association rule mining searches for interesting association or correlation relationships among items in a large dataset [6]. There are two measures to represent whether a mined rule meets the criteria of regularity: support and confidence [6][15].

This work proposes an event change identification technique to detect event changes. We apply association

rule mining on news data to detect the regulation of the news.

The format between news data and transaction data is very different. Transaction data is structured, and the scope of attributes and values is often fixed. In contrast to transaction data, news data is unstructured, and the scope of attributes and values often changes. For example, the protagonist of the same event may change.

Therefore, mining association rules from news data needs to address these difficulties. In this study, we used event property selection and extraction and concept hierarchy to solve these problems.

### 2.4. Change Mining

The objective of change mining is to discover changes of data from different time periods. The researches of change mining can be classified into two main groups:

1. Decision Tree Model: This method first constructs decision trees from different datasets. It obtains differences via comparisons with two decision trees [10]. Through graphic presentation, the user can discover the differentiae and understand the data.

2. Association Rule: This method obtains changes via comparisons with association rules mined from a different dataset [11][12]. The types of changes defined by [5][8][9][12] are emerging patterns (the emerging pattern concept captures significant changes and differences between datasets.), unexpected changes (can be found in newly discovered association rules with consequence/conditional parts different from previous rules), added rules (is a newly appearing rule in the present which could not be found in the past) and perished rules (is a rule that can only be found in the past). Association rule change mining is used to discover changes in customer behavior.

In this study, we adopted the association rule change mining technique to discover changes of events. As mentioned above, transaction data and news data are quite different. We modified the conventional change mining approach, and used event property and concept hierarchy to improve the quality of change detection.

## 3. EVENT CHANGE DETECTION (ECD) TECHNIQUE

In a dynamic environment, the state of events is constantly changing and evolving. It is important for business managers to capture environmental changes to adjust their business strategies.

### 3.1. Overview

The proposed event change detection (ECD) technique comprises two main processes: learning and detection. From a set of news stories, the learning process (as shown in Figure 1) seeks to identify event properties, concept hierarchy of property, and association rules representing the subject behaviors of event. The purpose

of the detection process is to identify event change, according to the association rules discovered in the learning process (as illustrated in Figure 2).

### 3.2. Learning process

The learning process of the ECI technique is to identify which event in the news story should belong and induce event association rules from a set of news stories. The learning process consists of four steps, including news fetcher, event identification, property extraction and association rule matching.

The news fetcher component of the ECD technique is to fetch news stories from online news providers.

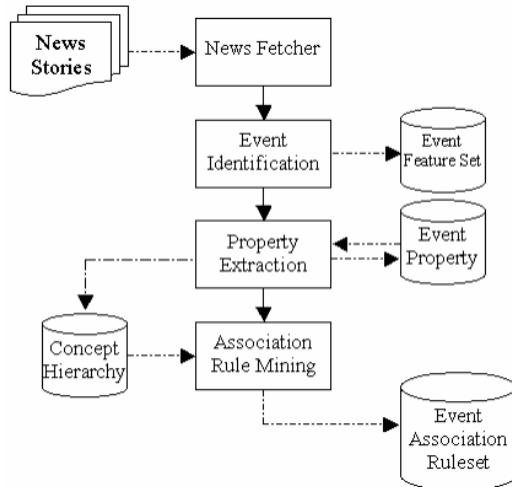

Figure 1. Learning process of identifying event change

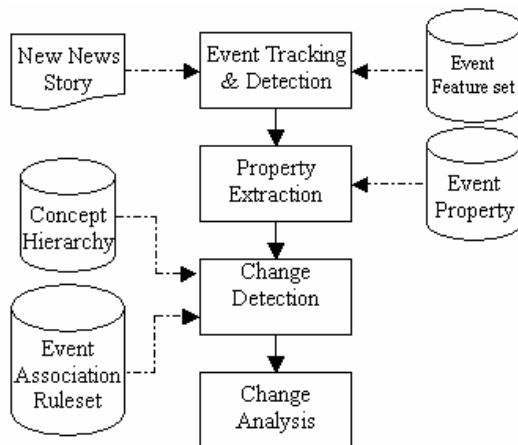

Figure 2. Detection process of identifying event change

#### 3.2.1. Event Identification

The objective of event identification is to determine the set of features that will be used for representing individual news stories within pre-classified training news stories. The search for news categorization patterns uses feature extraction and feature selection. Feature extraction extracts a set of terms based on the news stories. For producing a set of features, we used feature extraction with the Chinese Dictionary [3] which contains

one hundred and sixty thousand terms to parse each training news story to produce a list of terms commonly referred to as features.

Following feature extraction, feature selection is initiated to condense the size of the event feature set (the size of feature set is 30). The purpose of this phase is to remove unnecessary terms from the set that were produced in the previous phase. Several feature selection methods have been proposed in the literature, including TF, TF\*IDF and so on. We selected the features in this research by TF\*IDF. The top 30 features with the highest feature score are selected as features for representing news stories.

TF\*IDF is defined as [6]:

$$TF \times IDF(t, d) = tf(t, d) \times \log(N / n_t) \quad (1)$$

where

$N$  is the size of the news stories in the collection;

$n_t$  is the number of news stories where  $t$  occurs;

$tf(t, d)$  is the term frequency (TF) within a news story  $d$ ;

$\log(N / n_t)$  is the inverted document frequency (IDF).

#### 3.2.2. Event property

Feature-based technique is one of the most popular methods to represent the content of a news story. But feature-based representation often performs poorly because of its inherent problems, such as vocabulary discrepancies between reporters, news stories for different events containing similar feature sets, and so on. To overcome the problems of the traditional feature-based technique, event property has been used to improve event detection [1][14]. To improve the accuracy of content representation, we adopted event property to identify the subject behaviors of events. Event properties are classified into four categories (4Ws) as summarized below.

1. When: Date, Time
2. Who: Person, Organization
3. Where: Location
4. What: Action, Claim, Standpoint, Statement

#### 3.2.3. Concept hierarchy

As previously mentioned, business decision makers may require different levels of information for developing different strategies. Such different levels of information form a concept hierarchy. In this work, we adopted concept hierarchy to meet all possible information needs. Concept hierarchy is used to define the relations of concept levels between a group of attributes [13].

In the process of event change detection, we need to determine the difference between the values of attributes. Subject behaviors of two time periods are compared. These values can be regarded as the nodes of concept hierarchy.

The node difference in a concept hierarchy is:

$$h_H(A, B) = \frac{\text{Max}\left(\sum_{L_i \in P_A} WL_i, \sum_{L_j \in P_B} WL_j\right) - \sum_{L_k \in P_{\text{comm}}(A, B)} WL_k}{\text{Max}\left(\sum_{L_i \in P_A} WL_i, \sum_{L_j \in P_B} WL_j\right)} \quad (2)$$

A and B are nodes in concept hierarchy

$P_A$ : the path from root to node A.

$P_B$ : the path from root to node B.

$P_{\text{comm}}(A, B)$ : the common path between  $P_A$  and  $P_B$ .

$L_i$ : a link in  $P_A$ .

$L_j$ : a link in  $P_B$ .

$WL_i$ : the weight on the level of link  $i$ .

$WL_j$ : the weight on the level of link  $j$ .

### 3.3. Event tracking and detection

The event tracking and detection process identifies which event a recent news story belongs to and whether the news story discusses a new event. To achieve this, the event tracking and detection process consists of three steps: news document representation, similarity comparison and event assignment.

#### News document representation:

Each news document is represented using representative features. The feature set for each event is extracted and selected from a set of labeled training news stories.

#### Similarity comparison:

This step is to calculate the similarity between recent news story  $D$  and all known events. The cosine distance is used to compute the similarity, as shown as below:

$$\text{Sim}(D, e) = \frac{\sum_{f_k \in D \cup e} t_{Dk} \times t_{ek}}{\sqrt{\sum_{f_k \in F_D} t_{Dk}^2} \sqrt{\sum_{f_k \in F_e} t_{ek}^2}} \quad (3)$$

where  $F_D$  and  $F_e$  are the feature sets of document  $D$  and event  $e$  respectively.  $t_{Dk}$  is the weight of the representative feature  $f_k$  of  $D$ , and  $t_{ek}$  is the weight of the representative feature  $f_k$  of  $e$ .

#### Event assignment:

Upon obtaining the similarity scores between the latest news story  $D$  and all known events, we set a pre-specified threshold in this step, and assign an event label according to similarity scores. If the maximum similarity score between  $D$  and the known events is below the threshold, the new document is labeled as the first story of a novel event; otherwise, we assign the news document to the event where the maximum similarity score is obtained.

## 4. DETECTION OF EVENT CHANGE

Event change is the change of event trends in two time periods. Those trends are discovered from news stories of the same event during different times. In order to detect event changes from a great quantity of news stories, we extended the idea of change detection methodology [13] and integrated concept hierarchy into the event change detection technique. The detection of event change is revealed in Figure 3.

Based on past research and business requirements, there are five types of possible mining changes: emerging

patterns, unexpected consequent changes, unexpected condition changes, added rules, and perished rules.

### 4.1. Discovery of changed rule

In order to discover the five types of event changes between different time periods, we employ the rule matching method proposed by Song et al. [12] and modify it to fit event change detection by considering concept hierarchy.

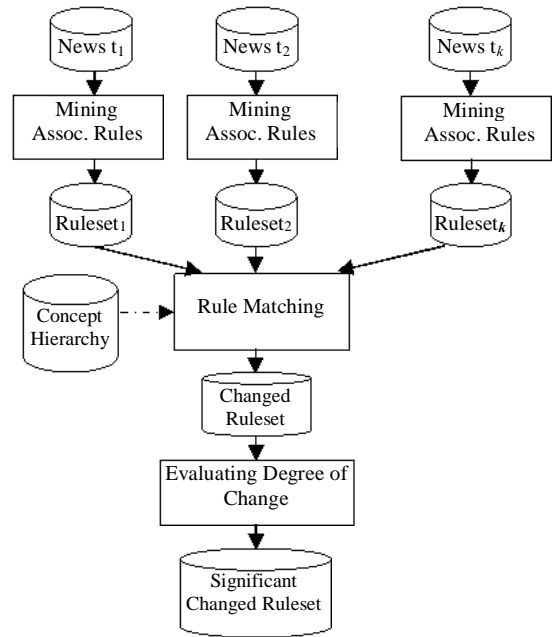

Figure 3. The process of event change detection

The rule matching method consists of three steps:

1. Calculate the maximum similarity value. For each rule in different time periods, calculate the maximum similarity value.
2. Calculate the difference measure. For each rule  $r_i^t$  in time  $t$ , calculate the difference measures between  $r_i^t$ ,  $r_i^{t+k}$ .
3. Decide type of changes. According to the judged factors (maximum similarity value and the difference measures), this step determines the type of change for the rules.

Before we introduce the methods to calculate judged factors, some notations are defined as below.

#### Conditional part of rules:

$p_{ij}$ : Degree of attribute match of conditional part

$$p_{ij} = \frac{|A_{ij}|}{\max(|X_i^t|, |X_j^{t+k}|)}$$

$A_{ij}$ : Set of attributes common to both conditional parts of  $r_i^t$  and  $r_j^{t+k}$

$X_i^t$ : Set of attributes in the conditional parts of  $r_i^t$

$X_j^{t+k}$ : Set of attributes in the conditional parts of  $r_j^{t+k}$

$A_{ijk}$ : The  $k^{th}$  attribute in  $A_{ij}$ .

$v(r_i^t, A_{ijk})$ : Value of the  $k^{th}$  attribute in  $A_{ij}$  of  $r_i^t$ .

$v(r_i^{t+k}, A_{ijk})$ : Value of the  $k^{th}$  attribute in  $A_{ij}$  of  $r_i^{t+k}$ .

$l_{ijk}$ : Degree of value match of the  $k^{th}$  matching attribute in  $A_{ij}$

$$l_{ijk} = 1 - h_H(v(r_i^t, A_{ijk}), v(r_i^{t+k}, A_{ijk}))$$

Consequent part of rules:

$q_{ij}$ : Degree of attribute match of consequent part

$$q_{ij} = \frac{|B_{ij}|}{\max(|Y_i^t|, |Y_i^{t+k}|)}$$

$B_{ij}$ : Set of attributes common to both consequent parts of  $r_i^t$  and  $r_i^{t+k}$

$Y_i^t$ : Set of attributes in the consequent parts of  $r_i^t$

$Y_i^{t+k}$ : Set of attributes in the consequent parts of  $r_i^{t+k}$

$B_{ijm}$ : The  $m^{th}$  attribute in  $B_{ij}$ .

$v(r_i^t, B_{ijm})$ : Value of the  $m^{th}$  attribute in  $B_{ij}$  of  $r_i^t$ .

$v(r_i^{t+k}, B_{ijm})$ : Value of the  $m^{th}$  attribute in  $B_{ij}$  of  $r_i^{t+k}$ .

$f_{ijm}$ : Degree of value match of the  $m^{th}$  matching attribute in  $B_{ij}$

$$f_{ijm} = 1 - h_H(v(r_i^t, B_{ijm}), v(r_i^{t+k}, B_{ijm}))$$

The similarity measure  $S_{ij}$  between  $r_i^t$  and  $r_i^{t+k}$  is calculated using the following formula: ( $0 \leq S_{ij} \leq 1$ )

$$S_{ij} = \begin{cases} \frac{p_{ij} \times \sum_{k=1}^{|A_{ij}|} l_{ijk}}{|A_{ij}|} \times \frac{q_{ij} \times \sum_{m=1}^{|B_{ij}|} f_{ijm}}{|B_{ij}|}, & \text{if } |A_{ij}| \neq 0 \text{ and } |B_{ij}| \neq 0 \\ 0, & \text{otherwise} \end{cases} \quad (4)$$

Where  $\frac{p_{ij} \times \sum_{k=1}^{|A_{ij}|} l_{ijk}}{|A_{ij}|}$  represents a similarity of conditional

part, and  $\frac{q_{ij} \times \sum_{m=1}^{|B_{ij}|} f_{ijm}}{|B_{ij}|}$  represents a similarity of consequent

part between  $r_i^t$  and  $r_i^{t+k}$ . If the conditional parts and consequence parts  $r_i^t$  and  $r_i^{t+k}$  are the same,  $S_{ij}$  equals 1.

Accordingly, the maximum similarity value of  $r_i^t$  is as below:  $V_i = \max(S_{i1}, S_{i2}, \dots, S_{i|R_i|})$

Accordingly, the maximum similarity value of  $r_i^{t+k}$  is as below:  $V_i = \max(S_{i1}, S_{i2}, \dots, S_{i|R_i|})$

The second judged factor, difference measure  $\partial_{ij}$  between  $r_i^t$  and  $r_i^{t+k}$  is given by ( $-1 \leq \partial_{ij} \leq 1$ ,  $\partial_{ij} \neq 1$ )

$$\partial_{ij} = \begin{cases} \frac{p_{ij} \times \sum_{k=1}^{|A_{ij}|} l_{ijk}}{|A_{ij}|}, & \text{if } |A_{ij}| \neq 0 \text{ and } |B_{ij}| = 0 \\ \frac{p_{ij} \times \sum_{k=1}^{|A_{ij}|} l_{ijk}}{|A_{ij}|} - \frac{q_{ij} \times \sum_{m=1}^{|B_{ij}|} f_{ijm}}{|B_{ij}|}, & \text{if } |A_{ij}| \neq 0 \text{ and } |B_{ij}| \neq 0 \\ -\frac{q_{ij} \times \sum_{m=1}^{|B_{ij}|} f_{ijm}}{|B_{ij}|}, & \text{if } |A_{ij}| = 0 \text{ and } |B_{ij}| \neq 0 \end{cases} \quad (5)$$

If attributes of conditional parts and consequent parts between the two rules are different, it makes no sense to compare the degree of difference, i.e.,  $|A_{ij}| = 0$  and  $|B_{ij}| = 0$ , because these two rules are completely different.

Although  $r_i^{t+k}$  is determined to be an unexpected change with regard to  $r_i^t$  by  $\partial_{ij}$ , it may be an emerging pattern of other rule. An emerging pattern may be misjudged to be an unexpected change. To improve the accuracy of judging change type, the third judged factor, modified difference measure  $\partial'_{ij}$  is denoted as:

$$\partial'_{ij} = \partial_{ij} - j_{ij}, \text{ where } j_{ij} = \begin{cases} 1, & \text{if } \max(V_i, V_j) \geq q \\ 0, & \text{otherwise} \end{cases} \quad (6)$$

The parameters  $q_1$ ,  $q_2$ , and  $q_3$ , (event change thresholds) are thresholds to determine the types of change. The five types of change can be classified according to the three kinds of judged factors and the three predefined thresholds:  $q_1$  for emerging patterns,  $q_2$  for unexpected consequent and unexpected condition changes, and  $q_3$  for added and perished rules. In general,  $q_1 > q_2 > q_3$ , and  $q_1$  approaches to 1. Table 1 shows the value of measure for each type of change.

**Table 1.** Value of measure for each type of change

Type of Change	Value of measure to classify
Emerging Pattern	$S_{ij} > q_1$
Unexpected Consequent	$\partial_{ij} > 0, \partial'_{ij} \geq q_2$
Unexpected Condition	$\partial_{ij} < 0, \partial'_{ij} \geq q_2$
Added Rule	$V_i < q_3$
Perished Rule	$V_i < q_3$

## 4.2. Evaluating degree of event changes

Changes of environment are varied. Managers need to focus on essential changes. To achieve this goal, it is important to evaluate the degree of change, and rank changed rule by degree. Table 2 shows a simple formulation of change degree evaluation.

**Table 2.** Degree of event change

Type of Change	Degree of Change
Emerging Pattern	$\frac{\text{Support}^{t+k}(r_i) - \text{Support}^t(r_i)}{\text{Support}^t(r_i)}$

Unexpected Change	$\frac{Support^t(r_i) - Support^{t+k}(r_i)}{Support^t(r_i)} \times Support^{t+k}(r_i)$
Perished Rule	$(1 - V_i) \times Support^t(r_i)$
Added Rule	$(1 - V_i) \times Support^{t+k}(r_i)$

Let  $support^t(r_i)$  and  $support^{t+k}(r_i)$  represent the support value of  $r$  at time  $t$  and  $t+k$ , respectively. Degree of change for emerging pattern shows the change of support value between time  $t$  and time  $t+k$ . Degree of change for unexpected change is the change ratio of  $r_i$  multiplied by the support value of  $r_i$  at time  $t+k$ . The change ratio of  $r_i$  represents the degree of unexpectedness of  $r_i$ , namely the proportion of the difference between  $support^t(r_i)$  and  $support^{t+k}(r_i)$  to the  $support^t(r_i)$ . The degree of change is larger, if the change ratio of  $r_i$  is larger and  $support^{t+k}(r_i)$  is larger. Degree of change for perished (added) rule is obtained from the support value of perished (added) rule multiplied by the value of 1 minus the maximum similarity value. The degree of change is larger, if the perished (added) rule has less maximum similarity value.

## 5. CONCLUSION

The business environment today is more and more complicated. The ability to capture environment changes and be sensitive to the environment becomes a critical success factor for business. Research on environment scanning currently puts great emphasis on event tracking and event detection. But the main purpose of event tracking and event detection is to identify which event the news story describes. Business administrators cannot obtain environment change information until a new event occurs. It is insufficient for managers to be notified only when a new event happens.

To capture the changes of events, this research proposes an event change detection (ECD) technique. The proposed technique combines the change mining approach and concept hierarchy to detect changes to enhance environmental scanning.

### ABSTRACT

The fuzzy logic is applied to resolve the monitoring problem of products quality and products quantity increasingly varying as market requirement. A series of fuzzy rules are employed and the fuzzy system may generate suggested supply change rate. At the same time, the operation of supplier is also dynamically changing and the evaluation and selection for supplier are the basis of supply-chain co-operation. So whether it is scientific to select a supplier is crucial for sustaining and developing a company. Therefore, in this paper the neural network is introduced to dynamically assess suppliers and recommend to substituting for new ones when necessary, only supplementing fuzzy logic system with its advantages. This paper describes the methodology for the deployment of this proposed hybrid approach to enhance the machine intelligence of a supply chain network with the description of a case study to exemplify its underlying principles.

**Keywords:** supply chain, product monitoring, fuzzy logic, neural network

### 1. INTRODUCTION

It has been found by statistics that the top criteria of enterprises selecting suppliers are product quality. In other words, how the output products quality be is vital for a company's sustaining. With the variation of required output products quality and quantity, it is essential to decide the supply quality and quantity. Thereby, monitoring the supply products quantity and quality in a supply chain is a crucial factor for company to win competency and consolidate the supply chain.

An efficient supply chain network needs to have the capability of assessing the performance among various business partners, thereby enabling the effective selection of enterprise members to form an alliance for certain value chain activities such as the provision of certain products to a certain marketplace. In this respect, every partner contributes its core capability to the alliance in its certain dominant field. So the alliance members may make up for the demerits commutatively to cope with the increasingly complex setting of organizations and markets.

As such a 'smart' approach which allows a company to assess and to select business partners to jointly undertake a business project with the focus on customer demands is critical to leverage the operational performance of the network. To tackle the issue, a product monitoring approach is discussed in details in this paper and the monitoring problem for required products quality and quantity is analyzed based on the real time market, and meanwhile developed the performance assessment and selection suggestion of business partners focusing on fuzzy logic principle and neural network training. In short, the hybrid scheme which takes full advantages of the two reciprocal

intelligence technologies, will support the whole supply chain network to compute the updated performance scores of candidate supplier partners, hereby comprehensively evaluate and select supplier partners and, subsequently, recommend of the exact quantity of supply goods for various partners. In order to further the proposed approach, an example is cited to fully demonstrate the feasibility of implementing the suggested methodology.

### 2. ASSOCIATED RESEARCH

Fuzzy logic is a problem-solving control system methodology that lends itself to implementation in systems ranging from simple, small, embedded micro-controllers to large, networked, multi-channel PCs of workstation-based data acquisition and control systems (Kaehler, 1998). In other words, it is a method of reasoning that allows a fuzzy description of very flexible rules. But it must be sure that fuzzy logic does not mean fuzzy answers for only the reasoning process is set on vague terms. In fact, many objects and method to need decision and choice in the real world are hard to describe by discrete mathematic module. Fuzzy rules probed a methodology for dealing with the gray areas that involve fuzzy concepts. By allowing rules to have blurry boundaries rather than sharp ones, rules are more flexible, compact and intuitive for modeling complicated processes whose components cannot be clearly separated into categories. Fuzzy logic system involves information fuzzification, fuzzy reasoning and defuzzification. Therefore, as stated above, fuzzy logic does not mean fuzzy answers. Indeed, a discrete answer will be generated through the process of data fuzzifying, fuzzy reasoning and crisp computation.

In general, the knowledge exists plainly in a fuzzy-logic

system that has the advantage of compact, intuitive in algorithm and low in data quantity of processing. However, fuzzy reasoning sacrifices some explanation for accuracy, reliability and compactness, and often cannot explain how outputs change in response to inputs. Fuzzy rules are usually established on field experts and the basis of factual experiments. However, these experts may not be able to state their decision-making process in detail and it may not be feasible and economical for the experts to be around all the time.

In contrast with fuzzy logic, neural networks can be used with data promising results where there are data, even without experts to make judgments about the data. They were found to be very useful at modeling large amounts of data that help to solve complex problems. Indeed, neural networks can be powerful for problem solving because of their predict-compare-adjust process by which the result is next to optimum.. In brief, neural network systems have great self-adjusting and self-studying ability and full parallel character in structure. However, knowledge is stored at net nodes in the course of NN processing, therefore, NN system is difficult to describe itself specifically, large in quantity of information processing and much complicated in structure.

As stated above, the two intelligent technologies both have merits and defects. So a hybrid approach which focuses on the fuzzy logic scheme with the addition of the neural network technology will enable the two to complement and supplement each other with their own advantages. However, this research domain in which the synthetic approach is applied to support of a complex supply chain network has not received the attention it deserves. This paper attempts to provide some insights for the framework with a demonstration to show its feasibility.

### 3. THE FUZZY LOGIC APPROACH OF MONITORING PRODUCTS SUPPLY

#### 3.1 Adapted background

The paper is focused on procurement-quantity allocation policy of goods supplied for distribution center prior to selling to the public. But the scheme proposed is also adapted for the problem of procurement-quantity allocation among suppliers in the process of products procurement of enterprises, given the total required quantity and sure quality.

Products quality is variable with the different suppliers in a complex supply chain environment and the different allocation of products supply quantities among them will lead to the fluctuation of the output products quality. In real supply situation, the overall products quantity and quality required in the distribution center are ever-changing in corresponding with real-time market dynamically. Since the change rate of these data is often

vague, the products quantity allocated for suppliers is also blurry. Therefore, fuzzy logic system applied for thus complex supply situation may provide the validity of decision-problem-solving. In the following, the paper offers a simplified scenario of actual circumstances that only involves two suppliers. This case demonstrates that the fuzzy logic approach can deal with this situation and the same approach can be applied to multiple suppliers.

Figure 1: fuzzy pattern of supply change

#### 3.2 Establishment of fuzzy rules

Product quality is variable with the different suppliers in a complex supply chain environment and the different allocation of product supply quantities among them will lead to the fluctuation of the output product quality. On the other hand, the product supply quantities of suppliers vary with every of the two criteria that mean product quality and quantity required by enterprises. In order to provide suggestion supply change rate, a series of fuzzy rules are created to monitor the overall quality and quantity of the supplying products. The fore wares and post wares of rules both encompass fuzzy terms. For example,

If (the overall product quality can be considerably improved and the overall quantity can be significantly increased) Then (Maintain the supply of company-B and increase the supply of company-A significantly)

The meaning of the above fuzzy rule is plain. As the product quality can be considerably improved, i.e. the product quality is considerably lower than the market can appreciate, it is acceptable to supply more units from company A (higher quality supplier), and maintain the quantity of supplier B (lower quality supplier), thereby increasing the overall product quantity at the same time.

Output quality	Output quantity	Supplier A	Supplier B	Output quality	Output quantity	Supplier A	Supplier B
I	L	XBI	NC	OK	CH	SD	SD
I	CL	BI	SD	OK	H	CD	CD
I	OK	BI	CD	CS	L	NC	BI
I	CH	CI	CD	CS	CL	NC	CI
I	H	CI	BD	CS	OK	SD	SI
CI	L	CI	SI	CS	CH	SD	NC
CI	CL	CI	NC	CS	H	CD	NC
CI	OK	CI	SD	S	L	SD	XBI
CI	CH	SI	SD	S	CL	CD	XBI
CI	H	SD	CD	S	OK	CD	BI
OK	L	CI	CI	S	CH	CD	CI
OK	CL	SI	SI	S	H	BD	CI

Table 1: Control rules of supply change rate

The fuzzy rules that the actual output products quality and quantity vary as market requirement can be found in Table 1. One of the fore wares, the output product quality is divided into five degrees in fuzzy pattern which are inferior (I), considerably inferior(CI), ok(OK), considerably superior(CS), superior(S). The other fore wares, the output product quantity is also divided into five degrees in fuzzy pattern which are low (L), considerably low (CL), ok (OK), considerably high(CH), high(H). Additionally, the supply change rate of suppliers is fuzzified as 8 degrees that are extendedly-big increase (XBI), big increase (BI), considerably increase (CI), small increase (SI), no

Figure 2 : Fuzzy set for output quality

Figure 3: Fuzzy set for output quantity

change (NC), small decrease(SD), considerably

decrease(CD), big decrease(BD). The fuzzy rules based on Table 1 may be created in fuzzy-CLIPS, For example,

```
(defrule quality-inferior-quantity-considerable-low)
(output-quality inferior)
(output-quantity considerable low)
=>
(supplier-A BI)
(supplier-B SD)
```

Figure 1 shows the fuzzy pattern of supply change rate. It is stated that these data are determined on the basis of field knowledge and past experience.

### 3.3 Fuzzification and fuzzy reasoning

It is assumed that products quality of supplier A and B is examined by defect point (DP). And the DP of supplier A and B is separately 0.8 and 1.5. Any single quality-problem such as color mismatch of a certain component or malfunction of a certain feature can be regarded as a DP. It is key for seeking optimum allocation rate of supply goods among suppliers, when it is targeted for reaching the best price and maintaining quality level as high as possible. In this case it is promised that the integrated quality level is 1.2DP, and the promising output quantity is 10000 per day. The current supply quantity of supplier A is 4150 per day, while that of supplier B is 3850 per day. Then the overall output quality ( $Q_0$ ) of the combined product is  $(4150 \times 0.8 + 3850 \times 1.5) / (4150 + 3850) = 1.14DP$ .

That is to say the actual output quality is 1.14DP while the required quality output is 1.2DP. Referring to Figure 2, the measured value should be categorized as considerably superior quality through fuzzified analysis by the fuzzy expert systems. In the same way, the current overall products quantity is 8000 per day, belonging to low quantity (L) in fuzzy sets (Figure 3).

The conclusion through reason by fuzzy rules (Table 1) after fuzzifying the actual output figures is maintaining the supply quantity of supplier A (NC), while significantly increasing that of supplier B(BI).

### 3.4 Defuzzified process

Fuzzy logic is a process that involves data fuzzification, fuzzy reasoning, fuzzy decision and, clarifying linguistic values. In order to achieve a crisp value for the problem, the next step is to defuzzify the results generated from the fuzzy interference process by applying a single discrete action. Crisping computation is also known as defuzzification process referring to transforming a fuzzy set to a crisp value.

Defuzzification can be done with several methodologies, such as mean of maxima, center of area and mean of increasing gravity. As for all methods, there are advantages and drawbacks with each. However,

whichever of those you choose, special attention and consideration should be paid to the company's constraints on the system. The details of each method can be found easily on some references and will not be discussed again here. Referring to Figure 1, if the mean of maxima is considered, the supply change rate of supplier B is 0.5(BI in fuzzy set), while that of supplier A is no change (NC in fuzzy set). Therefore, the new supply quantity of supplier B is  $3850 + 3850 * 1.5 = 5775$

### 3.5 Evaluating the final results

The new overall products quantity after adjusting the supply of supplier B is

$$4150 + 5775 = 9925$$

The new overall products quality is

$$(4150 * 0.8DP + 5775 * 1.5DP) / 9925 = 1.206DP$$

From Figure 2 and Figure 3, it is not seen that the new output results are both within the OK level. The fuzzy sets are concretely classified in the paper with a view to achieving propel output result after one fuzzy resolving procedure. However, if the new supply quality is out of the OK range, another mending rule will be fired to obtain the appropriate output values.

## 4. ASSESSING SUPPLIER DYNAMICALLY WITH NN NETWORKS

### 4.1 modeling

Artificially neural network (NN) is a complex net system broadly interconnected by a great deal of simple processing cells (neural cells). The neural network which mimics many foundational functionalities of human brain is also a highly complicated nonlinear dynamic system. NN is especially adapted to deal with indiscrete and linguistic information-processing problem required for giving a thought to great many of factors and conditions at the same time, because of its abilities of large-scale parallel, distributed storing and processing, self-organizing, self-adjusting and self-studying.

However, as to the monitoring for product supply, it is far from sufficiency to only pay attention to the supply distribution among suppliers. Because the performance of suppliers is also an ever-changing factor and the evaluation and selection for suppliers is the operating basis of supply chain correlation. In this paper, a neural network module is introduced to assess the suppliers dynamically and suggest the replacement of suppliers when necessary, only supplementing the fuzzy logic system.

The comprehensive performance of suppliers is constrained by multiple factors such as price, in-time delivery, quality, technologic potential, service after selling, historic performance and etc. It is a non-structured information-searching problem to apply

NN to the evaluation of suppliers' performance. It is practiced that application of NN in this respect is effective. A NN module includes two parts: network training and operation evaluation of suppliers. First of all, quantities of historic data required no less than 100 data sets should be collected around suppliers' performance and potential business problems. The next step is training the net on the basis of BP neural network. A reliable automatically operating network may be generated after repeated predict-compare-adjust process. A neural network consists of one input layer, one or more hidden layers, and one output layer. Connections exist between the nodes of adjacent layers to relay the output signals from one layer to the next. Once the net gravities are trained well, the neural network may be used to evaluate the operation and provide decision support for choosing promising suppliers.

As Figure 4 shows, the input layer in the module encompasses four characteristic values (that are price, quality, delivery efficiency, service after sell), each of which selects five recent related records. The output layer is the five assessment suggestions as for suppliers (that are Price decreases slightly, Suggestion to replace supplier, Further assessment of company, Quality

Figure 4: The neural network model of partner evaluation

increases slightly, Delivery time seems to be inconsistent). The database has acquired a great deal of useful data. Accordingly, NN model may create a reliable well-trained network.

### 4.2 The analysis of a case

Here the further analysis about the reliably trained neural network from a case indicates the feasibility of the neural network system for evaluation and selection of suppliers. At first, the input data should be transformed as one scale. In concrete the five latest track records of a company gathered are scored in performance according to the promising price, quality, delivery efficiency and service level after sell for goods of suppliers. The performance score point (PSP) ranges from 1(lowest score) to 10(highest score). The PSP values are the input of the neural network module which will generate an assessment report for the user to make decisions. The case of Table 2 shows the recent PSP of

supplier A. The output report (Table 3) may be obtained which can be referred to making decision, after inputting the PSP values into the NN modules. In Table 3, “1” output from the NN mode indicates a positive suggestion to the associated statement and “0” is the negative suggestion, whereas “0” means that the related parameter almost is no change.

**Table 2:PSPof supplier A**

Supplier A(latest record)	Product price PSP	product quality PSP	Delivery schedule PSP	Service after sell PSP
1st	7.5	6.0	8.0	8.0
2nd	7.5	6.5	7.4	7.5
3rd	7.5	7.0	7.5	7.7
4th	7.5	6.0	7.8	7.5
5th	7.5	4.5	7.5	7.8

**Table 3:Assessment report of supplier A**

Supplier A	NN output
Price decrease slightly	0.5
Replacement of supplier	0
Quality is increasing slightly	0
Need to further assessment	1
Inconsistent delivery efficiency	0.5

As for the report of Table 3, it is obvious that there is question about supply quality of supplier A. In general, if the supplier A is one of main suppliers of the company, the further investigation of the issue should be put on. And if the investigation shows that supplier A has tackled the current difficulty through some urgent steps. Then the evaluation result is determined. Hereby, users can easily and objectively evaluate collaborative partners, find out problem timely and seek business chances without specialists or experts' instructions, according to the output suggestion of the NN model..

## 5. CONCLUSION

The problems are analyzed in the paper how enterprises assess and select suppliers and how to decide the propel allocation among multiple suppliers about procurement quantity in complex supply chain environment so as to meet the requirement of the dynamical overall products quality. The fuzzy logic is applied to resolve the monitoring problem of products quality and products quantity increasingly varying as market requirement. A

series of fuzzy rules are fired and the fuzzy system may generate suggested supply change rate. In the mean while, the operation of supplier is also dynamically changing and the evaluation and selection of suppliers are the basis of supply-chain co-operation. So whether it is scientific to select a supplier needs to be emphasized for sustaining and developing a company. Therefore, in the paper the neural network is introduced to dynamically assess suppliers and suggest to substituting for new ones when necessary, only supplementing fuzzy logic system with its advantages.

However, the hybrid approach in the paper is by no meant perfect. Fuzzy logic needs generating rules by experts while NN needs an array of historic data to train a network complexly. However, the paper is aimed at constructing an intelligently technologic flat for reference in the complicated supply chain management, aiding decision-making, thus making SCM more “agile” and enhancing management efficiency.

<sup>2</sup>veena@iitk.ac.in

## ABSTRACT

A patent always contains some images along with the text. Many text based systems have been developed to search the patent database. In this paper, we describe PATSEEK that is an image based search system for US patent database. The objective is to let the user check the similarity of his query image with the images that exist in US patents. The user can specify a set of key words that must exist in the text of the patents whose images will be searched for similarity. PATSEEK automatically grabs images from the US patent database on the request of the user and represents them through an edge orientation autocorrelogram. L1 and L2 distance measures are used to compute the distance between the images. A recall rate of 100% for 61% of query images and an average 32% recall rate for rest of the images has been observed.

**Keywords:** Patent Search, Content Based Image Retrieval, Recall rate, Precision

## 1. INTRODUCTION

The sheer size of the information available about the patents has led many researchers to develop efficient and effective retrieval techniques for patent databases. The Web Patent Full-Text Database (PatFT) of United States Patent Office (USPTO) contains the full-text of over 3,000,000 patents from 1976 to the present and it provides links to the Web Patent Full-Page Images Database (PatImg), which contains over 70,000,000 images. The volume of this repository makes it prohibitive for humans to find similar images in them. This has motivated us to develop a content-based image retrieval system for the patent databases.

Initial image retrieval techniques were text-based that associated textual information, like filename, captions and keywords with every image in the repository. For image retrieval, keyword based matching was employed for finding the relevant images. The manual annotation required prohibitive amount of labor. Moreover, it was difficult to capture the rich content of images using a small number of key words apart from being an unnatural way of describing images.

Soon it was realized that image retrieval based on the contents is a natural and an effective way of retrieving images. This led to the development of Content-Based Image Retrieval (CBIR). The Content-Based Image Retrieval (CBIR) [8] is aimed at efficient retrieval of relevant images from large image databases based on automatically derived image features. The original Query by Image Content (QBIC) system [3] allowed the user to select the relative importance of color, texture, and shape. The virage system [1] allows queries to be built by combining color, composition (color layout), texture, and structure (object boundary information).

Moments [6] fourier descriptors [5], [11] and chain codes [4], [12] have also been used as features. Jain

and Vailya [7] introduced edge direction histogram (EDH) using the Canny edge operator [2].

The edge orientation autocorrelogram (EOAC) classifies edges based on their orientations and correlation between neighboring edges in a window around the kernel edge [9].

## 2. SYSTEM ARCHITECTURE

PATSEEK consists of two subsystems- one for Creation of Feature Vector and Image Database and another one for Retrieval of Images similar to the query Image. The components of both subsystems and their interaction are shown in figure 1 (next page).

In order to add the feature vectors and images to the database, the user interacts with the system through its graphical user interface and provides a set of keywords. A snapshot of the user interface for specifying the search criteria for the patents to be grabbed is shown in figure 2 (next page). The patents are grabbed from the USPTO website. The image grabber searches the patent database and grabs the image pages from the patents that satisfy the search criteria.

A page image may contain more than one individual image. To extract the individual images from these page images, we need to identify the connected components or blocks. In these pages, the connectivity is present at a very gross level and an individual image is well separated in both directions from other images. The occasional captions are insignificant compared to the images and can be treated as noise. Our experiment shows that these captions do not change the feature vector of an image in any significant way. To identify the connected components, we start scanning a page image from the first pixel row. If a row has no black pixel, the row is discarded from further consideration. If we find a row that contains at least one black pixel, the position of the row is recorded as the potential start

of a connected component. We continue the horizontal scan as long as we continue to find rows that contain at

least one black pixel.

Figure 1. System Architecture of PATSEEK

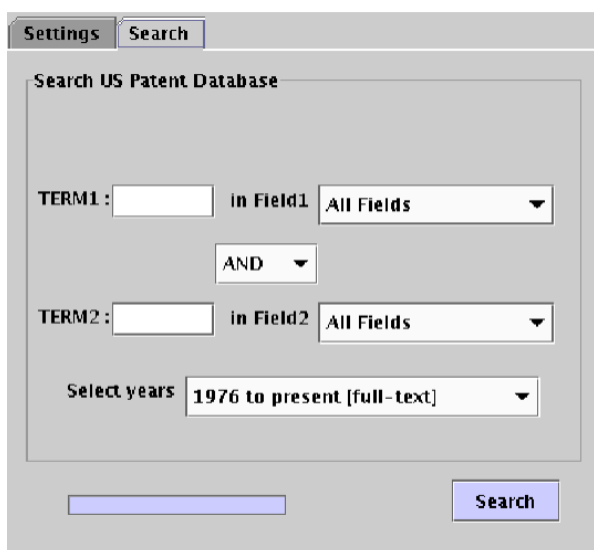

Figure 2. Patent Grabber

If we find enough (design parameter) contiguous horizontal rows that contain no black pixels, we have reached the end of the previous block if any. We continue horizontal scan till the end of the page image. For each horizontal block identified, we scan it vertically to segment it vertically using vertical threshold. These thresholds are set to 1 mm. A block that is less than 5 square cm is discarded as noise.

A document containing three images and their corresponding blocks that have been identified are shown in figure 3.

The separated images are stored in the image database along with patent number and the page number within the patent where these images were found.

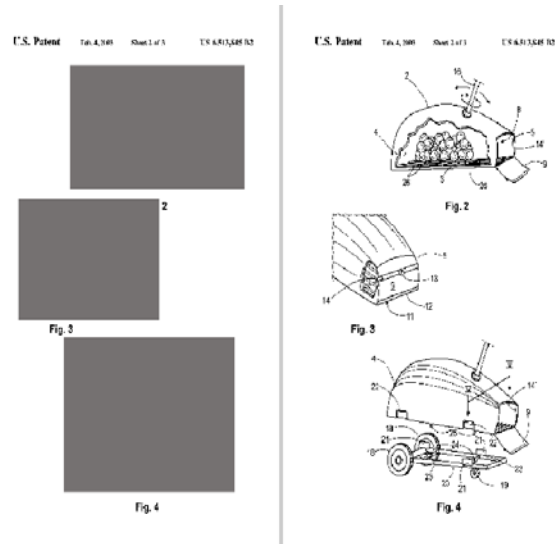

Figure 3. Blocks Identified for Individual Images

The graphic content are then used to calculate the image feature vector. We selected EOAC for our work because it is computationally inexpensive and independent of translation and scaling. Also, the size of the feature vector is small, 144 real numbers. We computed magnitude and gradient of the edges using Canny edge operator.

The edges that have less than 10 percent of the maximum possible intensity are ignored from further consideration.

The gradient of edges is then used to quantize edges into 36 bins of 5 degrees each. The edge orientation autocorrelogram is then formed which is a matrix, consisting of 36 rows and 4 columns. Each element of

this matrix indicates the number of edges with similar orientation. Columns 1, 2, 3 and 4 give the number of

edges that are 1, 3, 5 and 7 pixels apart. Each row corresponds to 5 degrees bin.

Figure 4. Query Image Selection

Two edges with  $k$  pixel distance apart are said to be similar if the absolute values of their orientations and amplitude differences are less than an angle and an amplitude threshold value, respectively [5]. These are user defined thresholds. The edge orientation autocorrelogram is stored in the database along with patent number and the page number within the patent where this image was found.

Feature vectors for the images are stored in an RDMBS table. We have created the feature vector database on Oracle as well as on Mysql.

### 3. THE DATABASE RETRIEVAL SYSTEM

For querying the database for images similar to a query image, the user interacts with the system through a graphical user interface (shown in figure 4). The user can specify the query image by providing its name and path. The image can be in any of the popular format such as tiff, gif, jpeg etc.

PATSEEK gives user an opportunity to specify the rotation angle for the query image. The angle may range between 0 degrees and 180 degrees.

We have used L1 and L2 distance measures to select 12-nearest neighbors and both have given almost identical results. The top twelve images, ranked on the basis of the distance are displayed as thumbnails along with the respective distance.

The graphical user interface displays the query image and the results for browsing to the user. A snapshot of the user interface is shown in the figure 5.

### 4. EXPERIMENTS

In this section, we report experimental results. All experiments were performed on an Intel Pentium IV Processor 2.4 GHz with 512 MBytes of RAM. The system was implemented in Java (Sun JDK 1.4.1). The feature vector database was initially created on Oracle and later on moved to MySQL Ver 12.21. We did not use the client of Oracle. We implemented the front-end using Java and its utilities.

Figure 5. The User Interface for query result navigation

Our database contains approximately 200 images that have been picked up from the patent database of United States Patent Office. For the performance evaluation, we have arbitrarily chosen 15 images from our collection. For each query image, a set of relevant images in the database have been manually identified. An ideal image retrieval system is expected to retrieve all the relevant images. One of the popular measures is *recall rate* [10] that is the ratio of number of relevant images retrieved and total number of relevant images in the collection. The *precision rate* is the ratio of the number of relevant images retrieved and total number of images in the collection.

Minkowski-form distance is used assuming that each dimension of image feature vector is independent of each other and is of equal importance. L1 and L2 (also called Euclidean distance) are some of the widely used Minkowski-form distance measures.

We have compared the performance of two similarity measures, L1 and L2 distance, in our experiments. For our experiment, we calculated precision and recall rate for each image. A recall rate of 100% for 61% of query images and an average 32% recall rate for rest of the images were observed. The precision rate varied between 10% and 35%. Precision rate greatly depend on the number of the images in the database. Graph 1 and graph 2 show the precision rates and recall rates for 15 query images. The image shown in figure 6 is one of the images selected for the query image shown on the left in figure 4 but it is not one of the top

ranking images. For the same query image, when we specify the angle of rotation as 180 degrees, the ranking of this image improves considerably.

Figure 6. An image obtained by rotating the query image

Graph 1. Precision Rate

Graph 2. Recall rate

## 5. CONCLUSION

In this paper, we have described PATSEEK that is an image retrieval system for the US patent database. The system has shown good performance and can be effectively utilized to locate similar patents before issuing a new patent by the patent office. A researcher or developer can locate all the images similar to the image in his document before filing for a patent. PATSEEK can compliment a text based search system.

The image feature vector database for PATSEEK is expected to grow and the retrieval system must give real-time performance even when database is large. At present, we have not made any effort to optimize the speed. The total time elapsed from the moment a query

image was given and to the moment relevant images are retrieved was about 90 seconds. We plan to use multidimensional indexing to cut down the retrieval time.

## ABSTRACT

In recent times, the development of privacy technologies has promoted the speed of research on privacy-preserving collaborative data mining. People borrowed the ideas of secure multi-party computation and developed secure multi-party protocols to deal with privacy-preserving collaborative data mining problems. Random perturbation was also identified to be an efficient estimation technique to solve the problems. Both secure multi-party protocol and random perturbation technique have their advantages and shortcomings. In this paper, we develop a new approach that combines existing techniques in such a way that the new approach gains the advantages from both of them.

**Keywords:** Privacy, data mining, association rule mining, secure multi-party computation.

## 1. INTRODUCTION

Business successes are no longer the result of an individual toiling in isolation; rather successes are dependent upon collaboration, team efforts, and partnership. In the modern business world, collaboration becomes especially important because of the mutual benefits it brings. Specially, the explosion in the availability of various kinds of data has triggered tremendous opportunities for collaboration. This paper studies a very specific collaboration that becomes more and more prevalent. The problem is the collaborative data mining. The objective of our research is to develop technologies to enable multiple parties to conduct data mining collaboratively without disclosing their private data. Since its introduction [7], privacy-preserving collaborative data mining problem has attracted many researchers. The approaches applied to solve the problem can be categorized into two aspects: one is based on secure multi-party computation [3, 10]; the other is based on randomization techniques [1, 4, 5]. The first approach can achieve precise results but its computation cost is usually much greater than that of the second approach. The second approach is computationally efficient but its accuracy is not as good as that of the first approach. This motivates us to find a combination in which the two approaches are integrated. The combined approach gains advantage of good accuracy that the first approach has, without losing benefit of high efficiency that the second approach has. In this paper, a secure integrated protocol is presented to deal with collaborative data mining problems. Collaborative data mining includes a number of different tasks, such as collaborative association rule mining, classification, and clustering, etc. This paper studies collaborative association rule mining problem. The goal is to discover meaningful association rules among the attributes of a large quantity of data contributed by all the collaborative parties.

The paper is organized as follows: Section 2 discusses the related work. Section 3 formally defines the

privacy-preserving multi-party association rule mining problem. We develop a secure protocol in Section 4. We describe our experimental results in Section 5. Further discussion is provided in Section 6. Section 7 concludes the paper and lays out the future work.

## 2. RELATED WORK

### 2.1 Secure Multi-party Computation

Briefly, a Secure Multi-party Computation (SMC) problem deals with computing any function on any input, in a distributed network where each participant holds one of the inputs, while ensuring that no more information is revealed to a participant in the computation than can be inferred from that participant's input and output [6]. It has been proved that for any polynomial function, there is a secure multi-party computation solution [6]. The approach used is as follows: the function  $F$  to be computed is first represented as a combinatorial circuit, and then the parties run a short protocol for every gate in the circuit. Every participant gets corresponding shares of the input wires and the output wires for every gate. This approach, though appealing in its generality and simplicity, is highly impractical for large datasets.

### 2.2 Privacy-Preserving Data Mining

In early work on such a privacy-preserving multi-party data mining problem, Lindell and Pinkas [7] propose a solution to privacy preserving classification problem using oblivious transfer protocol, a powerful tool developed by secure multi-party computation (SMC) research. Other techniques based on SMC were then proposed in [3, 10]. Randomization approaches was firstly proposed to solve privacy-preserving data mining problem by Agrawal and Srikant in [1]. People proposed more random perturbation based techniques to tackle the problem in [1, 4, 5]. The techniques based on SMC have characteristics that mining results will be the

same as original results without considering data privacy. In contrast, mining results using techniques based on randomization will be the estimation of original results but performance is usually better than SMC-based techniques. In this paper, we propose an approach which requires integrated use of two existing approaches. Through integration of two approaches, we can gain advantages of both approaches.

### 3. INTRODUCING THE PROBLEM

We consider the scenario where multiple parties, each having a private data set denoted by  $D_1, D_2, \dots$ , and  $D_n$  respectively where  $n$  is the total number of parties, want to collaboratively conduct association rule mining on the union of their data sets. Because they are concerned about their data privacy, neither party is willing to disclose its raw data set to others. Specially, we consider the scenario where data sets of collaborative parties are binary and vertically partitioned [10]. In other words, the identities of the  $i$ th (for  $i \in [1, N]$ ) record in  $D_1, D_2, \dots$ , and  $D_n$  are the same, and  $D_1, D_2, \dots$ , and  $D_n$  contain the same number of records (we use  $N$  to denote the total number of records for each data set).

## 4. SECURE MULTI-PARTY ASSOCIATION RULE MINING PROTOCOL

### 4.1 The Commodity Server Model

The commodity server model was proposed in [2]. The collaborative parties could send requests to the commodity server and receive data from the server, but the commodities must be independent of the parties' private data. The purpose of the commodities is to help the parties to conduct their desired computations. The commodity server is semi-trusted in the following senses: (1) It should not be possible to derive private information of data from the parties; it should not learn computation result either. (2) It should not collude with all the parties. (3) It follows the protocol correctly. Because of these characteristics, we say that it is a semi-trusted party. In real world, finding such a semi-trusted party is much easier than finding a trusted party. Based on this commodity server model, we study privacy-preserving multi-party association rule mining problem. In our solution, the commodities are randomly generated permutation functions [8]. Our goal is to permute all the parties' data in such a way that a designated party (data collector) can conduct association rule mining on permuted data and obtain the same mining results. The challenge is to prevent the designated party from knowing how the other parties' data are permuted.

### 4.2 Notations

For convenience, we define the following intuitive

notations:

1. Let  $V$  represent a permutation function that is used to permute the order of the columns in a data set. We call it the column permutation function. We use  $V^{-1}$  to represent the inverse of  $V$ .
2. Let  $H$  represent a permutation function that is used to permute the order of the rows in a data set. We call it the row permutation function. We use  $H^{-1}$  to represent the inverse of  $H$ .
3. Let  $VH = (V, H)$  represent a permutation function that contains a row permutation  $H$  and a column permutation  $V$ .  $VH$  means that we firstly apply  $H$  on the data set,  $V$  is then applied. We use  $(VH)^{-1}$  to represent the inverse of  $VH$ .
4. We use  $\Rightarrow$  as the permutation sign. For instance,  $R_1 \Rightarrow R_3$  means that Row 1 will be permuted to Row 3 and  $C_1 \Rightarrow C_4$  means that Column 1 will be permuted to Column 4.

### 4.3 Privacy-Preserving Multi-Party Association Rule Mining Protocol

At the beginning of our protocol, a data collector is randomly selected from all the collaborative parties. For simplicity, let's assume Party  $n$  is selected as data collector. The commodity server then generates a set of permutation functions satisfying some properties and sends them to the collaborative parties. Party 1, 2, ...,  $n-1$  permute their data by themselves and send permuted data to Party  $n$ . Since Party  $n$  also contributes its data set to the mining computation, its data must also be permuted similarly, i.e., the row permutation effects have to be the same. To avoid information leak, the permutation of Party  $n$ 's data has to be handled differently. In our protocol, the permutation of Party  $n$ 's data is done by itself together with another party (Party  $i$ ) who is randomly selected from Party 1, 2, ...,  $n-1$ . Party  $i$  and Party  $n$  will together permute the Party  $n$ 's data such that the permuted data have the same row permutation as other permuted data sets. To prevent Party  $n$  from conducting possible attacks, multi-variant randomized response technique [4] is applied on the data of Party  $n$ .

### Multi-Party Mining Protocol

#### Step I: Permutation Function Generation

1. The Commodity Server (CS) generates a set of column permutation functions  $V_1, V_2, V_3, \dots, V_{n-1}$  and a row permutation function  $H$ . It then sends  $V_1H$  to Party 1,  $V_2H$  to Party 2, ..., and  $V_{n-1}H$  to Party  $n-1$ .
2. The CS generates the other two sets of permutation functions  $V_n'H$  and  $V_n''H$ . It then sends  $V_n'H$  to Party  $n$ ,  $V_n''H$  to Party  $i$  where Party  $i$  is randomly selected from Party 1, Party 2 ... and Party  $n-1$ .

3. The permutation functions have the following property:  $V_1H, V_2H, \dots, V_{n-1}H$  and  $V_n'H''V_n'H'$  have the same row permutation effects.

**Definition 1** We say two permutation functions  $PF_1$  and  $PF_2$  have the same row permutation effects if  $PF_1(D_1)$  and  $PF_2(D_2)$  have the same row permutations.

#### Step II: Data Permutation

*Sub-step 1:* Permute  $D_1, D_2, \dots$ , and  $D_{n-1}$

1. Party 1 applies  $V_1H$  on its data set  $D_1$  to get a permuted data set  $PD_1$ , then sends  $PD_1$  to Party n.
2. Party 2 applies  $V_2H$  on  $D_2$  to obtain  $PD_2$ , and then sends it to Party n.
3. Repeat the above process until Party n-1 applies  $V_{n-1}H$  on its data set  $D_{n-1}$  and obtain  $PD_{n-1}$ , then sends it to Party n.

*Sub-step 2:* Permute  $D_n$

1. Party n applies  $V_n'H'$  on  $D_n$  to obtain  $PD'_n$ , then sends it to Party i.
2. Party i applies  $V_n''H''$  on  $PD'_n$  to obtain  $PD''_n$ , then randomizes  $PD''_n$  using the multi-variant randomized response technique described in Section 4.5, finally obtains  $PD_n$  and sends it to Party n (We will explain why Party i randomizes  $PD''_n$ ).

*Sub-step 3:* Combine the Permuted Data Sets

1. Party n concatenates all the data sets  $PD_1, PD_2, \dots, PD_{n-1}$  and  $PD_n$  such that the  $i$ th row in the  $PD_1, PD_2, \dots$  and  $PD_n$  becomes the  $i$ th row in the joint data set PD.

#### Step III: Mining

1. Party n conducts the association rule mining on the joint data sets PD and gets the permuted association rules denoted by  $PAR_n$ . Since the data collector's data are randomized, the standard association rule mining algorithm cannot be employed. Section 4.7 shows how to conduct association rule mining on data sets which contain both non-randomized data (e.g., the data of Party 1, 2... n-1) and randomized data (e.g., the data of Party n).

#### Step IV: Final Association Rules

*Sub-step 1:* Find the Final Rules Containing the Attributes from Party 1, Party 2, ..., and Party n-1

1. Party n sends the attributes, which the permuted association rules contain, to the corresponding parties (from Party 1 to Party n-1) who send the name of the

original attributes to Party n. For example, if the permuted rules contains a rule  $PD_3(A_1) \Rightarrow PD_5(A_4)$  with  $PD_3(A_1)$  from Party 3 and  $PD_5(A_4)$  from Party 5, Party n then sends  $PD_3(A_1)$  to Party 3 and  $PD_5(A_4)$  to Party 5. Without loss of generality, assume the original attributes of  $PD_3(A_1)$  and  $PD_5(A_4)$  are  $D_3(A_8)$  and  $D_5(A_3)$  respectively, they then send the attribute names of  $D_3(A_8)$  and  $D_5(A_3)$  to Party n. Note that the attribute indices are used in the protocol, e.g.,  $PD_3(A_1)$  denotes the first attribute in the permuted data set of Party 3. However, the data collector does not know whether  $PD_3(A_1)$  stands for *bread*, *butter*, or others. After the parties remove the column permutation functions and obtain the original attribute indices, e.g., Party 3 gets  $D_3(A_8)$ , they will not send the original attribute indices (e.g.,  $D_3(A_8)$ ) to the data collector and only sends the real attribute name that the original attribute indices denote to Party n. For instance, if the  $D_3(A_8)$  stands for *bread*, it sends *bread* to the data collector. The purpose of the above process is to prevent the data collector from inferring other parties' column permutation functions based on the resultant rules.

*Sub-step 2:* Find the Final Rules Containing Party n's Attributes

1. Party n sends its permuted attributes that the permuted association rules contain, to Party i who applies the inverse of  $V_n''H''$  on the permuted attributes and obtains some attributes. We call them the middle permuted attributes since they are still in permuted form (e.g., permuted by  $V_n'H'$ ).
2. Party i sends the middle permuted attributes to Party n who applies the inverse of  $V_n'H'$  on them and obtains the original Party n's attributes.

*Sub-step 3:* Find the Final Rules

After obtaining all the original attributes of the permuted attributes that the permuted association rules contain, Party n gets the final association rules and shares them with all the other parties.

#### 4.4 Why Party i Randomizes the Party n's Data

Assume that after Party i applies  $V_n''H''$  on the data  $V_n'H'(D_n)$  obtained from Party n, Party i directly sends  $V_n''H''V_n'H'(D_n)$ , without randomization, back to Party n. Since the total number of records  $N$  is usually much larger than the total number of attributes  $M$  in a large-scale data set, the probability of the sum of each column being unique is high. Thus, Party n is likely to find out the column permutation function  $V_n''H''$  by comparing  $V_n'H'(D_n)$  with  $V_n''H''V_n'H'(D_n)$  using the sum of each column. After finding  $V_n''H''$ , she can

remove  $V''_n$  from  $V''_n H''_n V''_n H''_n (D_n)$ . If Party  $n$  can somehow find out  $H''_n$ , Party  $n$  then knows  $V''_n H''_n$ . In other words, she knows  $V''_n H''_n V''_n H''_n (D_n)$ . Since all the parties' data are permuted in a way with the same row permutation effects and Party  $n$  also obtains other parties' permuted data, Party  $n$  can find out other parties' row permutation function  $H$ .  $H''_n$  is likely to be disclosed for any row of  $D_n$  that has a unique pattern. To avoid this problem, we let Party  $i$  randomize  $V''_n H''_n V''_n H''_n (D_n)$  before sending it to Party  $n$ . Even if the Party  $n$ 's data has the above special characteristics, Party  $n$  cannot exactly identify the Party  $i$ 's permutation function  $V''_n H''_n$  because of randomization. The challenge is how Party  $n$  conducts association rule mining after obtaining data set  $PD$ . Obviously, Party  $n$  cannot apply the traditional association rule mining algorithm [9], since part of the data set are not randomized and part of them are randomized. We will show how Party  $n$  conducts the association rule mining on the hybrid data set  $PD$  in Section 4.7.

#### 4.5 How Party $i$ Randomizes The Party $n$ 's Data

We propose to use randomization technique [4] to disguise  $V''_n H''_n V''_n H''_n (D_n)$ . The basic idea is that, for each record, we keep the same values with a predefined probability  $q$ ; we reverse the values with the probability of  $1-q$ . For example, assume there are 3 attributes for a record and the values for the record is  $(A_1=1, A_2=1, A_3=0)$ . We generate a random number between 0 and 1. If the number is less than  $q$ , the record is kept the same, that is  $(A_1=1, A_2=1, A_3=0)$ . If the number is greater than  $q$ , the record becomes  $(A_1=0, A_2=0, A_3=1)$ . For each record, we generate a random number to decide whether the record keeps the same values or being reversed. Finally, Party  $i$  obtains the data set  $PD_n$  and sends it to Party  $n$ . To conduct association rule mining on the randomized data set, we need to compute  $P(A_1=1, A_2=1, A_3=0)$ . To simplify our presentation, we use  $P(110)$  to represent  $P(A_1=1, A_2=1, A_3=0)$ ,  $P(001)$  to represent  $P(A_1=0, A_2=0, A_3=1)$ . Because the contributions to  $P^*(110)$  and  $P^*(001)$  partially come from  $P(110)$ , and partially come from  $P(001)$ , we can derive the following equations:

$$P^*(110) = P(110) \cdot q + P(001) \cdot (1-q)$$

$$P^*(001) = P(001) \cdot q + P(110) \cdot (1-q)$$

By solving the above equations, we can get  $P(110)$ . The general model is described in the following:

$$P^*(E) = P(E) \cdot q + P(\bar{E}) \cdot (1-q)$$

$$P^*(\bar{E}) = P(\bar{E}) \cdot q + P(E) \cdot (1-q)$$

where  $E$  is a logical expression. In the above example,  $E=(A_1=1, A_2=1, A_3=0)$  and  $\bar{E}=(A_1=0, A_2=0, A_3=1)$ . To evaluate the proposed randomization approach, we conduct extensive experiments in Section 5.

#### 4.6 How Can We Obtain the Final Association Rules from The Permuted Association Rules

In the mining step, Party  $n$  obtains the permuted association rules  $PAR_n$ . To obtain the final association rules from  $PAR_n$ , the parties need to apply the inverse of their column permutation functions on the permuted association rules. In the following, we use a simple example to illustrate the computation. Without loss of generality, we assume the original data, permuted data and permutation functions are shown in Fig. 1. Based on the permuted data, suppose that we obtain the permuted association rules as shown in Fig. 2. We can then apply the inverse of the column permutation functions and get the final association rules (Fig. 2).

#### 4.7 Multi-Party Association Rules Mining On Randomized Data

The following is the procedure for mining association rules on  $PD_1 \cup PD_2 \cup \dots \cup PD_n$ . It differs from traditional association rule mining procedure [9] in the computation of the frequency count (denoted as  $c.count$ ). When the data are not randomized, we can easily compute the  $c.count$ , but when part of the data are randomized using the multi-variant randomized response techniques, computing it becomes non-trivial.

FIGURE 2

For the part which is randomized, we do not know whether a record in the data set is true information or false information. Therefore, we cannot directly compute  $c.count$  on the randomized data. In the following, we will show how to compute  $c.count$  when some attributes are randomized. For example, we want to compute  $c.count$  for  $A_1$ ,  $A_2$ , and  $A_3$ . Let's assume  $A_1$  and  $A_2$  are not randomized and  $A_3$  is randomized. We can use the following estimation model.

$$P^*(A_1 A_2 A_3) = P(A_1 A_2 A_3) \cdot q + P(A_1 A_2 \bar{A}_3) \cdot (1-q)$$

$$P^*(A_1 A_2 \bar{A}_3) = P(A_1 A_2 \bar{A}_3) \cdot q + P(A_1 A_2 A_3) \cdot (1-q)$$

In general, when part of the attributes (denoted by RE) are randomized and the other part (denoted by NE) is not randomized, then the estimation model becomes:

$$P^*(RE \wedge NE) = P(RE \wedge NE) \cdot q + P(\bar{RE} \wedge NE) \cdot (1-q)$$

$$P^*(\bar{RE} \wedge NE) = P(\bar{RE} \wedge NE) \cdot q + P(RE \wedge NE) \cdot (1-q)$$

where  $\wedge$  is logical and operator.  $P^*(RE \wedge NE)$  and  $P^*(\bar{RE} \wedge NE)$  can be obtained from the randomized data set and  $q$  is known (With the knowledge of  $q$ , Party n only knows the probability of each value of  $PD_n$  comes from the values of  $V_n H_n V_n H_n (D_n)$ ). We can solve the above equation and get  $P(RE \wedge NE)$ . We can then compute  $c.count = P(RE \wedge NE) \cdot N$ .

## 5. EXPERIMENTAL RESULTS

To evaluate the effectiveness of our proposed scheme, we conduct association rule mining on the original data using the traditional association rule mining algorithm [18] and get a benchmark rule sets  $T_D$ . We then induce our rule set  $T_G$  from PD using our modified algorithm. We test the difference of these two sets. Since Party n's data are randomized by the multi-variant randomized response technique, we modified the association rule mining algorithm to handle the randomized data based on our proposed methods in Section 4.7. We run this modified algorithm on the randomized data, and find a set of association rules (e.g., our rule set  $T_G$ ). We also apply the original association rule mining algorithm to the original data set and find the other set of association rules. We then compute the error which is defined as the number of rules that the benchmark rule set  $T_D$  contains but our rule set  $T_G$  does not contain. The error rate is defined as the error divides the total number of rules in the benchmark rule set  $T_D$ . In this section, we will show the experimental results on two real-life data sets.

### 5.1 Data Setup

We conducted experiments on two real life data sets. We obtain the data sets from the UCI Machine Learning

Repository. The first data set is *Adult*. The second data set is *Breast-Cancer*.

### 5.2 Experimental Steps

Our experiments consist of the following steps:

Step I: Since we assume that the data set contains only binary data, we firstly transformed the original non-binary data to the binary (D). We split the value of each attribute from the median point of the range of the attribute.

Step II: We use D and the original association rule mining algorithm to build a rule set  $T_D$ .

Step III: We randomly select 10% number of attributes from D. For  $q = 0, 0.1, 0.2, 0.3, 0.4, 0.51$  (We use 0.51 instead of 0.5. Because when  $q = 0.5$ , estimation equation doesn't have a unique solution. We call this point an exception point in our approach.), 0.6, 0.7, 0.8, 0.9, 1, we conduct the following 4 steps:

1. Randomization: We create a randomized data set G. For each record in the training data set D, we generate a random number  $r$  from 0 to 1 using uniform distribution. If  $r \leq q$ , we copy the record to G without any change; if  $r > q$ , we copy the opposite values of selected attributes in the current record to G and we copy the original values of non-selected attributes in the current record to G. For instance, suppose there are three attributes (e.g.,  $A_1$ ,  $A_2$ , and  $A_3$ ) in D and the original values for them are  $A_1=0$ ,  $A_2=0$  and  $A_3=0$ . If the selected attributes are  $A_1$  and  $A_2$ . When  $r > q$ , the values for these two attributes will be  $A_1=1$  and  $A_2=1$  in the current record of G, but the value for  $A_3$  is still 1. We perform this randomization step for all the records in the training data set D and generate the new data set G.
2. Build a rule set: We use the data set G and our modified association rule mining algorithm to build our rule set  $T_G$ .
3. Compute the error: We compare  $T_D$  and  $T_G$ , and compute the error rate.
4. Repeating: We repeat the above steps for 50 times, and get  $E_1, E_2, \dots, E_{50}$ . We then compute the mean of these 50 error rate scores.

Step IV: We randomly select 20% and 50% number of attributes respectively from D. We repeat Step III (1-4). Since there are at least two parties in the multi-party data mining, Party n has at most 50% number of attributes in the combined data set PD if we assume that each party's data have the same number of attributes. Therefore, we didn't conduct experiments when more than 50% attributes are randomized.

$\theta$	0	0.1	0.2	0.3	0.4	0.51	0.6	0.7	0.8	0.9	1
Error Rate	0	0	0	0	0.023	0.256	0.024	0	0	0	0

(a) 10% Attributes Are Randomized

$\theta$	0	0.1	0.2	0.3	0.4	0.51	0.6	0.7	0.8	0.9	1
Error Rate	0	0.12	0.12	0.2	0.352	0.336	0.24	0.24	0.12	0.06	0

(c) 50% Attributes Are Randomized

FIGURE 3

### 5.3 Result Analysis

Fig. 3 shows the mean of error for *Adult* data set with the  $\text{minsup}=0.6$ . Fig. 4 depicts the mean of error for *Breast-Cancer* data sets with the  $\text{minsup}=0.45$ . We can see when  $q=1$  and  $q=0$ , the results are exactly the same as the results when the original association rule mining algorithm is applied. This is because when  $q=1$ , the randomized data sets are exactly the same as the original data set  $D$ ; when  $q=0$ , the randomized data sets are exactly the opposite of the original data set  $D$ . In both cases, our algorithm produces the accurate results comparing to the original algorithm. However, the privacy is not preserved in either case because an adversary can know the real values of all the records provided that she knows the  $q$  value. When  $q$  moves from 1 and 0 towards 0.5, the mean of error has the trend of increasing, and the probability of disclosing the original data is decreasing. Therefore the privacy level of the data increases. When more and more data are randomized, the mean of error will increase.

## 6. DISCUSSION

In this paper, we combine the secure multi-party computation approach with the random perturbation approach to tackle the problem of privacy-preserving collaborative association rule mining. As shown in previous sections, all parties' data are permuted, but Party  $n$ 's data are also randomized. As a result, the

mined rules containing Party  $n$ 's attributes are degraded with a certain level of inaccuracy. On the other hand, the rules that do not contain Party  $n$  attributes will be 100% accurate comparing to the results obtained by applying the traditional association rule mining algorithm [9] on the non-randomized and non-permuted data. Therefore, the results will be the tradeoff between the SMC-based approach and the randomization approach. Our secure multi-party mining protocol gains the advantage of good accuracy that the SMC-based approach has, without losing the benefit of high efficiency that the randomization approach has. Although we deal with the association rule mining problem in this paper, the proposed approach can be extended to solve other data mining problems, e.g., decision tree, Bayesian network classification, etc. To improve privacy level, we can also use multi-group randomized response [11] to randomize the Party  $n$ 's data. We need also point out that, Party  $n$  can apply maximum likelihood estimation method to attack  $H^n$  when the distribution of rows of  $D_n$  is highly skewed, and the number of records of  $D_n$  is small. Therefore, the data distribution should be considered when selecting the data collector.

## 7. CONCLUSION

We have presented a secure protocol to let multiple parties to find association rules on the joint data sets without comprising their data privacy. In the protocol, the data collector is firstly selected. All the parties except for the data collector permute their data using the permutation functions obtained from the commodity server. To prevent the data collector from conducting possible attacks on other parties' permutation functions, the multi-variant randomized response technique is utilized to randomize data collector's data. Finally, we conduct a set of experiments to evaluate the effectiveness of our proposed scheme.

In this paper, we only consider the semi-trust case in which all the collaborative parties honestly follow the protocol. The more challenging scenario is the malicious case where the collaborative parties may cheat with each other. As future work, we will develop the protocol to deal with the malicious case.

# Privacy-Preserving Data Mining In Electronic Surveys

Justin Zhan, Stan Matwin

School of Information Technology & Engineering, University of Ottawa, Canada  
{zhizhan, stan}@site.uottawa.ca

## ABSTRACT

Electronic surveys are an important resource in data mining. However, how to protect respondents' data privacy during the survey is a challenge to the security and privacy community. In this paper, we develop a scheme to solve the problem of privacy-preserving data mining in electronic surveys. We propose a randomized response technique to collect the data from the respondents. We then demonstrate how to perform data mining computations on randomized data. Specifically, we apply our scheme to build a Naive Bayesian classifier from randomized data. Our experimental results indicate that accuracy of classification in our scheme, when private data is protected by randomization, is close to the accuracy of a classifier build from the same data with the total disclosure of private information. Finally, we develop a measure to quantify privacy achieved by our proposed scheme.

**Keywords:** Privacy, Data mining, Randomization

## 1. INTRODUCTION

Data mining has emerged as a means for identifying patterns and trends from large amounts of data. To conduct data mining computations, we need to collect data first. However, because of privacy concerns, people might decide to selectively divulge information, or give false information, or simply refuse to disclose any information at all. There is research evidence [4] that providing privacy protection measures is a key to the success of data collection.

There are many ways to collect data. For instance, data may be collected using transaction records. This can often be done without people's knowledge, and individuals have no control over what information can be collected. The evolving legal developments will hopefully soon preclude this questionable practice. Another way to collect data is to solicit respondents' responses via surveys, for example, respondents might be asked to rate certain products, or they might be asked whether they have a certain medical condition, etc. The collected data is entered into a database. Although answering survey questions gives respondents control over whether they want to disclose their information or not, privacy concerns might hinder the respondents from telling the truth or responding at all (we will refer to this problem as *respondent privacy in electronic surveys*). How can we improve the chance to collect more truthful data that are useful for data mining while preserving respondents' privacy? How can respondents contribute their personal information without compromising their privacy?

We propose to use *Randomized Response* techniques [9] to solve the problem of respondent privacy in electronic surveys. The basic idea of randomized response is to scramble the data in such a way that data collector cannot tell with probabilities better than a pre-defined threshold whether the data from a respondent contain truthful information about the sensitive, private

information. Although information from each individual respondent is scrambled, if the number of respondents is significantly large, the aggregate information of these respondents can be estimated with reasonable accuracy. Such property is useful for naive Bayesian classification since it is based on aggregate values of a data set, rather than individual data items. The contributions of this paper are as follows: (1) We have modified naive Bayesian classification algorithm [7] to make it work with data disguised by randomized response techniques, and implemented the modified algorithm. (2) We then conducted a series of experiments to measure accuracy of our modified naive Bayesian algorithm on randomized data. Our results show that if we choose appropriate randomization parameters, the accuracy we have achieved is very close to the accuracy achieved by standard, unmodified naive Bayesian classifier on undisguised data. (3) We have developed a method to measure privacy achieved by our proposed approach.

There are some related works [1, 2, 3, 5, 6, 8, 10] in privacy-preserving data mining. We do not discuss them in details because of space.

## 2. BUILDING NAÏVE BAYESIAN CLASSIFIERS USING MULTI-VARIANT RANDOMIZED RESPONSE TECHNIQUES

Randomized Response techniques were first introduced by Warner [9] to solve the following survey problem: to estimate the percentage of respondents in a population that has attribute A, queries are sent to a group of respondents. Since the attribute A is related to some confidential aspects of human life, respondents may decide not to reply at all or to reply with incorrect answers. For the purpose of this discussion, we will distinguish two types of questions in a survey: questions about the respondent's private information, and questions about the respondent's personal information. Both kinds of information refer to the attributes of the

respondent. The private information is an attribute the respondent would rather not disclose, including its probability distribution (e.g., whether the respondent has a certain medical condition; or whether she takes a given medication); personal information is also an attribute of the respondent, but unlike private information the respondents do not normally mind that data collector knows the probability distribution of personal information (e.g., what is the probability that the color of the respondent's hair being black, or what is the probability that she lives near a lake). We also assume that private and personal information are unrelated - e.g., taking a medication is unrelated to one's hair color. To enhance the level of cooperation, instead of asking each respondent whether she has the attribute A, data collector asks each respondent two unrelated questions. One of them asks private information, i.e., the one that data collector is interested in. The other refers to personal information. The answers to the two questions are unrelated to each other [9]. For example, the survey questions can be designed as follows:

1. Do you have the *private* attribute A?
2. Do you have the *personal* attribute Y?

In practice, the first question could be "Are you taking medicine A?", and the second question could be "Do you live near a lake?". Respondents answer one of these two questions. They use a randomization device to decide which question to answer, without letting data collector know which question is answered. Each randomization device tells the respondent which question she is to answer: the probability of choosing

The first question is  $q$ , and the probability of choosing the second question is  $1-q$ . Although data collector learns a response (i.e., "yes" or "no"), he does not know which question was answered by the respondents. It is important to engineer the interaction between data collector and respondent in such a way that the respondent will trust the system, i.e., the respondent will clearly understand that data collector has no way of knowing which of the two questions is answered. Thus the respondent feels that her privacy is preserved. We further comment on this in Sec.4. Note that data collector only knows the probability distribution of the respondent's attribute Y. This is consistent with the interpretation of a personal attribute - data collector could know the distribution of the values (e.g., hair colors) of the personal attribute in the general population, without knowing the value of that attribute for a specific respondent.

The randomized response technique discussed above considers only one attribute. However, data sets usually consist of multiple attributes; finding the relationship among these attributes is one of the major goals for data mining. Therefore, we need techniques that can handle multiple attributes while supporting various data mining computations. In this paper, we provide multi-variant

randomized response technique (MRR) to address the problems of respondent privacy in electronic surveys.

## 2.1 Notations

In this work, we assume data are binary, but the techniques can be extended to categorical data. Suppose there are  $N$  *private* attributes ( $A_1, A_2, \dots, A_N$ ) in a data set A. We construct  $N$  *personal* attributes ( $Y_1, Y_2, \dots, Y_N$ ). We want one *private* attribute (question) to pair with one *personal* attribute (question), therefore we make the number of attributes of Y and the number of attributes of A be equal. Let A and Y represent any logical expression based on those attributes  $A_i (i \in [1, N])$  and  $Y_i (i \in [1, N])$ . For example, A can be  $(A_1 = 0) \wedge (A_2 = 1)$  and Y can be  $(Y_1 = 0) \wedge (Y_2 = 1)$ . Let  $P(Y)$  be the proportion of the records in the personal data that satisfy  $Y = \text{true}$ . Let  $P^*(A)$  be the proportion of the records in the whole randomized data set that satisfies  $A = \text{true}$ . Let  $P(A)$  be the proportion of the records in the whole non-randomized data set that satisfy  $A = \text{true}$  (the potential non-randomized data set which in reality does not exist).  $P^*(A)$  can be observed from the randomized data, but  $P(A)$ , the actual proportion that we are interested in, cannot be observed from the randomized data because the non-randomized data set is not available to anybody; we have to estimate  $P(A)$ . The goal of MRR is to find a way to estimate  $P(A)$  from  $P^*(A)$ .

## 2.2 Multi-variant Randomized Response Scheme

In this scheme, all the attributes including the class label will be treated as a group. They either keep the same values or obtain the values from personal data. In other words, when sending the private data to data collector, respondents either tell their answers to the private questions or tell their answers to the personal questions. The probability for the first event is  $q$ , and the probability for the second event is  $1-q$ . For example, assume a respondent's attribute values  $A_1$  and  $A_2$  are 11 for private data; and the respondent's attribute values  $Y_1$  and  $Y_2$  are 01. The respondent generates a random number between 0 and 1; if the number is less than  $q$  she sends 11 to data collector; if the number is bigger than  $q$ , she sends 01 to data collector. Since data collector only knows  $q$  which is the same for all respondents and does not know the random number generated by each respondent, he cannot know whether the respondent tells the values from private data or personal data. To simplify our presentation, we use  $P(A(11))$  to represent  $P(A_1 = 1 \wedge A_2 = 1)$ ,  $P(Y(11))$  to represent  $P(Y_1 = 1 \wedge Y_2 = 1)$  where " $\wedge$ " is the logical *and* operator. Because the contributions to  $P^*(A(11))$  partially come from  $P(A(11))$ , and partially

come from  $P(Y(11))$ , we can derive the following equation:

$$P^*(A(11)) = P(A(11)) \cdot q + P(Y(11)) \cdot (1-q)$$

Since  $P(Y(11))$  is known as  $Y$  is personal data,  $q$  is determined before collecting the data, and  $P^*(A(11))$  can be directly computed on the disguised (randomized) data set. By solving the above equation, we can obtain  $P(A(11))$ , the information needed to build a naive Bayesian classifier. The general model is described in the following:

$$P^*(A) = P(A) \cdot q + P(Y) \cdot (1-q) \quad (1)$$

### 2.3 Building Naïve Bayesian Classifiers

The naive Bayesian classifier is one of the most successful algorithms in many classification domains. Despite of its simplicity, it is shown to be competitive with other complex approaches, especially in text categorization and content based filtering. The naive Bayesian classifier applies to learning tasks where each instance  $x$  is described by a conjunction of attribute values and where the target function  $f(x)$  can take on any value from some finite set  $V$ . A set of training examples of the target function is provided, and a new instance is presented, described by the tuple of attribute values  $\langle a_1, a_2, \dots, a_n \rangle$ . The learner is asked to predict the target value for this new instance. Under a conditional independence assumption, i.e.,

$P(a_1, a_2, \dots, a_n | y_i) = \prod_{i=1}^n P(a_i | y_i)$ , a naive Bayesian classifier can be derived as follows:

$$\begin{aligned} v_{NB} &= \operatorname{argmax}_{v_i \in V} P(v_i) \prod_{i=1}^n P(a_i | v_i) \\ &= \operatorname{argmax}_{v_i \in V} P(v_i) \prod_{i=1}^n \frac{P(a_i \wedge v_i)}{P(v_i)} \end{aligned}$$

To build a NB classifier, we need to compute  $P(v_i)$  and  $P(a_i \wedge v_i)$ . To compute  $P(v_i)$ , we can use the general model (Eq.(1)) with  $A$  being  $(C = v_i)$  and  $Y$  being  $(CY = v_i)$  where  $C$  is the class label for the private data  $A$  and  $CY$  is the class label of personal data  $Y$ .  $P^*(A)$  can be computed directly from the (whole) randomized data set.  $P(Y)$  is known since it is personal and  $q$  is known as well. By knowing  $q$ , data collector, who conducts the training, only knows the probability of the training data being private, but does not exactly know if each value is private data or not. By solving the above equation, we can get  $P(A)$  which is  $P(C = v_i)$  in this case. Similarly, we can compute  $P(a_i \wedge v_i)$  using the general model (Eq.(1)) with  $A$  being  $(A_i = a_i \wedge C = v_i)$  and  $Y$  being  $(Y_i = a_i \wedge CY = v_i)$ .

### 2.4 Testing

Conducting the testing is straightforward when data are

not randomized, but it is a non-trivial task when the testing data set is randomized. When we choose a record from the testing data set, compute a predicted class label using the naive Bayesian classifier, and find out that the predicated label does not match the record's actual label, an we say this record fails the testing? If we knew whether the record represents the private or the personal data, and if we knew the true class for each data, we could easily answer this question. But how can we compute the accuracy score of a NB classifier when data are randomized? Our answer is to apply the multi-variant randomized response technique once again to compute the accuracy. Let us use an example to illustrate how to compute the accuracy. Assume the number of attributes is 2. To test a record  $(A_1 = 1, A_2 = 0)$  denoted by  $A(10)$ , we feed  $A(10)$  and  $Y(10)$ , where  $Y = (Y_1 = 1, Y_2 = 0)$  to the NB classifier built in Sec.2.3. Let  $P^*(A(cc))$  be the proportion of correct predictions using the disguised (randomized) testing data set,  $P(Y(cc))$  be the proportion of correct predictions in the personal data, and let  $P(A(cc))$  be the proportion of correct predictions in the private data.  $P(A(cc))$  is what we want to estimate. Because  $P^*(A(cc))$  consist of contributions from  $P(A(cc))$  and  $P(Y(cc))$ , we have the following equation:

$$P^*(A(cc)) = P(A(cc)) \cdot q + P(Y(cc)) \cdot (1-q)$$

Where  $P^*(A(cc))$  can be obtained from disguised testing data set.  $q$  is known and by knowing  $q$ , data collector, who conducts the testing, only knows the probability of the testing data being private, but does not exactly know if each value is private data or not. How does data collector know  $P(Y(cc))$ ? One implementation is as follows: each respondent is given the same classifier by data collector. The classifier is constructed during the training (Sec.2.3). Each respondent applies this classifier on her personal data  $Y$  and communicates the number of correct predictions (0 or 1) to data collector, who then computes  $P(Y(cc))$ . Note that data collector does not know the values of the  $Y$  attributes, only the result of the classifier. Data collector can solve the above equation and get  $P(A(cc))$ , the accuracy score of testing.

## 3. EXPERIMENTAL RESULTS

To evaluate the effectiveness of our proposed scheme, We conducted experiments on two real life data sets *Adult* and *Breast Cancer* which were obtained from the UCI Machine Learning Repository.

### 3.1 Experimental Steps

We modified naive Bayesian classification algorithm to handle randomized data based on our proposed scheme. We applied our scheme to obtain a privacy-oriented classifier. We also ran naive Bayesian classification algorithm on original data set, and obtained a base classifier. We then applied the same testing data to both

classifiers. Our goal is to compare classification accuracy of these two classifiers. Obviously we want accuracy of privacy-oriented classifier to be close to accuracy of the base classifier. Our experiments consist of the following steps:

#### Step I: Preprocessing

Since we assume that data set contains only binary data, we first discretize original non-binary data to become binary. We split the value of each attribute from the median point of the range of the attribute. After preprocessing, we randomly divided data sets into a training data set D (80%) and a testing data set B (20%). Note that B will be used for comparing our results with benchmark results.

#### Step II: Benchmark

We use D and the original NB classification algorithm to build a classifier  $T_D$ ; we use data set B to test the classifier, and get an accuracy score. We call this score original accuracy (or benchmark score).

#### Step III: $q$ Selection

For  $q = 0, 0.05, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9$  and 1.0, we conduct the following 4 steps:

##### Sub-step 1: Randomization

We create a disguised data set G. For each record in training data set D, we generate a random number  $r$  from 0 to 1 using uniform distribution. If  $r < q$ , we copy the record of D to G without any change; if  $r \geq q$ , we randomly generate the values for a record of Y according to the pre-defined probability and copy the record values to G. In this paper, each record of Y is randomly generated such that each logical expression (Y) appears with the probability of 0.5. That is  $W_y = 0.5$  (ref.Sec.4). We perform this randomization step for all the records in the training data set D, then generate the new data set G.

##### Sub-step 2: Classifier Construction

We use data set G and our modified NB classification algorithm to build a naive Bayesian classifier  $T_G$ .

##### Sub-step 3: Testing

We use data set B to test and get an accuracy score S.

##### Sub-step 4: Repeating

We repeat steps 1-3 for 1000 times, and get  $S_1, S_2, \dots, S_{1000}$ . We then compute mean and variance of these 1000 accuracy scores.

Figure 1

Figure 2

## 3.2 Accuracy Analysis

### 3.2.1 Analysis of Mean

Fig.1 and Fig. 2 shows mean values of accuracy scores for *Adult* and *Breast-Cancer* data sets respectively. We can see from figures that when  $q=1$ , the results are exactly the same as the results when standard, unmodified classification algorithm is applied. This is because when  $q=1$ , randomized data sets are all from private data D. When  $q$  approaches 1, contribution of private data is enhanced; with  $q$  deviating from 1, the contribution of private data is decreasing (when  $q=0$ , collected data set is all from personal data). Therefore, when  $q$  moves from 1 towards 0, the mean of accuracy has the trend of decreasing.

### 3.2.2 Analysis of Variance

Fig. 3 and Fig.4 shows variances of accuracy scores. When  $q$  moves from 1 towards 0, the degree of randomness in disguised data is increasing, variance of estimation used in our method becomes larger. Variance changes with different randomization levels  $q$ . When  $q$  is near 0, randomization level is much higher and private data is better disguised. We do not show variance when  $q=0$ . In this case, since collected data set is actually personal data and the probability

distribution for it is always the same for each iteration, variance is 0.

Figure 3

Figure 4

#### 4. MEASURING PRIVACY

Various privacy enhancing techniques [5, 8, 11, 14, 15, 16] have been developed to protect data privacy. To trust a privacy enhancing technology, we need to know how much privacy that a particular technique protects. A challenge faced by privacy-preserving data mining community is how to measure privacy. A general privacy measure which can quantify privacy for any privacy protection scheme is still an open question. In this section, we develop a privacy measure for our proposed multi-variant randomized response technique. Our measure contains two steps: First, we measure privacy for a single entry. Second, we select the minimal privacy value and treat it as the privacy level for the group. The reason why we choose the minimal value for the group is that, when the entries are randomized together, finding the original value for one entry will cause disclosing the original values for other entries in the group.

For a single entry, original value can be 1 or 0; randomized value can be 1 or 0 as well. Privacy comes from uncertainty of original value given a randomized

value. In other words, if original value is 1, given randomized value 1 or 0, privacy will be the probability that data collector guesses the original value being 0. There are four possible randomization results:

- Original value is 1, value after randomization is 1;
- Original value is 1 but value after randomization is 0;
- Original value is 0 but value after randomization is 1;
- Original value is 0, value after randomization is 0.

Let's use the following denotations:

- Let's  $O_m$  be the original value;
- Let's  $R_m$  be the value after randomization;
- Let's  $G_m$  be the guessed value.
- Let's  $W_a$  be the probability that a value is 1 in data set A, and the probability that a value is 0 in data set A is  $(1-W_a)$ ;
- Let's  $W_y$  be the probability that a value is 1 in data set Y, and the probability that a value is 0 in data set Y is  $(1-W_y)$ ;

Privacy for a single entry, denoted by  $PSE$ , can be derived as follows:

$$\begin{aligned}
 PSE = & \Pr(O_m = 1) \cdot \Pr(R_m = 1 | O_m = 1) \cdot \Pr(G_m = 0 | R_m = 1) \\
 & + \\
 & \Pr(O_m = 1) \cdot \Pr(R_m = 0 | O_m = 1) \cdot \Pr(G_m = 0 | R_m = 0) \\
 & + \\
 & \Pr(O_m = 0) \cdot \Pr(R_m = 1 | O_m = 0) \cdot \Pr(G_m = 1 | R_m = 1) \\
 & + \\
 & \Pr(O_m = 0) \cdot \Pr(R_m = 0 | O_m = 0) \cdot \Pr(G_m = 1 | R_m = 0) \\
 = & Comp_1 + Comp_2 + Comp_3 + Comp_4
 \end{aligned}$$

The first component contains three parts:

1.  $\Pr(O_m = 1)$  is the probability that a value is 1 in private data set (A), which is  $W_a$ .
2.  $\Pr(R_m = 1 | O_m = 1)$  is the probability that a randomized value is 1 given the original value is 1. There are two possibilities: (1) a randomized value comes from data set A, and the probability for the case is  $q$ ; (2) a randomized value comes from data set Y, and the probability for this case is  $(1-q) \cdot W_y$ .
3. Let  $(G_m | R_m)$  be the guessed value given a randomized value and  $(O_m | R_m)$  be the original value given the same randomized value. For the same  $R_m$  value, there are two possibilities:  $G_m = O_m$  or  $G_m \neq O_m$ . We should notice when  $(G_m | R_m) \neq (O_m | R_m)$ , there is zero contribution to  $PSE$ . For instance, in the first component, the original value is 1, the guessed value is 0 given the randomized value is 1. When  $(G_m | R_m) \neq (O_m | R_m)$ , then the guessed will be 1. That is the guessed value and the original value is the same (both of them are 1s) and it contributes zero to the  $PSE$ . Therefore, we only consider the case where

$(G_m | R_m) = (O_m | R_m)$  for the third part. We can apply Bayes rule to tackle this part. After applying the Bayes rule, we obtain  $\Pr(R_m=1 | O_m=0) \cdot \Pr(O_m=0) / \Pr(R_m=1)$ .  $\Pr(O_m=0)$  is the probability that a value is 0 in private data set (A), which is  $1-W_a$ .  $\Pr(R_m=1 | O_m=0)$  is the probability that a randomized value is 1 given the original value is 0. In this case, randomized value cannot come from private data since original value is 0 and randomized value is 1. The only possibility is that randomized value is from personal data set Y, and the probability is  $(1-q) \cdot (1-W_y)$ . As for  $\Pr(R_m=1)$ , we can extend this term and details are shown as follow:

$$\begin{aligned} Comp_1 &= W_a \cdot [q + (1-q) \cdot W_y] \cdot \frac{\Pr(R_m=1 | O_m=0) \cdot \Pr(O_m=0)}{\Pr(R_m=1)} \\ &= \frac{W_a \cdot [q + (1-q) \cdot W_y] \cdot (1-q) \cdot (1-W_y) \cdot (1-W_a)}{\Pr(R_m=1 | O_m=1) \cdot \Pr(O_m=1) + \Pr(R_m=1 | O_m=0) \cdot \Pr(O_m=0)} \\ &= \frac{W_a \cdot [q + (1-q) \cdot W_y] \cdot (1-q) \cdot (1-W_y) \cdot (1-W_a)}{[q + (1-q) \cdot W_y] \cdot W_a + (1-q) \cdot (1-W_y) \cdot (1-W_a)} \end{aligned}$$

Similarly, we can obtain other components, and we then get

$$\begin{aligned} PSE &= \frac{(1-W_a) \cdot W_a \cdot (1-q) \cdot [q + (1-q) \cdot W_y]}{[q + (1-q) \cdot W_y] \cdot W_a + (1-q) \cdot (1-W_y) \cdot (1-W_a)} \\ &\quad + \\ &\quad \frac{2W_a \cdot (1-W_a) \cdot (1-q) \cdot (1-W_y) \cdot [q + (1-q) \cdot (1-W_y)]}{[q + (1-q) \cdot (1-W_y)] \cdot (1-W_a) + (1-q) \cdot (1-W_y) \cdot W_a} \end{aligned} \quad \text{Eq. (2)}$$

We compute  $PSE$  for each single entry. We then select the smallest value  $PSE(\text{Min})$  as the privacy value for the group. We can see from Eq.(2) that,  $PSE$  is determined by three parameters: (1) control parameter  $q$ ; (2) private data (ref. to as data set A in Sec.2) distribution  $W_a$ ; (3) personal data (ref. to as data set Y in Sec.2) distribution  $W_y$ . What we can see from  $PSE$  equation is that, when  $W_a = 0.9, 0.8, 0.7, 0.6$  privacy is symmetric with respect to privacy when  $W_a = 0.1, 0.2, 0.3, 0.4$ . In other words, given a certain  $q$ ,  $PSE$  value will equal to the  $PSE$  value when control parameter is  $1-q$ .

Figure 5

To get better sense of our proposed privacy measure, we conducted a set of experiments on private data sets with

various distributions and personal data set with  $W_y = 0.5$ . Specifically, we conduct experiments when  $W_a = 0.1, 0.2, 0.3, 0.4$ , and  $0.5$ . For each data distribution, we compute privacy value for the cases where  $q = 0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1$ . As we see from results in Fig. 5:

- When  $q=1$ , private data is fully disclosed. Privacy value is 0;
- When  $q=0$ , data collector gets no private data, and the data obtained are all personal data. In this case, privacy level of private data is the highest.
- When  $q$  is away from 1 and approaches 0, the elements of private data contribute less to the classification, and the probability of disclosing private data is decreasing. Therefore privacy level of private data increases.
- When private data (A) distribution approaches to uniform ( $W_a = 0.5$ ), privacy level is increasing. Since uniform distribution will make original data recoverability be the lowest.

Empirical results from Sec.3 and Sec.4 confirm that recoverability and privacy are complementary goals. Given  $W_a$  and  $W_y$ , the best privacy is achieved when control parameter  $q$  is 0; however, the accuracy will be the worst in this case. The best accuracy is attained when  $q=1$  but privacy is the worst. Trade-offs are also applied when  $q$  has a value between 0 and 1. In practice, how to select  $q$  is dependent upon our primary goals. If we want the results to be very precise, we need choose the values near 1; in contrast, if privacy is the primary goal, we choose the values near 0.

## 6. CONCLUDING REMARKS

In this paper, we have presented a method to build naïve Bayesian classifiers using multi-variant randomized response technique. Experimental results show that when we select an appropriate randomization parameter  $q$ , we can get fairly accurate classifiers comparing to the classifiers built from undisguised data. A privacy measure was developed and privacy analysis was also conducted. Trade-offs between privacy and accuracy are discussed. The proposed multi-variant unrelated question model has a broader impact in the sense that it can be used not only for naïve Bayesian classification, but also can be utilized in many other privacy-preserving data mining computations, such as decision tree induction, Bayesian classification, probabilistic-based clustering. As future work, we will apply the proposed scheme to other data mining problems.

# Proposal of Improving Model for Default Probability Prediction with Logit Model on Non-Compensatory Rule

Sakamaki, Yoshikazu

Department of Value and Decision Science, Tokyo Institute of Technology, Tokyo, 1528550, Japan

## ABSTRACT

Financial statement analysis is widely used for credit risk analysis. This method was developed at the end of 19's for the purpose of surveying credit reliability of credit customers. However, the result of analysis with financial statements is likely to be controlled by the work experience of analysts. As the result, it is difficult to maintain consistency of risk measurement, and moreover, it is expensive and time consuming to perform the vast amount of precise evaluations required in a short time. Many researchers have studied financial statement analysis scientifically applying mathematical and statistical methods, especially with use of multivariate statistical analysis.

This report presents the history of preceding risk control studies and considers issues of the preceding default forecasting model based mainly on the binominal logit model on compensatory rule. Moreover we propose the improving scoring model on the non-compensatory rule and verify that our model is superior to the binominal logit model, and is useful in business using based on actual financial data.

## 1. INTRODUCTION

During the period of long economic stagnation, Japan has been faced with the task of reestablishing the reliability of its financial systems. The financial markets must be reformed in order to obtain high evaluations worldwide. The Financial Services Agency claims that they will reduce the bad debt ratio of Japanese main banks by 50% by the end of 2004, and resolve the issue of non-performing loans. Adding to this policy, they also suggest that they intend to build a much stronger financial system that can support the promotion of structural reform. To achieve our goal, all financial institutes, personal investors and business corporations must recognize the existence of credit risk and understand the techniques of risk control.

Financial statement analysis is conventionally used as the basic method of credit risk analysis. Credit risk analysis based on financial statements developed at the end of the 19's for the purpose of surveying the credit reliability of loan customers. However, the result of financial statement analysis is likely to be controlled by the level of work experience of analysts. As a result, it is difficult to maintain the consistency of risk measurement on such a subjective basis. Moreover, it is expensive and time consuming to perform the vast amount of precise risk analysis in the limited time.

Since W. H. Beaver (1967)[1], many researchers have studied financial statements analysis scientifically using mathematical and statistical methods, especially with the use of multivariate statistical analysis. One of the most well known studies is the Z-score model proposed by E. I. Altman(1966)(1968).

This report presents the history of the statistical approach of risk control and considers issues of the preceding default forecasting model with the linearly linked binominal logit model on compensatory rule, which is

conventionally used as the scoring model. In addition, an improved version of the scoring model with the binominal logit model on non-compensatory rule is presented.

## 2. PRECEDING STUDY

This chapter introduces studies of credit risk measurement with a statistical approach in the default forecasting model. As mentioned in Chapter 1, the study of default forecasting originates from Altman's discriminant model (1968). The result of his study is well known as the Z-score model, and it remains one of the most widely used methods for default forecasting all over the world.

Altman's z-score model is based on discriminant analysis. In this model, they assume that each firm has its own risk factor, assigning appropriate weight to each risk factor and adding all of the weighted factors. As the result, we obtain a linearly linked risk factor for a bankrupt company and a non-bankrupt company.

That is, let  $x_{mi}$  be the  $m^{\text{th}}$  risk factor for company  $i$  ( $m=1,2,\dots,M$ ) and  $\beta_m$  be the parameter for variable  $x_{mi}$ , and we define z-score as

$$z_i = \sum_{m=1}^M \beta_m x_{mi} \quad (1).$$

Here, the company is default if  $z_i < 0$ , and non-default if  $z_i > 0$ .

Now, we define

$Z^{(1)}$ : Average of z-score for default companies

$Z^{(2)}$ : Average of z-score for non-default companies

---(2)

and let variance of the linearly-linked risk factors through all the sample data be  $Var(Z)$ . Then, unknown parameters are given by maximizing

$$\eta^2 = \frac{(\bar{z}^{(1)} - \bar{z}^{(2)})^2}{Var(z)} \quad (3)$$

With the discriminant score calculated from the linearly linked risk factors weighted by the estimated parameters, we can estimate whether each debtor belongs to the default or non-default group.

The evaluation methods of credit risk based on the linear discriminant function is mathematically easy to handle and analogous to traditional credit risk evaluation analysis using a score card. That is the reason why the scoring model with discriminant analysis is used all over the world. However, when we apply discriminant analysis to credit risk control, we have to be very careful of the following statistical assumptions specific for credit risk measurement.

#### <1> Normality and variance equivalence

If the variables used in the discriminant analysis is not distributed normally or variance is not equivalent between the default and the non-default group, default forecasting with the discriminant score and statistical testing for the parameters cannot always be performed correctly.

#### <2> Uniformity of default/non-default probability

When we use discriminant analysis, we cannot have any information about the ratio of the default and the non-default firms. The discriminant model is usually built with the assumption that the ratio of the default firms and the non-default firms is equal. However, the ratio of default/non-default firms generally differs among banks.

#### <3> Meaning of calculated weighting parameters

Unlike the parameters estimated in regression analysis, the absolute value of discriminant parameters is not decided uniquely, and only the relative ratio among parameters is decided uniquely. That is, the absolute score in discriminant analysis cannot also be decided uniquely. In discriminant analysis, only the distance from the discriminant point is statistically significant.

Discriminant analysis is widely used but, as shown above, it involves the issue of statistical difficulty. Moreover, we need to make clear when bankruptcy occurs and what the default probability is, in order to qualify the credit risk. Even if we can know the relative default score as the result of discriminant analysis (z-score), we cannot know the absolute default probability.

To solve such an issues, normal regression analysis has begun to be used. Next we consider linear regression analysis. That is, let

$y_i$ : Bernoulli random variable (If firm  $i$  is non-default, it takes 0. And if firm  $i$  is defaulted, it takes 1.) ( $i=1,2,\dots,J$ )  
 $x_{ij}$ :  $j^{\text{th}}$  credit risk factor of firm  $i$  ( $j=1,2,\dots,J$ )

$\beta_j$ : Estimated parameter for  $j^{\text{th}}$  risk factor  
 and we define the default probability of firm  $i$  by

$$y_i = \beta_0 + \sum_{j=1}^J \beta_j x_{ij} \quad (4)$$

And the expected value of the dependent variable given by equation (4) becomes the estimated default probability. However, in the linear regression analysis, when the summation of all of the weighted risk factor becomes very large, the default probability exceeds 1. On the other hand, if the summation becomes very small, the default probability is less than 0. And it becomes contradictory to the definition of statistics. To solve this issue, the following method is used to adjust the expected default probability estimated through the above regression analysis. That is, when the expected default probability exceeds 1, we truncate the default probability to 1, and when the expected default probability is less than 0, we truncate the default probability to 0. However, it is not statistically natural to put the expected default probability between 0 and 1 compulsorily.

To resolve these issues, logistic regression analysis (binominal logit model on compensatory rule) began to be used (Martin;1977)[3]. In the logistic regression analysis, let the summation of all of the weighted risk factors be

$$Z_i = b_0 + b_1 x_{i1} + \dots + b_m x_{im} \quad (5),$$

and the default probability of firm  $i$  ( $p_i$ ) be

$$p_i = \frac{1}{1 + \exp(-Z_i)} \quad (6)$$

If the default probability of firm  $i$  is given by equation (6), the likelihood function for parameter vector  $\mathbf{B}$  is given by

$$L(\mathbf{B}) = \prod_{i=1}^I p_i^{y_i} (1 - p_i)^{1-y_i} \quad (7)$$

Here,  $y_i=1$ : If firm  $i$  is defaulted and  $y_i=0$  if firm  $i$  is not defaulted

Moreover, log-likelihood function is defined by

$$l(\mathbf{B}) = \sum_{i=1}^I \{y_i \log p_i + (1 - y_i) \log(1 - p_i)\} \quad (8)$$

Generally, parameters that maximizes equation (8) are estimated by the maximum likelihood estimation method.

### 3. MODEL IMPROVEMENT

#### 3-1. Issues in the preceding model

Default probability estimate based on logistic regression analysis is very significant because it enables measurement of default probability on an absolute scale, which cannot be performed in the classical credit risk models such as that of Altman (1968). However, in the normal logit model based on the compensatory rule, even if only one risk factor deteriorates, the default probability becomes very high although the firm does not actually confront management distress.

Regarding this point, researchers have shown very interesting report in preceding studies of marketing

research. In the study of marketing research, compensatory rule is used widely in the consumer's choice behavior model today because compensatory rule is widely believed to be able to mimic consumer's choice behavior on non-compensatory rule, when the following two conditions are satisfied.

That is,

- (1) Attributes are related monotonically to consumer's preferences.
- (2) There is no error or uncertainty about these preferences. (Dawes and Corrigan (1974)[4]).

Because these conditions are thought likely to be satisfied in most choice behavior cases, compensatory models are widely used even when it does not reflect the actual decision making process (Cattin and Wittink (1982)[5]).

Despite these reports, there is still reason for concern that compensatory models may not always mimic non-compensatory processes. Several researchers (Curry Louviere, and Augustine (1981)[6]; Einhorn, Kleinmuntz and Kleinmuntz (1979)[7]) have argued that studies demonstrating robustness in linear models have underemphasized a major influence on predictive accuracy: the correlation among attributes of each alternatives.

Newman (1977) was the first to examine explicitly the relationship of correlations among attributes and the fit of linear models, following brief discussions offered by Einhorn (1970)[8] and Goldberg (1971) [9]. He noted that though Wainer et al (1976)[10] conjecture that small departures from optimal coefficients in a linear model do not make no nevermind, will often hold in practice, it will not hold when the attributes describing alternatives are negatively correlated.

Negative correlations also can diminish model performance because they make predictions more sensitive to the particular choice strategy used Einhorn, Kleinmuntz, and Kleinmuntz (1979) illustrate this effect through the example of a negatively correlated environment containing two options, described on two attributes.

The first is good on attribute A and bad on B whereas the second is bad on A and good on B. The option that will be picked in this case depends on how a choice strategy weights the two attributes. A lexicographic strategy that selects the option best on attribute A, for example, would choose the first option. A similar lexicographic strategy looking first at attribute B would pick the second. In contrast, a compensatory rule that weights the two attributes equally would be indifferent. If the two attributes were correlated positively, if the first option were good on both attributes and the second bad on both, one would pick the first option regardless of how the attributes are weighted. Hence, in general, the less the redundancy among attributes in a choice environment

(the more negative the average inter-attribute correlation), the greater the difference in predictions made by different models.

A more precise discussion regarding this issue was made by Curry and Faulds (1986), who described the theoretical relationship that should be present between two different linear weighting schemes given different correlational structures. They noted that when two models are compared in a maximally negative inter-correlational environment, even small deviations in their weight can induce major discrepancies in prediction, approaching a complete rank-order reversal in overall preferences for options.

In this study, we propose an improving default probability forecasting model based on these discussions.

Table 1 shows the basic statistical value and correlation matrix of trunk seven representative financial ratios of default firms and non-default firms on the BULK database system provided by Nikkei group. As you can see, in the firms confronting bankruptcy, most of the financial indexes deteriorate compared with non-default firms.

\*Correlation is calculated with use both of default and non-default data.

As shown in Table 1, on many risk factors, especially firms confronting bankrupt have deteriorating financial ratios. That is, it can be predicted that all of the financial ratios should become worse at the same time when bankruptcy occurs. And there seems to be very negatively strong correlation among the major financial ratios.

Taking these points into consideration, applying the logit model on the non-compensatory rule in which default probability increases only when all of the risk factors used in the model deteriorate seems to be more appropriate than applying the model of the compensatory rule.

In this study, we propose an improving default probability forecasting model based on non-compensatory rule. Moreover, we apply the actual financial data to our model and reveal a higher default forecasting power than the preceding model.

### 3-2 Model Improvement

In this section, we show two ways of improving the default probability forecasting model: the conjunctive type and the disjunctive type.

#### <Conjunctive type>

In this type of model, borderline for each risk factor is decided, and we assume that firm fails only when all risk factors go over the borderline. Borderline varies among risk factors, and if we assume that correlation among error terms become zero implicitly and variation fluctuates based on logistic distribution at random, we can define the probability for firm  $i$  to fail as

$$\begin{aligned} P_i(y_i = 1) &= P_i(x_{ik} - t_k + e_{ik} \geq 0, \forall k) \\ &= \prod_{k=1}^K P_i(x_{ik} - t_k + e_{ik} \geq 0) \\ &= \prod_{k=1}^K \frac{1}{1 + \exp(-b_k(x_{ik} - t_k))} \end{aligned} \quad (9)$$

It means that the default probability for firm  $i$  is in proportion to the distance from the borderline of each risk factor.

#### <Disjunctive type>

In this type of model, we assume that firm fails if, at least, any one of the risk factors goes over the borderline. Just as mentioned in the conjunctive type model, assuming that borderline varies among firms and variation fluctuates based on logistic distribution, we can derive the following equation.

$$\begin{aligned} P_i(y_i = 1) &= P_i(\exists k, x_{ik} - t_k + e_{ik} \geq 0) \\ &= 1 - P_i(x_{ik} - t_k + e_{ik} < 0, \forall k) \\ &= 1 - \prod_{k=1}^K P_i(x_{ik} - t_k + e_{ik} < 0) \\ &= 1 - \prod_{k=1}^K \left(1 - \frac{1}{1 + \exp(-b_k(x_{ik} - t_k))}\right) \end{aligned} \quad (10)$$

Here,

$x_{ik}$ :  $k^{\text{th}}$  risk factor of firm  $i$  ( $i=1,2,\dots,I; k=1,2,\dots,K$ )

$\beta_k$ : Scale parameter for  $k^{\text{th}}$  risk factor ( $k=1,2,\dots,K$ )

$t_k$ : Border line of  $k^{\text{th}}$  risk factor ( $k=1,2,\dots,K$ )

$y_i$ : Bernoulli random variable (If firm  $i$  is non-default, it takes 0. And if firm  $i$  is defaulted, it takes 1.)

### 3-3 Comparison model

As the comparison model, we use the normal logit model shown by equation (6).

### 3-4 Parameter estimation

Parameters are estimated by equation (11) based on the MLE (Maximum Likelihood Estimation method). If we use MLE for the parameter estimation of nonlinear model, parameter solution sometimes drops in the local

minimum.

To avoid this issue, parameters are estimated by comparing all of the combination patterns of variables to decide the most suitable variable combination, and we generated 20 combination patterns of values at random in advance which was used as the initial value for each combination pattern of variables.

$$L(b) = \prod_{i=1}^I p_i^{y_i} (1 - p_i)^{1-y_i} \quad (11)$$

### 3-5 Calibration of model fitness

In this study, log-likelihood, AIC criteria, Kolmogorov-Smirnov distance, and divergence are used as the index of model fitness to compare the appropriateness of the normal linearly linked binomial logit model on the compensatory rule and improving logit model on the non-compensatory rule.

Here, the Kolmogorov-Smirnov test measures the maximum distance between two distribution functions. In our case, we look at the difference between the default/non-default distribution. This difference is known as the KS distance and it is used to assess the fitness degree of our model.

Divergence is the statistical index that shows the separation of the distribution of the default and non-default firm, which is calculated with the average and variance of the score.

It can be calculated by

$$Divergence = \frac{2(m_A - m_B)^2}{V_A + V_B} \quad (12)$$

Where,

$\mu_A, \mu_B$ : Expected value of score given to default/non-default firms

$V_A, V_B$ : Variance of score given to default/non-default firms

## 4. CALIBRATION

This chapter verifies the appropriateness of the proposed model. Publicly disclosed financial data of companies sold by Nikkei Group (BULK system) is used as the calibration data.

### 4-1 Outline of calibration data

1. Data source: Account settlement data of the company (From April 2000 to March 2001)

2. Data volume: 2,914 companies

3. Default ratio:

If the company defaulted in three years after the accounting date, the company is regarded as defaulted. (Default ratio: 84/2,914=2.88%)

Here, especially, in the case of normal logit model, which has a linear structure of risk factors, outliers in financial ratios often cause the problem of biased default probability estimation. In this study, we set the lower cap at the 1 percentile point and the upper cap at 99 percentile point.

#### 4-2 Parameter estimation

Based on this actual financial data, we estimate model parameters for the normal logit model, conjunctive/disjunctive type of logit model on the non-compensatory rule.

Generally, the fitness of the model on the training data set is fine, but the most important question is how the

model works in out-of-sample data. So that in estimating parameters, we have chosen 60% of the sample data at random and used for in-sample-data, and 40% for out-of-sample data. Moreover, we generated 20 combination patterns of values at random in advance and used as the initial value of the maximum likelihood estimation method for the search algorithm, and prevented from dropping to the local minimum. Based on the value of the Log-Likelihood and AIC criteria, the proposed model adopts the estimated parameters which have minimum Log-Likelihood and AIC as the optimum parameters. It is probable that we obtain the result by chance, so that we tested several datasets to examine the superiority of our model. We show one of the results of parameter estimates in Table 3 due to the limitation of spaces.

**Table 2 Result of parameter estimation**

Parameters	Normal Logit Model	P-value	Compensatory Model (Conjunctive)	P-value	Non-Compensatory Model (Disjunctive)	P-value
$B_0$ Intercept	0.0021	0.00001	-	-	-	-
$B_a$ Capital adequacy ratio	-3.9091	0.0219	-8.21248	0.00036	-2.94515	0.01859
$t_a$	-	-	0.21756	0.00083	0.10701	0.02643
$B_b$ Ratio of check account degree of dependence	-0.63388	0.01226	5.51058	0.01922	2.48401	0.00053
$t_b$	-	-	0.56535	0.01228	0.13795	0.09182
$B_c$ Ratio of interest expenses to sales	-10.9863	0.51632	-	-	-	-
$t_c$	-	-	-	-	-	-
$B_d$ Acid Ratio	-1.93705	0.03417	4.76147	0.0274	6.9669	0.05109
$t_d$	-	-	-3.63163	0.0917	-2.07471	0.07811
$B_e$ Deposit-loan ratio	-5.31485	0.03125	-	-	-	-
$t_e$	-	-	-	-	-	-
$B_f$ Ratio of return on sales	-3.59059	0.00069	-1.85393	0.13607	-	-
$t_f$	-	-	-0.01782	0.0021	-	-
$B_g$ Cash Ratio	-	-	-	-	-	-
$t_g$	-	-	-	-	-	-
Log-Likelihood(-2logL)	357.25248		310.964		386.42998	
AIC	369.25248		326.964		398.42998	
Divergence	0.153		0.162		0.108	
K-S Distance	71.66%		75.26%		69.69%	

Here, parameter estimates are obtained from in-sample data. And Log-Likelihood (-2logL), AIC, Divergence and K-S Distance are calculated based on the out-of-sample data.

## 5. RESULTS

### 5-1 Findings

As we can see in the financial policy for the revision of capital adequacy ratio based on BASEL II, application of rating technology for credit risk control is attracting significant attention from all over the world. For example, in BASEL II, it is permitted for each bank to use an original rating model, so-called internal rating grades, to grasp the total credit risk. And to realize the suitable increase of capital adequacy ratio, a more elaborate statistical model that can grasp total credit risk in the bank on time is needed. The linearly linked binominal logit model on the compensatory rule is used as the conventional model. However, generally, financial ratios that have strongly negative correlation are often used as a risk factor in the model, and as mentioned in the previous chapter, when we apply the normal logit model to the risk factors that have mutually negative correlations, it is expected that there exist stochastic issues.

So, this study proposed a default probability forecasting

model on the non-compensatory rule and resolved these issues. Simultaneously, based on the actual financial ratio data, we have shown that our model was superior to the preceding model.

### 5-2 Considerations

**Figure 1 Comparison of Lift Curve**

Figure 1 shows the lift curve of the number of bankrupt firms based on both of the linearly linked normal logit model on the compensatory rule and the improving logit model on the non-compensatory rule. As shown in this graph, the logit model on the non-compensatory rule (disjunctive type) does not have so high default capturing power, but the improved logit model on the compensatory rule (conjunctive type) shows a much higher default capturing power than the linearly linked normal logit model on the compensatory rule. It can also be proved by log-likelihood and the AIC statistical values shown in Table 3. As a result, we can conclude that the non-compensatory rule with conjunctive type has significantly superior power for default forecasting.

As mentioned in the previous chapter, when there exist strongly negative correlations among variables of the model, it is suggested that model performance reduces on the model of compensatory rule like normal logit model.

At first, to confirm the level of correlation among some financial indexes, we made correlation matrix and confirmed that there existed strongly negative correlations among some variables. (Show Table 1).

And after that, we proposed improving default probability forecasting model that enabled to improve the model performance. We proposed two types of models (Conjunctive type and disjunctive type), and as the result of model validation, we confirmed that we could improve model performance dramatically with use of conjunctive type model.

It can be thought as the major cause that most of the financial indexes tend to deteriorate at the same time when firm fails in addition to there exists strongly negative correlations among financial indexes.

### 5-3 Parameter Estimates

In this study, parameters are estimated by comparing all of the combination patterns of variables to decide the most suitable variable combination. However, this method does not always decide the optimum combination pattern of variables. Moreover, as the number of variables used in the model increases, the number of combination patterns of variables that have to be considered in the model increases rapidly. And as a result, considerable time is needed to find the optimum model parameters.

To respond to such issues, in the normal logit model or linear regression model, some statistical variable choice algorithms such as Stepwise/Backward/Forward are proposed. Regarding this point, the same type of variable choice algorithm is needed to find the most appropriate combination pattern of variables for the non-compensatory logit model. Further study is required to resolve these issues.

## 6. SUMMARY AND FUTURE INVESTIGATIONS

In this study, we proposed improving logit model based on non-compensatory rule instead of traditional normal logit model based on compensatory rule. We applied actual financial data for our model and showed superiority of our model.

Only financial ratios are used as the calibration data. But generally, when we apply default forecast model for small and medium entertainments or small individual firms, financial data may be window-dressed or the data may be modified intentionally. As a result, reliability for the financial data is reduced in such companies. To remove this issue, it is advocated that not only financial ratios but also individual attributes should be included in the model. However, including and combining such individual attributes is problematic. In an actual business, models are built by considering individual attributes and financial ratios simultaneously in the same logit model or mixing both of the estimated scores with a certain ratio after parameters are estimated independently on both of individual attribute data and financial ratio data. We can expect to build much stronger model through these processes.

# Study of SOA Component Dynamic Scheduling Based on Mobile Agent Coalition

Tao He<sup>1</sup>, Bin Tang<sup>2</sup>, Leqiu Qian<sup>3</sup>

Computer Science and Engineering School, Fudan University, Shanghai 200433, China

<sup>1</sup>eGrid@msn.com, <sup>2</sup>edesk@126.com, <sup>3</sup>iAgent@163.com

## ABSTRACT

Service-oriented components differ greatly with the traditional ones in the Service-Oriented Architecture. The ways of scheduling components seamlessly according to the agile computing needs to fit the e-business requirements is the key technology in the highly distributed, paralleled environment. In this paper, Based on the Multi-Agent Coalition, a new service-oriented component dynamic scheduling model is proposed, including the Multi-Agent Organization to schedule and coordinate the component assembly, the design of virtual execution task list table and self-learning algorithm, the definition of the Services component model, and the mechanism of collaboration Agents to search, discovery, concurrent schedule, dynamic assembly when execution in an heterogeneous network environment. To a large extent, the thesis solves the traditional problem of over-emphasis on centralized control logic, which leads to lacking flexibility in e-Business computing presently, and helps e-business service-oriented components become more adaptive, mobility and intelligence.

**Keywords:** Service-Oriented Component, Multi-Agent, e-Business, Scheduling, Algorithm

## 1. INTRODUCTION

Automation is the most effective way to improve the efficiency of e-business. With the widely use of Service-Oriented Architecture software engineering, there is at least two problems emerged: too much service-oriented components which lack of automatic management system and too weak technology now-used which cannot support the dynamic and agile computing to meet e-business demand, especially to fully considerate the enterprise individuation. Multi-Agent technology as the research focusing on Artificial Intelligence and distribution computing, gives an effective way to solve these problems, which make business becomes more agility and interconnectivity.

A new service-oriented component-scheduling Model based on the Multi-Agent Coalition is proposed. In the architecture, every kinds of agent can enhance mobile agility by self-learning mechanism and by storage of personal information in every dynamic and distributed execution. This approach use a fully new method model to construct the virtual business activities by simulating transactions in the real business world, such as locate customs, negotiate with them, and so on. We use the model in the following by build a MAGE (Multi-Agent Environment) to put the conception into practice, and the process of e-business is simplified greatly.

## 2. DYNAMIC COMPOSITION

Agent-based component dynamic composition is the fundamental technique to shift from traditional components to virtual service-oriented ones. With the help of agents, components can aggregate or compose existing services and component into new styles. Some components are virtual ones when execution, in fact,

they don't exist at all. Such would allow third-parties to provide value-added components, which is similar with the real world services business. Five new features of services component are defined here.

**Dynamic Existence** It will not only being an entity as used to be, but a function correlation with the time.

**Autonomy** The Agent-based Services Component has the ability to take its own decisions in an independent way, including selecting the best of the available options according to e-Business computing requirements, Self-adaptation to different interfaces and protocols, being flexible, polytypic and extensible.

**Competitiveness** It should be competitive for a candidate to integrate into the SOA. More efficient and accuracy should be achieved with the lowest costs, and the self-learning mechanism which enhance the performance of components after execution is vital.

**Sociability** Communication protocol of different Agents is needed to enable them interaction with each other.

**Semantic matching** Semantic matching of component descriptions will make composition more transparent.

There are two basic composition styles under the control of composition Agent. One is Hierarchical Composition, and another is dialogic Composition.

Fig. 1 Agent-based Hierarchical Composition

In hierarchical compositions, some related components cooperate under the agent coordination act as a new component at a higher level.

Fig. 2 Agent-based dialogic Composition

In the dialogic pattern, interacting components are viewed as peers. One component may make use of the other by exchanging data or control signals supervised by coordination Agent.

### 3. RUN-TIME ASSEMBLY MODEL

The service-oriented component dynamic scheduling and assembly model during the run-time should be predictable, applicable and manageable. We investigate the mechanism from three perspectives including Agent Coalition Perspective, Component Dynamic Assembly Perspective and the Inside Control Gene Perspective.

#### 3.1 Agents Society Architecture in the Model

According to the dynamic assembly requirements, a main control-agent is introduced. It is an agent stored in migrating node with a virtual task list, and when the main agent runs in the migrating node, these service-oriented components can be assembled dynamically and the task table can be taken down after running at a previous node.

Fig. 3 Agents Society of Run-time Assembly Model

Secondly, the mobile Multi-Agent coalition is composed of some other kinds of agents including: services search agent, execution supervisor agent, learning agent,

integration agent, coordinate agent and safeguard agent, which make distributed services component composite, integrate, scheduling dynamically according to business logic. All of them function and cooperate with each other to overcome the shortcoming of traditional e-business system and create a real-time virtual cyber enterprise.

#### 3.2 Component Dynamic Assembly Model

The Dynamic Assembly Model covers the whole process of the service-oriented components discovery, composition, negotiation, and orchestration dynamically and seamlessly, which makes it possible when fulfilling some complex commercial tasks by interacting with distributed component resources. Nowadays, many distributed service-oriented applications designed to execute on Grid Computing Environment, require the simultaneous co-allocation of multiple service-oriented component resources in order to meet high business performance frequently. The approach via agent coalition mechanism for services allocation and management architecture is very helpful to the co-allocation resource efficiently. With the help of Mobile Agents, new component clusters are generated and coupled to run at a higher level. So, the main focus is to design more adaptive component interfaces to enable the assembly and scheduling process more flexible and context-aware. Agent is the best solution.

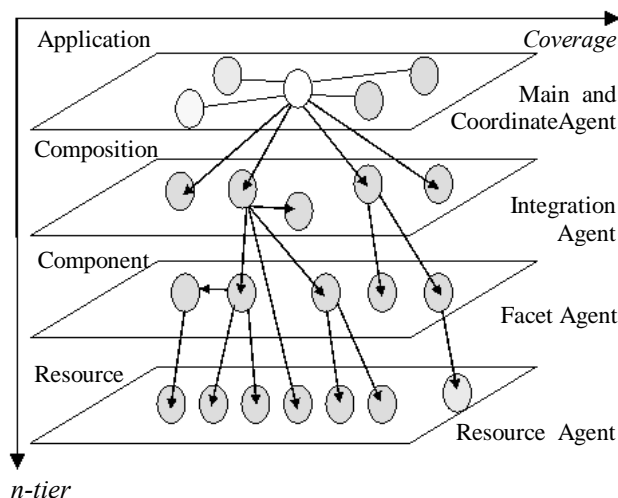

Fig. 4 Component Dynamic Assembly Model

The Facet Agent based on XML encapsulates the detail information of interface and was supported by the component assembly history information warehouse. It has self-descriptions and can communicate with other component agents to composite into a new style according to the e-Business requirements and the characteristic information retrieved from history data. Main Control Agent can migrate to other node to supervise the compiling and execution of local assembled component according to the Virtual Task List optimized by dynamic scheduling Algorithm. After each successful running, some key information about the component will be inserted to the knowledge base.

### 3.3 Run-time Agent Gene Design

A soft gene for agent is a hereditary unit that determines some particular characteristics in a component. After adopting certain soft genes, the software component can make certain practice activities, update its own behavior rules, etc. the main agent gene is the soul of the system in the run-time assembly process. It is define as XML, whose items can be easily updated by operation classes. We give the main definitions here:

```
<? xml Version="1.0" encoding = "utf-8">
<Main Agent url=" " KnowledgeBase=" " ...>
  <Agent id=0001 type="ExeAgent">
    <Infor>It is a Exe Supervisor Agent!</Infor>
    <IP>12.121.10.156</IP>
    <KnowledgeBase>url </KnowledgeBase>
    <DataPool>virtual execution lists</DataPool>
  </Agent>
  <Agent id=0002 type="SearchAgent">
    <Infor>It is a Search Agent!</Infor>
    <IP>12.121.10.100</IP>
    <KnowledgeBase>url </KnowledgeBase>
    <DataPool>search requirements</DataPool>
  </Agent>
  <Agent id=0001 type="CoordinateAgent">
    <Infor>It is a Coordinate Agent!</Infor>
    <IP>12.121.10.101</IP>
    <KnowledgeBase>url </KnowledgeBase>
    <DataPool>coordinate relations</DataPool>
  </Agent>
  <Agent id=0001 type="CompositeAgent">
    <Infor>It is a Composite Agent!</Infor>
    <IP>12.121.10.1</IP>
    <KnowledgeBase>url </KnowledgeBase>
    <DataPool>component id</DataPool>
  </Agent>
  .....
</Main Agent >
```

```
Gene MainAgent
{ Attribute:
  double Skillness, Intelligence, LeaderAbility;
  string IPaddress, State, Task ;
  struct *VirtualExeList, *MessageQueue ;
  Agent *xAgent[N] ;
Method:
  InitiateAllAgent();
  UpdateGene(XML DOM)
  SendControlMessage(Agent *Target);
  CheckGoal(*Compnent); //whether meet the goal
  Scheduling(struct *VirtualExeList);
  MigrateToDestin(string IPadress);
  .....
  Destroy();
}
```

```
Gene ExeAgent
{ Attribute:
  long int TaskNum;
```

```
struct *VirtualExeList, *MessageQueue ;
.....
Method:
  OptimizeExeList(*VirtualExeList);
  UpdateGene(XML DOM)
  .....
}

Gene CompositeAgent
{ Attribute:
  long int ComponentNum;
  struct *Compo, *MessageQueue ;
  .....
Method:
  ComponentInsert(*Compo, TagetAddress);
  ComponenDelete(*Compo, SourceAddress);
  SearchRequest(string Requirement)
  UpdateGene(XML DOM)
  .....
}.....
```

With the help of Agent Gene revised and optimized adaptively, components can be easy understood, assembly according to the commercial computing requirements compared with that of before.

## 4. SCHEDULING ALGORITHM

### 4.1 Agent-based Concurrent Algorithm

Agent-based concurrent scheduling algorithm processes requests for service between agents and the executions of the tasks list. We mainly use the Enhanced Coffman-Graham Algorithm to perform concurrent scheduling to reduce the time of execution. Applicable components of systems are organized logically according to the optimized virtual execution task list.

:

#### Algorithm

Tasks List:  $T = \{T_1, T_2, \dots, T_n\}$   $a(T_i): T_i \text{ Tag}$   
 $T_i$  successor aggregate :  $S(T_i) = \{T_k | T_i \Theta T_k\}$   
 $N_{EC}(T_i): \text{Max}\{\text{time}(T_i + S(T_i))\}$

Step1: Include tasks without successor and tag as  $\{R\}$ ;

Step2: for  $i=1$  to  $n$  do

- { a. Calculate  $N_{EC}(T_i)$  of all  $T_j$  in  $\{R\}$ ;
- b. take out the Task with  $\text{Min}(N_{EC}(T_i))$ ;
- c. if  $\text{Min}(N_{EC}(T_i)) > 1$ , Random select a  $T_R$ ;
- d.  $a(T_R) = i$ ;
- e. Add the task Which has no Tag but its successors are all tagged into  $\{R\}$  in  $T_R$  preceding aggregate.

}

Step3: Construct  $L' = (u_n, u_{n-1}, \dots, u_2, u_1)$ , to ensure  $a(u_i) = i$  ( $i=1, 2, \dots, n$ );

Step4: Eliminate virtual tasks in  $L'$  to construct  $L$ ;

Step5: To  $(T \Theta L)$ , use common Graham algorithm to scheduling tasks in  $L$ ;

Reference: common Graham algorithm<sup>[7]</sup>

#### 4.2 Mismatch Component Assembly algorithm

The semantic matching of service-oriented component is always hindered by mismatches when assembly. Formalized definition of matched component is:

a)  $Match(O, O') = m_{spec}(O_{spec}, O'_{spec}) \wedge m_{sig}(O_{sig}, O'_{sig})$

If  $O$  and  $O'$  signature and specification match, then they are matched components.

b)  $R_i$ : the e-Business Required Components vector space

$C$ : the exist component in service environment

$$M(C, R_i) = \frac{\sum_{i=1}^N r_{i,j} \times c}{\sqrt{\sum_{i=1}^N r_{i,j}^2} \times \sqrt{\sum_{j=1}^N c_j^2}}$$

If  $M(C, R_i) < allow_{min}$  then they are match.

When the Search Agent find unmatched component, it can solve in the follow ways by coordinate agent:

- Send a message to Main Agent to adjust to suit the component if the execution can meet the goal
- Search another component to composition as a matched one
- Use Interface Agent to mask unnecessary function and parameters
- Function as middle ware to cover the discrepancy
- Duplicate and revise the original code to produce a new suitable component according to knowledge base.
- Specialized the component some control parameters to get the sub-function of a component
- Use learning mechanism to enhance the component function to match the requirement
- Translate the component I/O data format

#### 4.3 Run-time Agent Self-learning Algorithm

Collaborative and Shareable Learning System is used to improve the performance of Mobile Agent Coalition on service-oriented components dynamic scheduling. It's the integration of Reinforcement Learning, Bidding, Genetic and other Algorithms.

We use shared knowledge and commercial logical by refining each agent's particular knowledge to improve the assembly of components and scheduling of task. During the run-time, the agents can dynamically alter the learning contents and presentation over time. Specifically, the agents can migrate and participate in a number of important tasks such as automatic composition of component according to the commercial logic, analysis and delivery services to users and adaptation to new patterns and services. This self-learning algorithm system is hierarchical in terms of its distribution to different agents. Agent Coalition can use learning mechanism to upgrade other algorithms includes component evolution and aberrance algorithm, virtual task list optimization algorithm, and commercial logical pattern auto-builder algorithm.

Every type of Agents can have its own and common knowledge base, locally or remotely, to build a

cooperative, co-evolutionary mechanism in which agents can learn by using a team-based reward system. System will obtain the best team for achieving the task in e-business computing environment which requires coordination to succeed. These agents mainly use the auction mechanism to negotiate their roles dynamically. Agents bid individually according to their perceptions. The system chooses the best combination of bids for the team; the chosen bids may not be optimal for each individual, but the system learns to bid as a team and develops the best team-based strategy. We develop our learning algorithm in a distribute, simulated version of the real environment intelligence

#### 5. CONCLUSION AND FUTURE WORK

Services-oriented Component based on Multi-Agent is the revolution to the traditional computing technologies, which make the information infrastructure be more quickly adapt to changing business priorities. Here we propose the framework and main part algorithms' brief view, which is an effective way to achieve our goals. But, some algorithms is far more satisfied, and still need to give deeply research for better solutions, especially for more matured Self-learning, effective assembly and efficient scheduling Algorithms.

# Temporal Association Rule Mining in China's Closed-end Fund Data

Ying Liu, Guoqing Chen

School of Economics and Management, Tsinghua University, Beijing 100084, China  
{liuy6, chengq}@em.tsinghua.edu.cn

## ABSTRACT

Financial market plays an important role in economy. Although funds developed only a few years in China, it has been a focal point in research and practice. The conventional methods analyzing fund data are fundamental analysis and technical analysis. Data mining can extract implicit, previously unknown and potentially useful knowledge from data. This paper presents the new technique to analyze China's closed-end fund data and temporal association rules (TAR) are discovered which reflect the relationship among open price, close price, trading volume and grail index. Experimental results show some interesting outcomes.

**Keywords:** data mining, temporal association rules, closed-end fund

## 1. INTRODUCTION

Fund is an important investment tool. During the past several years, fund market has developed rapidly in China. By the end of 2003, there were totally 50 fund management companies issuing 54 closed-end funds and 56 opened-end funds. Closed-end funds had reached 86.2 billion RMB by net assets and opened-end funds had been up to 76 billion RMB by circulation [1]. There are at least two types of methods, namely fundamental analysis and technical analysis, for analyzing fund data, which are widely recognized and applied. Fundamental analysis typically focuses on the general economy, the condition of the industry and the condition of company. Technical analysis is an approach to stock investing where the past prices are studied and using charts as the primary tool [2].

Data mining is to discover interesting patterns from large amounts of data. Data mining functionalities include the discovery of association, classification, prediction, clustering and so on. As a promising technology, which may be supplementary to conventional methods, data mining in financial data has increasingly attracted attention of academia and practitioners. This paper focuses on finding potential association from closed-end fund data which is deemed helpful in fund investment decision-making.

## 2. TEMPORAL ASSOCIATION RULE

Association rule is one of the most important forms of knowledge [3]. It is of the form  $X \Rightarrow Y$ , where  $X$  and  $Y$  are item sets in databases. Two thresholds, namely degree of support and degree of confidence, are defined to evaluate the rule. For example, rule: trading volume rises  $\Rightarrow$  close price rises, reflects a sort of association relationship between price fluctuation and trading volume. Apriori algorithm is regarded a classical algorithm [4] for association rules mining. Several efforts have been made to extend the classical association rule mining to inter-transactional association rule mining [5] and certain applications have been proposed in stock movement predictions [6].

Notably, fund data is typically time-series, which results in the need of temporal association rules mining. A Temporal Association Rule (TAR) is of the form

$X \xRightarrow{t} Y (t \geq 0)$  where  $X$  and  $Y$  are item sets, and  $t$  is the time-lag [7]. TAR is an extension of a conventional association rule, and represents that  $Y$  will occur at  $t$  time units after  $X$  occurs. Its degree of support (Dsupp) and degree of confidence (Dconf) are:

$$Dsupp(X \xRightarrow{t} Y) = \frac{\|X \cup_t Y\|}{\|D\| - t}$$

$$Dconf(X \xRightarrow{t} Y) = \frac{\|X \cup_t Y\|}{\|X\|}$$

where  $\|X\|$  is the number of records containing  $X$  at time point  $T$ ,  $\|X \cup Y\|$  is the number of records that contain  $Y$  at time point  $T + t$  in correspondence to the records containing  $X$  at  $T$ , and  $|D|$  is the number of records in dataset  $D$ .

Chen et al [8] proposed an algorithm so as to obtain a balance between the semantics and complexity. Two types (i.e. upward and downward) of the stock returns patterns are considered, which result in Boolean data items. Furthermore, in many real world applications, discovering associations for multiple stock returns patterns (e.g., categorical with 3 values: upward, unchanged, downward) is meaningful in supporting financial decision-making. Moreover, for continuous returns (e.g., return values in continuous domains), the respective domains can usually be discretized into several intervals. This method is further investigated and applied to closed-end fund data in China in this paper.

## 3. TAR MINING IN CLOSED-END FUND DATA

The characteristic of fund data is numerical, enormous and time-series. Our data for 2000-2003 come from the security database of TianXiang investment consulting. Every fund has its individual IPO time which results in different data volume. In order to assure the same external environment (i.e., policy, macroeconomics), selecting complete data in a same interval is necessary. Data from 2000.1.4 to 2002.12.31 were selected as the mining set and data from 2003.1.1 to 2003.12.31 will be used for test purposes. There are totally 20 funds that have complete data during this period in China market.

Let  $p(T)$  and  $p(T-n)$  denote the values of attribute  $p$  (i.e.,  $p$  can be open price, close price, trading volume or grail index) of some fund on time points  $T$  and  $T-n$  (e.g., unit of  $T$  is day). The  $n$ -day rate of increase  $P_n(T)$  is defined as in (1).

$$P_n(T) = \frac{p(T) - p(T-n)}{p(T-n)} \quad (1)$$

Theoretically the domain of  $P_n(T)$  is  $[-1, +\infty)$ . For association rule mining purposes, numerical data need to be transformed into discrete data. Thereby what we want to discover is the temporal association rules between rates of increase for funds. Note that  $n$  is the time units during which the rate changes for a fund, and  $t$  is the time-lag for association rules. Figure 1 is an illustrative description for  $n$  and  $t$ .

Figure 1: Description of  $n$  and  $t$

Let  $\max(p)$  and  $\min(p)$  respectively denote the maximum and minimum value of attribute  $p$ .  $K$  denote the number of discretized intervals. Then  $c$  denotes the interval span which is defined as in (2).

$$c = \frac{\max(p) - \min(p)}{K} \quad (2)$$

Let  $q_1, q_2, \dots, q_{(K-1)}$  represent  $(K-1)$  points used to discretize the domain of  $P_n(T)$ . Then the values of  $P_n(T)$  can be discretized into  $K$  intervals, where  $q_i$  ( $i=0, 1, 2, \dots, K$ ) is defined in (3).

$$q_i = \begin{cases} -1 & i=0 \\ \min(p) + i \cdot c & i=1, 2, \dots, K-1 \\ \max(p) & i=K \end{cases} \quad (3)$$

When  $P_n(T)$  belongs to  $[q_i, q_{i+1})$ , it is labeled as  $(i+1)$ .

An example of the process is illustrated in Table 1 as follows with  $K=4$ ,  $n=1$ ,  $t=1$ . The values in Table 1 represent data of fund 500001 from Jan, 1<sup>st</sup>, 2000 to Jan, 10<sup>th</sup>, 2004 including open price, close price, trading volume and grail index.

Table 1: Data of fund 500001

date	open price(¥)	close price(¥)	trading volume(share)	grail index
2000-01-04	1.17	1.19	250,737	1,494.50
2000-01-05	1.2	1.17	228,309	1,498.05
2000-01-06	1.17	1.21	210,202	1,555.95
2000-01-07	1.21	1.25	628,288	1,611.81
2000-01-10	1.26	1.25	455,134	1,642.53

Each value in Table 2 represents the corresponding 1-day rate of increase of open price, close price, trading volume and grail index calculating by (1).

Table 2: Rate of increase of fund 500001

date	Rate of increase of open price	Rate of increase of close price	Rate of increase of trading volume	Rate of increase of grail index
2000-01-05	2.564103	-1.68067	-8.94483	0.237538
2000-01-06	-2.5	3.418803	-7.93092	3.865025
2000-01-07	3.418803	3.305785	198.8973	3.59009
2000-01-10	4.132231	0	-27.5597	1.905932

The discretization values of the rates are represented by integers in Table 3.

Table 3: Discretization data of fund 500001

date	Discretization of open price	Discretization of close price	Discretization of trading volume	Discretization of grail index
2000-01-05	3	1	1	1
2000-01-06	1	4	1	4
2000-01-07	4	4	4	4
2000-01-10	4	2	1	3

The price of funds fluctuates greatly at ex-dividend data. It is usually regarded as a kind of noise which needs to be filtered out.

In Table 4, each of the first five columns represents fund 500001's discretization value of every attribute. The last two columns represent temporal data of open price and close price. Considering these temporal data as new attributes, temporal association rules can be obtained by Apriori algorithm on the new table. For example, if in this table, rule: *grail rises*  $\Rightarrow$  *temporal open price rises* can be discovered, then it is a rule with a time-lag of 1 day. A detailed description of the results can be seen in section 4.

Table 4: Fund 500001's discretization data added temporal attributes

ID	Open price	Close price	volume	grail	Temporal open price	Temporal close price
1	3	3	1	4	1	4
2	1	4	1	4	3	4
3	3	4	4	3	3	3
4	3	3	3	1	2	2
5	2	2	2	2		

## 4. RESULTS

Temporal association rule mining technique has been applied to closed-end fund data in China and a few interesting temporal association rules have discovered which reflect the potential knowledge hidden in the fund data.

Concretely, 10 rules with high level of  $D_{supp}$  and  $D_{conf}$  are discovered. Most of the rules are consistent with those with conventional methods. However, some of the rules discovered are new that cannot be easily obtained by conventional methods including fundamental

analysis and technical analysis.

#### 4.1 Relationship among funds

According to the results of experiments, all funds support the rule *grail rises*  $\Rightarrow$  *open price rises* with both high Dsupps and Dconfs, except for the funds with small sizes as 1 to 1.5 billion RMB. In addition funds issued by the same fund management company have similar Dconf with grail index.

First, we display the association between fund price and grail index. Over half of the rules are involved in 80 percent of the twenty funds, and parts of them are consistent with those with conventional methods. Rules are listed in Table 5. The result indicates that funds are very similar with each other. It is supposedly relevant to great similarity in stock-pick, means of manipulation, stock centralized degree, stock position noted in quarterly reports of each funds. All of these may lead to similar rules among funds and the extremely trend-similarity between funds with grail index.

Especially, it also can be noticed that small funds with 1 to 1.5 billion RMB did not follow the same pattern *grail rises*  $\Rightarrow$  *open price rises*, which indicates that small funds operating with the limited capital have to keep centralized stock investment, and thus behave less dependent on grail index.

Table 5: Temporal association rules

Temporal association rules: (minsupp=0.8 minconf=0.8)

<i>grail rises</i> $\Rightarrow$ <i>open price rises</i>
<i>open price rises</i> $\Rightarrow$ <i>grail rises</i>
<i>volume falls</i> $\Rightarrow$ <i>close price falls</i>
<i>grail falls</i> $\Rightarrow$ <i>close price falls</i>
<i>volume falls, grail rises</i> $\Rightarrow$ <i>open price rises</i>
<i>grail rises, open price rises</i> $\Rightarrow$ <i>open price rises</i>
<i>close price rises, grail rises</i> $\Rightarrow$ <i>open price rises</i>
<i>volume falls, grail falls</i> $\Rightarrow$ <i>close price falls</i>
<i>grail rises, close price rises</i> $\Rightarrow$ <i>volume rises</i>
<i>volume falls, open price falls</i> $\Rightarrow$ <i>close price falls</i>

Thus, the investment strategy of the small-sized funds is different from that of larger funds. Small funds may be more independent and their stock-picks are of more concern. When it comes to large funds, the focus should be on the present price and the volume of grail index should be focused rather than on a certain stock, since there exist strong association between larger funds and grail index.

Figure 2: Dconfs of rule: *grail rises*  $\Rightarrow$  *open price rises*

Second, Dconfs among 20 funds are compared. Figure 2 shows the Dconfs of rule: *grail rises*  $\Rightarrow$  *open price rises* of all funds grouped by the fund management company. Funds which pertain to the same fund management company are indicated by parenthesis. It is obvious that most funds under the fund management company have similar values of Dconf. It implies that each fund management company carries out similar operation modes and manipulation ideas on its funds. The Dconfs of the funds in a certain fund management company are similar in most situations despite of different fund managers, which show that the characteristic of the manager is not as remarkable as that of the company. Figure 2 also reveals that it did not seem helpful to reduce the risk by purchasing different funds of the same company because of the similarity of the funds.

#### 4.2 Price trend of funds

If both minsupp and minconf are set to 0.9, the rule: *close price rises*  $\Rightarrow$  *close price rises* can be found in 8 funds which are listed in Table 6. The rule indicates that the higher the Dconf is, the longer that price keeps rising. Notably, six of the eight funds are also ranked very high based on the rate of increase of net asset.

Table 6 Rule: *close price rises*  $\Rightarrow$  *close price rises*

Fund code	Dsupp	Dconf	Rank by rate of increase of net asset	Rate of increase of net asset
184690	0.942	0.956	1	29.99%
500003	0.915	0.932	2	29.93%
500002	0.904	0.921	3	28.66%
500011	0.972	0.977	5	21.44%

184693	0.929	0.939	7	19.17%
500006	0.957	0.967	8	17.82%
184689	0.905	0.913	12	14.63%
500001	0.915	0.935	13	14.45%

Results also show that more than 90% funds remain the same in content of association rules as time-lag changes, although Dconf changes in a small range. Experiments were carried out by setting time-lag as 1, 2, 3 days respectively.

Take Fund TongYi (184690) as an example. The results are listed in Table 7.

Table 7: Results of different temporal time

rule	t=1	t=2	t=3
grail rises $\Rightarrow$ open price rises	0.925	0.900	0.899
Close price rises, grail rises $\Rightarrow$ open price rises	0.939	0.910	0.898
volume falls, grail rises $\Rightarrow$ open price rises	0.928	0.899	0.896
grail rises, open price rises $\Rightarrow$ open price rise	0.935	0.908	0.909
grail rises, close price rises $\Rightarrow$ volume rises	0.956	0.953	0.9595
volume falls, grail falls $\Rightarrow$ close price falls	0.889	0.887	0.886
grail falls $\Rightarrow$ close price falls	0.891	0.892	0.891
volume falls, grail falls $\Rightarrow$ close price falls	0.893	0.889	0.890
volume falls, open price falls $\Rightarrow$ close price falls	0.895	0.895	0.899

Although values of Dconf change a little, they are still high, which implies that price trend is stable.

Investment suggestions may be summarized from above analysis: synthetically considering macroeconomic situation and trend of grail index, buying in and holding funds once the price of one of the eight funds rises, because the price of these funds will continue rising.

#### 4.3 On test data

Data from Jan, 1<sup>st</sup>, 2003 to Dec, 31<sup>st</sup>, 2003 are used for test purposes. Because of space limitation, only two of the rules supported most in 20 funds are tested and listed in Table 8.

Table 8: Test results

Fund code	Dconfs of rule1	Dconfs of rule2
184688	0.85	0.86
184689	0.8	0.81
184690	0.71	0.74
184691	0.89	0.89
184693	0.87	0.88
184695	0.83	0.87
184698	0.83	0.83
184699	0.82	0.81
500001	0.79	0.8
500002	0.8	0.79
500005	0.81	0.82
500006	0.89	0.89

500007	0.79	0.8
500008	0.95	0.94
500009	0.8	0.73
500011	0.9	0.9
500016	0.71	0.73
500018	0.95	0.95
Average	0.83	0.83

These two rules are *grail rises*  $\Rightarrow$  *open price rises* and *volume falls, grail rises*  $\Rightarrow$  *open price rises*. The values of Dconfs are both averaged above 0.80. It demonstrates that funds followed the same patterns in long term, as the rules derived from the first three years data were still supported by the forth year data.

#### 5. CONCLUSION

Nowadays, fund market plays a more and more important role in China economy. This paper introduced a new technique, temporal association rule mining, into the research of predicting fund return. Different from conventional methods, temporal association rule mining provides a data-driven method to discover interesting patterns in large-scaled fund data, which are previously unknown and potentially useful. The experiments on real closed-end fund data have shown that the method of mining temporal association rules in fund data was effective and could be used to support investment decisions.

### ABSTRACT

Recently natural disasters and man-made calamities happened very frequently in Taiwan, some of which caused hundreds of inhabitants died and injured. The most important thing that makes the emergency medical treatment system work effectively during these catastrophes is dependent on the accuracy and immediacy of the information among ambulances, hospitals, fire bureaus, public health bureaus or offices, and emergency executive centers. With this information, the medical system can arrange the resources efficiently.

Radio frequency identification (RFID) is a kind of wireless technology that it uses radio frequency (RF) to identify target objects. The characteristics of RFID are its identification and orientation. Through tracing electronic signals, RFID is able to identify, orientate and trace patients or medical materials directly and continuously. Thus, RFID can help managers of medical institutions to promote emergency medical treatment quality, reduce medical mistakes effectively, and increase efficiency and effectiveness in hospitals.

A series of emergency medical delivery applications that use 915MHz RFID rings is developed in this paper. Through the help of RFID, the paper integrates the information of the whole emergency medical supply chain, and establishes a new model of emergency medical activities to solve the problems of information blocking among different medical rescue units. By solving these problems, the new model can enhance the rescue quality, reduce the damage of the disaster and strengthen the patient-oriented emergency care system.

**Keywords:** Emergency medicine, RFID (Radio Frequency Identification), data exchange, patient reference. emergency care quality

### 1. INTRODUCTION

Natural disasters and man-made calamities happened very frequently in Taiwan in recent years. From the 921 earthquake in the middle of Taiwan and the typhoons from HERB, TORAJI to MINDULLE, these disasters had caused a lot of serious damages. After the accidents, we found several faults through the investigation of the emergency medical rescue system when facing these catastrophes. For example, the uninformed distribution of the patients, the lack of the concordance among the departments of the government, inappropriate allocation of resources, the unknown injured degrees of the patients, and the un-reach of the right and instant information to the officers of disaster rescue teams who have been recognized as major faults [3-6].

It is needed for the government to establish a more efficient system to handle such a situation when disasters happen. The system is useful in the processes of the crisis management, especially when the communication of messages is crucial and the integration of the related medical resource is needed. If the advantage of the information technology is suitably applied, it is expected that the rescue team can provide the health service in the first time and then reduce the damage of the major disasters.

RFID is known as the one of the top ten important technologies in this century [7], since of its identification and orientation characteristics. RFID, if applied in medicine, can provide the tracing of patients or medical materials directly and continuously. Thus, RFID can help the managers of medical institutions to enhance its emergency medical treatment quality, reduce medical mistakes, and increase efficiency and effectiveness in hospitals [1].

When crucial disasters take place, how to deliver information quickly and accurately among ambulances, hospitals, fire bureaus, public health bureaus, and emergency executive centers is a major key to save the lives. This paper is to design and apply RFID to the emergency medicine. The application of RFID in emergency medicine can be the process from the time when the patient in the ambulance to the time when the patient is moved to the emergency room. Through the whole process involved, the application of RFID can integrate the logistics of the emergency medicine and provide a solution for the questions that they can not be solved in the time that the information count not be shared and integrated.

The purpose of the paper is to aid rescue systems to

obtain the newest information for the different level of stages, namely, the operation stage (such as ambulances and hospitals), the management stage (such as fire bureaus and public health bureaus) and the strategic stage (such as control centers). In the operation stage, RFID system can utilize the medical resources according to the deployment of these resources and the injured degree of the patients that are classified before arrive the emergency room. In the management stage, RFID system can improve the coordination of data exchange and reduce the problems of disagreed information among the hospitals in responsibility, fire bureaus and public health bureaus. In the strategic stage, RFID system can help the directors of the government to get the condition of the casualties in disaster event, and help the directors to make adequate decisions to rescue victims of the disaster.

## 2. RFID EMERGENCY MEDICAL SYSTEM DEVELOPMENT

### 2.1. System development

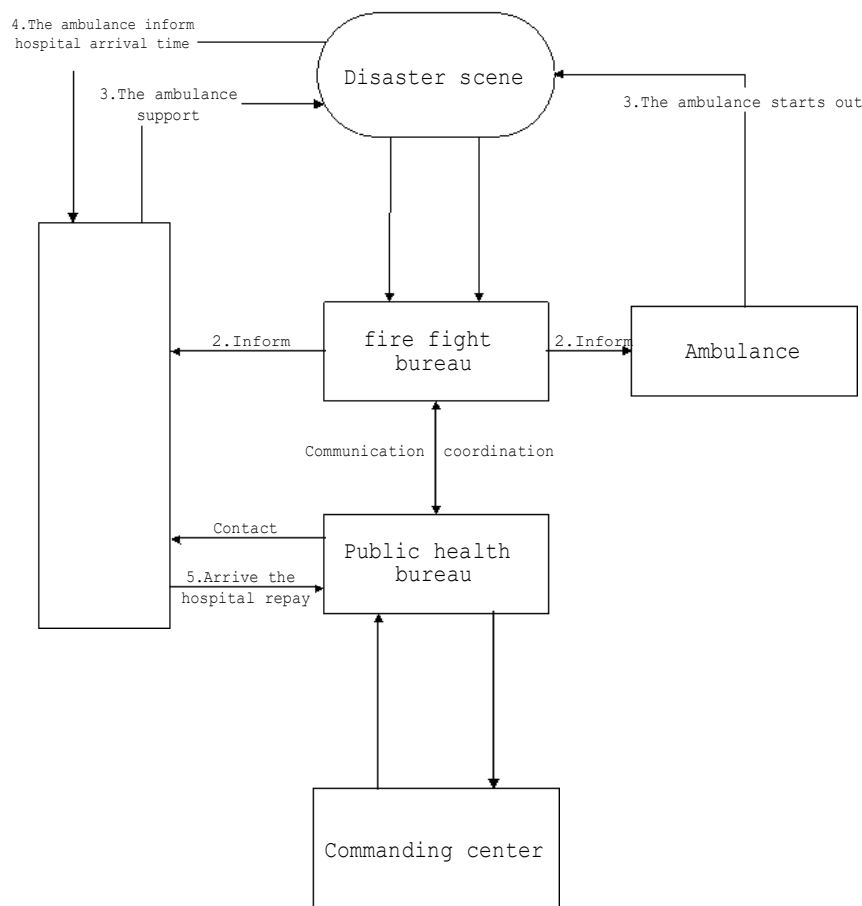

Figure 1. The flow of emergency medical rescue.

4. Before arriving the hospital, the rescue team notifies the hospital in the ambulances about their arrival time and the preparation of the treatment;

5. When the ambulance arrives to the hospital emergency room, the hospital will notify the public

The proposed RFID emergency medical system develops and designs based on the related technique specified in the white paper in EPC Network [8-10]. We designed the system with the method of prototyping. The users' satisfaction and demands were considered in the developing process. The emergency rescue process and its flow chart are showed in Figure 1.

The rescue process contains six steps, as is discussed in the following:

1. The people who witness or encounter the disaster event call or inform the local fire bureau whatever they have seen;
2. The commander of the fire bureau dispatches fire-fighting trucks immediately and notifies the related hospitals to send ambulances to the spots to offer emergency medical treatment;
3. The ambulances arrive at the spots to salvage the victims and pick them up to these ambulances;

health bureau of the patient's information. If the public health bureau doesn't receive the information, it can inquire the hospital. The information between the public health bureau and the hospital must be coordinated with each other;

6. The commander in the public health bureau notifies the command center about the information of the disaster. The commander in the command center arranges the relative units to deploy the resources to the injured patients.

According to the analyses of emergency rescue process,

we designed the emergency medical treatment with the introduction of RFID. The modified rescue system flow represented in a sequence diagram is showed in Figure 2. Then we program the framework for the RFID emergency medical rescue system, which is divided into the operation, management and strategic stages, as is shown in Figure 3.

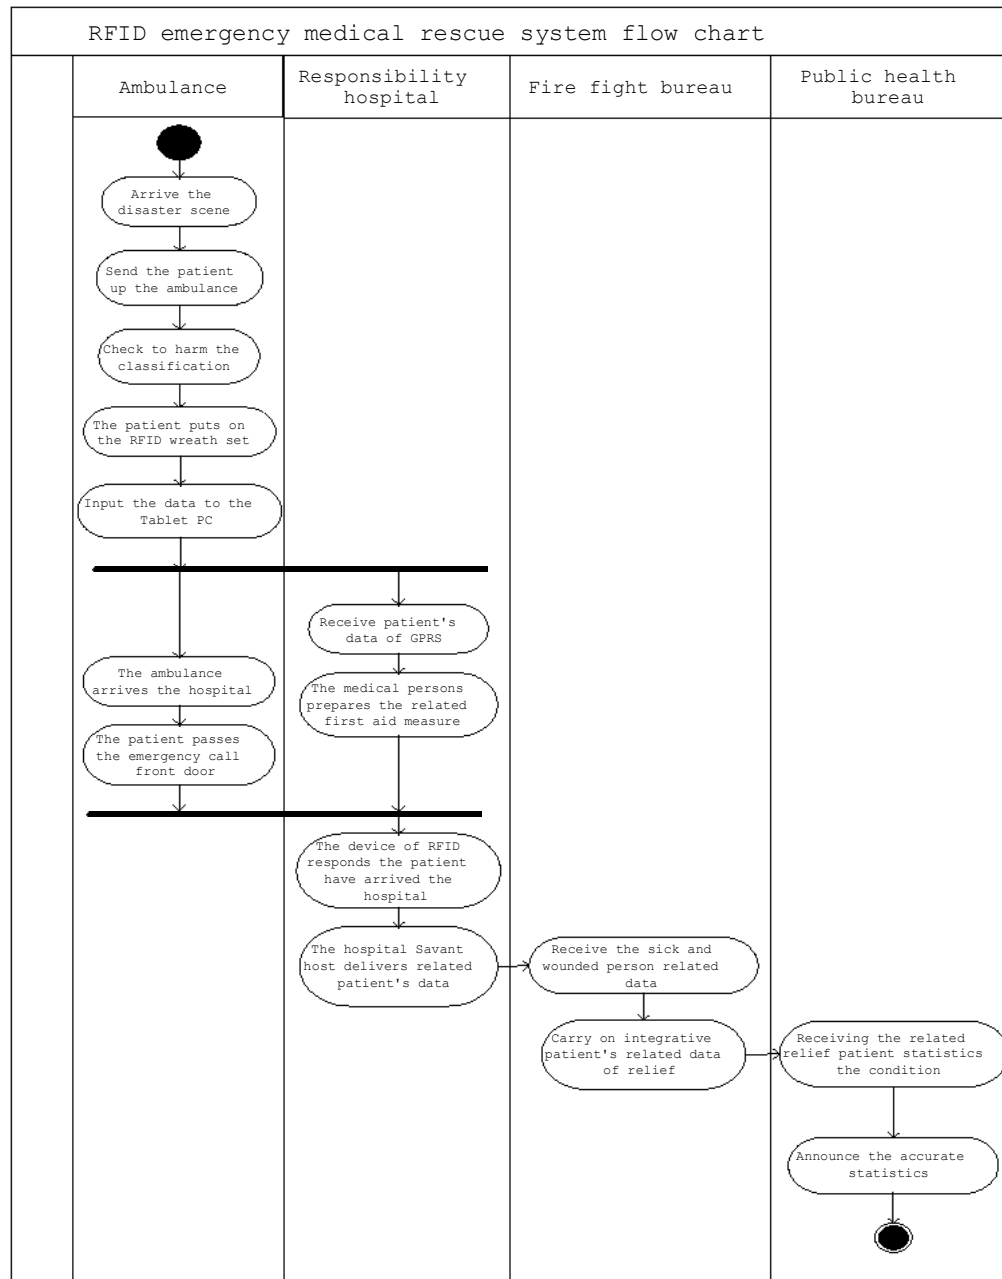

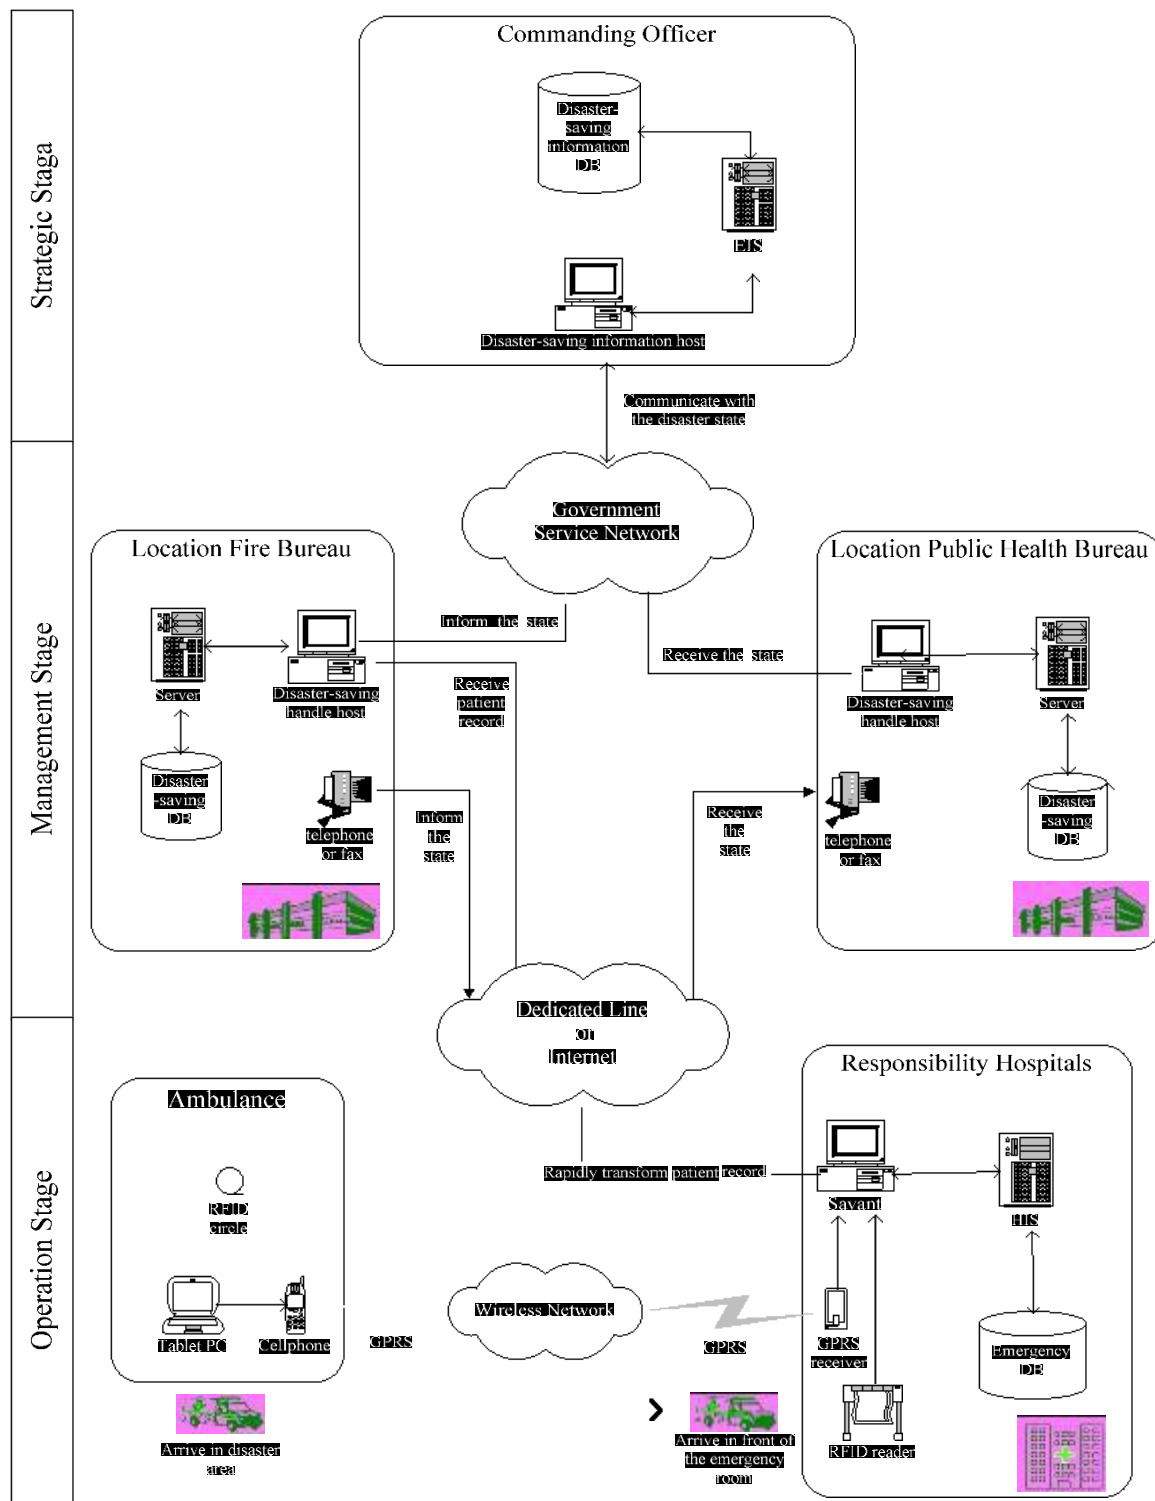

Figure 2: RFID emergency medical rescue system flow chart

middleware, which handles the RFID events, carrying out the extraction and summary of data and translating the information such that the information can be processed by other computer systems;

3. The middleware also integrates the Savant server and the HIS's database. The middleware transfers data in XML format to call other system components that is encapsulated in the Web Service. Using SOAP standard, the system integration is done.

### 3. BENEFIT ANALYSIS

The development of RFID emergency medical rescue system follows the guideline to establish an information system. The process of system analysis, system design, the hardware installation and the system construction can be easily achieved. In addition, we need to evaluate the system from four dimensions, namely, practicability, accuracy, efficiency and completeness:

#### 1. Practicability

The feasibility, affordability and the future extension of the proposed system can be validated by the three facts: (1) the wider and wider coverage as well as the good quality of the mobile telecommunication and wireless Internet access system, (2) the appearance of the acceptable handwriting input system such as tablet PC and (3) the maturity of EPC Network, system have been developed maturely

#### 2. Accuracy

The RFID tags are independent with each other. All rescue units can receive the messages sent from the tags accurately and automatically. Compared to human-entry system, the automatic operation system can reduce the risk of mistakes and malpractice;

#### 3. Efficiency

The efficiency of the RFID emergency medical rescue system can be discussed in three viewpoints:

##### (1) The viewpoint of healthcare providers:

The system can directly connect to the HIS of hospitals. The system provides an easier and faster way to key in and recognize the patient in arranging the process of medical treatment. With this system, the healthcare providers can alleviate the stuffs and focus on saving the lives;

##### (2). the viewpoint of fire bureaus and public health bureaus:

Through the system, the local fire bureaus and public health bureaus can correctly and immediately allocate the available medical resources to the patients. In addition, the communications between them will be

smoother than ever;

##### (3). the viewpoint of the governments:

By the precise information, the leaders of the government can promptly make decisions to rescue lives. Even when the local salvage resources are run out in a big casualty, the leaders can be aware the condition immediately and then ask the aids from adjacent areas or countries to provide the sufficient medical treatments;

#### 4. Completeness

As a result of implementing the RFID emergency medical rescue system, the county government can get over integrated information about emergency healthcare demand quantity and the number of casualties whenever catastrophes happen.

### 4. CONCLUSION

We have designed and implemented the RFID emergency medical system for the emergency medical rescue system. The motivation is to design a complete process from the time when the patients are taken into ambulances to the time when they arrive to the emergency rooms. The primary characteristics of RFID can provide the function of identification, orientation and traceability of patients. The communication of information at anytime and anywhere will make the emergency medical rescue more efficient. The proposed system offers a chance to integrate the whole medical supply chains and solve the medical information flow problems that can't be effectively shared and integrated before.

Through the development of the RFID emergency medical rescue system, we establish a better model of emergency medical rescue system. With the successful experience of a pilot experiment in Nantou, Taiwan, we established the relative performance indexes, models and standard operating procedures, and will transfer the successful paradigm to the other seventeen local emergency medical rescue networks. Through the integration of the object (i.e., patient) flows traced by the RFID and the information flows exchanged in HL7 standard, we can connect each local medical network and establish an emergency medical information integration network. The system can promote rescue quality, decrease medical mistakes, diminish the damage of disasters and finally build a patient-oriented healthcare environment.

# The Design of a Web Document Snapshots Delivery System

David Chao

College of Business, San Francisco State University, San Francisco, CA 94132

dchao@sfsu.edu

## ABSTRACT

A web document snapshot is a point-in-time capture of its code and the resulting presentation of executing the code. It is used as a way of electronically preserving historical information published in web documents enabling an organization to audit a web document's contents at a point in the past and perform business analyses with historical information recorded in it. It is also an archived copy of a web document when it is changed. This research develops a system to deliver snapshots of a web document's static and dynamic contents when it is requested. The system consists of a Database Snapshot Manager for providing database snapshots and a Web Document Snapshot Manager for providing web document snapshots. Algorithms supporting the two managers are presented.

**Keywords:** web document snapshot, website snapshot management

## 1. INTRODUCTION

A web document snapshot is the state of a web document at a point in time (snaptime).

It enables an organization to audit a web document's contents at snaptime and perform business analyses with historical information recorded in it. It is also an archived copy of a web document when it is changed [6]. Many organizations such as government are mandated to electronically archive official web documents [7] [8], a web document snapshots management system will help to meet that requirement.

However, what is the state of a web document? A web document has dual definitions. Physically, it is a text file containing code, such as HTML or XML that defines its contents and presentation. Logically, it is a web page as displayed with a browser. From a user's perspective, the rendering of a web document matters more than its source code. Considering the fact that the code of a dynamic web document may render different contents at different times, therefore, the state of a web document is a point-in-time capture of its code and the resulting presentation of executing the code.

Factors affecting the state of a web document include:

a. Web document code: This includes the code that creates web page's static and dynamic contents. Frequently code creating dynamic contents is stored separately in a different file as in the case of Server-Side-Include and Code-Behind technologies.

b. The state of internal resources it references: Internal resources are files managed by a web site and are available in creating the web site's contents. Typical examples of internal resources referenced by a web document that affect its rendering are style sheets, files embedded by a Server-Site Include directive, image files, script files, and databases. These internal

resources may create dynamic contents that change every time the document is opened, and they are subject to change that consequently changes the web document's rendering. Many of these files are *internal supporting files* that are created for supporting a web document and are not for publishing individually.

c. The state of external resources it references: External resources are files not managed by the web site but can be referenced in creating the web site's contents. A web document may reference external style sheets, components, web services, or databases. These external resources are also subject to change.

d. Web site host environment variables: Script code may reference a host's system variables in creating dynamic contents. A typical example is using the system clock to get the current date and time. A web document that displays the current date and time is always in a new state.

**Four levels of web document snapshot** Based on the four factors affecting web document's rendering, four levels of a web document's snapshot can be defined.

Level 1 snapshot: A web document snapshot is the state of web document code at snaptime. Creating level 1 snapshot enables a web site to trace the changes to the web document code over time.

Level 2 snapshot: A level 2 snapshot is a level 1 snapshot with the additional requirement that all the internal resources it references are at least level 1 snapshots at the same snaptime. These internal resources can be categorized into two groups: database and non-database files. For a database file to be a level 1 snapshot, it must be consistent with its state at the snapshot time. For a non-database file to be a level 1 snapshot, it must meet the definition above.

**Level 3 snapshot:** A level 3 snapshot is a level 2 snapshot with the additional requirement that all the external resources it references are at least level 2 snapshots at the snaptime.

**Level 4 snapshot:** A level 4 snapshot is a level 3 snapshot with the additional requirement that all the web site host's environment variables are reset to their values at snaptime.

The level 1 and level 2 snapshots are related to files that are managed by the web site, and changes to these files can be recorded. The level 3 and level 4 snapshots involve resources that are not managed by the web site and it's difficult, if not impossible, for the web site to keep track of changes to these resources. This research develops a web document snapshot management system to deliver web documents' level 1 and level 2 snapshots. Thus, the system consists of two modules: Database Snapshot Manager for maintaining database snapshots and Web Document Snapshot Manager for maintaining web document snapshots. The system is designed to deliver snapshots with any snaptime requirement, and snapshots are created only when requested. The Database Snapshot Manager is presented first.

## 2. DATABASE SNAPSHOT MANAGER

Database snapshot management and related materialized view management have been the topics of much research [2] [3] [4] [5]. Many schemes have been developed in maintaining database snapshots. This research adopts a generalized scheme that will meet the requirement of web document snapshots. It is presented below.

The objective of this module is to provide a database snapshot at any snaptime requested by users. This requires recording all updates in a log. The log uses time stamp to record update time, and use flags to indicate deletions and insertions where a modification is treated as the deletion of the old version followed by an insertion of the new version. With such an update log available, rolling back the current database using updates with time stamp later than the snaptime can generate a snapshot at any snaptime.

An alternative scheme is creating snapshots at different intervals. These snapshots can be *refreshed* to a new snaptime by applying updates between the old snaptime and the new snaptime. The refresh operation can go forward if the new snaptime is later than the old snaptime, otherwise it can go backward. With the availability of the two refresh operations, the optimal way is to select the snapshot whose snaptime is closest to the new snapshot, and only use updates between the snaptimes of the selected snapshot and the new snapshot. Let  $\text{UpdateLog}(t_{\min})$  represent the update log whose minimum time stamp value is  $t_{\min}$ ; and let  $\text{UpdateLog}(t_a,$

$t_b)$  represent the segment of the update log with time stamp between  $t_a$  and  $t_b$ ; assume there are  $n$  snapshots created each with snaptime  $t_i$  represented by  $S(t_i)$  where  $i$  assumes values between 1 and  $n$ ; assume the new snapshot's snaptime is  $t_s$ , the algorithm  $\text{GenerateDatabaseSnapshot}$  takes  $t_s$  as input and returns  $S(t_s)$ :

### Algorithm GenerateDatabaseSnapshot:

Inputs:  $n$  snapshots, update log, and snaptime  
Output: Database snapshot at snaptime

```

If  $t_s < t_{\min}$  Then
  Unable to generate snapshot using this log
Else
  Select  $S(t_i)$  where  $t_i$  has the min  $|t_s - t_i|$ 
    where  $i = 1$  to  $n$ 
  If  $t_i < t_s$  Then
     $S(t_s) = S(t_i).\text{RefreshForward}(\text{UpdateLog}(t_i, t_s))$ 
  Else
     $S(t_s) = S(t_i).\text{RefreshBackward}(\text{UpdateLog}(t_i, t_s))$ 
  End if
End if

```

## 3. WEB DOCUMENT SNAPSHOT MANAGER

The objective of the Web Document Snapshot Manager is to generate level 2 snapshots for all internal non-database files including the supporting files. On the Internet, a Uniform Resource Locator (URL) uniquely identifies a web document. The snapshot manager is designed to let users to use a URL with a specified snaptime to retrieve the document's snapshot. An analysis of the problem is given below.

### 3.1 Problem analysis

At a specific point of time, a Uniform Resource Locator (URL) uniquely identifies a document on the Internet. At the web site, it translates to a physical path to the web document. Although there exists a 1:1 relationship between a URL and a web document at a given time, in the life of the document the relationship is M:M. In a document's life, it may have associated with many URLs. The web site may reorganize by changing its directory structure, hence changing the path to a document; a document may be renamed, or moved to a different directory. These changes will give the document a new URL. A URL may have associated with many documents also. It may point to a document that is different from the one it pointed to earlier. For instance, a document A may be renamed to C and another document B may be renamed to A; hence the URL originally pointing to A is now pointing to a different document. It may also happen when a web site removes a URL but later reinstates the URL for another document.

Figure 1: Relationship between URLs and web documents.

Figure 2: An example of the progression of a web site with changes since its initiation.

A web document may change its contents. Hence a URL may not only associate with many different documents, it may also associate with many versions of the same document. Figure 1 illustrates the relationship between URLs and web documents. Let  $D_{ij}$  represents document  $i$ , version  $j$ . In Figure 1a,  $URL_x$  initially points to  $D_{11}$  and  $D_{12}$ , then points to  $D_2$ . In Figure 1b, document  $D_3$  initially associates with  $URL_A$ , then associates with  $URL_B$ .

URLs can become invalid and users may submit invalid URLs. In Figure 1b,  $URL_A$  changes to  $URL_B$  and points to  $D_{33}$ . Is the web site able to return  $D_3$  if users submit  $URL_A$ ? Or is it able to return  $D_{32}$  it originally pointed to? Even valid URLs don't necessarily retrieve the documents users intend for it to. In Figure 1a, a user may use  $URL_x$  saved in browser's Favorites or Bookmarks trying to retrieve  $D_1$ . URLs invalidated by a web site due to reorganization, document removal, renaming, or relocation, plus the links to document snapshots are a web site's historical links. Tracking historical links by recording the time and the type of changes that occurred to a document and its URL enables a web site to retrieve the documents associated with the historical links.

Figure 2 illustrates the progression of a web site.  $T_0$  is the time when the web site is initiated, and  $T_i$  denotes a point in time when its contents change. Period  $i$  is the interval of time between  $T_i$  and  $T_{i+1}$ . Assuming the path of a valid URL is unique within the web site, a valid path leads to a document currently published. In the sequel, paths and URLs are used interchangeably.

There are two sets of paths in period  $i$ :  $VP_i$ , a set of all valid paths, and  $HP_i$ , a set of paths becoming historical at  $T_i$ . Note that  $HP_0$  is null. In Figure 2, paths that produce two dotted arrow lines such as  $P_1$  in period 0, and  $P_4$  and  $P_5$  in period 3 represent documents that are renamed or relocated. In this case, only the document's path has changed but the document has not changed. Therefore, there is no need to archive any documents, but it is necessary to chain the old path to the new path in order to track the change. Paths that produce two solid arrow lines such as  $P_3$  in period 1, and  $P_3$  and  $P_5$  in period 2 represent documents that are modified. In this case, the path is still valid but the document before the change needs to be archived as the document's snapshot. Paths that produce one solid arrow line, such as  $P_2$  in period 1 and  $P_3$  in period 3, represent documents that have been deleted. Those documents must be archived.

A path in  $HP_i$  may be repeated in  $HP_j$ , just as  $P_3$  is repeated in  $HP_2$  and  $HP_3$ . To make a historical link unique, the time the path was published is added to the path. Hence  $P_3$  in  $HP_2$  is identified as  $P_3 + T_1$  and  $P_3$  in  $HP_3$  is identified as  $P_3 + T_2$ . Similarly, a current path may duplicate a path in the historical links, as is the case of  $P_1$ . By adding its published time,  $P_1 + T_3$  is distinguishable from the historical link  $P_1 + T_0$ . The historical links of a web site before  $T_i$  are the union of sets  $HP_0$  to  $HP_{i-1}$ , ( $HP_0 \cup HP_1 \cup \dots \cup HP_{i-1}$ ). Assuming  $T_i$  is the last time the web site has changed, then the web site's historical links are the unions of sets  $HP_0$  to  $HP_i$ , and the current links are  $VP_i$ . The union of historical links and the current links represents all the paths that

are currently in use or have been used in the past. Every link in the union is uniquely identified by the value (path + path published time). This composite value is an example of a Temporal URL (discussed in the next section). For any path  $P_x$  published at time  $T$ , the temporal URL ( $P_x + T$ ) uniquely identifies a document that is currently, or was once, associated with  $P_x$  at time  $T$ .

### 3.2 Solution Designs

This section explains the scheme to track the historical links of a web site. The scheme has two major components: logging the changes to web documents and archiving deleted documents including document snapshots. The log, named TemporalURLLog, is designed to keep the history of changes to web documents. It has four fields: URL, PublishDate, ExpireDate, and NewURL. The URL field records a document's path; the PublishDate records the time the document is published; the ExpireDate field records the time this URL becomes invalid; should the change create a new URL for the document, the NewURL field records the document's new URL and serves as a link to chain all log entries related to the same document together. This log has a composite key of URL + PublishDate. The value of URL + PublishDate uniquely identifies a document in a web site's history. The Archive is a directory that stores deleted files and document snapshots. Those archived files are saved in the Archive using URL + PublishDate as its file name. The log is maintained according to the log maintenance algorithm described below:

**TemporalURLLog maintenance algorithm** Changes to web documents are recorded in the log by the following rules:

**New document:** When a new document is added to the web site, a new entry is entered with its path and the time the document is published. The ExpireDate and the NewURL are set to null. Hence, log entries with a null ExpireDate are current document entries. Initially, all current documents have an entry in the log with null ExpireDate and null NewURL.

**Deleted document:** The log entry associated with the document is the entry with the URL equal to the document's URL with a null ExpireDate. First, it locates the entry and changes its ExpireDate to the time the document is deleted. Then, it saves the deleted document in the Archive with URL + PublishDate as its file name.

**Modified document:** When a document is modified, its old version becomes a snapshot and its new version is treated as a new document. The log entry associated with the document is the entry with the URL equal to the document's URL with a null ExpireDate. First, it locates the entry and changes its ExpireDate to the time

the document is modified. Then, it saves the old version in the Archive with URL + PublishDate as file name. Then, it adds a new entry with the same URL and the PublishDate is set to the time the document is modified. The ExpireDate and NewURL are set to null.

Consequently, log entries with a non-null ExpireDate and a null NewURL may be related to snapshots or deleted documents. For such an entry, if there exists another entry with the same URL and its PublishDate equals to this entry's ExpireDate then this entry is a snapshot entry and the snapshot it associates with can be retrieved from the Archive using URL + PublishDate as its file name. The snapshot is valid from the PublishDate to the ExpireDate. Otherwise, the entry is associated with a deleted document which can be retrieved from the Archive using URL + PublishDate as its file name.

**Relocated or renamed page:** When a document is relocated or renamed, its old URL is expired and a new URL is created. The log entry associated with the document is an entry with the URL equal to the document's URL and with a null ExpireDate. First, it locates the entry and changes its ExpireDate to the time the document is relocated or renamed and changes its NewURL field to the document's new URL. Then, it adds a new entry with the new URL and the PublishDate is set to the time the document is relocated or renamed. Hence, log entries with a non-null NewURL field help chain a document's log entries.

Using this log maintenance algorithm for the changes described in figure 2, the contents of the TemporalURLLog are shown in Figure 3, with five files in the Archive:  $P2T_0$ ,  $P3T_0$ ,  $P3T_2$ ,  $P5T_1$ , and  $P3T_3$ . With the TemporalURLLog, a web server is able to determine that:

. A URL  $P2$  valid between  $T_0$  and  $T_1$  is deleted, and the document it pointed to is in the Archive with the name  $P2T_0$ .

. A URL  $P3$  has been modified repeatedly and is eventually deleted. All documents associated with  $P3$  can be found in the Archive.

. An old URL  $P5$  is now renamed to  $P7$ . It has been modified on  $T_3$ , and a copy of its snapshot can be found in the Archive with the name  $P5T_1$ .

. The log is able to determine that a historical link  $P1$  is now renamed to  $P8$ .

. A URL  $P12$  has never existed in the web site.

URL	PublishDate	ExpireDate	NewURL
P1	$T_0$	$T_1$	P4
P2	$T_0$	$T_2$	Null
P3	$T_0$	$T_2$	Null
P4	$T_1$	$T_4$	P8
P5	$T_1$	$T_3$	Null
P3	$T_2$	$T_3$	Null
P3	$T_3$	$T_4$	Null

P5	T <sub>3</sub>	T <sub>4</sub>	P7
P6	T <sub>3</sub>	Null	Null
P1	T <sub>3</sub>	Null	Null
P8	T <sub>4</sub>	Null	Null
P7	T <sub>4</sub>	Null	Null

**Figure 3: The contents of TemporalURLLog based on changes described in Figure 2.**

### 3.3 Snapshot-retrieving algorithm

This section presents an algorithm for retrieving document snapshots. The input to this algorithm is a URL  $P_x$  with a snaptime  $T$ . It assumes  $P_x$  is a current URL to simulate a scenario in which users who are viewing a current document would like to view the document's snapshot at time  $T$ . The algorithm is presented in [1] and is explained below.

It processes log entries backward starting from a document's current entry to trace back its changes in order to locate the snapshot. If the current URL's PublishDate is less than  $T$ , then the current document itself is its snapshot at  $T$ . Otherwise the backward search starts. To trace back, an entry's predecessor has one of the following properties:

1. Its URL equals the current entry's URL and its ExpireDate equals the current entry's PublishDate. This indicates the predecessor is an old version of the document and it is the document's snapshot from the predecessor's PublishDate to its ExpireDate.
2. Its NewURL equals the current entry's URL and the ExpireDate equals the current entry's PublishDate. This indicates the predecessor has been renamed or relocated.

Initially, the current document is treated as a candidate for the snapshot. Before reaching past time  $T$ , whenever an old version is found it becomes the new candidate for the snapshot. Note that an old document's life may span before its PublishDate. If a document  $Y$  is originally derived from a document  $X$  through a series of renaming or relocation, then this document's life span is from document  $X$ 's PublishDate to document  $Y$ 's ExpireDate. The search reaches the last entry when its PublishDate is before  $T$  or it no longer has a predecessor. If the last entry's PublishDate is greater than  $T$  then snapshot does not exist at  $T$ .

To illustrate, if a request  $P7$  with snaptime  $T_2$  is submitted, the backward search will pick up three entries:  $(P7, T_4, \text{Null}, \text{Null})$ ,  $(P5, T_3, T_4, P7)$ , and  $(P5, T_1, T_3, \text{Null})$ . They show that the document associated with  $P7$  has been unchanged since  $T_3$  and was originally associated with  $P5$  and renamed to  $P7$  at  $T_4$ . The document has been modified at  $T_3$ . Therefore, the algorithm returns  $\text{Archive}(P5 + T_1)$  as a snapshot. If  $P7$  with snaptime  $T_3$  is submitted, the backward search will pick up two entries:  $(P7, T_4, \text{Null}, \text{Null})$  and  $(P5, T_3, T_4, P7)$  and return  $\text{Document}(P7)$  as a snapshot.

If a request  $P8$  with snaptime  $T_0$  is submitted, the backward search will pick up three entries:  $(P8, T_4, \text{Null}, \text{Null})$ ,  $(P4, T_1, T_4, P8)$  and  $(P1, T_0, T_1, P4)$ . These show that the document associated with  $P8$  has been renamed at  $T_1$  and  $T_4$ . It has not been modified since  $T_0$ . The algorithm will return  $\text{Document}(P8)$  as a snapshot.

## 4. WEB DOCUMENT SNAPSHOTS DELIVERY METHODS

This section discusses schemes for users to submit a request for a snapshot. Such requests must include the document's URL and snaptime required by the snapshot-retrieving algorithm. Three schemes for submitting a request are proposed below:

**Using TemporalURL** A temporal URL is a URL submitted with temporal requirements of which the documents associated with the URL must meet [1]. A typical way to submit additional information with a URL is through query strings. A query string is a set of name=value pairs appended to a URL. It is created by adding a question mark (?) immediately after a URL followed by name=value pairs separated by ampersands (&). For instance, a Snaptime query string may be defined as:  $P_x?\text{Snaptime}=T$  to retrieve the web document's snapshot at time  $T$ .

Problems with using TemporalURL are: (1) implementing this scheme requires the web server be changed to distinguish between requests for regular documents and requests for snapshots. This causes interruption for non-snapshot requests. (2) Users must be informed of such service and be trained to use temporal URL.

**Using a snapshot management site** This is a site designed to handle snapshot requests. Its objectives are: (1) educating users about the web document snapshot systems and (2) providing interface to enter request for snapshots. The interface can be a form with textboxes to enter web document's URL and snaptime. The snapshot-retrieving algorithm can be implemented with the server-side program that handles the form.

The advantage of this approach is that the web server does not need to change its behavior because of snapshots.

**Using web services** A web service is an application logic accessible via the Internet [9]. It is defined as a function that takes inputs from its arguments to perform a task. It uses standard Internet protocols such as HTTP and SOAP for communication. Inputs to a web service can be submitted with HTTP GET, or HTTP POST, or enclosed in a SOAP Envelop encoded in XML. The output from the web service is typically returned in a SOAP Envelop encoded in XML. The inputs and outputs are all in text format. A web service can be

accessed from a browser. In this mode, it will provide an interface page with textboxes to enter inputs to the service along with an information page explaining input data type. It can also be integrated in an application where it is referenced as a component. In this mode, it is used as a function where the application provides inputs through its arguments.

The snapshot-retrieving algorithm can be implemented as a web service that takes URL and snaptime as its inputs and returns the document snapshot as output. Because web services communicate in text, the snapshot returns to the user will be in text format. This implies that it is the web document's code that is sent to the user, not the web page as displayed with a browser. Hence any server-side program in the web document is unable to run. Therefore, it is a level 1 snapshot.

## 5. SUMMARY

Web document snapshots are useful for archiving or performing business analysis with historical data. This paper defined four levels of snapshot contents where the level 1 and level 2 snapshots involve resources managed by the web site, and level 3 and level 4 involve resources not managed by the web site. This paper proposes a web document snapshot management system designed to deliver level 2 snapshots. The system consists of a Database Snapshot Manager for providing database snapshots and a Web Document Snapshot Manager for providing web document snapshots. Algorithms supporting the two managers are presented. These algorithms use logs with time stamps to record changes to the database and web documents. With the logs, snapshots can be generated dynamically when requested. Three types of interface between the web site and users regarding snapshot delivery are proposed: temporal URL, snapshot handling site, and web service. With the proposed snapshot management system, a web site is able to deliver snapshots with dynamic contents.

{coyette, kolp, faulkner}@isys.ucl.ac.be

## ABSTRACT

Agent architectures are gaining popularity for building open, distributed, and evolving software required by e-commerce applications. Unfortunately, despite considerable work in software architecture during the last decade, few research efforts have aimed at truly defining patterns and languages for agent architectural design. This paper proposes a modern approach based on organizational structures and architectural description languages to define and specify agent architectures notably in the case of e-commerce system design.

**Keywords:** Agent Systems, Architectural Description Language, Organizational Styles, E-commerce Application

## 1. INTRODUCTION

The meteoric rise of Internet and World-Wide-Web technologies has created overnight new application areas for enterprise software, including e-commerce applications. These areas demand software that is robust, can operate within a wide range of environments, and can evolve over time to cope with changing requirements. Moreover, such software has to be highly customisable to meet the needs of a wide range of users and sufficiently secure to protect personal data and other assets on behalf of its stakeholders.

Not surprisingly, researchers are looking for new software designs that cope with such requirements. One promising source of ideas for designing such e-commerce software is the area of agent architectures. They appear to be more flexible, modular and robust than traditional including object-oriented ones. They tend to be open and dynamic in the sense they exist in a changing organizational and operational environment where new components can be added, modified or removed at any time.

To cope with the ever-increasing complexity of the design of software architecture, architectural design has received through the last decade increasing attention as an important field of software engineering. Practitioners have come to realize that getting an architecture right is a critical success factor for system life-cycle and have recognized the value of making explicit architectural descriptions and choices in the development of new software.

To this end, a number of architectural description languages (ADL) and architectural styles [4] have been proposed for representing and analyzing architectural designs. An architectural description language provides a concrete syntax for specifying architectural abstractions in a descriptive notation while an architectural style constitutes an intellectually manageable abstraction of system structure that

describes how system components interact and work together.

Unfortunately, despite this considerable work [9], few research efforts have aimed at truly defining styles and description languages for agent architectural design. To fill this gap, we have defined, in the SKwyRL project (<http://www.isys.ucl.ac.be/skwyrl/>), architectural styles for agent systems based on an organizational perspective [2] and have proposed in [3] SKwyRL-ADL, an agent architectural description language. This paper continues and integrates this research: it focuses on an agent perspective for designing and specifying e-commerce software architecture based on organizational styles and SKwyRL-ADL. The structure-in-5 organizational style will be instantiated to design the architecture of the system and the specifications will be expressed in a formal way with SKwyRL-ADL. The rest of the paper is organized as follows. Section 2 introduces some perspectives of SKwyRL insisting on the BDI model, our ADL and organizational styles. Section 3 describes our agent oriented approach on e-commerce system development, including the design of the global architecture with organizational styles, its formal specification with SKwyRL-ADL and the corresponding implementation on an agent-oriented platform. Finally, Section 4 concludes the research..

## 2. ADLAND STYLES IN SKWYRL

We have detailed in the SKwyRL project an agent ADL called SKwyRL-ADL [3] that proposes a set of abstractions that are fundamental to the description and specification of agent architectures based on the BDI (Belief-Desire-Intention) agent model. To help the reader to understand our ADL specification in the rest of the paper, we briefly present the main elements of SKwyRL-ADL including the BDI agent model. SKwyRL-ADL is composed of two sub-models which operate at two different levels of abstraction: internal and global. The internal model captures the states of

an agent and its potential behavior. The global model describes the interaction among agents that compose the agent architecture. We will also introduce organizational styles through the description of one of them, the structure-in-5, that will be used later on in the paper.

## 2.1 The BDI Agent Model

An agent defines a system entity, situated in some environment that is capable of flexible autonomous action in order to meet its design objective [11].

An agent can be useful as a stand-alone entity that delegates particular tasks on behalf of a user. However, in the overwhelming majority of cases, agents exist in an environment that contains other agents. Such environment is a agent system that can be defined as an organization composed of autonomous and proactive agents that interact with each other to achieve common or private goals [6].

In order to reason about themselves and act in an autonomous way, agents are usually built on rationale models and reasoning strategies that have roots in various disciplines including artificial intelligence, cognitive science, psychology or philosophy. An exhaustive evaluation of these models would be out of the scope of this paper or even this research work. A simple yet powerful and mature model coming from cognitive science and philosophy that has received a great deal of attention, notably in artificial intelligence, is the Belief-Desire-Intention (BDI) model [1]. This approach has been intensively used to study the design rationale of agents and is proposed as a keystone model in numerous agent-oriented development environments such as JACK [5]. The main concepts of the BDI agent model are in addition to the notion of agent itself we have just explained:

- Beliefs that represent the informational state of a BDI agent, that is, what it knows about itself and the world;
- Desires (or goals) that are its motivational state, that is, what the agent is trying to achieve;
- Intentions that represent the deliberative state of the agent, that is, which plans the agent has chosen for possible execution.

## 2.2 Internal Model

Figure 1 illustrates the main entities and relationships of the internal model of SKwyRL-ADL. The agent needs knowledge about the environment in order to reach decisions. Knowledge is contained in agents in the form of one of many knowledge bases. A Knowledge base consists of a set of beliefs that the agent has about the environment and a set of goals that it pursues. A belief is a finite set of objects, things with individual identities and properties, that represents a view of the current environment states of an agent. However, beliefs about the current state of the environment are not always

enough to decide what to do. In other words, as well as a current state description, the agent needs some sort of goal information, which describes an environment state that are (not) desirable.

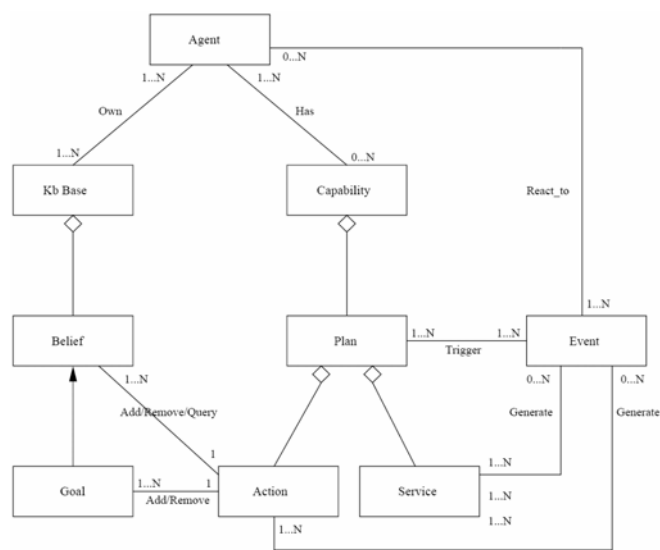

Figure 1: Conceptual representation of the internal model

The intentional behavior of an agent is represented by their capabilities to react to events. An event is generated either by an action that modifies beliefs or adds new goals, or by services provided from another agent. Note that these services are represented in the global model because they involve interaction among agents that compose the agent system.

An event may invoke (trigger) one or more plans; the agent commits to execute one of them, that is, it becomes intention. A plan defines the sequence of action to be chosen by the agent to accomplish a task or achieve a goal. An action can query or change the beliefs, generate new events or submit new goals.

## 2.3 Global Model

Figure 2 conceptualizes the global model which describes the interaction among agents that compose the agent system. Configurations are the central concept of architectural design, consisting of an interconnected set of agents. The topology of a configuration is defined by a set of bindings between provided and required services.

An agent interacts with its environment through an interface composed of sensors and effectors. An effector provides to the environment a set of services. Then, a sensor requires a set of services from the environment. A service is an action involving an interaction among agents.

The whole agent system is specified with an architecture which contains a set of configurations. An architecture

represents agents by one or more detailed, lower-level configuration descriptions.

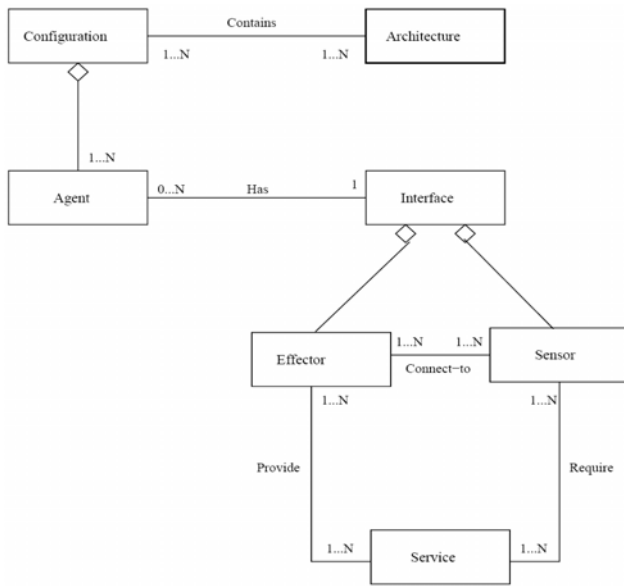

Figure 2: Conceptual Representation of the Global Model

## 2.4 Agent Architectural Styles

A key aspect to conduct architectural design in SKwyRL is the specification and use of organizational styles [2, 6]. These are socially-based design alternative inspired from models and concepts from organizational theories that analyze the structure and design of real-world human organizations.

For instance, the agent architecture we propose in Figure 3 has been designed following the structure-in-5 organizational style detailed in [2]. In a few words, the structure-in-5 style is a meta-structure that defines an organizational architecture that as an aggregate of five sub-structures, as described by Mintzberg [8]. It consists of five typical strategic and logistic components found in many organizations. At the base level one finds the Operational Core where the basic tasks and operations -- the input, processing, output and direct support procedures associated with running the system -- are carried out. At the top lies the Apex composed of strategic executive components. Below it, sit the control/standardization, management components and logistics: Coordination, Middle Agency and Support, respectively.

## 3. AGENT ARCHITECTURE FOR E-COMMERCE SYSTEM

E-Media (<http://www.isys.ucl.ac.be/skwyrl/emedi>) is a typical business-to-consumer application we have developed using the architectural concepts explained in Section 2. The application offers an e-commerce architecture supporting the creation of information

sources that facilitate the on-line transaction of products, services, and payments resulting in an effective and efficient interaction among sellers, buyers and intermediaries.

This section describes how we have applied the structure-in-5 style to design the architecture of E-media and used SKwyRL-ADL to formally specify each architectural aspect (belief, goal, plan, action, interface, configuration, service ...) of the application. Based on this architectural specification, we have implemented the application using JACK, a JAVA agent-oriented development environment.

### 3.1 E-Media Architecture

E-Media includes the following features:

- An on-line web interface allows customers to examine the items in the E-Media catalogue, and place orders;
- Customers can search the on-line store by either browsing the catalogue or querying the item database. An online search engine allows customers to search title, author/artist and description fields through keywords or full-text search;
- If an item is not available in the catalogue, the customer has the option to order it;
- Internet communications are supported;
- On-line financial transactions including credit card and anonymity are protected;
- All web information (e.g., product and customer turnover, sales average, ...) of strategic importance is recorded for monthly or on-demand statistical analysis;
- Based of this statistical and strategic information, the system permanently manages and adapts the stock, pricing and promotions policy. For example, for each product, the system can decide to increase or decrease stocks or profit margins. It can also adapt the customer on-line interface with new product promotions.

Figure 3 models the architecture of E-Media using the i\* model [12] following the structure-in-5 organizational style we have introduced in Section 2.

i\* is a graph, where each node represents an actor (or system component) and each link between two actors indicates that one actor depends on the other for some goal to be attained. A dependency describes an "agreement" (called dependum) between two actors: the depender and the dependee. The depender is the depending actor, and the dependee, the actor who is depended upon. The type of the dependency describes the nature of the agreement. Goal dependencies represent delegation of responsibility for fulfilling a goal; softgoal dependencies are similar to goal dependencies, but their fulfilment cannot be defined precisely; task dependencies are used in situations where the dependee is required. As show in Figure 3, actors are represented as circles; dependums -- goals, softgoals, tasks and resources -- are respectively represented as ovals, clouds, hexagons and rectangles;

dependencies have the form depender  $\rightarrow$  dependum  $\rightarrow$  dependee.

Figure3: The E-Media Architecture in Structure-in-5

The Store Front plays the role of the structure-in-5's Operational Core. It interacts with customers and provides them with a usable front-end web application for consulting, searching and shopping media items.

The Back Store constitutes the structure-in-5's Support component. It manages the product database and communicates to the Store Front relevant product information. It stores and backs up all web information about customers, products and sales to be able to produce statistical information (e.g., analyses, average charts and turnover reports). Such kind of information is computed either for a predefined product (when the Coordinator asks it) or on a monthly basis for every product. Based on this monthly statistical information, it provides also the Decision Maker with strategic information (e.g., sales increase or decrease, performance charts, best sales, sales prevision, ...).

The Billing Processor plays the role of the structure-in-5's Technostructure in handling customer orders and bills. To this end, it provides the customer with on-line shopping cart capabilities. It also ensures the secure management of financial transactions for the Decision Maker. Finally, it handles, under the responsibility of the Coordinator component, stock orders to avoid shortages or congestions.

As the structure-in-5's Middle Agency, the Coordinator assumes the central position of the architecture. It is responsible to implements strategic decisions for the Decision Maker (Strategic Apex). It supervises and coordinates the activities of the Billing Processor (initiating the stock and pricing policy), the Front Store (adapting the front end interface with new promotions and recommendations) and the Back Store

(parametrizing statistical computing) ensuring that the system fulfills its mission in an effective way.

Finally, the Decision Maker assumes the Strategic Apex role of the structure-in-5. It defines the Strategic Behavior (e.g., sales and turnover, product visibility, hits, ...) of the system ensuring that objectives and responsibilities delegated to the Billing Processor, Coordinator and Back Store are consistent with respect to their capabilities.

### 3.2 E-Media Formal Specification

The architecture described in Figure 3 gives an organizational representation of the system-to-be including relevant actors and their respective goals, tasks and resource inter-dependencies. This model can serve as a basis to understand and discuss the assignment of system functionalities but it is not adequate to provide a precise specification of the system details. As introduced in Section 2, SKwyRL-ADL provides a finite set of formal agent-oriented constructors that allow to detail in a formal and consistent way the software architecture as well as its agent components and their behaviors.

```

Agent:{Back-Store
Interface
Effector[provide(strategic_info)]
Effector[provide(statistical_info)]
Effector[provide(product_info)]
Effector[provide(back-up)]
Sensor[require(strategic_behavior)]
KnowledgeBase:
Product_KB      Statistical_KB
BS_System_KB   BS_Customer_KB
Capabilities:
Statistical_CP  Strategic_CP
Data_Management_CP
}

```

Figure 4: Agent Description of the Back-Store

Figure 4 shows a high-level formal description of the Back-Store agent. Three aspects of this agent component are of concern here: the interface representing the interactions in which the agent will participate, the knowledge base defining the agent knowledge capacity and the capabilities defining agent behaviors.

SkwyRL-ADL allows to work at different levels of architectural abstractions (i.e., different views of the system architecture) to encapsulate different components of the system in independent hierarchical descriptions. For instance, in Figure 4 the Back Store agent has three knowledge bases (KB) and three capabilities (CP), but the description level chosen here does not specify the details of the beliefs composing the KB or the plans and events composing each capability.

The rest of the section focuses on the Back Store agent to give an example of a refinement specification with

our ADL for each of the three aspects of the agent: interface, knowledge bases and capabilities.

**Interface.** The agent interface consists of a number of effectors and sensors for the agent. Each of them represents an action in which the agent will participate. Each effector provides a service that is available to other agents, and each sensor requires a service provided by another agent. The correspondence between a required and a provided service defines an interaction. For example, the Back Store provides the statistical\_info service that the Coordinator requires.

Such interface definition points two aspects of an agent. Firstly, it indicates the expectations the agent has about the agents with which it interacts. Secondly, it reveals that the interaction relationships are a central issue of the architectural description. Such relationships are not only part of the specification of the agent behavior but reflect the potential patterns of communication that characterize the ways the system reason about itself.

```
Service: {Ask(statistical_info)
sender: Coordinator
parameters: (tw: TimeWindows), (id: Id_product)
reply_with: to: Turnover v sl: Sales
receiver: Back-Store
Effect:Add(Statistical_KB, Achieve (stat("today","on_product")
)}
```

Figure 5: A Service Specification

The specification of a service is given in Figure 5. Each provided or required service is detailed by specifying the sender agent that initiates the service, the set of receiver agents that interact with the sender, the reply-with and content statements that define the information about which the service expresses an interaction and optionally a set of parameters to define the information required to execute the service. Like the parameters the reply-with information is represented with a belief or a set of terms (e.g., function, constant or variable).

**Knowledge Bases.** A knowledge base (KB) is specified with a name, a body and a type. The name identifies the KB whenever an agent wants to query or modify them (add or remove a belief). The body represents a set of beliefs in the manner of a relational database schema. It describes the beliefs the agent may have in terms of fields. When the agent acquires a new belief, values for each of its fields are specified and the belief is added to the appropriate KB as a new tuple. The KB type describes the kind of formal knowledge used by the agent. A Closed world assumes that the agent is operating in a world where every tuple it can express is included in a KB at all times as being true or false. Inversely, in an open world KB, any tuple not included as true or false is assumed to be unknown. Figure 6 gives the specification the Product\_KB:

```
KnowledgeBase: {Product_KB
Kb_body:
```

```
product(Id_Prod,Title,Class,Description,Price)
purchase(Id_Card,Id_Prod,Date,Quantity,Pay_Means)
audio(Id_Prod,Artist(+),Compositor(+))
book(Id_Prod,ISBN,ISNN,Author(+),Publisher)
dvd(Id_Prod,Actor(+),Realizator(+))
...
kb-type: closed_world
}
```

Figure 6: A Knowledge Base Specification

Capabilities formalize the behavioral elements of an agent. They are composed of plans and events that together define the agent's abilities. They can also be composed of sub-capabilities that can be combined to provide complex behavior.

```
Capability: {Data_Management_CP
CP_body:
Plan Send_Product_Data
Plan Backup_Database
Plan Check_Identification
Plan Interface_Custom_Id
endEvent update_interface
PostEvent backup
}
```

Figure 7: Capability Specification

Figure 7 shows the Data\_Management capability of the Back-Store agent. The body contains the plans the capability can execute and the events it can post to be handled by other plans or it can send to other agents. For example, the Data\_Management capability is composed of four plans: Send\_Product\_Data is used to send product information to the Store-Front, Backup\_Database backs up all information about customers, products and sales in order to provide statistical information, Interface\_Custom\_Id allows user registration and Check\_Identification checks the customer login/password when an order is made.

A plan defines the sequence of actions and/or services (i.e., actions that involve interaction with other agents) the agent selects to accomplish a task or achieve a goal. A plan consists of:

- an invocation condition detailing the circumstances, in terms of beliefs or goals, that cause the plan to be triggered;
- an optional context that defines the preconditions of the plan, i.e., what must be believed by the agent for a plan to be selected for execution;
- the plan body, that specifies either the sequence of formulae that the agent needs to perform, a formula being either an action or a service to be executed; an end state that defines the post-conditions under which the plan succeeds;
- and optionally a set of services or actions that specify what happens when a plan fails or succeeds.

**Configuration** To describe the complete topology of the system architecture, the agents of an architectural description are combined into a SkwyRL configuration.

Instances of each agent or service that appear in the configuration must be identified with an explicit and

unique name. The configuration also describes the collaborations (i.e., which agent participates in which interaction) through a one-to-many mapping between provided and required service instances.

### 3.3 E-Media Implementation

Based on the structure-in-5 architecture described in Section 3.1 and the formal SKwyRL-ADL architectural specification overviewed in Section 3.2, the E-Media application has been implemented with JACK (JACK), a BDI agent-oriented development environment for JAVA. We briefly describe the E-Media implementation to illustrate the role of the agents and their interactions.

Figure 8: E-media Main Interface

When an on-line customer gets connected to E-media, an instance of the Front-Store is created to display the interface depicted in Figure 8. It allows the new coming user to register (1). The Back-Store handles the information provided by the user and checks its validity (2). If the access is granted, the user can purchase products on E-Media by adding catalogue items to the shopping cart (4) managed by the Billing-Processor. At any time the user can use the navigation-bar (3) to switch from one section of the website to another. Promotions (5) and best sales (6) are part of the strategic behaviour objective. The promotions policy is initiated by the Decision-Maker based on the strategic information provided by the Back-Store. The Coordinator chooses the best promotions and consequently adapts the Store Front layout. The Coordinator acts similarly for the best sales: the Back-Store computes the five best sellers and the Coordinator accordingly updates the Store-Front.

## 6. CONCLUSION

Nowadays, software engineering for new enterprise application domains such as e-Business is forced to build up open systems able to cope with distributed, heterogeneous, and dynamic information issues. Most of these software systems exist in a changing organizational and operational environment where new components can be added, modified or removed at any

time. For these reasons and more, agent architectures are gaining popularity in that they do allow dynamic and evolving structures which can change at run-time.

Architectural design has received considerable attention for the past decade which has resulted in a collection of well-understood architectural styles and formal architectural description languages. Unfortunately, this work has focuses on object-oriented rather than agent-oriented systems. This paper has described an approach based on organizational styles and an agent architectural description language we have defined to design agent architectures in the context of e-commerce system engineering. The paper has proposed a validation of the framework: it has been applied to develop E-Media, an e-commerce platform implemented on the JACK agent environment.

### ABSTRACT

The data that most organizations possess is considered a valuable asset. To really benefit from it, organizations must be able to analyze these data efficiently and effectively. This activity is nowadays referred to as business intelligence and one class of algorithms used within this activity are called data mining methods. There are some famous success stories about knowledge discovered via data mining but there is also a lot of disappointment so far. The paper argues that one of the reasons for some failures to produce better results with data mining is the reliance on transactional and master data only. It points to other types of data that can enrich transactional data and help in this way to produce more interesting and more rewarding data patterns.

**Keywords:** knowledge discovery, data mining, data warehouse, business intelligence

### 1. INTRODUCTION

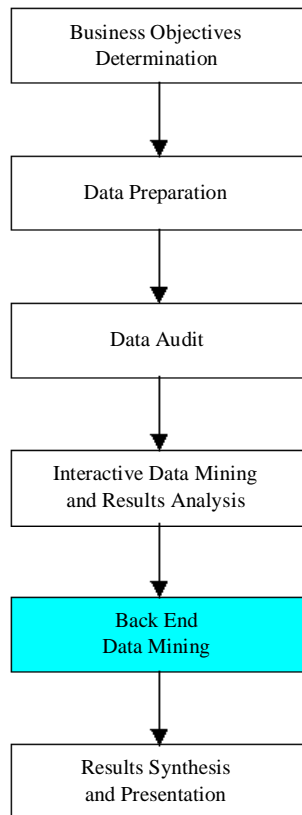

The computerization of most (business) processes has led to a dramatic increase in transactional data. One of the latest reasons for a revolutionary increase in transactional data is the wide-spread use of the world-wide web where each request for information is recorded in a log file. Transactional data always contain information on *what* happened and often but not always *who* the actor was. For example, in web log mining it is often not known who the web site visitor was. If we know the actor, we can combine transactional data with master data if they exist. Practitioners often misinterpret the most cited process model (see Figure 1) in such a way that transactional (and master) data are sufficient to perform knowledge discovery. A typical statement is "Data mining can help companies extract additional value from piles of accumulated customer transaction data"[7]. This is not wrong but transactional data are often not sufficient to perform successful knowledge discovery as will be shown below. Many companies first build a data warehouse, primarily for regular reporting and ad-hoc queries, and then they start thinking which more complex data analyses to perform. Building a data warehouse usually comprises merging transactional and master data from several applications and sources, a tedious task that takes a lot of resources and time [3]. If additional data are needed later for data mining they may not be available anymore or the management is reluctant to restart the process of building the data warehouse. So data mining is only performed with the data that have been collected before independently of any knowledge discovery objectives.

**Figure 1: Knowledge Discovery Process [2]**

Following such an approach, the results of the data mining process are often disappointing; they are not

interpretable, not interesting, or not actionable. Other authors suggest, therefore, to enrich data during the preprocessing step [7] or they propose an alternative process model (see Figure 2).

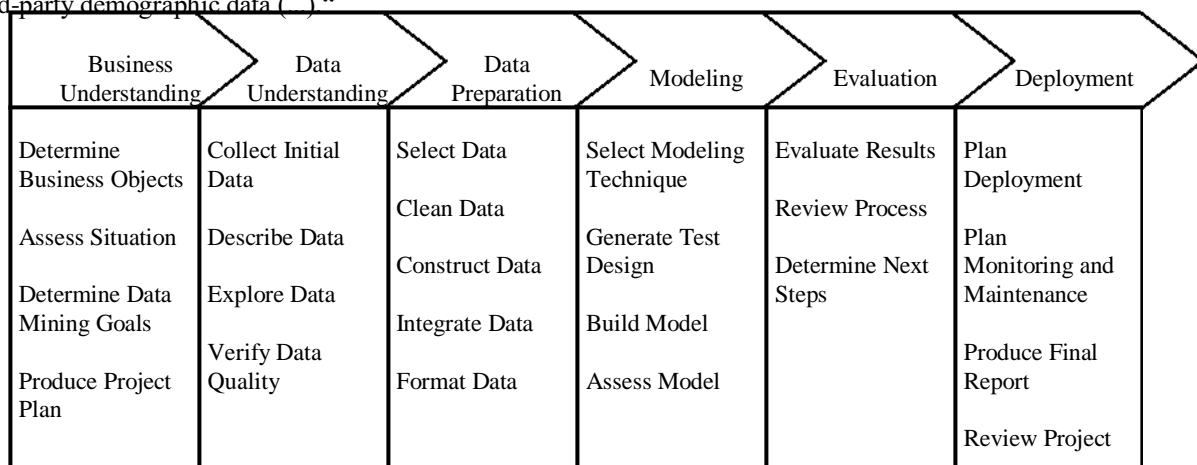

**Figure 2: Knowledge Discovery Steps [4]**

It is especially the step of “back end data mining” that gives rise to the hope that this process will lead to better results. According to Hirji [4] “Back end data mining involves data enrichment and additional data mining algorithm execution (...) in order to increase the dimensionality of the data mining data set with third-party demographic data ( )”

Our view, based on carrying out a number of data mining projects, is that additional data, not just demographic data, may be needed at collection time, in the selection step, and in the preprocessing step. The collection or creation of these data is based on knowledge that is sometimes loosely referred to as background, domain, or application-specific knowledge. It enables an analyst to collect, create, or select data that are relevant to the analysis task without being an explicit part of a transaction. To be able to initiate the necessary activities in due time, the analyst should roughly know ahead what s/he will be mining for. A process model proposed by SPSS, a statistical software vendor, in collaboration with some industry representatives, called CRISP-DM (Cross Industry Standard Process for Data Mining), explicitly requires to collect data only after the business and data mining objectives have been defined (see Figure 3). Further, it suggests constructing and integrating data, if needed, during the phase of data preparation. This model is, however, not specific about why and what type of new data should be generated via construction or integration.

We try to determine various types of data that may play a role in a data mining task without being part of transactional or master data. The importance of such data is demonstrated through examples from specific projects that we have conducted in the last years. The data types have been determined inductively through action research [6] so they are biased by the kind of projects undertaken. The projects cover several industries and almost all widely used data mining methods (decision trees, artificial neural networks, association rules, case-based reasoning, various clustering other statistical methods, scoring). However, it may be that mining in scientific data would reveal that additional or other data types are important.

**Figure 3: CRISP-DM Reference Model [1]**

## 2. CIRCUMSTANTIAL DATA

Circumstantial data relate to the conditions when the transaction occurred. It is usually easier to create or collect such data at the time that transactional data are collected than later, perhaps after months or years, when data mining takes place. For example, to get detailed

regional weather data by the hour and minute for each transaction after several months or years might be possible but it is certainly more difficult and expensive than recording the data when a transaction occurs. Table 1 shows an example where the task was to segment customers of a telecommunication product.

**Table 1: Enriched call data**

Col No	Column Name	Format	Description
...	...	...	...
5	from_connect_tm	...	...
6	from_weekend_ind	numeric1	Set if day called at origin = Sunday or Saturday
7	to_country_cd	...	...
8	to_connect_dt	...	...
9	to_connect_tm	...	...
10	to_weekend_ind	numeric1	Set if day called at destination = Sunday or Saturday
11	vacation_ind	numeric1	Set if day called at origin in {24.12 - 31.12 or 1.7 -31.8}
12	days_since_last_call_qty	numeric	No of days since customer called last
13	destination_typ	...	...
...	...	...	...

The basic call data (numbers of the caller and the person called as well as the time) were immediately augmented by data that indicate whether the call took place on the weekend (column 6), during vacation time (column 11), and a number of other indicators. Some of these played an important role during the clustering of customer groups. As can be seen from column 11, such data can be soft in the sense that they reflect an assumption or perception. In this case, it is assumed that the caller is on vacation if the call was made in the indicated time period.

Circumstantial data can be also important in the selection step. In another application, the task was to develop a scoring model with which customers of a financial institution can be targeted for specific investment products [5]. One of the variables that played an important role was the value of the customer's stock portfolio. This obviously can fluctuate considerably. To control for the fluctuations of the stock market, data about the German stocks index DAX were used in such a way that customer data were selected for training purposes from a period of time when the DAX was relatively stable (see Figure 4). In this case, this was the period between January 2, 2001 and June 29, 2001.

**Figure 4: Run of the DAX between April 20, 2000 and December 31, 2001**

### 3. STRUCTURAL DATA

While in some cases a simple categorization of data can be helpful, in many cases the knowledge of more complex relationships among objects involved in transactions is needed. For example, in the analysis of purchase baskets in a supermarket the scanner data allow to mine for associations at the level of universal product codes. However, given that many products from the same brand and kind come in different packages, it may be meaningful to summarize them as a pre-processing step. Sometimes, further aggregations along product categories (across brands) are needed to discover association rules. Therefore, the structure of product groups needs to be applied to transactional data before data mining can be performed.

### 4. QUALIFICATION DATA

Qualification data describe more precisely what has happened. Transactional data contain the facts, qualification data add meaning to these facts. In the above mentioned example, segmentation of customers of a telecommunication product, each transaction contains the origination and destination phone number. Through a comparison of the destination number with the customer's home and office numbers, which are usually recorded in the master data, each call was qualified to be a call *home*, to the *office*, to the *home city*, to the *home country*, or *other*. Another comparison of the origination and the destination numbers qualified the calls as being *in-country* or *out-of-country* calls. It turned out that one of these variables played a role in forming the customer clusters. Another example is visits to a web site. They can be relatively easily distinguished by the number of web pages requested, the visit length, or the action taken (e. g., a registration, an information request, or a purchase). However, if visitors usually do not take an action at a web site, it may be helpful to characterize each visit before further analyzing the visiting behavior. One simple qualification using cookie technology can be the distinction between *first visit* and *repeat visit*.

Another example relates to a set of purchase data from mail orders. Some of the customers acted as sales people in the sense that they were also placing collective orders for several customers. Their pay-off was a bonus on the accumulated sales amount. The mail orders did not contain any information whether an order was placed for one or several customers. The goal of the analysis was to search for association rules among products in a sales transaction (basket analysis). Collective orders would distort the results since they contain several transactions. Therefore, the mail orders were qualified as collective orders if the total order value

exceeded a threshold value. These purchases were then excluded from further analysis.

The first example shows that transactions can be qualified based on facts while the second one shows that, sometimes, they must be based on "educated guesses."

### 5. NON-TRANSACTIONAL TRACKING DATA

Non-transactional tracking data record the behavior of objects of interest, often customers, even when no transactions occur. When a transaction occurs transaction processing systems carry out necessary actions including the update of stock values (e.g., customer account balance or number of seats available on a plane). However, the lack of activity of an object can also be an important information worth recording. As an example, we look at data of a direct order company. The orders come via phone, mail, or internet. In each of the cases, a quick credit assessment takes place. Most cases are decided automatically by a program that decides whether to deliver the merchandise to the customer and what kind of payment to accept. This process is referred to as *behavioral scoring* in the case of existing customers because the decision is based on their past buying and paying behavior (in the case of new customers *application scoring* takes place). The method used to derive rules for the decision can be a decision tree or a scoring scheme. Obviously, the relating data are generated and updated when a purchase or a payment takes place. But it is also important to update data when a customer with a balance due does not make a payment. Table 2 shows some of the data used in the example. The variable *number of successive months overdue* is a variable which value is updated monthly even if a customer has no transactions with the company in a given month.

**Table 2: Customer data of a direct order company**

CHAR005	Average of monthly balance
CHAR007	Balance of the actual month
CHAR008	Percent of used debt limit
CHAR013	Number of successive months overdue
CHAR022	Longest time of overdue in the last 12 month
...	...
CHAR516	Average of all payments
...	...
CHAR553	Percent of returns and refusals
CHAR555	Number of months since last return or refusal
...	...

### 6. SUMMARY

Table 3 gives an overview of the described data types with respect to some attributes. The values of the attributes should be understood as typical values.

Data type	Time of generation with respect to transactional data	Transaction dependent?	Ownership (ass.: company is owner of transaction data)
Circumstantial	at the same time	yes	others
Structural	before or after	no	company
Qualification	after	yes	company
Non-transactional tracking data	at any time	no	company or others

**Table 3: Additional Data Types for Data Mining**

Our findings are more specific with respect to types of data that can be used to enrich transactional and master data than general knowledge discovery process models but they are still not “cooking recipes” for data collection for data mining. Each case requires its own business analysis. Our findings may help to make management more aware of the data needs in data mining while data miners may find them helpful to conceptualize their thoughts.

nell10@korea.com, jaek@khu.ac.kr

## ABSTRACT

Recommender system is a popular technique for reducing information overload and finding digital contents that is most valuable to users. However, most recommender systems are based on a centralized client-server architecture in which servers and clients represents contents providers and users respectively. The existing recommender systems depend on contents providers and give a number of disadvantages to users. Therefore, we propose a recommender system based on a distributed P2P architecture that has originated with user-oriented principle rather than business itself. The proposed system consists of fully functioning personal recommender agents that automatically select neighbors and recommend contents. The agents learn user preference from users' content usage without requiring users' explicit ratings. We believe that the suggested P2P based recommender system should provide the users with more qualified recommendations, while it reduces the effort and time of users.

**Keywords:** Recommendation, Peer-to-Peer, Collaborative Filtering, Content-Based Image Retrieval

## 1. INTRODUCTION

According to a recent report, 93% of information produced worldwide is in digital form and the unique data added each year exceeds one exabyte, and more than 513 million people around the world are now connected to the global information resource [11]. However, all of those people have problems to search for digital contents they are most interested in. This trend calls for equally recommender systems with scalable searching capability. Recommender systems have been proved to be one of the most successful techniques to help people find contents that are most valuable to them in research and practice.

But, most existing Recommender systems are based on centralized client-server architecture in which servers and clients represent service providers and users respectively. The existing recommender systems depend on content providers and give a number of disadvantages to users. Centralized recommender systems collect users' sensitive information at one server. This makes recommender systems a serious risk for violating the privacy of users. Furthermore, from the users' perspective, the information about their preference is fragmented across many service providers reducing the quality of recommendations to them. Besides, each service provider requires users to indicate their specific preferences. So users must provide redundant information to obtain suitable recommendations from each service provider.

One solution to the problems with centralized recommender system is to distributed peer-to-peer (P2P) architecture, recent alternative to the dominating client-server architecture. Users in P2P architecture works as servers and clients simultaneously.

In this paper, we propose a collaborative filtering-based image content recommender system in distributed P2P architecture as a solution to the problems with centralized recommender system. Our system consists of users connected by personal recommender agents which reside on each user's computer. All processing to recommend contents is done locally by the agent. It allows users to maintain a fraction of the information about other users only, not all users' information, and generates recommendations themselves. Our proposed recommender agent selects more similar neighbors dynamically by learning preference, what image the user want, from the user's content usage without requiring user's explicit ratings. The system combines the two most popular information filtering techniques: Collaborative Filtering and Content-based Image Retrieval. This paper describes the reasons for and by which these two techniques were combined to recommend images in P2P architecture.

## 2. RELATED WORK

### 2.1 CF-based Recommender Systems

The recommender system is one of possible solutions to searching for individually preferred images from amount of images. A recommender system is defined as a system that assists customers in finding the items they would like to purchase. One of the most successful recommendation techniques is Collaborative Filtering (CF) [1,3,12,13], which has been widely used in a number of different applications.

Collaborative filtering is an information filtering technique that depends on human beings' evaluations of items. It is an attempt to automate the "word of mouth" recommendations. It identifies customers whose tastes are similar to those of a given customer and it

recommends items those customers have liked in the past. In general, CF-based recommender systems make recommendations according to the following steps [3,12]: (1) A customer provides the system with preference ratings on items that may be used to build a customer profile. (2) The system applies statistical or machine learning techniques to find a set of customers, known as neighbors, who had in the past exhibited similar behaviors. A neighborhood is formed based on the degree of similarity between a target customer and other customers. (3) Once a neighborhood is formed for a target customer, the system generates a set of items that the target customer is most likely to purchase by analyzing the items in which neighbors have shown an interest.

Despite their success, none of the previously proposed approaches can be an adequate solution for image recommendations in distributed P2P architecture. In this paper, Content-based Image Retrieval (CBIR) [5,6,10], the most widely used image retrieval technique, was used as a technique for content-based similarity search and was combined with CF.

## 2.2 Content-Based Image Retrieval

Content-based image retrieval represents an image as a point in multi-dimensional feature space and performs similarity-based retrieval using its visual features such as color, texture and shape. In CBIR, the customer describes visual characteristics of desired images using a query that is a set of example images. A query is internally represented as multiple points (i.e. query points) that have visual characteristics of example images. In general, CBIR systems retrieve images according to the following steps [15]: (1) A customer presents a query to the system via selection or sketching of images as a request for desired images. (2) The system searches for images similar to the query. The similarity between an image in the database and a query is calculated using the distance between corresponding points in the feature space. (3) The images with the highest degree of similarity are retrieved and recommended to the customer.

In spite of the virtues of CBIR in retrieving images similar to a query, CBIR rarely brings a customer to the desired images immediately. The reason for this is that any combination of example images may not precisely represent the images that a customer desires. For a system to handle this gap properly, it needs the ability to learn about what image the customer really wants through iterative interactions. The customer's current preference on the presented images needs to be fed back so that CBIR can learn from this preference to retrieve, in the next iteration, images more similar to the one customer really wants. This learning process, the *preference feedback*, is an essential mechanism for a faster search of desired images. We will refer to a set of preferred images as a *saved image set*. The images in

the saved image set are used for query refinement for the purpose of learning customer's current preference.

## 2.3 P2P (Peer-to-Peer) System

With the pervasive deployment of computers, P2P is increasingly receiving attention in research and practice. P2P system is direct communication or collaboration between two or more agents, such as personal computers or devices that bypass a centralized computer server. Current P2P applications can be classified into one of the following three categories [4]: Content File sharing, Distributed processing, Instant messaging

As the main usage of P2P systems are to share content files among a group of computers called peers in a distributed way, by direct exchange between peers. The using contents in P2P architecture differs markedly from the client-server architecture. A client-server based system depends on a single server storing information and distributing it to clients. The information repository remains essentially static, centralized at the server, and subject only to updates by the provider. Peers assume a passive role in that they receive, but do not contribute, information. A P2P system, on the other hand, considers all peers equal in their capacity for sharing information with other users. Each peer makes an information repository available for distribution, which, combined with anyone's ability to join the network, each peer can make information available for distribution and can establish direct connections with any other peers to download information. Instead of looking at what is available in a centralized repository, a peer seeking information from a P2P system searches across scattered collections stored at numerous peers, all of which appear to be a single repository with a single index. P2P system can use protocols that make it easier for each peer participate and share information, but the trade-off can be decreased quality of service.

Any P2P system doesn't provide recommendations to peers so that the peers have problems to search for contents that are most valuable to peers. To add value to P2P system, it needs to provide efficient search to peers to reduce information overload. We believe that P2P system with recommender functions make it possible. Therefore we propose contents recommender system in P2P architecture[2,8,9].

## 3. PROPOSED RECOMMENDER SYSTEM

Our system is designed to deal with the problems we face in recommending image files in a decentralized domain, P2P architecture. All processing to support a peer in finding desired images by generating personalized recommendations of image is done locally by a personal agent resides on each peer's computer without central server.

The system consists of interconnected peers of agents are implemented to be fully functioning recommenders. The agent keeps watch its peer (called the *host peer*)

and learn what images the host peer find relevant. That knowledge is then used to find both other relevant images and similar peers (called the **neighbor set**). The agent exchanges recommendations with the agents of its neighbor set.

The personal agent consists of two modules: CF agent and CBIR agent. Two components collaborate each other to decide whom should receive a recommendation, whom to keep as a neighbor, and what contents relevance to the host peer. Figure 1 shows proposed recommender agent with overall procedure.

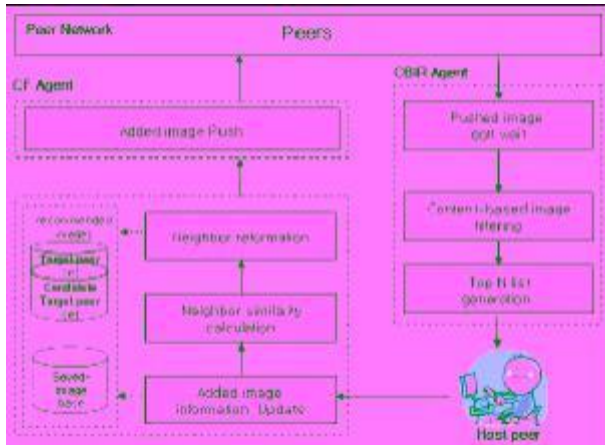

Figure 1. Personal Recommender Agent

The agent dynamically selects which peers to include its neighbor set. When a peer is discovered to frequently provide good recommendations, the peer attempts to move closer to the host peer. Thus an agent might keep better constituent neighbors and recommendations should be reached to more related peers. This mechanism provides a wide peer network with efficient image sharing being spread faster with less communications.

### 3.1 Peer Model

In P2P architecture, a personal recommender agent builds a peer model respectively to generate personalized recommendations for a host peer. The peer model should include information about a host peer's preference for image and its neighbors to exchange recommendations with other agents.

**Image representation:** To analyze peers' preference for images, we use the HSV (i.e. hue, saturation, and value of color) based color moment over other choices of features such as shape or texture, because color moment is the most generally used feature and HSV represents human color perception more uniformly than others [9]. For all pixels in images, we translated the values of three-color channels (i.e. RGB: red, green, and blue) into HSV values. Then, the mean, standard deviation and skewness for HSV values were calculated to represent images as vectors in a nine dimensional feature space.

**Peer Profile:** A peer profile consists of two parts: saved image set and neighbor image set. A set of preferred images is called the saved image set,  $Q = (q_1, q_2, \dots, q_j)$ , denotes all images that host peer has saved, which is used to refine the query for the purpose of learning host peer's current preference. The neighbor image set,  $P_{ij} = (p_{i1}, p_{i2}, \dots, p_{ik})$ , denotes image  $j$  recommended by neighbor  $i$  which is used to calculate similarity of the neighbor  $i$ . The neighbor image set includes images a host peer has saved only.

Saved image set includes information about peer's preferences on images, while neighbor image set includes information about similarity of each neighbor according to their recommendations. The peer profile is constantly updated with newly obtained relevance images and similarity of its neighbors to dynamically reflect peer's most recent preference. This is significantly different from the user profiles used in traditional server based recommender systems [11].

### 3.2 Neighbor Definition

The agent of host peer  $h$  has a neighbor set  $N_h$  consists of peers who have recommended relevance images to host peer  $h$ . Each Neighbor has a  $s(n_k, h)$  respectively.

Here,  $s(n_k, h)$  denotes the similarity between a neighbor  $n_k$  and host peer  $h$ . As equation (1), a similarity accumulates the reciprocal of the  $Dist(p, Q)$  calculated by CBIR agent is discussed in section 4.2 to reflect both the similarity and the success times of recommendations.

$$s_{i+1}(n_k, h) = s_i(n_k, h) + Dist(p, Q^h)^{-1} \quad (1)$$

The neighbors of host peer  $h$  divided into two sets: the target peer set ( $N_h^t$ ) and the candidate target peer set ( $N_h^c$ ).

$$N_h = N_h^t \cup N_h^c \quad (2)$$

Using the  $s(n_k, h)$ , the agent generates a set of target peers,  $N_h^t = \{n_1, n_2, \dots, n_k\}$ , such that  $s(n_1, h)$  is maximum,  $s(n_2, h)$  is the next maximum, and so on where  $k$  is a limited number of target peers. The agent of a host peer forwards recommendations to its target peers only. Besides target peers, the rest of neighbors is included to candidate target peer set ( $N_h^c$ ). But, neighbors are dynamically exchanged: adding new peers and moving between two sets to reflect host peer's current preference.

#### 4. RECOMMENDER AGENT

The personal agent consists of two modules: CF agent, CBIR agent. In this section, we describe the roles of two agents respectively.

##### 4.1 CF Agent

CF agent is implemented with a learning algorithm to model a host peer and with a set of neighbor peers. CF agent makes it possible to find more relevance neighbors. The agent updates the peer profile using feedback information (*saved or not*). The updated profile is used to choose whom to keep as neighbors and target peers but also refine the query. The refined query is passed to the CBIR agent to predict the relevance of images for current preference of the host peer. CF agent can only generate recommendations of its host peer, and forward other peers' recommendations to its target peers.

**Initialization** To initialize a new peer, agents can use a different algorithm. This is implemented by initializing the peer with neighbors taken from an artificially created. To determine initial neighbor set for new host peer  $p$ , the agent calculates the similarity between new host peer  $p$  and other peers using all saved image set as follows:

The agent determine initial neighbors for a peer  $p$ ,  $B = \{b_1, b_2, \dots, b_m\}$  such that  $p \notin B$  and  $\text{sim}(p, b_1)$  is maximum,  $\text{sim}(p, b_2)$  is the next maximum, and so on. Here,  $\text{sim}(p, b)$  denotes the similarity between two peers  $p$  and  $b$ , and is calculated using equation [3][4].

$$\text{Dist}(P, Q) = \sqrt{\frac{\sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \text{dist}^2(p_i, q_j)}{n_1 n_2}} \quad (3)$$

$$\text{dist}(p_i, q_j) = \sqrt{\sum_{s=1}^S (p_{is} - q_{js})^2} \quad (4)$$

Where  $n_1$  and  $n_2$  are the number of saved images of the peer  $b$  and peer  $p$  respectively, and  $p_i$  and  $q_j$  are the  $i$ th and  $j$ th image, and  $\text{dist}(p_i, q_j)$  is a distance function between an image  $p_i$  and  $q_j$ . And in equation (4),  $s$  is the number of dimensions of the feature space and  $p_{is}$  and  $q_{js}$  are coordinates of an image  $p$  and  $q$  on the  $s$ th dimension respectively. It has characteristics of treating neighbors with similar saved images using the shortest distance.

The set of similar peers to new peer  $p$ ,  $B = \{b_1, b_2, \dots, b_m\}$ , will be the agent's initial neighbor set. Additional neighbors will be found by the exchange of recommendations.

**Recommendation Generation** An agent generates recommendations to each other not on request but whenever a host peer saves a new image. However, each agent can only collaborate directly with its target peers, and hence to reach agent beyond the target peers they have to forward recommendations for each other. Figure 2 illustrates it.

Figure 2. Communications of an agent with its target peer set

**Neighbor Reformation** The recommender agent dynamically selects which users to be included in neighbors. When a host peer receives a suitable recommendation, the recommending peer might be added to neighbor set. When an agent receives a forwarded recommendation from other peer  $i$ , the recommending peer  $i$  might be added to the candidate target peer set and discards an old one  $j$  with the lowest similarity value as equation (5).

$$\begin{aligned} & \text{if } i \notin N \\ & \text{then } N_c \leftarrow N_c - \{j\} + \{i\} \end{aligned} \quad (5)$$

Moreover, if a candidate target peer recommends relevant images continuously, it becomes a target peer. If the candidate target peer is more similar to the host peers than the target peer, the candidate target peer will replace the target peer and vice versa in each neighbor set.

$$\begin{aligned} & \text{if } \text{arc max}_{n_{c_j} \in N_c} (\text{sim}(h, n_{c_j})) > \text{arc min}_{n_{t_i} \in N_t} (\text{sim}(h, n_{t_i})) \\ & \text{then } N_c \leftarrow N_c - \{n_{c_j}\} + \{n_{t_i}\} \ \& \ N_t \leftarrow N_t - \{n_{t_i}\} + \{n_{c_j}\} \end{aligned} \quad (6)$$

According to this mechanism, an agent finds more similar neighbors resulting to be given relevant images. Thus an agent might keep better constituent neighbor members and recommendations should be reached to more similar users.

##### 4.2 CBIR Agent

A recommender agent can receive from other recommender agent. All received images are put in a queue except the same as saved images. The CBIR

agent uses all saved images of the host peer as multiple query points, and retrieves images based on distance between the multiple query points and images in the queue. For all images in the queue, this agent calculates the distances from the multiple query points and generates a list of  $k$  nearest images ( $k$ -NNs) as recommendations. This agent retrieves  $k$  images entirely based on visual features of query that represents the peer's current preference.

The calculation to retrieves  $k$  images is as follows: CBIR agent uses the all saved images as the query  $Q$ , and continuously refines the query by adding the query points in  $Q$  with the newly saved images. Since a query is allowed to have multiple query points, the distance function between an image  $x$  and a query  $Q$  should aggregate multiple distance components from each query points to the image. We use the following aggregate distance function:

$$Dist(x, Q) = \sqrt{\frac{g}{\sum_{j=1}^g 1/dist^2(x, q_j)}} \quad (7)$$

where  $g$  is the number of query points in a query  $Q$ ,  $q_j$  is the  $j$ th query point of  $Q$ , and  $dist(x, q_j)$  is a distance function between an image  $x$  and a query point  $q_j$ . We derived the Equation (7) from the FALCON's formula [14]. It has characteristics of treating an image with the shortest distance component to any one of query points as the image with the shortest aggregate distance.

Just as this system continuously refines the query in newly added images, it also updates the Equation (7) to reflect the peer's current preference. For this purpose, we define the  $dist(x, q_j)$  in Equation (7) as:

$$dist(x, q_j) = \sqrt{\sum_{l=1}^L w_l (x_l - q_{jl})^2} \quad (8)$$

where  $L$  is the number of dimensions of feature space,  $w_l$  is a weight of the  $l$ th dimension in the feature space, and  $x_l$  and  $q_{jl}$  are coordinates of an image  $x$  and a query point  $q_j$  on the  $l$ th dimension, respectively.  $w_l$  in Equation (8) is substituted by  $1/s_l$  at the end of every connection of the peer, where  $s_l$  is a standard deviation of coordinates of  $l$ th dimension of images. Note that  $s_l$  is calculated using all images in the relevant set accumulated. This distance function update is to better reflect a peer's current preference by allowing different weights by dimension and putting more emphasis on the features with smaller variance. Note that equal weights are to be used for all dimensions when there is only one query point in  $Q$ .

Based on the above definitions and discussions, CBIR agent generates Top  $k$  recommendation list for the host

peer,  $X=\{x_1, x_2 \dots x_k\}$  such that  $Dist(x_1, Q)$  is the minimum,  $Dist(x_2, Q)$  is the next minimum, and so on.

The retrieved  $k$  images are presented when the peer connects the network. And the peer skims through the list to see if there are any images of interest. Then, the peer may save desired images on the peer's computer. This relevance judgment on the presented images passes to CF agent to learn the peer's current preference.

## 5. EVALUATION

In order to performance evaluation the proposed image recommender system we implement a simulator with variable parameters: size of the neighbor set, exploration propensity of the user for simulated 30 days. The components of the simulator are some parts of the recommender system. One of the simulated parts is images including their representation as vectors in a nine dimensional feature space for HSV values. For the simulations, the 1000 images that Korea Telecom Freetel (KTF), a leading Korean CDMA carrier, is currently offering were used. Other parts consist of 1000 peers modeled as having distinctive preference for some images. And they have initial neighbor set to exchange recommendations. Last, the recommender agents work as described in section 4.

Proposed recommender system is compared with centralized recommender system. In our system, each peer has a unique recommender agent with a limited neighbor set, while in the compared system, a single agent manages all users for recommendations. For performance evaluation of the system, we use metrics most widely used for recommender systems, *precision* and *recall* defined as follows:

$$\begin{aligned} Precision &= \text{recommended relevant images} / \text{all recommended images} \\ Recall &= \text{recommended relevant images} / \text{total relevant images} \end{aligned}$$

The quality of recommendations is known to vary by the size of the neighbor set, the number of TTL. The metrics for each individual peer were computed and the average value for use as the metric was calculated. We watch how performance of the system changes for every simulation day.

For analysis of experiment results, two statistical tests are conducted. One is the  $t$  test for comparison of the average performance of our system with the centralized system. The other is the two-way ANOVA test with repetition for assessment of the effects of two factors, size of the neighbor set and  $n$ , on  $t$ tl.

## 6. CONCLUSION

We propose a recommender system based on a distributed P2P architecture that has originated with

user-oriented principle rather than business itself. This could extend research area of the recommender systems to distributed architecture.

We develop an adequate solution for image recommendations in distributed P2P architecture, combines two techniques: collaborative filtering and content-based image retrieval. The system supports peers of the P2P system in finding a desired image by generating personalized recommendations of images. We implemented fully functioning personal recommender agent that automatically selects neighbors and recommends contents by learning user preference from user's content usage without requiring user's explicit ratings. We believe that the suggested P2P based recommender system should provide the users with more qualified recommendations, while it reduces the effort and time of users.

The proposed system has flexible algorithm to share any contents to can be analyzed. Therefore our future work includes varying contents, such as music and text, and implementing other techniques besides CBIR for image.

## ABSTRACT

A number of researches have been focused on improving the productivity of knowledge workers. Effective communication is determinative, and one important problem has been to find the right person for collaboration. The Semantic Web efforts improve it by better wide-range knowledge management. Through extending the FoaF (Friend of a Friend) vocabulary, knowledge workers can share their machine-readable knowledge world widely, so that their PCs can facilitate effective collaboration efficiently. This paper presents an approach to support networked personal knowledge management. An example of extended FoaF is also described

**Keywords:** FoaF, Social Network, Peer 2 Peer, Knowledge Management

## 1. INTRODUCTION

Efforts in improving the productivity of knowledge workers are on the cutting edge of technology development. Recent research has proved that social network is important for the successful generation, acquisition, diffusion, and exploitation of knowledge, which is the keys to strong performance in the Knowledge Based Economy (KBE). Various efforts were devoted to discover and release the “strength of weak ties”[1]. By adding metadata management capacity, Peer 2 Peer networks are in the early stage in evolving its application from ‘file sharing’ to ‘collaboration infrastructure’[2]. In the mean time, FoaF is being widely used to connect people over the Internet. However, by only sharing the name, address etc. is inadequate for effective and efficient collaboration among peers. Furthermore, all these initiatives are facing challenge due to the emergence of Semantic Web (i.e. the next generation web) [3]. Therefore, it is necessary to investigate how semantic technology can facilitate Peer 2 Peer application and personal knowledge management, and improve the productivity of knowledge workers consequently.

This paper presents an application architecture with the purpose of manage personal knowledge management in social network environment. It manages the knowledge generated by user, structures collaboration-relevant information with an extended FoaF vocabulary, and publishes them into shared space. In addition, agents are used to make some processes automatic.

The structure of the paper is as follows. In section 2, theory foundation such as social network, knowledge workers, and FoaF are introduced and discussed. Afterward, a FoaF-based approach for networked personal knowledge management is presented in section

3. Finally section 4 concludes the paper by discussing the applicability of this approach and potential further research.

## 2. SOCIAL NETWORKING AND FOAF

This section focuses on the human side of knowledge application and innovation management. At first, the importance of social network is briefly introduced and how FoaF can support collaboration is discussed at last.

### 2.1 Social Networks

There have already been several organization structures so far (see Fig 1). Despite that functional organization is still the basic structure of enterprise, a number of organization structures, such as market-oriented, team-based, cop-based, appeared as a result of seeking comparative and competitive advantage.

**Fig. 1.** Structures of organization (source: COP Consortium 2000)

Even in a traditional function-oriented organization (e.g. a corporation), there are various informal organizational channels, which is important for the internalization of organizational knowledge and externalization of individual knowledge. Fig 2 illustrates the difference between formal and informal organizational structure.

<sup>1</sup> Sponsored by China 863 Program No : 2001AA415340 and China National Natural Science Fund No : 60474060

Suppose that Paine is an expert in one production equipment, and Bell is going to do some work with that, which is totally new to him. In formal organizational structure, Bell can not contact directly with Paine due to organizational barrier. The problem must be reported one level after another, and responded in the same route. The easier way is to appeal to the social network: Bell can contact Cole through Hussain, and ask who is the expert of that subject, and hopefully Cole will find Paine and return the relevant knowledge or arrange a meeting. Thus, a social network can impact the effectiveness and efficiency of communication [4].

A number of online applications focusing specific topic (such as disabled people employment, children nursing) have attracted some eyeballs. However the real power of social network is to help members to share knowledge instead of 'reinvent the wheels', yet none of the applications support intelligent web pages (i.e. containing knowledge of expert). The reasons lay in two aspects. On the one hand, the technology of the Internet is limited, machine can not help his user to find the knowledge, since they do not understand the static and plain content of web pages, which contains rich information. On the other hand, few of them support advanced knowledge management (e.g. data mining), and the structured information is very limited. So nothing happens after registered online. Fig 3 illustrates a personal profile in a typical online Community Of Practice (COP), indicating his basic information and other members (registered in this centralized service)

Knowledge workers need more effective and efficient collaboration. In order to support automatic information manipulation by machine, the information must be coded before machine can read and understand (in the way human do). In addition, the information needs to be organized with certain structure and linkage so as to be easily discovered. That is, the connections between information make more sense [6].

The Internet nowadays has changed the way we communicate. Moreover, the recent development of Semantic Web leads to more possibility and capability for machines to understand the encoded knowledge. Moreover, it is a better way of keeping track of the scattered fragments of data currently represented in the Web.

Traditionally, yellow pages are used to help locate people. They are centralized services, and are easy to use when provided with index. However, they are very difficult to maintain since all the information must be centralized. FoaF codes the machine-readable personal information in distributed way, and its vocabulary consists of ‘name’, ‘email’, etc. so computer can find these information easily through the Internet, without any interference of user.

1240

In other words, there are no further information about the friend's value, goal, current plan etc. Furthermore, the exiting class and property in FoaF vocabulary can not carry the information for collaboration. An important feature of FoaF is that its vocabulary (classes and properties) can be extended according to requirement. For example, some researchers in DERI ([www.deri.org](http://www.deri.org)) are extending the FoaF vocabulary for a semantic web portal [9], and there is also an effort in defining often changing variables in FoaF [10]. However, little attention has been conducted on FoaF extension for improving the productivity of knowledge workers. Therefore this study proposes a corresponding approach, and an example of FoaF extension is presented in section 3.

### 3. APPLICATION FRAMEWORK BASED ON EXTENDED FOAF

Based on previous analysis, it is possible to extend FoaF vocabulary and build an application in pursuit of the productivity of knowledge worker community. In this section, the application background and methodological framework are introduced, and some design specifications for personal information management in a community context is also presented.

#### 3.1 Application Background

There are lots of applications dedicated to managing personal knowledge, and most of them are document based. The Internet/intranet is also a carrier of knowledge, which became more and more popular due to its convenience. As for the system, it is generally accepted that lifecycle support feature can largely affect the effectiveness. Fig. 4 illustrates one paradigm for individual knowledge management.

Fig. 4. Personal knowledge management matrix

Each goal, action, and their relationship are measured by qualitative indicators (see the following step 4). Thus, Goals, Actions, and their relations form a 'matrix', which is an excellent channel to monitor in order to achieve individual efficiency and effectiveness. Furthermore, sharing the general description of goals and actions will facilitate knowledge reuse, improve collaboration consequently. There are four steps in utilization of this matrix:

*Step 1. Define personal Goals:* Identify and populate the most important Goals. Goals are defined as the objectives of effort. They are also known as strategies or visions (e.g. ).

*Step 2. Define personal Actions:* Identify and populate the most important Actions. Actions are defined as expenditure of effort and are also known as projects or tasks (e.g. ).

*Step 3. Link Goals with Actions:* Indicate the strength of the relationship between each action and goal. An empty box indicates no relationship; a half full box indicates a partial relationship; and a full box indicates a strong relationship (i.e. completing the action will have a high impact on attaining that particular goal).

*Step 4. Indicate the status of Goals and Actions:* Continuously monitor and report the status of goals and actions. In this case, red indicate that urgent attention is required, yellow indicates that more work is needed and green indicates that the goal or action requires no immediate attention.

After finish all the steps, we will get a picture as Fig 5 illustrates.

Actions [New]	Goals [New]			Help
	Goal1	Goal3	Goal2	Results
Action1				
Action2				
Action4				
Action3				
Results				

Fig. 5. Example of personal knowledge management modules

It should be noted that this methodology is based on the concepts which any knowledge workers are sharing. However, in order to be proficient in it, one must practise projecting his ideas into the matrix items. Moreover, if any action does not have relationship with any goal, or if any goal does not have relationship with any action, their necessity needs to be reconsidered. Thus an iterative process is necessary for accuracy.

#### 3.2 Information Exchange Framework

A personal knowledge management paradigm, described in section 3.1, is established by three major objects. However, not every piece of information from them is good for sharing. In fact, information about the 'result' is designed for individual feedback control. Therefore it is necessary to make a distinction between the two kinds of information. In addition, the data format will be likely different since the consumer of them are inhomogeneous. Furthermore, the data will accumulate with time going on, and publish publicly the past data will not make any sense. Fig 6 illustrate a model for information exchange.

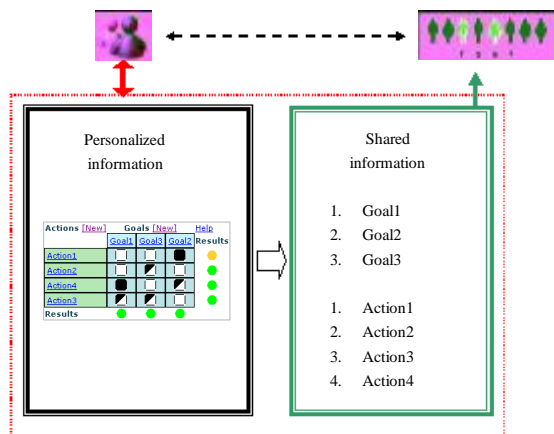

Fig. 6. Information for personal knowledge management and exchange model

From Fig 6, we can see, information is divided into two categories: Personalized information and Shared information:

-*Personalized information*: operated with traditional user interface; can be located in a PC or a repository on a server; and contains all the data, including past data.

-*Shared information*: stored in a web server which is accessible to the public; in standard format (in this case, it is an extended Foaf); and only contains the current published data.

Knowledge workers will change their personalized information occasionally, while shared information, as a subset of Personalized information, will impel collaboration among knowledge workers. In this way, one can find a friend with interesting goal or similar action through extended Foaf. At the mean time, everyone can update their personal information easily with their traditional tools (e.g. Planplus from frankincovey). Fig 7 illustrates this scenario.

Fig. 7. An framework of networked personal knowledge management system

In this design, data are structured with extended Foaf vocabulary. Thus we can share straightly information based on Foaf files, distributed across web servers. However, the data are stored in plain text with human language, which cannot be directly understood by machines. In order to make machine manage more tasks for users, agents are necessary for interaction on behalf of 'friends'(see Fig7). Therefore, the basic roles of agent

should consist of: (1)Publishing- provide information to user's Foaf file; (2)Searching- search in the Foaf files across the web; (3)Reasoning- analysis the language to discover the relationship between different pieces of data; (4)Contact- send and receive message to and from other people.

### 3.3 Extension of Foaf

The individual information about 'goal'and 'action'is similar to 'interest'and 'plan', which are two developing concept included in Foaf vocabulary. However, the purpose of them are not the same, 'interest'and 'plan' are more about personal life, which could be 'water surfing', 'go to Valencia for vacation'etc. In other words, they are not mission critical, and it is necessary to extend Foaf vocabulary to facilitate collaboration by sharing individual goals and actions(see Fig 8).

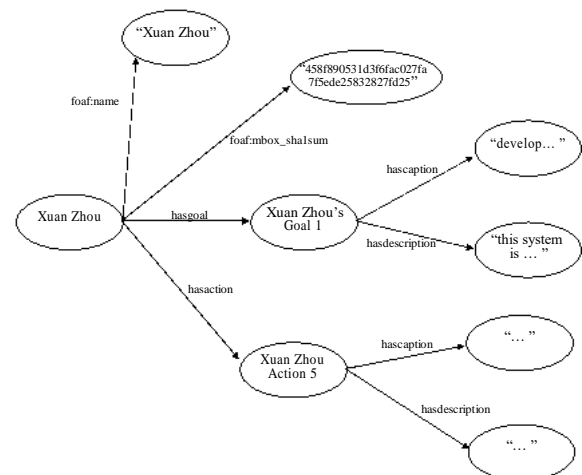

Fig. 8. RDF description of Foaf extension

There are two classes created, i.e. goal and action (in Fig8, they are two instance). They are linked to the person with two properties: 'hasgoal'and 'hasaction'. And each goal has two properties: 'hascaption'and 'hasdescription'. The content of goal or action are strings stored in these two properties. Table1 is an example of vocabulary extension in Foaf.

With extended vocabulary, we can now build the machine-readable Foaf file for collaboration. Table 2 is an example of the content of an extended Foaf file.

In this incomplete example, there are one instance of goal and one instance of action. The content of them are stored in two properties respectively (the description is omitted for concision). This is a first step for knowledge worker to collaborate over Internet. However, more artificial intelligence can be added to the initiative by define the connection between goals, actions. For example, friend1:goal3 is associated with friend8:aciton2. In addition, it is also reasonable to define several relationships for the connection.

**Table 1.** FoafF vocabulary extension

<b>Class: foaf:Goal</b> <i>Goal</i> –An objective of this person. The <b>foaf:Goal</b> class represents an objective of a <a href="#">foaf:Agent</a> .
<b>Class: foaf:Action</b> <i>Action</i> –An objective of this person. The <b>foaf:Action</b> class represents an action of a <a href="#">foaf:Agent</a> .
<b>Property: foaf:hasgoal</b> <i>define</i> –something which is defined by this person. <b>Status:</b> Testing <b>Domain:</b> <a href="#">foaf:Person</a> <b>Range:</b> foaf:goal The <b>foaf:hasgoal</b> property represents an objective of a <a href="#">foaf:Agent</a> .

---

#### 4. CONCLUSION

The productivity of knowledge workers are impacted by both technology and social aspects. The approach presented in this paper extended the FoafF vocabulary to support personal knowledge management in a networked environment. Knowledge workers will benefit from a dedicated front-end application for managing their personalized knowledge and an open interface (extended FoafF) for managing their shared knowledge.

It should be noted that this framework is mainly a conceptual and logic design, and can be easily used to setup a centralized service(e.g. within a corporation) or improve it. However, to implement it in totally distributed way(e.g. internet) is another pair of shoes, because several underground technologies are still in their developing phase. In addition, trust relationships between knowledge workers are another practical issue needs further discussion.

Notwithstanding its limitation, this study does suggest a framework, which provides a channel for knowledge workers to collaborate more productively over the Internet. It can improve the productivity of researchers in public section (e.g. universities) immediately after implemented and further research and development will make it more practical and effective.

#### ACKNOWLEDGEMENT

The authors would like to thank Knud Möller and Dieter Wolf for some important discussions about the issues addressed in this paper. The research was supported by a fellowship from Science Foundation Ireland.

## ABSTRACT

In this paper, we address the load balancing problem in the context of peer-to-peer computing environments. The key challenge to employ peer-to-peer networks for distributed computing is to exploit the heterogeneous processing capability of the participating hosts as well as the diverse network conditions. The contribution of our work is twofold. First, we model the load balance problem as an optimization problem with the objective of minimizing the system response time. This modeling considers not only the current loading of hosts, but also the fluctuation of network delay, which completely captures the characteristics of the P2P systems. Second, we propose a gradient projection algorithm to solve the optimization problem, which is fully distributed and easy for implementation. Simulation results demonstrate that our scheme has satisfied performance in terms of convergence, response time and load distribution.

**Keywords:** peer-to-peer computing, load balancing, constrained optimization, gradient projection

## 1. INTRODUCTON

The Peer-to-Peer (P2P) systems are composed of a set of end hosts that work collaboratively for some common tasks, such as file sharing, on-demand streaming, collaborative computing etc.. They differ from the traditional distributed systems from several aspects. First, the participating hosts in the P2P systems are often distributed across the Internet and higher end-to-end delay is expected between logically closet neighbor nodes. Second, most of these nodes are normal PCs and have diverse processing speed, storage capacity and access bandwidth. These features make it challenging task to design the load balancing scheme to coordinate the distribution of items to be stored, data to be downloaded, or computations to be carried out to the participating hosts so that the heterogeneity of the hosts can be fully exploited.

Addressing this problem, several solutions have been proposed in literature [1]-[4]. These schemes are focused on the load balancing for structured P2P systems. Structured P2P systems employ a class of distributed hash tables (DHT) for item storage and retrieval. The main limitation of this kind of systems is that the distributed hash tables may not produce load balance as good as standard hash function, so there is a  $\Theta(\log(N))$  imbalance factor in the number of items stored at a node [2]. In [2], Rao et. al. assume that the system is static, i.e., the membership and data items are stable over a timescale that the load balancing algorithm can be performed. They employ the concept of virtual server that represents a peer in DHT. Each physical node can host one or more virtual servers so that the storage and retrieval of data items are conducted at the virtual server level instead of the physical node

level. The key to achieve load balance is then to move virtual servers from overloaded physical nodes to lightly loaded physical nodes. This concept is extended to the dynamic P2P systems by Godfrey et. al. in [4], where data items can be continuously inserted and deleted, and nodes may change their states frequently. They propose to maintain the loading information of the peer nodes on a set of directory servers. These directory servers periodically schedule the reassignment of the virtual servers among the physical nodes that they are serving. However, these solutions do not consider the cost to move the virtual servers between the hosts. In [5], Zhu and Hu proposed a proximity-aware load balancing scheme to address this issue. The basic idea is to utilize the proximity information of the physical nodes, so that the virtual servers are only reassigned and transferred between physically close heavy nodes and light nodes so that the cost of performing reassignments is reduced.

The drawback of the virtual server based load balancing schemes is that running multiple virtual nodes may increase the bandwidth consumption in maintaining the network connectivity across neighbor nodes in the peer-to-peer network. In [6], Karger et. al. address this problem by arranging for each node to activate only one of its virtual nodes at any given time. Specifically, the node checks its inactive virtual nodes periodically. If it finds that the load distribution has changed, it may migrate to one of these virtual nodes. In this way, previous load is shifted to other nodes, and it will take responsibility for loading of the newly migrated virtual nodes.

All of the aforementioned schemes are based on the structured P2P systems where the load distribution is tightly controlled by the distribution hash functions. Although the virtual server concept is elegant and easy

to implement, the achieved load balancing is ad-hoc in that it relies on the reassignment or migration of data items after they have been assigned. The fineness depends on the space allocated for each virtual server. The tradeoff, however, is not easy to justify. Furthermore, the scheme adopted in [4] essentially resorts to the centralized solution, which makes the directory servers vulnerable to single-point-failure.

In this paper, we consider the load balancing problem in the context of unstructured P2P systems. Example of this kind of systems includes Gnutella, KaZaA, etc. A salient feature of these unstructured P2P systems is that the host can fully control where its data items can be placed, and the amount of the data items that should be assigned to these hosts. This feature is desirable for load balancing purpose since it allows for a fine-grained allocation of load across all participating hosts according to their loading. However, the results is not only limited to unstructured P2P system, it is also applicable for structured p2p system. For example, it can be used to find a finegrained reassignment of virtual servers for this kind of p2p systems.

The contribution of our work is twofold. First, we model the load balance problem as the minimum cost problem. This modeling considers not only the current loading state of the participating hosts, but also the fluctuation of network delay, which completely captures the characteristics of the P2P systems when they are employed for massive computing purpose. Second, we propose a gradient projection algorithm to solve the optimization problem, which is fully distributed and easy for implementation.

In the rest of this paper, we first present the system model and problem formulation in Section 2 and discuss the necessary conditions for the optimization problem. In Section 3, we then propose an algorithm based on the classic gradient projection methods. By identifying the difficulties to implement the algorithm in practice, we propose an approximation solution which is suited for practical implementation. We also discuss the inherit reasonability of our model for the p2p computing environments. Simulation results are presented in Section 4 and finally we conclude this paper in Section 5 and suggest some possible directions for future research.

## 2. SYSTEM MODEL AND PROBLEM FORMULATION

### 2.1 Problem Statement

We are given a peer-to-peer system and a set of  $N$  hosts. Each host  $i \in N$  can choose a set of  $S_i$  hosts from these  $N$  hosts as its servers to carry out the computation for its raw data. These servers can be chosen randomly as in the unstructured peer-to-peer networks, or can be determined according to the distributed hash function as that of the structured peer-to-peer networks.

For each host  $i$ , we are given a scalar  $r_i$  referred to as the generating rate of the raw data of host

$i$  to be computed. In the context of the peer-to-peer computing,  $r_i$  (measured in units/second) could be the data rate exporting from host  $i$  to its servers for computation for the final results. The objective of our problem is to divide  $r_i$  of host  $i$  among the set of  $S_i$  servers in a way that the resulting loading distribution across the overall peer-to-peer system minimizes a suitable cost function.

We denote  $x_{ik}$  as the data rate that is assigned by host  $i$  to its server  $k \in S_i$ . The collection of assignment  $x_{ik}$  must satisfy the following constraints

$$\sum_{k \in S_i} x_{ik} = r_i, \quad \forall i \in N \quad (1)$$

$$x_{ik} \geq 0, \quad \forall k \in S_i, i \in N \quad (2)$$

For peer-to-peer computing, the primary design objective is to minimize the response time for the tasks, which is the duration from the time that a host assigns the raw data to the server to the time that the final result is computed and retrieved. In peer-to-peer systems, the participating hosts have highly diverse processing speeds and are widely distributed across the Internet. As a result, the response time is composed two components, one is host dependent processing delay and the other is network dependent end-to-end delay.

For host-dependent delay, we adopt the response time model from [7] by treating the computing process as an M/M/1 system. Specifically, suppose a host  $k$  is chosen by a set of  $A_k$  hosts as their servers. Then the aggregated data rate to be carried by this host is

$$J_k = \sum_{i \in A_k} x_{ik} \quad (3)$$

Suppose the host  $k$  has a processing speed  $\sigma_k$ , then the cost function of the processing delay for each host  $i$  to get the computation result from this host can be obtained following M/M/1 queuing model as follows

$$D_{ik}^h(x_{ik}) = \frac{J_k}{\sigma_k - J_k} \quad (4)$$

For network delay, it consists of the time for delivering the raw data from the host to the server plus the time for retrieving the results from the server. Without losing generality, we can assume the volume of the raw data is very larger than that of the results, so the delay of getting the results can be ignored and we only consider the former one. Assume the path  $P_{ik}$  between a node  $i$  and node  $k$  consists of a set of links of  $l_0, l_1, \dots$ . Then the cost function between  $i$  and  $k$  can be represented by a superposition of delays of all links along the path by modeling each link as M/M/1 queue as follows

$$D_{ik}^n(x_{ik}) = \sum_{l \in P_{ik}} \left[ \frac{Y_l}{C_l - Y_l} + d_l Y_l \right] \quad (5)$$

where  $Y_l$  is the aggregated traffic over link  $l$  including  $x_{ik}$ ,  $C_l$  and  $d_l$  are the link capacity and propagation delay of link  $l$  respectively.

Summing up, the overall cost function for response time between host  $i$  and  $k$  is

$$D_{ik} = D_{ik}^h + D_{ik}^n \quad (6)$$

Consider the overall cost function of the form

$$\sum_{i \in N} \sum_{k \in S_i} D_{ik}(x_{ik}) \quad (7)$$

The problem is to find a set of job assignments  $\{x_{ik}\}$  that minimize the cost function (6) subject to the constraints of equations (1)-(3). More formally, the load balancing problem can be stated as follows

$$\begin{aligned} & \text{minimize } D(x) \\ & \text{subject to } \sum_{k \in S_i} x_{ik} = r_i, \quad \forall i \in N \\ & \quad x_{ik} \geq 0, \quad \forall k \in S_i, i \in N \end{aligned} \quad (8)$$

where

$$\begin{aligned} D(x) &= \sum_{i \in N} \sum_{k \in S_i} D_{ik}(x_{ik}) \\ &= \sum_{i \in N} \sum_{k \in S_i} (D_{ik}^h(x_{ik}) + D_{ik}^n(x_{ik})) \end{aligned} \quad (9)$$

## 2.2 Necessary Conditions for Optimality

We first calculate the partial derivative of the objective cost function (9) with respect to  $x_{ik}$ , which is

$$\frac{\partial D}{\partial x_{ik}}(x) = D_{ik}^h + D_{ik}^n \quad (10)$$

where  $D_{ik}^h$  and  $D_{ik}^n$  are the derivatives of  $D_{ik}^h(x)$  and  $D_{ik}^n(x)$  respectively. Equation (10) can be interpreted as the overall response time between host  $i$  and server  $k$  if the server's processing delay is taken to be the first derivative  $D_{ik}^h$  and the network delay to be the first derivative  $D_{ik}^n$ .

According to the Kuhn-Tucker theorem(see also [9]), at optimality, a host only assigns its jobs over servers that have the minimum response time given by (10). More specifically, let  $x^* = \{x_{ik}^*\}$  be an optimal assignment vector. Then if  $x_{ik}^* > 0$  for some  $k \in S_i$ , we have[9]

$$\frac{\partial D}{\partial x_{ik}}(x^*) \geq \frac{\partial D}{\partial x_{ik}}(x^*), \quad \forall k' \in S_i \quad (11)$$

That is, the optimal assignment is *positive* only on servers with the minimum first derivative response time.

## 3. LOAD BALANCING ALGORITHM AND DISTRIBUTED IMPLEMENTATION

### 3.1 Gradient Projection Methods

The standard technique to solve the equality constrained optimization problem (8) is the *gradient projection algorithm* [9]. The basic idea is to iteratively adjust the amount of assignment in opposite to the gradient of the objective function and projected to feasible space specified by the constraint functions. In general, the gradient projection algorithm takes the iterative form as follows

$$x^{t+1} = \left[ x^t - \alpha \nabla D(x^t) \right]^+, \quad t = 0, 1, \dots \quad (12)$$

where  $\alpha > 0$  is the step size at time  $t$ ,  $\nabla D(x^t)$  vector with the  $(i, k)$ th element to be the first derivative of  $D(x)$  with respect to  $x_{ik}$ , which is  $\frac{\partial D}{\partial x_{ik}}(x)$  as shown in (10) at time  $t$ , and for any vector  $z$ , the function  $[z]^+$  denotes the projection of  $z$  onto the feasible space.

The iterative algorithm in (11) can be expressed individually for each host-server pair as the following

$$x_i^{t+1} = \left[ x_i^t - \alpha \nabla D_i(x^t) \right]^+ \quad (13)$$

where  $x_i^t = \{x_{ik}^t, k \in S_i\}$  is the assignment vector of host  $i$  over all its servers at time  $t$ .

### 3.2 Practical Implementation

The projection algorithm in (13) can be carried out individually by each host according to the locally received cost function information, so it is well suited for distributed implementation. The most straightforward approach is for each host to broadcast the value of the current total aggregated loading  $J_k$  to all hosts that select it as the server. Each host then computes the host-dependent cost  $D_{ik}^h$  and its derivative. The difficult here, however, is that the network-dependent cost  $D_{ik}^n$  can only be implicitly obtained since in general it is not practical to ask intermediate network nodes for detailed traffic information.

Notice that the parameters involved in the projection algorithm are only the first derivative  $D_{ik}^h$  and  $D_{ik}^n$ , which, as we have discussed, can be interpreted as the response time during the host and the network respectively. For host-dependent response time, it is actually the time for waiting for the computation results, while for network-dependent response time, it is actually the end-to-end delay between the host and server. So we can actually directly measure these two

values and use them to approximate the first derivative of two cost functions.

Let  $d_k$  be the measured processing delay at host  $k$  and  $d_{ik}$  be the network delay between host  $i$  and  $k$ .

Here  $d_{ik}$  can be measured by host  $i$  itself, while  $d_k$  can be measured and fed back by host  $k$ . Host  $i$  receiving all these information from all its servers can determine the optimal assignment of its task among these servers using the iterative algorithm as follows

- 
- 
- (1)  $d_{i,\min} \leftarrow \min\{d_{ik} + d_k \mid k \in S_i\}$
  - (2)  $k_0 = \arg \min\{d_{ik} + d_k \mid k \in S_i\}$
  - (3) **foreach**  $k \in S_i$ , **do**
  - (4)    $\Delta_{ik} \leftarrow d_{ik} + d_k - d_{i,\min}$  ;
  - (5)   **if**  $k \neq k_0$ , **do**
  - (6)      $x_{ik} \leftarrow \max\{0, x_{ik} - \alpha \times \Delta_{ik}\}$  ;
  - (7)   **end**
  - (8) **end**
  - (9)  $x_{ik_0} \leftarrow \frac{r_i}{\sum_{k \in S_i, k \neq k_0} x_{ik}}$
- 
- 

In this algorithm,  $k_0$  is the index of the server with the minimum total response time  $d_{i,\min}$ . In step (4), the algorithm computes the difference of the response time between any server and this minimum one. In step (6), it decreases the assignment to each non-minimum server in proportion to this difference and projection to the feasible space. The max projection function guarantees that nonminimum with zero assignment originally always stays at zero. In step (9), it simply assigns the rest task to the server with the minimum response time. It is trivial to prove that the assignment to the minimum response time server is always increased, while the nonminimum servers are always reduced until to zero, eventually only these servers with minimum (and identical) response time have positive assignment as (11) indicates. This guarantees that the assignments approach to optimality eventually.

### 3.2 Discussion

Unlike traditional distributed computing system, the participating hosts in the peer-to-peer network may be distributed across wide area network, which make the network delay a non-negligible factor. At the same time, computers involved in the p2p computing are normally personal computers that have diverse processing speeds. The processing delay is the major concern for the p2p

computing. Our model incorporates both factors into the same framework. Therefore the load balance problem exhibits distinct features from the traditional distributed computing as well as other delay-insensitive p2p systems. Depending on the relation of the network delay and processing delay, we can envision the following two scenarios;

- If the processing delay is the dominate part of the overall response time, i.e., process delay is far more longer than network delay, our model is close to the traditional load balance problem where the objective is to assign the jobs across the servers according to their processing capability.
- If the network delay is the dominate part of the overall response time, our model is close to the optimal routing problem. The objective here becomes to assign the tasks across the servers to avoid overloading the network connections with longer delay.

Clearly, under this framework, in contrast to the conventional wisdom that a host should choose these physically closet nodes as the servers, which may led to task concentration over these nodes and a higher processing delay is expected. Instead, a tradeoff should be achieved to between the processing delay and network delay, which makes the selection of the server a rather challenging problem.

## 4. PERFORMANCE EVALUATION

In this section, we evaluate the distributed load balancing scheme proposed in this paper using simulations based on a randomly generated network. The objective is to investigate the convergence of the distributed implementation, the effects of the number of servers for each host on the performance of the scheme, and the behavior of the scheme under different composition of the network delay and processing delay. The network used in the simulations has 100 nodes, among of them, 10 nodes are randomly selected as the hosts which generate the raw data at a rate of 10k bits per seconds. The rest nodes serve as the servers for these hosts. The number of servers for all hosts is the same and the map of host and server is randomly determined.

Fig. 1 illustrates the convergence of the mean response time of these 10 hosts within a 200-seconds run of simulation. In this simulation, each host randomly selects 5 servers and distributes its task evenly across its servers at the beginning, which are far from optimal as shown in the figure: all of them incur higher response time which is the mean value of the response time to all the servers of each host. The response time of all hosts drops quickly within the first 20 seconds of the simulation and converges to the stable value after the simulation is run for about 30 seconds. The result suggests that proposed algorithm can reduce the tasks from the overloaded servers or servers with congested network connections and distribute them to the under-utilized servers or these that have good network conditions.

Fig. 2 compares the mean response time of all hosts under different number of servers for each host. We consider five cases where the number of servers of each hosts varies from 2 to 10. As this figure shows, the hosts incur a very higher response time when they have only two servers for each. This is reasonable because in this case a host has little freedom to adjust the assignment of the task if both of its two servers are overloaded or under severe network conditions. The response time is significantly reduced as the number of the servers of each host is increased to four as well as from four to six. However, the improvement of the response time is slowed down as the number of servers is further increased, and the convergence of the response time has a subtle increment when the number of servers is increases. This simulation suggests that the server number should be chosen at a reasonable value so to achieve the tradeoff between the response time and the convergence time.

Fig. 1 Convergence of response time vs simulation time

Fig. 2 Response time under different number of servers

As discussed in the previous section, our model tries to capture two factors that affect the performance of p2p computing environments. The proposed scheme may exhibit different properties depending on the composition of the overall response time. In this simulation, we will verify this characteristic using two set of settings. We use the same network topology as above simulations so that the average network delay is

simulations so that the average network delay is roughly fixed. We then adjust the processing speeds of the nodes so that in the first case, the ratio of the processing delay to the network delay is about 5:1, while in the second setting, this ratio is about 1:5. In Fig. 3 and Fig. 4, we illustrate the throughput (the message processed in bits per seconds) of the host under these two settings respectively. Each figure shows the max, min and mean throughput of all nodes. As shown in Fig.3, since in this case the processing delay is very larger comparing to network delay, the algorithm behaviors like the normal load balancing scheme that can distribute tasks as evenly as possible overall servers. So the max, min and mean value are very closer. While as shown in Fig. 4, here the network delay is comparable to processing delay, so the algorithm considers not only the server load but also the network delay, so the server throughput is not distributed evenly, however, the overall response time still approaches to the optimality not shown here.

Fig. 3 Throughput under first setting

Fig. 4 Throughput under second setting

## 5. CONCLUSION AND FUTURE WORK

In this paper, we have presented the modeling and solution for the loading balancing problem for a p2p computing system. In this system, the primary challenge is to allocate the tasks overall all participating nodes so that the overall response time is minimized. We model

this as a constrained optimization problem. The model captures the distinct features of p2p computing, that is, the cost involved in the computation includes not only the processing delay, but also the network delay. Leveraging some well studied analysis techniques, we can solve the constrained optimization problem using the gradient projection algorithm, which is well suitable for distributed implementation. Using extensive simulation experiments, we evaluate the proposed scheme in terms of convergence, response time as well as the tradeoff the processing delay and network delay. Experimental results demonstrate our scheme has satisfied performance.

In this study, we have only considered the static situation where the nodes are stable in the network, and a host never changes its servers once selected. It is interesting to investigate the case where the node can join or leave the p2p networks dynamically. A leaving node may broke the ongoing computing, this lead to another problem that a host may have to change its servers for better performance or for failure of the existing servers. It is interesting to investigate the stability of the proposed scheme in this dynamic environment, which will be the focus of the further work.

Graduate School of the Chinese Academy of Sciences (GSCAS), Beijing 100080, China  
Jianfang02@ios.cn

### ABSTRACT

This article provides a survey of Security in Grid Services coming from a study of many papers most of which were done by the Grid Forum OGSA-SEC (Open Grid Service Architecture Security) working group, GSI (Grid Security Infrastructure) working group, and Globus Alliance team and other people who contributed to Grid. It describes the best practice in terms of Grid Security Challenges, Grid Security Requirements, and the GT3 (Globus Toolkit version 3) Security Model for OGSA. Most of these were further refined in separate documents.

**Keywords:** Grid, Security, GSI, Globus

### 1. INTRODUCTION

The term "Grid" denotes a proposed distributed computing infrastructure for advanced science and engineering [1, 2]. The Grid Security Infrastructure (GSI) was subsequently developed, based on existing standards, to address the unique security requirements that arise in Grid environments, as described in [3, 4, 5].

Research and development efforts within the Grid community have produced protocols, services, and tools that address the challenges arising when we seek to build scalable *virtual organizations* (VOs). Here a virtual organization is defined as a set of individuals or institutions sharing resources and services under a set of rules and policies governing the extent and conditions for that sharing [6].

Controlling access to services through robust security protocols and security policy is paramount to controlling access to VO resources and assets. Thus, authentication mechanisms are required so that the identity of individuals and services can be established, and service providers must implement authorization mechanisms to enforce policy over how each service can be used. The requirement for composition complicates issues of policy enforcement, as one must be able to apply and enforce policy at all levels of composition and to translate policies between levels of composition [6].

Grid computing research has produced security technologies based not on direct interorganizational trust relationship but rather on the use of the VO as a bridge among the entities participating in a particular community or function. The results of this research have been incorporated into a widely used software system called the Globus Toolkit (GT)[3] that uses public key technologies to address issue of single sign-on, delegation [7], and identity mapping, while supporting standardized APIs such as GSS-API [8].

The recent definition of the Open Grid Services Infrastructure specification and other elements of the Open Grid Services Architecture (OGSA) [9] within the Global Grid Forum introduce new challenges and opportunities for Grid security.

Integration of GSI with OGSA enables the use of Web services techniques to express and publish policy [10], allowing applications to determine automatically what security policies and mechanisms are required of them. Implementing security in the form of OGSA services allows those services to be used as needed by applications to meet these requirements [11].

The remainder of this document is structured as follows. First, the following sections present a review of security challenges encountered in grid environments. Then discuss the security requirements. At last the document survey an OGSA security model and the GT security model.

### 2. SECURITY CHALLENGES IN A GRID ENVIRONMENT [6]

The security challenges faced in a Grid environment can be grouped into three categories. A solution within a given category will often depend on a solution in another category.

#### 2.1 The Integration Challenge

It is unreasonable to expect that a single security technology can be defined that will both address all Grid security challenges and be adopted in every hosting environment. Thus, to be successful, a Grid security architecture needs to step up to the challenge of integrating with existing security architectures and models across platforms and hosting environments. This means that the architecture must be *implementation agnostic*, so that it can be instantiated in terms of any existing security mechanisms (e.g., Kerberos, PKI); *extensible*, so that it can incorporate new security

services as they become available; and *integratable* with existing security services.

## 2.2 The Interoperability Challenge

Services that traverse multiple domains and hosting environments need to be able to interact with each other, thus introducing the need for interoperability at multiple levels: At the *protocol level*, we require mechanisms that allow domains to exchange messages. This can be achieved via SOAP/HTTP, for example; At the *policy level*, secure interoperability requires that each party be able to specify any policy it may wish in order to engage in a secure conversation—and that policies expressed by different parties can be made mutually comprehensible; At the *identity level*, we require mechanisms for identifying a user from one domain in another domain. This requirement goes beyond the need to define trust relationships and achieve federation between security mechanisms (e.g., from Kerberos tickets to X.509 certificates).

## 2.3 The Trust Relationship Challenge

Grid service requests can span multiple security domains. Trust relationships among these domains play an important role in the outcome of such end-to-end traversals. A service needs to make its access requirements available to interested client entities, so that they understand how to securely request access to it. Trust establishment may be a one-time activity per session or it may be evaluated dynamically on every request. The dynamic nature of the Grid in some cases can make it impossible to establish trust relationships among sites prior to application execution [4]. Given that the participating domains may have different security infrastructures (e.g., Kerberos, PKI) it is necessary to realize the required trust relationships through some form of federation among the security mechanisms.

The trust relationship problem is made more difficult in a Grid environment by the need to support the dynamic, user-controlled deployment and management of *transient services* [1]. End users create such transient services to perform request-specific tasks, which may involve the execution of user code.

More details about Security Challenges in a Grid Environment occurred in Ref. [6].

## 3. GRID SECURITY REQUIREMENTS [5, 6]

That the goal and purpose of Grid technologies is to support the sharing and coordinated use of diverse resources in dynamic, distributed VOs: in other words, to enable the creation, from distributed components, of virtual computing systems that are sufficiently integrated to deliver desired qualities of service. Security is one of the characteristics of an

OGSA-compliant component. The basic requirements of an OGSA security model are that security mechanisms be *pluggable* and *discoverable* by a service requestor from a service description. This functionality then allows a service provider to choose from multiple distributed security architectures supported by multiple different vendors and to plug its preferred one(s) into the infrastructure supporting its Grid services.

OGSA security must be seamless from edge of network to application and data servers, and allow the federation of security mechanisms not only at intermediaries, but also on the platforms that host the services being accessed.

A Grid security solution should be based on existing standards wherever possible. Security is an extremely complex problem, with specific solutions incrementally developed over many years by many extremely talented people. Further, the community generally only trusts a particular security solution if it has stood the tests of time and repeated scrutiny.

However, Grid environments have a broad range of security requirements [3, 4]. Unfortunately, no single, existing, standard security solution addresses all of these requirements, though ideally a Grid security solution would extend existing standards.

Grid authentication requirements include: Single sign on, Delegation, Integration with various local security solutions, User-based trust relationships.

Grid requirements for communication protection include: Flexible message protection, Supports various reliable communication protocols, Supports independent data units (IDU).

Grid authorization requirements include: Authorization by stakeholders, restricted delegation.

Specification about the Security Requirements can be seen in Ref. [5, 6].

## 4. GT2 GRID SECURITY MODEL [11]

We first review briefly the security technologies incorporated in the Globus Toolkit version 2 (GT2) [12] before we survey the OGSA and GT3 security. GT2 includes some services that use a common Grid Security Infrastructure (GSI) [3,4] to provide security functionality.

*Diverse site security mechanisms.* GSI defines a common credential format based on X.509 identity certificates [13,14] and a common protocol based on transport layer security (TLS [15], SSL [16]).

*Dynamic creation of entities and the granting of privileges to those entities.* GSI introduces X.509 proxy

certificates [14] that allow a user to assign dynamically a new X.509 identity to an entity and then delegate some subset of their rights to that identity. Users create a proxy certificate by issuing a new X.509 certificate signed using their own credentials instead of involving a CA. This mechanism allows new credentials and identities to be created quickly without the involvement of a traditional administrator.

*Dynamic creation and management of overlaid trust domains.* The requirement for overlaid trust domains to establish VOs is satisfied by GSI using both proxy certificates and security services such as the Community Authorization Service (CAS) [17]. GSI has an implicit policy that any two entities bearing proxy certificates issued by the same user will inherently trust each other. This policy allows users to create trust domains dynamically by issuing proxy certificates to any services that they wish to collaborate.

In designing GSI we evaluated several related efforts before electing to build on PKI. We noted the following shortcoming in other approaches with respect to Grid security requirements [11]:

Kerberos [18] requires the explicit involvement of site administrators to establish interdomain trust relationships or to create new entities.

The CRISIS wide area security system [19] defines a uniform and scalable security infrastructure for wide area systems but does not address interoperability with local security mechanisms.

Secure Shell (SSH) [20] provides a strong system of authentication and message protection but has no support for translation between different mechanisms or for creation of dynamic entities.

The Legion security model [21] is perhaps the most similar to that of GT2, using X.509 certificates for delegation. However, it lacks mechanisms for creation of dynamic entities.

## 5. THE GT3 SECURITY MODEL FOR OGSA [11]

We now turn to the question of how Grid security challenges can be addressed within the context of the Open Grid Services Architecture (OGSA) [9], a set of technical specifications that align Grid technologies with emerging Web services technologies [16].

Web services technologies allow software components to be defined in terms of access methods, bindings of these methods to specific communication mechanisms, and mechanisms for discovering relevant services. While particular mechanisms and methods are not prescribed, some mechanisms are emerging as ubiquitous.

OGSA defines standard Web service interfaces and behaviors that add to Web services the concepts of stateful services and secure invocation. These interfaces and behaviors define what is called a “Grid service” and allow users to manage the Grid service’s life-cycle, as allowed by policy, and to create sophisticated distributed services. Grid services can define, as part of their interface, service data elements (SDEs) that other entities can (again, subject to policy) query or subscribe to.

OGSA introduces both new opportunities and new challenges for Grid security. Emerging Web services security specifications address the expression of Web service security policy (WS-Policy [10], XACML [22]), standard formats for security token exchange (WS-Security [23], SAML [24]), and standard methods for authentication and establishment of security contexts and trust relationships (WS-SecureConversation [25], WS-trust [26]). These specifications may be exploited to create standard, interoperable methods for these features in Grid security. But they may, in some case, also need to be extended to address the Grid security requirements listed above.

GT3 and its accompanying Grid Security Infrastructure (GSI3) provide the first implementation of OGSA mechanisms. GT3’s security model seeks to allow applications and users to operate on the Grid in as seamless and automated a manner as possible. Security mechanisms should not have to be instantiated in an application but instead should be supplied by the surrounding grid infrastructure, allowing the infrastructure to adapt on behalf of the application to meet the applications requirements. The application should need to deal with only application specific policy. GT3 uses the following powerful features of OGSA and Web services security to work toward this goal [11]:

- ①. Cast security functionality as OGSA services to allow them to be located and used as needed by applications.
- ②. Used sophisticated hosting environments to handle security for applications and allow security to adapt without having to change the application.
- ③. Publishes service security policy so that clients can discover dynamically what credentials and mechanisms are needed to establish trust with the service.
- ④. Specifies standards for the exchange of security tokens to allow for interoperability.

### 5.1 Security as Services

Secure operation in a Grid environment requires that applications and services be capable of supporting a variety of security functionality, such as authentication, authorization, credential conversion, auditing, and delegation. Grid applications need to interact with other applications and services that have a range of security mechanisms and requirements. These mechanisms and

requirements are likely to evolve over time as new mechanisms are developed or policies change. Grid applications must avoid embedding security mechanisms statically in order to adapt to changing requirements.

The OGSA security model casts security functions as OGSA services. This strategy allows well-defined protocols and interfaces to be defined for these services and permits an application to outsource security functionality by using a security services with a particular implementation to fit its current need.

## 5.2 Hosting Environment

It is not a trivial task to find and use security services such as those described in the preceding section: in fact, it can require considerable sophistication on the part of the application. Ideally, application developers should not be burdened with the details of this process.

Grid services, like the Web services they leverage, may be built on sophisticated container-based hosting environments such as J2EE or .NET. These hosting environments provide a high level of functionality and allow for much security implementation complexity to be pulled from applications. It is envisioned that most security functionality will be placed in hosting environments, simplifying application development and allowing security functionality to be upgraded independently of applications.

## 5.3 Publishing of Security Policy

In order to establish trusts, two entities need to be able to find a common set of security mechanisms that both understand. The use of hosting environments and security services, as described previously, enables OGSA applications and services to adapt dynamically and use different security mechanisms. However, an application can select the proper security mechanisms and credentials only if it knows what mechanisms and credentials are acceptable to the service with which it wishes to interact.

The WS-Policy [10] specification and its related specifications define how a Web service can publish its security policy along with its interface specification as part of a WASL document. Such a published policy can express requirements for mechanisms, acceptable trust roots, token formats, and other security parameter. An application wishing to interact with the service can examine this published policy and gather the needed credentials and functionality by contacting appropriate OGSA security services.

## 5.4 Specified format for Security Tokens

The WS-Security [23], WS-SecureConversation [25], and WS-Trust [26] specifications contain conventions

and formats for the communication of various mechanism specific tokens (e.g., Kerberos tickets and X.509 certificates) inside SOAP envelopes. This enveloping standardizes the protocol for security mechanisms and allows mechanisms to be independent of any application protocol. Hosting environments can recognize security-related messages and route them to an appropriate service for handling, and entities in the Network can recognize whether and how an interaction is secured.

## 5.5 GT3 Security Advantages

The Grid Security Infrastructure version 3 (GSI 3) of the Globus Toolkit version 3 is an initial implementation of key components of the OGSA security model described above. This implementation has two key advantages over its GT2 predecessor described in Section 4:

- ① Use of WS-Security protocols and standards. GT3 uses SOAP and the Web services security specifications for all of its communications. This allows it to leverage and use standard current and future Web service tools and software.
- ② Tight least-privilege model. In contrast to GT2, the GT3 resource management implementation uses no privileged services. All privileged code is contained in two small, tightly constrained setuid programs.

How these two advantages were implemented in GT3 and more details about Section 4, 5 were described in Ref. [11].

## 6. CONCLUSIONS

Besides the human factor (Users may become a threat to the security of the systems sometimes), Grid computing presents so many security challenges that building a secure Grid environment is a complex task. The use of security technologies (e.g. policy languages, authorization services, encryption mechanisms) alone does not make for a secure system. GT3 implements the emerging OGSA; its GSI implementation (GSI 3) takes advantage of this evolution to improve on the security model used in earlier versions of the toolkit [11]. Its development provides a basis for a variety of future work.

## A Study of Internet Book Sale

Gaojia Jin, Takasi Nemoto

Department of Business Administration, The Graduate School of Meiji University, Tokyo 101-8301, Japan  
{Gaojia Jin}cg44002@kisc.meiji.ac.jp

### ABSTRACT

This report has analyzed the business model of KINOKUNIA online book service, by comparing the service of KINOKUNIA online book shop with the other four big online book shop in Japan, some advantages and disadvantages of KINOKUNIA have been found. By analyzing and comparing the service between the services of different online book shop, a more competitive advantage e-business model with quicker response and lower cost was proposed.

**Keywords:** book sale, e-business model, competitive advantage, net-sale

### 1. INTRODUCTION

While the term e-commerce refers to all online transactions, B2C stands for "business-to-consumer" and applies to any business or organization that sells its products or services to consumers over the Internet for their own use. When most people think of B2C e-commerce, they think of Amazon.com, the online bookseller that launched its site in 1995 and quickly took on the nation's major retailers. However, in addition to online retailers, B2C has grown to include services such as online banking, travel services, online auctions, health information and real estate sites.

In recent years, with the rapid development of communication technology, the Internet shopping has been more and more popular within the consumer behaviors. The internet business has got a significant development in Japan from 1998. This new kind of selling has supplied multi-choices to the customers before they made their decisions of purchase.

### 2. THE SITUATION OF INTERNET BOOK SALE

#### 2.1 Background

Because of the widely use of internet in these years, there were significant changes happened on business environment, this new low cost, high efficiency communication method made the quick transfer of information of demand and supply be possible, and which formed a new business mode--- e-business. E-business can be described as "doing business by an electronic mode", much of the interest in e-business in the 1990s was driven by the belief that it would be the source of exciting new revenue opportunities both for existing businesses and for new start-up businesses. Both the business-to-consumer (B2C) and business-to-business(B2B) models proliferated as traditional companies and new e-commerce companies entered the online marketplace. The book sale by internet is a typical model of business-to-consumer. The revenue opportunities these models represent are almost endless. Nevertheless it is possible to understand them as falling into several broad categories driven by the nature of online commerce itself:

- ò Enhanced access to customers
- ò Enhanced sales to existing customers
- ò Electronically enabled products

From 1998, E-business has got a significant development in Japan, one of the pertinent causes is the increasing amount of internet users, until Feb. 2004, there were 62,844,000 internet users in Japan, and in the foreseeable future, this amount would increase to 67,000,000 in Dec. 2004, which would be the third large amount of internet users in the world. [6] (Fig 1)

Fig. 1, the number of internet users in Japan from 1997 to 2004 Source: Internet White Paper 2004 pp46 by author

With the widely use of internet, more and more people have accepted the new internet sale mode, in Jun. 2003, vagabond and eye bridge company has investigated 1000 internet users for internet shopping, more than 70% of them have used internet shopping services, and in all the things they bought on internet, most of them were low price things, books are the most regular bought things which was 13.3% in all.[13]

#### 2.2 Today's online book sale in Japan

The online book sale has begun from 1995 in Japan, at that time, one of the biggest book-shop---MARUZEN has built a database of 3.6 million books which were written not only in Japanese language but also in foreign languages including Chinese, English, and French etc,

the services of this online bookshop also included credit payment and home delivery. The MARUZEN online bookshop was the first big online book-shop in Japan. In the following several years, nearly all the biggest book shop in Japan have built their own online website, including KINOKUNIYA, SANSEIDO, BUNKYODO.

Because of the high profit of online book sale, some publishers and big book-agents also joined in this kind of service, even some big delivery company, for example, the YAMATO transport service group has built its own book service website. Now, there are about 100 online book shop in Japan, about 10 of them are leading the way. The classification of them is (1) Combination of actual bookshop and online bookshop--- normally, the online bookshop is built based on actual bookshop for purpose of increasing sales and supplying better services, such as KINOKUNIYA, MARUZEN, SANSEIDO, and BUNKYODO; (2) Simplex virtual bookshop--- only online bookshop without actual bookshop, such as ESBOOKS, RAKUDEN, and BKI; (3) Books selling on a commission basis virtual bookshop--- this kind of bookshop is run by several shareholders, including book publishers, sale agents and even delivery companies, such as E-HON, HONYA-TOWN, and YAMATO.[5]

The common ground of all the online book shops is they all have a public database on their website and their customers can search and order their books online and their homepages, you can use key-words, author or theme to books would be delivered to their home. The difference between different online book shops is the results got from the database are different and the different payment, supply and delivery methods chosen and time. (Fig. 2)

Fig. 2, Classification of Payment, Supply and Delivery

### 3. THE ONLINE BOOK SHOP OF KINOKUNIA ANALYSIS

#### 3.1 General situation of KINOKUNIA

KINOKUNIYA is one of the biggest online bookshops

in Japan. In 1996, it has launched its virtual bookshop--- KINOKUNIYA BOOKWEB. It was a new online ordering and search service for Japanese books and foreign language books for individual customers. Even in the situation of drastic horizontal competition, it got more than 200 million sales per month in average. Now, as a representative internet shop in Japan, it got a significant development and more and more comprehensive concern.

The online service can only be used by members, although non-members could use the service too, but the search results and display pages are limited by the server, and they couldn't use some special only for member services, so to use all functions of the online book shop of KINOKUNIA, the best way is to be member of it. It is easy to become a member of it, you can do it online, before 2002, it charged 1,500 Yen to become a member, and now, it is free. After you become a member of KINOKUNIA, you can use the huge database of the book shop to choose your favorite books either in Japanese or in foreign languages. The database includes 1.85 million Japanese books and 2.85 million foreign books, which is one the biggest database in the world, under each book, you can find the details of it, including the contents, the author, publisher, and the stock. In addition, KINOKUNIA online book shop has supplied recommend service to members on their own get your results from the server. For its good quality services and easy use functions, the book-web of KINOKUNIA has got a lot of encouragements in Japan.

#### 3.2 The processes of online book sale by KINOKUNIA

The KINOKUNIA online book shop has limited some of its services to be used by members only, so the first step for customer to use the online service is to become a member, in the registration step, the customer was required to provide name, home address, contact number, credit card details, etc., after that, the customer would get a KINOKUNIA ID and password, by using this ID and password, the customer can use the online book shop services for search and order books.

After logging on to the homepage of KINOKUNIA, the member can use the database of the online book shop to search the books they want, the result would present the details of the books including the author, content, publisher, edition and price, the customer can also choose the nearest branch to order his book. After the online book shop received the order from the customer, if there are stocks in the shop, the online book shop will give a answer to the customer through its Quick Response System and post the books to the customer, if no stock in the shop, the online book shop would order the books from the publisher or agent, and the customer would get a mail to tell them the situation of his order. The KINOKUNIA online book shop would send the

books to the customer by its specially assigned delivery company. During the process of delivery, the customer can get some auto mail from the online book shop to tell order the books online, or pay when the books are delivered to his home, and when the payment happen, books are delivered and when the books can arrive to the customer's personal details are needed, which makes the customer, normally, it would take 4 days for Japanese books and 7days for foreign books.

The payment methods can be chosen by the customer, you can pay by credit card when you order the books online, and for using this payment, the online book shop would charge 380 Yen for delivery, or you can choose to pay when the books arrive, it would charge 200 Yen by the delivery company. (Fig. 3).

### 3.3 The advantages of online book shop of KINOKUNIA

A. Its particular virtual bookshelves that make the customers have a feeling of searching in a real bookshop, some book lovers like to choose their books just before the real bookshelves and which give them a special feeling of reading, to satisfy the need of this kind of customers, KINOKUNIA online book shop has set its virtual bookshelves and by this setting, it can give the customers a feeling like choose books in a real book shop.

B. Huge book database that include 1.85 million Japanese books and 2.85 million foreign books; detailed book information introduction; convenient delivery, the customer can choose the nearest branch and get the books in the shortest time, all these services can supply more convenience to the customers, and easier for customer to choose their favorite books.

### 3.4 The disadvantages of online book shop of KINOKUNIA

A. No bonus system, some of the online book services have a kind of system to return profit to customer, for example, the point return system, the regular customers can get bonus points when they purchase the things from the website, and they can use their points as money on this website. Although it is not the necessary condition for a customer to choose the service, but some customers would be affected by this kind of system, if this kind of bonus system was used by KINOKUNIA, the sales would have an increase. In the modern management, the bonus system is an important method to attract new customers and keep the regular customers. To increase the sales, some promotion methods should be used.

B. The extra cost of delivery of the books, the delivery cost 380 Yen per time, the extra cost would affect the customers who only buy one or two books each time, some of them would choose to the real book shop instead of shopping online, to reduce this kind of customer's burden, the online book shop could charge by each book instead of charge by delivery time.

#### 4 THE COMPETITIVE ADVANTAGE E-BUSINESS MODEL

The business model could be affected by the customers shopping requirements; Japan is a shop high consistency country, customers have a lot of opportunities to get their needs by real shops, so consider of this situation of Japan a more competitive e-business model is needed for the customers; and EBOOKS gives more choices of the internet shops. To satisfy the need of customers, we need to know their concerns about the services, the following figure is an investigation by Myvoice. Com for the concerns when the customers choosing to buy books from online book shop: from this figure, we can see that 33% of customers paid attention to the delivery fee, the category of books, book review, delivery time, bonus points, delivery place choices, and no answer were the categories, book review, delivery time, bonus convenient delivery choices was proposed.

Fig 4, the concerns of customers about services

Source: <http://www.myvoice.co.jp/voice/enquete/2203/index.html>

By consider of the concerns of the customers in the business management, the biggest online book shops have supply their own special services to their customers, the following table is the services comparison between each online book shop.(Table 1)

Each online book shop has its own characteristics; JBOOK is the online book shop of BUNKYODO book shop, the customer can get 3% bonus points when purchase books online; HONYA-TOWN is the online

book shop of a group of publishers and book agents, the benefit of purchase books there is no charges for the delivery from the nearest branch of its group;

BOOKSERVICE is a online book shop of YAMATO transport company, the advantage of it is the BOOKSERVICE can use YAMATO company's transport to deliver the books and which save time of the delivery places to the customers, they can choose the most convenient place to pick up the books.[12]

By analyzing and comparing the service of KINOKUNIYA BOOKWEB and the other 4 online bookshops in Japan, a competitive advantage e-business model with quicker response, lower cost and more convenient delivery choices was proposed.

The major challenges of B2C online book sale are:

ò Getting browsers to buy things — your online book shop site cannot live on traffic alone. Getting visitors to the site is only half the battle. Whether they buy something is what determines if you win. The so-called conversion rate for B2C e-business sites is still fairly low. (Boston-based Yankee Group said in November 2000 that the average rate was 1 percent.) Some ways to boost your conversion rate include improving navigation, simplifying checkout process (such as one-step checkout and easily replaced passwords), and sending out e-mails with special offers. For the online book shop, the best way to attract customers is to make your database user friendly, which means all customers can use your website easily and conveniently.

ò Building customer loyalty — with so many online book shop sites out there, how can you build a strong relationship with customers? Here are some tips:

Focus on personalization: a wide array of software packages are available to help the online book shops create unique boutiques that target specific customers. For example, American Airlines has personalized its website so that business fliers view it as a business airline and leisure travelers see it as a vacation site. Amazon, which built its own personalization and customer relationship management (CRM) systems, is

well known for its ability to recognize customers' what they concern and make changes to satisfy the needs of the customers, which means build the individual preferences.

2. Create an easy-to-use customer service application the online service. After all, good customer relationships Providing just an e-mail address can be frustrating to are at the heart of business success.

customers with questions. Live chat or, at the very least, a phone number will help. For the online book shop, customers should get quick respond for their questions, so the customer service is important to the online book shop.

## 5 CONCLUSION

3. Focus on making your site easy to use. Fulfillment preparation to the new chance for their promotion. — E-commerce has increased the focus on customer satisfaction and delivery fulfillment. One cautionary tale The competitive advantage e-business model can help is Toys "R" Us' holiday debacle in 1999, when the online book shop use technology and human fulfillment problems caused some Christmas orders to be delivered late. Since then, companies have spent billions and the value of those customers. If it works as hoped, to improve their logistical systems in order to guarantee the online business can: on-time delivery. Providing instant gratification for customers still isn't easy, but successful B2C e-commerce operations are finding that fulfillment headaches can be eased with increased focus and investment in supply chain and logistical technologies.

- ò provide better customer service
- ò make book shop branches more efficient
- ò cross sell products more effectively
- ò simplify marketing and sales processes
- ò discover new customers
- ò increase customer revenues

In the interest to increase the online book sales, some steps could be taken. First, know your customers, all of them, for the purpose of attracting new customers and

## REFERENCES

- keeping the existing customers, the online bookshop should consider more on the sight of customers. Such as both members and non-members can purchase the books on the web site freely, but the members can get some bonus points or discount; the places of book delivery can be chosen by the customers, they may choose from their nearest branches of KINOKUNIYA BOOKWEB, and the cost of different deliveries are different; the BOOKWEB can get the book orders directly from the publisher instead of the agents which can lower the purchase price of the books; more payment methods should be added, such as paying by mail or by BOOKWEB purchase recharge card.
- Second, develop IT strategies for specific customer needs, when the customers trying to buy books online they want their orders to be respond as quick as possible, which means they should get the books they ordered quickly, and the payment method they choose should be safe, so that needs the IT support of the online book shop by using the correct IT strategies, the orders of the customers can be deal quickly, safely and correctly.
- Third, more communications with customers, the management team should know what the customers need,

## ABSTRACT

Rapid advances in technology and the advent of the Internet have redefined public expectation of the government and its services. With the great support from Hong Kong and Singapore government, e-government system has achieved temporary success by offering some everyday services through virtual Internet. During last year's Severe Acute Respiratory Syndrome (SARS) outbreak, e-governments in Hong Kong and Singapore ensured the proper running of government services despite of massive physical restrictions caused by SARS outbreak. E-government started to show its value through continuous development in the past decade. The idea of "virtual government" implementation had been proved in some extent. In the meantime, SARS outbreak introduced new challenges to e-government in dealing with abrupt events. The paper will present the new trends and dynamics in e-government development enlightened by feedbacks from fighting with SARS outbreak. The paper will also provide assessment for those functional specifications raised under the SARS outbreak.

**Keywords:** E-government, CRM, information sharing, e-procurement, SARS

## 1. TITLE OF THE PAPER

E-government has been broadly defined as the production and delivery of government services through IT applications [6]. Government use of technology, particularly web-based internet applications, to enhance citizen access to government services and to enable citizens to make online transaction is called e-government [9]. E-government has been developed for the delivery of government services using information technology for many years in different countries. E-Government initiative is not just about using IT for government services; it is also an initiative to increase government transparency and increasing governmental efficiency.

E-government includes several types of framework and it behaves differently from country to country. There are three major domains of e-Government – E-Administration (process improvement), E-Services (connecting citizen) and E-Society (building interaction with and within civil society) [3]. Most literature points out the need for e-government initiatives is to reach out to four core groups, in a bid to enhance the total experience level – citizens, business community, government employees and government agencies itself [2][6]. These give rise to the four major category of e-government services, commonly known as Government-to-Citizen (G2C), Government-to-Business (G2B), Government-to-Employees (G2E) and Government-to-Government (G2G).

In this paper, we will first review the various stages towards the e-government maturity, followed by presenting the achievement of the e-government service performance in Hong Kong and Singapore. Other than successful achievements, the paper will review

e-government's role during the SARS outbreak and hence investigate the functional improvement in each of the four major sub-categories. The objective of the analysis and evaluation is the identification of potential improvement area arises from SARS outbreak at growth stage of e-government services globally.

## 2. PAST ACHIEVEMENTS

Through years of evolvments, developments in G2B, G2C, G2E and G2G services has resulted in two major benefits – efficient governments and innovative governments. E-Government also provides a strategy for addressing the challenges most governments face – such as reduction of operation costs, retention and training of staff and responsiveness to change and for creating an environment for transformation of government activities by the application of E-business methods throughout the public sector E-Government is also positioned by researchers as a promising approach for reducing bureaucracy in Government organizations and increasing citizens' access to the quality services [2].

Past literatures have addressed the achievement of e-government system towards maturity [6]. These stages are summarized as the evolution in terms of interaction, technical sophistication and service hospitality.

### 2.1 Information online stage

This stage is the most basic form of e-government marked by the one-way communication between government and users. When Internet gradually goes into everyday life in the mid-90s, governments in developed countries choose to post information or data

on the Internet for public reference. Although this implementation doesn't involve much technical sophistication, it is an effective way for public to be conscious about how government runs and reduces the deviation of information passing between government and users.

Singapore's e-government initiative can be traced back to the early 80s, with the launch of the Civil Service Computerization Program (CSCP). This initiative was conceived as a clear direction of turning government into a world class exploiter of IT and stimulates the IT penetration in Singapore Public Services. Since CSCP's launch in 1981, it had progressively advanced and evolved with the shifting trends in the technological, business and social climate to bring about stimulating changes to the way that government interacting with the public. In the mid 90s, Internet was introduced as a new delivery channel providing information. The Singapore ONE broadband initiative stimulated the delivery of interactive, multimedia applications and services to homes, businesses and schools throughout Singapore.

Hong Kong government started uploading governmental information to their website since the promulgation of the first Digital 21 Information Technology Strategy in 1998. By bring e-government into the agenda of all government bureaus, citizens has gain more accessibility and awareness to the government information and services. Weather forecast and government announcement information are initial service offering in Hong Kong at this stage.

## 2.2 Simple Communication Stage

This stage involves two-way communication as an interactive mode between Government and constituents [6]. In terms of technical effort, government has used email and feedback panel to answer constituents' request. Most idea of further e-government development is generated from this stage, where government archives constituents' request

In Hong Kong, the average monthly number of page views of all government websites amounts to 155 million, an 80% increase in the Year 2000. Over 1500 government forms can be downloaded online and 400 e-forms are available for completion and submission online. Requests for access to government information are available for submission online.

Singapore's ground breaking e-government service in this stage is the One Stop Change of Address Reporting Services (OSCARS).

## 2.3 Transactional Stage

The true interaction between government and citizens is enabled by online execution of governmental services

and subsequent financial transactions. The milestone of this stage is connecting the government system with users through web interfaces and allowing citizens with Government electronically anytime – saving hours of paperwork. On the other hand, citizens saved time and inconveniences of traveling to a government agency and queuing time as well.

Typical achievement of this stage in Singapore is the development of the electronic import/export trade documentation system – TradeNet. In the meantime, Hong Kong government opted to put the tax reporting service online as well.

## 2.4 Service Integration Stage or Seamless Stage

After the development at the transaction stage, most government agencies put up their services on the Internet. However, there may also result in chaos with less integrated service. Some even don't run on the same platform and don't share a common look and feel. Under this context, government attempts to integrate various government services horizontally (integrate with other governmental agencies) and vertically (integrate similar services together) for the enhancement of efficiency, user friendliness, and effectiveness [6]. The development at this stage requires tremendous amount of time and resources to integrate online and back-office systems. Citizens hope to have a uniformed way in accessing all governmental services. Through function re-assessment and combination, the ultimate goal of this stage is to enable user to accomplish all services from a single access point [5].

## 3. EFFECTIVENESS OF E-GOVERNMENT SYSTEM DURING SARS OUTBREAK

E-government can be explained as the public-sector adoption of e-commerce or e-business. From previous literature [2][6][7]. There are five key principles summarized to measure e-government system's effectiveness:

- *Increased general accessibility.* In the first place, as an e-commerce or an e-business application, it should have. Most literature points out the need for e-government initiatives to reach out to three core groups, in a bid to enhance the total experience level – citizens (or individuals), business community and with itself (interactions within the government).
- *Pure digital processing.* In the meantime, as an IT system, e-government system should have embodied the principle of "put everything online and do everything online", i.e. successful e-government system should have an aggressive approach to move of information from paper form to digital form and completely replace the paper form processing.
- *Dynamic Capabilities.* It should have dynamic capabilities, which is the e-Government's ability to integrate, build and reconfigure internal and external

organization skills, resources, and functional competencies within a changing environment.

### 3.1 SARS Outbreak

SARS outbreak in 2003 originated from China. It was previously unrecognized to be potentially fatal. The contagious *Coronavrius* infection emerged in East Asia with subsequent global spread. SARS officially hit the global headline on March 12<sup>th</sup>, 2003 through a global alert by World Health Organization (WHO). Hong Kong and Singapore both were largely affected.

In Hong Kong, in the five-month intensive fighting with SARS from February to June, there are 299 reported deaths. During March 2003, health officials in Hong Kong and Singapore have implemented quarantine and isolation measures to try and limit the spread of SARS. Temperature screening and health declaration by travelers have been a standard practice at all cross-boundary and international immigration checkpoints. Both two governments have founded hard to management the large scale of data sharing between governmental agencies, hospitals and civil service personnel. E-government system could further improve its functional capabilities upon the challenge encountered during the SARS outbreak.

In the following section, the paper will illustrate the potential trend in each subsection of the e-government arise during the SARS outbreak.

### 3.2 G2E & G2C Service Under SARS outbreak

One of the initial motivations of e-government service is to simplify its citizen services and decreases the number of paper processing which is costly and difficult to process. G2E services can be seen as an internal B2C services which is nothing special in the Internet era. The G2C services offered by Hong Kong and Singapore government are quite comprehensive. Common functions like tax paying, vehicle license application, identity card application and facility booking has all been available in Singapore and Hong Kong. In this section I will focus on the contrast between people's different attitude towards e-Government service before and after the SARS outbreak according to statistics conducted by Hong Kong and Singapore government.

Although SARS has brought disastrous effect o the regional economy and social order, it stimulates the public adoption to e-government system. During SARS outbreaks, people in Hong Kong normally choose to stay at home and wouldn't be able to access to government agencies through physical means. They gradually exploring other approaches to accomplish those tasks which used to available through physical contact. As a result, the percentage of public utility bills paid through electronic means increase from 29% a year ago to 53% at the end of year 2003. Before the SARS

outbreak in December 2002, 39% of the income tax declaration is done through the e-government system in Singapore to pay income tax, however, this figure has increased to 67% after the SARS outbreak in 2003. The e-government system in Hong Kong and Singapore proves its effectiveness in increasing accessibility during the SARS outbreak.

When citizens are getting used to e-government services, ensuring users' loyalty to e-government services becomes increasing important. Moreover, in order to make e-government system to be more effective, it should leverage on private sector's business ideas and innovation so as to improve services to customers [4]. Therefore, Customer Relationship Management (CRM) features have become increasingly popular among e-government services.

During the SARS outbreak, citizens realized that most e-government services aren't specific to user itself, e.g. they cannot find the SARS regulation pertinent to their own interest. The current e-government B2C services are more uniform, where different users cannot enjoy customized services. However, the core idea of CRM theory is to provide more customer-centric and tailor-made services to citizens and business [8].

Common e-business application like online bookstore usually keeps a profile for returning users and offer personalized search according to the user's profile. Hong Kong and Singapore have the world's highest mobile phone penetration rates, with 3G service impending in the next year. Leveraging the mobile phone concentration would stimulate the e-government to offer more personalized system. The most tempting feature of the m-commerce system is offering the location-based services. For example, users could receiving the booking of nearby public sports facilities through there mobile phone. This further motivates the e-government system to garner the concept of CRM and offer the service to the user who really needs the service.

To implement such a customer orientated e-government system, we can leverage on the current CRM framework. The critical success factor for most CRM system includes:

*Knowledge of Customer:* E-government system needs to gain users knowledge such as preference, and then use business intelligence tools such as data mining, processing and reporting to form a generic profile. Further possible information to be collected includes customer's demographic information, service history and all previous transaction with the e-government system [1]. When dealing with mobile users, while methods like forms and cookies can be used to collect data, there must be new ways to consolidate customer data through their mobile device with limited storage space. Moreover, the mobile ways of collecting data

must be able to conform to the database formats using web interface.

*Capturing and increasing added value.* E-government system must continuously innovate to stay ahead of users to make the service more superior after each user transaction. For example, if a user access a sports facility where he used to use his mobile phone to book, e-government system could provide better booking information.

*Customer Interaction:* E-government system could provide customized user interface and periodically seeking online feedback from users. E-government system could also integrate the real-time online service answering features.

*Customer Acceptance:* Before a customer-orientated e-government initiative to put into practice, developers need to decide the best mean to implement those functional requirements. For a particular service, they need to decide whether needs to use a graphical rich interface or pure text interface. For integration of mobile service, they need to decide the technology (WAP, SMS, GPRS etc) by considering which technology is more appropriate to reach all users.

The key value proposition for G2C initiatives rests on providing electronic services to citizens that are integrated and user-centric, on a 24\*7 timeframe, anytime, anywhere, and through a range of channels.

### 3.3 G2B Services

G2C and G2E services are e-services for individuals with limited transactions and technical sophistications. However, G2B & G2G are the extensions that generate most potential. A centralized G2B e-procurement system, in the framework of e-government, reduces the cost of issuing invoices and other administrative work for low-value, high-volume goods. It also simplifies the CRM in the government sector. However, the largest potential saving originates from lower prices due to centralized spending. This is motivated by the lack of organization in governmental purchase of SARS-related items like thermometer and masks during the SARS period. The critical success factors (CSFs) of such e-procurement system includes:

- Efficient processes without excessive idle times
- Existence of monitoring and evaluation systems that permit the continuous improvement of the process
- Adequate training of the employees in order to enable them taking advantage of the new system.

The above CSFs should be coupled by a set of KPIs that should be monitored as used in enterprise level e-procurement system:

- Tender lead times
- Percentage of governmental purchasing with accepted quality (in accordance with the predefined

technical specifications).

- Productivity of resources
- Budget accuracy (deviation of the actual governmental purchasing compared with the related budget).
- Cost (including all the relevant cost categories, together with the cost of the purchased goods or services).

Another possible trend in e-government is public-private partnerships. Firstly, having business involvement brings about competitive pressures in the e-government journey, in line with Osborne and Gaebler's principles of reinventing government [7]. Secondly involvement of business brings in the required expertise from the market to turn "e" quickly as it is not possible for government agencies to train staff overnight or attract large amount of such talents from the market easily.

### 3.4 G2G Services

G2G service is very limited in both e-governments of Singapore and Hong Kong, where different government agencies could integrate their services or form partnerships to offer better service and information transparency between agencies as well. By performing vertical and horizontal integration, an e-government system could leverage the strength of e-services provided by different government agencies.

During the SARS outbreak, the *Contact Tracing Information System* implemented in Singapore has been a good start of G2G system where different governmental agencies provide and demand different domains of information. The Ministry of Health, Immigration Checking Authority, Hospitals, Ministry of Education are sharing the same information knowledge base but perform different tasks during the combating with SARS.

Inter-governmental information sharing could be an inflexible process nowadays. During the SARS outbreak, Asian countries failed to establish a joint monitoring and collaboration system to combat SARS because of a lack of information sharing service capabilities. Bilateral free trade treaties signed in Asia Pacific Region, gives more incentives for one government to provide services via internet to other governments to facilitate better information exchange. Governments which share resources could be more motivated to implement the inter-governmental G2G service (e.g. Singapore purchases water regularly from Malaysia).

## 4. CONCLUSION

Despite of the negative economical impact of the SARS outbreak, it has provided a big stage for e-government system to show its magic in Asian countries. It provided an excellent test ground to evaluate our current

development achievement and indicated a clear way to achieve the ultimate goal in e-government development. The successful operation of the e-government system during the SARS outbreak is a milestone in the history of e-government development. In some extent, the e-government system development could determine a government's effectiveness under emergency situation.

The e-government system started from some G2E and G2C applications, where the current focus has shifted to more valued-added G2B and G2G applications. The ultimate (mature) stage of the e-government development (See Figure 1) is to achieve a *Virtual Government* where all government service and interaction is available without any physical interaction. This is also coincidental to what the current ubiquitous network development tries to achieve.

### ABSTRACT

Some studies show that Internet markets are more efficient than conventional markets with respect to price levels, menu costs, and price elasticity, except substantial and persistent dispersion in prices on the Internet. Is price dispersion in Internet markets higher than that of conventional markets? This paper examines the nature of price competition in books among five online book-sellers in China, i.e. dangdang.com, joyo.com, bjbb.com, china-pub.com and welan.com. Unlike the researches before, we not only consider the products' prices, but also the whole price level. According to the investigations and analyses of 50 books price observations collected in August 2004, we conclude that the whole price dispersion in Internet markets is not higher than conventional markets, and high price dispersion on one sample is the results of firm's discrimination strategy. When the competition is very complete, the prices show a tendency to be consistent.

**Keywords:** E-Commerce, Price Dispersion, Internet Markets, Market Efficiency

### 1. INTRODUCTION

Electronic commerce is a significant force in the consumer economy. Consumers can now go online and comparison shop between hundreds of vendors with much less effort than in the physical world. One widely-reported prediction with respect to electronic commerce is that the availability of low-cost information on price — specifically the rise of comparison shopping agents — will lead all Internet retailers to charge the same price for mass-produced physical goods and that price will be approximately cost.<sup>[1]</sup>

However, several studies have found that Internet markets are more efficient than conventional markets with respect to price levels, menu costs, and price elasticity, except substantial and persistent dispersion in prices on the Internet. This price dispersion was not consistent with Internet markets efficiency.

Is price dispersion in Internet markets truly higher than conventional markets? This paper approaches this question by investigating the price dispersion in Chinese electronic markets with examining the nature of price competition in books among five online book-sellers, i.e. dangdang.com, joyo.com, bjbb.com, china-pub.com and welan.com. In section 2 we discuss the researches of price dispersion in electronic markets. In section 3 we discuss the investigation in Chinese online book markets, and then in section 4 we compare it with traditional retail markets. In section 5 we discuss the phenomena of large price dispersion in online book

market and its competition, and then we present the basic results. In section 6 we conclude.

### 2. PRICE LEVEL AND PRICE DISPERSION IN ELECTRONIC MARKETS

An efficient market means in which consumers are susceptible to the changes of price, and product prices are susceptible to the changes of consumer demands, and operation costs of enterprise, product prices, marginal production costs and average production costs are equal. According this definition, the market efficiency can be measured by four parameters related to price: price level, price dispersion, menu cost, and price elasticity.

Generally, when consumers search costs decrease, product prices will decline and close to marginal cost. The less search costs, the lower price level, the less price dispersion, the higher market efficiency. According to the traditional economic view, by using search engine and electronic agent technology, consumers can search information of products more easily on the Internet, and compare the prices among many producers. Therefore, we would expect more violent competition and lower prices than in conventional channels. In addition, Internet is open to each enterprise, including big company and small firm, so it reduces enterprises' enter costs, and make the competition more intense.

Despite this presumption of increased competition, however, existing empirical works on the Internet have not been so supportive of the theory as one might expect. Because demand price elasticity and menu cost cannot be measured directly, existing work has mainly entailed collecting prices on and offline for a specific category such as books, and compared their price dispersion rate. Although the results from the works have not

conformed to the traditional views of reducing search costs. These studies have generally found large dispersion of prices online and prices either modestly lower or actually higher than their offline counterparts.<sup>[2]</sup>

Early works yield conflicting results. Lee (1997) found that prices for second hand cars were higher on the Internet than in conventional channels. Brynjolfsson and Smith (2000) focused their research on the index of price level, price dispersion, and variety rate (menu cost) in online books and compact disks market for 1998-99. They found that Internet retailers had lower prices, smaller price adjustments, and larger or smaller price dispersion than conventional channels, depending on whether prices were weighted by proxies for market share. And their studies show that Internet retailer prices differ by an average of 33% for books and 25% for CDs, and some even reached 50%. Another study of interest is Clemons, Hitt, and Hann (1998) on the online travel industry. They found that online ticket agents engaged in significant product differentiation, i.e., agents responded to identical requests with different time/price pairs. Clay (2001) found that online bookstore had lower prices or the same, but had larger price dispersion.

Zhu<sup>[3]</sup> proposed his interpretation frame on this paradox. He attributed the large price dispersion in E-markets to the weak position of consumer contrasted with the producer on deciding exchange prices. Although consumer can collect the information of retail price and related product prices, and have the decreasing tendency on prices, Zhu thought that E-markets reduce the search cost of online retailers at the same time. In his opinion, with lower search cost the online retailers can make a different price by customization and other strategies, to strengthen their market position and control consumer.

However, Zhu's theory lack evidences and is not appropriate in interpreting price dispersion, because on condition of complete competition, product prices of different companies tend to be consistent. Especially with improvement in their capability of obtaining information, they can respond to the market quickly. Zhu also did not explain how online environment improves enterprises' decision abilities, and enhances their price discrimination abilities.

### 3. INVESTIGATION OF PRICE DISPERSION IN ONLINE BOOKSTORES

In this paper, we will present the first empirical evidence on the impact of Internet competition on prices and dispersion offline. In this sense, our results are similar to the existing empirical works on search. By analyzing the data collected from five online bookstores, we are able to document the price level and price dispersion in Chinese electronic market. Moreover, unlike the researches before, we not only consider the products' prices, but also compare the whole price level.

We examine online bookstores because of the following three aspects: First, each book has fixed publishing price on it which we can see, though different retailers can sell with different prices. Second, Internet book retailers were the forerunner in electronic commerce, so the competition in this market is more complete than others. Third, other Internet retailing is not developed at present in Chinese.

Since Internet bubble had broken down in 2000, many online retailers disappeared. Nowadays, Internet book retailers have formed a big industry in China. The top 5 in total sale and sale categories are approximately Dangdang, Joyo, China-pub, Welan and Bertelsmann. There are many concrete bookstores engaged in online business, such as Shanghai book-city, Beijing book building. And some integration Internet retailers sale book, for example 8848.com.

We investigated the top four Internet book retailers and a mouse&brick bookstore: Dangdang, Joyo, China-pub, welan, and BJBB (Beijing Book Building) Online. Dangdang ([www.dangdang.com](http://www.dangdang.com)) is one of the biggest and earliest online bookstores in China, which claims to be the biggest Chinese Internet mall in the world. Besides books Dangdang sells CD, VCD, DVD, software, magazines and general merchandises, and deals in C2C business. Nearly founded as early as Dangdang, Joyo ([www.joyo.com](http://www.joyo.com)) claims to be the biggest book and audio&video products mall on the Internet. Their business is similar to Dangdang, including books, music, video, etc., with the functions of community and personal auction. China-pub ([www.china-pub.com](http://www.china-pub.com)) claims to be the most professional online bookstore in China, and mainly sells computer, communication, economics, management and foreign language books. Electronic books are its particular business. As a professional online bookstore Welan ([www.welan.com](http://www.welan.com)) only sells books, and claims to be the most professional academic bookstore in China. Its primary business is restricted in Beijing. Bjbb Online ([www.bjbb.com](http://www.bjbb.com)) is an Internet book retailer attached to BJBB.

We collected data from five companies mentioned above because of the following points. ① All of them except Welan are well known in China. ② All of their headquarters are in Beijing, and they have oriented the same client group in the same place. ③ All of them are professional in book retailing, and most of them sell more than 300 thousand kinds of books. ④ Except China-pub, others were founded at the end of 90s, and underwent the shock of Internet bubble break in 2000.

A data set of 50 popular books' prices collected in August 2004 in different fields was selected as samples to analyzing price dispersion phenomena. We chose popular books because most of them can be found in five online bookstores. Because of different operation strategies among five companies, if we select

professional books as samples, we cannot find them in all of bookstores, as a result, many data cannot be collected, and the data set will not be integrity, therefore we cannot analyze it.

Our sample books consist of three categories: economics, English learning and computer programming. One of rules to select book is popular we have mentioned before. Another rule is that selected book's prices distribute dispersal. We lean to select high price book, because consumers show different action in buying different price books. People do not hesitate in buying low price books even no discount. But if there is a large discount for higher price books, they maybe get a great customer value. Therefore, the average price of sample books is 48.2RMB.

In fact, because each bookstore differs from operation strategies, customer groups and professional fields, it is difficult to find fifty books which all five bookstores have and satisfy our standards. We had met many cases that cannot find in five bookstores at the same time when collecting data, for example, there is not the same edition of *Three Empire*, a famous classic novel came down from Ming dynasty.

Although Joyo claims to be the biggest book and audio&video products mall on the Internet, we find its book categories are fewest in five companies. Dangdang faces to the masses. China-pub faces to professionals in computer field, economics and management. Welan was founded by a few students of Tsinghua University in 1999, and mainly faces to students and teachers of university in Beijing.

Table 1 shows some index we obtained.

Table 1. Price comparison of five online bookstores

Index	Value
Max Discount (Off)	52%
Min Discount (Off)	0%
Average Discount (Off)	20%
Max Price Dispersion	46.2%
Min Price Dispersion	10%
Average Price Dispersion	15.2%

Where price dispersion  $p$  equals

$$p = \frac{\max\{i_t\} - \min\{i_t\}}{\max\{i_t\}} \times 100\% \quad (1)$$

and average price dispersion  $p_a$  equals

$$p_a = \frac{\max\{\sum i_t\} - \min\{\sum i_t\}}{\max\{\sum i_t\}} \times 100\% \quad (2)$$

We analyzed the data and worked out the following results:

- ò Big discount is given in some books. The biggest discount is 48%, and the average discount is 80%. It possibly relates with the samples we selected,

because some books, especially computer books, are expensive, and have a big discount space. Some books are sold with very low price because of sales promotion.

- ò There is high price dispersion in online book markets. Max price dispersion reaches 46.2%, and min price dispersion is 10%, and average price dispersion is 15.2%. The max price dispersion is possibly due to sales promotion. Our results showed difference with Brynjolfsson's studies<sup>[5]</sup> which said average price dispersion was 33%.
- ò Compared with conventional bookstores, prices were lower in online bookstores. As a conventional bookstore, BJBB spreads their brand with starting online business and changed to a click-and mortar company. Other four bookstores are virtual company, and their average selling price is a little low.

However, after analyzing the data set we collected further, we find that the average price dispersion is only 6.8% if we remove the data of BJBB! This is an acceptable result which means the price dispersion of online market is not higher than conventional market.

#### 4. FARTHER STUDIES: COMPETITION BETWEEN ONLINE BOOKSTORES AND OFFLINE BOOKSTORES

Some of the results above are consistent with researches before, such as there is large price dispersion of one product, and max price dispersion reaches more than 46%. Compared to 90% discount in conventional bookstores (except for special bookstore), online bookstores have a large space in making a price. All those data seem to support the theory that electronic market has not been exhibited more efficient than conventional market, though it would be.

Because there is not a reasonable interpretation as yet, we have to carry on our research in another method. We change our research focus on the competition between online bookstores and offline bookstores. We investigated five offline bookstores which are located at and near Tsinghua University. We selected them basing on the following two aspects. On one hand they open to the same client group — students and teachers on the campus and at other universities hereabout, so they were intensely in competition with Welan. On the other hand, we are familiar with the evolvement of competition between them.

The main promotion measure of online bookstore is discounting. Welan resorted to it to absorb clients when it was founded. At the beginning (1999) Welan sold English-studying books published by New Oriented School (those reference books have been very popular in Chinese students who want to pass the English

examinations such as TOEFL, GRE, IELTS, etc.) at a 79% discount, and it advertised widely. Soon (about 3~4 months after) the five conventional bookstores adjusted the same books' prices from 90% discount to 80% discount, and then fell to 79% discount. In fact the competition spread to the bookstores further.

The competition mentioned above could be regarded as a game between online bookstores and offline bookstores. Online bookstores were a new entrant who had to introduce some new measures on purpose to absorb clients. So Welan chose discount. As a virtual shop, online bookstores need not a physical place, and they have all advantages that a virtual company have contrasted with offline ones.

When Welan opened the five conventional bookstores had not minded the new entrant. But after they found their turnover fell and had lost some clients gradually, they had to act. Firstly they do not think that they had to make the price as low as their new rival because of their advantages, for example, clients can obtain books immediately, so they just give 80% discount. But they found the clients who came to rivals were not easy to return, even they adopted lower prices measure then before, and it is inadequate to win the competition. Finally, the five conventional bookstores reduced their prices as the same as Welan.

The brick-and-mortar rivals' action made Welan lose its price advantage, so Welan adopted measures to keep customers. They sold books with 75% discount. Here online bookstore's profit was close to offline bookstores, and the customers' number of two kinds of bookstore tended to be steady gradually. Therefore, the competition was in equilibrium.

The game process was shown in table 2 and figure 1.

Table 2. Payment matrix of online and offline bookstore

		Conventional bookstore	
		Falling price	Keeping
Internet bookstore	Falling price	1,1	2,0.5
	Keeping	0,1.5	0,3

Figure 1. Competition between online and offline bookstore

From the investigation we conclude:

Under the competition in which client group overlaps and information transfers sufficiently, no matter what kind of bookstore, the price dispersion is low and prices will tend toward the same. It is consistent with the theory that Internet will improve market efficiency.

Consumer strength of bargaining is improved instead of declined as some researchers said. Decision capacities of enterprise are enhanced too, but not cost consumer's bargaining strength.

## 5. PRICE DISPERSION, COMPETITION IN ONLINE BOOKSTORES

With further analysis, we find that on condition sufficient competition price will trend to the sameness quickly. Our results differ from the former researchers' conclusion that the price dispersion of online book market is larger than offline. But our results based on different backgrounds of bookstores: we investigate the bookstores which have the same client group — they are similar in consumed level, knowledge level, reading taste, etc.

Therefore, we conclude that why there is high price dispersion that former researchers found due to the following points:

- ò Different Internet bookstore can carry on their price discrimination because of different client groups.
- ò Because of cost advantage Internet bookstore have a large spare in making a price, so there is big price dispersion.

Few consumers only buy one book once. For those consumers whatever bookstore is the same, and they tend to choose the cheapest one. However, for those consumers who need more than three books in several categories, it is difficult to choose bookstore (only consider price factor) because different bookstore have different promotion strategies. For example, Dangdang resort to using a very low price in best seller as a method to attract consumers, and as a professional bookstore the discrimination strategy of Welan is giving big discount for all. When books a consumer wants to buy include some best sellers and catena, he will find some of them should buy from Dangdang but others should from Welan, and if he selects the two it will take him more time and more delivery cost. It is very difficult to decide which bookstore he prefers.

So we attribute the price dispersion of online book markets to different client groups (purchasing power, knowledge level, professional background, etc.) and the

relationship between different books (many people have a few kind of reading taste)

## 6. CONCLUSION

In this paper we have examined some Internet bookstores in Aug 2004 and reviewed the competition between welan.com and some conventional bookstores from 1999 to 2000. We find that the phenomena that price dispersion of Internet markets is higher than conventional markets only exist in one book or single product instead of integer, and due to the discrimination strategies of enterprise. On the contrary, the whole price dispersion is not high, and on condition of sufficient competition different companies' prices trend to be the same. The data also show, consistent with the theory, that the efficiency of online markets is higher than conventional markets.

Another study of the competition between a virtual company and some conventional shops from 1999 to 2000 indicates that competitors adjusted their prices following the virtual shop. The results reveal that Internet market enhances the competition because information can be gotten easily.

Certainly, our studies are insufficient. We have only investigated five typical Internet bookstores and selected samples purposefully. In fact, we should consider consumer purchasing power, motivation, and

other consumer's characteristic, as well as market development, and enterprise's relative business, etc., which will infect our results.

### ABSTRACT

This paper aims at identifying the current state of China's online gaming market, and exploring the obstacles that keep China from developing this industry further on the basis of analyzing the value chain of online gaming industry. In the meanwhile, a case study will be made about the domestic leading online gamer—Shanda corporation, a listed corporation on NASDAQ. And in the end some conclusions will be made on how to assess the online gaming industry in China and how to remove the obstacles in accelerating the development of online gaming industry in China.

**Keywords:** online gaming industry, current state, China, obstacles, Shanda Corporation

After the dot-coms gradually lost their wizards in the past few years, the new economy firms never stopped seeking the potential lucrative industry that can make them "recovered". Recently, they have found a booming industry that can lure people from other things—online games. According to a recent survey made by the International Data Corporation, or IDC, China's online gaming market grew 46 percent in 2003, and in the next two years its Massive Multiplayer Online Role-Playing Games (MMORPG) are expected to dominate its online gaming market.

### 1. MARKET SCALE OF CHINA'S ONLINE GAMING INDUSTRY

#### 1.1 Global Online Gaming Market Size

The increase in broadband connectivity to the home has an explosive impact on the world of online gaming, thus, the online gaming sector is growing tremendously as the availability of faster processing hardware enables the development of more advanced games.

According to the most recent statistics, the global online game market scale reached 7.6 billions U.S. dollars in the year of 2003, and by estimate, the total revenue of online gaming industry in 2004 will reach 9.9 billion U.S. dollars (see Figure 1).

#### 1.2 Current State of China's Online Gaming Market

In 2003, China has become the second-largest country of installing PCs and has the third-largest internet users. According to the latest survey made by CNNIC in July 2004, the internet users in China has become 87 million, among whom 31.1 million people use broadband as the method of accessing internet. There is no doubt that high speed Internet accession is another reason why China is growing so rapidly in online gaming industry. [1]

Game developers in China are hoping that they can occupy more market share currently dominated by Korean companies. Legend of Knights, the first online game made by Chinese company has been quite successful with peak simultaneous players of 80,000. A variety of statistics made by iResearch Consulting Company recently demonstrate that internet games have become a great business in China. Earlier this year, of the Top 100 tycoons on the Forbes list, three from the IT industry confirmed that most of their revenue had come from the online gaming industry. [2]

Statistics show that the total revenue of China's online gaming industry reached 2.55 billion U.S. dollars in 2003. By estimate, the volume of total output of this industry in China will reach 6.65 billion U.S. dollars in 2005 (see Figure 2). Online gaming market estimate has also shown that China has the highest potential of growth in the Asia-Pacific region. The most optimistic remark on China's growth from IDC says that China will probably become the largest online gaming market in 2007 with

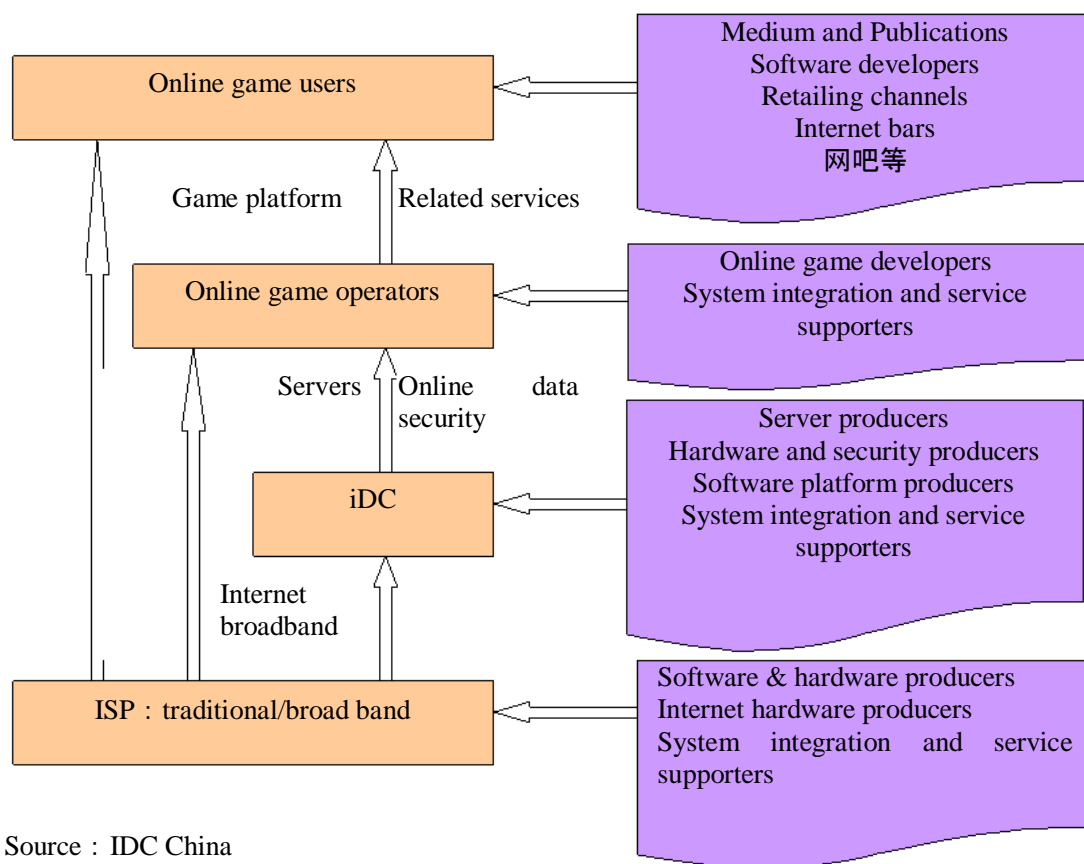

availability of broadband and wireless networks acting as the key to growth.

## 2. VALUE CHAIN OF ONLINE GAMING INDUSTRY AND THE POSOTION OF CHINESE FIRMS

As we know, the whole value chain of online games industry can be divided into the following categories: game developers, game operators, marketing channels, ISPs and peripheral services.

The main chain of the online game industry is as follows: online game players, online game operators, online game developers and ISPs; and the supporting chain of the online game industry is: internet Cafés, online game sellers, peripheral products for online games, mediums and publication industries, computer software industry, etc (see Figure 3).

In terms of the main value chain, the Chinese firms mainly concentrate on the marketing of online games, while the hi-end of the value chain, i.e. the development of online games is under the control of foreign companies especially at the hand of Korean companies.

Source : IDC China

Figure 3 Value Chain Of Online Gaming Industry

### 3. THE MAIN OBSTACLES THAT KEEP ONLINE GAMING INDUSTRY IN CHINA FROM DEVELOPING FURTHER

#### 3.1 Main Obstacles from the Perspective of End-Users of Online Games

Although the internet infrastructure construction has made great progress in recent years, connect speed is still the first factor that influences end-users in choosing what games they play. The fact that 69.4% of the Chinese online game players think that connect speed is the main factor on their game choosing demonstrates that the broadband service in China is not so satisfactory. Cost is the second factor that affects online game players (39.3%). Besides, difficult level, story design and visual design are roughly equal with about 30-40% players deem them as factors that influence them on choosing games respectively (See figure 4).

#### 3.2 Lack of Support from Government with Unclear Industry Policies

Apart from the negative attitude from the public who

tend to think that online gaming industry might be a potential threat that keep their children away from studying, the government also shows a vague attitude toward this industry. For example, it's not an easy thing to get licensing of setting up Internet Café in China. Another fact that can not be ignored is that the internet accession fee is still high compared to the income of the internet game player (Most of the game players are young students who still rely on their parents). There are still other problems such as piracy problem, monopoly problem in telecommunication industry, etc. [3]

#### 3.3 Weak Domestic Online Gamers at the Lower- end of Value Chain

At present, the Chinese online gaming market is still dominated by Korean companies. The domestic online game developers are facing stiff competition from Korea, Japan and other countries. Most of the Chinese online game developers lack capital and comprehensive abilities of developing and operating in this industry. Some companies are very slow in renewing their games and the R&D activities are at a lower level compared to the above mentioned advanced countries.

Figure 4 Factors That Influence Players On Choosing Games

### 4. CASE STUDY—SHANDA CORPORATION, AN OBSTACLE REMOVER IN CHINA'S ONLINE GAMING MARKET

Shanda is the largest operator of online games in China. This Corporation offers a portfolio of online games that are licensed from third parties and that are developed in-house. The games that Shanda offers include The Legend of Mir II, which is the most popular online game in China according to users surveyed by International Data Corporation ("IDC"), The World of Legend, which is Shanda's leading in-house developed game, and BNB, which was the highest ranked casual game in IDC's survey of the top ten most popular online games in China in 2003. Shanda is headquartered in Shanghai, China.

#### 4.1 Shanda's IPO Strategy

In May 2004, Shanda Interactive Entertainment filed with US regulators for an initial public offering valued at up to 200 million US dollars. According to a preliminary prospectus filed with the U.S. Securities and Exchange Commission, Goldman Sachs underwrote most of the IPO for Shanghai-based Shanda. Other groups like Piper Jaffray and the Hong Kong and Shanghai Banking Corporation or HSBC also took part. Shanda said it has applied to list its American depository shares on the Nasdaq stock market under the trading symbol "SNDA".

The IPO of Shanda brought this company both fame and wealth. And this had made Shanda a pioneer among Chinese online gamers. Also, Tianqiao Chen, the CEO of

Shanda Corporation has become the richest person in China according to the shares he holds and the most recent market price of SNDA on NASDAQ.

#### 4.2 Shanda's M&A Strategy

In August, 2004, Shanda acquired Hangzhou Bianfeng Software Technology Co., Ltd. Bianfeng is a leading developer and operator of chess and board games in China. Currently, Bianfeng offers over 50 different games, which attracted over 200, 000 peak concurrent users in July 2004.

The acquisition is based on the fact that board games are deep rooted in Chinese culture and have a large and loyal users especially among mature age groups. The acquisition of Bianfeng adds another important segment to Shanda's casual games platform and greatly broadens Shanda's user base demographics. [4]

#### 4.3 Shanda's Marketing Strategy

The focus of Shanda's marketing strategy is the so-called "experience marketing" style. This style means that Shanda Corporation attaches great importance in finding their customers' feelings and preferences in playing their online games. For example, the data base naturally generated from the records in the process of consumers' playing can be of great help in analyzing what kinds of games they like to play, at what price level customers can afford, and at which time periods during a day the customers frequently log in, etc. The above mentioned information can help Shanda Corporation do better job to improve their services to seize a clearer group of target market.

Another factor that leads to Shanda's success in its marketing strategy is that this company uses internet Cafés as their marketing channels. By using internet Cafés which are very popular in China, it's relatively easy for Shanda to establish its marketing channel in a short period of time. In the meantime, Shanda installs E-Sales system in each internet Café to build up an integrated information system among the distributors, and this helps a lot in doing business statistics and thus giving different discounts to distributors according to their business scale. Because there is no logistics problem in online gaming industry, Shanda utilizes banks and post-offices as its channel of collecting money for playing games.

## 5. CONCLUSIONS

The online gaming industry in China is still at an early stage, therefore, the online gaming market in China is immature at present. The main reason lies in the fact that the upstream of this industry is still dominated by foreign firms.

The online gaming industry has a long value chain including many industries such as medium and publication industry, telecommunication industry, hardware and software industry, retailing channels, etc, and the market opportunity is tremendously huge.

The main obstacles of online gaming industry in China include internet accession infrastructure to be improved, unclear industry policies and high industrial barriers and the internal reasons of Chinese online gamers including lack of capital, weak R&D abilities and relatively small scale, etc.

Some domestic online gamers in China have grown more and more strong. The Shanghai-based Shanda Corporation has set a good example in its IPO strategy, M&A strategy as well as its marketing strategy. We believe that more and more domestic corporations like Shanda will achieve great success in China's online gaming industry in not a long future.

### ABSTRACT

The e-commerce environment is changing fast and getting mature, the internet technology enabled evolution created many new business organizations and new business models. It also caused new competitions and new management challenges. Although B2B e-marketplace have been promoted as tools for reducing transaction costs, streamlining process efficiency, and enabling virtual collaboration among partners, there are still not many successful B2B e-marketplaces in Asian. This research tried to develop an evolution model based on the IOS (Inter-Organizational Systems) model defined by Benjamin (1990)(1) and Applegate et al, (1996)(2). Through over 100 firms' case studies in seven industries of Taiwan, the patterns of business partnership structures and the path of e-marketplace evolution were found. In order to explore the factors effected e-marketplace evolution, this paper summarized the possible impact factors based on 'Transaction cost theory', 'Resource dependent theory', 'Institution theory', and the 'Contextual Influences' which were highlighted as three levels in previous study – socio-cultural, national/regional, and structural (Hsiao and Ming, 2002)(3). The questionnaires were developed and mailed to 980 firms on the list of class-A members of 'Taiwan Taiwan Electric and Electronic Manufacturers' Association.' 178 valid questionnaires were received and investigated. The data analysis result suggested that factors of institutionalization effect may be one of the most significant impact dimensions of e-marketplace evolution.

**Keywords:** Inter-Organizational System, e-marketplace, Industry Value Chain

### 1. INTRODUCTION

The e-commerce environment is changing fast and getting mature, the internet technology enabled evolution created many new business organizations and new business models. Beside a mass of merit and chance, internet also created new competitions and new management challenges. The enterprises could connect to supplier, business partners and customers through internet. This could not only increase the efficiency and reduce the cost of business transactions but also create the changes to the value chain of enterprise and the supply chain crossed different organizations. There has been a rising interest in using e-marketplaces (electronic marketplaces) to enable closer B2B (Business-to-Business) collaboration (Hsiao and Ming, 2002)(3). Many IT solution providers and government agents put lots of effort and investment to encourage firms to implement e-business especially the B2B e-marketplace. But market analysts have reported that the majority of the e-marketplaces have either closed down or are facing difficulties in attracting buyers and suppliers (Markus and Soh, 2002)(4). The study is an initial attempt to building a three dimension evolution model to investigate the evolution path of the B2B e-commerce development progress and the reasons for the success or failure.

### 2. THE IOS REVOLUTION

The popularity of IOS (Inter-Organizational Systems) started in the late 1960s. Felix Kaufman (1966)(5) first described the "information partnerships" through the information systems cross the Organizational Boundaries. Barrett and Konsynski (1982)(6) highlighted the value of IOS is to share information cross the organizations. Cash and Konsynski (1985)(7) defined IOS as: 'the automatic information systems shared by more than two companies.' They stressed that IOS can improve the productivity, flexibility and competition advantages. Malone, et al., (1987)(8) classified the IOS as electronic hierarchy and electronic market. The electronic hierarchy is for the control, communication and coordination between the different hierarchical levels of organizations. The electronic market is to support the market functions between different organizations. Bakos (1991)(9) based on the function classified the IOS as 'Information Links' and 'Electronic Market.' The information links are the 'Communication Channels' between the organizations in the industry value chain. The electronic market is the 'Intermediaries' or 'Marketplace' for buyer and seller.

Benjamin (1990)(1) divided the IOS into the two dimension matrix as figure 1. Benjamin claimed that the IOS implementation of the organization is an evolution process, the type of IOS will be changed from time to

time as the business changed. Konsynski (1993)(10) based on the 'Interaction Patterns' to divide the IOS into one-to-one, one-to-many, and many-to-many. Applegate, McFarlan and McKenney (1996) in their book--*Corporate Information Systems*, created a two dimension model to describe the IOS evolution path from single sales channel to electronic marketplace. Figure 2 list these two dimensions as 'Interaction Patterns' and 'Levels of Control.'

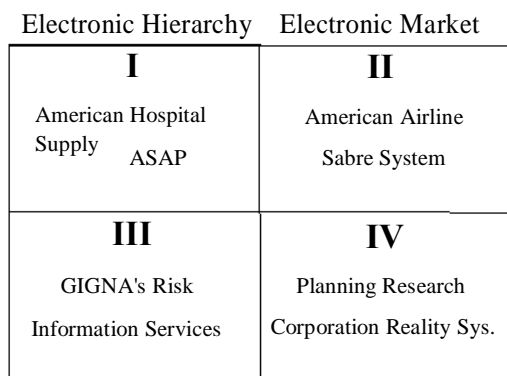

Figure 1. IOS evolution (adopted from Benjamin, 1990)

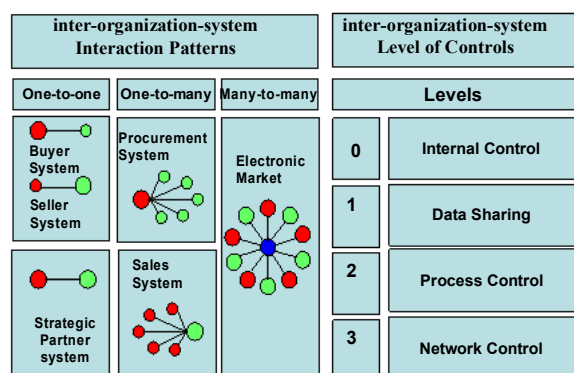

Figure 2. IOS Interaction Patterns and Level of Controls (Adopted from Applegate et al, 1996)

### 3. DEVELOPING A B2B E-COMMERCE EVOLUTION MODEL

This paper try to develop an evolution model by integrated the frame work created by Benjamin and Applegate et al., (Figure 3). The cases of America Airline (AA) and America Hospital Supplier Company (AHSC) were marked in the model to illustrate the path of 'evolution.' Both the AA and AHSC cases showed the IOS evolution started from Data sharing/Transaction processing to Network Control/Collaboration in the Control Level, and from one-to-one/electronic hierarchy to many-to-many/ e-marketplace.

This evolution model were tested and confirmed by over 100 cases study in seven different industries including grocery (30 companies), costume and accessories (8

companies), electronic (20 companies), books (14 companies), pharmaceuticals and cosmetics(12 companies), logistics(10 companies) and tourist(7 companies) industries. With the support from the Information Service Industry Association of Taiwan, a team of researchers and practitioners investigated the comprehensive files of over 100 firms that implement their B2B/IOS with their business partners during the period of three years from 2002 to 2004. The results confirmed the development of IOS in different industry do follow the similar path as AA and AHSC. The cases of Electronic, Books and Grocery are presented in Figure 4.

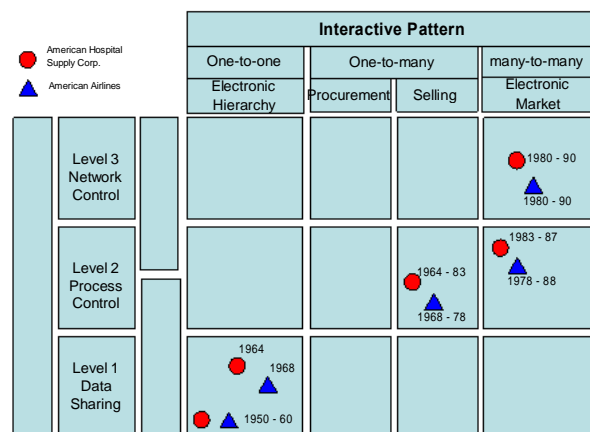

Figure 3. IOS evolution progress (the cases of America Airline and AHSC)

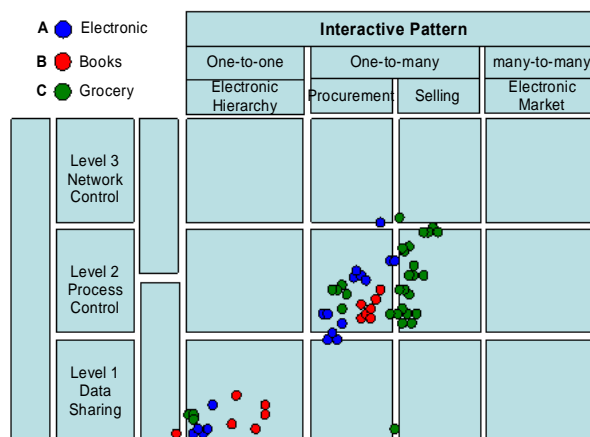

Figure 4. IOS evolution progress (the samples of three industries in Taiwan)

Although the progresses of IOS/B2B system development are different between different companies, there seems to be some similarities in the same industry. The overall maturity of e-business development in electronic industry and grocery industry are better than the books in average. In order to understand the reasons of these similarities, the researchers need to further explore the business partnership structures and the readiness of B2B e-commerce in different industries. According to the documents provided by the Information Service Industry Association of Taiwan, the researchers can investigate the important connections

between B2B e-commerce development and industry value chains. Over 100 copies of business plan and system implementation documents were reviewed and categorized. Five patents of business partnership structures and the path of e-marketplace evolution were found. Those five business partnership patterns— which were named as central competition, cross competition, intermediary dependant, crisscross and proprietary (figure 5); reflect the power structures in the supply chain of different industries. How are these different power structures effect the B2B e-commerce development in different industries? Lots of academic research mentioned many factors that might impact the success of B2B e-commerce. Could we find out the connections between those influence factors and the B2B e-commerce evolution?

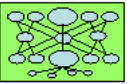

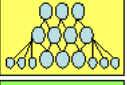

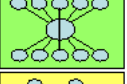

Type	Structure	Industry	Characteristics
Central Competition		Food? Grocery Retailing	Fewer leading companies with competition, each Competitor owns strong power in the Supply chain.
Cross Competition		3C (Electronics)	Many leading companies, each Competitor owns their channels and no one can control the supply chain.
Intermediary Dependant		Books	No leading companies in the retailing channels and suppliers Intermediaries owns the power to integrate the supply chain
Crisscross		Travel/tourist Logistics	Most of the leading companies are competitor and partner to each other. It's very difficult to integrate the supply chain.
Proprietary		Cosmetic Pharmaceuticals Costume	The branded leading companies Control the market and own their proprietary channels,

Figure 5. Patten of Industry Business Partnership

#### 4. EFFECT FACTORS OF THE EVOLUTION

In order to explore the factors effected e-marketplace evolution, this paper summarized the possible impact factors based on 'Transaction cost theory', 'Resource dependent theory', 'Institution theory', and the 'Contextual Influences' which were highlighted as three levels in previous study – socio-cultural, national/regional, and structural (Hsiao and Ming, 2002) (3).

All the factors and their related articles and the theory based are listed in table 1.

Table 1 Factors that Effect IOS/B2B e-commerce

Theory	Reference
Transaction Cost Theory	
Transaction cost	Dietrich (1994) (11) Mahoney (1992) (12)
Uncertainty	Robertson and Gatignon (1998) (13)
Dependence	Barney(1990) (14) Williamson(1988) (15) Anderson and Narus (1990) (16) Zaheer and Venkatraman

	(1994) (17)
Resource Dependent Theory	
Dependent	Emerson(1962) (18) Pferffer&Salancik(1978) (19)
Asset Specificity	Sengupta, Krapfel and Pusateri (1997) (20) Zaheer and Venkatraman (1994)(17)
Institution Theory	
Coercive	DiMaggio&Powell(1983) (21) Forgarty(1992) (22)
Mimetic	DiMaggio&Powell(1983) (21) Forgarty(1992)(22)? Galashiewicz (1985)(23)
Normative	DiMaggio &Powell(1983) (21) Lachman & Aranya (1986) (24)
Contextual Influences	
National/Regional	Avgerou (2001) (25) Hsiao and Ming (2002) (3)
Socio-cultural	Kumar( 1998) (26) Hsiao and Ming (2002) (3)
Structural	Markus & Soh( 2002) (4) Hsiao and Ming (2002) (3)

#### 5. DATA COLLECTION AND ANALYSIS

Based on the literature review and the summarized factors listed in table1, the questionnaires were developed to find out the possible factors effect the B2B e-commerce development in Taiwan. Due to the cost and time constrains, the survey is just for the electronic industry in the first stage. Data were collected from the list of class-A members of 'Taiwan Taiwan Electric and Electronic Manufacturers' Association.'and mailed to 980 firms between February 2004 and April 2004. There are 178 valid questionnaires were received and investigated.

Simple bi-variable associations among the collected variables reported as Spearman rank-order correlation coefficients. Factor analysis was used to describe the interrelationships of multiple variables. This kind of analysis is a multivariable analytic technique that users variable( with unknown correlations) to create a new set of variables called 'factors'( Sharma 1996) (27).

Examining the correlation among the studied factors revealed that there was significant overlap among various subgroups of factors. Next, with factor analysis it was possible to investigate the number of various subgroups and to identify what these subgroups represent conceptually.

There are fifty-four items in questionnaires and high

correlations among many of these items were observed, suggesting the appropriateness of data reduction techniques. To reduce variables, we began our investigation with the use of principal components analysis followed by varimax rotation for the thirteen indicators.

On 'Transaction cost theory', the factor analysis provided four factors with eigenvalues than 1.00( 4.46, 2.11, 1.38, 1.10) . These four factors explained 64.64% of total variance. On 'Resource dependent theory', the factor analysis provided four factors with eigenvalues than 1.00( 4.94, 2.08 ,1.27) . These three factors explained 55.23% of total variance. On 'Institution theory', the factor analysis provided two factors with eigenvalues than 1.00( 3.56, 1.13) . These two factors explained 66.92% of total variance. On 'Contextual Influences', the factor analysis provided three factors with eigenvalues than 1.00( 4.17, 1.95, 1.56) . These three factors explained 64.08% of total variance. On 'Electronic Integration performance', the factor provide one factors with eigenvalues than 1.00( 5.05) . This factor explained 63.15% of total variance.

Table 2 lists the alpha coefficients for the factor as well as the predicted alpha coefficients except 'Technological replacement'. Therefore, the below results suggest that the 'Technological replacement' factor that low homogeneous were deleted. On this background, it seemed appropriate to extract twelve factors in the present study.

Table 2 Alpha Coefficients

Factor	Alpha	Factor items
<b>Transaction Cost Theory</b>		
Dependence	0.782	5
Technological replacement	0.375	5
Transaction cost	0.778	3
Uncertainty	N/A	1
<b>Resource Dependent Theory</b>		
Resource dependent	0.794	6
Asset Specificity	0.806	7
Business Dependent	0.585	2
<b>Institution theory</b>		
Normative& Mimetic	0.791	4
Coercive	0.813	3
<b>Contextual Influences</b>		
National/regional	0.861	6
Socio-cultural	0.820	3
Structural	0.696	3
<b>Electronic Integration Performance</b>		
Integration performance	0.916	8

A further application of factor analysis uses the factors in a regression analysis. The regression coefficients obtained hereby would be more stable than the regression coefficients in the original variables. The eleven factors given above were independent in the

regression model and Electronic Integration performance was dependent. Eleven factors explained 51.8% of the variability in data. Resource dependent, Business Dependent, Normative and Mimetic, Coercive, national and structural were significantly. The results are shown in Table 3.

Table 3 Regression Analysis

## 6. CONCLUSIONS

The data analysis result suggested that factors of institutionalization effect may be one of the most significant impact dimensions of B2B e-marketplace evolution. This result explains the difference of e-commerce development in seven industries. The stronger of the power structure in business partnership, the easier for the leading companies to integrate the industry value chain. Coercive, Mimetic and Normative of institutionalization effect will make the firms of the same industry reach the similar status in the B2B e-commerce.

Figure 6. B2B e-Commerce Evolution Progress (The Samples of Seven Industries in Taiwan)

The evolution model was modified to reflect the environment factors that might impact the adoption of B2B e-commerce. The final three dimensions model indicates that the objectives, the control levels and the maturity of the B2B e-commerce will differentiate the status of B2B e-commerce in different companies and different industries. The summary of the seven

industries position in the e-marketplace evolution is presented in figure 6.

## Digital Divide: Adoption of Internet in China

Kanliang Wang, Qing Liu

The School of Management, Xi'an Jiaotong University, Xi'an 710049, China  
klwang@mail.xjtu.edu.cn

### ABSTRACT

With the development of information and communications technology (ICTs), Internet has been one of the major driving forces of the new economy. Nevertheless, access to the new technology remains extremely unequally distributed across and within societies, and there have a good deal of popular discussions about this "digital divide" in academia and business communities of every society. This study provides empirical evidence on China's Internet development and diffusion in recent years. Findings show that there is a clear digital divide among the nation's three economic zones, and while the growth rate for new Internet users is accelerating and the infrastructure of network is improving, the digital divide is growing narrower. In addition, by undertaking a set of regression analysis, the paper also finds that income and education play a critical role in shaping the divide. Based on the result, the paper offers some related policy suggestions to promote a wider diffusion of internet in poorer regions.

**Keywords:** Digital divide, Internet, Gini coefficient

### 1. INTRODUCTION

Information technology is changing the way people communicate, learn and work, and the competitive advantage enjoyed by those having Internet access is becoming increasingly obvious. However, not everyone has access to this technology. The idea of the "digital divide" that put forward by NTIA firstly refers to the growing gap between those who have access to computers or Internet and those who have not access, ranging from the global level, to nation states, to communities, and to individuals [1]. Though these applications have some common features, there are differences on the response of policy and the composition of stakeholders.

Digital divide has been a continuing buzzword in public discourse and international agendas after it had been put forward. However, existing studies have largely been confined to the boundaries of national states. The explosive growth of information and communications technologies (ICTs) in recent years, particularly the rise of Internet and its related applications, has created unprecedented opportunities, but also created threats for developing countries. From the opportunity aspect, some believe that ICTs will be a lever that may advance developing countries to enter into "leapfrogging" seedtime. This perspective is in line with Barlow's (1998) comment that Africa should skip industrialism entirely and leap directly into the information era [2]. This conclusion is shared by Hudson (2001) who suggests that the potential for "leapfrogging" lies in the use of wireless communication technology [3]. Nevertheless, According to Braga (1998), some believe that ICTs have and will contribute to even wider economic divergence between developing and developed countries [4]. This view is consistent with Brown's (2001) argument that there is still a lot of skepticism with regard to whether ICTs can reduce poverty in the developing countries [5]. This idea is also evident in Chowdhury (2000) that some skeptics

still do not see any positive role of ICTs in poverty alleviation. In his words, "the poor can't eat high-speed Internet access, of course" [6]. Opportunity may be outweighed by considerable threat arising from their second-mover position on the adoption of new technologies. Therefore, it is more difficult for an entire nation to leapfrog other nations technologically because of the infrastructure and human capital bottleneck [7]. What most important is that the developed countries have an advantage of exploring new technologies. While the developing countries learn, assimilate and understand original technologies, the developed countries have already applied the advanced ones. Therefore, there is a widening digital divide between the developed countries and the developing countries.

Research on Internet diffusion is accompanied by the evolution of Internet itself. With the increasing use of Internet in developed countries, research about its applications has been on the rise. Most studies have taken place in OECD countries, especially the US, Japan and Western European countries. The Department of Commerce's National Telecommunication and Information Administration's reports, generally entitled Falling Through the Net, have been the primary and most consistent way to track computer ownership and network access across broad demographic categories over a relatively long period of time (since 1995) [1]. Even though there is a deeper and wider digital divide, little research has paid attention to how Internet access and use fit into everyday life in developing countries, such as India and countries in Africa [8, 9]. These studies suggest that digital divide has been one of the leading economic and civil rights issues, and call for government action to ensure that all people are able to enjoy the competitive advantages gained by Internet participation.

Widespread diffusion does not imply ubiquity, even within developed countries. Digital divide appeared at the very start of Internet [10]. There is the same

challenge in China too. Adoption and development of ICTs drives the development of new economy in China. Meanwhile, there has always been great regional variation in three zones: the eastern, the central and the western zones [11]. From 1990 to 2002, the percent of GDP of the eastern zones contributed to the nation increased from 51.5% to 57.86%. But this percentage in the central and the western zones decreased 3.14% and 3.23% respectively. GDP of the eastern zones was 2.0 and 2.6 times than that of the central and the western zones in 2002 respectively. The Gini coefficient in China, the important index measuring the income inequality, reached 0.41 in 2000, which was well beyond the normal level. These indicate the increase of regional gap in economic development. Moreover, the number of Internet users in the eastern zones was 1.95 and 3.03 times than that of the central and the western zones respectively in 2003. There are some studies on digital divide in China at present. But most of them focus on the qualitative analysis [12, 13, 14]. In addition, there are also few studies on how Internet diffused in China [15]. Empirical researches on digital divide in China are scarce.

By undertaking a set of regression analysis on Internet-related data in China, this paper aims to analyze the status quo of Internet development and diffusion in China, and provides empirical evidence on the digital divide of Internet adoption across China. Moreover, it discloses the relation between the development of economy, education and Internet. These results may offer some implications to the policies that may bridge the digital divide.

## 2. RESEARCH QUESTIONS

At present, digital divide not only exists in the development of information technology, but also in the application of information technology. So, digital divide has multiple dimensions. This study focuses on the digital divides between users and non-users of Internet in China.

Early characterizations of the divide singled out income and educational attainment as correlating strongly to computer and network access [16]. Thus, although there are strong relations between income and education in this early data (one-third of the income gap can be attributed to education), education (and other variables) cannot completely account for the fact that the wealthy own more computers and have greater access to computer networks than the poor. Income and education considered as separate variables are significant contributors to the access. Among OECD countries, the digital divide between high income households and low income households varies from country to country, ranging from a gap of more than 60% in the UK to less than 20% in Denmark [10]. With respect to the NTIA's historical concerns, the effects of income and education still exist as well: the better educated and compensated

far outpace those of alternate class positions. Thus income and education continue to be the variables that correlate most strongly with Internet access and computer ownership [17]. Whether there is similar relation between these two factors and Internet digital divide of China is an important factor in formulating related policy to solve the problem.

China accesses firstly Internet by its CSTNET at April 1994, which has been a great development in recent years. By reports on Internet development in China (CNNIC, 2004), the number of Internet users is more than 79.5 million, and the number of computers that can access Internet is more than 30.89 million. However, there is serious regional inequality on development and diffuse of Internet. Recent report shows that the number of Web sites in three regions (eastern China, northern China and Southern China) is 90% of all sites across China. The digital divide is widening the gap of among these regions, which could bring serious social problems. Some domestic studies find that there is a regional digital divide. There are great differences in Internet host and Internet users among these regions. In general, the number of Internet users in the rich regions is far excess that of the poor regions [13]. But to what extent is the gap in Internet?

Computer and Internet use at home and work are increasing rapidly, but there is disagreement on whether access is increasing among all groups at similar rates. One analysis suggested that the divide may shrink in the near future because the number of computer users with lower incomes is increasing more rapidly than the total number of computer users overall [18]. In addition, Howard (2001) noticed the dynamics of digital divides, and he agreed that infrastructural access gaps are narrowing, though narrowing in unequal ways [19]. However, other researches have found that the digital divide also continues to grow at an alarming rate. On the one hand, the connected ones - such as those with higher income and better education - are adopting newer technologies faster and are connecting even more. On the other hand, groups with limited Internet and computer access continue to lag far behind [20]. One study concluded that these digital divides are increasing even after taking into account that "adoption of new technologies tends to be fairly slow at low penetration levels, faster thereafter and slower again as it reaches saturation" [18]. Then what direction does the digital divide of Internet adoption in China changed in several years ahead?

Based on above discussion, this paper aims to investigate the following questions:

- Is there any relation between the number of Internet users and the levels of income and education across different regions in China?
- To what extent are there digital divides in Internet adoption among three zones: the eastern, the central and the western zones?

- ° What direction will the digital divide in Internet adoption change across different regions?

### 3. METHOD

#### 3.1 Sample

The data summarized here emerged from all survey reports on Internet development in China published by CNNIC [21]. In addition, the study refers to relevant data in China Statistical Yearbook and Regional Statistical Yearly Report (2004) [22, 23]. The object of the study includes 31 provinces or regions of mainland China. Thus analysis is done on two aspects: one is the relation between income, education and digital divide across different regions of China, another is the status quo and the trend of the digital divide origins from inequitable diffuse of Internet.

#### 3.2 Variables

As the dependent variable, the digital divide on adoption of Internet is measured by the number of Internet users. According to CNNIC, Internet users include Chinese who accessed Internet for at least one hour per week in average. Income, as an independent variable, is measured by a common index, which is GDP per capita [24]. As another independent variable, education was measured by the number of primary, secondary and tertiary students [24], but these three types of students have a strong relation. It was also measured by the number of people who own senior secondary education [15], but it doesn't take into account of the fluidity of them. To avoid these problems, this paper measures education by the number of student enrolled at colleges and universities. To some extent, the index reflects the level of education in a region.

### 4. MODEL AND FINDINGS

#### 4.1 The relationship between income, education and Internet users

What relation is there between the number of Internet users and income, education across different regions in China? Simple regression results, as reported in Table 1, suggest the following.

Table 1. The relationship between income, education and Internet users

Variables	Internet users	Income	Education
Internet users	1		
Income	0.931**	1	
Education	0.876**	0.798**	1

Note. *Internet users* is measured by the number of Internet users per 1,000 people, *income* is measured by GDP per capita and *education* is measured by the number of student enrolled at colleges and universities. All data is calculated by a natural logarithm scale.

\*\* Statistical significance at the 1% level.

Figure 1. Internet user density and GDP per capita in 23 regions, 2002

Data source: *China Statistical Yearbook and Report on Internet Development in China (2003)*

We observed that the number of Internet users is still highly correlated with income and education. Income is the primary factor influencing the access and adoption of Internet, which possibly origin from the inequality of regional economy development (see Fig. 1). In addition, the level of education has a strong relation with the number of Internet users (87.6%), which can be attributed to two reasons. Firstly, education contributes directly towards basic literacy, and reading and writing skills are essential in using this technology. Well-educated people are also likely to be faster to adopt new innovations than people with little education. Secondly, given that the early users of Internet were people working in higher education and research, academic institutions may play an important role in spreading Internet. They are often among the first institutions in a nation to be wired. Moreover, there is a tight relation between income and education (coefficient is 0.798). The result has a little difference with prior conclusion [15], for the reason of the difference of index to measure education.

#### 4.2 Extent of digital divide

In order to measure extent of the digital divide in Internet adoption among three zones: the eastern, the central and the western zones, the number of Internet users of every region in China for the years 1997-2003 were analyzed. Table 2 summarizes the number of Internet users per 1,000 people for this period in different regions. It shows that there is a clear digital divide in Internet adoption among these three zones, though the adoption of Internet in the central and the western zones has been developing quickly from years 1997-2003. In 2003, the number of Internet users per 1,000 people in the central and the western zones was 1/3 of that in the eastern zones.

Moreover, the increase rate of Internet adoption in the western zones has been higher than that in eastern zones since year 2000, which is highest among three zones. The result maybe attributed to two reasons. One is the support of the central government policy. The central government released the Western China Development policy, which had a great promotion to information infrastructure development. Secondly, there was a great development in western economy. It brought more people to access the new technology.

Table 2. Internet users per capita 1,000 people by zones, 1997-2003

	Eastern	Central	Western
1997	3.05	0.37	0.18
1998	6.10	0.71	0.66
1999	27.71	3.26	2.53
2000	48.44	11.68	11.31
2001	70.25	17.11	15.26
2002	100.19	34.45	31.13
2003	123.65	42.63	45.53

Data source: *China Statistical Yearbook* (1998-2003), *China Regional Statistical Yearly Report* (2004) and *Report on Internet Development in China* (1997-2004)

Fig.2 characterizes the changing status of Internet users per capita in the three zones. It shows that the adoption of Internet is nearly similar between the central and the western zones, but there is a great gap by comparing with that of the eastern zones, and the gap is widening along with time. Therefore, there is a trend that the digital divide on the adoption of Internet is widening.

Figure 2. The difference of Internet users between three zones, 1997-2003

#### 4.3 Trend of digital divide

Because there is a gap in regional economy and education, the adoption of Internet has been developing unevenly. With government's regulating the policies of IT, whether the digital divide of regional unequal development is narrowing? By comparing two or more figures, or columns of figures, it can see which one is greater or lower. For example figures for the eastern zones can be compared with that of the central and the western zones to see which one is greater or lower. This is the easiest way to look at disparities. It is a simple way that every one interested can work out and get a feeling

of the level of disparity between different zones. However, it is crude, and may not tell us much. At times it is not possible to scan through all the figures at a time. This section utilizes Gini coefficient to measure the digital divide across regions. Gini coefficient can quantify the level of inequality.

Figure 3. The calculation of Gini coefficient, 2003

The Gini coefficient is based on the Lorenz curve, a cumulative frequency curve that compares the distribution of a specific variable with the uniform distribution that represents equality (See Fig. 3). This equality distribution is represented by a diagonal line, and the greater the deviation of the Lorenz curve from this line, the greater the inequality [25]. In general, scientists still use this coefficient to measure the level of wealth distribution between nations, income between households, health among community etc. When applying this index to Internet variables, the cumulative proportion of the population is generally shown on the X axis, and the cumulative proportion of Internet users on the Y axis. The greater the distance from the diagonal line, the greater the inequality.

The Gini Coefficient ranges from 0 to 1, 0 representing perfect equality and 1 total inequality. It corresponds to twice the area between the Lorenz curve and the diagonal. There are different methods to calculate the Gini Coefficient, but a simple formula, shown below, was provided by Brown (1994) [26].

$$Gini = 1 - \sum_{i=0}^{k-1} (Y_{i+1} + Y_i)(X_{i+1} + X_i)$$

where, Y=cumulated proportion of Internet variable;  
X=cumulated proportion of the population variable.

Table 3 summarizes the Gini coefficients of Internet for years 1997-2003. Generally, Gini coefficient of Internet has been decreasing. Internet Gini coefficient is 0.422 in 1997, which is twice of that in 2003. It indicates that there was a serious inequality in early period of Internet development. There was a wide decrease from 1999 to 2000. It should benefit from the government policies and intervention of venture capital. Since then, Internet has served Chinese people and enterprises really.

Table 3 Internet Gini coefficients in China, 1997-2003

Year	1997	1998	1999	2000
Gini coefficient	0.422	0.438	0.412	0.289
Year	2001	2002	2003	
Gini coefficient	0.293	0.248	0.215	

Data source: *China Statistical Yearbook* (1998-2003), *China Regional Statistical Yearly Report* (2004) and *Report on Internet Development in China* (1997-2004)

Figure 4. The trend of Gini coefficients in China, 1997-2003

Fig. 4 is based on data of Table 3. It shows that the digital divide on adoption of Internet is narrowing across regions for years 1997-2003.

## 5. BRIDGE THE DIGITAL DIVIDE

For any nation, the adoption of information technology doesn't stop its steps because of the lagger. The digital divide can be seen as both a symptom and a cause of underlying disparities in society. So whether the digital divide can be bridged quickly and effectively relate to sustainable development of a society, and this requests nation and local government to make great efforts. In this section, some policy suggestions for bridging the digital divide are proposed

### 5.1 Expediting establishment of info infra-structure

For a region to succeed in Internet area, information infrastructure plays a critical role. That is to say, establishment of information infrastructure is a basis for bridging the digital divide. Government plays an important role in creating such infrastructure, especially in the poorer regions. This role stems from a number of important considerations. First, in very poor regions, the market forces may be weak both because of lack of effective demand and because of lumpiness of investment. Second, in order to attract the private sector to invest in information infrastructure, government may have to play the role of a catalyst by instituting various innovative incentive mechanisms such as build-own-operate, build-own-transfer, etc. Finally, government opens its market to foreign investors, which can speed up transfer of technology and encourages investments on Internet infrastructure. Bridging the digital divide between the eastern and the western zones requires that the establishment of information infrastructure such as computer network and

communication links be expedited. Government should take network as a public establishment. They should offer more chance to access Internet and knowledge about IT for the public. In addition, the establishment of information infrastructure should be an important component of Western China Development Strategy. This can promote the popularization and development of Internet in the western zones.

### 5.2 Increasing investment in education

As above analysis suggests, the relationship between education and Internet is critical. Education is important because it provides basic skills required for creating, adapting, and utilizing such technologies. This is not to deny that even illiterate or near-literate can possibly take advantage of certain technological applications. But to go beyond elementary applications, education becomes increasingly important. Indeed, international evidence suggests that education is a strong complement, especially secondary and higher education. Therefore, if a region aspires to exploit in significant ways the opportunities offered by Internet, the creation of new industries in particular, it needs to emphasize secondary and higher education.

By the Report on Internet Development in China (CNNIC, 2004), those who have education level below senior secondary education is 13.5% of all Internet users [21]. It indicates that higher education basically provides trainings of Internet skills to students in China, but not for people below senior secondary education. There are two possible ways to deal with it. First, while developing higher education, government should pay much attention to Internet education for primary and secondary schools; Second, in addition to formal education, a rapidly changing technology like Internet would require continuous training on the part of the workforce. However, the government can also play an important role in inducing firms to impart such training through various types of tax incentives.

### 5.3 Reducing cost

Many countries in the world concern the problem of digital divide, and make every people take the advantage of IT by improving IT, infrastructures and service actively. In China, expense of accessing Internet is too high, which is a bottleneck hampering the popularization of Internet. Though the charge is lower than some developed countries in the world, but considering the level of income, the rate of network expenses to income is much higher, which restrict the diffusion of Internet. So government should develop leasing and low-cost purchasing schemes, and coordinate, develop and identify a range of low-cost technical solutions to Internet access provision, particularly in poorer regions. This would help to reduce the number of people who perceive Internet as unaffordable and increase the effectiveness of using limited resources. Moreover,

government should reduce cost of accessing network by continuing to develop a national infrastructure of low-cost or free access points in under-served regions. Income is one of most important factors affecting the digital divide. The reduced cost of Internet access may attribute to income increase. So reducing cost is one of essential measures to bridge the digital divide.

#### 5.4 Fostering favorable environment

Although the rapid development of Internet requires an open and competitive market, China still maintain strong barriers against entry in this market. The entry barrier, along with the heavy government involvement in such ICT-related sectors as telephones, has spawned pervasive corruption in many regions and has raised the cost of communication. It results in difficult access to Internet. Therefore, to bridge the digital divide and promote the adoption of Internet, government must foster a favorable environment. Open and competitive market is essential, which can ensure enterprises to take part in the establishment of information infrastructure, including private enterprises and foreign enterprises. This can decrease the pressure of government. In addition, governments in poorer countries should foster an environment that would encourage innovation through research and development. It may be noted that developed countries that have established their lead in Internet have invested heavily in R&D activities. With fiscal incentives and proper enforcement of property rights, the private sector would have the impetus to engage in R&D activities. However, in areas where the market fails, particularly in basic research, government should take the lead. Aside from direct investments in R&D, government can encourage linkages between universities and Internet industry in technology transfer.

#### 5.5 Cooperation between government, enterprise and community

In addition to regional efforts, national and international organizations can play a role in promoting Internet in poorer region. It is essential that regional government cooperate with enterprises and society in the establishment of information infrastructure. First, sector of telecommunication in China is generally regulated by government. It is difficult for international organizations to enter into the industry without admission. So central and regional governments should issue deregulation policies gradually, which ensure enterprises free entry of the private sector, including foreign firms. These firms can support a specific set of policy initiatives to bridge the digital divide through technical assistance and policy advice, such as free ISP. Second, regional governments should attract enterprises, multinational companies and venture capital, which is likely to be critical in the growth of the local Internet access. Governments can offer the necessary financial assistance to them.

Moreover, if governments in poor regions channel their

scarce financial and political resources to developing social and human capital, building the basic infrastructure and creating a proper playing field for the private sector, Internet access will flourish and digital divide will diminish. Thus, notwithstanding the concerns voiced on the perils of being left behind in this digital age, poor regions should carefully balance the resource conflict of adopting modern technology and economic development.

### 6. CONCLUSION

The ability to access internet has become increasingly important to completely immerse oneself in the economic, political, and social aspects of the world. The digital divide is arguably an indicator of deeper divides within society. It can be seen as both a symptom and a cause of underlying disparities in society. This paper investigates the adoption of Internet across different regions in China. The Gini coefficient is calculated using data on Internet users per capita for the years 1997-2003. The basic finding is that there is a clear digital divide about Internet adoption across regions, and the divide has grown narrower. In contrast with some earlier findings (Bikson, 1999; Besser, 2001), these access gaps are narrowing [18, 19]. This paper also finds that the divide is still highly correlated to income and education, the conclusion is consistent with early result (Grabill, 2003) [17]. Based on this analysis, the paper also offers some policy suggestions as to how to promote a wider diffusion of Internet in poorer societies.

There are at least two important avenues for future researches. One avenue is to analyze the factors affecting the adoption of Internet except for income and education, such as cost and race etc. This will help to understand the digital divide deeply. Another avenue is to study in greater detail the adoption of the cluster of Internet-related technologies, because digital divides on other technological aspects have an important effect on society.

### ACKNOWLEDGEMENT

The research was partly supported by the National Natural Science Foundation of China (grant number 70121001 and 70372049) and 211 project.

# E-business and Organizational Learning: A Case Study of Three Globally Operating Companies

**Marjatta Maula**

Institute of Business Information Management, Tampere University of Technology, Tampere, Finland  
marjatta.maula@tut.fi

## ABSTRACT

This paper analyzes how the web-based e-business solutions of three globally operating companies have served their organizational learning. The case companies represent metal and mining, pulp and paper machinery and pharmaceuticals industries. It can be concluded that while the e-business solutions may have been part of larger strategic development process, they were not originally designed to serve organizational learning. During the utilization phase, the learning opportunities had remained quite low or underutilized. However, all case companies had learned considerably as a by-product especially during the design and implementation phase. The study indicates that e-business solutions provide plenty of learning potential that should be taken into account in the design, implementation and utilization phases.

**Keywords:** e-Business, organizational learning, knowledge management, knowledge creation.

## 1. INTRODUCTION

Web-based e-business solutions enable efficient and intensive interaction with customers. They make possible to create personalized contents and various methods for producing, exchanging and collecting information. They help organization to reach its customers across time zones and geographic boundaries. These technologies also enable profitable solutions for a limited number of big customer firms, or for an unlimited number of individuals all over the world. The major motivation for firms to implement e-business solutions is to increase efficiency and service capability and to enable new kinds of business processes. It could also be assumed that web-based e-business solutions are used to facilitate organizational learning, knowledge creation and renewal that are increasingly important aspects for the firms' competitiveness. Firms could learn from their customers and markets by using information and knowledge that can be channeled through e-business solutions (Skyrme, 2001). However, it is not clear what are firms' real motivations, opportunities and methods to utilize e-business solutions for learning purposes. For this reason the research project "Strategic Management of Innovativeness, Renewal Capability and Knowledge, and the Role of e-Business" was established to study through selected case studies the following research question: "*How does a company learn and create new knowledge by utilizing e-business solutions?*" The purpose of the study was to create new knowledge and to facilitate learning from their experiences.

## 2. THEORETICAL APPROACH

The theoretical framework consists of an interpretation of the theory of self-producing systems (autopoiesis theory; Maturana and Varela, 1980;

Mingers, 1995). The interpretation, living composition<sup>®</sup>, emphasizes the role of 'boundary elements'. They consist of various roles, functions and systems that enable the firm's interaction with its business environment, help to absorb and create knowledge, and facilitate organizational change, learning and co-evolution with the business environment (Maula, 2000). The web-based e-business solutions are studied here as such organizational boundary elements.

## 3. EMPIRICAL APPROACH: WEB-BASED BOUNDARY ELEMENTS IN THREE CASE COMPANIES

The empirical part of the study was conducted in 2001-2003 in three globally operating case companies that were selected among internationally recognized frontrunners in the strategic application of e-business:

- Outokumpu Copper Products OCP Europe – EPC Electrical Power and Components Unit.
- Metso Paper
- A pharmaceuticals company.

The three companies differ considerably from each other in their e-business solutions.

### 3.1 Outokumpu Copper Products OCP Europe – EPC Electrical Power and Components Unit

The core businesses of *Outokumpu Group* are stainless steel, copper products and technology. The company has customers in a wide range of industries: catering and households, building and construction, transportation, industrial machinery and equipment and electronics and communication. The company has 19,000 people in more than 40 countries. The Group's net sales is EUR 6 billion. *Outokumpu Copper* is one of the core businesses. Its net sales

cover 26% of the Group's sales. Outokumpu Copper is the second largest producer in the world in fabricated copper products. The company employs 7,600 people. It has production plants in 15 countries. The products include anodes, brass rod, profiles, rods & bars, sheets & plates, strips, tubes, welding products and wire. *EPC Electrical Power and Components Business Line* employs 400 people. It has 6 production plants in Finland, England and Austria.

*EPC Electrical Power and Components Business Line* has created a business-to-business extranet solution for its selected customers. Customer relationships are based on long-term contracts, and interaction with them is complex in nature. EPC Business Line started in 1995 to implement the New Sales Mode solution that included a salesman tool box and back office tools. Based on the experiences and new technological and business opportunities the company started in 1998 the development of the New Sales Mode Web (NSMWeb). The objective was to develop a Key Customer Relationship Management and Service System. The development of NSMWeb was a rapid process. It was part of a profitability development program and strategic masterplan that included both strategy specification and operational improvement. It was based on an analysis of the customer contacts and the work of sales persons.

One of the points of departure for the NSMWeb development was the general development of marketing in Outokumpu Group. It meant a change from production oriented to sales oriented and further on to customer oriented marketing methods. Moreover, at EPC the strategy was specified (vision remained the same) and operative systems, such as order/delivery process, were developed simultaneously. Customer management had high priority, and the sales processes were to be reorganized. The e-business solution was built on existing technology (Lotus Notes) and databases. It was to provide "bullet proof reliability" and improve the image of the firm.

The solution enabled the design of customized business processes. The objectives of the solution was the inquiry & order management for selected key customers. The purpose was to create tailored services and to generalize them later. The development occurred in intensive co-operation between the producer and customer and it aimed at win-win solutions and learning.

One of the major objectives included the transformation of routine sales work into technical services. As a result the roles of the salespersons were radically changed into expert role, and they were supported by NSMWeb solution and incentive bonus plans. The sales work, customer contacts and

acquisition of new customers covered earlier only 20 % of the time of the sales persons. The objective was to increase it up to 60-70 % of their time, and the solution reached quite successfully these objectives.

The development of the NSMWeb solution helped to understand the real needs of the customers especially during the design and implementation phase. EPC could intensify the discussion with the customers, which evoked ideas of new services and products, and new methods to speed up the deliveries. It improved the communication with the customers and made it deeper.

The new roles of the salespersons and the web-based solution constitute thus two kinds of boundary elements that have strengthened customer relationships and enabled efficient order management and integration to scheduling and manufacturing. They also improve customer service, knowledge management, and learning and renewal capability of the firm. The new role definition and NSMWeb solution are examples of boundary elements that help to manage internal and external complexity better. NSMWeb was later developed into the One Common Application.

### 3.2 Metso Paper

Metso Paper is a business area of Metso Corporation that is a global supplier of process-industry machinery and systems, know-how and aftermarket services. Metso has business operations in more than fifty countries. In 2002, it had 17 technology centers, 30 manufacturing units, 32 service centers and 25 sales subsidiaries. With corporate net sales in 2002 of 4.7 billion euros, Metso had approximately 30,000 employees.

*Metso Corporation* has as its strategic objective the transformation of the corporation into a networked and knowledge-based technology company. *Life cycle technology*, enabled by the Metso Future Care business concept, forms a central part of this strategy. Life-cycle technology is an umbrella term for RTD (research and technological development) projects based on process life cycle knowledge. It aims to improve the customers' profitability by managing the product life cycles and product-related knowledge. *Metso Future Care* provides a powerful framework for corporate-wide knowledge management and organizational learning. It is a business concept for creating new market potential. It aims at creating new ways of managing customer relationships and developing earnings logic by exploiting previously installed machines and delivered processes to add to the competitiveness of the customer. Over the years, Metso has marketed to its customers 2,000 paper machines, 800 pulp systems, 30,000 crushers, 15,000 screens and 3,000 grinders. In 2002, the main focus

was on after-sales services, remote diagnostics in maintenance, support of the customers in preparing investments, and customer relationship management.

*Metso Paper* (fiber and paper technology) is the world's largest paper and tissue making line supplier. It covered 38 % of Metso's net sales in 2002. It also has a strong position as a supplier of pulping equipment and systems for the fiberboard and converting industries. In other words, Metso Paper designs and manufactures pulp and paper industry processes, machinery and equipment. Moreover, it provides expert services for developing customers' production processes. Metso Paper has several engineering and manufacturing locations and customers all over the world. Metso Paper's business lines include paper technology, pulping technology, and other businesses.

Metso's e-business solutions can be seen in a broader framework in which both interaction with customers and individual transactions form part of a corporate-wide strategy, customer-wide life-cycle and supplier-wide partnership. In-depth know-how concerning the customers' industrial core processes across the businesses, and the development of value-enhancing solutions necessitates an efficient reciprocal boundary (interface) between the customers and Metso. Specifically, the portals play a central role in organizational learning and knowledge management. The portals not only support internal and external users but also facilitate interaction with customers and suppliers.

*Metso Portal* is an extranet service that supports the businesses of pulp and paper industry customers. It is a coordinated Metso-wide project, providing an easy doorway to the services of Metso Paper, Metso Automation and Metso Drives through a single log-in. Metso Portal is not a marketplace, but rather enables interaction with the customers, complements other customer-contact channels, and provides a platform for new services. The portal service was started in 2001, and by the beginning of 2002 had over 400 customers using the service (Suvanto, 2002).

*PartnerWeb* is a tool for the engineering and manufacturing partner network, initiated by materials management. Technically, it utilizes Notes databases and web browsers. PartnerWeb provides several benefits. It improves the flow of information and allows the follow-up of delivery schedules. Engineering and manufacturing instructions are easier to update. PartnerWeb also improves the processing of revisions and claims. Process costs have been reduced at both ends, and document turn-around time has become shorter.

The new *remote diagnostics* centers in Finland, Sweden, and the USA serve pulp and paper industry customers globally. The remote diagnostics solution

involves monitoring, measuring and analyzing various aspects of the processes and machinery with ICT technology from a distance. Service is no longer bound by location. Remote diagnostics tools provide the following benefits: efficient utilization of expertise, reduced traveling, more efficient working time and screening of the essentials from the data.

Especially the portals have contributed to organizational learning and knowledge management at Metso Paper. The implementation phase has provided opportunities to learn about the customers. Also during the utilization phase they facilitate the accumulation, exchange and creation of knowledge. Information about the customers is collected in databases and utilized interactively by the customers and the corporation. Metso's portals help to develop new products, operations and market position. The PartnerWeb supports internal and external users and facilitates interaction with suppliers.

### 3.3 The Pharmaceutical Company

The Pharmaceutical Company is a globally operating healthcare company that manufactures and markets pharmaceutical products and services. The company has production facilities in almost ten countries, and affiliates or offices in about 70 countries. The Pharmaceutical Company reaches out to almost 200 countries around the world. The company has about 20,000 employees. It is a world leader in the care of one serious illness and also has a leading position in some other pharmaceutical product areas. The illness can occur at all ages and it is becoming increasingly common in developed and developing countries.

The company has implemented comprehensive web-based solutions that are centrally coordinated, locally maintained, and enable interactive communication between the company, consumers and professionals. Development of these solutions has resulted in much of the tacit knowledge becoming explicit. The e-business strategy of the company consists of three focus areas: (1) the websites for patient communities and professionals, (2) corporate communication, which covers the corporate site and all the affiliates, and (3) the websites concerning the products. The focus in this paper is on the first focus area. The web solutions have facilitated interaction with consumer and professional communities. Many parties outside the company have thus become more firmly involved in the learning processes and have gained the opportunity to improve their knowledge.

Although the content of the solutions is basically local, it is based on shared, centrally created structures and principles. The strong orientation towards localization allows for differences in culture and lifestyle, regulations, logistics, and other relevant aspects.

*The websites for patients and patient communities* are open to anyone in about 20 countries. They do not include any recommendations for the patients. Instead, they provide patients with tools to keep better track of their condition, such as 'Living with the illness' sites for sharing experiences, personal profiles, diary and scorecard for keeping track of the development of the person's own illness. All recommendations should come only from their own personal physician. The solution includes many kinds of applications that provide information for the patient. Examples of them are a library, dictionary (the medical words people don't understand), 'ask the experts' sites, an expert panel, a game for smaller children, and a jeopardy about the illness.

*The "Illness information for the professionals" website* is offered as a service from the company to health care professionals, such as physicians, nurses, pharmacists, and trainers. The site contains professional information and research, such as up-to-date medical information, educational resources, and the latest research in the illness. An editor reads through medical journals and creates a short calendar describing events and current debate within the field. An abstract database allows physicians to search in journals for abstracts. The site also includes praxis tools and a monthly newsletter co-edited by an in-house doctor, a medical advisor.

The Pharmaceutical Company is a knowledge-intensive company. The success of the company is based on the development and application of explicit scientific knowledge. However, also market knowledge and the understanding of the customer needs are important for the success of the firm. The development and maintenance of the websites have facilitated organizational learning in several ways on local and global levels. The development of the products occurs through a long and complex procedure overseen by R&D specialists. Through the web solutions, The Pharmaceutical Company has become more aware of its business environment and of many changes occurring within it. During the implementation of the web solutions, a large amount of knowledge that was previously in tacit form has now become explicit. This has facilitated organizational learning at the coordinating and local levels. For example, the creation of community sites has made the eBusiness Department and the affiliates more sensitive towards the different perspectives of the various customer groups and professionals, and of the cultural and regulatory differences.

The Pharmaceutical Company's web solutions also facilitate interaction within the consumer and professionals' communities, and promote their educational aim. These solutions have thus allowed The Pharmaceutical Company to reach many parties outside the company, to more tightly connect them to

the learning process, as well as provide these stakeholders with an opportunity to improve their knowledge. The websites serve as interactive boundary elements that help to distribute knowledge between the firm, user communities and professionals, as well as to monitor and collect information. The solutions facilitate the utilization of experts and opinion leaders within and outside the company.

The sites provide access to an extensive amount of data. However, the capability of the solution has not been fully utilized. Many regulations prevent the firm from using the information and knowledge produced by the system. Even that information which could be used within the confines of the regulations has not been very efficiently utilized. The legally available data has great potential as a source of organizational learning on global and local levels for market analysis, product development and other learning purposes. This potential has remained underutilized mainly due to the absence of a shared explicit framework or concept of organizational learning. Such a framework would help to coordinate various processes, knowledge resources and ICT systems to facilitate the learning process.

#### 4. COMPARISON AND SUMMARY

The results of the research project are summarized in Table 1 in the last page of this paper.

This paper analyzes how three globally operating companies have utilized their web-based e-business solutions for organizational learning. The case companies represent metal and mining, paper machinery and healthcare industries. All companies are among global market leaders in their industry. They differ from each other as to the type of customers (industrial, consumers) and their number (tens, hundreds, hundreds of thousands / millions). The solutions depend, for example, on the type and life-span of the product. In the metal industry company the sales is based on annual agreements with relatively few clients. Each individual sales activity of the products requires complex calculations and expertise. The e-business solutions are targeted to facilitate the sales process and to provide information about the products to the customers.

In the paper machinery company the products are very complex technical systems that may consist of hundreds of thousands of parts. The life-span of the product may cover tens of years. There is increasing need for faster design and delivery of the product and many kinds of services. The purpose of the e-business solution was to enable extended collaboration between the company and its customers and partners. The collaboration was enabled through a network centered around the case company as a business hub. Technically, the hub was based on the Internet and it

connected the customers' and partners' devices and solutions with the company's own systems and networks. Life-cycle thinking was developed on the corporate level to highlight the need for long-term partnerships, continual and accumulating learning, and the transformation of reactive services towards preventive and further to proactive type. The corporate Internet portals supported remote diagnostics, proactive services and integrated business solutions.

In the pharmaceuticals company the products are sold to millions of customers. However, the sales depend on various kinds of medical experts. The patients use the medicine daily, normally throughout their lifetime. The treatment of the illness requires education of the patients and experts. Because of many local legal restrictions that vary country by country the e-business solution cannot be used as a direct sales channel. Instead it is used mainly for education, for providing information and creating communities among patients and professionals. The solution is interactive, but the legal aspects restrict the storing, analysis and utilization of the data for learning purposes.

While the development of e-business solutions may have been part of a larger strategic development process, they were not originally designed to serve organizational learning and knowledge creation. The solutions targeted mainly to providing information to the customers, not to providing information about customers and market to the case companies. However, the study shows that web-based e-business solutions can create many opportunities for organizational learning. All three companies had learned considerably as a by-product. Learning had occurred mainly during the design and implementation phase because then the company was compelled to transform tacit knowledge about the products, company itself and the customers into explicit form and to share it within the company and among various partners. As to the utilization phase of the e-business solution, the learning opportunities had remained quite underutilized. Information that is channeled through the e-business system is used mainly for operational purposes. It is not consciously collected, analyzed and transformed into new organizational knowledge.

The study indicates two major aspects that could be taken into consideration. First, the emerging learning opportunities during the design and implementation phase could be utilized more consciously. In the case companies the learning occurred as a by-product. Second, the e-business solutions could be designed so

that they help to absorb new knowledge about the market and customers continually and to transform it into organizational learning, renewal and competitiveness.

## 5. BENEFITS OF THE RESEARCH PROJECT

The research project analyzes the role of e-business solutions from new angles, the ones of organizational learning, renewal and knowledge creation. These aspects have not been the main objectives for the firms when planning the solutions. The study also provides empirical evidence about boundary elements, and thereby helps to develop further the theoretical and methodological living composition<sup>®</sup> framework.

## **E-Business Evaluation in Australia: A Discussion Of Some Preliminary Findings**

**Mohini Singh, John Byrne**

School of Business Information Technology,  
RMIT University, GPO Box 2476V  
Melbourne 3001 Vic Australia  
mohini.singh@rmit.edu.au and john.byrne@rmit.edu.au

### **ABSTRACT**

This paper reports on research carried out into e-business evaluation in an Australian context. The main research instrument was a questionnaire based on a similar study in the United States, which was adapted to give an Australian dimension. The survey was sent to e-business managers in a random sample of Australian companies. The paper reports some preliminary results from the analysis of the survey data. The results identify the more important e-business drivers, transaction capabilities, impacts on financial performance and improvement; and problems experienced during implementation.

**Keywords:** E-business evaluation, B2B e-business, B2C e-business, e-business improvements, e-business drivers

### **1. INTRODUCTION**

Australian organizations have invested heavily to leverage the Internet and transform their traditional businesses into e-businesses in the last seven years. E-businesses are generally divided into the two main models of B2C and B2B e-business. In Australia B2B e-business was worth 1.1% of the gross domestic product in 2001, and B2C e-business was worth 0.17% [15]. Business organisations doing business on the Internet with digitised business processes are expected to achieve business improvements from reduced operation costs, labour, time and paper based errors. E-business investments are claiming a substantial share of overall IT budgets in most organisations based on anecdotal evidence that organisations achieve unprecedented benefits by leveraging the Internet as a medium of business. According to Kearney research report [12] e-business budgets in Australia are about 27% of overall IT budgets. However, senior managers are increasingly under pressure to justify e-business costs. Do these investments pay off? And if so, how can a company make sure they keep paying off? Managers in successful companies struggle to articulate where such benefits come from, and those without success strive to find a way to turn things around and cash in on e-business initiatives. Key value drivers for e-business in the USA have been identified by Barua et. al., [4] to be system integration, customer orientation of IT, supplier orientation of IT, informational (quality, supply continuity, and relationship management) and transactional; internal operation of IT, customer related processes, supplier related processes, customer e-business readiness and supplier e-business readiness. However, it is difficult to predict that the same set of factors is applicable to organisations in Australia and other parts of the world.

E-business research data in Australia to date is mostly on the number of business organizations trading electronically, type of e-business applications, potential benefits of e-business and the application of the Internet to certain business processes [15, 12]. These reports indicate a substantial increase in the uptake of e-business and Internet applications by Australian organizations. Earlier research in Australia [19] highlighted the need for e-business metrics to evaluate benefits. In the year 2001 a media publication [23] reported huge losses incurred by large Australian organizations such as Fosters and the National Australia Bank from their e-business projects. This research was therefore initiated to evaluate the financial and operational performance of e-business and to quantify the success of e-business in Australia. It was accomplished via an online survey and data was statistically analysed. This paper includes a brief review of literature on e-business evaluation, research methodology, analysis techniques, a discussion of e-business performance in Australia and presents some preliminary results from the survey.

### **2. LITERATURE REVIEW**

New technologies such as the Internet and the World Wide Web have made a profound impact on all businesses in Australia and around the world. E-business enables organisations to reduce costs, increase demand and create new business models. It has the potential to benefit all consumers through reduced prices and improved products and information flows [10]. Small and large firms alike can access the Internet and exploit near-zero marginal costs of distribution for their products [10]. Although e-business has been proved to be popular with large business enterprises, small and medium companies also create value by marketing and selling goods and services electronically [9]. Each company is constrained by the amount of graphics and design

capability that the Internet can deliver, so everyone starts from the same position with their Web sites. Australian organisations adopted the B2C e-business model to increase market share, offer better customer service and to reach out to customers at greater geographic distances [19]. Developments in B2B e-business in Australia has seen businesses and the government, both at the State and Federal levels adopting Web-based e-procurement to achieve volume purchase, dealing with a wider choice of buyers and suppliers, lower costs, better quality, improved delivery, and reduced paperwork and administrative costs [22]. E-business investments are claiming a substantial share of overall IT budgets in most organisations to capitalise on the benefits of e-business [12]. Benefits of e-business as outlined by [6, 21, 24] are increased revenue from enhanced sales; reduced marketing costs with online advertising, reduced time in customer service and online sales; supply chain cost reductions from reduced inventory levels, increased competition from suppliers and shorter cycle time in ordering; and reduced administrative costs from automated routine business processes, order confirmation, accuracy of data and an improved competitive position. Other non quantifiable improvements achieved from e-business include a better corporate image, improved communication with customers and business partners and customers via electronic templates, a faster product development lifecycle enabling faster response to market needs, improved customer service, better information and knowledge management, ability to incorporate positive feedback from customers to enhance sales and ability to incorporate intelligent applications of software for data mining and for forecasting trends and demands [19, 6, 24]. Amit and Zott [2] advocate that business conducted over the Internet in the 21<sup>st</sup> century with its dynamic, rapidly growing and highly competitive characteristics promises new avenues for the creation of wealth. E-business models, methods and the volume of digitisation vary from industry to industry and from organisation to organisation depending on their size, nature of business, technology capability and in-house technical expertise. Although the value of adopting e-business has been recognised, actual achievements from it are not known. Most e-business reports [15, 1, 12] provide an understanding of the level of e-business adoption. Returns from e-business implementations have not been formally evaluated. Grey et al [11] are of the opinion that much of the value associated with e-business comes not only from improvements in the technological infrastructure but from business and organisational transformations. They explain that a critical part of creating business value is identifying the processes to transform and selecting the right initiatives to enable the transformation. The IT infrastructure capability including speed, flexibility, capacity, efficiency, resilience, and security determine the type of applications that can be run and their performance. These applications affect the accuracy, speed and productivity of these business processes in various functional areas of the organisation which have an impact on the overall business

performance of the enterprise. E-business payoffs are generally assessed as IT payoffs under the themes of metrics, environment, technology and processes [13]. As suggested by Shi and Daniels [18] success in e-business includes functionality, integration and scalability, and an evaluation of e-business applications is necessary for further improvements, management strategies and the deployment of technological developments. Devaraj and Kohli [18] emphasise that it is necessary to determine the strategic role of IT in the organisation as compared to other projects and to get an overall economic picture. They also emphasise that IT projects have less apparent and longer payoff duration and IT metrics according to Devaraj and Kohli include profitability, productivity and customer value while e-commerce payoff measures address efficiency, effectiveness and innovation strategy measured along five dimensions of time, distance or geography, relationships, interactions, and product or service. IT evaluation is similar to benefits realisation as suggested by Ashburton and Doherty [3] and that IT evaluation should be explicitly concerned with the on-going management and direction of the project, suggesting that benefits have to be managed if they are to be collected. They also emphasise that evaluation should be concerned with assessing the process of systems development as well as its product so that the systems development process can be improved over time, and that evaluation should be performed as an on-going process. Cronholm and Goldkuhl [7] describe the strategies for Information Systems evaluation to be goal-based evaluation, goal-free evaluation and criteria-based evaluation. Goal based evaluation measure the IT system based on explicit goals from the organisational context. Goal free evaluation is an inductive and situational driven strategy, while criteria based evaluation means that some explicit general criteria are used as an evaluation yardstick.

Although all of the above IT evaluation issues discussed similar implications for e-business, the only research that evaluated e-business performance exclusively at the time this project was undertaken was by Barua et al [4], on which research discussed in this paper is based.

### 3. RESEARCH METHODOLOGY

This research was accomplished via mixed mode i.e. online survey method and a mail survey. Online surveys, were considered to be the apt method of investigating e-business organizations since it is technology based, quick, convenient, enables unlimited reach, seeks a response to all questions, responses are downloadable into a database and transportable to statistical packages for analysis. However, due to a disappointing response to online surveys, a mail survey was implemented to complete the research project.

A set of questions to evaluate the performance of e-business in Australia was initially developed in MSWord. Some of these were adopted the USA[4]. The

questionnaire was divided into sections and included questions presented on Likert Scales, as 'yes' and 'no' answers and some fill in the blanks. Respondents were expected to provide answers with radio buttons, choosing an option from the drop down menus or filling in a word or phrase in the space provided. The whole questionnaire was presented in six HTML pages. At the end of page one a respondent was asked to select the 'submit' button and proceed to the next page. The questionnaire was designed so that a respondent could not proceed to the next page unless an answer to all questions was provided. On submission of first page, HTML codes were included to generate a tracking number enabling the respondent to complete the rest of the questionnaire at a later time or date. The responses to the questionnaire were transferred to a database created in MySQL. Each page in the questionnaire was represented as a table in the database, and each response to a question was recorded as an element in the table. The database was designed to store both numeric and alphanumeric data. The questionnaire was sent to a random sample of 725 companies obtained from a database Business Who's Who <http://bww.dnb.com.au/default.asp>. The database was sorted using different criteria to ensure that they were e-business organizations and included the top 500. The questionnaire was disseminated via emails addressed to the e-business manager. A short explanation of the objectives of the research and the URL for the survey was included in the package.

#### Response Rate

At the end of one week 32 valid responses were received. Therefore a hardcopy of the questionnaire was sent by mail to elicit responses from the same organisations. In the month following the mail out of the survey, online responses increased to 91, and valid hard copy responses received were 78. This research analysis is therefore based on a response rate of 23.3 %.

#### Data Analysis

To complete the analysis, we grouped participants who responded with 5, 6 or 7 on Likert Scales as agreeing to the proposition proposed in the statement and calculated the overall percentage of participants agreeing to each proposition and the percentage agreeing in Small, Medium and Large enterprises. In order to assess whether there were significant differences between the level of response to a proposition from the Small Medium and Large enterprises and the overall responses, we carried out a statistical test. In the test we assumed that the number of participants,  $X$ , followed a Binomial ( $n, p$ ) distribution, where  $n$  is the number of respondents and  $p$  is the proportion of respondents agreeing to the proposition. In this paper, we use Binomial Confidence interval developed by Byrne and Kabaila [5]. This interval has the proven properties of increasing endpoints, is exact and cannot be shortened without violating the minimum coverage requirement.

## 4. FINDINGS

Findings of this research are presented in this paper reflecting the development, application and achievements of e-businesses in Australia. Responses to part 1 of the questionnaire reflect e-business adoption and development in Australia. From this research it is apparent that in Australia e-business is adopted by organisations of all sizes small (32%), medium (34%) and large (34%). Project leaders responsible for the implementation and development of e-business are largely IT managers (22%). Other project leader positions were e-business managers (14%), managing directors (11%), marketing managers (8%) and other middle managers (45%). It is important to note that most e-business project leaders in these organisations generally held postgraduate (30.8%) and graduate (37.2%) level qualifications. All Australian industries have some form of e-business in their organisations although it is most widely adopted by the manufacturing (24%) and the service industry (22%) sectors. Others were grouped as transport/utility (18%), retail/wholesale (15%) and other (21%). The most popular e-business model adopted was B2B (47%), followed by B2C (18.2%). Some adopted more than two types of trading models. Most e-business development in Australia took place in the year 2000 (22.4%), 2001 (11.2%), 2002 (6.6%), 1998 (16.4%) and 1999 (18.4%). The adoption percentages indicate a downward trend since 2000, which is commensurate with the concept that the dot.com crash slowed or discouraged e-business development. E-business like most new initiatives requires substantial resources in terms of technology, finance, people and time. Most Australian organisations made substantial investment in e-business resources as findings indicate that 71% assigned all development planning duties to a dedicated group, 65% indicated that they allocated large financial resources to e-business projects and 68% had allocated dedicated personnel to manage and implement e-business projects.

#### E-Business Drivers

E-business drivers according to Barua et al [4] are factors that impact e-business operational and financial performance. In Table 1, we consider the customer orientation of e-business propositions. Thus in the case of the first proposition in Table 1 (customers can contact representatives), there were 62 participants agreeing to the proposition out of a total of 114 responding to this proposition. Here  $n = 114$  and  $p = 62/114$  or 54.4%. The 95% confidence interval will have a lower endpoint of 45.2% and an upper endpoint of 63.6%. Thus when we consider the responses of small (51.3%), medium (58.5%) and large (55.6%) organisations to this proposition, we see that in each case the response rate is within the confidence interval. Thus we conclude that there is no statistically significant difference between the response levels of each of these groups and the overall response level. In the following tables we mark occasions where the response is below the confidence

interval with a single asterisk (\*) indicating that this response rate is significantly below the overall rate and those occasions where the response is above the confidence interval with a double asterisk (\*\*) indicating that this response rate is significantly above the overall rate. The discussion of findings in this paper is concentrated on issues where the difference in values is statistically significant.

Customer orientation data is presented in Table 1.

For customers to interact with business online it is imperative that customers are well oriented with all aspects of e-business. From the findings presented in Table 1, it is apparent that to reach out to customers the large organisations successfully promoted their e-business by listing their URL's on search engines, e-business promotion by medium sized e-businesses is seen to be fairly poor, and small e-businesses did not provide product related information satisfactorily on their web sites. Personalised web pages enable customers to create their own Web pages, and use it to record purchases and preferences, as well as capture information such as product details, and disseminate information on add-on purchases and warranty. This obviously is an advanced technology based feature which is better offered by large organisations only. Although the web technology is useful for establishing online communities with email, bulletin boards, online forums and chat facilities, this feature is seen to be least popular. However, medium enterprises utilised this feature better than others.

In Table 2, we consider the Supplier related processes analysed in the same way as the data in Table 1. For buyers and suppliers to interact in the B2B e-space it is imperative for the suppliers to be well oriented with electronic ordering, accessing and sharing information online with all business partners, participating in online auctions, and supporting the electronic supply chain for the replacement of inventory with information. For supplier interaction, medium sized enterprises were more successful in online business communication and providing information as FAQs as compared to large and small ones.

In Table 3, we consider the E-Business Processes. Findings indicate that medium sized organisations developed their processes to serve customers better than large and small organisations.

In Table 4, we consider the Readiness propositions. From the findings presented in Table 4 it is apparent that security of data interchange in small organisations is far less developed. It is also clear that this feature is well established in large organisations. The other finding worth noting is that only customers of large organisations are able to interact online with e-businesses.

In Table 5, we consider the System Integration propositions. Systems integration initiatives network the stakeholders (customers, suppliers and internal) systems in an e-business environment. Automated

processes for quick retrieval and processing of information, one set of data or integrated databases, easy access of information and in some cases a single contact point for customers, suppliers and employees are key attributes of e-business that are achieved from integrated system. Automated and integrated business processes form the back end e-business systems. This feature of e-business is significantly well developed in large organisations as evident from the data in Table 5.

In Table 6, we consider the Internal Orientation of IT application. The impacts of intranets and internal communication, project management, internal process improvements and internal orientation of electronic business processes are pivotal for e-business success. From Table 6 it is clear that this feature of e-business was only moderately achieved by all organisations investigated. As stated by Barua et al (2001), it is important for firms to ensure that employees can manage online customers and suppliers with easy to use internal information systems.

In Table 7 we consider the improvement in Financial Performance. The percentage of overall respondents who indicated an above average financial improvement is shown. For example, 32.5% of respondents overall indicated an above average improvement in return on investment, 28.9% on return on assets, 28.1% on gross profit margin and 20.4% on revenue per employee. In Table 8 we consider the improvements achieved from the implementation of e-business. The percentage of overall respondents who indicated an above average improvement in each measure is shown. For example, 55.3% of respondents overall indicated achieving an above average improvement in providing increased information to their customers via e-business. From the data presented in Table 8 the figures portray what e-business organisations have achieved from e-business. Availability of information which usually is a first step in e-business development has been achieved while other aspects of e-business are far from developed.

## 5. DISCUSSION AND CONCLUSION

Although all of the findings have not been explicated in detail in this paper the findings clearly indicate that e-business is the new way of doing business and adopted widely by Australian organisations irrespective of their size. From this it is inferred that the Internet is increasingly transforming traditional businesses to e-businesses. Although most industry sectors have embraced e-business, manufacturing and service industries are capitalising on the opportunities more than others. It is clear that IT managers popularly undertake e-business leadership indicating that IT knowledge is essential for e-business project leaders. Although it is not new that larger organisations are in a better position to allocate specific resources for new projects, e-business implementation in Australia shows that the medium and small organisations have also invested substantially in e-business. This indicates that the value of e-business has

been realised by all Australian organisations although real benefits of e-business have not been realised. While e-business has obtained some negative publicity in the recent past due to dot.com crash, it is apparent from this research that the Internet is increasingly transforming traditional businesses into e-businesses. This research is one of the first in Australia that has attempted to evaluate the performance of e-business. From the findings presented in this paper, it is apparent that e-business in Australia is not too different from the findings of the US study discussed earlier. We will discuss the value of e-business as it compares to the value in the USA in another forthcoming paper. From the findings discussed in this paper it can thus be concluded that in Australia e-business is very much alive and applied although its implementation is slow and improvised.

# E-Business: Factors of EAI Adoption in an Australian Electricity Company

Ying Chen, Alex Wong

School of Information Systems, Faculty of Commerce, University of Tasmania, Australia  
Ying.chen@utas.edu.au; Adwong@utas.edu.au

## ABSTRACT

The awareness of the scarcity of literature in EAI adoption in the public sector led to the current study of an investigation into the factors that influenced the adoption of EAI in an Australian electricity company. Using a case study approach and qualitative methods, data was collected through semi-structured interviews with five informants from different aspects of the EAI project. Data analysis was conducted using the grounded theory, resulting in 24 themes, which were then categorized into three broad themes of environmental influence, current problems and perceived benefits. These themes were taken as factors that contributed to the decision making of the EAI project of the case company. The informants considered environmental change as the trigger for the adjustment of the case organization's strategy. However, they all shared the view that the adoption of EAI was the consequence of a clear identification of the strategic positioning of the organization, the understanding of existing inhibitors and the awareness of the benefits of a chosen technology.

**Keywords:** EAI, enterprise systems, decision process

## 1. INTRODUCTION

Enterprise application integration (EAI) has over the past few years quickly become an alternative option other than Enterprise Resource Planning (ERP) to address organizations' problems on enterprise integration. An obvious indication is the rapid development of middleware technology originally designed for data-oriented integration that has quickly transformed into more sophisticated software architecture.

An examination of existing EAI literature reveals more research has been conducted in relation to the private sector as compared to the public sector. A possible explanation is that the public sector has been less dependant on IT than their private counterparts that utilize IT heavily to greater profitability. The bureaucratic structure of the public sector as well as government policy and regulation controlling competition has resulted in a more conservative approach to IT adoption [15]. However, the operational environment is changing for the public sector. In Australia, the government relinquished control of public sector investments in the 1990s, which included telecommunications and energy distribution industries, an endeavour known as deregulation. Deregulation transformed the operational environment of the public sector from a stable and predictable market to one characterised by dynamism and complexity, in which technology became a valued commodity [15]. The public sector became government business enterprises (GBE) and is required to generate profit.

The research presented in this paper aims to investigate an EAI project in a GBE within the electricity industry in Australia after deregulation. To confront competition with other electricity providers within Australia, the

company decided that it required an enterprise system that should streamline the data flow between three major business sectors within the organization: the human resources department, the assets department and the accounting department. The organization examined two alternative approaches of enterprise integration, ERP from one vendor and EAI with the best of breed. It was decided to pursue the latter option. This study intends to investigate the factors that influenced the decision to implement an EAI project. The findings will be of value to researchers in the area of EAI and the public sector and to organizations with a similar endeavour.

## 2. LITERATURE REVIEW

### 2.1 Importance of EAI

EAI is an umbrella term that encompasses technologies designed to unite disparate applications to address business problems. It aims at the unrestricted sharing of data and business processes among any connected applications and data sources in an enterprise [11].

Information technology has been utilised in organisations as a means of automating and improving business processes. However, before 1990s, IT was used to address problems based upon the unique needs and beliefs of business units within an organization, resulting in an IT architecture characterised by autonomous and heterogenous solutions [11]. This resulted in inefficient processes, reduced quality and accuracy of information that potentially impacted on coordination of activities and operational efficiency [8].

With increasing competition in the modern business environment, organisations view knowledge as the only source of competitive advantage with which they may

differentiate themselves from competitors [3]. The inherent decentralized IT architecture creates a big challenge for organizations' strategic planning and decision-making [12].

The trend towards E-business, E-commerce, corporate mergers, acquisitions and globalization in the past few decades has also created other incentives for an integrated enterprise system [2].

ERP emerged in the early 1990s as an enterprise-wide solution to address organisation's coordination issues. In 2001, the enterprise system industry was estimated to be worth US\$19 billion [5]. However, the complexity and cost of ERP in combination with the current economic crisis has made ERP an unattractive option [18].

EAI surged as an attractive alternative option for reduced cost [4, 21], for maximising an organization's existing investments as well as maintaining a unique business process that differentiates an organization and gives it a competitive edge [10]. The cost reduction of EAI was also evidently important to public enterprises [7, 8] as they do not have the high profit margins of their private sector counterparts.

## 2.2 Challenges of EAI

Challenges of EAI range from the incompatibility of different software, lack of standards in IT architecture and lack of expertise [11]. Middleware technology is a fast developing area aiming at the rising EAI market, but the currency of the technology sees a relative scarcity of individuals with the proficient skills necessary for application integration projects. Despite the fact that previous researchers have found EAI a cheaper option than ERP [4, 21], a full EAI implementation can cost up to AU\$10 million dollars, and in many cases represents the largest IT expenditure in the history of an organisation [20]

## 2.3 Public Enterprise and EAI

The public sector differs from its private counterpart with some unique attributes. It enjoys a significant establishment time, sometimes over 100 years [2], thus has cultivated the perfect breeding ground for a complicated, inconsistent software architecture [2]. It has a large number of employees requiring extensive management and coordination [7, 8]. It is geographically dispersed as a result of acquisitions and mergers to cut down overhead costs [7]. The culture of the public sector displays signs of bureaucratic control and homogeneity, resulting in a slow response to environmental changes. However, this culture will have to change due to deregulation that brings with it consistent unanticipated changes [2].

Although EAI is viewed by some researchers as a better fit for the public sector [7, 8, 12, 17] research within this context is limited. The existing literature reveals EAI has been adopted by public enterprises such as healthcare, education and telecommunications [7, 8, 21]. In the context of the electricity industry, researchers have identified two triggers of EAI. One relates to the wave of mergers and acquisitions and the other to the sudden increase in the adoption of IT as a result of deregulation. [2, 6, 14].

## 3. RESEARCH METHOD

The research question of the study is "What factors influence the adoption of EAI within an Australian GBE in the electricity industry?" The research, based on a case study technique, is subjective in nature and takes an interpretivist stance to explore informants' personal experiences, perceptions and opinions in relation to the EAI project within the organization.

The interview protocol, with a detailed design of questions to probe for information most relevant to the research, was pilot tested by the IS manager of the project for flow, timing, content and comprehensibility. Based on the feedback from the pilot test, the interview protocol was refined.

Five informants, representing various roles in the steering committee of the EAI project, were invited to take part in the research. Semi-structured interviews, each approximately one hour in length, were tape-recorded with the consent of the informants and transcribed in accordance with Yin's 24-hour rule [22]. To address validity, the research recorded in detail all aspects of the research process. Both the transcripts of the interviews and a copy of the findings of the research were provided to the informants for validity checks. Close collaboration with the IS manager of the project was conducted in relation to the identification of informants, interview design, accessing internal documents and clarification of issues and terms unfamiliar to the researchers. This practice was in close alignment with the recommendation of three methods for achieving validity from Bailey [1]: natural history, member validation and collaboration.

The research addressed the issue of reliability through a complete transcription of the interviews and a detailed documentation of the coding process to reach the final conclusion. This effort recommended by earlier researchers [1, 22] was to facilitate replication of the study by other researchers.

The data were analysed using a bottom-up, three-stage coding process: open, axial and selective as devised by Strauss and Corbin [19]. Each 'pass-over' was intended to refine and condense the data by identifying salient themes. Dominant themes were expected to be explicit by the conclusion of the coding process.

#### 4. FINDINGS

In order to facilitate discussion, and for ethical reasons, the informants are represented with their positions, as shown in Table 1: Profile of Informants. The initial coding of the interview data generated 24 unique themes, that were then categorized into three broad themes, namely environmental influences, perceptions of current problems and perceived benefits as shown in Table 2: Categorization of Emerging Themes.

##### 4.1 Environment Influences on EAI Adoption

An analysis of the data indicated that a series of external factors contributed to the organizational decision on EAI adoption. Most informants acknowledged that the push to enter the National Electricity Market changed the organization's operational environment as some informants stated:

*We're going from a fairly sedate market into a national commercial environment (External Contractor).*

*The entry to a national market essentially exposes us to full competition with other providers (IS Manager).*

Table 1: Profile of Informants

Position	Project Involvement	Employment in Company
IS Manager	Steering committee member	2 years
Process & operations (PO) Manager	Experience with similar projects	15 years
Financial Systems Manager	Consultative committee member	6 years
External Contractor	Project Manager	2 years
Engineering Manager	Business client	2 years

Table 2: Categorization of Emerging Themes

Broad Themes	Underlying Themes
Environmental Influences	Entrance to market; Competition; Competitive positioning; Opportunities; Shareholder ROI; Evolving business
Current Problems	Lack integration; Geographic dispersion; Low assets knowledge; Slow decision-making; Low IT expertise; Change resistant culture
Perceived Benefits	Efficiency; Data accuracy; Information accessibility; improved decision-making; improved productivity; cost control; investment maximisation; standardisation; Extensibility; Systems usability; High ROI; Risk reduction

New external products such as natural gas triggered the need to compete and define the organization's competitive positioning.

*It's more important that we position ourselves correctly in the market (IS Manager).*

*The performance of the asset is an important contributor to being part of the competitive market (External Contractor).*

*When we go into the national market, we're supposed to have machines that have high availability (Financial Systems Manager).*

However, a perception of new opportunities created another environmental factor.

*If we can improve capacity a minute portion, that provides sales opportunities (External Contractor).*

*The entry to a competitive market itself raises the opportunity to exploit higher availability (of assets). We could end up managing assets interstate – which would create another level of complexity... The degree to which opportunities could be exploited, were dependent upon the performance of the assets... essence of the project (IS Manager).*

Other environmental factors included shareholders' interests and the need to evolve the business.

*The major stakeholder, the government, will know we are running these things, we are sort of maximising the dividend and the tax that we have to pay to them (Financial Manager).*

*It is quite conceivable that within 4-5 years that 20–30% of our energy will be derived from wind – and that's a big change and the new EAI system is expected to manage the maintenance of the assets of wind farms (IS Manager).*

##### 4.2 Current Problems Leading to EAI Adoption

A series of problems were identified that initiated the necessity of the EAI project for the case organization. The first is the awareness of “no integrated approach to anything” as the External Contractor observed.

*We could see a big gap in the organisation in terms of the (assets) maintenance management system (that) was really stand-alone (Financial Manager).*

*We just need something to pull it all together. It's like having many horses. They all pull in different directions, the cart, not one coach driver to pull the thing into the right direction (Engineering Manager).*

The second problem lies in the geographically dispersed nature of the organisation.

*Geographic dispersion works against us in terms of being able to have very effective process and good maintenance procedures' (IS Manager).*

*Geographic dispersion has caused massive differentiation between processes; local processes rather than uniform processes across the entire company (Engineering Manager).*

Geographic dispersion appeared to be a particular problem for process standardisation attempts. It suggested that the organisation's control over geographically dispersed factions was tenuous.

The third identified problem was the lack of sufficient understanding and knowledge concerning their assets.

*The second, I guess, main aspect of what they need to do is that employees need to improve their understanding and management of those assets (IS Manager).*

*How long did it take to fix (the problem with assets)? Well the current answer is: 'it depends.' Well it shouldn't depend. Breakdowns of a certain calibre should be fixed in a certain period of time (Engineering Manager).*

The informants felt the lack of systems integration and geographic dispersion resulted in a slow organisational decision-making.

*Decisions tend to be taken in a fairly measured way and that can be a frustration sometimes because... you feel you need to respond quickly to something (IS Manager).  
We have a certain number of hurdles you have to go through to reach a decision (Financial Manager).*

The informants also pointed out the low level of IT expertise within the organisation.

*We need some good IT professionals as well as internal people (External Contractor).  
There would be a fair scarcity of expertise. The organisation's fairly, you know, short at the moment as far as those expertise (PO Manager).*

Further probing revealed that the IT component of the organisation had been outsourced to a third party. The last identified problem related to the organization's resistance to change.

*I think in general, our acceptance and willingness to change could be a lot better... I think more people resist change... People are just not prepared to really embrace a case for change (Financial Manager).  
Some people... don't have a lot of contact with the corporate side of the business and they've been there for a long time and are pretty entrenched in the way they do things, so sometimes, trying to get people like that to change is difficult (External Contractor).*

### 4.3 Perceived Benefits of EAI Adoption

Analysis of the data indicated that informants were well aware of the benefits that the EAI project would bring to the organization.

The first benefit is greater process efficiency as a result of the increased speed of information retrieval, the accessibility, and improved accuracy and quality of data.

*It will streamline a lot of the tedium they have to put up with (External Contractor).  
There will be asset efficiencies, and people utilisation by us having the information at our fingertips rather than having to search for it, make phone calls et cetera... It is supposed to provide them with the right information at the right time, it is supposed to save them time by not having to put information into that system... (Engineering Manager).  
At the end of the day the organisation should hopefully finish up with better data. They (steering committee) are after up-to-date, complete data on their generation assets, and I don't believe they're getting that at the moment (Financial Systems Manager).*

The informants felt an integrated system with improved accessibility and quality of information would also result in better operational decision-making in asset maintenance. Its significant role in this assets-based organization can be seen with these statements.

*Generation management are able to make better calls about when (to) and when not to run the machine. They'll have a lot better ability to make some of these decisions once they have an integrated system (Financial Systems Manager).  
A fully functional platform, which gives me the right information when I need it to make a right decision on the spot. (Engineering Manager).*

It was believed that an integrated system would improve employee productivity and reduce operation costs.

*Instead of spending our time doing time sheets three times a day, we only do them once, and in the two hours that we save, we're actually doing something a bit more useful towards managing the assets... It's certainly reducing a lot of our operating costs (External Contractor).*

All informants indicated that the reduction of cost could be realized through efficient assets maintenance management, mainly the maximization of the life span of existing assets. A rippled effect would be a higher return of investment (ROI).

*We can predict with reasonable certainty that the life of this particular piece of equipment in service is so long. So we will aim to maintain it inside that window (IS Manager).  
It (the integrated system) is to provide us with a suitable platform to maximise the return on investment, these assets which is the essence of asset management – get the best bang for your buck – this is the ultimate objective (Engineering Manager).*

Standardisation of processes for geographically dispersed organization was another crucial benefit.

*There is an impact there or a value in having a system that brings commonality to the way these people work (IS Manager).  
If I put this system in, all the regions are going to adhere to exactly the same processes, and you don't get a 'cowboy' manager in one area not adhering to it (Financial Systems Manager).*

The integrated system with its uniform processes and improved information sharing would ensure better asset management, thus reducing the level of risk toward the organisation.

*Unless they (assets) are maintained (with) a regular schedule (and) kept up to date the whole process of when, where, and how (they are) monitored - we put the whole organisation at a fairly big risk (PO Manager).  
If you start trading, signing contracts, and then your asset doesn't work to fulfil those contracts, you're likely to be hit with a fairly severe penalty (External Contractor).  
If we don't get our operation right, obviously we have the potential to be undercut, lose market share, lose revenue, potentially affecting profit (IS Manager).*

Other benefits included the new system's potential to support new emerging products and services of the organization.

*I imagine once (the system is) implemented, they'd (high level decision makers) probably see other advances, they'd say "OK, you can do this", they'd probably look at another area and do this as well, so I'd imagine it would get bigger or have more required of it as time goes by (PO Manager). I've got an idea because of its nature it will evolve gradually over time (Financial Systems Manager).*

The informants also believed that the system would support high usability and generate high returns.

*Usability would be high (PO Manager). They're also really strong on wanting a usable system (External Contractor). The payback period is only about eighteen months. It has a very high return on investment that is quickly paid back (IS Manager). The internal rate of return of the project when we put everything in there it came out as something 150% of 200% something huge – that's the beauty about such maintenance improvement, that anything that can assist the plant performance, directly or indirectly, has got a huge payoff (Engineering Manager).*

## 5. DISCUSSIONS

The data analysis shows that there are three contributing factors to the organizational decision on the EAI project: a thorough understanding of the operational environment of the organization, a clear identification of existing problems and a good knowledge of the benefits of the EAI project to the organization. The relationships of the three elements are demonstrated in Figure 1.

Figure 1: Relationship of factors of EAI adoption

This decision-making process is in alignment with the organismic approach to decision theory in which environment plays a significant role [9]. The organizational practice also suggests a close affinity with the game theory [9], which incorporates both environmental influences and organisational objective as being responsible for an organisation's actions. Another interesting observation was the similarity between the case organisation's objectives and those of private organisations. Foer and Moss [6] observed that private enterprises have an "entrepreneurial culture" that is characterised by an undue focus on profitability, reduced product cost, an increase in product diversity,

and meeting customer's needs. The case organization has adopted most of them except product price. This suggested that deregulation, to a certain degree, had served to dilute the characteristics that differentiated the public and private sectors. However, the public sector might still see an edge in their product availability rather than reduced prices. A possible explanation is a public organization is usually heavily assets based that gives it the potential of providing better service if the assets are well managed and utilized for maximum productivity.

The geographically dispersed nature of the company had its merits in pre-deregulation days when electricity generation companies were responsible for providing electricity to vast land masses [13] and decentralization provided a degree of flexibility [15]. However, in the deregulated regime, geographic dispersion became a weakness when competing against centralised rivals [13]. Furthermore, decentralisation was also viewed as a weakness for public sector organisations as it results in higher operating costs as compared to centralised rivals [16]. The informants expressed similar concerns, blaming the geographic dispersion to be the cause of inconsistent processes that had reduced the organisation's ability to perform efficiently.

The organisation's slow decision-making process can be viewed in the context of lack of information due to dis-integrated systems and the culture of public sector organisations. As mentioned previously, the culture of many public sector organisations tended to reflect their monopolistic nature [6]. Aspects of the monopolistic nature included a bureaucratic structure, and aversion to risk [6]. This implies that public organizations have a culture more unfavourable for change. Any business process reengineering endeavour that involves new cross-functional business processes can be expected to incur more resistance. This is certainly supported by the interview data of the study. The 'Mateship' program used in the organization to encourage loyalty of its employees seemed to further complicate any change initiatives. This accounts for the critical role of the "usability" as identified by the informants. Research indicates an EAI system is a more attractive solution for its minimal impact on culture change, which may account for the case organization's decision to take EAI instead of ERP.

The low level of IT expertise is common within public sector industries. However, like other public organizations that chose to resort to IT for competition [14], the subject organisation used the same strategy and attempted to enhance and cultivate its IT skills through training and recruitment.

The informants' perceptions of EAI benefits are consistent with existing literature. The case organization's paramount interest in work efficiency reflects the observation of many former researchers [17,

7, 21, 2, 8]. Also, the data analysis reveals the inter-relationship between the perceived benefits of EAI projects. Process efficiency was to be achieved through the increased accuracy and accessibility of data, that yields numerous other benefits such as improved organisation's decision-making process, increased productivity of employees and a better control over both cost and risk in relation to assets maintenance. The linked system, as a result of the EAI project aims to help overcome the physical boundaries, a big issue among the majority of public organizations, and help facilitate greater communication and greater control of a standardised business process.

## 6. LIMITATIONS AND FUTURE RESEARCH

As this research takes an interpretivist stance, the researchers of this study consider it improper and unrealistic to generalise the results to other organizations. However, the research provides some insights into the decision process of adopting advanced technology for the public sector, which will be of value to both academic research and practitioners. A number of issues have emerged for possible further research. They include the impact of organisational culture or top management support on EAI adoption within the public sector and the degree to which the objectives and operations of the public and private sector converge after deregulation.

# Electronic Business in Germany: Current Challenges and Future Perspectives

## - Results of an Explorative Survey -

Tomaso Forzi, Ediz Kiratli, Stefan Bleck

E-Business Engineering Department of the Research Institute for Operations Management (FIR)  
at Aachen University of Technology (RWTH Aachen), Pontdriesch 14/16, 52062 Aachen, Germany  
{Tomaso.Forzi, Ediz.Kiratli, Stefan.Bleck}@fir.rwth-aachen.de

### ABSTRACT

The objective of the present contribution is to present the results of an explorative survey in the field of E-Business conducted with German enterprises at the end of the year 2003. The survey aimed to convey a picture of the present stage as well the future trends of E-Business in the German entrepreneurial world. An analysis of the present and future developments of E-Business as well as of the related organisational, technical and human implications for enterprises will be presented. Limitations and open challenges of research as well as the planned further work will be eventually discussed.

**Keywords:** Electronic Business, Explorative Survey, Germany

## 1. BACKGROUND OF RESEARCH

### 1.1 Introduction

During the past years, the fast development of new Information and Communication Technologies (ICTs) has been revolutionising the market arena, it extended the horizon of competition, and it caused radical changes in all business branches [3] [12]. The effects of the introduction of E-Business (EB) were an enhanced globalisation process, an even more uncertain and dynamic economic environment, and a technology-driven development of new capabilities, products and services as well as new businesses [12] [13]. This was the case also in the German economy and entrepreneurial structure [3] [13].

In order to analyse the current state as well as the implications of the short but intense history of EB in the German entrepreneurial world, as well as in order to identify key success factors, challenges and future trends, at the FIR it was decided to start a series of empirical works, which the present work belongs to.

### 1.2 Scope of the explorative study

In this contribution we are going to present the results of an explorative survey, entitled "E-Business in Germany –Success Factors and Obstacles", which was conducted with a sample of German enterprises at the end of the year 2003. The survey aimed to convey a picture of the present stage as well the future trends of EB in the German entrepreneurial world. In particular, the research strived to analyse the current state of EB in German enterprises in order to identify its relation with their economic success, strategy, organisation, processes, ICT infrastructure, and personnel. Furthermore, critical success factors as well as most significant obstacles for companies within the deployment of EB were also sought.

This explorative survey has to be seen as the initial step of a wider research framework; as a matter of fact, its ultimate objective is to enable an initial analysis in order to identify patterns and research areas to be then further and deeply analysed within following empirical works.

## 2. RESEARCH METHODOLOGY

### 2.1 Phases of research work

The research work was structured in the following phases:

1. *Selection of an appropriate approach of empirical research*, in which after an analysis of different methodologies of market research [6] [7] [8] [9] [10] [11] [14] [15], the approach of explorative survey with partial census and proportional selection of participants was found to be the most appropriate within the several approaches of primary research. In particular, the survey was planned to internet-based [1]; all participants were to be approached only via email and were asked to fill in the questionnaire online. An option to fill in the questionnaire offline and to send it back by fax or snail mail was also to be offered.

2. *Survey design and technical implementation*, in which the core elements of analysis were identified, the different hypotheses were listed and structured, and the questionnaire was hence designed taking into consideration the requirements of empirical research [1] [6] [7] [8] [9] [10] [11] [14] [15]; furthermore, the execution of a pretest with selected companies helped to gain precious feedback that was integrated into questionnaire, which was hence implemented in a web interface and eventually tested.

3. *Sample selection*. Within this phase, the first step was to define the indices according to which the entrepreneurial quota were going defined: industrial sector as well as size of the enterprises [8] [9] [10] [14]. Such indices were obtained from the Classification of

Economic Activities in the European Community (NACE). The quota related to such indices for the proportional selection process of the survey participants were hence identified with the help of the data from the German Federal Statistical Office<sup>1</sup>. Hence, the list of enterprises to be invited to take part to the survey was prepared with data from the database of the market research firm Hoppenstedt<sup>2</sup> and the own FIR database.

4. *Realisation of the survey.* In this 3 month phase the selected enterprises were sent an email with an invitation to take part to the survey as well as some following reminders, also via email. It is interesting to note that 72,6% of the participants filled in the questionnaire online, while 27,4% preferred to fill in the printed questionnaire and send it back with the support of more traditional means (23,4% via fax and 4% via snail mail). This shows that, although all the participants had an internet access, about one third felt more comfortable with the offline and manual processing of the questionnaire.

5. *Follow up telephone interviews.* Since in the paper-based questionnaires some inconsistencies were found, some follow up telephone interviews were needed in order to clear few open issues with some of the participants [11] [14] [15]. This action enabled the clarification of the open issues and enabled the further use of the whole data set within the analysis phase.

6. *Collection and coding of data.* The automatic saving of the data of the online questionnaire in a previously programmed database enabled an efficient and error-free coding of such data; the paper-based questionnaires were manually coded and accurately doublechecked.

7. *Data analysis and documentation of the results.* The collected data were analysed with the help of univariate, bivariate, and multivariate statistical methods [2] [5] [11] [14]. Appropriate statistical testing methods were used to test the results of the analysis: Significance-test with  $\alpha < 0,05$  for the tested hypotheses, Chi<sup>2</sup>-test for bivariate and contingency analysis, F-test within the multivariate analysis. Furthermore, in order to avoid distortions caused by different scales (especially in the multivariate analysis), all different units and scales were standardised with the help of the Z-transformation. Cluster analysis that were conducted with different standardisation methods lead always to the same results. Eventually, all analysis and results were documented.

## 2.2 The sample

During the sample selection 8.150 enterprises (gross sample) that fulfilled the criteria were selected. Decision-makers of such enterprises were sent an email with the invitation to take part to the survey. During the mailing action 1.258 emails did not reach the targeted group, this meaning that 6.892 potential participants received the invitation email (net sample). By an analysis of the net sample it came out that the striven quota of

population, with an acceptable deviation, were still fulfilled by the net sample.

On the whole, 278 enterprises took part to the survey and sent back the filled questionnaire, with the result of rate of return of 4,03%. The distribution of the participants vs. the values of the population are given as follows: 48,6% vs. 21,4% in the industrial sector, 42,1% vs. 40,1% in the field of services (without commerce); 9,3% vs. 24,7% in the commerce sector, and 0,0% vs. 2,3% in the agricultural sector. As far as the entrepreneurial size is concerned, the distribution of the participants vs. the values of the population are: 62,2% vs. 89,4% small sized enterprises, 17,3% vs. 10,3 medium sized enterprises, 20,3% vs. 0,3 large sized enterprises. Some branches and some enterprise sizes are overrepresented, while other are underrepresented.

Because of the high unit non-response, a non-response analysis was conducted. The major reasons of non-response are lack of reachability, technical limitations, and noncompliance [4]; while the lack of reachability is the most appropriate explanation for the difference between gross and net sample, the technical limitations could be to a certain extent excluded because of the way in which the web questionnaire was implemented; as a result, the unit non-response of the net sample is likely to have its origin in the noncompliance of the invited persons [4]. An analysis of the reasons of non compliance would have required a new survey of a sample of the persons that did not fill the questionnaire in: this new survey would have gone beyond the scope of the present work.

As a matter of fact, since the objective of the empirical work was to conduct an explorative survey, and not necessary a representative survey (planned for a further research phase), the data was considered sufficient for the explorative scope of the research.

## 2.3 The questionnaire

The questionnaire of the survey had 39 questions divided in seven sections with a total of 556 items. It covered the following areas:

1. *E-Business in the considered company and in the economy*, in which along with the different items about the present state of EB in the own firm (e.g. involved areas, duration, strategic objectives as well as achievements of EB), also a qualitative evaluation of the state of EB in the considered firm, industrial sector and German economy in the present and in the coming one to two years was gathered. Furthermore, the issue of EB related innovation in the considered firm, its competitors and in the related industrial sector were dealt with.

2. *Strategy in E-Business*, in which data about strategic aspects of the EB deployment were collected, such as e.g. the existence of a EB strategy and its relation to the entrepreneurial strategy, experiences in the strategy

<sup>1</sup> see also [http://www.destatis.de/e\\_home.htm](http://www.destatis.de/e_home.htm)

<sup>2</sup> see also <http://www.hoppenstedt.de/>

finding process as well as experiences with approaches and methods used within such a process.

3. *Organisation and processes in E-Business*, in which organisational and process-related issues (such as the positioning of EB within the organisational hierarchy or the extent of the reorganisation of the entrepreneurial processes) as well as operational objectives of EB were focused on. The extent of reorganisation of processes was also inquired.

4. *Information and Communication Technology in E-Business*, in which EB budget and its temporal development, typology and evaluation of the involved solutions as well as of the involved ICT service providers, the information sources used for within the selection of the ICT service providers and the software criteria that ex-post were found to be critical.

5. *Personnel and E-Business*, in which data about EB trainings (such as type and targeted employees), a qualitative employees' evaluation of the EB deployment within the firm as well as of the employees' productivity variations caused by EB were collected.

6. *Further comments* about Electronic Business, could be then added within a section for free text remarks.

7. *Data about the interviewee and demographic data of the enterprise*, such as NACE-Sector, number of employees, turnover in the previous year as well as age of the firm.

### 3. RESULTS

#### 3.1 Selected results

In this chapter some of the results of the monovariate analysis of data are going to be presented and discussed.

1. *State-of-the-Art and E-Business in the future*. On average, the enterprises have been dealing with EB for 3 to 4 years and mainly see it as a strategic approach to conquer new market segments and new customers (27,4%), to increase their turnover (17,8%) and to improve their relationships with their customers (17,6%). While currently the degree of EB maturity of nearly half of the enterprises is considerably low (e.g. 48,4% of the firms concentrates their activities on a web presence and web marketing), in the coming future the trend is clearly towards a more complex and manifold understanding of EB deployment (e.g. 19,6% plan a holistic EB concept or even 25,7% an EB supported inter-organisational integration), see also Figure 1. This confirms the hypothesis of a trend towards an increasingly networked economy [12]. As far as the entrepreneurial functions are concerned, the ones which are currently mostly involved within EB are sales/ marketing (76,4%), procurement (61,6%) and after sales service (45%).

In the future, while de facto all firms will operate sales/ marketing over the Internet, almost 80% will be practicing e-procurement and web-based after sales services, about 70 % will be practicing web-based Customer Relationship Management (CRM). As far as

approaches of inter-organisational integration are concerned, within the coming years 60% of enterprises will implement e-logistics solutions, while about 40% solutions for Supplier Relationship Management (SRM) and Supply Chain Management (SCM). This result is consistent with the trend highlighted in Figure 1.

Figure 1: Current and planned EB deployment

While only a part of enterprises could achieve an increased turnover (33, %) or lower procurement cost up to 10% (29,3% of the firms) through EB, the majority of them estimates EB as important or very important for their enterprise (63,6%), while moreover 84,2% declare to plan to increase their EB deployment in the next one or two years. Comparable positive estimations were given regarding the EB growth in the own industrial sector and overall in the German economy in the coming future by 84% to 92% of participants.

2. *E-Business Strategy*. Within the analysis of data about strategic aspects of the EB deployment, it was noted that, even if only 37,8% of the firms formulated an explicit EB strategy, it was almost always adjusted and aligned to the entrepreneurial strategy (91,6% of them). This process is clearly important, especially if we consider the previous experiences related to the E-Business hype and to the hastily embedding of EB-solutions into organisations [12]: firms that have an EB strategy, are developing it with a structured and methodical approach and furthermore in alignment with the entrepreneurial strategy.

3. *Organisation and processes in E-Business*. Within the analysis of the positioning of EB within the organisational hierarchy, no dominant approach could be found. EB is either in the competence field of the management board through a dedicated staff unit (21,6%) or it is given an own organisational unit (only 6% of firms) or it is assigned a third level position in the organisational hierarchy, as subunit of an organisational unit (31,3%), mainly sales/ marketing or ICT. Interesting is that in 28,7% of firms uncoordinated EB competencies are to be found.

The extent of the reorganisation of the entrepreneurial processes following the introduction of EB was also inquired: only 22,8% of the firms carried out a (even partial) reorganisation of processes related to the EB

introduction. This fact seems to be a surprising result and it will be further discussed in section 3.5.

Furthermore, operational EB-objectives were also analysed, with the following top-three-ranking: better customer retention (23,6%), lower process costs (16,3%), and better communication with customers and suppliers (15,6%).

*4. Information and Communication Technology in E-Business.* Within the analysis of ICT solutions for EB, it came out that only 17% of the firms make use of Application Service Providers (ASP), while 83% implemented the solutions in the own enterprise; furthermore, the vast majority of such solutions are either standard solutions, with (51,0%) or without customisation (19,0%), or fully new solutions developed only for the own enterprise (21,9%). As far as the involved ICT service providers are concerned, they were selected mainly based upon information gained through personal contacts or recommendations, hardly ever after a systematical and structured analysis of capabilities and performances of the specific solution. Nonetheless, both the implemented ICT solutions and the collaboration with ICT service providers were evaluated as good. Furthermore, the software criteria that ex-post were found to be critical were the user friendliness, the capability of system integration, and flexibility of software.

*5. Personnel and E-Business.* It must be highlighted that enterprises are aware of the fact that the employees play an important role within the successful EB deployment. As a matter of fact, the majority of enterprises gives the own employees a generic training about Internet and EB (89,9% of the firms) and more specific training for the use of EB solutions (77,7%). Still, some differences arise while analysing the profile of the targeted employees.

On the whole, the employees of the participant firms welcomed EB in their daily work; in fact, in 61,1% of the firms, the employees' perception and consequent evaluation of EB is positive to very positive, in 25,7% neutral and only really seldom negative (1,8%). Last but not least, a significant amount of enterprises (40%) underlined that the productivity of the own employees increased because of EB.

### **3.2 Differences among small, medium and large enterprises**

With bivariate and multivariate analysis of the data, differences among enterprises of different enterprise sizes were analysed. On the whole it can be stated that there is a remarkable gap between large enterprises (LEs) on the one side and small enterprises (SEs) on the other side. Medium enterprises (MEs) are, depending on the issue, either leading with LEs or following together with SEs.

As a matter of fact, LEs are, within the degree of deployment of EB, pioneers with a holistic EB-concept (22,9%) or even inter-organisational integration (25%) and are in clear advantage to SEs and MEs, which are by far beyond LEs with e.g. initial EB-experiences (16% and 16,4%) or even simpler web marketing (44,8% and 38,8%) approaches.

As far as strategic issues are concerned, 52,8% of LEs and 45,7% of MEs have defined an EB-strategy, while only 30,8% of SEs defined it. The differences become smaller in the case of a planned EB-strategy in the future (69,7% LEs, 66,7% MEs, 66,7% SEs), this meaning that, even if coming from different experiences, enterprises are increasingly aware of the importance of the definition of an EB-strategy.

As far as strategic EB-objectives are concerned, LEs strive mainly to EB-driven cost reductions, while SMEs strive more to acquiring new customers. This aspect is confirmed by the operational EB-objectives, according to which LEs strive first of all to lower process costs (a), and then to a better customer retention (b), and hence to a better communication with customers (c). Even if the operational EB-objectives are basically the same, priorities are different (b-c-a for SEs and b-a-c for MEs).

After the introduction of EB in the own company, about the half of the LEs conducted a reorganisation of entrepreneurial processes (44,9%), while only 22,2% of MEs and 17,1% of SEs underwent such an important process to embed properly new technologies into the organisational structure and processes.

As far as Information Technology is concerned, ICT Budgets are somewhat in proportion to the entrepreneurial size: while 85,8% of SEs invest up to 25.000€ in the previous year, 81,9% of MEs invested up to 50.000€; LEs have a wider budget range, with a peak of 29% with values over 1 million € investment for EB-solutions. As far as EB-solutions are concerned, ASPs were chosen more frequently by SEs and MEs (respectively 20,1% and 18,5%), while more seldom by LEs (only 7,4%); as a matter of fact, 92,6% of LEs implemented EB-solutions, which are in 86,9% of the cases standard solutions with entrepreneurial adaptation or even complete individual solutions. In this respect, both SEs and MEs are opting preferably for simpler standard solutions without or with entrepreneurial customisation (79,3% and 68,9%). Furthermore, 93,3% of LEs and 81,1% of ME trained their employees to use specific EB-solutions, while only 65,9% of SEs did it; this fact means that 34,1% of SEs did not consider relevant to skill the personnel to make use of the adopted solutions.

### **3.3 Differences among economic sectors**

Differences between different sectors of the economy (namely industry, services without commerce, and

commerce) were also sought with the help of bivariate and multivariate data analysis. Even if enterprises from the services sector do show to be slightly further within the EB life cycle, on the whole, the data do not underline any remarkable and significant differences in the pattern of use and deployment of EB among the considered sectors. As a result, it can be concluded that the importance and the degree of deployment of EB industry, services without commerce, and commerce can be considered as comparable.

### 3.4 Cluster analysis

On the base of a factor analysis, 15 factors were identified and hence used as variables for a hierarchical cluster analysis. The objective of the cluster analysis was to search for patterns to characterise different enterprise profiles.

Three clusters of enterprises have been identified: E-Business Experts, E-Business Followers, and E-Business Conservatives. The distribution of enterprises between the three clusters was, respectively, the following: 60 enterprises in the first, 165 in the second, 53 enterprises in the third cluster. The clusters are going to be discussed with the help of some selected data.

*1. E-Business Experts* (19,1% of all survey participants) are quickly moving towards the most mature phases of the EB life cycle. Among them, 24,5% have already deployed an embedded a holistic EB concept in the own organisation, while even 41,5% are using EB as a means for inter-organisational ICT-based integration. A considerable amount of enterprises (more than 50%) embedded EB thoroughly in their whole organisation – both in direct entrepreneurial functions (procurement, manufacturing, logistics, sales/ marketing, after-sales service) and in indirect entrepreneurial functions (research and development, personnel/ human resources) –and used EB also as an approach to integrate with their suppliers, partners and customers (SRM, SCM, and CRM).

Enterprises from this cluster have a remarkable EB-driven success: respectively 62,3% and 56,5% of the cluster enterprises could achieve either higher sales volumes or lower procurement costs through EB. Only 11,3, % and 17% did not have any positive effects in sales volume or procurement cost. Furthermore, at least 50% of the firms fulfilled or even exceeded their objectives. These results are on the whole clearly positive.

Members of this cluster have started with EB for four to five years, are innovative to highly innovative, and consider EB as important or even very important for the own business. For all above-mentioned reasons, the members of this cluster can be hence considered as the successful pioneers in the field of EB.

*2. E-Business Followers* (59,3% of all survey participants), the largest of the three clusters. In this group, a lot of the enterprises concentrates their activities on a web presence and web marketing (49,1%), while only 26,1% deployed or used basic EB-solutions, such as e-shops or e-marketplaces, and only a minority implemented a holistic EB concept or even approaches of inter-organisational integration (9,1%). Enterprises from this cluster have started with EB in average for three to four years and currently do concentrate their EB activates in about three entrepreneurial functions (mainly procurement, sales/ marketing, and after-sales service).

Even if these enterprises are not innovators in the field of EB, they tend to give EB a relative importance and seem to be aware of the potentials that can be reached with its embedding into their organisations. Even if less than the previous cluster, respectively 31,5% and 34,5% of the cluster enterprises could achieve either higher sales volumes or lower procurement costs through EB. Still, 30,9% and 32,7% did not reach any positive effects in sales volume or procurement cost.

In the future, members of this cluster plan to extend their EB activities: 37,6% plan to implement stand-alone EB solutions, while 29,1 plan to deploy a holistic EB concept in the own enterprise or more advanced inter-organisational integration; this is reflected by the fact that such enterprises plan to extend EB to entrepreneurial functions such as logistics, and CRM, but also personnel/ human resources. To conclude, for all above-mentioned reasons, members of this cluster can be also defined as second-movers.

*3. E-Business Conservatives* (21,6% of all survey participants), a smaller group than the previous one. Also in this cluster, the majority of enterprises (53,4%) concentrates their EB activities on web presence and web marketing, while 35% gained initial experiences with EB-solutions. Enterprises from this cluster have started with EB in average for less than 3 years and currently concentrate their EB activities only in one or two entrepreneurial functions (mainly procurement and sales/ marketing). Many of the members of this cluster can be considered as late followers, since they started to deploy EB only when the related solutions reached a considerable degree of maturity. It is striking that about 40% of the members of this cluster did not define any objectives of their own EB activities. This could be interpreted with the fact that many of such enterprises were pushed from the market (competitors and customers) to adopt initial EB solutions, and hence just reacted to the new boundary conditions without defining any further objectives. For the same reasons, enterprises of this cluster are also not particularly innovative, but follow the mature solutions offered in the market; furthermore, they do give EB only a neutral importance. As far as economic success is concerned, only 18,3% had a higher sales volume, and also only 18,3% could achieve lower procurement costs through EB. About

40% of the members of this cluster did not reach either higher sales volumes nor lower procurement costs at all. In the future, EB Conservatives plan to implement some EB solutions (25%) or to deploy and implement a holistic EB concept or even approaches of inter-organisational integration (26,6%); this fact is being reflected by the fact that they plan to extend EB to entrepreneurial functions such as logistics, after-sales service and CRM. All in all, members of this cluster can be also defined as cautious followers or third-movers.

### 3.5 Critical success factors for E-Business

Last but not least, several hypotheses were tested, in order to identify critical success factors for EB on the basis of the available data. The success factors that were identified are: 1) the existence of an EB strategy, 2) the existence of an organisational form to coordinate EB activities, 3) the execution of reorganisational measures, 4) the choice to implement individual or customised solutions, and 5) the decision to train employees. By the analysis of such factors within the three clusters, it could be observed the majority of the EB Experts were fulfilling all criteria.

## 7. CONCLUSIONS, LIMITATIONS AND FURTHER NEED FOR ACTION

In this paper the results of a survey with German enterprises in the field of E-Business were presented and discussed. Among others, three entrepreneurial profiles in the field of E-Business could be identified and characterised: successful pioneers, second movers, and cautious followers.

The survey was of an explorative kind and it is not necessary representative. Anyhow, interesting results and some trends could be highlighted. Hence, the survey can be seen as the initial step of a wider research framework. As a matter of fact, its ultimate objective was to enable an initial analysis of the research field, in order to enable the identification of patterns, trends and research areas to be then further and deeply analysed within following works of empirical research. The results support the fulfilment of this objective.

With the help of the gained data, a basis for further analysis was identified. The next step will be a set of semi-structured interviews to be conducted with targeted German enterprises from the first cluster (EB Experts) from selected industrial sectors. The objective is to better understand the reasons that lead to the described results, to deepen the analysis of critical success factors, and to highlight differences between industrial sectors.

## ACKNOWLEDGEMENT

The research was conducted within the activities of the

“Aachen Competence Centre – Electronic Commerce (ACC-EC)”, a project (grant number: VI B4 –003068/4, see also [www.aixplorer.de](http://www.aixplorer.de)) funded by the German Ministry of Work and Labour.

ACC-EC is funded within the framework “Network Electronic Commerce” (“Netzwerk elektronischer Geschäftsverkehr”), which is a Germany-wide network of 33 local competence centres in E-Commerce and 7 federal competence networks that work in close contact with German enterprises in several fields related to E-Business (see also [www.ec-net.de](http://www.ec-net.de)).

# Exploring the Reality of E-Commerce Benefits among South African Businesses

Alemayehu Molla

IDPM, The University of Manchester, Manchester M13 QH, UK

Alemayehu.molla@man.ac.uk

## ABSTRACT

The use of e-commerce by businesses in developing countries is related to the potential benefits of improving linkage to international value chains, increasing market access and reach, enhancing internal and market efficiency and lowering transaction costs. The opportunity imperative has resulted in the adoption of e-commerce by some businesses in these countries. However, the questions of what and how much benefit businesses in developing countries are extracting from their e-commerce investments are not well covered. This paper attempts to explore the real benefits of e-commerce based on data from 92 businesses in South Africa. The findings indicate that e-commerce benefits are by and large limited to improving intra and inter-organizational communications. Strategic benefits such as improving relationships across the value chain, increasing market reach and reducing market, operation and supply chain management costs are not as widely dispersed as the standard model of e-commerce would have made us believe. These findings support the argument that cautions against an over-optimistic view of e-commerce for developing countries.

**Keywords:** E-commerce, E-commerce benefits, Developing countries, South Africa

## 1. INTRODUCTION

Many prognoses of e-commerce in developing countries emphasize the opportunities that e-commerce can unveil for firms in developing countries to easily access the global market, strengthen their linkage to global supply chains and the range of cost saving, disintermediation and competitive advantage benefits that would be expected to follow such access (Goldstein and O'Conner, 2000; UNCTAD, 2003).

Others question the feasibility (and general optimism) of e-commerce for developing countries based on untested extrapolations from the experiences of industrialized countries. For instance, Pare (2002) argues that the idea of efficiency gains promised by e-commerce is far-fetched and overlooks the lack of core capabilities. Based on case studies of Chinese organizations, Hempel and Kwong (2001) and Ho and Chen (1999) argue that there is a mismatch between the culture embedded in e-commerce. Odedra-Straub (2003) reinforces the above and opines that the opportunity imperative undermines the resource and local infrastructure realities of developing countries' businesses.

Therefore, understanding what and how much benefits businesses in developing countries are extracting from e-commerce investments is important. This paper aims to explore the real benefit of e-commerce for businesses in developing countries. First, we review the literature on the potential benefit of e-commerce in general and for developing countries in particular. Then, based on data extracted from a survey of South African businesses, we explore the benefits of e-commerce. We finalize the paper by discussing the findings and making some preliminary conclusions.

## 2. THEORETICAL BACKGROUND

Of the various potential benefits of e-commerce for developing countries argued in the literature, three broad themes can be identified. These are improving linkage and market access, disintermediation outcomes, and improving firm efficiencies.

### 2.1 Linkage and Market Access

In the era of increased internationalisation of goods, labour and information markets (Wigand et al, 1997), markets and more specifically access to markets remain one of the crucial problems of businesses in developing countries. Especially, with the dominance of global commodity chains, linkage to global supply networks influences not only access to markets but also firm competitiveness (Dolan and Humphrey, 2001; Moodley, 2003).

Information and communication networks have the potential to make location-related constraints less influential and provide a better worldwide access to markets and market information (Wigand et al, 1997). They also facilitate the integration of national trading systems to global systems (Gereffi, 2001). It, therefore, follows that using e-commerce, businesses in developing countries, irrespective of size and location, could overcome the geographical barrier of trading globally and could access markets and supply networks that would have otherwise been impossible to them. As a result existing firms would be able to increase their market 'reach' and new firms would be able to flourish.

### 2.2 Disintermediation Outcomes

Disintermediation refers to the death (or gradual elimination) of the middleman (the intermediary) from the market value chain as organizations rely on the

potential of electronic networks to establish direct linkages with consumers and suppliers (Wigand and Benjamin, 1995). Although the disintermediation effect of e-commerce on all types of intermediaries and in all types of industries is critically challenged (see for example Bakos, 1998; Sarkar et al, 1995), it is tenable to argue that networks could enable organizations to bypass (even if not to completely eliminate) some, if not all, of the intermediaries and reduce the producer-intermediary or the intermediary-consumer transaction costs.

On the other hand, businesses in developing countries including those in the agriculture sector often depend on long supply chains both to market their products and to purchase required inputs (Dolan and Humphrey, 2001). More often than not, the intermediaries take the lion's share of the profit and they decide which products are to be delivered to the market and from which supplier to purchase equipment and other necessary inputs. They also add to the cost of input materials and finished products. As indicated above, e-commerce can enable producers and/or consumers to bypass some of these intermediaries and/or the costs associated with them.

### 2.3 Efficiency Gains

One of the costs that significantly affect efficient performance of a business or any other economic activity is the coordination cost (Malone et al, 1989). Coordination costs include costs incurred in coordinating the activities of people and work and the costs of participating in the market (Wigand, 1995; Sarkar et al, 1995). Malone et al (1989) postulate that advances in information and communication networks improve the speed and cost of communicating the same unit of information and enable the design and deployment of strategic linkages among market players. It also facilitates an electronic market place where buyers and sellers easily compare offerings. This, in turn, leads to efficient utilization of resources in coordinating activities and in reduced costs of transaction (Malone et al, 1989). Wigand (1995) relates the above benefits of electronic networks to e-commerce and indicates that through e-commerce organizations would be able to achieve an even cheaper unit cost of coordinating activities.

It has been argued that businesses in developing countries incur high costs in both production and coordination of their economic activities because of inefficient systems of procurement, communication, inventory control and operation (Mann, 2001). Such high costs normally add to the market price of products and affect the competitiveness of most developing countries' products in the global market environment. Therefore, from the notion of the argument pursued above, it follows that through e-commerce, businesses in developing countries would be able to reduce the cost of coordinating the work of people and machines in all

the "information, negotiation and execution phases" (Wigand et al, 1997) of their systems and increase their efficiency. In addition, through e-commerce, firms in developing countries would be able to reduce the transaction costs they would have otherwise incur to participate in international trade and sell their products and services more competitively.

In the remaining part of the paper, we explore to what extent the businesses surveyed in South Africa realized the above-hypothesized benefits of e-commerce.

## 3. NOTES ON RESEARCH METHODS

The data used in this paper is extracted from a survey response of 150 businesses conducted as part of a doctoral research project. For the purposes of this paper though, the e-commerce capability of the businesses was used as a data extraction criterion. In order to talk about e-commerce benefits, we assumed that the businesses needed to have at least an informational e-commerce capability. As a result, only businesses that have attained an informational or interactive or transactional or integrated e-commerce capability were selected. This has resulted into 92 data subsets.

We drew a set of e-commerce benefit statements from the review of the literature. The respondents were asked to express their degree of agreement about each of the benefit statements on a five point Likert scale ranging from 1 (strongly agree) to 5 (strongly disagree). We specifically sought out the CEOs, general managers and managing directors of the organizations to respond to the survey questions. The data were analysed using descriptive and exploratory statistical techniques.

A wide range of demographic characteristics was covered by the data subset. The majority of the respondents (72%) held a job title of managing director or CEO or general manager. The remaining respondents held directorial positions in finance (11%), IT (10%), e-commerce (4%) and marketing (3%). Eighty six percent of the organizations have been in business for more than 10 years. In terms of size (using the conventional measure of employee number), 83% can be characterized as large. Some 58% of the responses were from the manufacturing and services sectors. While the primary sector, i.e., agriculture, construction and mining represents 17% of the responses, trade and tourism and the ICT sectors account for 15% and 10% of the responses respectively.

## 4. FINDINGS

### 4.1 E-commerce Benefit Constructs

Exploratory factor analysis was used in order to identify underlying constructs and investigate relationships among the 16 items used to assess e-commerce benefits. The factors were extracted using an iterative sequence

of principal components extraction technique with eigenvalues greater than one. To facilitate interpretability, this was followed by varimax rotation. The criterion used for assigning an item to a factor was a minimum factor loading of 0.5. In addition, single item factors and items with a factor loading greater than 0.5 on two or more factors were excluded from subsequent iterations. The final factor structure with 3 factors containing 12 items was obtained after the third iteration (Table 1). In addition, Cronbach's alpha was counted and the scores were above the accepted level (Cronbach, 1979).

Examination of the results in Table 1 indicates that the first factor with six items accounts for 42.8% of the variance. We labelled this factor as the *market performance* gains of e-commerce and is related to both the linkage and market access and disintermediation benefits of e-commerce. Factor one appears to represent variables that constitute benefits in the downstream of the value chain. Businesses that use e-commerce can potentially increase their market reach and at the same time implement mass customisation strategies to produce products and services that suit the needs and preferences of individual consumers (Fruhling and Digman, 2000). Organizations can also use e-commerce to reengineer the selling and distribution processes and eliminate some of the intermediary activities to develop direct contact with their customers. This allows locking-in of customers, improving their relationship with the business and developing their loyalty. As a result, e-commerce might contribute to increasing the business bottom line and promoting competitiveness (Warrington et al, 2000). The results of our survey (Figure 1) indicate that market performance e-commerce benefits among the South African businesses significantly fall short of the above expectations.

The second factor with two items accounts for 14.7% of the variance and is labelled as *communications* improvement benefits of e-commerce. Kalakota and Whinston (1996) consider communication as one dimension of e-commerce. Use of e-mails, intranets and extranets might help organizations to improve the reach and richness of the information to be communicated. In addition, such networks could improve the speed and cost of communicating the same unit of information and enable the design and deployment of strategic linkages among market players (Malone et al, 1989). Our finding (Figure 1) indicates that this is one area that the businesses seem to reap the most out of e-commerce.

The third factor with four items accounts for 10.66% of the variance. This factor is related to the firm efficiency theme identified in the literature review and is labelled here as the *transaction cost reduction* benefit of e-commerce. Wigand and Benjamin (1995) differentiate between market and hierarchy transactions. While market transactions refer to those that support coordination between multiple buyers and sellers, hierarchy transactions, on the other hand, refer to those supporting coordination within the firm as well as the industry value chain. The items under factor three appear to show hierarchy transaction cost savings. Such savings are expected from reductions in operation costs (such as personnel, rent and order processing) supply acquisition and supplier management costs and improvement on internal processes. However, such benefits of e-commerce appear to have eluded our respondents (Figure 1).

Table 1: E-commerce benefits factor analysis

Variable	Factor Loadings (Varimax raw) (ECbenefit) Extraction: Principal components (Marked loadings are > .500000)		
	Factor 1	Factor 2	Factor 3
Extending firms reach (market)	0.840		
Product/service differentiation	0.846		
Increased customer loyalty and retention	0.809		
Improved revenue	0.596		
Improved competitive position	0.620		
Improved customer relationship	0.733		
Improved internal communication		0.859	
Improved external communication		0.906	
Improve process speed			0.588
Reduced operation cost			0.735
Reduced cost of purchasing and procurement			0.833
Improved supplier relationship			0.736
Eigenvalue	5.142	1.768	1.280
Total Variance explained %	42.85	14.73	10.66
Cronbach's Alpha	0.87	0.71	0.78

Figure 1: Status of E-commerce Benefits

The three factors extracted above demonstrate some relationship (Table 2). Particularly, there is a relatively stronger correlation between market performance and transaction cost reduction. This implies that if a business is not successful in reducing transaction costs, then it is unlikely for that business to perform better in the market, which means it would find itself at a competitive disadvantage.

Table 2: Correlation coefficients

	Correlations (Ecbenefit)		
	Marked Correlations are significant at $P < .0500$		
	Market Performance	Communication	Transaction Cost Reduction
Market Performance	1.00	<b>0.29</b>	<b>0.54</b>
Communication	<b>0.29</b>	1.00	<b>0.35</b>
Transaction Cost Reduction	<b>0.54</b>	<b>0.35</b>	1.00

#### 4.2 Impact of Demographic Variables

To explore differences of e-commerce benefits in small and medium and large enterprises, the mean score values of the three factors were plotted (Figure 2). Examination of Figure 2 indicates a more or less similar pattern. In both small and medium and large organization groups, improvements in internal and

external communications are reported by most organizations while cost reduction and market performance benefits remain the least experienced. The graph also indicates a relatively better e-commerce benefit for small and medium enterprises in the first two factors, i.e., market performance and communications. The significance of this difference is further tested using a one-way ANOVA. The result ( $Wilks\ lambda=0.967$ ,  $F(3, 83)=0.9573$ ,  $p=.417$ ) indicates that the difference is not statistically significant.

Figure 2: E-commerce benefits by business size

In addition to size, we tested if businesses belonging to different sectors demonstrate variations in terms of e-commerce benefits. The sector wise mean benefit scores are plotted in figure 3. The result has not produced a single pattern indicating one particular sector benefiting more from e-commerce than other sectors. The ANOVA test ( $Wilks\ lambda=0.88446$ ,  $F(12, 211.95)=0.83895$ ,  $p=0.61022$ ) with no statistically significant result has reinforced this finding.

We anticipated the e-commerce capability of businesses to have some impact on e-commerce benefits. The mean plot (Figure 4) appears to indicate a clear distinction in terms of benefits between businesses with informational e-commerce capability and those that have developed integrated e-commerce capability. As anticipated, businesses that have developed an integrated e-commerce seem to have reported greater benefit from their e-commerce investment in all the areas. However, the ANOVA and discriminant function analysis tests did not produce statistically significant results showing the effect of e-commerce capability on the benefits of e-commerce.

## 5. DISCUSSIONS AND CONCLUSION

Our findings about the benefits of e-commerce for businesses in South Africa appear to contradict most of the themes outlined in the theoretical background section. They also appear to contradict to the buoyant optimism surrounding e-commerce's potential for developing countries. The majority of the businesses do not appear to have obtained e-commerce benefits in terms of expanding their market reach, improving their competitive position, and improving relationships with customers and suppliers. Cost reductions due to savings from improved internal processes and operations have not been as widely found as the standard model of e-commerce would have made us believe.

The results of the study reinforce many of the empirical findings of previous research on e-commerce in developing countries. For instance, Moodley et al (2003) based on a study of garment exporting firms in South Africa found that e-commerce has neither allowed those firms to by-pass middleman nor reduce trade coordination and transaction costs. Pare (2003) analysis of 117 B2B e-hubs discovered that neither are the e-hubs providing services that contribute towards transaction cost reduction nor are the businesses participating in those hubs reaping such benefits. Humphery et al's (2003) findings on the garment and horticulture industries of selected developing countries also suggest that many potential benefits relating to transaction facilitation and reach did not apply to the businesses they interviewed.

One variable that might have affected our results and perhaps the results of many other developing countries focused e-commerce studies is the embryonic nature of e-commerce there. Zhu and Kraemer (2002) have found a strong and significant relationship between the richness of e-commerce capability in terms of information, transaction, interaction and customisation and supplier connection and its value and impact on business performance. The majority of the businesses in our survey (68%) could be categorized as having an entry-level (informational and interactive) e-commerce

capability with only 26% and 6% achieving a transactional and integrated e-commerce status respectively. This is consistent with findings from Brazil (Tigre, 2003), China (Tan and Ouyang, 2004), Malaysia (Le and Koh, 2002) and South Africa (Moodley, 2003). Such capabilities would most likely support the conduct of basic communicational and informational but not transactional activities, hence limiting the extent of e-commerce benefits.

Further, the experience of developed countries suggests that at the early stage of e-commerce there was a significant gap between its anticipated and actual achievements (Marshall et al, 2000). The NNI (1999) supports this and suggests that expecting cost savings from e-commerce instantly is not realistic because benefits might take a long time before they actually materialize. In developing countries in particular, the marginal cost of adopting e-commerce tends to be much higher than in other environments. This is because adopting e-commerce requires additional investments to put in place basic automation and informatisation systems and business networks. Hence, in the short term, e-commerce might add to the transaction cost further delaying the realization of cost saving benefits.

Mansell (2001) and Patterson and Wilson (2000) argued that the capacity of DC businesses to achieve perceived benefits of e-commerce is dependent on their ability to reduce many facets of technological divides and improve the institutional arrangements that support the conduct of business. Likewise, elsewhere, we found that the e-readiness of developing countries' businesses to have significant impact on e-commerce success (Molla, 2004). In particular, we showed that the e-commerce governance model organisations put in place, senior management commitment, and human, business and technological resources all influence marketplace and cost saving benefits.

The findings documented above have some further implications. Many businesses in developing countries are encouraged to adopt e-commerce in order to take full advantages of this new business platform. The result

of this current study provides researchers and practitioners with initial guidance that can be used to manage expectations of returns on e-commerce investments. It also extends previous findings that caution against the over-optimistic view of e-commerce both in terms of organisation-specific gains and contributions to socio-economic development. Particularly, it indicates that entry-level e-commerce applications are unlikely to generate the potential benefits hypothesized in the literature. Rather, what is implied here is that, the capacity of developing country businesses to achieve the perceived benefits of e-commerce requires building up their internal organisational capabilities. It also requires improvements in the richness of e-commerce sites on all informational, transactional and interactive dimensions and the institutional arrangements that affect its conduct. The study also provides researchers with an initial set of factors and items that could be used in future research. This would facilitate an understanding of the antecedents and outcomes of e-commerce in developing countries.

To summarize, our result shows significant shortfall from the optimistic view of e-commerce. However, it is not tenable to extrapolate from this and make sweeping generalizations about either e-commerce in South Africa or the wider developing countries context. In fact, this current study is limited in terms of its sample coverage in both geographic and size terms. In addition, the results we observed here are likely to change in the future as businesses in developing countries accumulate experience and improve their organizational and e-commerce capability. Hence, in order to better understand the e-commerce phenomenon in developing countries, further research that expands both the geographic and sample size coverage of our research is recommended. Research is also recommended that not only assesses the benefits but also the antecedents that affect those benefits.

# Intended Usage of Online Supermarkets: The Singapore Case

Hui Tak Kee, David Wan

NUS Business School, National University of Singapore, Singapore 117592  
{bizhuitk, bizwantw}@nus.edu.sg

## ABSTRACT

The online grocery sales experienced a surge in Singapore especially in the early half of 2003 during the SARS outbreak. The Technology Acceptance Model and some basic demographic variables will be used to study the intended usage of online supermarkets. Based on a sample of size 211 shoppers, it was found that those 21-40 years old have a propensity in using the online grocery. However, those having income lower than \$1,500 have less inclination in using the e-grocery. The stepwise discriminant analysis shows that two perceived variables, usefulness and ease of use, and two demographic variables, age, income are significant in differentiating the intended customers. Our results are different from the past studies where the gender and education are found to be significant. This may be due to the fact that most respondents in the sample are under 41 years old with at least tertiary and above education.

**Keywords:** Online supermarket, factor analysis, discriminant analysis

## 1. INTRODUCTION

A supermarket is a large self-service food store (McClelland, 1962). As the grocery industry grew, this definition also expands to encapsulate items such as basic household requisites although its strongest association remains with groceries. Priluck (2001) revealed that consumers in US make an average of 2.2 visits to a supermarket per week to shop for groceries which is signaling the importance of such an activity.

However, grocery shopping has taken on a new dimension with the advent of the Internet. Riding on the rising trend of online retailing, supermarkets and logistics companies have equally come out with their own version of online supermarkets. Lorek (2001) indicated that online grocery sales seven years ago in the United States were only \$85 million but it was estimated that the online grocery store revenue may reach \$1.3 billion in 2002. Today, traditional brick-and-mortar stores are increasingly entering the online market in an attempt to leverage both brand awareness and create distribution (Kempiak et al., 2002).

Nonetheless, not all is rosy for the players trying to create their own sphere in the e-grocery businesses. Britain's No. 1 supermarket chain – Tesco – has watched one rival after another put up the white flag on their e-grocery businesses (The Business Week, 2000). In the U.S., the failure of the Webvan Group Inc. in trying to establish a purely Web-based grocer was fuelled by the low customer demand that was not sufficient for Webvan to operate the facilities at anywhere near their capacity.

Given the mixed success signal sent by online grocery retailers, it is vital for supermarket operators to understand how people decide whether they will use the grocery services provided online, for systems that are not used cannot be effective no matter what their

technical merits. This need is particularly relevant for the increasingly competitive online grocery retail market, in which numerous supermarkets compete among themselves within a relatively stable market (Rohm et al., 2004). Furthermore, from a managerial perspective, classification of potential users provides the basis for understanding and targeting different groups of consumers.

Given that online grocery shopping is nascent in Singapore, a typology specific to this medium of purchasing will enable us to identify distinct segments of potential consumers, thereby allowing retailers to effectively tailor their offerings to these customer types. Also, such a new retail channel cannot be effective unless they are used. Consequently, it is important for supermarket operators to understand their consumers' attitudes toward using online services. Our objective is thus to identify and profile the characteristics of such potential users of online supermarket and in turn, make a preliminary assessment of consumer demand for online grocery shopping services based on attitude measures.

More importantly, we have attempted to use a relatively new model, the Technology Acceptance Model (TAM), which serves to articulate the core psychological aspects associated with technology use. Based on a generic model of attitude and behavior, the TAM has provided a robust and valuable model when considering information technology acceptance by potential mainstream users (Taylor and Todd, 1995). It has also been able to provide good prediction of an individuals' intention to use a particular information system.

To date, Singapore enjoys reliable and sophisticated networks for information technology and telecommunications services, transportation and utilities. The information technology and

telecommunication infrastructure of the city-state is particularly well developed. During the height of dot-com boom, 47% of households have personal computers while 53.8% of the residential populations have Internet access or subscriptions. In 2003, online grocery sales experienced a surge, particularly in the early half of the year during the SARS outbreak. This was apparently good news for NTUC Fairprice and Cold Storage, the two main supermarkets in Singapore that offer online grocery shopping. It was reported that online sales of Fairprice Online have attained an increase of as much as 300% in one week at the peak of the outbreak.

It is our goal to construct a forecasting model to predict the intention of consumers to shop for groceries online, which in turn could give a reasonable estimation to actual system use. Specifically, we want to look at consumers who have access to the Internet, and to seek an understanding of their attitudes toward online grocery services. In short, we would like the prediction model that we have established to forecast an individual's intention to use the online service.

The paper is structured as follows. First, we take a look at the present situation of supermarkets in Singapore in the introduction section. Second, we review the literature on online grocery shopping and the TAM. Third, we discuss the methodology and data collection procedure. Fourth, we present our analyses and the results. Lastly, we discuss the limitations and the implications of this study, and draw a conclusion.

## 2. LITERATURE REVIEW

### 2.1 Profile of E-grocery Shoppers

Online grocery shopping accounted for less than 1% (\$150 million) of the total supermarket sales (\$440 billion) in 1998 (Beck, 1999). Sales of online grocers concentrated around specialty foods and it is likely that this trend will continue. In fact, market analysts expected that 5% to 8% of all groceries sales would transact through online within the next five years (Lundegaard, 1997; Kirsner, 1999). Furthermore, Anderson Consulting (Buss, 1999) had predicted the online supermarket market in US to increase significantly from 200,000 people currently to 20 million in 2007. With the increasing prevalence of online shopping in the long run, it is easy to understand the industry's interest in online grocery shopping. A recent forecast made in a Forrester research report predicted that online retail sales would increase from US\$45 billion in 2000 to US\$269 billion in 2005, which is a growth of close to 600 percent (Dykema, 2000). The study by Buss (1999) noted that even by achieving 1% of the grocery market would translate to a US\$1 billion per year business for online grocers.

There is an extensive range of literature that can be found with relation to online grocery shopping. In particular, various demographical studies had been carried out to identify the various groups associated with online grocery shopping. It has been pointed out that such online shoppers tended to be "boomers" with large households, with their demographic profile skewed towards the 35-49 age groups. In addition, those who shopped for groceries online were generally well educated, with three-quarters having obtained at least a college degree. In a study conducted by Park et al., (1998), they categorized online grocery shoppers into two groups: hi-tech baby boomers and older/ low-income suburban families. Not surprisingly, a survey carried out by Priluck (2001) also revealed that education was the main demographic variable affecting the tendency to buy groceries online, whilst the other demographic variables proved to be less significantly related to consumers' willingness to purchase grocery items online.

A similar study by Hiser, Nayga and Capps (1999) also found that variables such as income, the number of people living in the household, the presence of children and gender were not significant determinants to the usage of the online grocery shopping service. Age and education have proved once again to have a positive relationship in this study. However, it also revealed that people over age 50 were less likely to consider the service, as compared to people from age 18 to 29 years old.

These studies on online grocery shoppers' demographics provide the basis of understanding and targeting different customer groups. Furthermore, through the identification of definite online shopper segments, retailers can strategize their services to tailor to the needs of specific segments.

### 2.2 Technology Acceptance Model

In an attempt to better understand user acceptance of new information systems, Davies et.al. (1989) developed the Technology Acceptance Model (TAM). They postulated how users' attitudes toward using a computer system influences the actual use, or acceptance of this system. The two major design features are the 'perceived usefulness' of the system, and the 'perceived ease of use'. The former is defined as the "degree to which an individual believes that using a particular system would enhance his or her job performance. The latter is defined as the "degree to which an individual believes that using a particular system would be free of physical and mental effort" (Davies, 1993). It was argued that these two features formed the users' attitudes toward using a computer system.

Research in social psychology has shown that behavior is best predicted by an individual's attitude toward the

behavior. For instance, it is difficult to estimate eventual system use if the system does not exist yet. Still, it was widely believed that an individual's intention to use the system could be measured. There is also considerable evidence that intention to perform a behavior predicts actual behavior (Sheppard et al., 1988).

Davies (1989) found that the TAM was able to predict the intention to use a word processing package fairly well. Henderson and Divett (2003) have also successfully applied the TAM to an online supermarket setting, thus providing empirical support for the ability of the TAM to predict actual behavior. It is the latter case that propelled us to adopt this model in predicting potential consumers' intention to use the online grocery services.

### 3. Methodology

#### 3.1 Data Collection

The research sample employed in this empirical study consists of customers of two supermarkets in Singapore, namely NTUC-FairPrice and Cold Storage. Data were collected on February 2004 at each respective supermarket. A sample of 211 shoppers was taken altogether. These are customers who have just made their purchases from the supermarkets. Furthermore, we administered our questionnaires to those shoppers who have Internet access at home. The purpose of targeting only at grocery shoppers who have Internet access at home allows us to gain a specific understanding of the propensity of these actual grocery shoppers to shop for groceries online. Hence this group of grocery shoppers forms our target population. Furthermore, we only approach every third person that come out of the supermarkets to ensure randomness.

The majority of the respondents are below 40 years old (81.5 percent). Other than that, the profiles of the respondents are generally equitable, with approximately 50 percent of them being male and possessing some form of tertiary education. A total of 54 percent reports an annual income of \$2000 or below.

#### 3.2 Measures

The survey is divided into three sections. The first section requires the respondents to provide a broad detail of their socio-economic backgrounds. In section two, we present two dichotomous questions which are used to elicit their responses toward their use of and intention to use online supermarkets. As the e-grocery services in Singapore just take off, we postulate that the number of online grocery shoppers has yet to reach a critical mass. This is bore out by the fact that only two of our respondents have ever used the Internet to purchase groceries. It is thus appropriate for us to get acquainted with the consumers' intention to use, as

opposed to seeking consumers who have used such services. This is supported by the TAM model as explicated previously.

Finally, a set of multiple-item scales is constructed under two main variables which are guided by the TAM framework. The questionnaire contains 6 attitudinal statements on a five-point Likert scale anchored by strongly agree to strongly disagree. These items examine the consumers' attitudes and perceptions toward the use of online grocery services

Contingency analysis is first used to test whether the demographic variables are associated with the intention variable. This will at least give some ideas on which demographic characteristics are more inclined to the use of the internet for grocery.

Factor analysis is then used to classify the initial six variables derived from the attitudinal measures in the questionnaire into two distinct factors, namely 'perceived usefulness' and 'perceived ease of use' using principal component and varimax rotation. The resulting factor scores will be used for the subsequent analyses.

Using the factor scores from the two derived factors and the profile of the respondents, we proceed to use the discriminant analysis technique to evaluate whether the consumers' perceptions of Internet as a shopping medium for grocery purchase and their profile characteristics can be used to predict their intention of using e-grocery services in the next one year.

In this study, we have identified 6 predictor variables (based on the demographical profiles and the TAM model) to predict the intention of an individual to use the e-grocery services. Furthermore, we use only 190 responses as an estimation sample to construct the classification rule to enable us to perform a post-hoc test of our model later. Lastly, we would classify the remaining 21 hold-out cases according to our discriminant model in order to assess the predictive validity of the model, that is, to test whether our model that is estimated with one set of data continues to hold good for the hold-out data.

### 4. RESULTS

Based on the four demographical profiles against the intention to use variable, the chi-square tests derived from the contingency analysis only shows the presence of a relationship between the three profile variables, namely, age, education level, income level, and the intention to shop for groceries online (all p-value < 0.05), and not the gender variable (p-value = 0.710 > 0.05). We can thus conclude that the intention to use this service is dependent on the age, education and income levels of consumers.

From the same results, we also notice that generally, those around 21-40 years old have a higher propensity to use online grocery services. This is expected since this group is the most economically stable. On the same note, those who have some form of tertiary education also express their intention to use such services in the near future. Those who possess income of less than \$1500 tend to have little inclination to using e-grocery services. As mentioned previously, the chances of consumers of any gender having the intention to use such services are almost equal. This initial profiling of the variable relationship would provide a basis for the affirmation of the results in the later analyses.

Two factors were extracted using Principal Component Analysis and rotated using Varimax with Kaiser Normalization. About 74.8% of the result can be explained by the two components, namely, the 'perceived usefulness' and 'perceived ease of use'.

The factor scores derived from the above factor analysis for the components of *Perceived usefulness* and *Perceived ease of use* are included as independent variables in the stepwise discriminant analysis. Other independent variables consist of Gender, Age, Income level and Education level. The Wilks' Lambda ( $p$ -value = 0.00) shows that the discriminant function is highly significant. The success rate for the predictions of membership of the criterion grouping variable's (i.e. intention to shop for groceries online) categories using the discriminant function developed in the analysis is 87.4%. The classification results also reveal that subjects with no intention to shop for groceries online are accurately classified for most of the cases.

## 5. DISCUSSION

Our prediction model obtained through discriminant analysis is able to predict the intended usage of online grocers with an accuracy of 87.4%, given their demographic and psychographic profiles. It is interesting to note that the discriminant analysis has yielded a different result from those of previous studies in our literature review. From the results, it is observed that the variables Gender and Education level are removed from the analysis. This result is deviated from those put forth in past literature (Hiser et.al. 1999; Priluck, 2001) which concludes that Age and Education level are the main variables in the determination of online grocery shoppers. These studies find that online grocery shoppers tend to skew towards a certain age group and that they are mostly well-educated, having obtained at least a degree.

The inclusion of Income level and the exclusion of Education level from the discriminant analysis can be explained from observations noted from the survey data from a sociological perspective of our local context. An analysis of the survey data reveals that

most of our respondents under 41 years old with tertiary or above education level and, also those with income level below \$1500 do not intend to purchase their groceries online in the next one year. These respondents are made up mainly of tertiary educated students who have no necessity to purchase groceries on a regular basis. Their parents would purchase the groceries for the family in most cases. Even if this is not so, this group of respondents is not constrained by the lack of time and family commitments. Also, it is observed that a significant number of working professionals under the same age group with tertiary education level and above, have intentions to use the online grocery shopping service in the next one year. In-depth analysis of their survey responses reveals that their main motive for intending to shop for groceries online is the convenience and timesaving factors online grocers provide. The main differentiating factor between the above two groups of respondents is their income level, as the later group of respondents earns a monthly income of \$1500 and above. Therefore, this results in income level having a greater influence than education level in the determination of intention to shop for groceries online.

Our study has some potential limitations. First, given the few variables identified, the respondents might be given too few options to indicate their preferences over the choices provided. It is likely that there exist other important variables that could explain one's propensity to shop for groceries online or predict one's intention. These variables, such as price or Internet accessibility, have not been studied in this paper and thus constitute a limitation of this research. More variables should have been included to produce a more comprehensive and robust model in order to capture the variance that is not explained by the variables we have identified.

## 6. CONCLUSION

There is considerable evidence that intention to perform a behavior predicts actual behavior (Sheppard, Hartwick, and Warshaw 1988). Under this premise, the model that we have constructed using discriminant analysis validates the empirical support for the prediction of intention towards the use or acceptance of electronic supermarket. Other than attitudinal influence, the results have also illustrated how certain demographic variables such as age and income level significantly influence users' perceptions and intention towards the usage of online supermarket. These variables have helped us build a good forecasting model that provides good prediction of individual's intention to use the online grocery system. Our findings also suggest that consumers will be motivated to shop for groceries online if they perceive the services offered by the online grocer to be useful and easy to use. This has implications to retail and marketing managers who are intending or have already set up an online grocery business.

From the results reported, marketers can target the specific age and income groups that show a high tendency to shop for grocery online. They could design their online grocery service to cater to the needs of these consumers, such as providing a large variety of products or making the online shopping process quick and hassle-free. Furthermore, they could utilize the reported results to interpret the factors that are keeping other consumers from using such a service, e.g. online grocery shopping is not convenient and time-saving, and examine ways to improve their service to attract a greater proportion of other consumer segments.

Some of the limitations of this research would provide a premise for future research. Although our research has identified a few main variables influencing the motivations of consumers to shop for groceries online, however there is also a need to address some other key factors, such as the quality of product and price that are associated with home shopping, which will also have an impact on a consumer's perception.

Online grocery shopping is a relatively new phenomenon in Singapore. The characteristics of the sample used in our research may change when the trend starts to be widely adopted, signaling the need for future research. In addition, most of the past studies are conducted and analyzed in the U.S. context, which might culturally differ from the Singaporean context. Therefore, it is recommended that future research explore the factors associated with the possible mediation effect of usefulness upon ease of use in our local context.

## Positioning of Firms on an E-Business Value Chain: the Case of Video on Demand

Nabyla DAIDJ, Olivier EPINETTE, Pierre VIALLE

STRAT&MARKETIC Research Group, Institut National des Télécommunications, 91011 EVRY, France  
{nabyla.daidj, olivier.epinette, pierre.vialle}@int-evry.fr

### ABSTRACT

The provision of e-business services is supported by the implementation of value chains based on co-operation between firms combining different resources and capabilities in order to design, produce and market new products and services. The emergence of such value chains is characterised by the positioning of various players according to their specific resources and capabilities, whether they be existing or new firms. Our interest, by combining insights from the Resource-Based View and other perspectives, is to analyse according to what resources are necessary for actors to be able to successfully position themselves on a value chain, with a particular focus on relational assets, in the specific Video On Demand sector (VOD). This case is particularly relevant to show the structuring of a new value chain around new and “traditional” stakeholders. We shall first define the specific features of the movie industry. Secondly, we shall then present on the VOD value chain. Then we analyse how a company (called Moviesystem) has positioned itself on VOD value chain thanks to its specific resources and capabilities. We shall conclude by drawing general lessons from this case.

**Keywords:** e-business, Video on Demand, value chain, strategy, resources, relational assets

### 1. INTRODUCTION

The emergence of the so-called multimedia industry, based on the expected merging of three vertical industries (telecommunications, computing and the media) into a new horizontally layered one, raised tremendous interest at the end of the 1990s. There was a great deal of conjecture about how this new industry would be structured, and what types of player would be successful in positioning themselves in this emerging value chain ([6], [15]). A decade later, it seems interesting to analyse how value chains are finally structured and how and why some players have been able to position themselves successfully. Such a long delay is justified for two main reasons. First, the capabilities of the technical objects and systems at the time were clearly over-estimated, as was their speed of diffusion. In fact, it is only recently that adequate techniques and resources have become available to users. Second, different organisational arrangements and business models have been tested by various types of players, and time is therefore necessary in order to be able to draw lessons from these experiences.

This is particularly the case Video on Demand (VOD). On-line movies were probably the best-publicised example of multimedia service, and high business expectations gave rise to significant strategic moves from players of the three converging industries. VOD may be defined as content offered when demanded by consumers. Any video may be downloaded on a Personal Computer via the Internet. This service can be described very simply by the following value chain: it is developed by movie studios, bought by companies which package them and transform them into IP content, which are then sold to consumers either directly over a web site or

indirectly, through ISPs acting as distributors ([5], [10]).

Paradoxically, this business still remains largely under-developed among other on-line services. According to Jupiter Research, the world market for Video on Demand (VOD) amounted to only \$ 349 million in 2003, mostly in the United States. However, this market now appears promising. Until recently the bulk of the market was concentrated in the United States and was mainly served by cable operators. With the widespread uptake of ADSL connections, this market is expected to grow, and particularly outside the United States. The main ISPs are currently launching or preparing on line TV services that are or will soon be coupled with VOD services. According to Jupiter Research, The world market should reach a level of \$ 2 billion in 2006.

From our perspective, this case is especially relevant because it is a genuine case of convergence between three industries with different cultures, visions, business models and resources. Of particular interest is how a very specific industry has had to adapt to the constraints of electronic distribution. The provision of VOD services involve some significant adaptations of the movie value chain, such as content digitalisation and formatting, digital rights management (DRM), server platform management, movie catalogue management, relations with network operators or ISPs, or billing and customer management ([5], [10]).

We shall present how a VOD company, Moviesystem has positioned itself on the VOD value chain because of its specific resources and capabilities. These resources and capabilities allow Moviesystem to link the movie environment with the electronic distribution environment.

It is a good example of a company pioneering new forms of movie distribution by working with established film studios. Distributors are faced with strategic issues in terms of promotion and the associated time and geographic span of exhibition. Electronic distribution is a new step but it is also affected by the profit windows for film rights and by the distribution of the ownership of the film rights.

In this paper, we first of all present the specific features of the movies industry. Secondly, we will introduce the VOD market, the technological systems, the value chain and the challenges in providing VOD services. Then, we analyse how Moviesystem has positioned itself on the VOD value chain, in order to outline the critical resources that allowed Moviesystem to reach its current position. We conclude by drawing more general lessons from this case.

## 2. VIDEO ON DEMAND

### 2.1 The economical and technological context

VOD is a service providing video programs (typically movies, but other programs as well as requested by the customer in a catalogue and delivered at a time chosen by the customer. VOD is an expensive service, its cost depends on: the size of the program catalogue, the flexibility offered as to viewing and the quality of pictures sent. The VOD market must be put in perspective with the economics of the movie and media industry.

Movies are distributed through multiple channels in sequential release windows in a specific order. The majority of the revenues generated by a film are received within 18 months of a film's distribution cycle. After exhibition in its home country, the film passes over the following months into other channels: exhibition abroad, home video (cassette or DVD), Pay-Per-View, pay TV then free broadcast TV, leading to the profit release windows. This timeline must be respected by all stakeholders of the sector. This film cycle is based on its potential revenue along the different market segments, according to territoriality (by country and by linguistic zone) and time (duration and distribution rights) agreements [7].

VOD appears as a new release window in this film's distribution cycle. The question is to know when motion pictures will be available for VOD: should VOD share release dates with PAY-TV? Many VOD actors (in particular aggregators) insist on the necessity to link the VOD time window with the traditional and physical channel of delivering movies that are video rental/sell stores<sup>1</sup>. It should be a condition of VOD success [11].

<sup>1</sup> "Some 80% of a title's home-video rental and DVD purchase business is done within the first 30 days of its hitting the rental shelves. In other words, the newer a movie, the more valuable it is. The implication is that the closer the VOD release window gets to the video rental window, the more VOD operators can

As broadband offers new opportunities for the distribution of movies, the development of VOD interests several actors: telecommunications operators (opportunity for them to adopt a «triple play»<sup>2</sup> strategy), ISPs, ADSL providers, television channels, cable and satellite operators, film companies and production studios. Operators see VOD applications as a means to increase the return on their broadband investments. TV channels can take advantage of telecommunications deregulation in order to sign partnerships with alternative service providers. Movie studios and film companies consider VOD as the missing link for an accelerated and a more efficient marketing and distribution of the films. They try to attract service providers through their huge catalogue of movies and programming.

Today, end users have mainly three options for viewing VOD programming [4]:

- Pay-Per-View / Near Video On Demand on cable/satellite systems: Video technique used by broadcasters using broadband distribution mechanisms such as cable and satellite TV. This form of broadcasting uses large amounts of bandwidth and is only viable for operators with large amounts of spare capacity. Cable Multiple system operators (MSOs) are particularly interested in VOD looking for a return on their investments in upgrading their networks to support digital services. These services are well positioned in particular in the countries where cable is fully deployed (USA)
- Personal video recorder (PVR) on cable/satellite systems: in the USA, Tivo and Sony Digital recorder, and in France Pilotime/Canal Satellite. PVRs are the first step in introducing a home media server. These PVRs (with several functionalities such as stop, pause etc.) allow customers to download a movie during the day in order to watch it a few hours later (in the evening). This offer relies on a more limited range of movies.
- Peer-to-Peer systems characterised by low quality, very large catalogue and variable viewing flexibility.

### 2.2 The VOD value chain

The VOD value chain will depend on the nature of technical architecture used and on the complexity of the network [5]. While this framework can vary according to the nature of the technology used, the general structure is quite similar. In addition to content closely linked with Digital rights management (DRM) –that is a key issue for any kind of content distribution and especially for movies - the VOD system requires software, hardware and network assets and creates new middle layers in the value chain:

- head-end video servers and platforms (encoding content

---

charge for their content and the greater the usage that can be expected. Currently, the premiere pay-per-view window is lagging behind the home rental window by an average of 50 days. The effect of that gap is to dampen demand for VOD and limit the price that can be charged for a VOD movie"[11].

<sup>2</sup> by bundling together telephone, Internet, and TV services

servers, middleware)

- system management functions (control access, DRM, billing functions can be also included)
- transport/access (transport across the network from the head-end to the DSLAM or cable hub near the consumer and connection over the “last mile” to the subscriber’s Set Top Box)
- end-user equipment (Set Top Boxes)

The table 1 below presents a framework showing how the VOD industry is organised. For the first steps, it relies on the cinema value chain presented above. Some stakeholders have several positions in the VOD value chain by aggregating, selling VOD services directly to consumers and operating their own network (Ebiscom/FastWeb in Italy)

Table 1: VOD value chain

Activity	Function	Stakeholders involved
Content provision	produce movies, manage rights, market programs	Content providers, movie studios, film companies
Services provision	Stock films on servers (based on technologies for encoding such as digitalisation and compression) and then distribute them either through downloads (temporary) or streaming, deliver VOD for the consumer over DSL, cable. Multiple functions: <ul style="list-style-type: none"> <li>- negotiate rights with content providers,</li> <li>- ensure the remuneration of the holders of the rights,</li> <li>- manage all the data associated with the program (language),</li> <li>- ensure the protection of these programs by appropriate encryption,</li> <li>- update the offer according to consumption parameters and contractual rights,</li> <li>- produce programs guides and graphic interfaces,</li> <li>- set up a commercial policy suited to the various types of products</li> <li>- manage invoicing and payment</li> <li>- ensure promotion of the service</li> <li>- negotiate agreements with physical distributors (network operators) for integration in the platform’s offer, either under the name of the end distributor, or under the service provider’s own, or using the “co-branding” system that enables each party to make the most of its contribution</li> </ul>	Specialised portals, content, aggregators video services providers
“Physical” transport and/or commercial distribution	<ul style="list-style-type: none"> <li>- construct a server-client architecture dedicated to VOD (including a billing system)</li> <li>- provide the infrastructure and access networks to carry VOD</li> </ul>	Access network providers, broadband network operators, ISPs
Consumption		End-users

Source: Adapted from activities described in [10]

### 2.3 Issues at stake and threats

We have provided a basic level for how the VOD is organised and we have to highlight some issues it faces:

- the increasing weight of Microsoft in the film industry process with the use of Windows Media player.
- even if bandwidth and services issues are resolved, VOD will face the same problems of piracy and content protection as the music industry through freely available movies through peer-to-peer distribution over the net.
- DVDs have provided huge revenues to distributors over the last five years. Video rentals and DVD purchases account for as much as 50% of a film’s revenues. A possible risk of an online distribution is to jeopardise the revenue stream from DVDs.

## 3. THE MOVIESYSTEM CASE

### 3.1 Case presentation

Created in March 2000, Moviesystem has become the leading European VOD operator. Starting from a traditional activity of purchasing of exclusive rights for

movies and wholesale distribution of VHS cassettes to professionals, Moviesystem entered the VOD market with the acquisition of a VOD service on the Internet, NetCiné.com. Moviesystem was initially supported by Pathé and Europa Films (Luc Besson’s company), which provided funds and the VOD rights for their catalogues. Consequently supported by innovation funds such as OTC Innovation 1 and A plus Finance, Moviesystem has signed numerous agreements with content providers and now has a catalogue of 1500 films from 70 production companies. In May 2004, Moviesystem was bought by Canal +, a leading French and European Pay-TV company. Moviesystem’s three main activities in VOD business are:

- the purchase and management of exclusive rights,
- the development and operation of a specialised middleware platform,
- the commercial operation of VOD services.

Moviesystem’s middleware platform is organised around Windows Media™ 9 technology. This platform allows the addition of meta-data to protect rights, the digital coding and the encryption of films and other programmes. It also provides a full range of features, such as management of content, conditional access and

Digital Rights Management, user interface customisation, reporting and edition of statistics, and bandwidth management.

The IP-based streaming platforms can be installed in the operators' network. In order to ensure quality and speed of streaming, as well as to deal with peaks of demand, it is better to have numerous servers located as near as possible to the end users.

Moviesystem addresses the VOD market through both direct and indirect distribution. As concerns direct distribution, Moviesystem operates its own service directed at Internet users, called NetCine. NetCine's web site offers films for streaming that are grouped in various categories (such as news, comedy, drama, children, adult, etc). The film catalogue is updated every week with titles recently released on the video rental market. In order to simplify and secure transactions, Moviesystem introduced an electronic purse system with tokens. Customers can buy 5, 25 and 60 tokens, for a respective price of EUR 5, 20 and 40. A recent film is offered 9 months after its first showing for 5 tokens, that is between EUR 3.30 and 5.00 (depending on the token package concerned), a price that is comparable to the rental of videos. Once a programme has been purchased, it can be accessed for 24 hours after which the subscription expires. NetCine claims a customer base of 30,000 individuals, and direct distribution is not envisioned as the most promising channel compared to indirect distribution via ISPs or other distributors. However, it has the advantage of serving as a showcase for prospective distributors and also as a test market. It also allows the distribution of adult content, which may not be in accordance with the policy of some distributors.

As concerns indirect distribution, Moviesystem has mainly developed partnerships with ISPs<sup>3</sup>. Under each ISP's brand name, NetCiné's services are distributed by the main French ISPs, whether focused on ADSL, such as France Télécom's Wanadoo, Club Internet, 9 Télécom and AOL, or on cable TV (Noos). At the European level, Moviesystem is also present in the Netherlands with the operator KPN, and expects to extend its distribution in the short-term in Belgium and Italy. In France, the indirect distribution channel allows Moviesystem to address a potential market of 2 Million users out of a total of 3.3 Million broadband access subscribers. Moviesystem is also involved in new developments resulting from the adoption of "triple play" strategies by the main ISPs. It participates in the launch of an innovative VOD service with Monaco Telecom, where the film can be viewed directly on a TV screen, and also works with France Télécom, Free or 9 Télécom, on similar VOD services that complement their new on-line TV services.

Moviesystem is able to provide to its distributors with a complete and customised solution. Moviesystem is in charge of the updated provision of movies, the analysis of customers' habits, the customisation of the user interface, and the management of digital rights, whereas distributors are responsible for providing the suitable infrastructure, including servers located near end-users, and for billing users. The splitting of revenues is the following: rights owners get 50 % of the revenues, an average of 5 % is spent for the billing platform used, and the remaining 45 % is more or less equally shared between Moviesystem and the ISPs. Indirect distribution offers Moviesystem many advantages: a larger potential market, an extended server infrastructure, a billing system that users are already accustomed to, as well as benefiting from the attractiveness of bundled offers. However, as ISPs are keen to protect their customer base and to keep control of their billing system, Moviesystem does not have full access to customer information and lacks pricing and billing flexibility.

### 3.2 Case Discussion

Moviesystem's success can be attributed to the nurturing and ownership of critical resources, as well as the value created by its particular business model.

First, Moviesystem has been able to use and/or develop relational assets with both upstream and downstream partners. It was able to mobilise the relationships with producers it had developed with its original business of off line film distribution, in order to get its initial funding and most of all the VOD rights for their catalogues, and also to nurture new relationships with the main ISPs that distribute its offer. Secondly, because of its intellectual assets and its technical resources, it was able to link two different industries with different cultures, experiences and resources, thus reducing uncertainty and risks for both upstream and downstream partners.

On the one hand, firms in the media industry traditionally distributed their films via movie theatres, TV channels or video rental outlets. They were therefore not familiar with dealing interactively with end customers, such as analysing their behaviour and preferences and managing direct or indirect transactions with them. They are also not accustomed to the technical and management aspects of computing and communications systems. A firm such as Moviesystem offers them a simple solution in order to avoid these uncertainties and the risks associated. They provide their catalogue and Moviesystem manages all the various activities related to VOD, such as managing technical platforms and data associated with the programmes, processing customer information, ensuring protection of digital rights, and managing transactions with end users and distributors.

ISPs and network operators, on the other hand, lack experience in managing a catalogue of films. It requires

<sup>3</sup> A selection of the Moviesystem catalogue is also available on the web sites of FNAC, a French retailer of cultural and entertainment goods, and of Virgin.

artistic and marketing capabilities, such as the ability to assess the commercial value of films on this complementary market, to package them, and to put them together to provide an attractive offer. From this perspective, Moviesystem benefits from its experience in the videocassette market, of which the VOD market is expected to be a partial substitute. It also necessitates more technical capabilities such as conceiving programme guides and graphic interfaces or managing digital rights. Moviesystem provides its distributors with a full service, allowing them to focus on their core activities such as managing infrastructures, customer relationships and billing.

Drawing from different theoretical perspectives<sup>4</sup> [1] it is possible to assess the value creation potential of e-businesses on four interdependent dimensions, namely: efficiency, complementarities, lock-in, and novelty. We can use this framework to further evaluate the value created by Moviesystem.

Moviesystem clearly improves the efficiency of transactions. By being able to link two different industries, we have seen that it significantly reduces the uncertainty resulting from the strong information asymmetries between upstream and downstream partners, and therefore the search costs that they would have experienced without Moviesystem. It also contributes to reducing search costs for end consumers because of the provision of guides and interfaces. Furthermore, its technical platform allows opportunism to be reduced due to the efficient DRM and billing interconnection system implemented. Finally, by allowing a fully digital value chain, it simplifies transactions, increases their speed and contributes to reducing their monetary costs.

Concerning complementarities, Moviesystem does not really provide complementary outputs to customers by bundling separate products and services, as it is focused on a specific service, but a certain level of complementarity is nonetheless achieved with the creation of catalogues putting together an attractive set of various programs. By providing a digital service that fits with the services provided by ISPs, it also allows its downstream partners to benefit from complementarities.

In terms of "lock-in", referring to the level of dependence experienced by customers and partners that may prevent them from changing their supplier or partner, our opinion is more ambivalent. On the one hand, ISPs are dependent on Moviesystem because of its intellectual assets (ability to assess the value of a film, ability to bundle a catalogue of films and other items), as well as its relational assets (with the media industry). Content producers are also dependent on Moviesystem because of the trust resulting from its successful experience in

managing a DRM and billing interconnection system. However, the end consumers clearly belong to the ISPs, who manage customer relationships and billing. This will be certainly be accentuated by the bundling strategies of these ISPs, such as "triple play" strategies.

Allowing a new way of distributing movies by linking two industries and by providing an efficient support to new transactions, the business model of Moviesystem relies by definition on novelty. In fact, Moviesystem is applying to itself a process of Schumpeterian creative destruction, as its new VOD business may well destroy its traditional business of wholesale distribution of films on VHS cassettes. By being the first in France and one of the firsts in Europe, it may benefit from a competitive advantage over new players if strong learning effects, or time compression diseconomies [8], are present.

#### 4. CONCLUSION

The Moviesystem case suggests an interesting perspective on the topic of convergence: instead of one convergent industry, the persistence of two specific industries with specific resources (Media, and Information and Communications Technology industries) that are bridged by Moviesystem. It also outlines the importance of market-based assets, as advocated in [14], composed of relational and intellectual assets. In this case, the critical intellectual assets are the understanding of both environments, including their cultures, markets, products, processes and business models. The critical relational assets are the relationships developed with upstream and downstream partners, and the resulting trust and reputation. Moreover, Moviesystem was able to leverage these assets by managing efficiently processes such as product innovation, Digital rights Management, Customer Relationship Management or billing processes.

## Strategy and Risk Analysis of the ERP Projects in Three Chinese Cigarette Enterprises

Yan Zhu, J. Chen

Research Center for Contemporary Management, Tsinghua University, Beijing 100084, China  
{zhuyan,chenj}@em.tsinghua.edu.cn

### ABSTRACT

During the past decade, Chinese enterprises have achieved great improvement in terms of competition ability. Information techniques are playing even more important role in this period. In order to conclude principles of IT transformation processes of Chinese companies, three typical Chinese cigarettes companies have been investigated in this paper. After introducing the IT evolutions in each firm, we compared the main parameters of their ERP or similar IT projects with another foreign company. Based on the comparison, two problems are discussed further. Firstly, we use strategic grid analysis method to find what is the IT strategy of each firm and why they adopt such a strategy. The new possible IT transformation ways are discussed also. Secondly, risk management problems are another focus of this paper. Three main risk factors are integrated to judge the risk type of each ERP projects, and different risk management strategies are discussed also.

**Keywords:** ERP, e-business, risk analyses, strategic grid

### 1. INTRODUCTION

IT as a new kind of communication and innovation tools, it has had impacted enterprises management processes greatly. A lot of new management concepts, such as ERP (enterprise resource planning), CRM (customer relation management), SEM (strategy enterprise management), have been put forward to improve the core competition ability of enterprises. Especially for the globalizing enterprises, they can not survive without modern IT-based management methods. During the past decade, the pioneers have invested a lot in combining IT with traditional management methods.

Chinese enterprises are playing a more important role than ever in the global economic system now. As the most potential market, it is very important to analyze the IT-based business models of Chinese enterprises. These kind of research works will help Chinese companies to understand how to rapidly adapt the IT transformation process. At the same time, it will be also useful for the foreign enterprises to know the mutually impact between oriental culture and information technology.

The purpose of this paper is to survey several Chinese cigarettes companies, compare the different IT transformation ways of each company, and discuss their e-business strategies and risk management methods during the IT absorption processes.

By summarizing the different IT evolution of these enterprises, and concluding why they adopt current IT strategies and how they established these strategies, the effect of their IT strategies, especially the impact on the profit, human resources, and productivity is concluded.

Based on the conclusion, we use strategic grid method to further discuss IT strategies of each company, and put forward new IT transformation ways correspondingly. In terms of risk management of ERP projects, we list three important factors that affect risk management strategies, and analyze the risk of each company theoretically.

### 2. IT EVOLUTION IN EACH FIRM

#### 2.1 SAP R/3 in Yuxi Hongta Tobacco (Group) Co., Ltd.

In order to improve the group's competition ability, Yuxi Hongta has explored the IT-based manufacturing and management systems for nearly ten years. In 1993, the group began to invest on the automatic manufacture systems as well as some management systems year by year, by the end of 1998, more than 300 computers were running for line-control as well as management. In addition, the group also set up 10 ALPHA series mini-mainframe computers, 4 PC servers, 27 SGI Graphic workstations. In 1995, the FDDI project had been finished, and the local computer network was established in 1996 which had been upgraded to ATM in 2000. There were 48 application software systems in different sections of the group before 2001.

In 1998, the group started to contact ERP concepts, and compared different implementation strategies of ERP, such as applying advanced ERP software package, applying the manufacture-based medium ERP system, developing the ERP system by themselves. After serious consideration, they decided to adopt the first scheme,

and in 2000, the contract had been signed with SAP AG (China), and the ERP project began on Jan. 12, 2001, finished on Feb. 12, 2002.

On Feb. 12, 2002, the ERP system of Yuxi was online successfully. The improvement is dramatic, just as Mr. Zeng, the CIO of the group, mentioned, the enterprise change its operation way from the deep inside, the mainly improvements include:

- 1) Change of enterprise strategy. Close-loop business processes had been set up. So the leader group can get information about manufacture and market immediately and make decision more accurately. In addition, the enterprise has formed an IT-based strategy, which is mainly about how to convert data into knowledge of the enterprise.
- 2) Logistics had been optimized. Mr. Zhang, the chief manager of Hongta material company, said, ".....in the ERP system, Inventory management and finance management are integrated, once materials were shifted, the system will update the account automatically. At the same time, system can generate online inventory reports; it is very convenient for query. Because of the implementation of ERP system, the inventory cost had been reduced 0.2~0.5 billion Yuan (approximately 25~50 million USD). The system also enabled the total cost control, it is estimated that the production cost will reduce 50~200 million Yuan (approximately 6~25 million USD).....".
- At the same time, the loading efficiency had been improved also, loading ability had been changed from 8,000 cases per day to 11,000 cases per day.
- 3) Change of supply chain management. In the ERP system, information among the whole supply chain (suppliers, purchasers, manufacturers, wholesalers and retailers) was integrated, managers can learn the whole status of the supply chain, and make decision and coordination accurately and immediately. Especially for the suppliers management system, because of the RFQ (Require for Quote) and PO management system, managers can compare different suppliers, and greatly reduced the purchase cost.
- 4) Change of finance management. The budget was made and evaluated according to the standard cost system in ERP system. So, any finance problems can be found by querying the accounting system, and the reason and responsibility of these problems can be addressed easily also. The new characteristic of the finance system is integration; module FI (Finance) and CO (Control) are fully integrated with MM (Material Management), SD (Sales and Distribution) and PP (Product Planning), which make the whole system is consistent and efficient, and provide the manager accurate decision information.

## 2.2 Oracle Applications in Baisha Group

IT utilization in Baisha group can retrospect to the year of 1992; the former CEO realized that information technology will enforce the manufacturing ability, so they decided to invest on IT infrastructure. By the year of 2000, 60 million Yuan (approximately 7.5 million USD) had been spent on IT projects, the basic IT infrastructure had been established and a lot of application software systems were running in different departments.

Although the group had spent so much money, the CEO recognized that their IT expenditure was not successful until 2000. Especially for the manufacturing system, the group spent more than 2 years to implement MRPII (manufacturing resource planning), but the results were not satisfied. By that time, the leader group of Baisha analyzed experiences of their IT expenditure, and some defects were found out.

According to the analysis above, the group decided to implement totally IT-based management reform project. They called it BPR & ERP project. It was quite hard project, because the reform process will change the balance of the company, in case of the project was failure, the company may be disorder.

After carefully comparing different ERP software vendors, the group decided to adopt Oracle Applications 11i. The flexibility of Oracle Applications permits the group to design new business processes easily and quickly. And the implementing cost was relatively low also.

The typical characteristic of the implementation is that the group made great effort to do BPR Project first, and then implemented ERP software system. On Jun. 25, 2001, the BPR project had been completed; on Nov. 5, 2001 ERP system was launched.

Talking about the improvements, Miss LU Ping, the CEO of the group, said "..... the remarkable improvement is that we has rebuilt our Baisha culture, and the business processes have been optimized also, so the Baisha group become stronger and agile.....". To summarize, the achievement in detail includes:

- 1) Formed new enterprise culture. All employees have had a clear and same goal, and put great enthusiasm in their work now. They have learned the new position of themselves in the new business process, and were encouraged by the perspective of the enterprise. The new company culture, "long-lived brand, long-lived enterprise and long-lived Baisha people", has been carried into each job position.
- 2) Optimized business processes. During the 51 core business processes, the non-value-added processes had been eliminated, the value-added parts had been

reinforced. And the manufacturing recycling time had been shortened simultaneously.

3) Organization reform. According to the new strategy and the principle of lean and intensive of the new enterprise, the group re-designed their organization architecture, set up a new structure based on the new business process.

4) Improved manufacture and management efficiency. The ERP system had been successfully implemented, and the optimized business processes were solidified in the system. So the company is run more efficiently than before, and the reward was remarkable. Such as, accuracy of financial plan had been improved 15%; accessory material inventory cost had been reduced from 100 million Yuan to 50 million Yuan; delivery cycle (from moving out inventory to loading) had been shortened from 12 hours to 10 minutes.

### 2.3 Develop ERP by themselves: Honghe Group

Before the year of 1997, although Honghe Group never considered IT-based business strategy, their automatic manufacturing system had been an important infrastructure of the company. Leading by Mr Qiu, the CEO of the group, the company has established some special but efficient business processes.

When they began to consider the IT strategy in 1997, after comparing a lot of ERP software packages, they found that it was quite difficult to choose one kind of software which can be compatible with the automatic manufacturing system as well as the existing effective business processes. It seemed that the best way is to develop the integration system by themselves.

To make such a decision was quite hard, because the company had not enough information technical teams. But fortunately, during the past 5 years, the great partner—Kunmin Ship Company—had built a strong IT team which can accomplish the software development tasks.

The core of the project is how to design business processes. From 1998, Mr. Qiu, served as both CEO and CIO, lead the project himself, and attended to design each business process. It took 3 years to accomplish this work, during the 3 years, Mr. Qiu never left Yunnan province, he put all his efforts on the redesign of the processes. It is very rare that the CEO will design the processes by himself during an IT project, but Mr. Qiu made it.

Talking about the scheme of the IT project, Mr. Qiu is always exciting, “.....the project is a system, it must embody the characteristics of how to operate cigarettes manufacturing systems, so it is the operating software of the enterprise. The scheme must be efficient and optimized, the organization structure, business processes

and the operating rules must be totally designed in the scheme. And at the same time, the company should rebuild it's IT-based cultures as well.....”

The business processes scheme includes 8 modules, that is: office support, finance, manufacture, sales and distribution, raw materials management, auxiliary material management, equipment management and R&D. All of these modules can be fractionized into more than 11,000 sub-modules.

During the three years design process, the company reformed their organization structure accordingly as long as opportunity was proper. Before the HY-CIMS project began in June 2002, they have established firm fundamental of both organization and knowledge.

In June 2002, the company shifted their scheme to Kunming Ship Company (KS), and the KS finished the blueprint of HY-CIMS technically on Jun.18, 2002. From Jun. 2002 to Aug. 2002, KS accomplished the detail design of each module. Finance module had been developed at the same time, and the first training about new finance system was carried out simultaneously.

By the end of Oct. 2002, modules had been online continually, material management, manufacturing, office support, personnel management and equipment management modules were developed as well as trained. In Jan. 2003, the whole system had been integrated and tested; HY-CIMS had been accomplished.

The HY-CIMS project brought great effect on the company, although the investment is no more than 10 million Yuan (approximately 1.2 million USD). The direct benefits are the costs have been reduced and the efficiency improved. According to the preliminary estimation, HY-CIMS has improved the yield of the company by 3%, this means the company can get another approximately 75 million Yuan (9 million USD) each year.

### 3. STRATEGIC COMPARISON OF IT EVOLUTIONS

In table 1, we conclude the basic IT transformation process of each company.

It has been suggested that to fully realize the competitive advantages created by the strategic use of IT, organizations must have appropriate IT management strategies that fit with their culture, technology status, and business strategy.

This contingent nature of IT management has drawn much attention in the IT literature<sup>[1, 2, 3]</sup>. Given the importance of a proper alignment of IT management processes with the organizational role of IT, organizations need to have a clear and systematic understanding of the strategic relevance and impact of

their IT, and then develop IT management strategies appropriate to that role.

A framework for delineating the differences in the strategic relevance and impact of IT was proposed by Applegate, McFarlan and McKenney<sup>[1]</sup>. This framework

identifies four different IT roles which are referred to as categories of strategic relevance and impact or, simply, as the strategic grid. The grid is a useful framework for understanding the positioning of an organization's IT, and as the basis for designing appropriate planning and control systems for IT management.

**Table 1 Comparison of IT Transformation Process**

		Hongta	Changsha	Honghe	Dow Corning <sup>[4]</sup>
<b>Basic Information</b>	Yield (2002)	220	90	90	
	Income (Billion USD)	4	0.9	0.9	2.5 <sup>1</sup>
	Employee	4500	2600	1800	9000 <sup>1</sup>
	5 year Income Aver. Increase	15%	20%	20%	~4%

	IT Reporting Influence	Low	High	Medium	High

Note 1: Data in 1998

\* Yield unit: million cases

Applegate, L. M., McFarlan, F. W., and McKenney, J. L.,<sup>[1]</sup> describe two (future and current) aspects of strategic relevance and impact of IT and are referred to as the future and current portfolios, respectively. The strategic relevance and impact of IT for a firm can be positioned anywhere on a continuum ranging from low impact and relevance to high impact and relevance along each of these dimensions of the grid. Applegate, L. M., McFarlan, F. W., and McKenney, J. L., propose that understanding an organization's position along these continuums is critical to developing appropriate IT management strategies. The combination of future/current portfolio with high/low impact presents four types of IT environments and is represented by the four cells (strategic, turnaround, factory and support

cells) of the strategic grid.

**Strategic (Cell 1):** Organizations in this cell are critically dependent on the smooth functioning of the IT activity. This dependence relates to existing systems as well as to applications under development, i.e. to both the current and future portfolios.

**Turnaround (Cell 2):** While existing applications may provide operational support for organizations in this cell, they may not be critical to the organization's current operations. However, the impact of the applications under development is considered vital to achieving the organization's strategic objectives.

**Factory (Cell 3):** These firms are heavily dependent on

their existing, day-to-day IT operations and even a temporary disruption in service could have severe operational consequences. However, the applications under development for the future are not critical to the firm's ability to compete successfully and are mostly maintenance projects.

**Support (Cell14):** In these firms, neither current nor future IT activities are critical to the smooth operation of the firm. IT is viewed as playing the traditional back-office-support role without any potential for dramatically altering an organization's current or future operations and/or direction.

According to the characteristics of each firm, they can be located in different cells.

**Hongta:** this firm is in the strategic cell, because they have completely established an ERP system, and totally considered the business strategy based on IT strategy.

**Baisha:** this firm is in the transferring process from factory cell to strategic cell. The firm has reformed the business process and the integration system which has already been online and under development will greatly impact the business strategy.

**Honghe:** is in the process from turnaround cell to strategic cell. Although they also considered the IT-based business strategy, the firm still need integration of manufacturing system and management system.

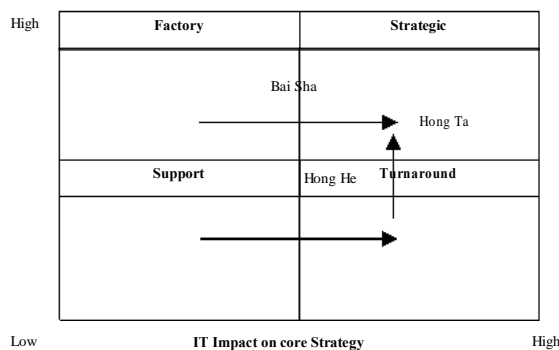

Figure 1 IT Strategic Grid of Each Firm

#### 4. RISK MANAGEMENT METHODS COMPARISON

IT projects are high risk projects, it need careful consideration of the risk management. During the

process of implementing the IT projects, all of the three firms considered the projects risks in different way, and adopted different way to avoid risks.

In a recent literature published by Prof. Cyrus Gibson<sup>[5]</sup>, the IT project risks can be managed through a process from risk reorganization, risk assessment to risk reduction and cope with remaining risk. The methodology can be described in Figure 2. According to leadership, employee's perspective and project urgency, different implementation strategy should be adopted to avoid risks. For example, if the leadership is positive, the employee's perspective is negative but the project urgency is positive, then the implementation strategy should be guided evolution.

The IT projects implementation processes of three cigarettes firms can be assessed in table 2. That is, for Hongta company, the leadership is positive but the employee's perspective and project urgency are negative, so the theoretical implementation strategy is top-down coordinate. In Baisha, all of the three factors are positive, so the theoretical implementation strategy is big-bang. In Honghe, the leadership is positive, employee's perspective is positive, the project urgency is negative, so the theoretical implementation strategy is improvisation.

Figure 2 Project Risk Assessments

In order to achieve the actual IT projects risk management strategy of each firm, we talked with three levels of each firm, including CEO and CIO, middle manager and project team member. According to the description of how they organize the project, the actual IT project risk management strategies have been concluded and depicted in table 2.

Table 2 IT Projects Management Strategy

	Leadership	Employee's Perspective	Project Scope & Urgency	Actual PM Strategy	Theoretical PM Strategy
Hongta	+	-	-	<b>Top-Down Coordination</b>	<b>Top-Down Coordination</b>
Changsha	+	+	+	<b>Big Bang</b>	<b>Big Bang</b>
Honghe	+	+	-	<b>Improvisation</b>	<b>Improvisation</b>

## 5. CONCLUSIONS

According to the comparison in chapter 3, we can reach following conclusions about the IT transformation processes of each firm.

1) All of the firms have invested on IT, but they are in different stage. each of these firms have found the importance of IT, and want to improve their management as well as manufacturing system using new information technologies. But because the background and geography are quite different, they are in different IT absorption stage now.

2) Because of lack of IT strategy originally, these firms can jump from one period to another. Except for Hongta, other companies are planning to adopt the jumping strategy. That is, they hope that they can jump from lower stage directly to the highest stage. Technically it is possible, but considering the enterprise culture and management level, it is quite hard to omit one or two stages. The best way is to form a IT-based business strategy and implementing IT-related reform continuously.

3) IT does matter in Chinese enterprises. Enterprises in China are facing a great chance; they must set up new business architectures which will be competitive with other companies, especially the foreign companies. So IT infrastructures are still a problem for most of Chinese companies, and the new IT-based business processes still need to be developed. In order to enhance competitive advantage, the IT-based business strategies of each company should be set up as soon as possible.

4) Successful implementation experiences are that all of the three companies considered their enterprise culture during the ERP implementation process, and adopted different implementing methods accordingly to avoid risk. According to the project risk management theory, the actual IT projects management method is consistent with the theoretical expectation as long as the project is successful.

The works in this paper are still limited, because there are so broad topics considering the IT innovation in Chinese enterprises. Further research works will focus on IT risk analysis of Chinese state-owned large enterprises. With the rapid development of Chinese enterprises, IT will get more and more attention as well as expenditures. It is a serious problem about how to manage the IT projects risk. Although we introduce a new method in this paper, further research must be done

considering the concrete culture and diversity implementation strategies. The detail information about IT project management in each company will be collected in the next step, and we will try to find the basic principles of the risk management of IT project.

In addition, it is important to judge whether an IT project is valuable or not. There are several methods to judge the IT project value<sup>[6]</sup>; one of these methods is using the evaluation index. But the index is quite different because of different culture background. According to the successful experience of Chinese companies, the evaluation index should be studied carefully, and a standard of evaluating IT projects should be given.

IT strategy is so close to business strategy. With the support of IT and IT-related new strategy analysis methods, how to establish competitive business strategy is very urgent problem. Some new characteristics and improvement should be made to use the strategic grid and other methods.

## Towards a Knowledge Based Society: A Case Study on Entrepreneurship in Malaysia

**Goh Hong Wee, Goh Pek Chen**

Faculty of Business and Law, Multimedia University, Malaysia  
{hwgoh, pcgoh}@mmu.edu.my

### ABSTRACT

This paper as a whole will discuss the entrepreneurship development in Malaysia. The 21<sup>st</sup> century promises a world of challenges and opportunities to all the nations in the world. Malaysia has launched the Multimedia Super Corridor (MSC) to spearhead Malaysia's challenges in the new millennium. In line with Malaysia's objective to produce world class Information Technology (IT) –savvy-working forces, a University was born in center of Cyberjaya called Multimedia University (MMU). MMU is playing a pivotal role in the national entrepreneurship development in Malaysia, similar to that of Massachusetts Institute of Technology (MIT) and Stanford University in United States. In Malaysia, various business plans are held throughout the year providing university students a platform to demonstrate their entrepreneur skills. Besides that, many venture capitals sources are available in Malaysia for potential technopreneurs to seek funding and advise. Successful Malaysian entrepreneurs such as Mark Chang (CEO of Jobstreet.com) and Tony Fernandes (CEO of AirAsia ) can be the inspiration for many Malaysia's aspirants.

**Keywords:** *Entrepreneurship, Knowledge, Society, Technopreneur*

The Knowledge Era has reached; most of countries in the world have tried to work towards a Knowledge based Society. Malaysia on the other hands, do not lose out in the race of the globalisation. As a major step in building up a Knowledge Based Society, Malaysia has established a major information technology (IT) project called Multimedia Super Corridor (MSC) in 1996 to prepare its people for the knowledge revolution in the new century.

Under the MSC project, the development of entrepreneurship is given a high priority. A MSC technopreneurship development flagship was then established in 2001. The core objectives of the flagships are to facilitate the developments of technopreneurs, start –ups and existing information communication and technology (ICT) companies and to assist and facilitate the growth of ICT small and medium enterprises (SMEs) into world-class companies. The flagship aims to drive entrepreneurship in Information and Communications Technology (ICT) and other high-tech areas. Not only that the Technopreneur Development Flagship aims to strengthen the ICT, Biotechnology and life science industries in Malaysia by spawning a critical mass of entrepreneurs and nurturing world-class companies.

In order to successfully steer the country into the Information Age, the flagship not only pull together all efforts at Federal and State level, but also the private sector to boost the development of SMEs throughout the country. It is because if the flagship is too concentrated at federal level only, the problem of digital divide in Malaysia will be worsened.

With the co-operation of State governments as well as support from the private sector, Technopreneur Development Flagship aim to expand this network through the cultivation of new incubators, with at least

one incubator in each state. To encourage the setting-up of incubators, operators will receive MSC status and enjoy the incentives outlined in the Bill of Guarantees. Companies based in these incubators will also benefit from some of these incentives

In order to prepare a conducive environment for Malaysia's aspirants, a National incubator network has been established. Under the National incubator network, there are currently 9 incubators in Malaysia namely MSC Central Incubator, Kulim Technology Park Corporation Sdn Bhd , BT Multimedia Sdn Bhd, N2N Venture Solutions Sdn Bhd, YTL e-Solutions Bhd, Makmal.com Sdn Bhd, Usains Tech Services Sdn Bhd, BioEnterprise Asia Sdn Bhd and Bureau of Innovation & Consultancy ( BIP ), Universiti Teknologi Malaysia. Attractive incentives are given to incubator operators such as freedom of ownerships, income tax exemption, intellectual property protection, competitive telecommunication tariff and many more.

2 prototyping labs focused on enhancing technology skills and building Malaysia's human capital in the areas of advanced software development, embedded systems, intelligent systems and wireless & mobility was established too namely Java Technopreneur Development Centre (JTDC) in partnership with SUN Microsystems (SUN) and Multimedia University and .NET Technopreneur Development Centre (NTDC) in partnership with Microsoft. Under the MSC Technopreneur Development Flagship programme, 9 teams of Microsoft .NET software developers have been selected out of 90 to help to turn their ideas into viable businesses.

At university level, the work of promoting entrepreneurship has been quite aggressive. Multimedia University, a university, which has been given the role of

producing entrepreneurs in Malaysia, has established the Centre for Commercialisation and Technopreneur Development [CCTD] for both the commercialisation of Multimedia University's research and also the development of technopreneurs among the university community. CCTD is seen to provide the link between academia and industry for the development of commercially viable technologies and is committed to building beneficial partnerships between academia and the commercial sector.

Currently there are a few starts-up companies set up by the Multimedia University students namely RiteUni Dot COM, Xirien Technologies, E-Transact and many others. Multimedia University latest start-up will be Roommart. Roommart was founded by an undergraduate of Multimedia University. Roommart is Malaysia's 1<sup>st</sup> online roommate finder. It is a portal, which helps students from higher learning institutions to find rooms, roommates and houses. Roommart define a new way of finding accommodation through Internet as most of the students today are avid Internet users.

In Malaysia, university students have a lot of business planning competition opportunities such as HSBC Young IT Entrepreneur Awards to serve as a platform for them to demonstrate their business writing skills. The 2004 HSBC Young IT Entrepreneur Awards has successfully attracted 250 proposals for the competition showing that entrepreneur competition like this are well received in Malaysia. University Cradle Investment Programme (U-CIP) is also being introduced to facilitate university research outputs into marketable products/services, as a first step in the commercialisation roadmap.

Many venture capitals sources are available in Malaysia too for technopreneur to seek funding such as Malaysia Venture Capital Management Sdn Bhd and MSC venture

capital corporation Sdn Bhd. The setting up of MALAYSIAN EXCHANGE OF SECURITIES DEALING & AUTOMATED QUOTATION BHD (MESDAQ) which is a stock exchange targeted to the growth of technology companies has creates a new vista for companies to seek for potential investors and vice versa. Through a listing on MESDAQ, companies can now have access to public funds. With the help of some organisations such as Technopreneurships Association Of Malaysia (TEAM), which acts as a think tank for technopreneurs in Malaysia, the future of entrepreneurship really look good in Malaysia.

For a developing country like Malaysia, it is very important for the nation to have its own successful entrepreneur who can become a fine example for the youth to follow. In Malaysia, the success story of Mark Chang (CEO of Jobstreet.com) and Tony Fernandes (CEO of AirAsia) has boost up the confidence of many young Malaysians and encourage them to start their own business and become an entrepreneur.

## Analysis of Trademarks Act of Thailand and a Case Study: Conflict of Domain Name and Trademarks

Settapong Malisuwan

Associate Professor, College of Business Administration, Touro University International, USA.  
Associate Judge of the Central Intellectual Property and International Trade Court, Thailand  
settapong.m@cmmu.net

### ABSTRACT

In the era of Information Technology, Internet plays an important role and becomes worldwide infrastructure of global communication. Domain Name is the key to reach the purpose derivable Website on the WWW. Confusion and conflict arise when words and names of Domain Name become low in resource and somehow have the same or similar identification among two or more parties. This paper provides a brief background on the interface between domain names and trademark. The paper presents examples of domain name disputes and analyzes some important aspects of legal principles of the Trademarks Act (No.2) of B.E. 2543 (2000). The paper also explains how the Act can protect the trademark and domain name rights. Finally, the roles of the Central Intellectual Property and International Trade Court in enforcing the Intellectual Property Rights in trademark and domain name protections are discussed including a case study. This paper will be a valuable contribution towards IT society and e-business sector.

**Keywords:** Domain Name, Trademark, Cyber-squatters, Intellectual Property, and Law.

### 1. INTRODUCTION

With the increase popularity of the Internet, e-commerce has become an increasingly important role for business and the value of domain names has increased accordingly. Internet users rely on domain names, which take the form of memorable and sometimes catchy words, to stand in their place. The uniqueness requirement creates an exclusivity that has important economic consequences. Domain names are interesting and controversial because they are meaningful. The semantic dimension allows domain names to act not only as unique addresses, but also as brand names. [1].

Companies and organizations want their websites to be easily accessible to potential consumers. They desire a domain name, which matches their corporate name or trademark, preferably in the .com top-level domain. As domain names have, in many ways, become the equivalent of a company name and address for Internet commerce, there has been increasing competition for the limited number of available domain names. Domain name trading has, therefore, resulted from this competition [2].

For examples, in July 1998, Compaq Computer Corp paid \$3.35 million for rights to "altavista.com", purchased from a California start-up called Alta Vista Technology. In late 1998, VA Software (then VA Research) bought the rights to the "linux.com" domain name for more than \$1 million. In 1999, eCompanies paid \$7,500,000 to purchase rights for "business.com" [2]. In April of 1999, "drugs.com" sold at auction for \$823,456 and "wallstreet.com" attracted a cool \$1.03M. In August 2000, the domain name "cyberworks.com" was sold for \$1,000,000. In February

1999, the Houston entrepreneur sold the domain name "eflowers.com" to the owner of Florida-based Flowers Direct for \$1M [2]. In 2000, Bank of America has purchased the domain name "loans.com" for US\$3 million. It bought the rights to the domain name from "GreatDomains.com" on January 28. The seller was San Jose computer consultant Marcelo Siero, who registered the domain name in September 1994 for creation of an e-commerce application but later decided to sell it, according to "GreatDomains.com" [3]. "Wines.com" were bought for \$3M. "Websites.com" was auctioned off for \$0.97M by Great Domains (www.greatdomains.com) and now the website provides Internet and web hosting services to businesses. "Telephone.com" was acquired for \$1.75M, while "bingo.com" sold for \$1.1M [4]. Barnes and Noble bought "books.com" for \$1M. In a recent example, the government of New Zealand paid US\$500,000 to U.S.-based Virtual Countries to obtain rights to the domain name "newzealand.com" [5].

In Thailand, e-commerce has come to people's attention a great deal when MWEB (Thailand) Ltd purchased the website "sanook.com" at a very high price from an individual, Mr Porameth Minsiri, a webmaster who subsequently became a millionaire and a very popular person [6]. In 1997, Mr. Adam Stanhope learned the domain name "bangkok.com" was for sale. He negotiated to buy the domain in installments. Fortunately, the Asian currency crisis hit and he ended up only paying \$4,200 for the domain name. The website "bangkok.com" sold 100 year-long subscriptions at \$35 each. They offered free email, added content and sold advertising to those interested in reaching people who wanted to do business with the Thailand market. In addition, they offered free Web site hosting for sites about Thailand. In late 1998, the

owners had created a significant virtual community who used their chat services, Web hosting and email capabilities [7]. In January 2000, Nation Multimedia Group Pcl, which published Thailand's largest business daily newspaper and the second rank of English-language newspapers, paid less than \$7 million for the Internet address "Thailand.com". It didn't identify the seller [8].

## 2. ICANN AND THE DOMAIN NAME SYSTEM

In 1995, World Intellectual Property Organization (WIPO) was requested by many member countries to find ways to solve disputes on domain name. In 1998, the Internet Corporation for Assigned Names and Numbers (ICANN), is an independent, non-profit organization which was created to oversee the assignment of names and numbering to ensure assignments are made on a global level with participation of all relevant stakeholders representing all of the world's regions. ICANN is a consensus development body for the global Internet community and its focus is the development of consensus policies relating to the single authoritative root and the Domain Name System (DNS). These policies include those that allow the orderly introduction of new top level domains (TLDs) [9].

In 1999, WIPO came up with suggestion to ICANN to deal with administering Domain Name and its conflicts. And in June 2000, WIPO reconsiders its suggestion and manages to put forward concrete conclusion to clarify all problematic matters including cause of confusion or unfair utilizing [10].

Due to low resource problem, ICAAN has tried to increase the number of top-level domains (TLDs), but many companies are worried that cyber-squatters will try to register a company's trademark or name in these new TLDs and then try to sell it to the owner. In 2002, ICANN announced the seven new domain names such as dot-biz, dot-info, dot-aero, dot-museum, dot-name, dot-pro and dot-coop. However, these new TLDs will be restricted. Dot-biz will be restricted to businesses; dot-aero to airline related ventures; dot-museum to museums; dot-name to personal names; dot-pro to lawyers, doctors and accountants; and dot-coop to cooperatives. For recommendation, to avoid cyber-squatting, the domain-name owners should set up pre-registration processes to allow trademark holders to claim or reserve domain names on a first-come, first-served basis [11].

Recently, more than 33,000,000 domain names have been registered, including tens of thousands of domain names that infringe on trademarks and service marks [12].

## 3. CYBER-SQUATTERING IN DOMAIN NAME SYSTEM

"Cyber-squatters" are defined as those who quickly

register someone else's trade name as a domain name with InterNIC, the Virginia-based central domain name registry service [12]. Generally, however, if someone who lacks a legitimate claim registers a domain name with the intent to sell the name, prevent the trademark holder from gaining access to the name, or divert traffic, this activity will be considered cyber-squatting. Despite this strong trend against cyber-squatters, new instances of cyber-squatting continue to arise. For instance, Intel filed suit against the registrant of "pentium2.com" which leads to a pornographic web site [12].

In many cases, an owner of trademark rights can find that other persons have registered as domain names that are the same as or similar to the owner's trade mark. There is also a different kind of conflict, which can apply where an owner has trademark rights but is not permitted to register it where domain name policy prevents registration of names such as geographic names and generic/descriptive names.

The trademark owner's trade mark may be very well known around the world in its commercial context but may be a name used by others in different commercial contexts. An example of this might be the trademark McDONALDS, which is registered and well known in many countries in connection with convenience food stores but, as a common surname, may be used by many others in connection with a range of business and other activities. The trademark APPLE in connection with computers may be an example of such a name. A geographic name example may be OXFORD for publishing.

## 4. DOMAIN NAME PROBLEMS IN THAILAND

A major problem arising out of e-commerce worldwide, including Thailand, is the one relating to domain name registration, especially, the problem of cyber-squatters who take other person's name, trademark, service mark or trade name to register in its own name. Therefore, this section discusses the domain name problems in Thailand. The followings are examples of domain name disputes in Thailand.

Bangkok Publishing Public Co Ltd or "Bangkok Post" has used trademark "bangkokpost" with newspaper and used domain name "bangkokpost.co.th" registered with the Thai Accredited Domain Name Registrar (THNIC). The company tried to register another domain name with Network Solutions Inc (NSI) for domain name "bangkokpost.com", but found that Solberg PM&P AB, a corporation in the United States, has already registered the "bangkokpost.com". This causes Bangkokpost to use domain name "bankokpost.net" with its website for a while. However, finally, Bangkokpost has bought the domain name "bangkokpost.com" to avoid disputes [6].

In August 1997, during "Amazing Thailand" campaign period, a Canadian tried to sell his domain names

“amazingthailand.com” and “amazingthailand.org” to the Thai Government in the amount of \$2.3m. However, the Thai government refused to purchase the both domain names and decided to use domain name “tourismthailand.org” [6].

In October 2000, a Thai cyber-squatter sent an email to many well-known websites such as “mweb.co.th”, “Thaiadclick.com”, and etc. He threatened the companies that if the companies refused to purchase his domain names which are similar to mentioned domain names, he would use his domain names with pornography pictures to dilute value of the dot com companies’ trade names. Finally, he was arrested and prosecuted for extortion and blackmail, in accordance with the Thai Penal Code [6].

### 5. THAILAND’S TRADEMARKS ACT: ANALYSIS

Thailand is required to implement the intellectual property laws into compliance with the current WTO Agreement regarding Trade Related Intellectual Property Rights (TRIPS Agreement).

Thailand’s Trademark Act was approved by Parliament earlier this year, was published in the Royal Thai Gazette on April 1, 2000 and, became fully effective on June 30, 2000. The most recent Trademark Act is referred to as the Trademarks Act B.E. 2534 (1991) as amended by the Trademarks Act (No.2) of B.E. 2543 (2000).

In this section, the Trademarks Act (No.2) of B.E. 2543 (2000) is analyzed and explained. However, this study focuses only on important parts of the Act related to the Trademark and Domain name issues [13].

The Act contains several significant changes [14]. These changes will make the application and registration process easier for many trademark applicants. The significant changes can be analyzed as follows:

- (1) Under Section 4 of the former Act, a mark was defined as a “photograph, drawing, device, logo, name, word, letter, numeral, signature, or any combination thereof but not including industrial designs under the law of patents.”

In section 4 of the new Act, “mark” means a photograph, drawing, device, brand, name, word, letter, manual, signature, combinations of colors, shape or configuration of an object or any one or combination thereof.

*Analysis:* In the new Act, the definition of a mark is expanded to include “phrases, color combinations and shape or configuration of goods.” This expanded definition means that consumers are now more sophisticated in distinguish the goods or services of one proprietor from another than before. For the section 4 of the Act, it shows that the Thai law

tries to enforce and protect the owner rights on Trademark.

- (2) Section 7 (2) of the former Act can be interpreted that the name of a juristic person could only be registered as a mark if it was “represented in a special manner” and, not a geographical name.

In section 7 (2) of the new act, it can be explained that one may now register a juristic name as a mark in block letters, provided it is not the *full* name, nor descriptive. This means that companies can omit “Inc.”, “Co.”, Ltd.”, “Corporation” or other business entity designation from the representation of their mark [14].

*Analysis:* In section 7 (2) of the former Act, the Act implies that the name of a juristic person in mere block letters could not be registered as a mark. Therefore, it can be seen that brick-and-click companies cannot protect their trademarks in term of domain names from cyber-squatters. Luckily, for the new Trademark Act in section 7 (2), the Act helps to solve this problem. It will be of great benefit to many companies, especially for the new dot com companies seeking trademark protection for domain names.

The analysis above shows that the amended Trademark Act, the Trademarks Act (No.2) of B.E. 2543 (2000), is a very positive step forward for Thailand, setting new standards for the e-business sector to protect their Domain name and trademark rights. An example of trademark and domain name case will be discussed in next section.

### 6. ROLES OF THE CENTRAL INTELLECTUAL PROPERTY AND INTERNATIONAL TRADE COURT: TRADEMARK AND DOMAIN NAME CASE STUDY

In order to fulfill its obligation under the Agreement on TRIPs and to promote the strong enforcement of intellectual property disputes in international trade, the Central Intellectual Property and International Trade Court (CIPITC) is established. The proposal for appointment of a committee for setting up of pattern of the CIPITC was submitted to the Cabinet on March 22, 1993. By approval of the Cabinet on May 4, 1993, the Committee was composed of the Permanent Secretary for Justice as vice chairman, and 22 other members from public and private sectors. The Committee finished the draft Bill for the Establishment of and Procedure for the Intellectual Property and International Trade Court within one year after its appointment. The Bill was approved by the Cabinet on May 12, 1994. Subsequently, it was approved by the House of Representatives and the Senate on May 15 and August 16, 1996 respectively. The Act was proclaimed in the Government Gazette on October 25, 1996. Besides the

Act, the Committee was also the architect for the first draft of the Rules for Intellectual Property and International Trade Cases concerning proceeding and taking of evidence in court [15].

The CIPITC has power to adjudicate both civil and criminal cases regarding intellectual property and civil cases regarding international trade. Criminal cases concerning intellectual property legislation are as follows:- Offences against trademark, copyright, and patent infringement under the Trademark (including Domain name), the Copyright and the Patent Acts [16]. Although the Court has only been in existence since 1 December 1997, it has already dealt with a considerable number of cases as shown in Table 1 [17].

**Table 1** Case Statistic of the Central Intellectual Property and International Trade Court: December 1, 2000 – September 30, 2003.

Case Type	2000	2001	2002	2003
International Trade	771	520	370	264
Intellectual Property (Civil Case)	102	138	157	142
Intellectual Property (Criminal Case)	2141	3252	3582	2803

Next, an example of trademark and domain name case will be discussed. Generally, the trademark owner is entitled to prevent other parties from using the trademark in respect of goods or services are of the same origin or are affiliated to or associated with or sponsored by such trademark owner. The trademark owner is accordingly entitled to prevent even an owner of noncompetitive goods or services from using the owner's trademark.

*Case study: Judgment of the Central Intellectual Property and International Trade Court* [18]

Case no. (Black) IP 132/2544

Case no. (Red) IP 121/2545

Intel Corporation (Plaintiff)

Intelcard Industries Co., Ltd. (Defendant)

Where the cause of this case arises out of the dispute regarding trademarks (and domain name) within Thailand, the case falls under the jurisdiction of the CIPITC, which is deemed a court competent jurisdiction. In this case, both the plaintiff and the defendant carry on the same computer business with certain overlapping objectives. The defendant uses the word "INTELCARD" to indicate as the trademark. Since the defendant's business relates to computer and is associated with or has some connection with the plaintiff's activity, the use by the defendant of the plaintiff's term "INTEL" is held to make the public think that the defendant's business is a part of or relation to the plaintiff's activity. Moreover, both the

plaintiff and the defendant keep trading via the Internet, the customers may be confused by similar trademark. Consequently, the plaintiff is entitled to prevent the defendant from using the word "INTEL" either in Thai or English version.

For the domain name aspect, the defendant holds "Intelcardgroup.com" for a domain name of the company. As earlier ruled and mentioned, the defendant has no right to use the word "INTEL" either in Thai or English version, the plaintiff is entitled to prevent the defendant from registering its company name as a domain name.

This case shows that the enforcement of trademark and domain name Rights in Thailand has been successful in a satisfied level. The newest challenge to court roles comes from the rise of Information Technology. However, not many cases in Internet issues have been brought to the Central Intellectual Property and International Trade Court in Thailand, but these additional issues will become one of the most controversial Intellectual Property issues in the near future.

## 7. CONCLUSIONS

The explosive growth of the Internet has resulted in a dramatic increase in the importance of domain names in the conduct of business. Businesses have traditionally developed brand name recognition of their products and services by the use of trademarks and service marks. The IT society needs to consider how best to address the conflicts between trademark rights and domain names recognizing the complexity of the range of situations that may apply and recognizing that any measures in domain name policies need to be practical and effective. This paper shows that the amended Trademark Act, the Trademarks Act (No.2) of B.E. 2543 (2000), is a very positive step forward for Thailand, setting new standards for the e-business sector to protect domain name and trademark rights.

In conclusion, Intellectual Property law is an exciting practice for Internet users and exciting area for academics. People in IT society should pay more attention on the Intellectual Property Rights to gain more understanding and to provide adequate protection.

# Are E-Bank Related Business Methods <sup>[1]</sup> Patent Subject Matter under Chinese Law?

Yongjun Jin

School of Economics and Management, Tsinghua University, Beijing 100084, China  
jinyj@em.tsinghua.edu.cn

## ABSTRACT

In the Citibank-Patent-Case, the underlying issue is whether E-bank related business methods are subject matter of patent under Chinese law. At first flash, there are at least two barriers to patent protection for Citibank to cover. The first, E-bank related business methods only function with the help of computer software, so the coming issue is whether computer software is patent subject matter. The answer is yes, the reasons for that are.... The second, E-bank related business methods are computerized ones, so the remaining issue is whether business methods are patent subject matter. The answer is also yes, the reasons for that are.... So the position of Chinese legislature and government regulation is....

**Keywords:** business methods, computer programs, patent subject matter, barrier to patent, reason methods and rule

## 1. INTRODUCTION

On the 5th day of September 2002, a piece of news review in Southern Weekend, headlined "Citibank [2] Has Been Stealing to Apply Patent, When Will Chinese State Owned Banks Wake up from Daydream?" disclosed that Citibank had conducted 19 cases of patent application in china, and all of them involved business methods. [3] When the newspaper scattered all over the country on that day, that piece of review therein had immediately catch people' eyes, no matter who were general readers or employees in the related industries. Even the title itself had meant something. [4]

From the legal point of view, the related patents in the story are patent to invention under The Chinese Patent Act ("PA"); the related business methods, in more specific words, are computer software based business methods; nearly all patents involve E-bank industry, so they may be called E-bank related business method patent. [5]

The issue underlying that story is whether E-bank related business methods are subject matter of patent under Chinese law. [6] This note will discuss this issue. [7] For discussion purposes, Part II will describe the conception of invention under patent law in simple words; Part III will focus on barriers to patent, mainly the barrier of reason rules and methods; And in this part business methods and computer software or programs themselves will also be discussed. Part IV analyzes in two perspectives whether E-bank related business methods are patent subject matter under Chinese law. The final part will give the conclusion to this note.

## 2. INTIOION UNDER THE CHINESE PA

### 2.1 Invention

Under the Chinese PA, invention is one of the three kinds patent subject matter. [8] But what is an invention?

In simple words, invention is a kind of technical solution. [9] For example, the traditional Chinese paintings are mostly drawn on one kind of paper called "Xuanzhi". Because of the special property of that kind paper, it is very difficult to print these paintings in Xuanzhi with modern print machine. This is a time-consuming and unsolved technical puzzle. There is a hero, who is a Shenzhennese, called Zhuang Zhihe, and he has succeeded in achieving a solution. With distinctive arrangement of printing process, the similar machine the industry has employed can print the traditional Chinese paintings in Xuanzhi. [10] What Zhuang Zhihe has achieved is a technical solution for a concrete technical issue. Invention under patent law is such kind of solution. [11]

It is necessary to remind, the cited invention above involves a solution to process of product. An invention may also be a solution concerning products themselves. The exact example is the solution concerning the traditional Chinese paintings [12] printed with the patented process. [13]

If we say those two kinds above are groundbreaking ones, then an invention under patent law may be an amendment to either of them too. For example, an amendment to the printing process or printed product for which Zhuang Zhihe claimed a patent. [14]

It is with those three kinds of invention in mind that the Chinese Implementation Rule of Patent Act("IPA") article 2 section 2, using legal terminology, generalize like this : "Invention is a ... technical solution concerning product, process or amendment to either of them."

### 2.2 Disclosing files to invention

In order to apply a patent for an invention, the applicant shall describe the invention as required and disclose. The required writings include abstract, specification, claims and so on. And the claims is the most important

one of them, since it is this file that describes the technical characteristics of the related invention. [15] For example, with regard to the process invention of Zhuang Zhihe, the claims to that states in such a structure: "a process for plate making and printing... the characteristics of it is..." [16]

The claims structure of products invention is similar. For example, the Chinese Patent No.90101931 is a process and product combined patent. Claim 1 to that Patent claims a solution about a battery and describes in the similar structure like this: "a battery is made up of... the characteristics of it is..." [17]

In a word, it is through describing the characteristics of the involved invention that the claimed invention is circled with bright lines from the prior art.

### 3. BARRIERS TO PATENT PROTECTION

Under the Chinese PA there are active and passive requirements for patent protection. The active requirements are novelty prong, non-obviousness prong and usefulness prong; the passive requirements are barriers or exceptions to patent protection. [18] What this note will involve is one kind of barrier, i.e., the barrier of reason rules and methods.

#### 3.1 Barrier of reason rules and methods

Reason rules and methods are rules and methods for thinking, recognizing, judging or remembering of human being. [19] In any sense they are not technical solutions, so they are not invention in the sense of patent law. [20] Just because of that, the Chinese PA holds that they are barrier to patent protection. [21] And those rules and methods include but are not limited to: special methods for patent examination, methods and systems for organizing, producing, executing or managing, computer languages or algorithms, statistic, accounting or recording methods, computer programs and so on. [22]

Another step further, the Examination Guide clarifies, if an application claims reason rules and methods only, the applied patent cannot be issued; however, an application claims something else besides reason rules and methods, and the decisive factors in that application are not the said reason rules and methods, the patent can be issued, that is, that application claims the patent subject matter. [23]

#### 3.2 Computer programs

One item of reason rules and methods is computer programs. [24] But what is a computer program? It will be pretty well that we take system program as an example to explain this issue. A system program is mainly a unit of integrated three parts. First, is User Interface; second, is hardware and software drive; third, is data process. And the third is the most important one. After a user has driven the hardware and software, he

will enter some data into the computer via the User Interface, and these data be processed by the data process. This process is made up of two parts, first is data structures and second is algorithms. The data structures will organize all input data for the algorithms to process and the algorithms will process all input data organized by the data structure first. [25]

The data process is written with computer languages. The languages may be assembly languages, high-level languages or something else. A program in one language of them is a program in source code. The basic unit of the program is statement. After the program is entered into a computer, it will be translated into machine languages, and the result from that translation is a program in object code. The basic unit is instruction. [26]

So the Chinese Regulation of Software Protection article 3 subsection 1 provides: "Computer program, refers to a sequence of coded instructions to achieving a specific result which can be executed by such devices as computers that have information-processing capacity, or a sequence of symbolized instructions or symbolized statements which can be automatically converted into a sequence of coded instructions. The source code text and object code text of the same program shall be deemed to be the same and one work." Examination Guide adopts this definition with the only one change that it substitutes the second sentence in the definition with this one: "Computer program includes source code and object code." [27]

With regard to whether a computer program is subject matter of patent, although Examination Guide holds that computer program is a special item of reason rules and methods, but separates it from the other items and deals with independently in other chapter. [28]

#### 3.3 Business method

Maybe the conception of business method was originally from the U.S. federal cases of patent. In patent cases judges sometimes used "business methods" and sometimes "methods of doing business", but they provided no clear definition on either of them. [29] The earlier U.S. federal cases had involved hotel security, [30] method for parking cars, [31] and bank account. [32] As far as these cases are concerned, some items of reason rules and methods under Chinese law at least are equivalents to the U.S. business methods. For example, methods and systems for organizing, producing, executing or managing, statistic, accounting or recording methods and so on. [33]

In the U.S., before *State Street Bank & Trust Co. v. Signature Financial Group, Inc.*, [34] it was only some judges who accepted barrier of business methods to patent protection only in dicta. But conventional wisdom and hornbook law had hold that "methods of

doing business" are not patentable, [35] they were exception to patent subject matter.

#### 4. E-BANK RELATED BUSINESS METHODS

With the appearance and development of the Internet, besides the traditional business methods, a new generation of business methods came into existence and became popular. This new generation was computer program based business methods. In general, these business methods may be methods for producing, distributing or accounts recording with the help of the Internet. [36] The business methods for which were applied patent by Citibank in china are mostly computer program based business methods, [37] and much more complicated ones. For example, the electronic money system for which Citibank applied patent and claimed the right of priority was a pending patent in China. Its Claim 1 described a system for transferring electronic notes between processor-based electronic modules; and Claim 5 described a method for transferring electronic notes between processor-based electronic modules. [38] Both of them were Chinese versions translated from the corresponding claims of the U.S. patent [39] upon which the related Chinese application claimed the priority right. [40] Claim 1 of the U.S. patent claimed a product invention and Claim 5 a process invention. [41] It is what Claim 5 of the U.S. patent claimed that deserves discussion. The technical solution claim 5 claimed is one hundred percent a business method. A method for transferring electronic notes between processor-based electronic modules comprises the steps of: establishing a secure session, creating a transfer electronic note and transferring the said transfer electronic note. This process does not work without either of hardware and software, for example, processor-based electronic modules are hardware; the cryptographic algorithms used to establish secure session, are software. But it is neither the hardware nor software themselves it employs. [42] In other words, the software and hardware are necessary for operation of the said process, but the technical solution Claim 5 claimed consists in the process, drives nothing from either of the software and hardware. Of course, the process itself may be integrated into a computer program, [43] but that is another issue. Such kind of E-bank related business methods is business method in its strict sense. [44] From this point of view, that Citibank applied 19 patents for its business methods is not an exact description. [45]

The decisive issue is whether such kind of E-bank related business methods is patent subject matter under Chinese law. Let alone the general requirement for patent protection, [46] from the analytic-logical point of view, there are two relied sub-issues that shall be discussed separately. First, Are computer programs patent subject matter? Second, Are business methods patent subject matter?

#### 4.1 Are computer programs patent subject matter?

##### (A) Legal position of China

First, the Chinese PA considers reason rules and methods as barrier to patent protection. Examination Guide interprets that reason rules and methods include computer programs. [47] In China Examination Guide is one of government regulations issued by the Patent Office, not statutes passed by the People's Congress. Although there is such a piece of interpretations in Examination Guide, but what it expresses is not bound to be the legal position of China. To our relief, before promulgation of the original version of Examination Guide, [48] there really were decisions of the People's Court that shared the common idea. [49]

Second, Examination Guide chapter 9 covers the application of computer program based invention. [50] This chapter holds that, if an application claims computer programs only, for example, a program recorded in ROM, PROM, VCD, DVD, the related patent cannot be issued; However, an application does not claim computer programs only, and what is claimed intends to resolve technical issues, takes technical measures, and produces technical results, then it is not permitted that the related patent be refused just because of computer programs. [51]

For example, Chinese character coding methods, although they can be used in lexicography and characters searching, but they do not intend to resolve technical issues, take technical measures, or produce technical results. Even if being programmed into computer programs, they are reason rules and methods. Otherwise, with the help of Chinese character coding methods and employing keys board of computer of general purpose, a method for entering Chinese characters into computer can be achieved. This method performs the function of characters inputting and something else. Such a design involves computer programs but itself is a solution for a concrete technical issue. So it is patent subject matter, or patentable. [52]

A little regret that, all above restated are only supported by the administrative regulations. But till now none of judicial decisions says no to that.

##### (B) Reasonableness of that position

Firstly, some scholar held such a position was also accepted by some other Patent Offices in this world, especially, in developed countries. [53] For example, in the U.S., the counterpart exception to patent protection for computer programs is mathematical algorithms [54] and computer programs are mainly algorithms or aggregate of algorithms. [55] As far as this doctrine is concerned, there is no special provision in the U.S. PA, but the U.S. Supreme Court had heard three related cases, and they were *Gottschalk v. Benson*, [56] *Parker v. Flook* [57] and *Diamond v. Diehr*. [58] Although the

Supreme Court did not interpret that doctrine extremely in similar language at these three cases, but the U.S. Court Appeals for the Federal Circuit ("CAPC") at *State Street Bank & Trust Co. v. Signature Financial Group, Inc.* [59] had expressed very clear in 1998 that, mathematical algorithms are not patentable to extent that they are merely abstract ideas, [60] however, a practical application of mathematical algorithms which produces a useful, concrete and tangible result is patentable. [61] Since the Supreme Court denied certiorari on January 11, 1999, that court's opinion had been the law of the land. [62] So the Chinese and U.S. legal positions are different in approach but equally satisfactory in result.

Secondly, the decisive reasonableness consists in computer programs themselves. We may take Adobe Acrobat 5.0 as an example. An end user uploads this program in an intranet, and users in that intranet can download it freely. Such a way of using programs, just involves one hand, using programs as literary work. [63] And another end user downloads and installs it in his computer with Windows XP, he operates the program and transfers a word file called Word-file into a PDF file called PDF-file. Although all steps work automatically, [64] but automate cannot change such a fact that from one product (Word-file) he produces another product (PDF-file). This does mean the program is a process of product. Such a way of using programs, involves another hand, using programs as process of product. In a word, the program has two faces, one face tells us literary work; another face tells us process of product. [65] From the face of literary work, copyright protection shall be accessible for that program; from the face of product process, patent law shall protect that program. [66]

Thirdly, as literary work, computer programs enjoy copyright protection. In nature, what copyright law protects is the expression of computer programs in language, such as machine languages, assembly languages, high-level languages or something else. As process of product, computer programs enjoy patent protection. What patent law protects is the technical solution that consists in computer programs, performing some function or processing something. Computer programs are expressed in languages, but designed to perform some technical function or process something. So enjoying both of them is not conflicting, on the contrary, necessary. [67]

In a word, computer programs as process of product are patent subject matter in China.

## 4.2 Are business methods patent subject matter?

### (A) Legal position of China

In China there is no independent business methods exception. Some items of reason rules and methods are

counterpart to business methods. [68] But there are no judicial decisions to make sure whether business methods may be listed adversely as items of reason rules and methods. For discussion purposes, here presumed they may.

As far as reason rules and methods are concerned, in much more definite words, Examination Guide does hold that, if an application claims reason rules and methods only, the applied patent cannot be issued; but an application involves reason rules and methods, the solution described in the application consists in something other than reason rules and methods themselves, the applied patent can be issued. [69] Such a position is similar to the one concerning computer programs. [70] In a word, if business methods intend to resolve a technical issue, take technical measures and produce technical results, they are patent subject matter. Since conception of business methods is from the U.S. origin, before going further we would restate the legal position of the U.S. first.

### (B) Legal position of the U.S.

As far as barrier of business methods is concerned, the U.S. PA is a sister to the Chinese PA. It does not utter a word about that doctrine. The U.S. common law also refuses to hold business methods being exception to patent protection. In *State Street Bank & Trust Co. v. Signature Financial Group, Inc.*, [71] CAPC put an end to that doctrine absolutely which had not really existed in the legal world.

Firstly, CAPC held that, since its inception, business methods exception had merely represented some general, but no longer applicable legal principle, perhaps arising out of the requirement for invention. [72] Since 1952, business methods had been subject to the same legal requirement for subject matter applied to any other process or method. [73] It was time to let business methods exception rest forever. [74]

Secondly, CAPC insisted that, business methods exception had never been invoked by CAPC or the former of that court initialed "CCPA". Even if the issue of subject matter was concerned, the court invalidated patents on Abstract Ideas exception [75] created by The Supreme Court. [76]

Lastly, CAPC held: "Even the case frequently cited as establishing the business method exception to statutory subject matter, *Hotel Security Checking Co. v. Lorraine Co.*, 160 F. 467 (2d Cir. 1908), did not rely on the exception to strike the patent." [77] Instead, the patent was declared invalid for lack of novelty and invention. [78]

### (C) What is the reason for that position?

Barriers to patent protection in patent law can be

classified into two groups, first, patent subject matter is invention, so what is not invention is barrier to patent protection; second, even if what is claimed in a patent application is an invention, in consideration of legislation policies such as national security patent act forbids to issue patent for that invention. Then all that are forbidden are also barriers. The former, for example, the scientific discovery listed in the Chinese PA Article 25; the later, for example, a matter gained by methods of atomic nucleus that is also listed in the Chinese PA Article 25. [79] Business methods, if they are, are the former. [80]

In the examination proceedings for patent, the Chinese PA Article 25 that lists barriers to patent protection is examination item to the preliminary examination or substantial examination. And the Chinese PA Article 22 that provides novelty prong, non-obviousness prong and usefulness prong is examination item to the substantial examination. [81] For any patent application, the preliminary examination is logically earlier than the substantial examination in time point. So the first step is make sure if an application claims invention; if yes, then the second step is make sure if what is claimed may pass the novelty prong, non-obviousness prong and usefulness prong.

From the two perspectives above, it is sufficient to conclude that, the issue whether business methods are barrier substantially is the issue whether business methods are invention. As far as the later issue is concerned, the conclusion in China and the U.S. are common. If they are technical solution, they are invention under patent law. [82] Logically, it is a sound conclusion. But the decisive word in that statement is "if". If no if, how about that? Are business methods absolutely not invention? Or business methods may be invention? This is a factual issue that needs evidence to confirm.

#### **(D) Is there evidence for that conclusion?**

Take the above examples first to prove that business methods may be invention. We have discussed the printing method of Zhuang Zhihe that has been issued Chinese patent. That printing process is a traditional product process. [83] And we also have discussed Adobe Acrobat 5.0 that has received the U.S. patent, a business method to produce one product (PDF-file) from another (Word-file). [84] Let alone the later was patented in the U.S., as far as these two examples are concerned, there is not so much hesitation for us to say that they are members of one family, business methods may be invention.

Perhaps the only pending doubt is that Adobe Acrobat 5.0 is software for office purpose, not the traditional product process. Even if definitely so, this factor is not decisive. Because the patent subject matter is invention, and invention is technical solution. May software only

for office purpose be technical solution? Of course, yes. Then that software may be invention in patent law. In fact, there is another kind of software for office purpose, a method for entering Chinese characters into computer, and that is patented in China. [85]

And the U.S. Patent Office has issued patent for business methods for a long time. In 1779, first business method patent was issued to Jacob Perkins of Massachusetts for "detecting counterfeit notes". Because of a fire in the Patent Office in 1836, all materials about that patent were lost. The first business method patent all files of which were kept well today was patent issued to John Kneass in 1815 titled "a mode of preventing counterfeiting". And from then on, a lot of patents have been issued for business methods. [86] All these are indirect evidence for the conclusion that business methods may be invention.

All in all, business methods, if intend to resolve technical issues, take technical measures and produce technical results, they are patent subject matter.

### **5. CONCLUSION**

In the Citibank-Patent-Case, the basic issue is whether E-bank related business methods are patent subject matter under Chinese law. The latest Chinese law and regulation hold that, computer programs upon which performance of E-bank related business methods depends, may be technical solution, then they are patent subject matter; and business methods, although are computerized ones in E-bank industry, but may be technical solution, then they are patent subject matter too. So E-bank related business methods are patent subject matter. Although China is a developing country, but in this special field of business method patent, China shares common property ideas with developed countries, for example, the U.S.

With regard to whether a patent may be issued for an individual business method, how that patent is issued, and whether there are some specially applied restrictions for that patent, all these topics afford another note. [87] (10/23/03)

Hong Kong, China  
{lychou, timon}@baf.msmail.cuhk.edu.hk

## ABSTRACT

Recently, the provision of the real-time accounting reports over the Internet for the public corporation became popular. In response to this change on the service requirement, audit professionals considered to provide “continuous auditing” to diminish or minimize the lag time of the provision of an audit opinion behind the occurrence of business events. Though has been proposed the concept at 80’s, the provided implementation models of continuous auditing are still far beyond feasible. Major obstacles to hinder wide adoption in industry lie on two issues. (1) The development of continuous auditing system should be independent to the development of client’s information system. (2) The audit procedures that could be implemented by agent base automatic audit system should not be limited to the analysis on corporation internal data. In this paper, an agent base continuous auditing model and system is proposed to tackle these two major concerns. Several kinds of mobile agents are initiated by an audit agency system to simulate the behaviors of a human auditor on the audit procedures to collect various audit evidences. Each kind of mobile agent simulates a specific kind of audit procedure and acts on behalf of a human auditor to access and to inspect audit-related information hosted in the distributed information sources

**Keywords:** continuous auditing, multiple agent base system

## 1. INTRODUCTION

In recent decades, the adoption of information technology and electronic business model has dramatically changed the way we manage business and business information. Consequently, audit professionals are confronting pressing pressure to retrospect the way they have being doing auditing for decades. The pressure is coming from two directions: (1) While implementing electronic business model, the documentation for the business communication among participating parties and the information to support business operation within corporation are generated and collected in electronic forms. Under such circumstances, more and more audit evidence, which is taken by audit professionals as verification support to validate the corporation statement in their auditing process, could be collected in electronic form. (2) It is getting more corporations to disseminate their financial reports over Internet in real-time basis. The improvement in information efficiency has provided decision makers convenience in collecting useful information online. Nevertheless, such improvement turns out to be the pressure to the audit professionals to provide real time auditing service (Robert K. Elliott, 2002). In responding to this demanding request, “continuous auditing” was therefore proposed as an alternative solution. The continuous auditing here represents the assurance service where the time between the occurrence of events underlying the particular subject matter of a client and the provision of an auditor’s opinion on the fairness of the disclosure of the information for the subject matter is diminished, or is minimized to an acceptable level (Alexander Kogan et al., 1999, Zabihollah Rezaee et al., 2002, Zabihollah Rezaee et al.,

2001).

The research for the continuous auditing models has been on-going for two decades (Roger Debreceeny et al., 2003, S. Michael Groomer and Uday S. Murthy, 1989, Harvey S. Koch, 1981, Miklos A. Vasarhelyi and Fern B. Halper, 1991). The proposals for implementing continuous auditing are executed mostly by monitoring the generation of transaction data or by analyzing the transaction data with a set of rules defined for auditing purpose. Violations to the rules are found within the transaction lifecycle or shortly after the completion of the transaction. Then certain alarms or “red flag” should be raised to call the auditor’s attention in corresponding to the exceptional situation (Yining Chen, 2004). Based on the collected evidence, Auditors not only could pinpoint the weakness spot of internal controls, but also provide improving method to the internal controls of the operation systems. However, the proposals for installing facilities for continuous auditing limit their actual implementation. Commonly proposed methods for implementing continuous auditing could be classified in two approaches: embedded audit modules (EAM), and audit data mart (ADM). Both implementations lead to certain limitations for wide adoption in industry. The limitation for EAM is at its installation. Additionally, Auditors has problems to implement EAM models independently and has difficulty to embed the modules into clients’ system after system being built up. The implementation of ADM is its constraints on the abilities on collecting various types of audit evidence.

In this study, a new continuous auditing model, which uses multiple mobile agents to simulate the behaviors of a human auditor on the audit procedures to collect

various audit evidences, is proposed. Each kind of mobile agent simulates a specific kind of audit procedure and acts on behalf of a humane auditor to access and inspect audit-related information hosted in the distributed information sources. As a whole, the numerous agents behave aggregately as an audit agency system. In addition to the benefits generally expected for the intelligent agent base system (Danny B. Lange and Mitsuru Oshima, 1998), we argue that this audit agency system would overcome the limitation and the concern of EAM and audit data mart. The obvious benefits provided by proposed system are listed as below:

(1) Audit procedures can be implemented continuously—The mobile agent simulates an inspector on the audit-related information, and not embedded as a sub-routine of the information system. Therefore, the mobile agent is not activated automatically by the events on the on-going basis. Rather, the mobile agent is scheduled to execute predefined audit procedures autonomously and periodically. Through a periodical inspection on the audit-related information, the audit agency system provides timely information, e.g. daily or weekly reports, depending to actual implementation requirement for various kinds of audit evidence.

(2) The development of the audit agency system is independent to the development of the information system – As for the mobile agent is a dispatched software object to the client's information system, instead of being embedded in the information system, the audit professionals could develop the audit agent system without the intensively involving the client's legacy systems. That is, to minimize the interference to the legacy system, only the authorized secure interface to the read-only access privilege to the audit related information is needed.

(3) The software agent is flexible to access various kinds of information, and the audit agency system is easy to adapt to the change of audit environment – A dispatched mobile agent interacts with local agents to acquire information. The behavior of the local agent is instructed by the local schema the needs of the mobile agents. Note that the local agent is also a software objects in which it is programmed, generated and resided in the local system. The design of the local agent provides some advantages. For example, when the audit environment changes, e.g. the changes of audit criteria, operation system, and information system, the local agent can be easily updated individually to adapt to the new environment.

(4) The mobile agents could be bestowed with different degree of intelligent activities corresponding to the needs of implementing the audit procedures. Therefore, the ability for mobile agents in executing audit procedures is not limited to the inspection of historical record in accounting information system. Rather, they

can do more advanced activities such as comparing the information consistency in various applications, carrying information to the third parties system for confirmation, consulting inventory database for most updated stock level, etc. Apparently, the capability of auditing is thus expanded by the mobile agent programs.

## 2. AGENT BASE CONTINUOUS AUDIT MODEL

A software agent is a software object that is able to achieve a goal by performing actions and reacting to events with prearranged activities in the dynamic environment (Timon C. Du et al., 2004, Alfonso Fuggetta et al., 1998). Typically, software agents are programmed to have motilities and certain degree of intelligence. The mobility implies that the agents are able to transport themselves to given service platforms through the network while the intelligence encapsulates the artificial intelligence. Therefore, intelligent mobile agents are able to provide sophisticated computational or behavioral model to the remote data sources while interacting with the local services or applications. In this case, the mobile agent paradigm benefits the applications like electronic commerce, secure brokering, distributed information retrieval, parallel processing, monitoring and notification (Jon Woodroof and DeWayne Searcy, 2001), telecommunication networks services, workflow applications and groupware (Danny B. Lange and Mitsuru Oshima, 1998). Successfully developed prototypes of the applications include supply chain SMART project (<http://smart.npo.org>), brokering service in electronic market (Timon C. Du, et al., 2004), virtual enterprise (Anuj K. Jain et al., 1999), information retrieval and internet-auction house (Tuomas Sandholm and Qianbo Huai, 2000), and distributed network management (Timon C. Du et al., 2003). In the following sections, we will successively describe the major components of the multiple audit agents system for the implementation of continuous auditing.

### 2.1 The agent platform

In this study, we select a platform of IBM's Tokyo laboratory (<http://www.trl.ibm.com/aglets/>) for developing the audit agent system. The platform has a set of abstract classes and application programming interfaces (API) for users to build their own agent platform. The agent platform provides an environment of agent servers. Among those abstract classes, Aglet, AgletProxy, and AgletContext are the three most relevant key components to the agent activities -- creation, clone, dispatch, messaging, and disposal. Elaborating the functions of these three classes can help us to get a better picture of the agent platform (Danny B. Lange and Mitsuru Oshima, 1998).

(1) Aglet: Aglets is an abstract java object proposed by IBM development team. The name is a composite word

coming from “agent” and “applet”. It is programmed to implement all basic agent activities we expected for the mobile agents. A system developer can model the behavior of their own mobile agents by Extending this class definition.

(2) Proxy: AgletProxies are the representatives of the Aglets. In stead of directly accessing to the Aglets public methods, the intra-Aglets messaging and the communication between Aglet and the environment all go through the interfaces of AgletProxies. This design serves for two purposes: (a). it serves as a shield to protect the aglet from malicious access and (b). the proxy also provides location transparency for the aglets, that is, it can hide the real location of Aglets. Thus, The Aglet and its proxies (more than one copy is allowed) are separated across a network. Additionally, the exchanges of message with the Aglet’s proxies are just made as the interaction with local service agents.

(3) Context: Conceptually, a context is the Aglet’s workplace. Every active Aglet must be hosted by an AgletContext. The function of the AgletContext is different from a server; it is a stationary object that provides a means for maintaining and managing running Aglets in a uniform execution environment. The interface to the AgletContext is used by Aglet to get information of active Aglets and their environment factors. Basically, one computer network node can run many Aglet servers (engines), one servers can host many AgletContexts, and one AgletContext could host many Aglets.

## 2.2 The audit agency system

In this study, the audit agent system uses the Aglet agent platform. The system functions include taking and executing the order for audit procedures from auditors to the end of consolidating the evaluation results as the reply to the auditors. The proposed system can offload human auditors’ workload on labor-intensive works, and can benefit audit professionals a reliable and cost effective system to continuous and automatic execution of audit procedures.

Fig 1 shows the operations of the audit agent system. The main component of the system is the Agency Services Server (ASS), which interprets the command from auditors and initiates necessary mobile agents to complete the assignment. Then, various kinds of mobile agents are spawned to perform operations on different information sources, according to specialties of each type of audit evidences. Examples of collecting available audit evidences are as follows:

(1) Process definition confirmation: The mobile agent compares the current process definitions with the historical records and replies with the discrepancy. Such process definitions are maintained by the process control system, such as workflow management system

(WfMS) or enterprise resource processing (ERP), and are identical to the conventional operation. This audit procedure assures the consistency of the business operation and alerts the auditors about the changes of the operation if any. During implementation, the mobile agent carries the process definition to the clients’ site and compares against information collected from local system (agent No 1 in figure 1)

(2) Query data and precede analytical process: The mobile agent performs analytic procedures on data to check whether the inter-relationship between documents, analytical index, and company policy are

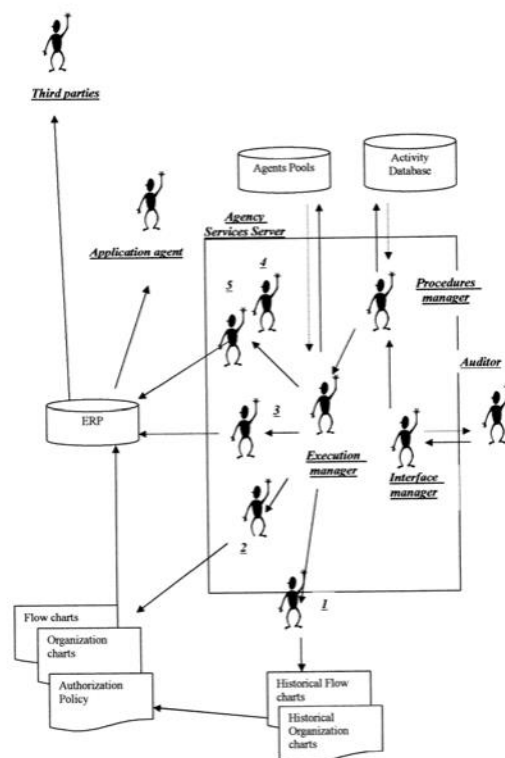

Fig 1 Audit Agency System

satisfied. By doing so, document with errors or suspicious to potential fraudulence can be allocated. During implementation, the mobile agent might visit many distributed information resources to collect related information then activate its pre-programmed analytic procedures (agent No. 2 in figure 1), or the agent can stay in ERP and complete its analytical process on the documents hosted in ERP (agent No. 3 in figure 1).

(3) Query data and take the data to third parties, e.g. customers, vendors, or bank, for further confirmation: The mobile agent retrieves and carries relevant information to the outside participants and requests their confirmation on the correctness of the information. In this design, the agent is programmed to communicate with the automatic online services of the third parties. The services can be provided by an online application or other agents communicated by standardized

communicating protocol, such as agent communication language (ACL), or Simple Agent Communication Protocol (SACP) (agent No. 4 in figure 1).

(4) Query data and take data to application agents for further confirmation: The mobile agent retrieves relevant information of the business operation in real-time and carries the information to other applications or devices for further confirmation. The example can be to examine the actual stock availability by communicating inventory management system (agent No. 5 in figure 1).

The functions of ASS include three modules: interface module, interpretation module and execution module, which are controlled by three software managers: Interface Manager, Procedures Manager, and Execution Manager (See Figure 1).

The Interface Manager manages the interfaces between the ASS and humane auditors. It is in charge of two functions: to capture required information for identification of specific audit procedure from audit requesters, and to present the execution result of the audit procedures to the audit requesters. (In adapting our study to a more automatic level, the entity for issuing audit procedures may not be limited to human auditors. An expert system which is capable to generate audit program is also technically feasible.) In order to pursue the first function, the Interface Manager needs a model to categorize the features of the audit procedures. As the conventional auditing professional has developed a framework for the organization of the comprehensive audit procedures, we will adopt the same framework. In the framework, the audit procedures are formulated as follows: audit\_procedure (accounting\_cycle, audit\_proc\_type, audit\_objective, sampling\_method, timing). That is, an audit procedure is specified by five procedure attributes: accounting cycle, audit procedure type, audit objectives, sampling method, and timing during the execution. The specific members (domain) of the first three properties are listed in table 1 (Alvin A. Arens, et al, 2003).

Regarding to the second function, two typical kinds of audit results will be presented: one is the error amount resulted from the execution of audit procedures, and another one is the alert to the auditors for the suspected operations that are prone to be error or fraudulence. The Procedures Manager is responsible for mapping the audit procedures identified by Interface Manager into a detail plan for necessary and sufficient activities to collect the audit evidence. In this plan many information are required, including the audit evidences needed to collect, the mobile agents needed to dispatch, and the configuration of the mobile agents. Moreover, the information specified in the configuration of the mobile agent includes itinerary for the agents to travel, the information sources for mobile agents to access, and the computation procedure for the specified assignment

of the mobile agents. The Procedures Manager is supported by an activity database to generate suitable activities plan, where the activity database must be maintained by the auditing firm to adapt to the changes of audit requirement and client's operation system.

Properties	Members (domain)
Accounting Cycle	Sales and collection cycle Payroll and personnel cycle Acquisition and payment cycle Inventory and warehousing cycle Capital acquisition and repayment cycle Cash balance cycle
Audit procedure type	Transaction-related audit objectives Balance-related audit objectives
Audit objective	Existence Completeness Accuracy Classification Properly classified Timing (Transaction-related audit objectives) Posting and summarization (Transaction-related audit objectives) Cutoff (Balance-related audit objectives) Detail Tie-In (Balance-related audit objectives) Realizable Value (Balance-related audit objectives) Rights and Obligations (Balance-related audit objectives) Presentation and disclosure (Balance-related audit objectives)

Table 1 Domain of property value for audit procedures

The Execution Manager is responsible for initiating and administrating mobile agents to perform required assignments. The mobile agents are initiated from the Aglet's compiled java class code. Various kinds of abstract audit classes are pooled in the Agents pools and are accessed by Universal Resource Identifier from Internet. The pooling of the Aglets classes could be maintained as one of following three different ways: by local file directory (accessed by file://c:/some/path/agent.class), by Aglets server (accessed by atp://some.server/path/agent.class), or by http server (accessed by http://www.some.host/path/agent.class). The configuration of the agents is formatted as a file accessed by the agents as an input. When the mobile agents complete their assignment outside the ASS, they come back to ASS and transfer their results to Interface Manager. Then Interface Manager consolidates the audit result and formats the report to the audit requester.

### 3. CONCLUSION

In this study, we did not try to develop a comprehensive

system for implementing continuous auditing, which involve large efforts on the integration of several available computerized audit assist tools and a continuous audit model to seamlessly automate the whole audit process. In stead, our elaboration focuses on proposing a feasible and promising model for collection of audit evidence with continuous timeframe. Reviewing on literature for the proposal of continuous auditing, several models have been proposed. But each proposal has its limitations in practical implementation. In fact, auditors have problems to implement EAM models independently and have difficulty to embed the modules into clients' system after system being built. Similarly, ADM has its constraints on collecting limited types of audit evidence. Fortunately, the agent-based continuous auditing model can provide auditors to have an auditing system independently on developing enterprise system. Moreover, the installation of the system can be done even the system is running and evolving.

## Jurisdiction and Consumer Contract in E-Business

Zheng Tang

University of Birmingham, School of Law, Birmingham, B15 2TT, UK

### ABSTRACT

The use of cyberspace increases tremendously in the past 20 years. An increasing number of businesses and consumers worldwide have accessed the Internet and there is few doubt on its growing significance for world trade. The unique features of E-business lead to the uncertainty and insecurity for the consumers as well as the companies, and incur great strikes to the traditional jurisdiction rules. It seems to be an exaggeration to argue that it would require totally new set of jurisdiction rules in E-business. It is, however, inevitable to reconsider appropriateness of the existing rules in some respects, including the reconstruction or reform of the resent rules.

This article will analyse the current jurisdiction doctrines to see how they work in the context of E-business and whether they advance the cause of consumers and the improvement of business. Specially, the article will study the Brussels Regulation as the recent most important and influential innovation trying to regulation jurisdiction on consumer contract in E-business. General suggestions will be given as to the future development to resolve this problem.

**Keywords:** Jurisdiction, Consumer Contract, E-Business, Brussels Regulation

### 1. INTRODUCTION

In the dawn of the new digital economy, “electronic business” shows its popularity in the wide world. Recent developments in the Internet communication technology have made it possible to sell goods and provide services through the Internet. The efficiency and convenience it provides encourage the consumers to take part in the new transaction model despite some concerns and doubts still remain. A non-bordered global market thus has been formed in the cyberspace, and an electronic business-to-consumer relationship has been built internationally, and at the same time, “inter-legally”. Jurisdiction problems thus arise as to which court will have the jurisdiction over the dispute on business-to-consumer contract in E-business.

To try to regulate activities carried out on the Internet by using the existing private international law rules is to put new wine into old bottle. The specific characteristics of the Internet pose uncertainty and lack of predictability to both the businesses and the consumers. When the consumer surfs on the Internet, he might easily unaware that he goes “abroad” and has transaction with a foreign company. The business also cannot identify the real origin of the consumer, thus submit itself to a potential court he has never expected. The present international trend on this problem is trying to protect the consumers by providing the court of the consumer’s domestic/resident country jurisdiction. This protective policy will subject the Internet businesses to the world-wide jurisdiction, which will greatly increase the cost and risk for doing E-business. The businesses may limit their markets much more than they would if the resolution of disputes were more predictable; correspondingly, the consumers may be frustrated because attractive products or services, or more competitive prices for certain goods or services are denied to them simply on the basis of their residence.

The net result of the situations is to the detriment of both the consumers and the businesses, and the whole promotion of consumer-orientated E-business.

This article will try to study the jurisdiction issues on consumer contract in E-business. It focuses on answering the following question: why the traditional jurisdiction rules do not work perfectly in E-business? What is the new development in this problem, and how is the effect of these new innovations, especially the Brussels Regulation? What are the possible suggestions for the future development and legislation on jurisdiction on electronic consumer contract?

### 2. THE DILEMMA OF TRADITIONAL JURISDICTION RULES IN CONSUMER ORIENTATED E-BUSINESS

Non-territoriality, non-discrimination access, intermediary involvement, and non-identity are some basic features of the Internet – the carrier of electronic business, which bring dilemma to the old doctrines of jurisdiction. The most basic and important feature of the Internet is its non-territoriality. The Internet is “a network of networks”, which is accessible from any computer locating anywhere in the world providing it is connected with the Internet Service Provider (ISP). The Internet communication thus breaks the territorial boundaries between the states in the physical world and makes distance disappear. As US District Court Judge Gertner stated that “The Internet has no territorial boundaries... as far as the Internet is concerned, not only is there perhaps ‘no there there’, the ‘there’ is everywhere there is Internet access”. [1] Secondly, the Internet is a decentralised system. There is no central or hierarchic controller in this system, which means the business that intends to establish a website dealing with the consumers only in a limited area cannot prevent the consumers worldwide accessing this information.

Thirdly, the Internet cannot run without the participation of intermediaries, which are the organisations whose services are used to facilitate a transaction between communicating parties. The intermediaries are usually not liable for the activities carried out by the Internet users. The location of the server thus often has rare or fortuitous relations with the liable online activities. Finally, the Internet technology enables users to communicate through the Internet anonymously, which blurs the information about the user's identity and location. However, in the traditional jurisdiction doctrines, such information may be important or even essential for determine the jurisdiction. These features challenge the function of the traditional jurisdiction rules in E-business.

### 2.1 Presence

The traditional practice in common law countries is to base the jurisdiction on the presence of the parties. If the defendant is present in the territory of a state, this state will have power to exercise jurisdiction over this person. The reason for presence basis is jurisdiction depends on physical control.[2] If the forum country has, directly or indirectly, an effective hold over the parties, it is practical for the forum to assume jurisdiction. In traditional English common law, an English court is competent to try action provided only the defendant has been serviced with a claim form. As to a company defendant, the English court can claim jurisdiction if this company registered in England, or outside England but has a business presence in England. [3] Other countries influenced by English law, such as Australia, Canada, New Zealand, Israel, and the United States, etc., all adopt this theory and base jurisdiction on the service of a claim form on the defendant.

Jurisdiction based on presence has faced challenges in E-business. The concept of "presence" has been questioned in the Internet age. As for individuals, a person might have some activities through the Internet and have actual connection with certain countries, which would make these countries appropriate fora. However, the person can just carry on these activities through the Internet and never be physically present in these countries. In order to settle this problem, it has been claimed that an individual is virtually "present" in the territory of one country if he appears on one website located within this country's territory. However, in this case, without the knowledge of the location of the server, the Internet user will hardly predict which jurisdiction his online action might bring himself into. This theory has a backward effect for the consumer, that it will make the business' home country in which the business locates its website server a competent forum.

A company can only have business presence in one country, either by its agent, its branch, or its place of business. However, in E-business, a company can get benefit from a foreign market only by establishing a

business website, without setting up any agent, branch, place of business or other physical establishment. Thus, no jurisdiction can be claimed based on presence principle. It has been suggested that the business website can be regarded as a business branch, or business establishment. If the website is accessible in one country, it can be regarded as a business presence in this country. The dilemma occurs that the business may thus be potentially subjected to all the jurisdictions in the world where the website can be accessed. Great uncertainty and unpredictability again exist. The presence principle thus turns more and more unpractical in the Internet age.

### 2.2 Residence/Habitual Residence And Domicile

Civil law tradition has based jurisdiction on residence/domicile of the parties. As the centre of the party's social activities, the domicile or resident country should be the most convenient forum for the concerned party. Subject one party to the judicial system of the party's habitual residence/domicile will satisfy the party's reasonable expectation in most cases. Further, a person will inevitably have close connect with his domicile/habitual residence, to subject a person to the close connected court will be appropriate and natural. However, it is not the case in E-business. Some activities carried out online may have very little connection with the businesses' residences/domiciles. For example, a business has established a website aiming at foreign markets only. In this case, for disputes arising over the business activities carried out through the website, it is unreasonable for the targeted court to decline its jurisdiction for the reason of the party has no residence/domicile in this country.

Another practical advantage of using residence/domicile to decide is certainty and predictability it provides. If the jurisdiction can be decided according to the parties involved, once the identities of the parties are settled, the probable jurisdictions are determined. However, in E-business, it is not the case. The Internet user is almost impossible to be identified. Without knowing anything about the true identity of the other party, the E-business participant cannot get any hint of where is the other party's domicile/habitual residence, and will not know in advance what is the probable jurisdiction this transaction may bring him into. Instead of certainty, residence and domicile bring unpredictability in E-business.

### 2.3 Nationality

Principle of nationality is another traditional doctrine to determine jurisdiction. The reason for this principle is based on personal bond between a party and a country. Use nationality as a basis for jurisdiction has been widely adopted by France and other Latin language countries influenced by France law.[4] However, this principle also cannot be efficient in E-business area.

Same as residence/domicile principle, when the Internet user is totally blind to the true identity of the other party, he will not know the other party's nationality, and will not have a sound prediction of the probable legal result of his activity. This principle has already lost its meaning in the virtual world.

## 2.4 Parties' Autonomy

Compared with the above doctrines, principle of parties' autonomy is a comparatively new principle in contractual area. Contractual parties can make agreement to determine which court may hear the dispute. This principle can help to protect parties' justified expectations and provide adequate certainty and predictability to foresee the legal result of a concerned transaction. These advantages make it a principle welcomed in the modern commercial world.

However, this principle has its limitations especially in E-business. The click-wrap contract is widely used in E-business. In this contract, the website provider, always the business, will display the terms and conditions of the agreement on the computer screen, and ask the other party, always the consumer, to click the button "I agree", in order to access this website or continue the purchase procedure. In a click-wrap contract, choice-of-court clauses are usually provided.[5] Although the click-wrap contract might be sound in efficiency, it is questionable whether it is also sound in fairness and justice. Without negotiating about the relevant rights and obligation, the consumer has to accept all the terms of the contract in order to make a purchase. The businesses thus have the advantage to choose the most convenient court to them, which might be vexatious or oppressive to the consumers. The result is unjust and unfair to one party with the benefit of another. This disadvantage might be detriment to the consumer's confidence to participate online transaction. Thus, the application of principle of parties' autonomy in E-business is also limited.

## 2.5 Place Of Performance

Place of performance has also been accepted as a basis to determine jurisdiction in commercial transactions.[6] However, it is quite difficult to determine where is the place of performance in E-business. Suppose an English company established a website based on the server in Japan, a Chinese consumer purchase an E-book through the website and directly download it to his computer. The consumer's ISP is located in Texas. The procedure of delivery is that: the product has been sent from the server, to the consumer's ISP, which will send it to the consumer's personal computer. Which country, Japan, China, or Texas, should be the place of performance? By holding the place of the performance is where the product is sent from, Japan will be the place of performance. However, Japan has little relation with both the parties and the transactions. Further, it is also

possible for the company to move the website into other server. The place of performance will change accordingly. If we take the place where the product has been received by the consumer as the place of performance, the remained question is whether the place of the consumer's ISP or the place of the consumer's computer can be the place of performance. Uncertainty still exists in this case.

## 2.6 Effect Has Been Caused In The State

Some country also bases their jurisdictions on the effect caused in their territories. Even if the party is outside the state's territory and has done actions elsewhere, if these actions cause effect in the state, this state will have jurisdiction.[7] Problem here is that by recognising this principle, a state greatly broadens its jurisdiction, and this broadness may cause uncertainty to the parties. Especially in E-business, a website accessible in one country will more or less cause some effect in this country. For example, an English company may just establishes a website to sell certain digital products to the consumers within Europe. The consumers in Texas who can access this website try to purchase some products online. It is reasonable to say the action of establishing website and uploading it has caused effect in Texas. However, is it fair enough to subject the company to the government of the Texas court? If so, an Internet company may be subjected to the jurisdiction all over the world. Criteria as to what kind of effect it must be have to be set up to take use of this principle.

## 3. BRUSSELS INNOVATION – DOSE IT WORK?

As mentioned above, the traditional jurisdiction rules have been questioned in E-business. It is an urgent problem to establish new approaches for the further development of consumer-orientated E-business. Many important international organisations have carried out certain work on this issue. EU Brussels Regulation might be the most influential and important innovation at present. Brussels Regulation re-organises and reforms some of the traditional jurisdiction rules and tries to make the variation efficient for the development of E-business.

Brussels Regulation has adopted domicile principle as the basic jurisdiction rule. It provides consumers the right of home forum action both as claimants and as defendants against the businesses. Parties' autonomy, as a general principle in private international law in contract, has been greatly limited in its efficiency and enforceability for consumer protection purpose. Brussels Regulation has also set up some conditions to keep balance between consumer protection and business promotion. It requires the businesses to pursue commercial or professional activities in the Member State of the consumer's domicile or, by any means, directs such activities to that Member in order to trigger the consumer protective jurisdiction provisions.[8] The

requirement in the Brussels Regulation is different from its previous precedent Brussels Convention, which requires the conclusion of the contract was preceded by a specific invitation addressed to the consumer or by advertising carried out in the consumer's domicile country and provided that the consumer took in that state the steps necessary for the conclusion of the contract itself.[9] The Brussels Regulation broadens the concept of "targeting" and removes the requirement of concluding contract in the consumer's home country. However, it is questionable whether the reform will achieve the goal of providing certainty and promoting E-business.

### 3.1 Targeting

First, is it required for the business to "target" or "aim specifically at" the jurisdiction in question in order to trigger the protective provisions? If we accept the requirement of targeting, problems will arise as to how to determine "targeting", especially in E-business. Brussels Convention has adopted the requirement of "targeting" by asking for "the conclusion of the contract was preceded by a specific invitation addressed to him (consumer) or by advertising" in the consumer's domicile.[10] This requirement has been criticized for it precludes where business can reasonably foresee the advertisement will reach consumer habitual resident/domicile in certain countries and will gladly accept the benefit thereof although the business may have had no specific intention to do business in such countries.[11] This difficulty is more obvious in E-business, for E-business brings worldwide consumers to the transactions without the necessary intentions of the businesses.

More problems will arise in E-business as to what the "special invitation" or "advertising" may be, and whether they can show the businesses' predict. The businesses generally will adopt the promotion method through email or website. The Email can be regarded as a special invitation sent to the consumers, and according to Brussels Convention, if the special invitation has been addressed to the consumer, it is enough to trigger the protective provision. The problem here is that it is not sure whether this "special invitation" by email is directed to the consumer's domicile/habitual residence.[12] For example, the business might send the consumer promotion email without knowing the actual residence of the consumer and it is hard to say the email can show his expectation to be governed by certain jurisdiction. Further, an Email is usually received and stored in the server, and then downloaded by the consumer. It is also possible to regard the place of the server as where the special invitation has been sent, and where the business is targeting. Even if we regard the place where the consumer accesses this email as the place being "targeted at", problem will arise when the consumer download and read the email in the place other than his residence.

More difficulties will arise about "advertising". Products promotion in the website can be regarded as advertising. According to Brussels Convention, the advertising in a website which is not really designed for the consumers in a particular jurisdiction is excluded from the scope of the consumer protection provision.[13] However, as the Internet is an open regime and accessible everywhere, the consumers outside the scope of the targeted countries have the equal opportunity to access the website and perform online purchase. The consumers online will not clearly know where this advertisement aims at, even if the business does give notice in the website that the products provided are for certain territories only, the consumers might be totally unaware of this announcement. In this case, is it fair to deprive these consumers protection from foreign litigation?

However, if we abolish the requirement of "targeting", it is also questionable. Since a website is accessible worldwide, and presently people have no truly efficient technologies to regulate its extension, a website with advertising "aiming at" a particular country will inevitably be viewed by the consumers from territories beyond the expected country. The potential result of refusing the requirement of "targeting" will subject the business to the actions in the unpredicted jurisdictions all over the world. For example, Brussels Regulation has made a somewhat radical reform in this point by providing "... the contract has been concluded with a person who *pursues* commercial or professional activities in the Member State of the consumer's domicile or, *by any means, directs* such activities to that Member State".[14] It is quite unclear what is the precise and authorized meaning of "pursue" and "direct". However, at least two points are certain. One is that the provision has been reformed purposely to include E-business, for "any means" will necessarily contain the means of Internet.[15] The other is the provision gets rid of the requirement that the concerned business activities must "aiming specifically at the country", which broadens the nature and scope of activity which can fall in the scope of the protective provision. Although the Commission in proposal for Brussels Regulation has stated that "a consumer simply had knowledge of a service or possibility of buying goods via a passive website accessible in his country of domicile will not trigger the protective jurisdiction",[16] it does not exclude the consumers who had more than simple knowledge of products information, to trigger the protective jurisdiction. For example, this provision enables the consumers to take action in their domiciles against foreign businesses, if they conclude contract via the active or interactive website which has been designed for special area outside the consumers domiciles. Suppose an English consumer accessed a French company's website, which was designed to sell music to the French consumers only. Although the French company made the statement to limit the service

area within France, the consumer did not notice it and purchased some music by providing credit card information and downloaded the music. Since present technology cannot efficiently prohibit this download, the company could do nothing to terminate the transaction but had to be potentially subject to the forum without previous expectation. That is the reason why many scholars and legal professionals hold the idea that this change goes too far to the development of online business.[17]

### 3.2 Necessary Steps To Conclude The Contract In The Consumer's Home Country

Secondly, is it required the contract must be concluded within the state of consumer's domicile/habitual residence? Brussels Convention has considered this issue and required that the consumer must have taken in the country of his domicile "the steps necessary for the conclusion of the contracts". However, in E-Commerce, it is clear the place of conclusion of contract becomes somewhat irrelevant to the matter. Without requirement of personal presence, a consumer can conclude contracts everywhere in the world. To the business, an English consumer concluding the contract online in his home country will have no difference if he concluding the contract in Japan. On the other hand, the business concluding contract online is not necessary to have a sound knowledge about the consumer's *concurrent* location, for it is quite often to be fortuitous without any connection with the consumer's domicile/habitual residence. In the above example, is it just to exclude the English consumer from the protective jurisdiction regime for the necessary steps to conclude the contract has been taken in Japan instead of England? If the invitation was sent individually to the consumer, or the advertising was designed aiming at the English market, is it reasonable to treat the consumer differently just because he happened to make this purchase outside England? Further, how about the business company has already known the domicile of the consumer before concluding contract? The fact that the consumer did not take necessary steps in his domicile will not damage businesses' reasonable expectation.

Furthermore, doubts might arise as to how to determine the places where the consumer has carried out the steps leading to the conclusion of the contract in E-Commerce. The character of the Internet makes it possible for "the steps necessary for the conclusion of the contract" to be taken in different States. For example, the consumer might begin the order in one country, continue negotiation in another, and complete it in the third country. Further, from the technical point of view, in a click-wrap contract, the contract is concluded in the server, instead of the place of consumer's location even if the consumer does click the bottom indicating his agreement in his domicile/habitual residence. In this case, the business can easily escape the protective provision by choosing the server located outside the

consumer's home countries. Even if we take the view that the contract is concluded in the consumer's location at the time of conclusion, it is for the consumer to prove that he has taken necessary steps to conclude the contract in his domicile in order to trigger the protective provision. The problem is how can the consumer prove the contract is concluded in his home other than in a foreign country?

By noticing these difficulties, Brussels Regulation has abandoned this requirement, but the reform has also been taken into question. It is claimed if the contract has been concluded totally outside the consumer's domicile/habitual residence, how can it be for the contract to have sufficient connection with the consumer's domicile/habitual residence? And how can it be just and fair for a court does not have sufficient connection with the contract to assert special jurisdiction over the case? Further, if the contract is concluded outside the consumer's home, the business will have no reason to expect the possible result of the transaction will subject himself to the unpredicted jurisdiction. For example, if the consumer performs the purchase in the business' domestic country, as to the particular contract, it is not clear from doubt that the consumer's unilateral behaviour is sufficient to bring the business to a foreign jurisdiction.[18] The language in the Brussels Regulation is so broad that it even can subject defendant company to the protective provision even if the contract were not concluded via the Internet but that nevertheless are related to and fall in the scope of the foreign defendant's website.[19] For example, a French company established active website with attractive advertisement in it to sell wine in France. This wine has never been put into the market outside France. An English consumer accessed this website and purchased the products in France during his one week travel. According to the provision, the company did direct "commercial or professional activities" to England "by any means", for the advertisement is accessible in England. However, is it reasonable and fair to subject the France Company to the English forum concerning lawsuit brought relevant to this wine?

## 4. CONCLUSION

Generally speaking, present jurisdiction rules, including some innovation tailoring the traditional jurisdiction rules to suit the development of E-business, are considered not satisfactory enough. The Brussels Regulation provides more certainty and security for the consumers, but may discourage the promotion of the business. Some undefined concepts, such as "direct to", "pursue" have been questioned and creates unpredictability to the parties. More work has to be done in this question. Although no systematic and detailed resolution recently, some general suggestions can be made to make this issue more clear:

First of all, certainty and predictability has to be guaranteed to both the businesses and the consumers. In this sense, if the traditional jurisdiction doctrines are adopted, further work has to be done to give precise definitions to some basic concepts in E-business.

Secondly, as unequal bargain power exists between the consumers and the businesses, more concerns have to be given for consumer protection. Restrictions should be set to regulation the effect of choice of forum clause in click-wrap contract.

Thirdly, in order to promote E-business, reasonable expectation of the businesses has to be protected. It is not sound to subject business to the jurisdiction of consumer's home country in any case. Some conditions have to be established to prevent over-protective solution for consumers.

Fourthly, as the technology is continuing growing, E-business in the future might rely on some technique other than the Internet. Thus, the resolution must be technology neutral so that it does not discriminate between different technologies.

## Jurisdiction over E Commerce

Bill Loving, Xianping Liu

Idaho State University, Pocatello, Idaho

### ABSTRACT

Expansion of business onto the Internet crosses national borders and creates uncertainty as to the propriety of jurisdiction by the courts of nations and their internal political units. Analysis of jurisdiction in United States law reveals that traditional rules provide guidance for resolving the question of constitutional jurisdiction in cases that cross geopolitical lines.

### 1. INTRODUCTION

Web commerce provides opportunities for international trading at low cost. Maintenance of Web sites and use of banner ads and search engines allow companies to enter highly desired United States markets and reach consumers who would otherwise be out of reach.

While both government and private businesses seek to take advantage of the annual estimated \$110 billion in U.S. imports,<sup>1</sup> this expanded commercial presence through the Internet means additional risk as American consumers and competitors turn to United States courts for redress of commercial injury.

The question of forum selection and jurisdiction has long been a central one in civil litigation in the United States.<sup>2</sup> Where can an aggrieved party seek redress: Where the injury took place, where the plaintiff resides or where the defendant lives? The question is complicated by the nature of e-commerce which bypasses national borders. For many Internet business models, the nationality of the consumer is relevant only in terms of exchange rates. That changes with the filing of a civil lawsuit. Then, the location of the forum in which the case is to be decided will be of great importance.

### 2. TRADITIONAL JURISDICTION ANALYSIS

<sup>1</sup><http://www.usashow.net/bmsc1.asp?id=381>

<sup>2</sup>Jurisdiction can be found as either general jurisdiction or specific jurisdiction. In general jurisdiction, the defendant will have an ongoing relationship and general activity in the state that is unrelated to the controversy at hand. See, *Helicopteros Nacionales de Colombia, S.A. v. Hall*, 104 S.Ct. 1868, (1984). An airline that operates in a state would be subject to general jurisdiction on the basis of its ongoing business presence. Specific jurisdiction arises when a defendant has sufficient contacts with the forum state that exercise of jurisdiction will not offend traditional notions of fair play and substantial justice. See, *International Shoe Co. v. State of Washington, Office of Unemployment*, 66 S.Ct. 154 (1945).

At the heart of jurisdiction is the due process clause of the Fourteenth Amendment of the United States Constitution. That clause has placed limits on which courts a defendant may be brought to answer for civil wrongs. That power of a court, tested in the enforcement of its judgments, is decided by the application of the Fourteenth Amendment, specifically the due process clause.<sup>3</sup>

The Supreme Court has dealt with the issue of defendant conduct and jurisdiction in three significant pre-Internet cases: *International Shoe Co. v. State of Washington, Office of Unemployment*, 66 S.Ct. 154 (1945); *World-Wide Volkswagen Corp. v. Woodson*, 100 S.Ct. 559 (1980); and *Burger King Corp. v. Rudzewicz*, 105 S.Ct. 2174 (1985).

*International Shoe* focused on the activities of an out-of-state corporation. *International Shoe* had between 11 and 13 salesmen who exhibited samples of the company shoes and solicited Washington residents to place orders with company headquarters in Missouri. The state of Washington sued to force the company to pay into the state unemployment fund.

The case reached the U.S. Supreme Court where *International Shoe* argued that due process restrictions would not allow the Washington courts exercise jurisdiction. Chief Justice Harlan Stone delivered the opinion affirming that *International Shoe* was subject to the power of that state courts. The key was the conduct of the shoe company in the state.<sup>4</sup>

<sup>3</sup>U.S.C.A. Amendment XIV II persons born or naturalized in the United States, and subject to the jurisdiction thereof, are citizens of the United States and of the State wherein they reside. No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any State deprive any person of life, liberty or property, without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws.

<sup>4</sup>*International Shoe Co. v. State of Washington, Office of Unemployment*, 66 S.Ct. 154, at 159-160, (1945).

It is evident that the criteria by which we mark the boundary line between those activities which justify the subjection of a corporation to suit, and those which do not cannot be simply mechanical or quantitative.

Whether due process is satisfied must depend rather on the quality and nature of the activity in relation to the fair and orderly administration of the laws which it was the purpose of the due process clause to insure. That clause does not contemplate that a state may make binding a judgment in personam against an individual or corporate defendant with which the state has no contacts, ties or relations.

As a general proposition, Stone wrote, single or irregular activity by a corporation agents in a state did not make it liable to suit there. But International Shoe had done considerable business in Washington and, in so doing, benefited from the state<sup>5</sup>

[T]o the extent that a corporation exercises the privilege of conducting activities within a state, it enjoys the benefits and protection of the laws of that state. The exercise of that privilege may give rise to obligations; and, so far as those obligations arise out of or are connected with the activities within the state, a procedure which requires the corporation to respond to a suit brought to enforce them can, in most instances, hardly be said to be undue.

World-Wide Volkswagen Corp. v. Woodson, 100 S.Ct. 559 (1980) helped to refine the scope of the application of jurisdiction. In Volkswagen, a family purchased a car<sup>6</sup> from a dealership that operated in New York. A year later, the family was involved in an accident in Oklahoma while en route to Arizona. The family brought a products-liability suit in Oklahoma. The Oklahoma Supreme Court ruled that the family could sue in an Oklahoma state court. It reasoned:<sup>7</sup>

The evidence presented below demonstrated that goods sold and distributed by the petitioners were used in the State of Oklahoma, and under the facts we believe it reasonable to infer, given the retail value of the automobile, that the petitioners derive substantial income from automobiles which from time to time are used in the State of Oklahoma.

Further, the Oklahoma Supreme Court reasoned, World-Wide could reasonably anticipate being brought into an

Oklahoma court.<sup>8</sup> In the case before us, the product being sold and distributed by the petitioners is by its very design and purpose so mobile that petitioners can foresee its possible use in Oklahoma. World-Wide appealed to the U.S. Supreme Court and, in an opinion by Justice Byron White, the Court reversed. Justice White wrote that World-Wide had no contacts with Oklahoma, certainly not enough to give Oklahoma courts jurisdiction over the company.<sup>9</sup> Here, there is a total absence in the record of those affiliating circumstances that are a necessary predicate to any exercise of state-court jurisdiction.

Justice White disposed of the Oklahoma Supreme Court analysis of the foreseeability of World-Wide being subjected to Oklahoma jurisdiction. Justice White acknowledged that World-Wide might foresee one of its cars being driven to Oklahoma and that such a car might be involved in an accident. But that was not the proper analysis of foreseeability, White wrote.<sup>10</sup>

The foreseeability that is critical to due process analysis is not the mere likelihood that a product will find its way into the forum state, but rather that the defendant conduct and connection with the forum are such that he should reasonably anticipate being haled into court there.

The mere fact that World-Wide injected a product into the stream of commerce that wound up in Oklahoma was not enough to create jurisdiction even though there was a claim that the product caused injury. In terms of libel, this case appears to foreclose most, if not all, jurisdictions outside the home state of the defendant publisher.

The Supreme Court fourth case in the quartet of jurisdiction decisions is Burger King v. Rudzewicz.<sup>11</sup> That case, involving a contract interpretation dispute between a fast-food franchisee and franchising company is relevant to the extent that it deals with the question of injuries that arise out of actions purposefully directed at forum residents.

Burger King sued Rudzewicz, the franchisee, in a Florida court. Rudzewicz opposed the exercise of jurisdiction and won in the 11th Circuit. Justice William Brennan delivered the opinion for the Court which reversed the 11<sup>th</sup> Circuit panel finding that jurisdiction was appropriate for the court in Florida.<sup>12</sup>

<sup>8</sup> Ibid.

<sup>9</sup> World-Wide Volkswagen Corp. v. Woodson, 100 S.Ct. 559, 566, (1980).

<sup>10</sup> Ibid.

<sup>11</sup> Burger King v. Rudzewicz, 105 S.Ct. 2174 (1985).

<sup>12</sup> Ibid. At 2186.

<sup>5</sup> Ibid. At 160.

<sup>6</sup> The car happened to be an Audi. The family was Harry and Kaye Robinson and their two children.

<sup>7</sup> Quoted in World-Wide Volkswagen v. Woodson, 585 P.2d 351, 354 (Okla. 1978).

Eschewing the option of operating an independent local enterprise Rudzewicz deliberately reach[ed] out beyond Michigan and negotiated with a Florida corporation for the purchase of a long-term franchise and the manifold benefits that would derive from affiliation with a nationwide organization.

When Rudzewicz failed to meet the terms of the contract, he caused foreseeable injuries to Burger King. Those injuries reasonably would lead to an accounting for the harm, Justice Brennan wrote. Rudzewicz availment of Florida laws before the relationship soured and his purposeful acts directed at Florida were enough to find jurisdiction.

### 3. APPLICATION OF FORUM ANALYSIS IN INTERNET COMMERCE

A case involving two United States companies from different states provides some direction to the question of jurisdiction over E Commerce. Zippo Mfg. v. Zippo Dot Com was a state law trademark dilution case brought by the Pennsylvania light maker against a California Internet company that maintained a Web site and provided an Internet news service.<sup>13</sup> The Internet company did not have any offices or employees in Pennsylvania and so moved to dismiss the case because the Pennsylvania court lacked jurisdiction.

U.S. District Judge Sean McLaughlin began his analysis by citing the traditional three-part test for jurisdiction from International Shoe and Burger King: (1) sufficient minimum contacts in the forum state, (2) whether the claim arose from those contacts and (3) whether the exercise of jurisdiction would be reasonable.

He then turned to the changes that had taken place with respect to jurisdiction, running from physical to virtual presence.<sup>14</sup> he Internet makes it possible to conduct business throughout the world entirely from a desktop. Judge McLaughlin then suggested a structure for deciding when jurisdiction clearly is and is not proper based on the quality and kinds of activity conducted over the Internet.<sup>15</sup>

This sliding scale is consistent with well developed personal jurisdiction principles. At one end of the spectrum are situations where a defendant clearly does business over the Internet. If the defendant enters into contracts with residents of a foreign jurisdiction that

involve the knowing and repeated transmission of computer files over the Internet, personal jurisdiction is proper. *E.g. CompuServe, Inc. v. Patterson*, 89 F.3d 1257 (6th Cir.1996). At the opposite end are situations where a defendant has simply posted information on an Internet Web site which is accessible to users in foreign jurisdictions. A passive Web site that does little more than make information available to those who are interested in it is not grounds for the exercise personal jurisdiction. *E.g. Bensusan Restaurant Corp., v. King*, 937 F.Supp. 295 (S.D.N.Y.1996).

Judge McLaughlin put interactive Web sites, sites that allow users to exchange information with the host, in a middle ground. The test for those sites would be<sup>16</sup> the level of interactivity and commercial nature of the exchange of information that occurs on the Web site. *E.g. Maritz, Inc. v. Cybergold, Inc.*, 947 F.Supp. 1328 (E.D.Mo.1996).

Applying that test to Zippo Dot Com, Judge McLaughlin noted that Zippo had some 3,000 Pennsylvania subscribers to its news service. While instructive, Judge McLaughlin's analysis is little more than an application of the principles enunciated in International Shoe and Burger King. Even Burger King, which predates the Internet phenomenon, recognized the power of interstate communication to confer jurisdiction.<sup>17</sup>

Although territorial presence frequently will enhance a potential defendant's affiliation with a State and reinforce the reasonable foreseeability of suit there, it is an inescapable fact of modern commercial life that a substantial amount of business is transacted solely by mail and wire communications across state lines, thus obviating the need for physical presence within a State in which business is conducted. So long as a commercial actor's efforts are "purposefully directed" toward residents of another State, we have consistently rejected the notion that an absence of physical contacts can defeat personal jurisdiction there.

A case involving international parties followed a different approach. In *Hy Cite Corp. V. Badbusinessbureau.com, L.L.C.*,<sup>18</sup> a U.S. district court in Wisconsin was called on to determine whether it could exercise jurisdiction in a dispute between an American company and a West Indian concern. In that case, the West Indian company operated a Web site called the Rip-Off Report, which featured critical statements about Hy Cite sued alleging unfair competition,

<sup>13</sup> Zippo Mfg. Co. v. Zippo Dom Com, Inc., 952 F.Supp. 1119 (W.D.Pa. 1997).

<sup>14</sup> Ibid. At 1123.

<sup>15</sup> Ibid. At 1124.

<sup>16</sup> Ibid.

<sup>17</sup> Burger King Corp. v. Rudzewicz, 105 S.Ct. 2174, 2184 (1985).

<sup>18</sup> Hy Cite Corp. V. Badbusinessbuearu.com. L.L.C., 297 F.Supp. 2d 1154 (W.D.Wisc. 2004).

false advertising, disparagement and trademark infringement claims under both state and federal law.<sup>19</sup>

Badbusinessbureau.com replied with a motion to dismiss for lack of personal jurisdiction. Judge Barbara Crabb, chief judge for the judicial district, concluded that the court did not have jurisdiction over badbusinessbureau.com either through general personal jurisdiction or specific personal jurisdiction. Judge Crabb cited the American constitutional requirements that a defendant have minimum contact in the forum state and, citing *International Shoe* and other federal cases, noted that those contacts must be purposeful and not andom, isolated or fortuitous.<sup>20</sup>

But where Judge McLaughlin in *Zippo* found jurisdiction based on a Web presence and the level of interactivity of the defendant business, Judge Crabb reached an opposite conclusion in *Hy Cite*. Judge Crabb rejected the *Zippo* approach on two bases: (1) Use of the interactivity test, and, (2) The lack of legal authority to craft a mechanical test for determining jurisdiction. Judge Crabb said it was not clear why interactivity should be a determining factor for jurisdiction.<sup>21</sup>

As even courts adopting the *Zippo* test have recognized, a court cannot determine whether personal jurisdiction is appropriate simply by deciding whether a website is "passive" or "interactive" (assuming that websites can be readily classified into one category or the other).

And, Judge Crabb noted, operators of passive Web sites have been subjected to jurisdiction of courts when those sites have been used to harm plaintiffs intentionally.<sup>22</sup>

#### 4. CONCLUSION

The risk of lawsuits and the question of where those suits can be brought will profoundly affect e-commerce. A developing model sends advertising messages to Web users based on information they provide, either directly or through analysis of their site visitation. This advertising is not targeted to particular states, but rather looks to individual consumers and is based on a market for information. The Web site is not interacting with the residents of a particular state within the borders of the United States, but rather is seeking all persons interested in travel. The fact that a Web visitor is from a particular state in a particular country, becomes fortuitous and

happenstance contacts should not be enough to maintain jurisdiction.<sup>23</sup>

Where, on the other hand, a business uses the Web to target consumers in a particular geographic or political entity, then jurisdiction should be proper in that foreign forum. The result from that system is foreseeability for businesses engaged in e-commerce that allows them to prepare to deal with litigants in foreign forums.

## ABSTRACT

E-business security is crucial to the development of e-business. Due to the complexity and characteristics of e-business security, the current approaches for security focus on preventing the network intrusion or misusing in advanced and seldom concern of the forensics data requiring for the investigation after the network attack or fraud. We discuss the method for resolving the problem of the e-business security from the different side of view - network forensics approaches - from the thinking of the active protection or defense for the e-business security, which can also improve the ability of emergence response and incident investigation for e-business security. It is also for the first time to systematically discuss the network forensics evidence source, network forensics principles, network forensics functions and network forensics techniques.

**Keywords:** e-business security, network security, digital forensics, network forensics

## 1. INTRODUCTION

Internet-based business operations offer many benefits, but also bring a broadened range of risks, some of them unprecedented. The actual and perceived lack of system security and reliability are significant deterrents to the rapid growth of the digital economy.

Daily progress is being made in reducing network risks through a variety of software patches, cryptographic algorithms and security tools. These efforts major focus on the prevention of the network intrusion, but always cannot eventually avoid the risk of the network misuse and fraud. We always pay more attention to the passive defensive measures of the e-business system, but ignore the computer evidence acquiring and forensics analysis after the attacks.

Although to some degree the legislation is relative later than the issues of computer and economics crime, once the system is compromised and leads to a large amount of economic lose of the enterprise, to obtain the computer evidence will become more and more important. On the other hand, forensics analysis of the system can also improve the protective and detective ability of network security system. To solve the puzzle of e-business security, we need different approaches to enhance the investigation of the network attack. Network forensics technology can be used for that purpose.

Judd Robbins, a prominent computer forensics investigator, defines computer forensics as "the application of computer investigation and analysis techniques in the interests of determining potential legal evidence." [1] Other experts, believing computer forensics has evolved into a science, define computer forensic science as "the science of acquiring, preserving,

retrieving, and presenting data that has been processed electronically and stored on computer media."

The term network forensics is commonly used to describe the task of analyzing information collected on active networks from various intrusion detection, auditing, and monitoring capabilities for the purpose of protection. The monitoring and analysis of data from live systems and networks will become essential to law enforcement as caseloads increase and juridical boundaries blur. [3,4,5,6,7]

In the First Digital Forensic Research Workshop, researches give the definition of Network Forensics, [2] that is: The use of scientifically proven techniques to collect, fuse, identify, examine, correlate, analyze, and document digital evidence from multiple, actively processing and transmitting digital sources for the purpose of uncovering facts related to the planned intent, or measured success of unauthorized activities meant to disrupt, corrupt, and or compromise system components as well as providing information to assist in response to or recovery from these activities.

For the purpose of the network forensics, we always need the toolkits to capture the network traffic fully. There are many toolkits for building network traffic analysis and statistical event records [8,9,10,11,12]. They often use a promiscuous packet interface to pass visible traffic into an internally decision engine which discloses the content of the packets and counting them into statistical data and logging key details into backend disks.

After obtaining the network traffic data, forensics analysis is needed. Data mining techniques can be used for mining stream data or email contents [13,14,15]. Utilizing artificial intelligent approaches to identify

special features [16], IP trace back approaches [17,18] to the attack origin identification and mapping topology approaches for the possible location of the attack origin [19,20,21,22,23,24,25].

Current incident investigation mostly focus on the after attack data analysis. Seldom discuss the active investigative approaches in advance for potential risk and the techniques of the speedup of the emergence response time.

In this paper, we discuss the e-business security from a different point of view. Network forensics system that implement to capture the attacker's behavior and log them for the future analysis and investigation.

The remaining of the paper is organized as follows: First, Section 2 characterizes e-business security issues. Current solutions for implementing e-business security are discussed in Section 3. Section 4 details the discussion of network forensics approaches for e-business security. We give the conclusion and look ahead in Section 5.

## 2. E-BUSINESS SECURITY ISSUES

### 2.1 Types of Typical Attacks

There are many types of typical attacks that e-business corporation have to face and consider. The most common types are listed below:

**Distributed Denial of Service (DDOS):** This type of attack is often used when other protections have provided adequate security to the network. When such protections have denied attackers access, such attackers may resort to denying authorized users access to the network by overloading and hence crippling the network such that its performance significantly degrades or ceases to function altogether.

**Viruses:** This type of attack is often distributed via email attachment and often infects large numbers of customers and may be created itself replication. Viruses, once activated, may destroy information; provide future improper access to a network.

**Data destruction:** Improper access is gained and an entity's information is improperly changed or destroyed. Physical perimeter penetration: It is unauthorized accessing to a user's facility or network.

**Password cracking:** lists of the most used passwords are tried as a means of unauthorized access to another's network. Numerous cracker, hacker, web sites post lists of the most often used passwords.

**Screen emulators:** This is where low level access is gained to a network and a screen emulator is placed on the access server that brings up a false screen that emulates the proper login screen. This false screen asks for the users login and password and the brings up a screen that states "login incorrect, please try again." Actually the login was correct and the false screen

emulation program has captured another user's correct login and password.

**Social engineering:** This attack relies on the element of human weakness in protecting access information.

Other attacks that require more sophistication, such as cryptanalysis, man in the middle attacks, Trojan horses, IP hijacking, IP spoofing, sniffing, masquerading, reverse engineering and steganography or covert channels.

### 2.2 Objectives of e-Business Security

While the list of actual attacking manifestation is long, conceptually, they break down to a few categories. These are spoofing, unauthorized disclosure, unauthorized action, and data alteration. A well-planned information security strategy will address all these areas.

E-business security concerns also fall into four main categories: loss of data integrity; loss of data privacy; loss of service; and loss of control. Responding to these concerns requires an integrated and effective information security policy. In conducting e-business, every organization ought to be able to:

Positively identify or confirm the identity of the party they are dealing with on the other end of the transaction. Determine that the activities being engaged in by an individual is commensurate with the level of authorization assigned to the individual.

Confirm the action taken by the individual and be able to prove to a third party that the entity did in fact perform the action.

To protect information from being altered either in storage or in transit.

Be certain that only authorized entities have access to information.

Ensure that every component of the e-business infrastructure is available when needed.

Be capable of generating an audit trail for verification of transactions.

Effective information security policy must have the following six objectives: privacy and confidentiality; integrity; availability; legitimate use (identification, authentication, and authorization); auditing or traceability; and non-repudiation. If these objectives could be achieved, it would alleviate most of the information security concerns or improve the e-business security circumstance.

## 3. CURRENT SOLUTIONS FOR E-BUSINESS SECURITY

### 3.1 Network Level Security

Network level security provides protection against attackers who attempt to deny service to legitimate users by gaining control of machines or resources within a

private network. The most common way to protect private networks that are connected to the Internet from these kinds of attacks is firewall technology. A firewall is located at a network gateway server that protects the resources of a private network from users from other networks. It is a combination of hardware and software used to implement a security policy governing the network traffic between two or more networks. The network firewall is the primary line of defense against external threats to an organization's computer systems, networks, and critical information.

In case an attacker successfully penetrates the firewall, IDS(Intrusion Detection System) can be useful to minimize the risk that any damage can be done to the servers or network. There are two kinds of IDS. One is Host IDS, which deploy on the host or server. The other is Network IDS, which set up in the network and detect the abnormal network traffic.

### 3.2 System Level Security

System level security is the ability to utilize operating system functions and applications in combination with hardware architecture to help protect against corruption of service and control user access to system resources, such as files, programs, databases and so on. Some technologies to improve system level security: host operating system harden, unsafe processes or services disabled, anti-viruses programs, database system security, data backup and recovery, application security and so on.

### 3.3 Transaction Level Security

The actual act of completing transactions on the Internet depends on transaction level security. Transaction level security refers to the ability of two entities on the Internet to conduct a transaction privately and with authentication. In assessing e-business security, all the components of a transaction have to be considered: the client, transport channel, servers, operating system, applications and database components. Both the authentication of the component of the transaction is crucial, so it always needs the support of PKI system. This level of security provides a basis to enable the payment for goods and services to occur in privacy. Currently, the leading technologies for implementing transaction security are Secure Socket Layer (SSL) and Secure Electronic Transaction (SET).

### 3.4 Weakness of Current Solution of e-Business Security

Assuring the availability and security of the network is complex challenge. Historically enterprises employ a patchwork of nonintegrated security products that provide incomplete coverage. There are two weakness of existing solution to the e-business security.

One is individual point of products. Over the past decade, security analysts and network managers have come to rely on a multitude of specialized solutions that address specific points of the network. These include firewall, IDSs, server log files and vulnerability scanners. They are not built into a cooperative or integrated system. Once system is compromised, all products are unfortunately do not present a holistic picture of network activity because their initial purpose is protection but not forensics.

The other weakness is limited sampling. Current products can only capture limited quantity of network traffic. This creates a frustrating guessing puzzle for network managers or incident investigator who must interpret these ambiguous snapshots of the network traffic or attack behavior.

## 4. NETWORK FORENSICS FOR E-BUSINESS SECURITY

### 4.1 Network Forensics Evidence Source

Computer evidence must keep the criterion of the traditional evidence, such as confidential, authentication, integration, legitimated. Moreover, it has its own characteristics listed as follows:

**Virtual:** Computer evidence consists of the computer binary data and files in the computer or devices. They cannot be touched and looked without the processing of computer software.

**Multiform:** The appearances of the evidence are diversity because they can be stored with different format, such as the words, picture, wave sound and video. Some of them even can be interactive with the computer user. They can be stored in the hard disk, USB disk, compact disk and so on.

**Fragile:** The computer evidence is easy to destroy by the software or the human interference. It can be deleted, modified and counterfeited by the mistakes of investigators or the premeditation of criminals.

**Instant:** Some evidence is altered with the time, such as the network traffic packets, process in the host, open ports. They will not replay if investigators do not record them on the disk. The forensics system can record the dynamic data and save them to a safe disk, where other softwares cannot modify the data, so that it will keep the originality and integration of the evidence.

There are four types of data source for the computer evidence.

**The data from host or server:** It includes the operation system audit trail, system event log, application event log, alert log file, file MAC (Modify/Access/Create) timestamp, recovery data, system time, file slack, erased files, swap files, memory contents, program files. It is the traditional computer forensics data.

**The data from network:** It is the network traffic data packets. Because the network becomes more and more frequent channel to launch attacks, the data of the traffic

becomes also more and more important to forensics analysis. Especially for the network forensics system, the traffic is a key data source. However, the traffic data always has large volume, therefore the efficiency of dumping data is the major issue of the network forensics system.

**The data from other security products:** It includes firewall log, IDS log, access control system, router, network interface, PDA and so on. The data on these systems give some digest information of the intrusion and misuse.

**The data from Internet:** For the Internet forensics, the data from Internet can give some basic information for investigation, such as the personal data from the personal website or search engine, the content of chat room.

#### 4.2 Network Forensics Principles

The evidence obtained after the network forensics process must keep the legal validity, so some principles must be satisfied in the network forensics procedure.

**To keep the originality of the data:** The analysis is not directly on the processing of the original data, but on the base of image mirror copy of the original data. The copy is a way of bit-to-bit copy and is the exactly copy of the original data. All the forensics analysis process on the copy version of data will keep the integration of original data and make the replay of analysis procedure possible.

**To keep the result believable:** It means the forensics software and hardware is safe and believable. The software to capture data, analysis data, process data, and display final evidence must be the authority software or satisfy the standard of the forensics procedure. Before the forensics standard becomes uniform and certificated software are available, the open source software may be a temporary way with believable.

**To keep the procedure believable:** Every step of processing action must keep the integration of the analysis data. The data signature or data digest approaches can be utilized for this purpose. Read-only property of files is not always believable because even read-only compact disks may also have data changes on special conditions.

**To keep the integration in transportation:** If the data need to be transported, the integration and confidentiality of the data must satisfy. Data signature also can be used in this occasion.

**Documentation and monitoring:** The whole procedure of the forensics must documentation, including the time, location, operator name, approaches, techniques, operations steps, processing results and so on. The procedure must be in the monitor of the third party or authority organization, and they must give the signature on the document of the result.

#### 4.3 Network Forensics Functions

##### (1) Network investigating

Before the enough evidence is available, some investigation can be provided by the network forensics system. Search engineering tools is the fundamental program in the network forensics system suite or integrated into the system. Browser tools, ftp tools, email tools and other Internet tools are also needed.

##### (2) Network surveying

Some network survey tools are also included. The first is footprinting tools, such as whois, nslookup, traceroute. The second is scanning tools, such as nmap, Hping2, which can be added into the network forensics package or customized development. The third is enumeration tools used for netbios enumeration, snmp enumeration and active directory enumeration.

##### (3) Network traffic recording

Network traffic is fully dumped by the network forensics system, which can also filter the traffic according to the rules. Rules can be customized for different purpose.

##### (4) Data aggregation

Logging data from different location give different feedback of the attacking behavior. The analysis of the aggregation of the data sets, which are from multiple sources, such as firewalls, IDSes and sniffers, can build the chain of the clues and display the full scene of the crime. Network forensics system can aggregation the data and transform the data into a uniform data file or database.

##### (5) Future attacking pattern predicting

The hacker group always has some features, such as the types of attacking tools, the frequently utilizing techniques, their often steps and trace routes for intrusion. Therefore the network forensics system can use data mining approaches to discover the potential pattern of attacks and provide the function of predication.

##### (6) Anomaly pattern discovering

The log data in the forensics system can be mined for the anomaly pattern, which will also give a feedback to influence the setting of firewall rules and intrusion detective signatures.

#### 4.4 Network Forensics Techniques

##### (1) Mapping topology

Building the topology database and IP location Mapping topology of the network may help to find fraud proxy server, ARP spoofing, or quicken the location of the attack origin.

##### (2) Honeypot/honeynet learning and collecting

Using the honeypot system and network forensics analysis, we can build a database to profile the blackhat, person or organization, such as the name, nickname, email address, home address, nationality, age and so on. We can store the IP address, blackhat techniques, tactics, motives and psychology in the database. We can use dig

tools to profile the main IP node domain name, topology of network or the location of the hackers. The data in the database can be update automatically and also keep the current data and old data for the future timeline analysis.

#### (3) TCP session replaying

To analysis the attack behavior by replay the attacking procedure. In the captured network traffic, unrelated packets appear in the order they were transmitted over the wire. Network forensics tools can reorganize the packets into individual transport-layer connections between machines. To reassemble the connections, more forensic details emerge.

#### (4) Protocol parsing

Protocol parsing and analysis is the major work of network forensics analysis. In the analysis, the POP3, HTTP, FTP and telnet protocols need to be paid more attention.

#### (5) Covert channel discovering

After the protocol parsing, we need to find the covert channel or data hiding in the traffic. Some attacker use steganography in the communication, it add the burden of the investigation.

#### (6) Potential pattern recognizing

Some artificial intelligence approaches can be used to forensics analysis. Two types of machine learning approaches can be built into network forensic systems: Artificial Neural Networks and Support Vector Machines. Since the ability to identify the important inputs and redundant inputs of a classifier leads directly to reduced size, faster training and possibly more accurate results, it is critical to be able to identify the important.

#### (7) Forensics data stream mining

We can also use some data mining approaches to network forensics analysis. Data mining generally refers to the process of extracting models from large stores of data. We choose several types of algorithms in our research: Classification, maps a data item into one of several predefined categories; Link analysis, determines relations between fields in the database. Finding out the correlations in forensics data will provide insight for discovering attack behavior quickly; Sequence analysis, models sequential patterns. These algorithms can help us understand the sequence of forensics events. These frequent event patterns are important elements of the behavior profile of a user or program.

#### (8) IP trace back to the attack origin

In the investigation we can use some methods to trace a steady stream of anonymous Internet packets back towards their source. These methods do not rely on knowledge or cooperation from intervening ISPs along the path. Sometimes tracing an attacking stream requires only a few minutes once the system is set up for a victim.

#### (9) Remote OS fingerprinting

Remote OS fingerprinting is always a technique on footprinting. It can obtain the general OS type of the target host. This is useful to estimate the experience level and the possible attack tools of the investigate

object. The result also can as a digital evidence for the future forensics.

#### (10) Remote network forensics

Remote network forensics is a program to capture the network traffic on the remote host. Always it is employed on the local area network forcedly or some key traffic center for capturing fully traffic that is used for the future forensics analysis.

## 5. CONCLUSION

Network forensics approaches for the e-business security can trace the behavior of the fraud in the e-business, discover the potential risk through the analysis the detail forensics data, quicken the speed of emergence response, enhance the ability of the rapid incident investigation, providing the evidence for the future legal action. The future work is the improvement of the dump performance of the network traffic in the network, development of more mining tools for the analysis of the forensics data.

## ACKNOWLEDGEMENT

Thanks go to Dr. Jin Hai for his insightful discussion of the project and paper. We also thank the security team of the Cluster and Grid Computing Lab in School of Computer, Huazhong University of Science and Technology.

## Regulating Copyrights in Cyberspace

Sylvia Mercado Kierkegaard

kierkegaard@privat.dk

### ABSTRACT

The explosive growth of the Internet has created critical new challenges to national and international intellectual property policies. Intellectual Property protection has become the most important issue in Cyberspace. When technological advances has outpaced the law, several problems arise which require an approach suitable to the digital age. Several international conventions have been enacted with principal objective of bringing world law into the digital world. The TRIPS Agreement and the WIPO Copyright Treaty were adapted, which require Member States to give protection to digital content providers against copyright infringements. However, as with the Berne Convention, TRIPS and WIPO do little to reduce substantial disharmonies in the substantive content of national copyright laws. The digital age has seen three controversial views on intellectual properties emerge. There are people who believe that intellectual property should be unprotected and unrestricted. On the opposing view, Intellectual Property Right (IPR) owners feel that the national governments need to pass and enforce laws to protect intellectual property. They claim that violation of intellectual property is inhibiting them from investing and making information more available in cyberspace. Others contend that traditional copyright law is able to deal effectively with digital copyright issues in cyberspace. At the same time, there is a need to maintain a balance between the rights of authors and the larger public interest. The core issue is how to protect copyrighted materials while at the same time serving the public's right for privacy, information access and dissemination.

**Keywords:** copyright, digital management, file-sharing, circumvention

### 1. INTRODUCTION

The advent of the Internet over the past 10 years has paralleled the emergence of globalization as a concept. It has become the principal means of global information. In a relatively short amount of time, the Internet has become a ubiquitous tool throughout the world. Net population is expected to hit 950 million by year 2005. Consumers are taking advantage of higher speed networks and new technologies to share and distribute information. The ease and speed in which contents are copied and distributed over the Internet have become a contentious issue with major companies, in particular the movie and recording industry, demanding stronger copyright regulation and enforcement. Concern over theft of intellectual property and the ensuing technological and financial losses have raised new clamours among legislators and Intellectual Property Rights (IPR) owners for a harmonized international intellectual property law to govern the Internet. IPR owners claim that violation of intellectual property is inhibiting them from investing and making information more available in cyberspace. Opponents of cyberspace regulation insist that there is little to fear on this issue as IPR owners could easily manage the problems through tighter technological safeguards and self-regulation. Traditional copyright law is able to deal effectively with digital copyright issues in cyberspace. Others contend that the current copyright law must be amended to adapt to the new technologies and to serve the public's right to information. At the heart of the opposing views is the issue of protecting ownership of copyrighted material, while at the same time facilitating greater ease of access and online content. This paper will examine the various issues and problems

surrounding copyright protection in Cyberspace and determine whether the current international conventions and enforcements are sufficiently applicable to the Internet regime.

### 2. COPYRIGHT

Copyrights are rights given to persons over what one has created. They usually give the creator an exclusive right over the use of his/her creation for a certain period of time. Copyrighted work can be a literary work, musical work, dramatic work, pantomime, choreographic work, pictorial work, graphic work, sculptural work, motion picture, audiovisual work, sound recording, architectural work, mask works fixed in semiconductor chip products, or a computer program. Also protected through copyright and related rights are the rights of performers, producers of phonograms (sound recordings) and broadcasting organizations. The main social purpose of protection of copyright and related rights is to encourage and reward creative work. The owner of a copyright has the right to exclude any other person from reproducing, preparing derivative works, distributing, performing, displaying, or using the work covered by copyright for a specific period of time. The rights of a copyright owner are subject to a number of qualifications such as fair use, compulsory licenses and substantiality.

### 3. INTERNATIONAL LEGAL FRAMEWORKS

Most countries are members of the Berne Convention for the Protection of Literary and Artistic Works (Berne Convention) which gives protection to works in countries of which one is not a citizen or national. It has

been signed by 156 countries since 1886. It is a multi-national agreement on copyrights which is administered by the WIPO, a specialized agency of the United Nations. In addition to proscribing discriminatory treatment of qualified foreign authors, Berne sets forth minimum standards of protection that must be accorded to those authors even if a country accords its own authors lesser protection. The provisions serve to protect the following author's rights: the right of reproduction including translations and adaptations, the right of dissemination to a non-material form including public performance, broadcasting (etc.), and the right to protect their moral interests. Under the Berne Convention, the following works may be protected: (i) both unpublished and published works of an author who is a national or resident of a country that is a member of these treaties; or (ii) published works, with permission, of an author who is not a national or resident of a country that is a member of these treaties (Art.5). In this case a work may be considered simultaneously published in several countries if it has been published in two or more Berne countries within 30 days of its first publication (Art.3). Copyright under the Berne Convention is automatic: no registration is required, nor is the inclusion of a copyright notice. The Berne Convention provided for a minimum term of copyright protection of the life of the author plus fifty years, but parties are free to provide longer terms of copyright protection. Indeed, the principal contribution of Berne to the international norms of copyright has been in persuading countries to agree on the principle of national treatment under which the works of foreign nationals receive the same level of protection as the country accords to its own nationals. Even though the Berne Convention has achieved some harmonization in national copyright laws by virtue of its establishment of minimum standards, it nonetheless defers to national traditions to a considerable degree. While national laws may be different in other countries, one is guaranteed at least certain protections. Unfortunately, the Berne Convention does not have the judicial nor police power to enforce the Convention. Neither does it have an effective means of calling signatory countries to account for non-compliance with Berne standards. It can, however, withhold copyright protection to authors from non-Berne countries and exert pressures on them to enact or amend their laws to conform to the same requirements as the Berne Convention.

The Universal Copyright Convention (UCC) provided an alternative mechanism by which states could enjoy international protection. It was adapted in 1952 under the auspices of UNESCO to cater to the US objections against the Berne Convention. The United States refused initially to become a party to the Berne Convention, since it would have required major changes in its copyright law (particularly with regard to moral rights and the registration of copyright works). Although it is not as exhaustive as Berne Convention, it requires formalities concerning deposits, registration and fee

payment. While the Berne Convention does not establish any formal requirements to benefit from the copyright protection other than having the author's name on the work, the UCC requires a copyright notice. It embodies the principle of national treatment, but not automatic protection. This notice should consist of the copyright symbol "©" accompanied by the year of first publication and the name of the copyright owner, all "placed in such a manner and location so as to give reasonable notice". Generally works are protected for a minimum of 25 years beyond the life of the author.

The World Intellectual Property Rights Organization (WIPO) has sought a leading role in the international copyright administration and harmonization. Since 1967, it has administered the Berne Convention. WIPO and the signatory nations to the Berne Convention have developed a new international treaty, known as the WIPO Copyright Treaty (1996), which extends the rights of authors in the digital era. 47 countries have signed the treaty. Explicit references to new technologies are found in Articles 4 and 5 which extend the copyright protection to computer programs and compilations of data. Article 7 creates rental rights in respect of computer programs. Articles 11 and 12 contain important provisions obligating member states to prevent circumvention of technological measures used to protect copyrighted works, and to prevent tampering with the integrity of copyright management information.

The Trade-Related Intellectual Property Rights (TRIPS) agreement appended to the General Agreement on Tariffs and Trade (GATT) went into effect on January 1, 1995 as part of the agreement that established the WTO. It was designed to remedy the perceived weaknesses in the Berne Convention and other multilateral intellectual property treaties. TRIP establishes minimum levels of protection that each government has to give to the intellectual property of fellow World Trade Organisation (WTO) members. The Agreement adds rights beyond those that it incorporates from Berne by requiring countries to make available effective remedies for copyright enforcement. By bringing copyright within the ambit of the WTO, it provides a mechanism for international enforcement through the imposition of trade sanctions against non-complying countries. The agreement covers five broad issues: how basic principles of the trading system and other international intellectual property agreements should be applied; how to give adequate protection to intellectual property rights; how countries should enforce those rights adequately in their own territories; and how to settle disputes on intellectual property between members of the WTO. Each of the main elements of protection is defined, namely the subject-matter to be protected, the rights to be conferred and permissible exceptions to those rights, and the minimum duration of protection. The Agreement sets these standards by requiring that the substantive obligations of the main conventions of the

WIPO, the Paris Convention for the Protection of Industrial Property and the Berne Convention must be complied with. All the main substantive provisions of these conventions, with the exception of the provisions of the Berne Convention on moral rights, are incorporated by reference and thus become obligations between TRIPS Member countries. Under Articles 10 and 11 of TRIPS, GATT countries are now bound to protect computer programs as literary works. It outlines how databases should be protected and expands international copyright rules to cover rental rights of authors of computer programs and producers of sound recordings. A similar exclusive right applies to films where commercial rental has led to widespread copying which is materially impairing the right of reproduction. It also requires performers to be given protection from unauthorized recording and broadcast of live performances (bootlegging). Producers of sound recordings must have the right to prevent the unauthorized reproduction of recordings for a period of 50 years. When there are trade disputes over intellectual property rights, the WTO's dispute settlement system is now available.

One hundred and forty seven (147) members of the WTO have accepted the terms of the Berne Convention as part of the trade-related aspects of intellectual property rights (TRIPS). Moreover, for the twenty five member states of the European Union, the rights are enshrined within Directive 29/2001/EC. However, as with the Berne Convention, TRIPS actually does very little to reduce substantial disharmonies in the substantive content of national copyright laws.

#### 4. COPYRIGHT ISSUES

Many legal issues arise in cyberspace, but no other single area of law presents such a variety of interesting and diverse legal problems. This is true in no small part due to the fact that people all over the world are increasingly becoming connected via the global telecommunications networks. As Internet usage grows, new legal questions associated with the technology continue to surface. Currently, all content available in cyberspace is protected under copyright law. The reality is that digital communications and the digitization of information of all types make the infringement of intellectual property rights, particularly copyrights, easier than ever before. Existing intellectual property doctrines may not provide the level of control that content-providers would like. Copyright law may not be able to protect authors' rights in cyberspace, in the same manner as it has in the physical world. The problem may not be the law, but the difficulty in enforcing copyright protection in cyberspace and the public perception that information on the Internet is public domain. Cyberspace is not as constrained by national boundaries as the physical world. The old legal system, developed during a time when borders were important,

is probably inadequate to deal with the borderless nature of the Internet and the rapid technological changes.

##### 4.1 Enforcement

According to the OECD's 2004 Information Technology Outlook, file-sharing networks are being used to freely download more movies, games and software than music. The number of people logged on simultaneously to popular file sharing networks approached close to 10 million in April 2004. The Motion Picture Association claims that it is losing hundreds of millions of dollars to Internet piracy. The origin of movies circulating on the Internet varies. Some are advance copies of blockbusters, apparently stolen from studios or otherwise leaked to the public before they are shown in theatres. The copies are converted into digital files and put on the Internet, or resold in the form of illegal DVDs and videocassettes. In other instances, people armed with digital video cameras make their way into an early screening of a movie, record the movie and turn it into a digital file. Once a movie has been released on the Internet, it spreads via peer-to-peer file-sharing services.

New studies show that contrary to protests from record labels, piracy is not responsible for the 15 percent drop in music sales in the past two years. According to Forrester Research, Inc., a research firm providing data and analysis that defines the impact of technology change on business, there is no evidence of decreased CD buying among frequent digital consumers. Times are tough on the music business, not because of downloading, but due to other factors such as economic recession, competition from videogames and DVD sales and the levies that are arbitrarily applied to music-playing equipment like MP3 players at wildly varying levels in different countries. It could also be that the introduction of CD anti-piracy methods has alienated the consumers. There is evidence that some of the protected CDs do not play correctly even on normal CD players and consumers complain that even when a CD is purchased, it cannot be played in the format of choice or the medium of choice.

Although the European Union (EU) has strict harmonised laws against piracy, the enforcement varies among Member States. In the first quarter of 2004, the Motion Picture Association sent out more than 350,000 cease and desist letters of which illegal downloads accounted for 90%. Seventy-seven % (271,000) of these letters were sent to Internet Service Providers (ISP) in the European region. The MPA uses tools to monitor and take evidence to sweep the Web for evidence that movies are illegally online and then asks Internet service providers to block access to illegal content. Many of the ISP providers in Europe have remained uncooperative and insist that anti-piracy groups present a valid search warrant before they can be allowed to access the user's file in order not to intrude on the

privacy of their customers and violate their trust.

The degree of enforcement of rules also varies from country to country, with Northern European countries more vigilant than their Eastern and Southern European counterparts. In the EU, the problem is not the lack of regulation, but the absence of uniform enforcement. Movies illegally downloaded from the Internet are hawked openly in the streets of downtown Madrid and restaurants, while such a brazen display of pirate copies will not be possible in Germany.

US authorities prosecute both downloading and uploading of files, but in Europe, the crackdown affects only uploaders. In April of 2003, three American college students became the first computer users who were forced to pay fines ranging from \$ 12,000 to \$15,000 by the Recording Industry Association of America (RIAA) for swapping unauthorized music online. They were sued by the RIAA for creating search engines on campus networks that made it easier to locate and share files that reside on others' computers, including term papers, research papers, photographs and MP3 music files. They settled their suits by agreeing to pay thousands of dollars over time. The targets were discovered by using exotic computer hardware called Spybots to scan publicly available peer-to-peer (P2P) networks and identify the ISP (Internet Service Provider) of each user. Under the Digital Millennium Copyright Act (DMCA), the RIAA can subpoena ISPs for each user's name, address and other personal information. This procedure requires only a court clerk's signature and need not come before a judge to be effective and the information can be used in collecting and identifying information of subscribers on the basis of mere suspicion. However, a recent decision by the U.S. Court of Appeals for the District of Columbia overturned a trial judge's decision to enforce copyright subpoenas, one of the most effective tools used by the recording industry. The court said the 1998 copyright law doesn't cover popular file-sharing networks used by tens of millions of Americans to download songs. Thus, the recording industry can't force Internet providers to identify music downloaders,

RIAA also went to court to shut down Napster, a peer-to-peer (P2P) file sharing service. Immediately, less centralized systems like KaZaA quickly replaced Napster. The industry has not so far persuaded the courts that these digital copying and sharing technologies are themselves "contributory" infringers of copyright. A US court has refused to order the shutdown of peer-to-peer file sharing services operated by Grokster and Streamcast Networks. Judge Stephen Wilson of U.S. District Court in Los Angeles in *MGM Studios, Inc. v Grokster Ltd* ( Case Nr. CV 01- 8541) has effectively ruled that those who have no direct control of the use of their services - over the files swapped - cannot be held responsible for any misuse of those services. Without evidence of their active and

substantial contribution to the infringement, the file-trading services cannot be held liable.

If enforcement is left to the national states, IPR owners fear that piracy will continue unabated because of the laxity of authorities and corruption that has not been eradicated in some places. Infringement is possible from any corner of the globe. Countries that have not signed to the Berne convention are often referred to as copyright jungles, as there are often rampant copyright violations in those countries. The absence of any international convention on jurisdiction regarding the Internet makes it difficult to enforce copyright authority, even if the infringer has already been identified. The *Convention on Cybercrime* is the first international treaty which addresses this problem by requiring member countries to adopt similar criminal laws on hacking, copyright infringement, and computer related fraud. It also contains provisions on investigative powers and procedures, such as the search of computer networks and interception of communications. It also requires cross-border law enforcement cooperation in searches and seizures and extradition.

IPR owners also oppose self-regulatory schemes. There is no real protection because self-regulatory schemes cannot produce enforceable decisions. It can only work if it can rely on a government apparatus for enforcement. Even if the legislative rights of authors are expanded, the availability of technology that enables rapid and cheap copying of content in the digital world, as well as the global and borderless character of the Internet will render enforcement difficult outside the national boundaries of the country. Although copyright law attempts to dissuade future copyright violations, rampant piracy continues to plague the Internet and piracy of computer software has risen to an alarming level even in countries with strict intellectual property rights laws. It is apparent that the present laws are not producing their intended deterrent effects.

## 4.2 New Technology

Time barrier is becoming less of an issue as more people gain access to high-speed Internet connections. The software and video industry thought that slow download speeds would be a safe haven from non-commercial file-sharing, but that time is gone. Now, consumers with broadband can download a feature-length film in about six hours. The movie industry fears that advances in technology will significantly reduce that time. Current technology (most P2P file-sharing software) allows constant connections with other computers on the network as long as the software is running. Although file-sharing software is frequently associated commonly with illegal downloading of music and movies, it is a powerful technology that allows efficient distribution of legitimate files and data of all types. Record companies and movie studios may not willingly cede control to

users who have legitimately purchased their products. It will be difficult for them to lock down digital video so tightly. Someone will eventually find a way around it. The Internet abounds with freely available software that lets consumers circumvent copy-protection systems used on commercial DVDs.

### 4.3 Free Speech and Human Rights Principle

Copyright can also interfere with free flow of ideas, information and commerce. The Internet serves as a worldwide public commune, exposing the people of the world to a dizzying variety of ideas, expressions, cultures and creations in a manner so free and easy that it sparks an immense amount of additional creativity and innovation. The Internet's shelves will be empty unless individuals and institutions possessing relevant information place it in the Internet. To gurus of copyright free cyberspace, information should be free—that is, the public should have the right to share, enjoy, criticize, and build on the works of others in order to promote progress. One extreme view states that there are no property rights in cyberspace, and therefore, there is no need to obtain authorization to reproduce a copyrighted work. It is argued that by posting materials on the Internet, copyright owners are granting implied licenses to users.

Large corporate interests seek to narrow the freedom of the Internet for their own economic advantage. Many countries have adopted the Digital Rights Management, which control the accessing and use of creative materials in ways that are often inconsistent with a free and democratic copyright system. These systems are developed on the assumptions that IPR owners can exercise complete control over works in which they hold copyright. Therefore by attempting to wall off portions of cyberspace they are destroying the Internet's potential to foster democracy and economic growth worldwide. In print publication, no license is required to purchase a book, but in the digital world, organizations are imposing copyright license. This requirement prevents access to information and infringes on the individual's right to privacy as identification requirements are demanded on the users.

Mistaking the free distribution of content with the placement of intellectual property in the public domain is common among web users. If there is no copyright notice posted on the website, it is assumed that anyone can feel free to use it. But this argument can be fallacious if the same principle governing copyright of books is applied on the Internet. An exemption would be "fair use" for scientific and educational purposes. Use of copyrighted works or portions thereof, for any other purpose is not deemed fair use. Property holders can distribute their works freely while retaining their right of control over that work.

### 4.4 Unfair Protection of a few interest groups

Increased copyright protection and enforcement in their countries, as mandated by TRIPS and the Berne Convention, has mainly benefited the industrialized countries, in particular the United States. Multi-national enterprises from industrialized countries are the main producers of copyright-protected works, and the developing countries (third world) are primarily copyright users. The Berne Convention has been sharply criticized for hindering the development of developing countries by making it too restrictive for the latter to access the materials. Many claim that the Berne Convention is an artefact of the 18<sup>th</sup> century intended for another type of works and not for the Internet technology. Critics contend that Berne protects the interest of the industrialised countries by ensuring that the creators will be able to recoup their cost and prevent copyist from the developing countries from offering identical products at very low prices. This will enable the creators to charge prices for access to those works substantially greater than they could in a competitive market. They contend that this is economically inefficient, wasteful of social resources and deter progress. In order to make the Convention relevant to the needs of the developing countries, pundits are advocating the creation of exemptions to copyright restrictions, improved affordable access and assistance to the developing countries.

In the United States, the "Sonny Bono Copyright Term Extension Act" extended the term of copyright protection to nearly a century for corporations and even longer for many individuals and their heirs. A number of products – books, films and music have been given unreasonably longer copyright protection and prevents them from being made available in the Internet. The 1998 law that extended copyright protection to 95 years for most existing copyrights and 70 years after the death of the author for most new ones. The Act has been criticized for protecting private groups and condoning their rent-seeking behavior by granting them a monopoly in order to solidify their dominant position in a marketplace and exempting them from the free market pressures. A constitutional challenge to the Sonny Bono law was rejected by the Supreme Court in 2003 (*Eldred v. Ashcroft* No. 01-618, No. 01-618). The Court's decision implies that Congress can freeze the public domain indefinitely. Defenders of public interest have organized to lobby for changes in the copyright system which would allow classical and valuable works to be made available for the public interest.

The law has been formulated and drafted by legal experts who are heavily influenced by IPR owners. These industry groups are well organized and have strong lobby powers with legislators and bureaucrats, and very often the latter relies on their views for decision-making. The current legal and political regime is inclined to extending more rigid protection to IPR

owners and not the user's rights. Copyright protection of the Internet cannot favour one group over another. Unfortunately, the consuming public has not been consulted, mainly because they are disorganized and consist of individual users. Any framework convention needs to be based on agreements involving different constituencies. There is a need to revise the law to accommodate individual user's rights and to draw a line between legitimate copying and not – what should be allowed on the web and what is illegal. A decade ago, lawsuits and clarifications of copyright law resulted in "fair use doctrine, which permitted the limited reproduction of copyrighted material by journalists and scholars.

#### 4.5 Difficulties in Legal Interpretation

Courts take a variety of approach in interpreting copyright law. In the light of furious litigation in the United States, the latter is seen as taking a stricter interpretation of the copyright law than its European counterparts. The Swedish MP3 case exemplifies the problems of applying the old intellectual property legislation to the digital media. The plaintiffs were a number of international record companies who claimed that the defendant, Mr. Olsson, made illegal copies of the CD's and then via hyperlinks from his own homepage made these copies available to the public. The court found that the hyperlinks on the defendant's homepage could not be regarded as a public display or performance. Neither was the hyperlink considered as "distribution of a work" based on the fact that Mr. Olsson did not produce the copies made available via his homepage because it was the Internet-users who downloaded the music file from the hyperlink. Although the putting up of a hyperlink is considered a public performance, the defendant was found not guilty because the Swedish Copyright Act exempts public performance of sound recordings from copyright.

The courts have not always been equal to the task of resolving copyright conflicts protection. In the US, there have already been many lawsuits involving the Digital Millennium Copyright Act (DMCA). In one early case, the federal government criminally prosecuted a company that created a device to decrypt electronic books. A jury eventually acquitted the company. But in another case, online journalists who distributed "DeCSS," a program for decrypting DVDs, were found to have violated the DMCA even though the program could be used in ways that would not infringe copyright.

There is a need for clarification and enforcement of copyright law. Court decisions have failed to settle various issues associated with copyright (such as hyper linking, circumvention, framing, and liability of access providers and users) and the question of how much sharing should be allowed or whether all of it should be stringently prosecuted as a violation of copyright law.

### 5. NEED FOR BALANCE

The Digital Millennium Copyright Act (DMCA), which was signed into law in 1998, created significant new rights for copyright owners. Whereas copyright law previously centered on the exclusive rights of copyright owners to perform certain acts with their works, this new legislation for the first time created a right to exclude access to copyrighted works. The DMCA prohibited the distribution of technology that circumvents the industry's electronic locks on books, films, articles, software, or songs, even though circumvention itself could contribute to research and technological innovation. The DMCA protects owners of copyrights, without regard to whether those owners were the creators of the protected work. It regulates technology that controls access to and use of works, rather than regulating the use itself. Its so-called "anti-circumvention" and "rights management" provisions facilitate copyright owners in preventing others from viewing their works and from performing acts that would previously have been allowed under the "fair use" exception to the copyright laws.

Copyright protection technology faces a legal challenge in France where a consumer association is filing damages in a legal action which contends that the copyright protection used by EMI label to prevent CDs from being pirated, stops consumers from making personal copies of their CDs - a privilege granted to French consumers by a 1985 law- and makes it impossible to play them on many car stereos, home stereos and personal computers

In the United States, a maker of software that enabled users to copy DVD's and computer games folded under the mounting weight of lawsuits filed by movie studies and video games producers. Unfavourable court rulings by three federal courts in 2004 assured the demise of 321 Studios. A federal judge in New York imposed a worldwide ban on the production and distribution of 321's Games X Copy software, which let users make what 321's Web site had called "a perfect backup copy of virtually any PC game." Hollywood and the computer-gaming companies accused 321 of violating the 1998 DMCA. The company's software was meant to let consumers make backup copies of their DVDs and computer games. Consumer advocates warn that the court decision restricts the rights of the consumers to make copies of their own legally obtained digital materials.

In contrast, a Norwegian Appeals Court (Case Nr. 02-507 M/94) upheld an earlier verdict that Jon Johansen, a 20-year old Norwegian man, had not broken the law by creating a system that could get around copy protection on DVDs. The ruling is a setback to anti-piracy efforts by the Hollywood studios. Mr Johansen, known as "*DVD Jon*" by the net community, created his program to watch films on a Linux-based

computer. He then posted the program onto the net in 1999. His software, called DeCSS, could decrypt disks by stripping the Content Scrambling System from DVDs. The US movie industry had accused DVD Jon of theft. But an Oslo court said in January 2003 that he was free to do what he wanted with DVDs he bought legally.

Song-swapping is not the only copyright infringement that the music industry is fighting. EMI music issued a cease-and-desist letter in February 2004 to a small-time record producer demanding that he halt distribution of a clever musical mix he had made. Producer Brian Burton's "*The Grey Album*" electronically combined sounds from the Beatles' recording commonly known as "*The White Album*" with rapper Jay-Z's "*The Black Album*", without seeking permission from the artists or their labels. More than 100 Web sites rallied to his defense by offering "*The Grey Album*" for unauthorized, free downloading as part of an ad-hoc protest.

## 6. CONCLUSION

Although the copyright law's penalty system attempts to dissuade future copyright violations, rampant piracy continues to plague the industries. It is apparent that the present statutory remedies are not producing their intended deterrent effects. Self-regulation and innovative new technology could be the answer.

The adaptation of IPR regimes to the digital economy is needed to protect rights embedded in the new technology developments. However, the new legal rules must take cognizance of the need to balance public interest, privacy, economics and copyright protection. Any international convention would have to define how the Internet is to be governed with consideration to the technological elements and the machineries for monitoring and enforcement compliance.

Since cyberspace is constantly and rapidly in transition, copyright law may not be able to catch-up with the speed of new technology. This suggests that copyright law may not be able to protect the author's rights in the digital world in the same manner as it has in the physical world. Because many countries prefer to preserve their own copyright tradition, it would be difficult to harmonize international law. IPR owners should find new technological remedies to assist the law. Any insufficiency in the law or in enforcement of authors' rights in cyberspace may be more than made up for by emerging technological means of protecting digital works. Adoption of technological means to protect works against unauthorized use or to track down infringements may, in fact, mean that authors' rights will become better protected in cyberspace than they have ever been in the physical world. Just as people use technology to infringe copyrights, people can use technology to stop it rather than relying on the threat of litigation. The marketplace already offers a variety of technology-based solutions to meet a variety of

copyright protections. Among the relevant emergent technologies are digital envelopes, encrypted signal streams, software metering schemes, digital watermarks, and copyright management information attached to digital copies of works.

There are legal file sharing websites which gives access to a vast catalogue for a monthly membership fee. Apple Computer's approach is to use the carrot instead of the stick. While recording labels' approach is to sue, Apple has set up the successful *iTunes* music store and has attracted people to that model of paying music legally. In the year since the introduction of iTunes in the United States, Apple has tweaked its system for managing music rights slightly - for example, by reducing the number of times a list of songs can be burned onto a CD, and increasing the number of computers that can play a copy of a purchased song.

The industry is being far too heavy handed by fining people hundreds of US dollars. The damages they seek are disproportionate to the cost of purchase of one song. One of the reasons people download music files is because of the high prices of CDs. Rather than fighting a losing battle, the IPR owners should be looking at ways of updating its failing business model. Record companies must be prepared to embrace the new technology, find out how people are using it, and work out how to profit from it. Instead of lobbying to preclude the use of MP3 files, they must ask themselves why customers are choosing to download files instead of legitimately purchasing the CDs. It is possible that people no longer want CDs or tapes, not only because of the cost implication. Compression breakthroughs have made it easy to quickly download and distribute music files. This distribution can allow consumers to discover and follow new bands and to meet other fans with shared interests. An MP3 can hold up to 10 archived albums and can be played in most modern car or stand alone stereos. It allows users to compile their own music play list, unlike purchasing legitimate CDs which often contain only few albums with significant appeal. It seems that record companies are having serious trouble when it comes to picking winning albums.

The economics of the Internet dictate that business must find a way to generate revenues without charging users for intellectual property. Any new regulation must be suitable and flexible to deal with the challenges posed by Internet technology and must balance the interest of the different stakeholders.

### ABSTRACT

Telecommuting (or Telework) is now relaxing more and more workers from traditional 9-to-5 routines in many countries. In this paper, we do some research on China's actuality, and try to give out some reasonable suggestions to support Telecommuting, on the basis of learning from the developed countries.

**Keywords:** Telecommuting /Telework, advantages, government, policy

### 1. INTRODUCTION

Telecommuting (or Telework) is a work practice that entails working at least some of the time, often conceptualized as remote working supported by information and communication technologies (e.g. Gray et al. 1993).

Early definitions characterized telework as working away from a traditional office (Grant, 1985; Kelly, 1985) or at home (Regeneye, 1985). Later definitions were broadened to include the use of information and communications technologies (ICTs) (Holti and Stern, 1986; Oslen, 1988).

The emergency of the telework has various reasons. For example, Knowledge workers are separated from line-workers and needn't always stay in their offices. At the same time the rapid development of communication technologies also made it possible for the companies to implement telework, such as e-mail, faxes and messenger.

Globalization and the establishment of multinational organizations have increased the distance between physical flows (concerning production, distribution and consumption of products) and information management and are enlarging the distance between business branches, also between producers and buyers. Employees, who are not on the same worksite, perhaps in the different countries, cannot contact each other face to face everyday. All these call for a kind of more flexible and convenient work style--- Telework.

Also, telecommuting was driven by concerns about traffic congestion and pollution in densely polluted areas such as southern California and telecommuting was treated as a means to reduce the expense of maintaining office space. More recently, organizations have begun to view telecommuting as a tool to attract and retain top personnel in fields with short labor supplies.

In the 1980s, the first telecenters were established in Europe. Ten years later the emergence of the digital

economy vastly expanded the potential for performing jobs in telework arrangements. In the 1990s the U.S. federal government also instituted a government-wide telework pilot project, and many states and local governments, as well as private-sector corporations, instituted telework programs and published results from their experiences. Today, with the proliferation of technology in the workplace, telework is one of the fastest-growing policies promoted by savvy employers. The 2000 Telework America Research Survey estimates that the number of teleworkers in the U.S. has increased by 2.8 million since 1999, bringing the current total to 23.6 million. Gartner Group predicts that more than 137 million workers worldwide will be involved in some form of remote work by 2003.

In the Office of Personnel Management's (OPM) 2003 report to Congress on the status of telework in the federal government, the Director of OPM described telework as an "invaluable management tool which not only allows employees greater flexibility to balance their personal and professional duties, but also allows both management and employees to cope with the uncertainties of potential disruptions in the workplace, including terrorist threats."

In this paper, our main interest is to give some suggestion for government and local authorities to support telecommuting based on china actuality.

### 2. DIFFERENT TYPES OF TELECOMMUTING AND THEIR ADVANTAGES AND DISADVANTAGES

#### 2.1 Different types of Telecommuting

A meaningful classification of telecommuting for the purposes of the present article is based on the geographical location of the workplace.

Satellite work centers;  
Neighborhood centers;  
Work at home; and  
Mobile work.

Satellite work centers are self-contained organizational

unites belonging to companies; it's in some sense a branch. The relocation of such unites is made possible by the separation of functions in modern organizations and by the possibility of integrating shared facilities, such as databases, through information technologies. The advantage of such relocation exists in the possibility to reduce office costs in the headquarters, usually located in central areas of the cities, and in the reduction of commuting for employees, and also for the customers. It's equipped with office furniture and equipment provided by the firm, and administrative help may be available.

Neighborhood centers, different from satellite offices, are remote offices for employees from several organizations, which share space and equipment. The location of such offices is not driven by the need to realize economies of scale. Therefore employees can choose to work in the neighborhood centers that are closest to their homes. The employees are sufficiently independent in their work and the employers can relay on remote control and communicate with them. A network of neighborhood centers is also a good support for the communication between itinerant employees and their headquarters. Office suits may be furnished by the site owner or by each renting firms.

The establishment of neighborhood centers may be critical for the development of some suburban areas, especially those that are suffering problems of unemployment. In these areas a neighborhood center may support the diffusion of computer knowledge and promote new activities and latent potential.

Work at home refers to employees who work at home on a regular basis, though not necessarily every day. It is the most common interpretation of telecommuting. Teleworkers need communication medias such as telephone, electronic mail, personal computer links to office servers through ISDN lines, and fax machines.

Home Telework does not provide the social interaction that a satellite or neighborhood working center would theoretically provide, but could provide employees with extreme flexibility in schedule and lifestyle. It would allow employees to decide autonomously when and where they want to work and how they wish to accommodate childcare and other family duties. Work at home also offers new job opportunities to the elderly and the handicapped.

In contrast to the three above, mobile workers are frequently on the road, using communication technologies to work at home, in a car, in a plane, or at a hotel—communicating with the office as necessary from each location. It gives employees the chance to accommodate their personal/family life as well as work responsibilities. Therefore, mobile workers should have a good access to information networks anywhere.

## 2.2 Advantage and disadvantage of telecommuting

These alternative work forms bring both advantages and disadvantages to organizations, individuals, and society. We will discuss them on the assumption that the teleworkers is away from the office a significant percentage of working time. The impact may diminish if telework is just a small fraction of normal working time. First let's talk about the advantages.

From the organization's perspective, telecommuting provides an opportunity to improve workplace productivity. Also, it enables them to cut cost related to office space, as well as to address space constraint. Besides, it widens the talent pool available, improve recruitment and retention of employees by providing workers with flexibility that allows them to keep their jobs in the face of external demands or desires. Finally, the organizational advantages cover a wide spectrum, including behavioral outcomes, productivity, and legal issues.

From the employees' viewpoint, they will have greater job satisfaction and higher work performance ratings. First, it greatly reduces the time and money spent on commuting, eliminates the necessity to relocate. Second, it provides employees with a relatively distraction-free environment, greater schedule flexibility and autonomy. Third, they and their families can benefit more from the new work/family balance.

To the entire society (table1), telecommuting can decrease traffic congestion on strained highways and reduce automobile-related air pollution-although its impact may be negligible if only a few people telework. Further, teleworkers discourage community crime and spend more time building community ties.

On the other hand, several shortages may hamper the willingness to integrate telecommuting into traditional office environment.

To the organization, there are problems from two points. For managers, the main problem is their inability to physically observe their subordinates' performance. Secondly, the difficulty to create team synergy, because telecommuting will negatively affect the social network by disrupting teamwork and so on. The other issue concern developing and transmitting organizational culture, a virtual culture is needed and clear telecommuting policy guidelines should be established.

To the employees, probably the most commonly expressed challenge of telecommuting is overcoming the isolation caused by the separation of the telecommuter from the social network in the traditional workspace. Besides, teleworkers should overcome the challenges of maintaining access to resources at work, and they need to be more technically savvy than their

office peers, since support services are not accessible on-site.

To the society (table 1), telecommuting does pose some challenges. Telework may cause a gradual degradation of a person's ability to interact with others in a personal,

intimate and human manner. This may at last change the nature of social intercourse. The main issue is to establish telework culture, zoning regulations that forbid business parcel delivery within residential neighborhoods.

Table1: Societal Advantages and Challenges of Telecommuting

	Advantages	Challenges
Home-Based Telecommuting	<ul style="list-style-type: none"> <li>●Less traffic congestion</li> <li>●Less pollution</li> <li>●Less neighborhood crime</li> <li>●Greater community involvement</li> </ul>	<ul style="list-style-type: none"> <li>●Telework culture</li> <li>●Loss of ability to interact with others</li> </ul>
Satellite Office	<ul style="list-style-type: none"> <li>●Less traffic congestion</li> <li>●Less pollution</li> <li>●Greater community involvement</li> </ul>	
Neighborhood Work Center	<ul style="list-style-type: none"> <li>●Less traffic congestion</li> <li>●Less pollution</li> <li>●Greater community involvement</li> </ul>	
Mobile Work		<ul style="list-style-type: none"> <li>●Telework culture</li> </ul>

Source: Nancy B. Kurland, Diane E. Bailey[15]

Table 2: Policies used in some developed countries and their Effects

Countries/ areas	Relative policies	Number of teleworkers	Effects
America Washington	The federal government and some of the largest businesses there are urging more of their employees to stay home.	About 15% of the region's 2.6 million employees work from home, up from 250,000 five years ago. They telework at least 1 day/month in 2003, with most averaging 1.5 days/ week according to the Metropolitan Washington Council of Governments.	If the effort's goal is met, 17,000 daily vehicle trips and 550,000 vehicle miles could be eliminated by June 30, 2005.
America	The American Disabilities Act (ADA); The Clean Air Act of 1990; The Family Leave Act of 1993.	Approximately 23.5 million teleworkers in the United States compared to 11.6 million in 1997.	The average business can save \$5,000 by reducing its workspace. (Said by Bob Smith, executive director of the International Telework Association and Council)
Toronto, Canada	A Toronto telework plan offering corporations free telework consulting and training help.		
Austin, Texas	Use a Web-based service to allow employees to telework at home, in order to improve poor air quality on July 2002.	Approximately 400 employees telework about one day a week through the program. The city has set a goal of 600 employees work from home one day/week by the end of the summer2003. Within two years, Austin officials want to see the total rise to 1,000.	Austin officials hope that telecommuting will help reduce the total vehicle miles traveled by its employees by 15 percent over the next five years
Malaysia	Amend the Employment Act 1955 to include new flexible employment regulations.	Prime Minister Datuk Seri Dr Mahathir Mohamad said the group's involvement in the workforce in 1995 was 43.5 per cent and 45.7 per cent in 2003.	Enable women's participation in the labor force and enable them to juggle between work and family responsibility.

### 3. TELECOMMUTING AND POLICIES SUPPORTING TELECOMMUTING IN SOME DEVELOPED COUNTRIES

Mainly the sales and financial management industry led the way for telecommuting, however, over the past few years much other business in U.S. have begun to implement telecommuting arrangements in several large cities. In Denver, Colorado, Bethesda, Maryland and Charlottesville, Virginia, IBM has furnished employees with furniture and equipment to work at home when they

are not in the field with customers. Recently, Ernst and young initiated in their Chicago accounting and consulting operation in 1992 "hoteling". According to the UC-Davis study, in the first year Ernst & Young reduce space requirements by 7 percent, and the company expects to eventually shrink its office space requirements nationwide by two million square feet for saving of \$40 million a year.

Since the implementation of telecommuting can also bring benefit to the whole society, so it is necessary for

the government and local authorities to do something useful to support telecommuting.

In general, there are four primary forces that will benefit the public interest in promoting telecommuting: the environment, the transportation demand, economics, and quality of life. Some developed countries have made some policies to support telecommuting. (Examples: Table 2)

National governments in the European Union advocate telecommuting both as a means to reduce traffic congestion and increase women's labor force participation. Throughout the European Union, an average of 60% of employees shows an interest in it. The interest among those looking for work is even stronger. Employers giving their employees the opportunity to telecommute may be regarded as attractive.

In Singapore a study of 285 employees of an IT company confirmed that employees would be less likely to end the employment relationship if the company offered telecommuting as an option. Experimental research with students reaffirmed the claim that the concept of telecommuting will attract well-qualified individuals to join the organization.

In U.S., Equal Employment Opportunity Commission (EEOC) encourages work at home (telework) as a reasonable accommodation. If the disabled employee is able to perform the essential functions of the job at home, then telecommuting may be a required accommodation---unless the employer can find a way to accommodate the employee's disability otherwise or prove that telecommuting would cause undue hardship on the company.

### 3. SOME SUGGESTIONS BASED ON CHINA ACTUALITY

Based on the analysis of china actuality, there are some reasons for implementation of telecommuting and corresponding suggestions.

#### 3.1 Attract elitist

China is a developing country and is developing very quickly. Especially during recent decades, the development of global information technology and the globalization accelerate china's speed to infiltrate the whole world. From the whole world, telecommuting makes it possible for the Chinese companies to attract more elites both at home and abroad, especially the ones oversea. The basic policy of government for supporting telecommuting is constructing, improving and perfecting the information speedway.

West development strategy is very important to the Chinese economic growth. In those regions, one of the big problems of economic development is lacking of

human resources, elites. Human resource is crucial to a country's economic growth. In contrast to cities in west and west middle regions, the developed cities in east regions following the line of the sea are full of all kinds of specialists. Although, there are a lot of persons of noble aspirations and young people full of passion have eagerly responded to the national call and devoted to the West and Middle West regions. Relative to the rich human resource in east regions, the number of persons who have devoted themselves to the development of West and Middle West is still very small. The reasons are various, but one is that because of less developed, the living standard in those regions is inferior to the East regions, especially the big cities of East regions following the line of the sea such as Shanghai, Shenzhen and so on, more people will choose to work or settle in developed regions in stead of West and Middle West regions, especially those whose hometown is far away the West and Middle West. How to attract those people work for the companies that site in the West and Middle West regions? The implementation of telecommuting comes up with the solution. For example, the company can provide the employees opportunities to work at their own places; these places may be the employees' home, the office in another city, or a telecenter.

In order to support telecommuting for such kind of reason, the government and local authorities can provide tax exemption or preferential duty. The beneficial tariff can be various. They can provide the beneficial tariff according to the ratio of the number of telecommuter versus the number of whole employees, also can according to the ratio of time which spent in work by telecommuting versus the whole time spent by the whole employees in the whole company work. The government and local authorities can also provide the telecommuters some kind of subsidy, which not only can encourage more people to work for those companies but also can lighten the financial burden of those companies.

#### 3.2 Consideration for Female employees and disabilities

In China, more and more women accept high education and the percentage of female employees is very high.

Different from male, female have the responsibility to procreate and most women want to be a mother. Because of inconvenience of pregnancy and traffic jam, many pregnant women give up their job. Furthermore, many new mothers after giving birth to a baby still can not go back to work; sometimes they have to look for another new work, sometimes they have to take care of their new-birth baby. As far as the companies which the pregnant women have worked for concerned, on one hand they want to retain those experienced employees, on the other hand they can not accept their a long-time-leave, because sometime the off-work time will reach one year. Now, the Information Technologies (IT) and Information System (IS) provide opportunities

for organizations/companies to provide telecommuting to their employees who need such kind of work arrangement. So the telecommuting cannot only benefit for the company but also the pregnant employees and new mother employees. The move which would see changes in women's workload, employment schedule and the facilitation of "telework" at workplaces is to enable women's participation in the labor force and enable them to juggle between work and family responsibilities.

In view of situations above, the government can take some measures to encourage or to say, to some degree, oblige some companies to implement telecommuting. For example, when a female employee has been pregnant, and by carefully redesigning, her work can be done at home, if the employee applies for working at home, the employer cannot refuse. Once the employer fires the employee for this reason, the employer should be punished. This is a measure to protect women's right.

The Chinese government always pays attention to the disabilities' right and employment. The government encourages welfare organizations to centralized arrange disabilities' employment by tax exemption or preferential duty. At the same time, the government has set a certain hired disabilities ratio and required all the companies should employ a certain number disabilities according to the ratio. It is believed that by implementing telecommuting, more and more disabilities can find a job, especially for those who have difficulties in traveling.

With the increase of population in cities, communications has been becoming more and more crowded. Quite a number of employees have to spend two or more hours going to the office building from their home and back, not to mention when meeting the traffic jam. So, working parents may highly value the time-savings of telecommuting due to the elimination of commuting time, or because telecommuting may allow a parent to stay at home with a sick child.

As far as many medium-sized and small enterprises are concerned, on one hand a lot of tasks are suited to telecommuting, on the other hand, at the present, they have not the ability to spend a great deal of money to equip their offices and their employees' home offices. Furthermore, the most important is that they worry about the data security. Under such kind of condition, the government itself can build several telecenters or organize several big companies to set several telecenters. And any companies that need telecommuting arrangement can rent some offices in these telecenters. Many people may have noticed that managers are more likely to accept a new program or innovation that has been widely and successfully used by other managers. So I think, in order to encourage all kinds of organizations to implementing telecommuting, the government department should be the first to set telecommuting arrangement and become an example in successful implementing telecommuting. For example, the

government can set a plan includes a goal to increase the percentage of government employees that telecommute to 6 percent by the end of some year say 2005. Another benefit of this measure is that once the telecommuting is successfully implemented in the government departments, which can provide experience and example the official who make the support policy and let him or her make more wise decision and more practical policy.

In spite of measures mentioned above, the government can also provide free training or financial support for the companies that are planning to implement telecommuting. For example, the government and local authorities may make budgetary allocations for installation of telephone lines, computers and related equipment and monthly funding the telecenters.

Certainly, the government and local authorities can provide various specific support policies (such as preferential telephone rate) for telecommuting implementation according to different conditions. Whether telecommuting in one company is suitable is akin to the employer, the employee and the task. For example, telecommuting is not suitable for employees who require intensive face-to-face interaction with coworkers and customers, or who require physical resources to handle their work.

In China, the environment to carry out telecommuting has not yet been well established. Although telecommuting is expected by the experts, for instance as a solution for the traffic congestion in the urban area, the concept of telecommuting has not spread over the peoples. So, from now on, not only the establishment of the telecommuting environment but also activities for recognition and enlightenment of telecommuting will be needed.

Several environmental factors are in place in China that would lead to successful implementation of telework programs. These include a proliferating telecommunications industry, more direct foreign investment and lifted trade restrictions that have created more jobs.

Although data regarding telework in China are very scarce, someone has made some predictions of the growth of telework, based on decades of experience in the US. The current forecast is shown in figure 1.

Figure 1: Estimated development of telework in China

Source: [http://www.ecatt.com/country/china/inhalt\\_cn.htm](http://www.ecatt.com/country/china/inhalt_cn.htm)

## 6. CONCLUSION

Implementing telework programs in China's public and private sectors could result in increased productivity with a declining workforce. Home-based telework programs could be the first solution for childcare and eldercare anxieties, and mobile telework can also play an important role.

In order to successfully implement telecommuting, the government must play an active role to help and encourage the companies to establish such kind of new work form.

Firstly, the government should help employer identify the jobs best suited to distance work. Some work lends itself naturally to off-site arrangements, such as sales, customer service, and auditing.

Secondly, the government should help employer approach telecommuting carefully by screening workers to determine eligibility and providing training in commonsense ways to avoid the potential risk of technological and financial failure of telecommuting program, decide which kinds of employees are suited to telecommuting, which kinds of employees are motivated, trustworthy and able to work independently.

Thirdly, the government should help employer develop guidelines, including approved reasons for telecommuting, using a personal vehicle for company business, and so on.

Finally, the government should help employer provide his or her employees an appropriate telework office with higher-speed broadband, cost-effective video that in a space totally dedicated to the work at hand and designed for comfort and injury prevention.

# The New Vigilantism: Combating the Piracy of Copyrighted Materials on Peer-to-Peer Networks

Alvin Stauber

College of Business, Florida State University, Tallahassee, Florida 32306-1110, U.S.A.  
astaube@cob.fsu.edu

## ABSTRACT

Non-existent just a few years ago, peer-to-peer networks have experienced phenomenal growth. One consequence of the expansion of these networks has been extensive unauthorized downloads of copyrighted materials. Losses attributable to music piracy alone are estimated to exceed \$4 billion. In response to this problem and to combat the misappropriation of copyrighted materials, the Peer-To-Peer Piracy Prevention Act ("Act") was introduced in the United States Congress in 2002. The aim of the law is to enable copyright holders to utilize technological self-help measures to stop copyright infringement on peer-to-peer networks. This paper describes the developments leading to the introduction of the Act and briefly analyzes the provisions of the Act. In addition, the paper discusses the legal issues raised by the self-help remedies contained in the Act and concludes that there is ample precedent to support the legal propriety of these measures.

**Keywords:** vigilantism, copyright, peer-to-peer network, self-help remedies, citizen's arrest, safe harbor

## 1. INTRODUCTION

"Hollywood Vigilantes v. Copyright Pirates"  
(Humphrey, 2003)

"Streamcast Opposes . . . Posse of Copyright  
Vigilantes" (Streamcast, 2002)

"Vigilantes v. Pirates: The Rumble Over Peer To Peer  
Technology" (Fazekas, 2003)

The foregoing headlines provide a glimpse into the battle that is being waged over the misappropriation of copyrighted materials on peer-to-peer networks. Words such as "vigilantism" and "piracy"—ordinarily reserved for portraying mischief in the Wild West or on the wild seas—are now part of the lexicon used to describe this cyber warfare. One of the principal contributors to this adversarial atmosphere was the proposed enactment in the United States of legislation known as the Peer-To-Peer Piracy Prevention Act (H.R. 5211, 2002). As one observer stated, it was "greeted by a swirl of controversy in the Internet community" (Humphrey, 2002). The purpose of this paper is: (1) to describe the developments that led to the introduction in the United States Congress of the Peer To Peer Piracy Prevention Act ("Act"); (2) to briefly analyze the provisions of the Act; and (3) to discuss the legal issues raised by the self-help remedies contained in the Act.

## 2. DEVELOPMENTS

Non-existent just a few years ago, peer-to-peer networks have experienced phenomenal growth. The leading peer-to-peer file sharing software has been downloaded over 200 million times, and its developer claims over 60 million users (Davidson, 2003). Peer-to-peer file sharing networks are different from other Internet applications in the following respects: they

tend to share data from a large number of end user computers rather than from the more central computers generally thought of as Web servers. A key innovation of peer-to-peer file sharing networks is their sophisticated mechanisms for searching millions of "shared" files to find data among many connected systems. Information on peer-to-peer networks tends to be less centrally controlled and more reflective of what end user participants believe is valuable or worth sharing (Davidson, 2003).

Napster first brought peer-to-peer networks into the limelight, but it was shut down by the courts because it facilitated—using a central directory and centralized servers—massive copyright infringement. Current peer-to-peer networks avoid the "Napster problem" by incorporating varying levels of decentralization. While unauthorized downloads of copyrighted software, games, photographs, tapes, and movies have occurred, the most rampant piracy of copyrighted work involves music. Losses attributable to music piracy are estimated to amount to \$4.3 billion annually (Sorkin, 2003).

Most of the efforts to thwart music piracy have focused on litigation instituted against companies and individuals that are involved in the distribution of pirated music. Last year, four college students settled a lawsuit initiated by the music industry by agreeing to halt their music swapping network and agreeing to pay penalties of \$12,000 or more. And recently a federal judge ruled that Verizon Communications must disclose to the Recording Industry Association of America the identities of customers suspected of distributing pirated music (Sorkin, 2003). But copyrighted works are spread over peer-to-peer networks so quickly that they wind up almost instantly on millions of computers, rendering litigation against

individual peer-to-peer users essentially ineffective. It is in response to these developments that the Peer To Peer Piracy Prevention Act was introduced by California Congressman Howard Berman in the United States Congress on July 25, 2002.

### 3. PEER TO PEER PIRACY PREVENTION ACT

In introducing the proposed legislation, Representative Berman explained the thrust of the Act as follows:

[E]nactment of the legislation I introduce today is necessary to enable responsible usage of technological self-help measures to stop copyright infringements on peer-to-peer networks . . . There is nothing revolutionary about property owners using self-help—technological or otherwise—to secure or repossess their property. Satellite companies periodically use electronic countermeasures to stop the theft of their signals and programming. Car dealers repossess cars when the payments go unpaid. Software companies employ a variety of technologies to make software non-functional if license terms are violated (Berman, H.L., 2002).

Lamenting the fact that “the primary current application of peer-to-peer networks is unbridled copyright piracy,” Representative Berman sought in the Act to permit copyright owners to employ a variety of technological tools—e.g., interdiction, decoys, redirection, file-blocking, and spoofs—to prevent the illegal distribution of copyrighted works over a peer-to-peer network (Berman, H.L., 2002). The protection afforded by the Act is to provide a “safe harbor” from liability when copyright owners employ self-help measures to prevent piracy of their works. But these self-help measures are narrowly tailored to ensure “acceptable behavior” by the copyright owner. Self-help measures that would involve planting a virus on a peer-to-peer user’s computer or otherwise removing, corrupting, or altering files or data on the user’s computer are prohibited and are subject to civil and administrative remedies (H.R. 5211, 2002).

In addition, the copyright owner is denied the safe harbor from liability if:

- (1) The copyright owner impairs the trading of files that do not contain any portion of the copyrighted work, unless such impairment is “reasonably necessary” to impair the trading of the copyrighted work;
- (2) The actions of the copyright owner cause economic loss to anyone other than the file trader;
- (3) The actions undertaken by the copyright owner cause more than fifty dollars of economic loss to the file trader, other than loss involving the copyrighted works; or
- (4) The copyright owner does not provide the required 7-day notice to the Department of Justice disclosing the

proposed method to be used to stop the copyright infringement (H.R. 5211, 2002; Humphrey, 2003).

### 4. LEGAL ISSUES

Immediately after its introduction, the Act was attacked by critics who claimed that the self-help remedies contained in the proposed legislation might result in a type of vigilantism in which copyright owners—taking the law into their own hands—might “hack” into computers, damaging the hardware, compromising legitimately downloaded files, and altering data. In addition, critics raised constitutional concerns, claiming that the self-help measures would violate the privacy of individual users (Streamcast, 2002).

#### 4.1 Vigilantism

To characterize the self-help measures proposed by Congressman Berman as “vigilantism” is hyperbole of the first order. Society undoubtedly welcomes the prospect of a “community of ‘vigilant’ citizens who watchfully and lawfully seek to detect and prevent crime” (Brandon, et al., 1984). Vigilantism, on the other hand, is defined as an “organized, extra-legal movement, the members of which take the law into their own hands” (Sklansky, 1999). Vigilantes typically engage in the violent exercise of police power authority in an unlawful manner; they “violate the law, often heinously, in the name of law and order” (Brandon, et al., 1984). Being vigilant, however, does not make one a vigilante. The Peer-To-Peer Piracy Prevention Act emphatically rejects any measures that are violent or heinous or unlawful. Indeed, odious behavior such as planting a virus, altering or corrupting files, or “freezing” a computer system is proscribed under the proposed law and would result in civil and administrative remedies (H.R. 5211, 2002). What the Act advocates are self-help measures that do not disrupt the technical operation of a person’s computer or networks. The Act encourages vigilance and self-help, not vigilantism.

If anything, the self-help remedies envisioned by the Act are the antithesis of the vigilantism of bygone years. The vigilante activity that first appeared in the United States in the late 1700s involved “the frontier justice afforded cattle rustlers, horse thieves, murderers, thugs, and desperados” (Brandon, et al., 1984). Students of vigilantism, while acknowledging that our legal system condemns the practice, nevertheless warn that:

society should heed the message that outbreaks of this behavior sometimes suggest. Although many instances of vigilantism probably reflect extremist behavior, some vigilante activity also may suggest a latent societal feeling of dissatisfaction with the operation of criminal laws and the justice system (Brandon, et al., 1984).

It is, indeed, the dissatisfaction with the operation of our legal system that motivated Congressman Berman and others to try to improve that system by seeking legal approbation of self-help measures employed by copyright owners for their own protection. If this is vigilantism, it is a 21<sup>st</sup> century version and ought to be re-named the “new vigilantism”, in recognition that it is a practice that advocates self-help through legal, as opposed to illegal, means, and is, therefore, significantly different from the “old vigilantism”.

## 4.2 Self-help Remedies

Traditionally, self-help remedies have been sanctioned by the law. As indicated earlier, satellite companies use electronic countermeasures to stop theft of their signals and programming; retailers repossess goods when loans go into default; and software companies employ a variety of technologies to make software non-functional if license terms are violated. In the case of repossession of goods, the retrieval of merchandise does not have to be carried out by judicial order or by law enforcement officers' action. Rather, upon default, the creditor or his agent is authorized to enter private or public property so long as the taking of the item to be retrieved is effected without a “breach of the peace”. Entering the debtor's private property is not usually considered a trespass (thereby eliminating the possibility of a breach of the peace), because although a lack of consent to the entry might be claimed, there is nevertheless a privilege to enter—rendering consent unnecessary—created by the repossession right (Brandt v. Dugent, 2000). In fact, in the case of automobile repossession, the retrieving person is authorized to “break into” the vehicle in order to effect the repossession, although liability for damage to the car might be incurred (Clarke, 2001; Foster, 1982). This lawful procedure involving self-help by entering the real and personal property of another provides a precedent for the self-help measures in the Act.

Another precedent that provides support for the Act's remedies is that found in the law of citizen's arrest. The self-help power of citizen's arrest is available in most states to those private persons and businesses that observe a theft or other crime being committed. In fact, the laws of at least six states in the United States permit an individual to use force or to break a door or window to effect a citizen's arrest and thereby possibly effect recovery of stolen property (Code of Ala., 2004; A.R.S., 2004; HRS, 2003; Miss. Code Ann., 2004; N.D. Cent. Code, 2003; Tenn. Code Ann., 2004). The concept of “breaking into” another's property has relevance to the self-help measures advocated by the Act. Indeed, one commentator described the Act as “a bill that would have given the film and music industries immunity from prosecution if they found ways to **break into the swappers' computers** (emphasis supplied) and block their swapping” (Farrar, 2003). Admittedly, breaking into an automobile to

recover tangible property differs from breaking into a computer to recover intangible (intellectual) property, but the underlying concept remains the same. Critics of the Act's self-help measures argue that the differences are significant, stating as follows:

There are important differences between the two given the more utilitarian construction of intellectual property rights in the Constitution. IP rights are more limited in scope and duration, and the “fair use” rights of users is part of today's copyright bargain. Then again, fair use doesn't necessarily mean free use. Artists deserve compensation (Farrar, 2003).

Predictably, Representative Berman rejects the notion that “breaking and entering” into a person's computer is sanctioned by the Act. He explains his position as follows:

Despite wildly inaccurate press reports, H.R. 5211 in no way allows a copyright owner to “hack” into anyone's computer. Copyright owners are only allowed to enter or look into a P2P user's computer to the same extent that any other P2P user is able to do so. In other words, if a KaZaA user has advertised to all 100 million other KaZaA users that he wants to download or distribute a copyrighted song, the songwriter is not “hacking” if she reads the advertisement like everyone else. H.R. 5211 then allows the songwriter to take certain, limited actions to stop the distribution of her copyrighted song between KaZaA users, but in no way allows her to enter or look into a private area of those KaZaA users' computers (Berman, H., 2002).

Another complaint leveled by critics is that self-help copyright holders can make mistakes when they take action against alleged infringers (Davidson, 2003). Interestingly enough, the analogy to the self-help remedy of citizen's arrest again provides useful insight into how this problem is dealt with. According to most state statutes, a retail merchant has the right to detain a suspect (i.e., effect a citizen's arrest) whom the merchant reasonably believes has engaged in shoplifting as long as that detention is done in a reasonable manner (Ohlin & Stauber, 2003). Illustrative is the Florida law, which provides as follows:

a merchant . . . who has probable cause to believe that a retail theft . . . has been committed by a person and . . . that the property can be recovered by taking the offender into custody may, for the purpose of attempting to effect such recovery or for prosecution, take the offender into custody and detain the offender in a reasonable manner for a reasonable length of time.

The taking into custody and detention by a . . . merchant, merchant's employee, or . . . agent, if done in compliance with all the requirements of this

subsection, shall not render such [person] criminally or civilly liable for false arrest, false imprisonment, or unlawful detention (Fla. Stat. Sec. 812.015(3), 2004).

In other words, the Florida statute provides a “safe harbor” for merchants who comply with the requirements of the law. That is, criminal and civil immunity is granted to merchants so long as they act **reasonably**, even if they mistakenly accuse someone of shoplifting. While erroneously accusing a person of retail theft can understandably result in a terribly unfortunate experience for the innocent suspect, the law providing merchants with immunity balances the right of merchants who undertake reasonable measures to apprehend suspected thieves with the rights of an innocent person who is mistakenly accused of theft. Because shoplifting has become a problem of epidemic proportions, the law tips the scales in favor of the merchant (Sparrow, 2003).

A similar argument can be made in the situation involving on-line theft of copyrighted materials. So long as the copyright owner’s impairment of the unauthorized distribution or reproduction of the copyrighted work does not “alter, delete, or otherwise impair the integrity of any computer file or data residing on the computer of a file trader”, the copyright owner incurs no liability (H.R. 5211, 2002). Similar to the reasonableness criterion of the merchant shoplifter apprehension statutes, the Act in Section 514(b) creates a safe harbor exception. According to the Act, impairing the trading of files that do not contain any portion of the copyright owner’s copyrighted work would result in liability unless such impairment is “reasonably necessary” (H.R. 5211, 2002). Critics of the proposed law contend that such language creates serious problems. As one critic observed: the ambiguity of the words “reasonably necessary” paves the road to future litigation over the issue. . . . Although [Representative Berman] has referred to the “reasonably necessary” exception as “certain necessary circumstances,” [he] has yet to reveal what those circumstances are. Considering that H.R. 5211 explicitly allows copyright owners to navigate around existing state and federal law, Representative Berman’s desire to create legislation that is “narrowly crafted, with strict bounds on acceptable behavior by the copyright owner” will not be achieved until this provision is made more clear and the ability of file traders to trade legally is adequately preserved (Humphrey, 2003).

It should be recognized, however, that many statutes—including the merchant shoplifter apprehension statutes earlier described—utilize a “reasonableness” standard to guide individuals in their conduct. Indeed, there are entire bodies of law—most notably the law of negligence in its utilization of the reasonable person standard—that are principally based on the concept of reasonableness. The term “reasonable” is used in

thousands of contexts in the law; its use simply acknowledges that all fact situations are different and must be viewed in their own particular contexts. The definition of what is reasonable in any given set of circumstances is, therefore, situation-specific. Incorporating a reasonableness standard into a law is not fatal to the law. It simply means that the finder of fact—a judge or jury—will have to make the determination as to whether a particular course of conduct is reasonable under the circumstances (Clarkson, et al., 2004).

With regard to constitutional concerns relating to the Act’s self-help measures and their potential for invasion of privacy, the focus appears to be on the Fourth Amendment’s prohibition of illegal searches and seizures. The problem with attacking the Act’s self-help measures on this basis is that, as many courts have stated, “The Fourth Amendment’s proscription against warrantless searches and seizures does not apply to searches by private individuals not acting as agents of the state” (State v. Cooney, 1995). The copyright owners seeking to protect themselves against the piracy of their copyrighted work through self-help measures thus appear to have some latitude that law enforcement officers and/or government officials would not necessarily enjoy.

## 5. CONCLUSION

The self-help measures embodied in the Act are innovative and potentially effective weapons in the battle to combat the piracy of copyrighted work. While certainly subject to abuse, these measures are restricted in the Act so as not to result in harm to the hardware or software of peer-to-peer users. Although these self-help remedies are subject to constitutional and other legal concerns, there is ample precedent to support the legal propriety of these measures.

# The Security Flaw of an Untraceable Signature Scheme

Chinchen Chang, Yafen Chang

Department of Computer Science and Information Engineering, National Chung Cheng University,  
Chiayi 621, Taiwan, China  
e-mail:{ccc, cyf}@cs.ccu.edu.tw

## ABSTRACT

In 2003, Hwang et al. proposed a new blind signature based on the RSA cryptosystem. The Extended Euclidean algorithm is employed in their proposed scheme. They claimed that the proposed scheme was untraceable and it could meet all requirements of a blind signature. However, we find that the signer can still trace the blind signature applicant in some cases. Thus, we present the security flaw of Hwang et al.'s scheme in this paper.

**Keywords:** blind signature, untraceable, RSA, Extended Euclidean algorithm

## 1. INTRODUCTION

In 1982, Chaum proposed the concept of blind signature [1]. In blind signature schemes, an applicant can obtain a signature of a message from the signer without revealing the content of the signed message to the signer. Blind signature can be used in many cryptographic applications, such as electronic voting systems and electronic cash payment systems. Thus, how to make the resulting message-signature pair not be able to be linked is an important issue. On the other hand, the personal information should be protected while the resulting message-signature pair is used in any application. As a result, Chaum proposed the first blind signature ensuring the user's private information. With the progressive improvement of the blind signature [2], [4]-[6], the requirements of the blind signature, (1) correctness, (2) blindness, (3) unforgeability, and (4) untraceability, are listed and described as follows:

- (1) Correctness: Anyone can check the blind signature of the signed message by using the server's public key.
- (2) Blindness: The signer has no idea of the content of the signed message.
- (3) Unforgeability: Only the signer can generate the signature. That is, no one can forge a valid signature and can have the forged signature verified successfully.
- (4) Untraceability: The signer of the blind signature cannot link the message-signature pair even if the signature has been revealed to be public.

Recently, Hwang et al. [7] proposed a blind signature based on the RSA cryptosystem [9]. It also employs the Extended Euclidean algorithm [8]. They claimed that the proposed scheme is untraceable and meets all requirements of a blind signature mentioned above. And the security of the proposed scheme is based on the difficulties of solving the factoring problem. However, in some cases, the signer can still trace the blind signature applicant. As a result, we present its security flaw in this paper.

The rest of the paper is organized as follows. First, we

review Hwang et al.'s untraceable blind signature in Section 2. Then the drawback of Hwang et al.'s scheme is shown in Section 3. Finally, the conclusions are given in Section 4.

## 2. A REVIEW OF HWANG ET AL.'S UNTRACEABLE BLIND SIGNATURE

In this section, we review Hwang et al.'s proposed untraceable blind signature, which consists of five phases: (1) the initialization phase, (2) the blinding phase, (3) the signing phase, (4) the unblinding phase, and (5) the verification phase. The five phases are presented in Subsections 2.1 to 2.5, respectively.

### 2.1 The Initialization Phase

In this phase, the signer  $S$  makes the essential information public as follows:

- Step 1.  $S$  randomly selects two large prime numbers  $p$  and  $q$  and computes  $n = p \cdot q$  and  $\phi(n) = (p-1)(q-1)$ .
- Step 2.  $S$  chooses two large random numbers  $e$  and  $d$ , where  $\gcd(e, \phi(n)) = 1$ ,  $e \cdot d \bmod \phi(n) = 1$ .
- Step 3.  $S$  keeps  $p$ ,  $q$ , and  $d$  secret and makes  $e$ ,  $n$ , and  $H$  public, where  $H$  is a one-way hash function—MD5 and SHA-1 [3] for example.

### 2.2 The Blinding Phase

Suppose the requester  $R$  has a message  $m$  and wants  $m$  signed without being known by  $S$ .  $R$  performs the following steps to make  $m$  concealed.

- Step 1.  $R$  randomly selects two distinct numbers  $t_1$  and  $t_2$ .
- Step 2.  $R$  chooses two random primes  $a_1$  and  $a_2$ , where  $\gcd(a_1, a_2) = 1$ .
- Step 3.  $R$  computes  $s_1 = t_1^e \cdot H(m)^{a_1} \bmod n$  and  $s_2 = t_2^e \cdot H(m)^{a_2} \bmod n$ .
- Step 4.  $R$  sends  $s_1$  and  $s_2$  to  $S$ .

### 2.3 The Signing Phase

After getting  $s_1$  and  $s_2$  from R, S generates the corresponding blind signature of  $m$  as follows:

Step 1. S randomly chooses two primes  $b_1$  and  $b_2$ , where  $\gcd(b_1, b_2) = 1$ .

Step 2. S computes  $r_1 = s_1^{b_1 d} \bmod n$  and  $r_2 = s_2^{b_2 d} \bmod n$ .

Step 3. S sends  $(r_1, r_2, b_1, b_2)$  to R.

### 2.4 The Unblinding Phase

Upon receiving  $(r_1, r_2, b_1, b_2)$ , R performs as follows to derive the blind signature  $s$  of  $m$ .

Step 1. R computes  $g_1 = r_1 \cdot t_1^{-b_1} \bmod n$  and  $g_2 = r_2 \cdot t_2^{-b_2} \bmod n$ .

Step 2. R finds  $w$  and  $t$  according to Extended Euclidean Algorithm [3], where  $(a_1 b_1)w + (a_2 b_2)t = 1$ , and keeps  $b_1$ ,  $b_2$ ,  $w$ , and  $t$  secret.

Step 3. R computes  $s = g_1^w \cdot g_2^t \bmod n$  and then publishes  $(m, s)$ .

### 2.5 The Verification Phase

In order to verify the signature  $s$  of  $m$ , the verifier V computes  $H(m)$  and  $s^e \bmod n$ . Then V checks whether  $H(m) = s^e \bmod n$  holds or not. If it holds, it denotes that  $s$  is indeed the signature of  $m$ .

## 3. THE SECURITY FLAW OF HWANG ET AL.'S UNTRACEABLE BLIND SIGNATURE

In this section, we are going to show how the signer traces the blind signature in Hwang et al.'s proposed scheme. To make tracing the blind signature easier, S chooses two primes  $p$  and  $q$ , where  $4|p+1$  and  $4|q+1$ , and computes  $n = p \cdot q$  and  $\phi(n) = (p-1)(q-1)$ . Then S randomly chooses two large numbers  $e$  and  $d$ , where  $\gcd(e, \phi(n)) = 1$ ,  $e \cdot d \bmod \phi(n) = 1$ .

First, as shown in the blinding phase, R has a message  $m$  and wants  $m$  signed without being known by S. Then, R performs as follows:

Step 1. R randomly selects two distinct numbers  $t_1$  and  $t_2$ .

Step 2. R chooses two random primes  $a_1$  and  $a_2$ , where  $\gcd(a_1, a_2) = 1$ .

Step 3. R computes  $s_1 = t_1^e \cdot H(m)^{a_1} \bmod n$  and  $s_2 = t_2^e \cdot H(m)^{a_2} \bmod n$ .

Step 4. R sends  $s_1$  and  $s_2$  to S.

Second, as shown in the signing phase, S generates the corresponding blind signature of  $m$  as follows:

Step 1. S chooses two random primes  $b_1$  and  $b_2$ , where  $\gcd(b_1, b_2) = 1$ .

Step 2. S computes  $r_1 = s_1^{b_1 d} \bmod n$  and  $r_2 = s_2^{b_2 d} \bmod n$ .

Step 3. S sends  $(r_1, r_2, b_1, b_2)$  to R.

Third, as shown in the unblinding phase, R gets  $(m, s)$ , where  $s = H(m)^d \bmod n$ . After performing the above procedures several times, S can get  $(s_1, s_2)$ 's and  $(s_1^d \bmod n, s_2^d \bmod n)$ 's. Because  $s_1 = t_1^e \cdot H(m)^{a_1} \bmod n$  and  $s_2 = t_2^e \cdot H(m)^{a_2} \bmod n$ , we can have  $s_1^d = t_1^e \cdot (H(m)^d)^{a_1} \bmod n$  and  $s_2^d = t_2^e \cdot (H(m)^d)^{a_2} \bmod n$ . That is, S can collect all the  $(t_1^e \cdot (H(m)^d)^{a_1} \bmod n, t_2^e \cdot (H(m)^d)^{a_2} \bmod n)$ 's.

Now, suppose that S knows  $(m', \delta)$ , where  $\delta = H(m')^d \bmod n$ . If  $t_1, t_2$ , and  $(H(m)^d \bmod n)$  are co-prime and  $a_1 < a_2$  possibly, S can find the relation between  $(s_1^d \bmod n, s_2^d \bmod n)$  and  $\delta$  as follows:

Step 1. S computes  $\gcd(t_1^e \cdot (H(m)^d)^{a_1} \bmod n, t_2^e \cdot (H(m)^d)^{a_2} \bmod n) = H(m)^{d \cdot a_1} \bmod n$ .

Step 2. S computes  $\eta = (H(m)^{d \cdot a_1} \bmod n) \cdot \delta \bmod n$ .

Step 3. S computes

$$c_1 = \eta^{(p+1)/4} \bmod p,$$

$$c_2 = (p - \eta^{(p+1)/4}) \bmod p,$$

$$c_3 = \eta^{(q+1)/4} \bmod q,$$

$$c_4 = (q - \eta^{(q+1)/4}) \bmod q,$$

$$x = q(q^{-1} \bmod p), \quad y = p(p^{-1} \bmod q),$$

$$\beta_1 = (xc_1 + yc_3) \bmod n,$$

$$\beta_2 = (xc_1 + yc_4) \bmod n,$$

$$\beta_3 = (xc_2 + yc_3) \bmod n, \text{ and}$$

$$\beta_4 = (xc_2 + yc_4) \bmod n \quad [8].$$

Step 4. If there exists a  $\beta_j$  such that  $\beta_i \cdot \delta^{(\phi(n)/2)} = \beta_j \bmod n$ , where  $i \neq j$  and  $1 \leq i, j \leq 4$ , this denotes that  $\delta$  is related to  $(t_1^e \cdot (H(m)^d)^{a_1} \bmod n, t_2^e \cdot (H(m)^d)^{a_2} \bmod n)$ .

If  $m = m'$ , we have

$$\eta = (H(m)^d)^{a_1+1} \bmod n. \quad (1)$$

Because  $a_1$  is odd,  $a_1+1$  is an even number. As a result,

$$\eta = ((H(m)^d)^{(a_1+1)/2})^2 \bmod n. \quad (2)$$

Equation (2) can be rewritten as the follow equation.

$$\eta = (((H(m)^d)^{(a_1+1)/2})^2 \bmod n) * (H(m)^{\phi(n)} \bmod n) \bmod n. \quad (3)$$

Since  $m = m'$ , we have

$$\eta = (((H(m)^d)^{(a_1+1)/2})^2 \bmod n) * (H(m')^{\phi(n)} \bmod n) \bmod n \quad (4)$$

$$= ((H(m)^d)^{(a_1+1)/2} \bmod n) * (H(m')^{\phi(n)/2} \bmod n)^2 \bmod n. \quad (5)$$

According to the above equation, we can get

$$\eta^{1/2} = ((H(m)^d)^{(a_1+1)/2} \bmod n) * (H(m')^{\phi(n)/2} \bmod n) \bmod n. \quad (6)$$

From Equation (1), we have

$$\eta^{1/2} = ((H(m)^d)^{(a_1+1)/2} \bmod n). \quad (7)$$

According to the properties of Rabin's [8], we know

there exist at most four distinct solutions for  $\eta^{1/2} \bmod n$ . That is, at least one  $\beta_i$  will equal to  $((H(m)^d)^{(a_1^{-1})/2} \bmod n)$  for  $1 \leq i \leq 4$ . Therefore, if  $m = m'$ , we have

$$\beta_j = \beta_i * (H(m')^{\phi(n)/2} \bmod n) \bmod n \quad (8)$$

$$= \beta_i * \delta^{\phi(n)/2} \bmod n. \quad (9)$$

As a result, S checks whether any  $\beta_i * \delta^{(\phi(n)/2)} = \beta_j \bmod n$  for  $1 \leq i, j \leq 4$  and  $i \neq j$ , in Step 4.

According to the above procedures, it is obvious that S can trace the blind signature in Hwang et al.'s proposed blind signature scheme.

#### 4. CONCLUSIONS

Hwang et al. proposed a new blind signature based on the RSA cryptosystem by employing the Extended Euclidean algorithm. Though they claimed that the proposed scheme was untraceable and it could meet all requirements of a blind signature, however, we find that the signer can still trace the blind signature applicant in some cases. On the other hand, the computation load of Hwang et al.'s scheme is too heavy. There still exists space for improving the proposed blind signature scheme.
